Theorem 4076.17 (Equicontinuity family-modulus consumer exhaustion)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, every compact-uniform modulus consumer of* E *must read exactly the rows* $K, F, \epsilon, \rho, M, T, R, P, N$*. The consumer may use* K *as the compact source,* F *as the displayed family ledger,* ϵ *as the tolerance request,* ρ *as the shared radius,* M *as the modulus handoff, and* T, R, P, N *as the structural transport, replay, provenance, and naming rows. It cannot detach a pointwise radius schedule from* F*, replace* ρ *by memberwise radii, or insert a selected finite-net row into the carrier.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityCarrier family modulus consumer exhaustion`

Proof. Start from shared-radius stability in Definition 4076.8. It pins ρ to the displayed compact source K, family ledger F, tolerance row ϵ, and modulus handoff M.

Use finite-net readiness from Definition 4076.16. A finite-net-facing or compact-uniform consumer may begin only after K, F, ϵ, ρ, M have been exposed, while T, R, P, N preserve that same route.

Finally apply nonescape from Definition 4076.4. Since the carrier has no coordinate for memberwise radius schedules, selected finite nets, subsequences, host continuity, or ambient completeness, the rows $K, F, \epsilon, \rho, M, T, R, P, N$ exhaust the compact-uniform consumer surface. □

Theorem 4076.18 (Equicontinuity finite-net selector readiness)**.** *Let* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$ *be an accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier. A* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *selector may start only after the compact-source row* K*, continuous-family row* F*, shared-radius row* ρ*, and modulus-handoff row* M *are exposed for the same tolerance request* ϵ*. The structural rows* T, R, P, N *may transport and replay that readiness boundary, but they do not authorize a selected finite net before the compact source, family, shared radius, and modulus handoff have all been read.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityFiniteNetSelectorReadiness`

Proof. Read the prerequisite order from Definition 4076.16. It places a finite-net consumer after the compact source, continuous family ledger, tolerance request, shared radius, and modulus handoff.

Apply shared-radius stability from Definition 4076.8. The selector cannot split the family into detached pointwise radius schedules, because the radius row ρ is transported with K, F, ϵ, M.

Use nonescape from Definition 4076.4. Selected nets, subsequences, limiting maps, convergence certificates, host continuity, and ambient completeness are absent from the carrier, so the selector receives only readiness at the displayed boundary. □

Theorem 4076.19 (Equicontinuity shared-modulus sibling route)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, any downstream consumer of the equicontinuity packet must read the compact source through chapter 129, the continuous family through chapter 130, the uniform modulus handoff through chapter 369, and the finite-net boundary through chapter 2362. The route preserves the same shared radius* ρ *and exports no selected finite net, subsequence, host continuity theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityRootUnblockSharedModulusScope`

Proof. Project the carrier of Definition 4076.1. The row K is the compact source, F is the finite continuous-family ledger over that source, and ϵ, ρ, M are the shared tolerance-radius and modulus handoff rows.

Use the compact-source admission and continuous-family admission theorems, Definition 4076.25 and Definition 4076.26. They identify the source and family reads with the sibling surfaces named by chapter 129 and chapter 130.

Apply shared-radius stability, modulus-handoff admission, and finite-net readiness, Definition 4076.8, Definition 4076.27, and Definition 4076.16. These rows keep the same ρ attached to the handoff into the $\mathsf{UniformModulus}^{\uparrow}$ and $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ consumers.

Finally use Definition 4076.4. Since the selected-net, subsequence, host-continuity, and ambient-completeness coordinates are absent from the carrier, the sibling route just listed is the whole public dependency surface. □

Theorem 4076.20 (Equicontinuity modulus-ledger exactness)**.** *Let* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$ *be accepted. The modulus ledger exported by* $\mathsf{Equicontinuity}^{\uparrow}$ *is exactly the handoff from the compact source* K *and finite family* F *at tolerance* ϵ *to the shared radius* ρ *recorded by* M*, transported by* T*, replayed by* R*, sourced by* P*, and named by* N*. It has no additional ledger row for host continuity, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected covers, or an Arzela–Ascoli limit.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityCarrier modulus ledger exactness`

Proof. The analytic part of the carrier is K, F, ϵ, ρ, M. The compact-metric row supplies the source, the continuous-map row supplies the finite family, and the uniform-modulus row records the tolerance-to-radius handoff.

The ledger is exact because T, R, P, N refer back to those same rows. They cannot add a second modulus, a selected cover, a limit candidate, or a host-level continuity predicate; they only preserve and name the displayed handoff.

The exclusions are also forced by Definition 4076.4. Any consumer needing compactness output, selected nets, subsequences, or completeness must obtain those data from a separate chapter after reading the exact modulus ledger here. □

Definition 4076.21 (Equicontinuity finite-modulus subcarrier)**.** *An* $\mathsf{Equicontinuity}^{\uparrow}$ *finite-modulus subcarrier is the finite row packet*

$$E_{\mathrm{fin}} = (K, F, \epsilon, \rho, M, G, T, R, P, N)$$

projected from an accepted carrier $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*. The rows are, in order, the compact metric source* K*, finite continuous-family ledger* F*, shared tolerance request* ϵ*, shared radius row* ρ*, uniform-modulus handoff* M*, finite-net consumer boundary* G*, componentwise* hsame *transport* T*, displayed* Cont *replay* R*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{Equicontinuity}^{\uparrow}}$ *row* N*. The boundary row* G *is readable only as readiness for* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *over the displayed* K, F, ϵ, ρ, M *route; it is not a selected net, subsequence, compactness conclusion, or Arzela–Ascoli limit.*

Theorem 4076.22 (Equicontinuity compact-metric finite-modulus handoff)**.** *Every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *finite-modulus subcarrier* $E_{\mathrm{fin}} = (K, F, \epsilon, \rho, M, G, T, R, P, N)$ *hands downstream consumers a compact-source route only after* K *has been read as the compact metric source and before* F, ϵ, ρ, M, G *are inspected. The rows* T, R, P, N *preserve this compact-source handoff and cannot replace it by an ambient compactness assertion or selected finite net.*

Proof. Project E_{fin} from Definition 4076.21. Its first row is the same compact source K already displayed in Definition 4076.1.

Apply Definition 4076.25 and Definition 4076.3. They force every continuous-family, uniform-modulus, and finite-net-facing read to pass through K before F, ϵ, ρ, M are consumed.

The boundary row G is therefore only a consumer boundary for the existing route. Transport, replay, provenance, and naming through T, R, P, N preserve that route and add no selected net or ambient compactness coordinate. □

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityFiniteModulusCarrier compactmetric handoff`

Theorem 4076.23 (Equicontinuity continuous-map finite-modulus route)**.** *For every accepted finite-modulus subcarrier* $E_{\mathrm{fin}} = (K, F, \epsilon, \rho, M, G, T, R, P, N)$*, the family row* F *is read only as a finite* $\mathsf{ContinuousMap}^{\uparrow}$ *ledger over the already displayed compact source* K*. The shared tolerance request* ϵ*, radius row* ρ*, and modulus handoff* M *are attached to that same ledger, so no consumer may detach the modulus route into host-level continuity, a source-changing family, or memberwise radii.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityContinuousMapModulusRoute`

Proof. Read the finite family row F after the compact source K. By Definition 4076.21, these are the same rows projected from the accepted $\mathsf{Equicontinuity}^{\uparrow}$ carrier.

Apply Definition 4076.26 and Definition 4076.32. They identify F as the finite $\mathsf{ContinuousMap}^{\uparrow}$ ledger over K and exclude host continuity, source-changing maps, and infinite-family replacement.

Use Definition 4076.8. The shared radius row ρ is transported with K, F, ϵ, M, so the modulus route remains attached to the same finite family ledger. □

Theorem 4076.24 (Equicontinuity uniform-modulus consumer boundary)**.** *For every accepted finite-modulus subcarrier* $E_{\mathrm{fin}} = (K, F, \epsilon, \rho, M, G, T, R, P, N)$*, a* $\mathsf{UniformModulus}^{\uparrow}$*,* $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$*, or* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *consumer may read the boundary* G *only after the shared handoff*

$$K, F, \epsilon, \rho, M$$

has been displayed. The boundary exports readiness for the finite-net consumer and no selected finite net, subsequence, compactness proof, Arzela–Ascoli limit, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityCarrier uniform modulus consumer boundary`

Proof. Project the handoff rows K, F, ϵ, ρ, M and the boundary row G from Definition 4076.21. The row G appears downstream of the shared tolerance-radius handoff.

Apply Definition 4076.16 and Definition 4076.33. They require every finite-net-facing consumer to preserve the compact source, family ledger, tolerance request, shared radius, and modulus handoff before reading any consumer boundary.

Finally use Definition 4076.20 and Definition 4076.4. The displayed handoff is the whole exported modulus ledger, and the excluded selected nets, subsequences, compactness conclusions, limits, quotient equalities, and completeness principles are absent from the packet. □

Theorem 4076.25 (Equicontinuity compact-source admission)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the compact source row* K *is admitted through* $\mathsf{CompactMetric}^{\uparrow}$ *before any finite-net, shared-radius, or modulus consumer may inspect* F, ϵ, ρ, M*. No downstream* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*, or Arzela–Ascoli-facing read can bypass* K *or replace it by an ambient compactness assertion.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityCompactSourceAdmission`

Proof. Project the carrier of Definition 4076.1. The row K is the only compact-source coordinate, and the introduction fixes it as the same compact metric surface used by chapter 129.

Use the compact-metric route and finite-net readiness theorems, Definition 4076.3 and Definition 4076.16. They order every consumer read through K before the family ledger, tolerance, shared radius, and handoff rows.

The nonescape theorem then excludes an ambient compactness replacement. Since selected finite nets and compactness conclusions are absent from the carrier, the admitted compact source is precisely the displayed $\mathsf{CompactMetric}^{\uparrow}$ row. □

Theorem 4076.26 (Equicontinuity continuous-family admission)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the family row* F *is a finite ledger of* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise-modulus rows over the same source* K*. Transport through* T *and replay through* R *preserve this common source, so a consumer cannot read the family as host-level continuity, source-changing maps, or pointwise-only radius data detached from* K*.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityContinuousFamilyAdmission`

Proof. Read F from Definition 4076.1. Its entries are continuous-map rows over the compact source row K, matching the continuous-map sibling cited in the chapter introduction.

Apply shared-radius stability. The theorem keeps ρ attached to the transported compact source, finite family, tolerance, and modulus handoff, so F cannot be split into unrelated pointwise-radius ledgers.

Finally apply nonescape. Host-level continuity and source-changing maps are not coordinates of E, and T, R, P, N only transport, replay, source, and name the displayed family ledger. □

Theorem 4076.27 (Equicontinuity modulus-handoff admission)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the shared tolerance-radius row* ϵ, ρ, M *is the only* $\mathsf{UniformModulus}^{\uparrow}$ *or* $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ *handoff available to downstream finite-net consumers. A consumer that reads* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *must receive the handoff through this row and cannot add a second modulus ledger, a memberwise radius schedule, or a selected finite-net radius outside the carrier.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityModulusHandoffAdmission`

Proof. Project the handoff rows ϵ, ρ, M. The carrier displays one tolerance, one shared radius, and one modulus consumer row.

Use the shared-radius obligation and finite-net readiness theorems. They force every finite-net or Arzela–Ascoli-facing consumer to read ϵ, ρ, M after K, F and before any finite-net action can begin.

The modulus-ledger exactness theorem identifies this handoff as the whole exported modulus ledger. Since there is no coordinate for a second modulus, a memberwise radius family, or an outside selected radius, the downstream read is confined to the displayed $\mathsf{UniformModulus}^{\uparrow}$ or $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ handoff. □

Theorem 4076.28 (Equicontinuity compact-source root lock)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the root source lock is the compact metric row* K *together with the transported route* T, R, P, N*. Every* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{UniformModulus}^{\uparrow}$*, or* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *consumer must read* K *before the family ledger* F*, tolerance* ϵ*, shared radius* ρ*, and modulus handoff* M *become available. The lock exports no selected finite net, subsequence, or Arzela–Ascoli limit.*

Proof. Project the carrier. The only source row is K, and the rows F, ϵ, ρ, M are displayed downstream of that source in the finite packet.

Apply compact-source admission and the compact-metric route. These place every continuous-family, uniform-modulus, and finite-net-facing read after K and before the structural rows T, R, P, N can expose the named packet.

Finally use nonescape. Since the carrier has no selected-net, subsequence, or convergence-limit coordinate, the root lock is exactly the displayed compact-source route. □

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityRootCompactSourceLock`

Theorem 4076.29 (Equicontinuity family-ledger root lock)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the root family ledger is the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *row* F *over the already-read compact source* K*. Transport, replay, provenance, and local naming through* T, R, P, N *preserve that ledger before* ϵ, ρ, M *are consumed by* $\mathsf{UniformModulus}^{\uparrow}$ *or* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$*. No consumer may replace* F *by an infinite family, host-level continuity, selected finite net, subsequence, or Arzela–Ascoli limit.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityRootFamilyLedgerLock`

Proof. Read K and F from the carrier. The row F is finite and its entries are continuous-map rows over the same compact source.

Use continuous-family admission and continuous-family ledger admission. They force the consumer route through the displayed $\mathsf{ContinuousMap}^{\uparrow}$ ledger rather than through host continuity or a source-changing family.

The rows T, R, P, N only preserve, replay, source, and name the same ledger. Nonescape excludes the listed outside objects, so the root lock is the finite family ledger itself. □

Theorem 4076.30 (Equicontinuity root family modulus ledger)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the root family-modulus ledger exposed to finite-net consumers is exactly the compact-source row* K*, finite continuous-family row* F*, shared tolerance-radius rows* ϵ, ρ*, modulus handoff* M*, componentwise* hsame *transport* T*, displayed* Cont *replay* R*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{Equicontinuity}^{\uparrow}}$ *row* N*. No consumer may replace this ledger by selected nets, selected subsequences, host compactness, host continuity, a second modulus ledger, or Arzela–Ascoli convergence.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityRootFamilyModulusLedger`

Proof. Project the carrier. The compact-source lock and family-ledger root lock identify K and F as the only source and family rows available before any modulus-facing read.

Apply shared-radius stability, modulus-handoff admission, and modulus-ledger exactness. These place ϵ, ρ, M after K, F and identify the shared handoff as the whole exported modulus ledger for finite-net consumers.

Finally use transport replay provenance and nonescape. The rows T, R, P, N preserve the displayed ledger without adding a selected net, subsequence, host compactness proof, host continuity theorem, second modulus ledger, or Arzela–Ascoli convergence row. □

Theorem 4076.31 (Equicontinuity modulus-consumer root lock)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the root modulus-consumer lock is the shared handoff* ϵ, ρ, M *after the compact source* K *and family ledger* F *have been displayed. Any* $\mathsf{UniformModulus}^{\uparrow}$ *or* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *consumer must preserve this handoff through* T, R, P, N *and cannot add a selected finite net, memberwise radius schedule, subsequence, or Arzela–Ascoli limit.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityRootModulusConsumerLock`

Proof. Project the handoff rows. The packet contains one tolerance row, one shared radius row, and one modulus consumer row.

Apply modulus-handoff admission and shared-modulus handoff preservation. These theorems make ϵ, ρ, M the only modulus handoff available after K and F have been read.

Since the carrier has no coordinate for a selected finite net, memberwise radii, subsequences, or Arzela–Ascoli limits, transport and replay through T, R, P, N preserve only the displayed shared-modulus consumer lock. □

Theorem 4076.32 (Equicontinuity continuous-family ledger admission)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the family row* F *is admitted only as a finite* $\mathsf{ContinuousMap}^{\uparrow}$ *ledger over the compact source* K*. No consumer may reread* F *as host-level continuity, a source-changing family, or an infinite family outside the displayed compact-source route.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityContinuousFamilyLedgerAdmission`

Proof. Project the carrier of Definition 4076.1. It displays K as the compact metric source and F as the finite continuous-family row over that same source.

Use the compact-metric route and continuous-family admission theorems, Definition 4076.3 and Definition 4076.26. They force every consumer to read K before F and keep the family inside the displayed $\mathsf{ContinuousMap}^{\uparrow}$ ledger.

Finally apply Definition 4076.4. The excluded host-continuity, source-changing, and infinite-family coordinates are absent from E. □

Theorem 4076.33 (Equicontinuity shared-modulus handoff preservation)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, any* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *or* $\mathsf{UniformModulus}^{\uparrow}$ *consumer must preserve the shared tolerance-radius rows* ϵ, ρ, M *before reading a finite-net selector. The consumer cannot replace them by memberwise radii, a second modulus ledger, or a selected net radius outside the packet.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityCarrier shared modulus handoff preservation`

Proof. Read the shared-radius stability and finite-net readiness rows, Definition 4076.8 and Definition 4076.16. They place ϵ, ρ, M after the compact source and family rows, and before any finite-net-facing read.

Apply modulus-handoff admission and modulus-ledger exactness, Definition 4076.27 and Definition 4076.20. These identify the shared tolerance-radius handoff as the whole exported modulus ledger.

Since the carrier has no selected-net coordinate, preservation of ϵ, ρ, M is forced before a finite-net selector can be read. □

Theorem 4076.34 (Equicontinuity transport replay provenance)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the transport row* T*, replay row* R*, provenance row* P*, and naming row* N *preserve only the displayed compact-source, continuous-family, tolerance-radius, and modulus-handoff rows. They cannot add pointwise radius choice, selected nets, subsequences, or Real completeness.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityCarrier transport replay provenance`

Proof. Project T, R, P, N from Definition 4076.1. Their only analytic inputs are K, F, ϵ, ρ, M.

Use shared-radius stability and modulus-ledger exactness. Transport and replay preserve the same shared radius row and the same modulus ledger rather than a pointwise-radius family.

The nonescape theorem excludes selected nets, subsequences, and ambient $\mathsf{Real}^{\uparrow}$ completeness. Provenance and local naming therefore record the displayed route only. □

Theorem 4076.35 (Equicontinuity shared-radius family-cover readiness)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the shared-radius family-cover boundary is the displayed route*

$$K, F, \epsilon \longmapsto \rho, M \longmapsto T, R, P, N.$$

The row ρ *is readable only after the compact source* K*, finite continuous-family ledger* F*, and tolerance row* ϵ *have been exposed, and every family-cover consumer must keep* M, T, R, P, N *visible. The route cannot be replaced by selected nets, selected subsequences, host continuity, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuitySharedRadiusFamilyCoverReadiness`

Proof. Project the carrier. The rows K, F, ϵ are the only source, family, and tolerance data available before the shared radius is read.

Use shared-radius stability and shared-modulus handoff preservation. These results place ρ and M after the displayed source-family-tolerance rows and before structural transport and replay.

Finally apply transport replay provenance and nonescape. The rows T, R, P, N preserve the same boundary, and the carrier lacks coordinates for selected nets, selected subsequences, host continuity, and ambient real completeness. □

Theorem 4076.36 (Equicontinuity compact family-net readiness)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, a finite-net consumer may read the family only through the compact-source route*

$$K, F, \epsilon, \rho, M \longmapsto T, R, P, N.$$

The compact family-net boundary consists of the compact metric source K*, the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *family row* F*, the tolerance-radius handoff* ϵ, ρ, M*, and the transport, replay, provenance, and naming rows* T, R, P, N*. It does not choose a net, choose a subsequence, supply host continuity, or invoke ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityCompactFamilyNetReadiness`

Proof. Start with continuous-family ledger admission. It admits F only as a finite $\mathsf{ContinuousMap}^{\uparrow}$ ledger over the already displayed compact source K.

Next use finite-net readiness and modulus-consumer root lock. They force any finite-net-facing read to pass through ϵ, ρ, M before the structural rows are replayed.

The rows T, R, P, N do not add a selector. By transport replay provenance and nonescape, the accepted family-net read remains a compact-source ledger route, excluding selected nets, selected subsequences, host continuity, and ambient real completeness. □

Theorem 4076.37 (Equicontinuity Arzela–Ascoli boundary readiness)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, an Arzela–Ascoli-facing consumer may cite* $\mathsf{Equicontinuity}^{\uparrow}$ *only as the displayed boundary*

$$K, F, \epsilon, \rho, M, T, R, P, N.$$

This boundary supplies compact-source admission, finite continuous-family admission, shared tolerance-radius handoff, modulus-consumer readiness, transport, replay, provenance, and local naming. It does not supply a selected subsequence, a selected limiting map, host continuity of the limit, selected nets, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityArzelaAscoliBoundaryReadiness`

Proof. Read the root family ledger and modulus-consumer root lock. Together they make K, F, ϵ, ρ, M the whole analytic boundary exposed by the packet.

Use compact family-net readiness. Any later compactness-facing consumer receives only the routed family-net boundary and not a selected net or subsequence.

Finally replay transport, provenance, and nonescape through T, R, P, N. Since no coordinate carries a limiting map, host continuity proof, selected subsequence, selected net, or ambient real-completeness proof, an Arzela–Ascoli-facing consumer can cite only the displayed boundary. □

Theorem 4076.38 (Equicontinuity compact-family total-bounded consumer)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$ *whose downstream read also displays the* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *boundary over the same compact source, the packet exports exactly the finite total-bounded consumer package needed by Arzela–Ascoli-style chapters:*

$$K, F, \epsilon, \rho, M \longmapsto T, R, P, N.$$

The package ties the $\mathsf{CompactMetric}^{\uparrow}$ *source row, finite* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, finite-net equicontinuity boundary,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, and* $\mathsf{Real}^{\uparrow}$ *seal to the same* BHist, hsame, Cont, Pkg, *and* NameCert *route. It refuses selected subsequences, open-cover compactness, choice, selected limiting maps, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityCompactFamilyTotalBoundedConsumer`

Proof. Use compact family-net readiness and Arzela–Ascoli boundary readiness. They make the compact source K, finite family F, tolerance ϵ, shared radius ρ, and modulus handoff M the whole analytic boundary visible to downstream consumers.

Apply shared-modulus handoff preservation and finite-net readiness. These force the $\mathsf{UniformModulus}^{\uparrow}$ and $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ reads to preserve the same shared-radius route rather than replacing it by memberwise radii or an outside finite-net selector.

Finally use transport replay provenance and nonescape. The rows T, R, P, N carry the same finite route through BHist, hsame, Cont, Pkg, and NameCert, while the carrier has no coordinates for selected subsequences, open-cover compactness, choice, limiting maps, or ambient real completeness. □

Theorem 4076.39 (Equicontinuity compact-source root row)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the compact source row* K *is the first root row that finite-net and Arzela–Ascoli consumers must read. The rows* $F, \epsilon, \rho, M, T, R, P, N$ *are available only as rows over that same* $\mathsf{CompactMetric}^{\uparrow}$ *source, and no downstream net, subsequence, or convergence consumer can bypass* K *by reading the shared-radius or finite-net boundary directly.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityRootUnblockCompactSourceRow`

Proof. Project the carrier of Definition 4076.1. The row K is the only compact metric source row, while $F, \epsilon, \rho, M, T, R, P, N$ are displayed after it.

Use compact-source root admission and compact-metric route, Definition 4076.9 and Definition 4076.3. They force the family ledger, tolerance row, shared radius, and modulus handoff to remain attached to K.

Finally apply finite-net readiness and Arzela–Ascoli boundary readiness. Both consumers must read the displayed compact-source route before any downstream finite net, subsequence, or convergence object is available. □

Theorem 4076.40 (Equicontinuity shared-radius root handoff)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the shared radius row* ρ *is a root handoff between the compact-source family rows* K, F, ϵ *and the finite-net or uniform-modulus consumer row* M*. The transport, replay, provenance, and naming rows* T, R, P, N *preserve this same* ρ*; they do not create memberwise radii, a detached pointwise modulus, or a selected finite-net radius.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityRootUnblockSharedRadiusHandoff`

Proof. Read K, F, ϵ, ρ, M from the carrier. The single row ρ appears after the tolerance request and before the modulus handoff.

Apply shared-radius stability and shared-modulus handoff preservation, Definition 4076.8 and Definition 4076.33. These results keep the same ρ visible through every $\mathsf{UniformModulus}^{\uparrow}$ or $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ read.

The structural rows T, R, P, N preserve the displayed route only. Nonescape then excludes memberwise radii, pointwise-only modulus data, and selected finite-net radius rows. □

Theorem 4076.41 (Equicontinuity finite-net root boundary)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the finite-net boundary is the ordered read of* K, F, ϵ, ρ, M *followed by* T, R, P, N*. A* $\mathsf{FiniteNetEquicontinuity}^{\uparrow}$ *or Arzela–Ascoli consumer may start only after the compact source and shared radius have been exposed, and the consumer must obtain any actual*

finite net, subsequence, limiting map, or convergence certificate from a downstream packet rather than from $\mathsf{Equicontinuity}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityRootUnblockFiniteNetBoundary`

Proof. Project the displayed rows. The carrier contains the compact source K, finite family F, tolerance ϵ, shared radius ρ, modulus handoff M, and the support rows T, R, P, N.

Use finite-net readiness and compact family-net readiness, Definition 4076.16 and Definition 4076.36. They place every finite-net-facing read after the compact-source and shared-radius route.

Finally apply the finite-net consumer boundary and nonescape results, Definition 4076.11 and Definition 4076.4. The downstream consumer may cite the boundary, but selected nets, subsequences, limiting maps, and convergence certificates are not rows of the $\mathsf{Equicontinuity}^{\uparrow}$ carrier. □

Theorem 4076.42 (Equicontinuity carrier root obligation)**.** *For every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, root admission requires the finite* BHist *rows for a family of* $\mathsf{ContinuousMap}^{\uparrow}$ *maps over the displayed source row* K*. The source row may be read as* $\mathsf{CompactMetric}^{\uparrow}$ *when finite net consumers are present, or as the underlying* $\mathsf{Met}^{\uparrow}$ *row for metric distance comparisons, but the family row* F *is admitted only as a finite continuous-map ledger over that same source. No host open-cover compactness, selected subcover, quotient real equality, or choice principle is a carrier row.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityRootObligationCarrier`

Proof. Project the carrier and the compact-source root row. The source coordinate K is displayed before the family row F, and the chapter reads all finite-net and Arzela–Ascoli-facing material through that source.

Use the $\mathsf{ContinuousMap}^{\uparrow}$ family surface over the same source. The finite ledger F is a BEDC row over K; it is not a host-indexed family and it does not carry a selected subcover or open-cover compactness proof.

Finally replay the metric and real readbacks through T, R, P, N. The $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{StreamName}^{\uparrow}$ rows are visible only as routed support for the displayed family, so quotient real equality and choice cannot enter the carrier admission step. □

Theorem 4076.43 (Equicontinuity finite-net locality root obligation)**.** *Every finite-net read exported by an accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$ *routes through the displayed* $\mathsf{Met}^{\uparrow}$ *distance row, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, and the* $\mathsf{Real}^{\uparrow}$ *tolerance rows already sealed by the same* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *request ledger. A finite-net consumer may cite this local route only after* K, F, ϵ, ρ, M *have been displayed; it cannot replace the route by host open-cover compactness, a selected subcover, quotient real equality, or choice.*

Proof. Read the compact-source and shared-radius root handoff first. They place the metric source, family ledger, tolerance row, shared radius, and modulus handoff in a fixed order before any finite-net consumer can start.

Next use finite-net readiness. The finite-net surface is local to the displayed $\mathsf{CompactMetric}^{\uparrow}$ row and its underlying $\mathsf{Met}^{\uparrow}$ comparisons; the $\mathsf{Real}^{\uparrow}$ tolerance row is read through the same regular rational and stream-name ledger.

The remaining rows provide transport, replay, provenance, and local naming. Since those rows preserve only the displayed route, no open-cover compactness argument, selected subcover, quotient real equality, or choice principle can replace the finite-net locality obligation. □

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.RootObligationFiniteNet.EquicontinuityRootObligationFiniteNet`

Theorem 4076.44 (Equicontinuity uniform-modulus root obligation)**.** *The exported* $\mathsf{UniformModulus}^{\uparrow}$ *row* M *of an accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$ *is available only after the equicontinuity family row* F *and the finite-net ledger over* K *have been displayed. The handoff consumes the same* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{StreamName}^{\uparrow}$ *rows as the preceding locality route, and it refuses host open-cover compactness, selected subcovers, quotient real equality, and choice.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityRootObligationUniformModulus`

Proof. Begin with the family row and finite-net locality obligation. They expose the source K, family ledger F, tolerance ϵ, and shared radius ρ before any uniform-modulus consumer may read M.

Use shared-modulus handoff preservation. The $\mathsf{UniformModulus}^{\uparrow}$ row is a handoff from the displayed equicontinuity family and finite-net ledger, not a free-standing modulus selected outside the packet.

Finally apply transport replay and nonescape. The rows T, R, P, N preserve the same $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{StreamName}^{\uparrow}$ route. Therefore the uniform-modulus handoff cannot be supplied by host compactness, a selected subcover, quotient real equality, or choice. □

Theorem 4076.45 (Equicontinuity source-family root obligation)**.** *Every accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *read exposes the* $\mathsf{CompactMetric}^{\uparrow}$ *source row* K *and the* $\mathsf{ContinuousMap}^{\uparrow}$ *family row* F *before the tolerance* ϵ*, shared radius* ρ*, or modulus handoff* M *can be consumed. The read is therefore rooted in the displayed source-family packet of Definition 4076.1, not in an ambient compact space or an unlisted family selector.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityRootObligationSourceFamily`

Proof. Read the carrier of Definition 4076.1. Its first two rows are the compact metric source K and the finite continuous-family ledger F, and Definition 4076.2 makes those rows part of the local NameCert surface.

Next use the compact metric route of Definition 4076.3. It sends every later tolerance, radius, and modulus read through the displayed K, F source-family route.

Finally apply Definition 4076.4. A consumer that asks for ϵ, ρ, M before the source and family rows has left the accepted packet rather than extracting a hidden compact-source or family coordinate. □

Theorem 4076.46 (Equicontinuity shared-radius root obligation)**.** *The radius row* ρ *of an accepted* $\mathsf{Equicontinuity}^{\uparrow}$ *carrier is a single shared radius row transported by the displayed* hsame *and* Cont *routes. It is not a memberwise selector indexed by the family row* F*, and it cannot be replaced by a choice schedule over individual maps.*

Proof. Begin with the carrier and NameCert obligations of Definition 4076.1 and Definition 4076.2. They display one row ρ between the tolerance row and the modulus handoff row.

Use the compact metric route of Definition 4076.3. The row ρ is transported through the same hsame and Cont replay rows that preserve K, F, ϵ, M.

Apply nonescape by Definition 4076.4. Since the accepted packet has no coordinate for a family-indexed selector, a memberwise radius choice cannot be recovered from the shared-radius row. □

Theorem 4076.47 (Equicontinuity downstream nonescape root obligation)**.** *The* Equicontinuity$^{\uparrow}$ *root surface contains no finite-net selector, no subsequence selector, no Arzela–Ascoli convergence row, no host-continuity oracle, and no ambient* Real$^{\uparrow}$ *completeness coordinate. Those rows must be supplied by downstream chapters before a consumer may read compact-uniform consequences from an accepted equicontinuity packet.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityRootObligationNonescape`

Proof. Project the displayed rows of Definition 4076.1. The local surface records $K, F, \epsilon, \rho, M, T, R, P, N$ and the NameCert obligations of Definition 4076.2; it does not add selector, subsequence, convergence, host-continuity, or completeness rows.

Next use the compact metric route of Definition 4076.3. It keeps compact-source information visible as a finite route, while refusing to turn that route into open-cover compactness, selected finite nets, or selected subsequences.

Finally apply Definition 4076.4. Any Arzela–Ascoli, host-continuity, or real-completeness read must therefore enter through a downstream certificate rather than through the root Equicontinuity$^{\uparrow}$ packet. □

Theorem 4076.48 (Equicontinuity shared-radius family nonescape)**.** *For every accepted* Equicontinuity$^{\uparrow}$ *carrier* $E = (K, F, \epsilon, \rho, M, T, R, P, N)$*, the shared radius* ρ *is read over the same* CompactMetric$^{\uparrow}$ *source row* K *and* ContinuousMap$^{\uparrow}$ *family row* F *through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. A consumer cannot split* ρ *into memberwise radii, detach it from the* UniformModulus$^{\uparrow}$ *handoff* M*, or read it outside the finite family packet.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuitySharedRadiusFamilyNonescape`

Proof. Project the carrier and use the shared-radius root obligation. The rows K, F, ϵ, ρ, M occur in one displayed packet, so the radius row is already tied to the compact source and continuous-family ledger.

Apply shared-modulus handoff preservation. It makes the UniformModulus$^{\uparrow}$ consumer preserve the same ϵ, ρ, M rows rather than replacing them by a memberwise or selected finite-net radius.

Finally use transport replay provenance and nonescape. The rows T, R, P, N only preserve the displayed BHist, hsame, Cont, Pkg, and NameCert route, so no extra family selector can escape the shared-radius packet. □

Theorem 4076.49 (Equicontinuity compact-net modulus readiness)**.** *Every* FiniteNetEquicontinuity$^{\uparrow}$ *consumer of an accepted* Equicontinuity$^{\uparrow}$ *packet must first read the* CompactMetric$^{\uparrow}$ *source* K*, the finite* ContinuousMap$^{\uparrow}$ *family ledger* F*, the shared tolerance-radius rows* ϵ, ρ*, and the* UniformModulus$^{\uparrow}$ *handoff* M *through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *surface. The finite-net handoff is readiness data only; it does not choose a net or assert open-cover compactness.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityCompactNetModulusReadiness`

Proof. Begin with finite-net readiness and compact family-net readiness. Those results place any finite-net-facing read after the compact-source and continuous-family rows and before any downstream selector can be consumed.

Use the uniform-modulus root obligation to keep M attached to ϵ, ρ over the same K, F route. The modulus handoff therefore arrives as part of the finite packet, not as a second compactness principle.

The structural rows T, R, P, N then replay only the displayed route. Nonescape excludes selected nets, open-cover compactness, host continuity, and ambient $\mathsf{Real}^{\uparrow}$ completeness from the readiness surface. □

Theorem 4076.50 (Equicontinuity Arzela–Ascoli consumer route)**.** *An Arzela–Ascoli-facing consumer may cite* $\mathsf{Equicontinuity}^{\uparrow}$ *only as the routed packet* $K, F, \epsilon, \rho, M, T, R, P, N$*:* $\mathsf{CompactMetric}^{\uparrow}$ *source data, finite* $\mathsf{ContinuousMap}^{\uparrow}$ *family data, shared* $\mathsf{UniformModulus}^{\uparrow}$ *readiness, finite-net handoff, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The consumer must supply its own subsequence, limiting map, convergence, and Real-facing certificate rows.*

Lean4 ✓ `BEDC.Derived.EquicontinuityUp.EquicontinuityArzelaAscoliConsumerRoute`

Proof. Use the Arzela–Ascoli boundary readiness theorem. It presents $\mathsf{Equicontinuity}^{\uparrow}$ as a boundary over compact-source, continuous-family, shared-radius, and modulus-handoff rows.

Next compose compact-net modulus readiness with the finite-net root boundary. This gives the downstream consumer a finite-net-ready route, but not the selected net, subsequence, limiting map, or convergence certificate.

Finally apply downstream nonescape. Since the carrier has no ambient completeness or host-continuity coordinate, every Arzela–Ascoli conclusion must be supplied by a later packet over the same displayed structural rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{Equicontinuity}^{\uparrow}}$**.**

Constructive story: An $\mathsf{Equicontinuity}^{\uparrow}$ packet is generated from a compact metric source row, a finite continuous-family ledger, shared tolerance and radius rows, a $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ or $\mathsf{UniformModulus}^{\uparrow}$ handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Equicontinuity}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 4076.1, Definition 4076.2, Definition 4076.3, Definition 4076.4, Definition 4076.8, Definition 4076.15, Definition 4076.16, and Definition 4076.20 export the public finite-net and Arzela–Ascoli-facing handoff through the checked root-obligation target over compact-source, continuous-family, tolerance, shared-radius, modulus-handoff, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Equicontinuity}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.EquicontinuityUp.EquicontinuityRootObligationSourceFamily`

Bridge status: none

Not claimed: This chapter does not close compactness, selected finite nets, selected subsequences, Arzela–Ascoli convergence, host-level continuity, pointwise-only radius choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{Equicontinuity}^{\uparrow}$.

Upgrade path: The remaining work is the standard bridge check for the same public finite-net and Arzela–Ascoli-facing handoff, not additional paper closure.

Chapter 4077

A Concrete Naming Certificate for $\mathsf{ChoquetGame}^{\uparrow}$

Following Choquet and Oxtoby on topological games and Baire category, the $\mathsf{ChoquetGame}^{\uparrow}$ packet records the finite nested-open game route used by complete-metric Baire arguments. It sits over the Baire prefix of chapter 334, the dense-open and category surface of chapter 1542, the complete-metric handoff of chapter 128, the finite schedule discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names the standard Choquet-game interface as BEDC NameCert data without importing a chosen winning strategy, a host intersection point, countable choice, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4077.1 (Choquet-game carrier)**.** *A* $\mathsf{ChoquetGame}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (B, M, L, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix row naming the inspected basic-open source, finite prefix probes, and legal initial open row.*
2. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *metric-ball row, including displayed centers, positive rational radii, inclusion checks, and shrinking-radius obligations for successor moves.*
3. *L is the nested legal-move ledger, recording each finite play prefix, the predecessor ball, the successor ball, the player tag, and the proof that the successor remains inside the predecessor.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting the finite play prefixes and ball observations visible to the consumer.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational centers, radius budgets, and tolerance comparisons used by the nested ball thread.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the Baire prefix, complete-metric ball data, legal-move ledger, stream schedule, and regular rational readback have been displayed.*
7. *T records componentwise* hsame *transport for Baire prefixes, complete-metric ball rows, legal-move ledgers, stream schedules, regular rational readback, Real seals, replay data, provenance, and local naming.*

8. *C records displayed* Cont *replay from a game request to the Baire prefix, complete-metric ball route, nested legal-move ledger, finite schedule, rational readback, Real seal, transport, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* $\mathsf{ChoquetGame}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ChoquetGame}^{\uparrow}}$ *row.*

The carrier has no coordinate for a global winning strategy, a selected limit point, countable choice, quotient equality of streams, ambient completed-real principles, or a hidden dense-open oracle.

Lean4 ✓ `BEDC.Derived.ChoquetGameUp.ChoquetGameTasteGate single carrier alignment`

Theorem 4077.2 (Choquet-game NameCert obligations)**.** *For every accepted* $\mathsf{ChoquetGame}^{\uparrow}$ *carrier* $G = (B, M, L, S, R, E, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ChoquetGame}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed Baire prefix, complete-metric ball, legal-move ledger, stream schedule, regular rational readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *Baire-prefix coverage, requiring every play prefix to begin with the* $\mathsf{BaireSpace}^{\uparrow}$ *row B;*
3. *metric-ball legality, requiring M to supply displayed centers, radii, inclusions, and shrinking obligations before L records a successor move;*
4. *nested-play exactness, requiring L to store only finite legal play prefixes and no unbounded strategy object;*
5. *schedule and readback discipline, requiring S, R, E to be read in that order before any terminal Real-facing consumer receives the packet;*
6. *structural preservation, requiring T, C, P, N to transport, replay, source, and name only the displayed game route;*
7. *ledger non-escape, excluding global winning strategies, selected limit points, countable choice, quotient stream equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and hidden dense-open oracles.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4077.1. The analytic rows are B, M, L, S, R, E, and the structural rows are T, C, P, N.

Baire-prefix coverage fixes the source of every finite play. Each accepted game request begins at the displayed $\mathsf{BaireSpace}^{\uparrow}$ prefix row and therefore cannot read an external open-set universe.

Metric-ball legality is confined to M and L. The complete-metric row supplies centers, radii, inclusion checks, and shrinking obligations, while the legal-move ledger records only the finite nested prefixes admitted by those checks.

The terminal handoff is scheduled. A consumer reads the finite play schedule through S, the rational tolerances through R, and the Real-facing seal through E only after the earlier rows have appeared.

Finally T, C, P, N preserve, replay, source, and name the same displayed packet. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4077.3 (Choquet-game Baire-category handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{ChoquetGame}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{BaireSpace}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{ChoquetGame}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route supplies the Baire-category consumer surface of chapter 1542 by exposing nested legal move prefixes and complete-metric ball obligations, not by selecting a host intersection point or importing a completed-real principle.

Proof. Start with an accepted carrier. The Baire prefix B names the basic-open source, and the complete-metric row M names the ball data through which legal moves are checked.

The game content is finite. The ledger L records the displayed nested play prefixes and the successor-in-predecessor evidence needed by a Baire-category handoff, while S exposes the finite schedule consumed at the current stage.

Regular rational readback and Real sealing are downstream. The row R records the rational center and radius tolerances, and E seals the terminal read only after B, M, L, S, R have been displayed.

Transport, replay, provenance, and local naming in T, C, P, N preserve that route componentwise. Thus the handoff supplies Baire-category arguments with the visible nested-ball interface while exporting no global strategy, selected point, countable-choice enumeration, quotient stream equality, or ambient completed-real principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChoquetGame}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ChoquetGame}^{\uparrow}$ packet is generated from a BaireSpace prefix, CompleteMetric metric-ball rows, a nested legal-move ledger, a StreamName schedule, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ChoquetGame}^{\uparrow}}$, seed)

Scope closed: Definition 4077.1, Definition 4077.2, and Definition 4077.3 seed the Choquet-game route over BaireSpaceUp, BaireCategoryUp, CompleteMetricUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ChoquetGame}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim global winning strategies, selected limit points, countable choice, quotient stream equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Baire-prefix coverage, complete-metric ball legality, nested-play exactness, StreamName scheduling, RegSeqRat readback, Real seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.ChoquetGameUp.

Chapter 4078

A Concrete Naming Certificate for LocatedCoveringNumber$^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley-style metric-cover language, the LocatedCoveringNumber packet records a covering-number request whose centers, tolerance, and budget are all displayed before any compactness or dimension consumer can use it. It sits after the metric covering-number surface of chapter 2187, the finite epsilon-net carrier of chapter 1767, the compact metric route of chapter 129, and the doubling-metric finite-growth packet of chapter 2035. The packet names a finite located cover certificate; it is not an open-cover compactness theorem, selected subcover principle, quotient metric equality, or ambient choice of centers.

Definition 4078.1 (Located covering number carrier)**.** *A* LocatedCoveringNumber$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, Q, T, E, B, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the metric source row, including the carrier classifier, distance requests, and ball-membership rows used by the cover.*
2. *Q is the located request row, naming the displayed subset or inspection window together with the cover request whose membership must be witnessed.*
3. *T is the tolerance ledger, recording the positive ε row and its rational or dyadic comparison data.*
4. *E is the finite ε-net center row, listing the centers and their point-name evidence through chapter 1767.*
5. *B is the covering-number budget row, recording the displayed natural-number bound and the count of center rows used by the certificate.*
6. *W is the location witness row, assigning each inspected request point to one displayed center with a distance comparison below the tolerance ledger.*
7. *H records componentwise* hsame *transport for the metric source, request, tolerance, center list, budget, witness, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a located cover request through the tolerance ledger, finite center list, budget row, and witness row.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedCoveringNumber}^{\uparrow}$, $\mathsf{MetricCoveringNumber}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{DoublingMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCoveringNumber}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, Q, T, E, B, W, H, C, P, N$. It has no coordinate for arbitrary open covers, selected subcovers, hidden dense enumerations, quotient metric equality, host compactness, or a choice-selected center family.

Lean4 (definition) `BEDC.Derived.LocatedCoveringNumberUp.LocatedCoveringNumberCarrier`
Lean4 ✓ `BEDC.Derived.LocatedCoveringNumberUp.LocatedCoveringNumberTasteGate single carrier alignment`

Theorem 4078.2 (Located covering number NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCoveringNumber}^{\uparrow}$ *carrier $L = (M, Q, T, E, B, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedCoveringNumber}^{\uparrow}}$ *surface consists exactly of carrier admission, located-center visibility, tolerance exactness, budget exactness, finite-net handoff, location-witness replay, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming. Every covering-number consumer must read these rows before using the displayed budget, and no consumer may read a stronger compactness, selected-subcover, or choice-of-centers object from the packet.*

Lean4 ✓ `BEDC.Derived.LocatedCoveringNumberUp.LocatedCoveringNumberNameCertObligations`

Proof. Project the carrier of Definition 4078.1. Carrier admission exposes the metric source, located request, tolerance ledger, finite center list, budget row, location witness, transport, replay, provenance, and local name.

The located-center and tolerance obligations are read through E, T, W. A center can serve a request only when the witness row displays the center and the corresponding distance comparison against the same tolerance ledger.

Budget exactness is read through B and E. The count in B is attached to the displayed finite center row, so the covering number cannot be justified by an unlisted center or a selected subcover outside the packet.

Finally use H, C, P, N. Transport, replay, provenance, and local naming preserve the same finite-net handoff to the metric covering-number, compact-metric, and doubling-metric consumers. Coordinate exhaustion blocks arbitrary covers, host compactness, quotient metric equality, and choice-selected center families. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCoveringNumber}^{\uparrow}$ consumer displays a metric source row, located request row, tolerance ledger, finite epsilon-net center row, covering-number budget row, location witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before a covering-number budget is public.

Independence witness: metric-covering-number, finite-epsilon-net, compactmetric, doubling-metric: $\mathsf{LocatedCoveringNumber}^{\uparrow}$ is not bijective to any listed sibling because it binds the request locator, tolerance ledger, center list, budget row, and witness assignment into one finite covering-number certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCoveringNumber}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCoveringNumber}^{\uparrow}$ packet is generated from a metric source row, located request row, tolerance ledger, finite epsilon-net center row, covering-number budget row, location witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCoveringNumber}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4078.1 and Definition 4078.2 seed the located finite-cover budget route over MetricCoveringNumber, FiniteEpsilonNet, CompactMetric, DoublingMetric, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{LocatedCoveringNumber}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, arbitrary open-cover compactness, selected subcovers, quotient metric equality, hidden dense enumerations, or choice-selected center families.

Upgrade path: Obligation closure requires checked carrier admission, located-center visibility, tolerance exactness, budget exactness, finite-net handoff, witness replay, transport, provenance, and local naming for BEDC.Derived.LocatedCoveringNumberUp.

Chapter 4079

A Concrete Naming Certificate for $\mathsf{SupportNerveRealization}^{\uparrow}$

Following the finite combinatorics of abstract simplicial complexes, the $\mathsf{SupportNerveRealization}^{\uparrow}$ packet records the support-family-to-boundary-subcomplex theorem of Definition 9462.1659 as concrete NameCert data. It sits between the finite support census of chapter 4048, the lifted-Betti consumer of chapter 4035, and the simplicial-complex carrier of chapter 238. The packet names support rows, complement-face rows, boundary-subcomplex rows, facet witnesses, census handoff, transport, replay, provenance, and local naming; it does not import an ambient topological realization or unrestricted homology computation.

Definition 4079.1 (Support nerve realization carrier)**.** *A* $\mathsf{SupportNerveRealization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, F, K, A, B, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the support-family row, listing the inspected nonempty support symbols.*
2. *F is the complement-face row, sending each support to its face in the tetrahedron boundary.*
3. *K is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *boundary-subcomplex row generated by the downward closure of the displayed complement faces.*
4. *A is the realization admission row, recording that every displayed support family produces a subcomplex of $\partial\Delta^3$.*
5. *B is the reverse realization row, recording the finite facet-to-support construction for each displayed boundary subcomplex.*
6. *L is the census handoff row, exposing the realized subcomplex to* $\mathsf{SupportNerveCensus}^{\uparrow}$ *and* $\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}$ *consumers.*
7. *H records componentwise* hsame *transport for the support, face, subcomplex, admission, reverse, handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from support-family inspection through complement faces, downward closure, reverse facet witnesses, and census handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{SupportNerveRealization}^{\uparrow}$, $\mathsf{SupportNerveCensus}^{\uparrow}$, $\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{SupportNerveRealization}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, F, K, A, B, L, H, C, P, N$. It has no coordinate for host geometric realization, ambient equality of complexes, unrestricted chain homology, coefficient-field choice, or an infinite support universe.

Lean4 ✓ `BEDC.Derived.SupportNerveRealizationUp.SupportNerveRealizationTasteGate single carrier alignment`

Theorem 4079.2 (Support nerve realization NameCert obligations)**.** *For every accepted* $\mathsf{SupportNerveRealization}^{\uparrow}$ *carrier $R = (S, F, K, A, B, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SupportNerveRealization}^{\uparrow}}$ *surface consists exactly of support-family exposure, complement-face exposure, finite* $\mathsf{SimplicialComplex}^{\uparrow}$ *boundary-subcomplex admission, reverse facet-to-support realization, census handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 4079.1. The rows S, F, K display the support family, its complement faces, and the resulting downward-closed boundary subcomplex.

The two realization directions are stored in A and B. The admission row verifies that displayed supports produce a subcomplex of $\partial\Delta^3$, while the reverse row records the finite facet-complement supports that realize a displayed subcomplex.

Finally use L, H, C, P, N. The handoff row sends the same finite subcomplex to census and lifted-Betti consumers, and the structural rows transport, replay, source, and name the packet. Since no ambient geometric realization, unrestricted homology computation, coefficient-field choice, or host equality coordinate is present, the listed rows exhaust the local obligations. □

Theorem 4079.3 (Support nerve realization census handoff)**.** *Every* $\mathsf{SupportNerveCensus}^{\uparrow}$ *or* $\mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}$ *consumer of an accepted* $\mathsf{SupportNerveRealization}^{\uparrow}$ *carrier must first read the finite route*

$$\mathsf{SupportNerveRealization}^{\uparrow} \longmapsto \mathsf{SimplicialComplex}^{\uparrow} \longmapsto \mathsf{SupportNerveCensus}^{\uparrow} \longmapsto \mathsf{SupportNerveCensusLiftedBetti}^{\uparrow}.$$

The route exposes support rows, complement-face rows, boundary-subcomplex rows, reverse facet witnesses, transport, replay, provenance, and local naming before any census or lifted-Betti entry is exported.

Proof. Start with S, F, K. These rows build the finite support nerve as a displayed subcomplex of the tetrahedron boundary.

Use the realization obligations A and B. They identify both directions of the support-family-to-subcomplex correspondence without leaving the finite face inventory.

Repack through L, H, C, P, N. The census and lifted-Betti consumers receive the same displayed subcomplex and its support witnesses, while the structural rows preserve the packet. Coordinate exhaustion prevents an ambient realization, unrestricted homology computation, or coefficient-field selector from entering the handoff. □

Falsifiable prediction: Every accepted $\mathsf{SupportNerveRealization}^{\uparrow}$ consumer displays support-family rows, complement-face rows, a finite $\mathsf{SimplicialComplex}^{\uparrow}$ boundary-subcomplex row, reverse facet witnesses, census handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before a census or lifted-Betti read is public.

Independence witness: support-nerve-census, support-nerve-census-lifted-betti, simplicialcomplex: $\mathsf{SupportNerveRealization}^{\uparrow}$ is not bijective to any listed sibling because it binds the forward

support-to-subcomplex construction and reverse facet-support realization before the census handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{SupportNerveRealization}^{\uparrow}}$.

Constructive story: A $\mathsf{SupportNerveRealization}^{\uparrow}$ packet is generated from support-family rows, complement-face rows, finite SimplicialComplex boundary-subcomplex rows, reverse facet-to-support witnesses, census handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SupportNerveRealization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4079.1, Definition 4079.2, and Definition 4079.3 seed the finite support-family-to-boundary-subcomplex realization packet and its census handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SupportNerveRealization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host geometric realization, ambient equality of complexes, unrestricted homology, coefficient-field choice, or infinite support universes.

Upgrade path: Obligation closure requires checked support exposure, complement-face exposure, boundary-subcomplex admission, reverse facet-support realization, census handoff, transport, replay, provenance, and local naming for BEDC.Derived.SupportNerveRe

$\mathsf{CauchyDiagonalSelection}^{\uparrow}$ consumes the non-quotient classifier route of chapter 1820 before selecting a displayed diagonal regular-Cauchy handoff.

Chapter 4080

A Concrete Naming Certificate for $\mathsf{CauchyDiagonalSelection}^{\uparrow}$

Following Bishop and Bridges on constructive diagonal arguments for Cauchy families, the $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ packet records the finite row that chooses a diagonal observation window from displayed regular-Cauchy data before any Real or Completion consumer reads a seal. It sits after the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the Bishop Cauchy-modulus extraction route of chapter 4071. The diagonal-selection route is consumed by chapter 1809 as a countable dense handoff for completion-facing density reads. The same diagonal window is later consumed by chapter 7328, where the selected index is normalized into a dyadic schedule before RegSeqRat and Real consumers read the endpoint. The packet supplies a named L10 diagonal-selection handoff for Real and Completion routes; it does not assert a host sequence selector, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4080.1 (Cauchy diagonal selection carrier)**.** *A* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, R, M, W, T, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source schedule, exposing the finite family of observation windows available to the diagonal request.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the displayed stream windows.*
3. *M is the Cauchy-modulus extraction row, read through* $\mathsf{BishopCauchyModulusExtraction}^{\uparrow}$ *as the finite threshold discipline for the request.*
4. *W is the diagonal-window row, selecting the single displayed window whose source index and precision index have both passed through S, R, M.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the comparison between the requested tolerance, the extracted threshold, and the chosen diagonal window.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the regular readback, modulus row, diagonal window, and dyadic ledger have been displayed.*
7. *H records componentwise* hsame *transport for the stream schedule, regular readback, modulus extraction, diagonal window, tolerance ledger, Real seal, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from the tolerance request through S, R, M, W, T, E and then through the structural rows.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BishopCauchyModulusExtrac $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, M, W, T, E, H, C, P, N$. It has no coordinate for an external diagonal selector, quotient stream equality, hidden subsequence choice, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyDiagonalSelectionUp.CauchyDiagonalSelectionTasteGate single carrier alignment`

Theorem 4080.2 (Cauchy diagonal selection Real uniform-structure anchor)**.** *Every* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *consumer that reads the diagonal window as Real completion data first passes through the* $\mathsf{RealUniformStructure}^{\uparrow}$ *surface of chapter 1624. For an accepted carrier $D = (S, R, M, W, T, E, H, C, P, N)$, the visible route is*

$\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, hsame, Cont, Pkg, NameCert.

Thus the diagonal consumer reads finite uniform-entourage, stream-window, regular-rational, dyadic-tolerance, transport, replay, provenance, and naming rows before any completion-facing Real seal is consumed. It cannot replace those rows by a detached selector, quotient stream equality, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4080.1. The rows S, R, T, E, H, C, P, N already expose the finite stream windows, regular-rational readback, dyadic tolerance ledger, terminal Real seal, transport, replay, provenance, and local naming data.

Read the Real completion request through chapter 1624. The uniform-structure packet supplies the displayed Real entourage discipline consumed by the diagonal window before the downstream Real-facing seal is inspected.

The structural rows H, C, P, N then preserve that same route. Since the carrier has no coordinate for a detached selector, quotient stream equality, host real equality, countable choice, or ambient Real completeness, the Real-uniform-structure anchor is the only completion-facing dependency exposed by this theorem. □

Theorem 4080.3 (Cauchy diagonal selection NameCert obligations)**.** *For every accepted* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *carrier $D = (S, R, M, W, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyDiagonalSelection}^{\uparrow}}$ *surface consists exactly of five finite obligations:*

1. *diagonal-window selection, requiring the selected row W to display both the stream source window from S and the regular readback from R before the diagonal observation is admitted;*

2. *regular-Cauchy preservation, requiring R and M to keep the readback inside the same regular Cauchy family under the extracted threshold;*

3. *dyadic tolerance control, requiring T to compare the requested tolerance with the modulus threshold and the selected diagonal window;*

4. *Real-seal handoff, requiring E to be downstream of S, R, M, W, T and to export only the displayed diagonal observation;*

5. *ledger non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed packet, with no external selector, quotient stream equality, hidden subsequence choice, countable choice, trichotomy, host equality, or ambient completeness coordinate.*

Proof. Project the carrier of Definition 4080.1. The row W is meaningful only after the stream schedule and regular readback rows have been displayed, so the diagonal observation has no source outside S and R.

The modulus row M supplies the finite threshold discipline consumed by the regular-Cauchy read. Thus the readback remains inside the same displayed family rather than becoming a selected subsequence or a host-level limit.

The tolerance ledger T checks the requested dyadic scale against the extracted threshold and the chosen diagonal window. Only after that finite comparison can the Real-facing row E be consumed.

Finally, H, C, P, N preserve and name the same coordinates. Since none of the refused objects appears in the carrier, the five displayed obligations exhaust the local certificate surface. □

Theorem 4080.4 (Cauchy diagonal selection Real-seal handoff)**.** *For every accepted* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *carrier $D = (S, R, M, W, T, E, H, C, P, N)$, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is reachable only after the* $\mathsf{StreamName}^{\uparrow}$ *schedule S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{BishopCauchyModulusExtraction}^{\uparrow}$ *row M, diagonal window W, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T are displayed. The handoff exports no external diagonal selector, quotient stream equality, hidden subsequence choice, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier in Definition 4080.1. The Real-facing row E appears only downstream of the displayed schedule, regular readback, modulus extraction, diagonal window, and dyadic tolerance ledger.

Use the five obligations in Definition 4080.3. They require diagonal-window selection through S, R, W, regular-Cauchy preservation through R, M, dyadic tolerance control through T, and Real-seal handoff through E after those rows are visible.

The structural rows H, C, P, N transport, replay, source, and name that same finite route. Since the carrier has no coordinate for an external diagonal selector, quotient stream equality, hidden subsequence choice, countable choice, trichotomy, host real equality, or ambient completeness, none can be exported at the seal. □

Theorem 4080.5 (Cauchy diagonal selection RegSeqRat threshold stability)**.** *Let $D = (S, R, M, W, T, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *carrier. Suppose another accepted carrier*

$$D' = (S, R, M', W, T, E, H, C, P, N)$$

has the same $\mathsf{StreamName}^{\uparrow}$ *schedule S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, diagonal window W, tolerance ledger T, Real seal E, transport row H, replay row C, provenance row P, and local naming row N, and suppose the displayed threshold row M' is a stronger Cauchy-modulus threshold compatible with the same S, R, W, T rows. Then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and terminal* $\mathsf{Real}^{\uparrow}$ *seal of D' remain on the same finite route as those of D:*

$$S, R, M', W, T \longmapsto E \longmapsto H, C, P, N.$$

In particular, strengthening the modulus threshold does not introduce an external diagonal selector, quotient stream equality, hidden subsequence choice, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project both carriers through Definition 4080.1. The two packets differ only in the modulus row, while $S, R, W, T, E, H, C, P, N$ are displayed as the same rows in both packets.

Apply the NameCert obligations of Definition 4080.3. The regular-Cauchy preservation obligation reads the modulus row only as the finite threshold discipline attached to R, and the dyadic tolerance obligation reads T against the chosen diagonal window W.

Since M' is a displayed stronger threshold compatible with the same S, R, W, T rows, the replay through C transports the regular readback along the same finite request route. No new selector or quotient comparison is needed to read the strengthened threshold.

Finally apply the Real-seal handoff of Definition 4080.4. The terminal seal E can still be consumed only after S, R, M', W, T are displayed, and the structural rows H, C, P, N keep the route inside the listed coordinates. □

Theorem 4080.6 (Cauchy diagonal selection finite-window induction)**.** *Let $D = (S, R, M, W, T, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *carrier. Induction over the displayed finite window schedule preserves the route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{BishopCauchyModulusExtraction}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

In particular, strengthening or extending any finite prefix keeps the selected diagonal read inside $S, R, M, W, T, E, H, C, P, N$ and cannot introduce an external selector, quotient stream equality, countable choice, trichotomy, host equality, or ambient completeness.

Proof. The base window is the carrier projection of Definition 4080.1. The rows S, R, M, W, T, E already display the StreamName schedule, regular readback, modulus threshold, diagonal window, dyadic tolerance ledger, and Real seal in the stated order.

For the induction step, extend a displayed finite prefix by one accepted window. The NameCert obligations of Definition 4080.3 force the new window to be read through S and R, then checked by the modulus row M and tolerance ledger T before the Real-facing row E is consumed.

If the extension strengthens the threshold instead of adding a new observation, apply RegSeqRat threshold stability, Definition 4080.5. The strengthened row remains compatible with the same S, R, W, T route and does not add a separate selector.

Finally use the Real-seal handoff, Definition 4080.4. Since H, C, P, N transport, replay, source, and name only the displayed packet, the induction cannot acquire quotient stream equality, countable choice, trichotomy, host equality, or ambient completeness from outside the carrier. □

Theorem 4080.7 (Cauchy diagonal selection subsequence route)**.** *Let $D = (S, R, M, W, T, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *carrier. When D is read as a subsequence corridor, every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *seal consumer factors first through the* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *surface of chapter 5902. The diagonal window is therefore consumed only along the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{BishopCauchyModulusExtraction}^{\uparrow},\ \mathsf{CauchySubsequenceSelector}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{R}$$

with structural support carried by H, C, P, N. The route exposes no external diagonal selector, quotient stream equality, countable-choice subsequence, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 4080.1. The rows S, R, M, W, T display the source schedule, regular readback, modulus threshold, selected diagonal window, and dyadic tolerance ledger before E is available.

Apply finite-window induction, Definition 4080.6. Each accepted prefix keeps the selected window inside S, R, M, W, T, so the diagonal read has the same finite selector shape required by the $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ carrier surface.

Read the selector monotonicity and Cauchy-gap rows from chapter 5902. They supply the subsequence corridor between the displayed stream windows and the regular-rational handoff, while preserving the diagonal packet's structural rows H, C, P, N.

Finally apply the Real-seal handoff, Definition 4080.4. Since the consumer reaches E only after the selector corridor, regular readback, modulus threshold, diagonal window, and tolerance ledger have been displayed, it cannot import an external diagonal selector, countable choice, quotient stream equality, host real equality, or ambient completion principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyDiagonalSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ packet is generated from StreamName source windows, RegSeqRat regular readback, a BishopCauchyModulusExtraction threshold row, a selected diagonal window, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyDiagonalSelection}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 4080.1, Definition 4080.3, Definition 4080.4, Definition 4080.5, Definition 4080.6, and Definition 4080.7 give the obligation surface over StreamName, RegSeqRat, BishopCauchyModulusExtraction, CauchySubsequenceSelector, DyadicRatCore, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyDiagonalSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected subsequences, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires a checked scope boundary for downstream Real-separability and regular-modulus-normalization consumers.

The diagonal selector reads $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, and $\mathsf{Real}^{\uparrow}$ seal rows through the non-quotient classifier route of chapter 1820. This keeps the selected diagonal handoff attached to displayed regular-Cauchy evidence rather than to a quotient class, representative selector, ambient completeness rule, or host equality oracle. The $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ packet forwards its selected finite tail through the $\mathsf{CauchyFilterLimit}^{\uparrow}$ handoff of chapter 1558 before any Real-facing consumer inspects the terminal seal. This route preserves the existing $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ dependencies from the diagonal-selection carrier, so the handoff is a displayed completion-facing dependency rather than a detached selector or ambient limit principle. Every completion-facing $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ read consumed by chapter 1558 must first display the $\mathsf{StreamName}^{\uparrow}$ finite-window row, the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback row, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the diagonal-window selection row, and the terminal $\mathsf{Real}^{\uparrow}$ seal. The $\mathsf{CauchyFilterLimit}^{\uparrow}$ consumer therefore receives a lattice route through displayed rows, not a detached diagonal selector, quotient stream equality, selected host limit, countable-choice schedule, or ambient completeness principle. The $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ route consumes the regularized Cauchy-modulus handoff of chapter 7888 before any diagonal subsequence or Real seal is read. Thus a diagonal consumer must expose the $\mathsf{CauchyModulus}^{\uparrow}$ threshold row, $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal route rather than reading the diagonal as a detached selector, quotient stream, or ambient completeness coordinate. The $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ consumer link records the downstream read shared by diagonal-selection, regular-Cauchy extraction, and L10 completion consumers.

Theorem 4080.8 (Cauchy diagonal selection consumer link)**.** *Every* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *consumer reaches its selected diagonal only through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, and the diagonal-selection sibling routes of Definition 4080.15 and Definition 4080.16. When the consumer is compared with the regular-Cauchy diagonal-extraction*

surface of chapter 1773, the shared route is the finite handoff through the source windows, regular readback, dyadic tolerance ledger, diagonal window, terminal $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local* NameCert *row. It exports no detached selector, quotient stream equality, countable-choice schedule, selected host limit, or ambient completion principle.*

Proof. Project the carrier $D = (S, R, M, W, T, E, H, C, P, N)$ from Definition 4080.1. The rows S and R expose the finite $\mathsf{StreamName}^{\uparrow}$ windows and the $\mathsf{RegSeqRat}^{\uparrow}$ readback before the selected window W can be consumed.

Use Definition 4080.15 to fix the displayed StreamName, RegSeqRat, DyadicRatCore, and Real-seal route. Then use Definition 4080.16 to compare that route with the regular-Cauchy diagonal-extraction chapter.

The structural rows H, C, P, N preserve this handoff under transport, replay, provenance, and local naming. Since the carrier contains no coordinate for quotient stream equality, countable choice, a selected host limit, or ambient completion, every consumer that reaches the selected diagonal remains inside the displayed finite route. □

The $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ dossier is consumed by chapter 4202 through the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows recorded in the local carrier. This cross-reference keeps the diagonal-selection window visible as the finite input to the rational interval locator, rather than as a self-contained selector detached from the surrounding real-name lattice. The $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ dependency route also consumes the rectangular-window and cofinal-schedule surface of chapter 1689 together with the single diagonal-index route of chapter 1873 before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ readback is exposed. Thus the selected diagonal window is a finite handoff through displayed double-diagonal and diagonal-argument rows, not a detached selector or an ambient completion claim. The $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ L10 route consumes the source windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the Real seal of chapter 38 through the carrier displayed in Definition 4080.1. These dependencies are already part of the diagonal-selection packet; this child route makes them visible to the top-level dossier scan without adding a second closure ledger or theorem surface. The $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ forward route consumes the regular Cauchy modulus transfer of chapter 7610, the finite $\mathsf{StreamName}^{\uparrow}$ source windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback rows of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38 before any diagonal-selection read is exported. Thus the sibling lattice records the diagonal window as a displayed finite dependency route, not as an isolated selector, quotient stream, selected limit, or ambient completeness coordinate.

Theorem 4080.9 (Cauchy diagonal selection rational-interval locator route)**.** *Every* $\mathsf{RationalIntervalLocator}^{\uparrow}$ *consumer that reads a* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *diagonal window must first display the finite* $\mathsf{StreamName}^{\uparrow}$ *observation windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal carried by the diagonal-selection packet. The route then hands the visible rational lower and upper interval data to chapter 4202; it exports no new selector, quotient stream equality, selected real limit, countable-choice schedule, or ambient completeness claim.*

Proof. Project the diagonal-selection packet through its displayed child routes. The only analytic rows available before locator consumption are the finite StreamName windows, regular rational readback rows, dyadic tolerance ledger, and Real seal.

The rational-interval locator may therefore read the selected diagonal window only after those rows are visible. At that point the lower and upper rational interval data are already finite packet

data, so the consumer receives a local locator route rather than a new diagonal selector or a completion theorem.

Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve that same route into chapter 4202. Since no carrier row contains quotient stream equality, a selected real limit, a countable-choice schedule, or ambient completeness, the route exports none of those objects. □

The CauchyDiagonalSelection$^{\uparrow}$ diagonal window selected from the StreamName$^{\uparrow}$ source schedule, RegSeqRat$^{\uparrow}$ regular readback, and DyadicRatCore$^{\uparrow}$ tolerance ledger is the finite window read by RationalIntervalLocator$^{\uparrow}$ in chapter 4202 before a Real$^{\uparrow}$-facing interval consumer can inspect rational lower and upper bounds. This route records that the locator consumes the displayed diagonal window as interval data, rather than importing a selected real limit, quotient stream equality, countable-choice schedule, or ambient completeness coordinate. The rational lower and upper endpoint exports of chapter 4202 consume the CauchyDiagonalSelection$^{\uparrow}$ finite-window route before any Real$^{\uparrow}$-facing read treats those endpoints as interval evidence. This downstream use keeps the locator's bracket rows tied to displayed StreamName, RegSeqRat, and dyadic tolerance data rather than to a selected real limit, quotient stream equality, or ambient completeness coordinate. The CauchyDiagonalSelection$^{\uparrow}$ route feeds the RealLocator$^{\uparrow}$ interval read of chapter 1669 only after the finite source windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38 have been displayed. Thus the locator-facing consumer reads the same diagonal-selection window and sibling rows before any completion-facing seal is exposed, rather than importing a detached selector, quotient stream, selected limit, or ambient completeness coordinate. The RealSeparability$^{\uparrow}$ countable-dense handoff of chapter 1809 consumes the CauchyDiagonalSelection$^{\uparrow}$ window only after the StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, and Real$^{\uparrow}$ rows have been displayed. Thus the diagonal-selection packet supplies the finite diagonal route for the separability consumer without introducing a quotient stream, a selected real representative, or a choice schedule.

Theorem 4080.10 (Cauchy diagonal selection real-spread route)**.** *Every* CauchyRealSpread$^{\uparrow}$ *or* Real$^{\uparrow}$ *completion consumer that reads a* CauchyDiagonalSelection$^{\uparrow}$ *diagonal window must first pass through the StreamName-RegSeqRat route of Definition 4080.15. The handoff then feeds the real-spread completion surface of chapter 4161 and the terminal real-name seal of chapter 38 using only the displayed finite source windows, regular rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming rows.*

Proof. Project the StreamName-RegSeqRat route already displayed in this chapter. It exposes finite StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readback, dyadic tolerance data, and the terminal Real$^{\uparrow}$ seal before a diagonal-selection consumer can read the selected window.

The CauchyRealSpread$^{\uparrow}$ handoff consumes exactly that finite completion-facing data. Its sibling chapter records a real-spread completion route, and the Real$^{\uparrow}$ chapter supplies the terminal seal; neither sibling adds a new selector to the diagonal-selection packet.

Transport, replay, provenance, and local naming preserve the same rows. Thus the route to CauchyRealSpread$^{\uparrow}$ and Real$^{\uparrow}$ is the displayed completion route, not countable choice, quotient stream equality, selected representatives, or a detached host completion. □

Theorem 4080.11 (Cauchy diagonal selection nonescape)**.** *Every completion-facing consumer generated from a* CauchyDiagonalSelection$^{\uparrow}$ *packet and the real-spread route above remains inside the displayed StreamName, RegSeqRat, dyadic-tolerance, Real-seal, transport, replay, provenance,*

and local-name rows. It cannot become countable choice, a selected representative family, quotient stream equality, a detached diagonal selector, or an ambient completeness principle.

Proof. Induct over the displayed diagonal-selection packet. The base case has only the source windows, regular readback, tolerance ledger, and Real seal already named by Definition 4080.15.

In the finite step case, the real-spread consumer may read a new diagonal window only after those rows are visible. The sibling $\mathsf{CauchyRealSpread}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ chapters receive the same finite completion-facing data and do not add a choice schedule or selected representative coordinate.

The structural rows then transport, replay, source, and name the packet. Since no row contains countable choice, quotient stream equality, selected representatives, a detached selector, or ambient completeness, none of those objects can escape from the displayed route. □

Theorem 4080.12 (Cauchy diagonal selection RealSpread dependency anchor)**.** *Any* $\mathsf{CauchyRealSpread}^{\uparrow}$ *or Real-separability consumer reading a* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *diagonal route must pass through the* $\mathsf{StreamName}^{\uparrow}$ *windows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of chapter 301, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows of chapter 291, the* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *diagonal schedule of chapter 4080, and the* $\mathsf{CauchyRealSpread}^{\uparrow}$ *dependency route of chapter 4161 before it consumes the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38. The route is a finite projection of displayed dependency rows, not a compactness principle or choice principle.*

Proof. Project the diagonal-selection carrier through Definition 4080.15. The visible rows are the finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, selected diagonal schedule, and terminal Real seal.

Read the real-spread dependency route before the Real-facing consumer. That sibling route receives the same displayed window, readback, tolerance, and schedule rows; it does not add a branch selector or a countable-choice schedule.

Finally pass to the terminal $\mathsf{Real}^{\uparrow}$ seal. Since every row in the path is already displayed by the diagonal-selection and real-spread packets, the anchor only projects a finite dependency route and does not assert new compactness, quotient equality, host real equality, or ambient completeness. □

The $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ Real-completion route consumes the finite diagonal-meet surface of chapter 909 after the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are visible, and before any completion-facing selector is public. This records the diagonal-selection handoff as a displayed dependency through the regular Cauchy meet route rather than as a detached selector, quotient stream, selected limit, or ambient completion coordinate. The $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ handoff consumes the $\mathsf{RegularCauchySandwich}^{\uparrow}$ cofinal-tail mesh of chapter 5874 before any completion-facing diagonal route is read. Thus the selected diagonal window is constrained by displayed lower-tail, upper-tail, common-modulus, and regular readback rows rather than by a detached selector, quotient stream, or ambient completeness coordinate. The $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ dossier reads its diagonal-selection window through the same L10 route used by the regular Cauchy modulus siblings: the $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ budget of chapter 4158, the $\mathsf{RegularCauchyModulusTransfer}^{\uparrow}$ handoff of chapter 7610, and the existing $\mathsf{StreamName}^{\uparrow}$-$\mathsf{RegSeqRat}^{\uparrow}$-$\mathsf{Real}^{\uparrow}$ path recorded in Definition 4080.15. Thus diagonal selection consumes finite stream windows, dyadic tolerances, regular rational readback, and terminal real seals as displayed sibling rows rather than as a detached tail selector or quotient-completion representative. The diagonal-selection packet consumes chapter 4158 as the visible uniform tail-budget surface before handing data to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers.

Theorem 4080.13 (CauchyDiagonalSelection regular-Cauchy dependency)**.** *Every accepted* CauchyDiagonalSelecti *read that exports a selected diagonal window first consumes the regular-Cauchy diagonal route of*

chapter 909, the regular rational readback of chapter 301, and the finite stream-window row of chapter 126. The exported diagonal window is therefore downstream of the RegularCauchyDiagonalMeet, RegSeqRat, and StreamName sibling surface, not a detached selector or host-side choice function.

Proof. Project the local $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ route through the existing diagonal-selection carrier. The selected window is read only after the stream schedule and regular readback rows have been exposed.

The regular-Cauchy sibling route supplies the diagonal-meet dependency. Once the consumer has passed through chapter 909, the RegSeqRat row fixes the displayed rational readback and the StreamName row fixes the finite window schedule.

Thus the exported selected diagonal window is a named sibling handoff. No row in the packet supplies a detached selector, quotient stream equality, countable-choice schedule, or host completion representative. □

Theorem 4080.14 (Cauchy diagonal selection regular-Cauchy gluing forward route)**.** *Every* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *consumer that uses a diagonal-selection window from* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *must first expose the finite subsequence window, rowwise Cauchy budget, diagonal index ledger, and componentwise replay rows supplied by the diagonal-selection packet. The handoff supplies the finite window consumed by chapter 5899; it does not choose endpoints, assert completion, select a limit, or replace the gluing packet's own regular-Cauchy compatibility rows.*

Proof. Read the diagonal-selection packet through its local carrier rows. The selected diagonal window, rowwise Cauchy budget, index ledger, transport, replay, provenance, and local naming rows are the only data exported to a downstream gluing consumer.

Feed exactly those rows to the regular-Cauchy gluing route of chapter 5899. The gluing packet may use the finite subsequence window as input, but it must still display its own regular-Cauchy compatibility and gluing rows.

Since the diagonal-selection packet contains no endpoint selector, completion principle, selected limit, or ambient Real-completeness row, the forward route exports none of those claims. □

Theorem 4080.15 (Cauchy diagonal selection StreamName-RegSeqRat route)**.** *Every accepted* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *packet must first expose the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows of chapter 126, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows of chapter 291, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows of chapter 301, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before any diagonal selector is consumed. Thus a completion-facing diagonal request reads the same displayed* S, R, T, E *route recorded by the local carrier and cannot replace it by a detached tail selector, quotient stream, selected limit, or hidden completion representative.*

Proof. Project the carrier $D = (S, R, M, W, T, E, H, C, P, N)$ from Definition 4080.1. The source schedule S supplies the finite $\mathsf{StreamName}^{\uparrow}$ windows, the readback row R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ values, the tolerance row T supplies the $\mathsf{DyadicRatCore}^{\uparrow}$ comparison, and the terminal row E supplies the $\mathsf{Real}^{\uparrow}$ seal.

Use the visible L10 dependency route recorded in chapter 4080. Its sibling route binds the diagonal-selection packet to the displayed StreamName, RegSeqRat, DyadicRatCore, and Real rows before the top-level dossier can be consumed.

Now apply the rational interval locator forward route in the same dossier. That route reads the selected diagonal window as interval data only after the displayed source, readback, and tolerance rows have been exposed.

The structural rows H, C, P, N then transport, replay, source, and name this finite route. Since the carrier has no coordinate for a detached tail selector, quotient stream, selected limit, or hidden completion representative, none of those objects can replace the displayed S, R, T, E route. □

Theorem 4080.16 (Cauchy diagonal selection regular-diagonal extraction link)**.** *Every accepted* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *packet that exposes the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows can be consumed by the regular-Cauchy diagonal-extraction route of chapter 1773 only through those finite windows. The link exports the same schedule, tolerance, regular-readback, and Real-seal rows; it does not supply countable choice, quotient stream equality, a selected representative, or a detached host diagonal.*

Proof. Project the rows already isolated by Definition 4080.15. The visible part of the accepted packet contains the finite StreamName schedule, the DyadicRatCore tolerance ledger, the RegSeqRat readback, and the terminal Real seal.

Now compare with the carrier surface of chapter 1773. Its diagonal extraction route consumes a source family, a unary selector, aligned StreamName windows, one dyadic tolerance ledger, one regular rational diagonal readback, and a terminal Real seal.

The shared rows therefore identify the only admissible handoff. The Cauchy diagonal selection packet may feed the regular-Cauchy extraction route through the displayed windows, but no row introduces countable choice, quotient equality of streams, a selected representative, or a detached host diagonal. □

The diagonal-selection read first fixes the finite stream windows and regular-rational readback before any terminal real seal is available. This places the route beside the $\mathsf{StreamName}^{\uparrow}$ certificate of chapter 126 and the $\mathsf{RegSeqRat}^{\uparrow}$ certificate of chapter 301.

Theorem 4080.17 (Cauchy diagonal StreamName RegSeqRat route)**.** *Every accepted* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *read that exports a diagonal real candidate first consumes the finite* $\mathsf{StreamName}^{\uparrow}$ *windows and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows before the* $\mathsf{Real}^{\uparrow}$ *seal is inspected. The route exposes no direct real equality test, selected infinite subsequence outside the displayed diagonal ledger, quotient stream equality, countable-choice functional, or host completeness principle.*

Proof. Start with the finite diagonal ledger. Each selected row is read through a displayed stream window, so the consumer sees only the finite $\mathsf{StreamName}^{\uparrow}$ observations attached to the diagonal route.

The regular-rational readback is downstream from those windows. It repacks the observed rational approximants as $\mathsf{RegSeqRat}^{\uparrow}$ data before any real-facing seal is offered.

Only after these two sibling dependencies have been replayed may the $\mathsf{Real}^{\uparrow}$ seal be read. The refused objects are not coordinates in the displayed route, so the diagonal-selection packet remains a finite StreamName and RegSeqRat dependency certificate. □

Theorem 4080.18 (CauchyDiagonalSelection RegSeqRat-StreamName real-completion route)**.** *Every completion-facing* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *consumer that reads a diagonal candidate must expose the* $\mathsf{StreamName}^{\uparrow}$ *finite windows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows of chapter 301, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before the selected diagonal window is consumed. The route is therefore a displayed L10 dependency through finite stream windows, regular rational readback, and the real-name boundary, not a detached selector, quotient stream, selected limit, or ambient completeness coordinate.*

Proof. Project the local $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ carrier. Its diagonal window is read only after the stream schedule, regular rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming rows have been exposed.

The cited StreamName, RegSeqRat, and Real sibling chapters provide the three completion-facing boundaries. Since none of those rows stores a selector outside the packet, quotient stream equality, a selected host limit, or ambient completeness, the diagonal-selection consumer remains inside the displayed route. □

Chapter 4081

A Concrete Naming Certificate for $\mathsf{ApproachSpace}^{\uparrow}$

Following Lowen, the $\mathsf{ApproachSpace}^{\uparrow}$ packet records convergence by finite distance-to-set and tolerance observations rather than by a quotient completion or a selected limit object. It sits between the metric carrier of chapter 57, the open-neighbourhood carrier of chapter 88, and the Cauchy-filter completion boundary of chapter 1569. The packet names an L10 convergence object that can be consumed by metric, topology, and filter-completion routes while keeping quotient points, host real equality, countable choice, and ambient completeness outside the carrier.

Definition 4081.1 (ApproachSpace carrier)**.** *An* $\mathsf{ApproachSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, D, T, F, H, C, P, N)$$

with the following displayed rows:

1. *X is the point row, naming the finite point observations and the local classifier surface used by later convergence consumers.*
2. *D is the distance-to-set and tolerance row, recording displayed requests of the form "the observed point is within the listed tolerance of the listed observed set" without importing a host-valued distance function on all subsets.*
3. *T is the topology-neighbourhood row, recording the open-neighbourhood observations generated by the displayed tolerances and the topology-facing classifier inherited from* $\mathsf{Topology}^{\uparrow}$*.*
4. *F is the Cauchy-filter handoff row, naming which finite Cauchy-filter requests may consume D and T before a completion-facing read reaches* $\mathsf{CauchyFilterCompletion}^{\uparrow}$*.*
5. *H records componentwise* hsame *transport for point observations, distance-to-set tolerances, topology-neighbourhood rows, Cauchy-filter handoffs, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay from a convergence query through X, D, T, F, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{ApproachSpace}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{CauchyFilterCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ApproachSpace}^{\uparrow}}$ *row.*

The classifier of an accepted packet compares convergence observations only through X, D, T, F, H, C, P, N. It has no coordinate for quotient completion points, equality in a host real line, countable-choice selectors, ambient completeness, or a hidden global distance-to-all-subsets oracle.

Lean4 ✓ `BEDC.Derived.ApproachSpaceUp.ApproachSpaceTasteGate single carrier alignment`

Theorem 4081.2 (ApproachSpace NameCert obligations)**.** *For every accepted* $\mathsf{ApproachSpace}^{\uparrow}$ *carrier*

$$A = (X, D, T, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ApproachSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the point row, distance-to-set tolerance row, topology-neighbourhood row, Cauchy-filter handoff row, componentwise transport, displayed replay, provenance, and local naming;*
2. *classifier transport, requiring every accepted convergence comparison to preserve* X, D, T, F *through the displayed* hsame *row* H*;*
3. *metric and topology compatibility, requiring metric-origin tolerance reads to enter through* D *and topology-origin neighbourhood reads to enter through* T *before they are compared as one approach-space observation;*
4. *Cauchy-filter handoff, requiring completion-facing reads to pass through* F *before any* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumer uses the packet;*
5. *non-escape, excluding quotient points, host* $\mathsf{Real}^{\uparrow}$ *equality, countable choice, ambient completeness, selected completion representatives, and any hidden bridge claim.*

No local obligation is stored outside these five rows.

Proof. Project the carrier of Definition 4081.1. The finite tuple displays point observations, distance-to-set tolerances, topology-neighbourhood observations, the Cauchy-filter handoff, componentwise transport, replay, provenance, and local naming.

The metric and topology routes meet only at the displayed classifier surface. A metric-origin read must expose D, while a topology-origin read must expose T; transport through H preserves both rows componentwise before the replay row C compares them as one convergence observation.

The completion-facing route is similarly visible. The row F is the only Cauchy-filter handoff coordinate, so a completion consumer reaches $\mathsf{CauchyFilterCompletion}^{\uparrow}$ only after reading the finite rows named by F together with the same transport, replay, provenance, and local naming rows.

Finally inspect the carrier inventory. No coordinate stores quotient completion points, host real equality, countable-choice selectors, selected representatives, ambient completeness, or bridge data. Hence the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.ApproachSpaceUp.ApproachSpaceNameCertObligations`

Theorem 4081.3 (ApproachSpace completion handoff)**.** *For every accepted* $\mathsf{ApproachSpace}^{\uparrow}$ *carrier*

$$A = (X, D, T, F, H, C, P, N),$$

every Cauchy-filter completion consumer must read distance-to-set tolerances through D*, topology-neighbourhood observations through* T*, and the Cauchy-filter handoff through* F *before reaching any completion-facing row. The shared finite convergence packet is therefore*

$$D, T \longmapsto F \longmapsto H, C, P, N.$$

It exports no quotient completion point, selected representative, host $\mathsf{Real}^{\uparrow}$ *equality, countable-choice selector, or ambient completeness row.*

Proof. Project the carrier of Definition 4081.1. The rows D, T, F are the only distance-to-set, topology-neighbourhood, and Cauchy-filter handoff coordinates available to a completion-facing consumer.

Apply the metric and topology compatibility clause of Definition 4081.2. A metric-origin tolerance read must enter through D, and a topology-origin neighbourhood read must enter through T, before the packet treats them as one approach-space observation.

The Cauchy-filter handoff clause then forces the completion-facing read through F. The structural rows H, C, P, N only transport, replay, source, and name that same finite packet.

Finally use the non-escape clause from the obligation theorem. Since the carrier contains no quotient completion point, selected representative, host real equality, countable-choice selector, or ambient completeness coordinate, none of those objects can be reached after the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ApproachSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{ApproachSpace}^{\uparrow}$ packet is generated from point rows, distance-to-set tolerance rows, topology-neighbourhood rows, Cauchy-filter handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApproachSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4081.1 and Definition 4081.2 seed the finite approach-space convergence object over point, tolerance, topology-neighbourhood, Cauchy-filter, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApproachSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion points, host Real equality, countable choice, ambient completeness, selected completion representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, metric/topology compatibility, Cauchy-filter handoff exactness, componentwise transport, replay, provenance, and ledger non-escape for BEDC.Derived.ApproachSpaceUp.

Chapter 4082

A Concrete Naming Certificate for MetaCICConfluenceDiamondBoundary$^{\uparrow}$

The MetaCICConfluenceDiamondBoundary$^{\uparrow}$ packet realizes the confluence audit boundary of chapter 9378 as a finite diamond-frontier object. It sits beside the critical-path carrier of chapter 765, the confluence audit packet of chapter 735, the local diamond witness of chapter 3595, the residual checker of chapter 3827, and the subject-reduction discharge socket of chapter 719. The packet names local peaks, candidate joins, residual frontiers, substitution boundaries, bounded checks, and obstruction rows without claiming full confluence or subject reduction.

Falsifiable prediction: Every accepted MetaCICConfluenceDiamondBoundary$^{\uparrow}$ confluence-frontier read exposes local-peak, candidate-join, residual-frontier, substitution-boundary, bounded-check, obstruction, transport, replay, provenance, and local NameCert rows before any diamond-boundary handoff is consumed.

Independence witness: metaciccriticalpath, metacicconfluenceauditpacket, metacic-local-diamond-witness, metacic-confluence-residual-checker, subject-reduction-discharge-socket: the critical-path carrier records dependency pressure without a per-diamond boundary; the confluence audit packet records global audit rows without bounded local frontier status; the local-diamond witness records a peak and candidate join without residual-checker obstruction retention; the residual checker records bounded residual windows without the subject-reduction socket boundary; and the discharge socket records typing-side rows without confluence peak data. None is bijective to MetaCICConfluenceDiamondBoundary$^{\uparrow}$.

Definition 4082.1 (MetaCIC confluence-diamond boundary carrier)**.** *A* MetaCICConfluenceDiamondBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, J, R, S, B, O, H, C, P, N)$$

with the following displayed rows:

1. *K is the local-peak row, naming the source term and the two outgoing reduction or parallel-reduction observations.*
2. *J is the candidate-join row, recording the proposed common reduct and the two route requests into it.*
3. *R is the residual-frontier row, listing residual redex descendants, binder-depth exposure, and branch-local frontier checks.*

4. *S is the substitution-boundary row, naming the substitution-sensitive input that remains visible whenever the candidate join is not an unconditional diamond.*
5. *B is the bounded-check row, recording the finite closedness, support, branch-compatibility, and variable-escape checks applied to the displayed peak.*
6. *O is the obstruction row, naming the still-open endpoints: unrestricted substitution compatibility, premise-free closed parallel diamond, arbitrary closed Church–Rosser, subject reduction, evaluator equality, and kernel consistency.*
7. *H records componentwise* hsame *transport for local peaks, candidate joins, residual frontiers, substitution boundaries, bounded checks, obstruction rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a confluence query through $K, J, R, S, B, O, H, P, N$.*
9. *P is the* Pkg *provenance over* MetaCICConfluenceDiamondBoundary$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, MetaCICConfluenceA MetaCICLocalDiamondWitness$^{\uparrow}$, MetaCICConfluenceResidualChecker$^{\uparrow}$, SubjectReductionDischargeSocket$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{MetaCICConfluenceDiamondBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, J, R, S, B, O, H, C, P, N$. It has no coordinate for a global confluence theorem, a subject-reduction theorem, unrestricted substitution compatibility, quotient equality of terms, evaluator equality, or kernel consistency.

Theorem 4082.2 (MetaCIC confluence-diamond boundary obligations)**.** *For every accepted* MetaCICConfluenceDi *carrier*

$$D = (K, J, R, S, B, O, H, C, P, N),$$

the local NameCert$_{\text{MetaCICConfluenceDiamondBoundary}^{\uparrow}}$ *surface consists exactly of local-peak exposure through K, candidate-join exposure through J, residual-frontier exposure through R, substitution-boundary retention through S, bounded-check exposure through B, obstruction retention through O, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.MetaCICConfluenceDiamondBoundaryUp.MetaCICConfluenceDiamondBoundaryCarrier namecert obligations`

Proof. Project the carrier of Definition 4082.1. Rows K, J, R, S, B, O are the diamond-facing data, and rows H, C, P, N are the structural certificate data.

The local peak and candidate join must be read together. Row K displays the source and the two outgoing observations, while J records only a proposed common reduct and route requests rather than a global Church–Rosser theorem.

The residual and substitution boundaries remain visible next. Rows R and S expose residual descendants, binder-depth data, and substitution-sensitive inputs, while B records the bounded finite checks that have actually been performed.

Finally O keeps the open endpoints named, and H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate contains full confluence, subject reduction, unrestricted substitution compatibility, quotient term equality, evaluator equality, or kernel consistency, the listed rows exhaust the local NameCert obligations. □

Theorem 4082.3 (MetaCIC confluence-diamond boundary handoff)**.** *Every confluence consumer of an accepted* MetaCICConfluenceDiamondBoundary$^{\uparrow}$ *carrier factors through*

$$K, J, R, S, B, O, H, C, P, N$$

before it may export a diamond-boundary handoff. The handoff may feed the confluence audit packet, local-diamond witness, residual checker, critical-path packet, or subject-reduction discharge socket named above, but it does not fill the substitution boundary, prove subject reduction, prove full confluence, decide evaluator equality, or establish kernel consistency.

Proof. Begin with the obligation surface of Definition 4082.2. It forces every consumer read through the peak row, candidate join row, residual frontier, substitution boundary, bounded checks, and obstruction row before the structural rows are consumed.

The sibling handoffs preserve that boundary. The audit packet may read the confluence-frontier data, the local-diamond witness may read the peak and join rows, the residual checker may read R, S, B, O, the critical-path packet may read the obstruction pressure, and the discharge socket may read only the subject-reduction-facing boundary.

No sibling read adds a hidden theorem row to D. Therefore the handoff remains finite diamond-boundary data and cannot be cited as unrestricted substitution compatibility, subject reduction, full confluence, evaluator equality, or kernel consistency. □

Theorem 4082.4 (MetaCIC confluence-diamond typed-window nonescape)**.** *Any typed-window consumer of an accepted* $\mathsf{MetaCICConfluenceDiamondBoundary}^{\uparrow}$ *packet must display the local peak row K, candidate join row J, residual-frontier row R, substitution-boundary row S, bounded-check row B, obstruction row O, and structural rows H, C, P, N before reading the handoff. The typed window may feed the local-diamond witness and residual-checker siblings named above, but it cannot export subject reduction, full confluence, evaluator equality, or kernel consistency.*

Proof. Start from the carrier of Definition 4082.1. A typed-window read has no coordinate outside $K, J, R, S, B, O, H, C, P, N$, so it must expose the peak, join, residual, substitution, bounded-check, and obstruction rows before any structural replay or provenance row can name the handoff.

Apply the obligation surface of Definition 4082.2. The local $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceDiamondBoundary}^{\uparrow}}$ row records exactly those visible obligations, including obstruction retention and the absence of unrestricted substitution compatibility, subject reduction, evaluator equality, and kernel consistency.

Finally apply the handoff theorem Definition 4082.3. The local-diamond witness may consume K, J, and the residual checker may consume R, S, B, O, but neither sibling adds a theorem row to the typed window. Thus the exported data remain a typed local diamond boundary rather than a global confluence, subject-reduction, evaluator-equality, or kernel-consistency theorem. □

Lean follow-up for `BEDC.Derived.MetaCICConfluenceDiamondBoundaryUp` requires Nontrivial and FieldFaithful TasteGate instances at the displayed carrier surface.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceDiamondBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICConfluenceDiamondBoundary}^{\uparrow}$ packet is generated from local-peak rows, candidate-join rows, residual-frontier rows, substitution-boundary rows, bounded-check rows, obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetaCICConfluenceDiamondBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 4082.1, Definition 4082.2, and Definition 4082.3 seed the finite confluence-diamond boundary packet for MetaCIC audit consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetaCICConfluenceDiamondBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unrestricted substitution compatibility, full confluence, subject reduction, evaluator equality, quotient equality of terms, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local-peak exposure, candidate-join exactness, residual-frontier coverage, substitution-boundary retention, bounded-check exactness, obstruction retention, TasteGate nontriviality, FieldFaithful coverage, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICConfluenceDiamondBoundaryU

Chapter 4083

A Concrete Naming Certificate for ??

Following Darboux and Riemann, the **??** packet isolates the finite upper-sum side of the Darboux interface before a consumer asks for a full upper/lower gap. It sits between the dyadic step-function surface of chapter 428, the tagged finite-sum consumer of chapter 1615, the Darboux integration handoff of chapter 1460, and the tagged-mesh integral boundary of chapter 1526. The packet supplies a finite upper-bound ledger for later Darboux and Riemann criteria without importing host suprema, open-cover compactness, quotient function equality, selected mesh limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4083.1 (Upper Darboux sum carrier)**.** *An **??** carrier is a finite* BHist *packet*

$$U = (P, B, D, S, I, R, H, C, Q, N)$$

with the following displayed rows:

1. *P is the partition row, naming the finite ordered cell list, cell-width ledger, endpoint order, and refinement handle used by every later read.*
2. *B is the cell upper-bound ledger. For each displayed cell it records the chosen upper value row and the comparison proof that every admitted sample value in that cell is below the carried bound.*
3. *D is the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *row over the same partition cells, carrying the step value used to display the upper envelope.*
4. *S is the* $\mathsf{RiemannSum}^{\uparrow}$ *row computed from the displayed widths of P and the upper values exposed by B and D.*
5. *I is the* $\mathsf{DarbouxIntegral}^{\uparrow}$ *provenance row, recording that the upper-sum read is available to the Darboux handoff before any lower-sum or gap row is requested.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *comparison row, exposing the finite real-name comparison used by upper-bound consumers.*
7. *H records componentwise* hsame *transport for the partition, upper-bound ledger, dyadic step row, Riemann-sum row, Darboux handoff, comparison row, replay, provenance, and local naming row.*
8. *C records displayed* Cont *replay from partition cells to upper-bound reads, from upper-bound reads to the dyadic step row, from the dyadic step row to the Riemann-sum row, and from the sum row to the Darboux handoff.*

9. *Q is the* Pkg *provenance over* ??, DyadicStepFunction$^{\uparrow}$, RiemannSum$^{\uparrow}$, DarbouxIntegral$^{\uparrow}$, RiemannIntegral$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{??}$ *row.*

The classifier reads accepted packets only through $P, B, D, S, I, R, H, C, Q, N$. It has no coordinate for a host supremum, an open-cover compactness theorem, a selected mesh limit, a lower Darboux sum, quotient equality of functions, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.UpperDarbouxSumUp.TasteGate.UpperDarbouxSumTasteGate single carrier alignment`

Theorem 4083.2 (Upper Darboux sum NameCert obligations)**.** *For every accepted ?? carrier*

$$U = (P, B, D, S, I, R, H, C, Q, N),$$

the local NameCert$_{??}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the displayed partition row, cell upper-bound ledger, dyadic step row, Riemann-sum row, Darboux handoff, comparison row, transport, replay, provenance, and local naming row;*
2. *partition-refinement stability, requiring each transported refinement of P to carry the same cell-width ledger and to route upper-bound reads through the displayed refinement handle;*
3. *upper-bound ledger transport, requiring B and D to move componentwise by* hsame *while preserving the stated upper relation on every displayed cell;*
4. *Darboux handoff, requiring the row I to expose the upper-sum read to* DarbouxIntegral$^{\uparrow}$ *without producing a lower sum, a gap witness, or a host supremum;*
5. *Riemann-sum consumer boundary, requiring every* RiemannSum$^{\uparrow}$ *or* RiemannIntegral$^{\uparrow}$ *consumer to read the finite widths, upper values, replay, provenance, and local name before it can use the upper-sum row.*

Proof. Carrier admission is the projection of Definition 4083.1. The accepted packet displays exactly the partition, upper-bound, dyadic step, finite sum, Darboux handoff, comparison, transport, replay, provenance, and local naming rows.

Partition-refinement stability comes next. The partition row P names the finite cells and widths, so a transported refinement can only expose an upper read through the same displayed cell ledger and refinement handle.

Upper-bound ledger transport is then componentwise. The rows B and D move together under H, and replay through C recomputes the dyadic upper envelope before the finite sum row S is available.

The Darboux and Riemann boundaries are exhausted by S and I. The Darboux consumer receives only the upper-sum handoff, while a Riemann-facing consumer must read the same finite widths, upper values, replay, provenance, and local name before using the sum.

The excluded analytic objects are absent from the carrier. No row stores a host supremum, open-cover compactness, selected mesh limit, quotient function equality, lower-sum datum, or ambient completeness principle. □

Theorem 4083.3 (Upper-sum consumer boundary)**.** *Every* DarbouxIntegral$^{\uparrow}$, RiemannSum$^{\uparrow}$, *or* RiemannIntegral$^{\uparrow}$ *consumer of an accepted ?? carrier $U = (P, B, D, S, I, R, H, C, Q, N)$ must first read the partition row P, the upper-bound ledger B, the* DyadicStepFunction$^{\uparrow}$ *row D, the finite sum row S, the Darboux handoff I, and the comparison row R, with transport, replay, provenance, and*

local naming supplied by H, C, Q, N. The consumer therefore receives a finite upper-sum route rather than a host supremum, an open-cover compactness proof, a selected limiting mesh, or a quotient function-equality principle.

Proof. Project the accepted carrier. The rows upstream of every exported upper-sum read are P, B, D, S, I, R with structural support H, C, Q, N.

For a Darboux-facing read, the handoff row I is reachable only after the partition, upper-bound ledger, dyadic step row, and finite sum row have been replayed. For a Riemann-facing read, the row S is already the displayed finite sum built from those same cells and upper values.

Since the packet has no additional analytic coordinate, every listed consumer reads the same finite route and cannot bypass it through a host supremum, compactness theorem, selected mesh limit, quotient equality, or ambient completeness. □

Closure status for NameCert$_{??}$**.**

Constructive story: An **??** packet is generated from finite partition rows, cell upper-bound ledgers, dyadic step-function rows, Riemann-sum rows, DarbouxIntegral handoff rows, Real comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{??}$, seed)

Scope closed: Definition 4083.1, Definition 4083.2, and Definition 4083.3 seed the finite upper-sum packet over displayed partition cells, cell upper-bound reads, dyadic-step rows, finite-sum rows, Darboux handoff, Real$^{\uparrow}$ comparison, transport, replay, provenance, local naming, and consumer-boundary rows for Darboux, Riemann, DyadicStepFunction$^{\uparrow}$, RiemannSum$^{\uparrow}$, DarbouxIntegral$^{\uparrow}$, RiemannIntegral$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert consumers.

Formal verification: FormalStatus(NameCert$_{??}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host suprema, open-cover compactness, selected mesh limits, lower Darboux sums, lower-sum gap data, quotient function equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition-refinement stability, upper-bound ledger transport, dyadic step readback, Darboux handoff exactness, Riemann-sum consumer boundary, componentwise transport, displayed replay, provenance, local naming, local NameCert rows, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.UpperDarbouxSumUp.

Chapter 4084

A Concrete Naming Certificate for $\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}$

Following Kuratowski, the $\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}$ packet records a constructive compactness-defect ledger by finite diameter-cover and finite-net rows rather than by a host infimum over all covers. It sits over the complete metric boundary of chapter 128, the total-bounded finite-net route of chapter 127, the compact metric consumer of chapter 129, the finite epsilon-net witness of chapter 1767, and the dyadic tolerance ledger of chapter 291. The packet names a finite compactness-defect surface for later compactness and functional-analysis consumers; it is not an open-cover compactness theorem, not a choice-selected cover, not a quotient hyperspace, and not an ambient real infimum principle.

Definition 4084.1 (Kuratowski measure of noncompactness carrier)**.** *A* $\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, C, T, E, D, V, H, R, P, N)$$

with the following visible rows:

1. *X is the displayed* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *source row whose bounded subset is being inspected.*
2. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary row exposed before completion-facing consumers read any defect claim.*
3. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net comparison row, recording the tolerance-indexed route by which defect zero may be compared with total boundedness.*
4. *E is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *witness row, listing the displayed centers, tolerance cell, and coverage ledger available at the inspected scale.*
5. *D is the finite diameter-cover row, recording the listed cover pieces and their displayed dyadic diameter bounds.*
6. *V is the compactness-defect value ledger, comparing the requested dyadic threshold with the finite diameter and finite-net rows without taking a host infimum.*
7. *H records componentwise* hsame *transport for the source, completeness, total-boundedness, finite-net, diameter-cover, value, replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from a compactness-defect request through $X, C, T, E, D, V, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, C, T, E, D, V, H, R, P, N$. It has no coordinate for an open cover, a selected compactness proof, a host powerset, a quotient compactum, a chosen finite subcover, countable choice, or an ambient real infimum.

Lean4 ✓ `BEDC.Derived.KuratowskiMeasureNoncompactnessUp.KuratowskiMeasureNoncompactnessTasteGate`
`single carrier alignment`

Theorem 4084.2 (Kuratowski measure of noncompactness NameCert obligations)**.** *For every accepted* $\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}$ *carrier $K = (X, C, T, E, D, V, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}}$ *surface consists exactly of carrier admission, complete-metric source exposure, total-bounded finite-net comparison, finite epsilon-net witness visibility, finite diameter-cover exactness, compactness-defect value readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Every compactness or functional-analysis consumer of the packet must read the displayed route

$$X, C \longmapsto T, E, D, V \longmapsto H, R, P, N$$

before treating the defect ledger as compactness-facing evidence.

Proof. Project the carrier of Definition 4084.1. The only source and completion-facing rows are X and C, and the only compactness-defect rows are the finite total-boundedness, finite-net, diameter-cover, and value ledgers T, E, D, V.

The finite-net and diameter-cover rows are displayed before the value ledger is read. Thus a consumer sees centers, coverage data, cover pieces, dyadic diameter bounds, and the requested threshold as finite rows rather than as a hidden open-cover or infimum argument.

Finally H, R, P, N transport, replay, source, and name the same finite route. Since the carrier has no open-cover, selected subcover, host powerset, quotient compactum, countable-choice, or ambient-infimum coordinate, those objects cannot be exported by the local classifier. □

Theorem 4084.3 (Kuratowski measure complete-metric handoff)**.** *Let $K = (X, C, T, E, D, V, H, R, P, N)$ be an accepted* $\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}$ *packet. Any completion-facing consumer that reads the compactness-defect value ledger V must first expose the complete-metric row C, the total-boundedness comparison row T, and the finite epsilon-net row E, and must then replay the same finite diameter-cover row D through H, R, P, N before reaching a* $\mathsf{CompactMetric}^{\uparrow}$ *or functional-analysis consumer.*

The handoff exports only a finite compactness-defect packet over complete metric and finite-net rows. It does not claim open-cover compactness, selected finite subcovers, quotient compacta, countable choice, or an ambient $\mathsf{Real}^{\uparrow}$ *infimum.*

Proof. Start from the accepted carrier in Definition 4084.1. The value row V is downstream of X, C, T, E, D, so it cannot be read before the complete-metric source and finite compactness rows have been displayed.

Use the finite epsilon-net route of chapter 1767. The row E supplies centers, tolerance, and coverage data, while T records the total-bounded comparison and D records the finite diameter cover at the inspected scale.

The replay rows H, R, P, N preserve that route when a $\mathsf{CompactMetric}^{\uparrow}$ or functional-analysis consumer asks for compactness-facing evidence. Because no carrier coordinate stores an open

cover, selected subcover, quotient compactum, countable-choice schedule, or ambient infimum, the consumer receives only the displayed compactness-defect handoff. □

Falsifiable prediction: Every accepted $\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}$ compactness-defect read factors through one complete metric source row, one total-boundedness comparison row, one finite epsilon-net witness, one finite diameter-cover ledger, one dyadic value ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before it can be consumed by a compact metric or functional-analysis route.

Independence witness: completemetric, totallybounded, compactmetric, finite-epsilon-net, dyadicratcore: $\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}$ is not bijective to any listed sibling because those siblings separately supply completeness, finite-net coverage, compact-metric consumption, and dyadic tolerance rows, while this packet binds them to one compactness-defect value ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}$ packet is generated from a metric or complete-metric source row, total-bounded finite-net comparison, finite epsilon-net witness, finite diameter-cover ledger, dyadic compactness-defect value row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4084.1, Definition 4084.2, and Definition 4084.3 seed the constructive compactness-defect packet over complete metric, finite-net, diameter-cover, dyadic value, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KuratowskiMeasureNoncompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, choice-selected finite subcovers, quotient compacta, countable choice, host powersets, ambient Real infima, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, complete-metric handoff, total-bounded finite-net comparison, finite epsilon-net witness visibility, finite diameter-cover exactness, compactness-defect value readback, structural transport, and non-escape for BEDC.Derived.KuratowskiMeasureNoncompactnessUp.

Chapter 4085

A Concrete Naming Certificate for ??

Following Plotkin-style structural operational semantics, the **??** packet records a finite replay of displayed Cont execution rows as BEDC NameCert data. It realizes the computation-as-continuation reading of chapter 9365 between the small-step ledger of chapter 469, the monadic continuation surface of chapter 485, and the unary composition substrate of chapter 931. The packet supplies a reusable execution replay carrier for later operational and MetaCIC chapters without importing a host evaluator, quotient trace equality, global confluence, or an external normalization oracle.

Definition 4085.1 (Continuation replay carrier)**.** *A **??** carrier is a finite* BHist *packet*

$$R = (S, T, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite list of* Cont *step rows, each naming its source history, transition mark, tail context, and target history as displayed BEDC data.*
2. *T is the* $\mathsf{ContinuationTrace}^{\uparrow}$ *ledger that reads the same ordered steps as a small-step trace.*
3. *E is the endpoint row, recording the initial history, terminal history, and boundary read reached by replaying the listed steps.*
4. *H records componentwise* hsame *transport for step rows, endpoint rows, trace ledger, replay route, provenance, and local naming row.*
5. *C records displayed* Cont *replay from the initial endpoint through every row of S to the terminal endpoint, with the unit and composition route readable by* $\mathsf{ContinuationMonad}^{\uparrow}$ *and* $\mathsf{UnaryContMonoid}^{\uparrow}$ *consumers.*
6. *P is the* Pkg *provenance over **??**,* $\mathsf{ContinuationTrace}^{\uparrow}$, $\mathsf{ContinuationMonad}^{\uparrow}$, $\mathsf{UnaryContMonoid}^{\uparrow}$, *chapter 9365,* BHist, hsame, Cont, *and* NameCert.
7. *N is the local* $\mathsf{NameCert}_{??}$ *row.*

The classifier reads accepted packets only through S, T, E, H, C, P, N. It has no coordinate for a host evaluator, quotient trace equality, infinite execution object, global confluence theorem, external normalizer, or hidden monadic semantics.

Lean4 ✓ `BEDC.Derived.ContinuationReplayUp.TasteGate.ContinuationReplayTasteGate single carrier alignment`

Theorem 4085.2 (Continuation replay NameCert obligations)**.** *For every accepted ?? carrier*

$$R = (S, T, E, H, C, P, N),$$

the local NameCert$_{??}$ *surface consists exactly of carrier admission, step-row exposure, endpoint exposure,* ContinuationTrace$^{\uparrow}$ *ledger readback, endpoint transport by* hsame*, displayed* Cont *replay,* Pkg *provenance, local naming, and ledger refusal for host evaluators, quotient traces, infinite execution objects, global confluence, external normalization, and hidden monadic semantics.*

Proof. Carrier admission is the projection of Definition 4085.1. The accepted packet displays only the step list, trace ledger, endpoint row, componentwise transport, replay route, provenance, and local name.

Step-row exposure and endpoint exposure are finite. The row S lists the displayed source, mark, tail, and target data for each step, while E records only the initial and terminal histories reached by replaying that list.

The trace and algebraic consumers read the same route. The ContinuationTrace$^{\uparrow}$ row T supplies small-step readback, and the replay row C supplies the displayed continuation composition route available to ContinuationMonad$^{\uparrow}$ and UnaryContMonoid$^{\uparrow}$ consumers.

Finally, H, P, N transport, source, and name this same finite route. Since no carrier coordinate stores a host evaluator, quotient trace equality, infinite execution, global confluence, external normalization, or hidden monadic semantics, the ledger refusal clauses exhaust the remaining obligation surface. □

Theorem 4085.3 (Continuation replay endpoint transport)**.** *Every endpoint-facing consumer of an accepted ?? carrier $R = (S, T, E, H, C, P, N)$ receives the endpoint row E only after reading the displayed step rows S, the* ContinuationTrace$^{\uparrow}$ *ledger T, and the replay route C, with componentwise transport, provenance, and local naming supplied by H, P, N. The consumer therefore reads finite* Cont *execution rather than a host evaluator graph, quotient trace, global confluence certificate, or external normalizer.*

Lean4 ✓ `BEDC.Derived.ContinuationReplayUp.ContinuationReplayCarrier endpoint transport`

Proof. Project the accepted carrier. The endpoint row E is carried with the same step list S, trace ledger T, replay route C, and structural rows H, P, N.

Replay precedes endpoint export. The route C starts from the initial endpoint, consumes each displayed step row in order, and reaches the terminal endpoint named by E; transport through H preserves this endpoint relation componentwise.

The sibling consumers cannot bypass the route. ContinuationTrace$^{\uparrow}$ reads T as the small-step ledger, while ContinuationMonad$^{\uparrow}$ and UnaryContMonoid$^{\uparrow}$ read the same replay through unit and composition rows. The excluded host objects are not fields of the packet. □

Closure status for NameCert$_{??}$**.**

Constructive story: A **??** packet is generated from finite Cont step rows, ContinuationTrace$^{\uparrow}$ ledgers, endpoint rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{??}$, seed)

Scope closed: Definition 4085.1, Definition 4085.2, and Definition 4085.3 seed the finite continuation replay packet over displayed continuation steps, trace readback, endpoint exposure, componentwise transport, replay, provenance, local naming, and endpoint-boundary rows for ContinuationTrace$^{\uparrow}$, ContinuationMonad$^{\uparrow}$, UnaryContMonoid$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert consumers.

Formal verification: FormalStatus(NameCert$_{??}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host evaluator graphs, quotient trace equality, infinite execution objects, global confluence, external normalization, hidden monadic semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, step-row exposure, endpoint exposure, ContinuationTrace$^{\uparrow}$ readback, hsame endpoint transport, replay exactness, replay stability, componentwise transport, displayed Cont replay, provenance, local naming, local NameCert rows, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.ContinuationReplayUp.

Chapter 4086

A Concrete Naming Certificate for $\mathsf{CauchyCompletenessTheorem}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyCompletenessTheorem}^{\uparrow}$ packet records the theorem-level exit surface for regular Cauchy completeness as finite BEDC NameCert data. It sits after the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the limit operator of chapter 3392, the uniqueness route of chapter 3390, the located-limit route of chapter 4049, and the terminal real-name seal of chapter 38. The packet gives the L10 Real and Completion phase one theorem object whose rows bind construction, uniqueness, locatedness, and Real sealing without quotient streams, selected host limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4086.1 (Cauchy completeness theorem carrier)**.** *A* $\mathsf{CauchyCompletenessTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, S, Q, L, U, A, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger read by every regular Cauchy estimate.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing only the requested observation windows.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row associated to those windows and tolerances.*
4. *L is the* $\mathsf{RegularCauchyLimitOperator}^{\uparrow}$ *row that turns the displayed regular Cauchy data into a Real-facing limit route.*
5. *U is the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *row ensuring that the Real seal does not depend on the chosen regular representative.*
6. *A is the* $\mathsf{RegularCauchyLocatedLimit}^{\uparrow}$ *row exposing the located-limit boundary for the same displayed regular Cauchy name.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, Q, L, U, A have been displayed.*
8. *H records componentwise* hsame *transport for the tolerance, window, readback, limit-operator, uniqueness, located-limit, Real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through*

$$D, S, Q, L, U, A, R \longmapsto \mathsf{NameCert}_{\mathsf{CauchyCompletenessTheorem}^{\uparrow}}.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletenessTheorem}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyLimitOperator}^{\uparrow}$, $\mathsf{RegularCauchyUniqueness}^{\uparrow}$, $\mathsf{RegularCauchyLocatedLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *dependency rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletenessTheorem}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness.

Lean4 (definition) `BEDC.Derived.CauchyCompletenessTheoremUp.CauchyCompletenessTheoremUp`
Lean4 ✓ `BEDC.Derived.CauchyCompletenessTheoremUp.CauchyCompletenessTheoremTasteGate single carrier alignment`

Theorem 4086.2 (Cauchy completeness theorem NameCert obligations)**.** *For an accepted* CauchyCompletenessThe *carrier*

$$T = (D, S, Q, L, U, A, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletenessTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, dyadic tolerance accounting through D, finite-window inspection through S, regular rational readback through Q, limit construction through L, representative independence through U, located-limit boundary control through A, terminal Real sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.CauchyCompletenessTheoremUp.TasteGate.CauchyCompletenessTheoremTasteGate single carrier alignment`

Proof. Project the carrier of Definition 4086.1. The accepted tuple exposes exactly the dyadic ledger, finite windows, regular readback, limit-operator row, uniqueness row, located-limit row, terminal Real seal, and the structural transport, replay, provenance, and naming rows.

The constructive part is exhausted by D, S, Q, L. The dyadic ledger controls the tolerance requests, the stream row bounds the inspected windows, the regular readback supplies the Cauchy name, and the limit operator is the only route from that name to a Real-facing limit.

The theorem-level seal then reads U, A, R. The uniqueness row makes the seal independent of the displayed representative, the located-limit row records the location boundary, and the Real row is available only after both routes have been displayed. Thus no quotient stream, selected host limit, choice schedule, trichotomy decision, or ambient-completeness coordinate remains available as a NameCert obligation. □

Theorem 4086.3 (Cauchy completeness theorem regular seal route)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{CauchyCompletenessTheorem}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RegularCauchyLimitOperator}^{\uparrow} \longmapsto \mathsf{RegularCauchyUniqueness}$$

The consumer receives the terminal $\mathsf{Real}^{\uparrow}$ *seal only as the endpoint of that finite route.*

Proof. Begin with an accepted packet T. Its non-structural rows require the consumer to open the dyadic ledger, finite windows, and regular rational readback before any completion-facing row is visible.

Next the route passes through the regular Cauchy limit operator. The operator supplies the finite construction of the Real-facing limit, while the uniqueness and located-limit rows constrain the same seal by representative independence and locatedness.

The terminal row R is therefore downstream from D, S, Q, L, U, A. Since H, C, P, N only transport, replay, source, and name that route, every L10 phase-exit read factors through the stated chain and cannot bypass it by using quotient streams, selected host limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletenessTheorem}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal while omitting the DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, RegularCauchyLimitOperator row, RegularCauchyUniqueness row, RegularCauchyLocatedLimit row, transport row, replay row, provenance row, or local naming row refutes the packet.

Independence witness: dyadicratcore, streamname, regseqrat, regular-cauchy-limit-operator, regular-cauchy-uniqueness, regular-cauchy-located-limit, real: $\mathsf{CauchyCompletenessTheorem}^{\uparrow}$ is not bijective to any listed sibling because it binds tolerance, window, regular readback, limit construction, uniqueness, locatedness, terminal Real sealing, and the structural rows into one theorem-level L10 exit certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletenessTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletenessTheorem}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat regular readback, RegularCauchyLimitOperator route, RegularCauchyUniqueness route, RegularCauchyLocatedLimit route, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletenessTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4086.1, Definition 4086.2, and Definition 4086.3 seed the L10 Real and Completion theorem exit surface over regular Cauchy construction, uniqueness, locatedness, terminal sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletenessTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance accounting, finite-window inspection, regular readback, limit-operator routing, uniqueness routing, located-limit routing, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletenessTheoremUp.

Chapter 4087

A Concrete Naming Certificate for $\mathsf{CauchyModulusMajorant}^{\uparrow}$

Following Bishop and Bridges on explicit moduli in constructive analysis, the $\mathsf{CauchyModulusMajorant}^{\uparrow}$ packet records the finite certificate that turns an arbitrary displayed Cauchy threshold schedule into a monotone majorant before completion consumers inspect the seal. It sits after the modulus rows of chapter 292, reads dyadic tolerances from chapter 291, reads finite windows from chapter 126, supplies regular rational schedules for chapter 301, and keeps the terminal real read public only through chapter 38.

Definition 4087.1 (Cauchy modulus majorant carrier)**.** *A* $\mathsf{CauchyModulusMajorant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, D, S, R, E, G, H, C, P, N)$$

with the following displayed rows:

1. *A is the incoming* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold schedule;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare requested precisions and majorant bounds;*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming which threshold windows may be inspected;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row consumed by regular rational sequence certificates;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the finite schedule and dyadic comparison rows have been displayed;*
6. *G is the monotone majorant graph row, recording a displayed bound for every inspected threshold window and recording monotonicity as finite comparison data;*
7. *H records componentwise* hsame *transport for the incoming modulus, dyadic ledger, stream windows, regular readback, real seal, majorant graph, continuation, provenance, and local naming rows;*
8. *C records displayed* Cont *replay through the same rows in the order seen by consumers;*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusMajorant}^{\uparrow}}$ *row.*

The carrier has no coordinate for countable choice, hidden convergence witnesses, host-level supremum selection, or a real-number read that bypasses the displayed majorant route.

Theorem 4087.2 (Cauchy modulus majorant NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusMajorant}^{\uparrow}$ *carrier* $M = (A, D, S, R, E, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusMajorant}^{\uparrow}}$ *surface consists exactly of carrier admission, incoming modulus exposure through* A*, dyadic tolerance exposure through* D*, finite-window exposure through* S*, regular readback through* R*, real sealing through* E*, majorant graph exposure through* G*, componentwise transport through* H*, replay through* C*, provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.CauchyModulusMajorantUp.TasteGate.CauchyModulusMajorantTasteGate single carrier alignment`

Proof. Project the carrier of Definition 4087.1. The tuple lists exactly the incoming modulus schedule, dyadic tolerance ledger, stream windows, regular readback, real seal, majorant graph, transport, replay, provenance, and local naming rows.

The majorant obligation is displayed by G. It records a finite bound for each inspected threshold window and records monotonicity as comparison data against the dyadic ledger D.

The consumer route is then forced by C. A RegSeqRat or Real consumer reads S, D, G, R before reaching E, and H transports only the displayed coordinates componentwise.

Since no coordinate for countable choice, hidden convergence witnesses, host supremum selection, or bypassed real reads appears in the carrier, the listed rows exhaust the NameCert surface. □

Theorem 4087.3 (Cauchy modulus majorant normalization route)**.** *Let* $M = (A, D, S, R, E, G, H, C, P, N)$ *be an accepted* $\mathsf{CauchyModulusMajorant}^{\uparrow}$ *packet. Every consumer that replaces an arbitrary Cauchy threshold by a monotone schedule must route the replacement through the displayed graph row* G *after reading the finite windows* S *and the dyadic tolerance ledger* D*, and before exposing the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *or the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*.*

Proof. Start from the carrier definition. The only row that records the monotone majorant is G, while S supplies the inspected windows and D supplies the tolerance comparisons.

The replay row C orders the consumer route through S, D, G, R, E. Thus a regular rational sequence consumer sees the majorant schedule before it receives the readback row R, and a real-number consumer sees the same route before the seal E is opened.

The transport row H is componentwise, so it cannot replace the displayed graph by a host-level monotone choice. The provenance row P records the same dependencies, and N names the local certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusMajorant}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyModulusMajorant}^{\uparrow}$ packet is generated from an incoming Cauchy modulus schedule, DyadicRatCore tolerance comparisons, StreamName finite windows, RegSeqRat readback, a Real seal, a displayed monotone majorant graph, componentwise transport, replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyModulusMajorant}^{\uparrow}}$, seed)

Scope closed: Definition 4087.1, Definition 4087.2, and Definition 4087.3 seed the route that replaces arbitrary Cauchy thresholds by a monotone majorant before RegSeqRat and Real consumers inspect the seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyModulusMajorant}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, choice-free extraction from every external modulus presentation, completion uniqueness, real-order completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, majorant graph exposure, finite-window routing, dyadic comparison routing, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusMajorantUp.

Chapter 4088

A Concrete Naming Certificate for ??

Following Grothendieck's tensor-norm program and Banach-space tensor products in Ryan and Defant–Floret, the **??** packet records the projective tensor norm as finite BEDC NameCert data over displayed tensor-product, norm, Banach, and bounded-operator rows. It is grounded in the algebraic tensor-product surface of chapter 87, the norm row of chapter 89, the Banach carrier of chapter 90, the bounded-linear-operator interface of chapter 1644, and the Banach-algebra consumer surface of chapter 2189. The packet names only the displayed finite decomposition ledgers and their norm bounds; it is not a host infimum, a quotient completion primitive, a selected optimal decomposition, or a choice principle.

Definition 4088.1 (Projective tensor norm carrier)**.** *A **??** carrier over displayed Banach rows E, F is a finite* BHist *packet*

$$\Pi = (E, F, T, D, B, Q, O, H, C, P, N)$$

with the following rows:

1. *E and F are the source* $\mathsf{Banach}^{\uparrow}$ *rows, including their displayed* $\mathsf{Norm}^{\uparrow}$ *and regular-Cauchy surfaces.*
2. *T is the algebraic* $\mathsf{TensorProduct}^{\uparrow}$ *source row over the carried endpoints of E and F.*
3. *D is the finite decomposition ledger: each entry names a finite list of elementary tensors whose displayed tensor sum represents the inspected tensor row.*
4. *B is the crossnorm-bound ledger, recording for each displayed decomposition the finite scalar estimate obtained from the product of the visible source norms.*
5. *Q is the quotient-facing boundary row, stating that equality of tensor representatives is read only through the tensor-product classifier and the displayed decomposition ledger.*
6. *O is the bounded-operator handoff row used by bilinear and operator consumers; it reads through* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *only after T, D, B, Q are displayed.*
7. *H records componentwise* hsame *transport for Banach endpoints, tensor-product rows, decomposition ledgers, bound ledgers, quotient-boundary rows, operator handoff rows, replay data, provenance, and local naming.*
8. *C records displayed* Cont *replay of the route*

$$\mathsf{TensorProduct}^{\uparrow}, \mathsf{Norm}^{\uparrow}, \mathsf{Banach}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow} \longmapsto \textit{??}.$$

9. *P is the* Pkg *provenance over ??,* $\mathsf{TensorProduct}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{BanachAlgebra}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{??}$ *row.*

The carrier exports only finite decomposition and bound data. It has no coordinate for a host infimum over all decompositions, a completed quotient tensor product, a selected minimizing decomposition, ambient Banach-space choice, or hidden operator-space equality.

Theorem 4088.2 (Projective tensor norm NameCert obligations)**.** *For every accepted ?? carrier* $\Pi = (E, F, T, D, B, Q, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{??}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed Banach endpoints, tensor-product row, finite decomposition ledger, crossnorm-bound ledger, quotient-boundary row, bounded-operator handoff row, transport, replay, provenance, and local naming;*
2. *crossnorm bound, requiring each elementary tensor read to pass through the displayed source norms and each finite decomposition estimate to pass through B;*
3. *finite decomposition ledger, requiring every inspected tensor norm claim to name a finite decomposition in D before any bound is exported;*
4. *Banach completion handoff, allowing completion-facing consumers to use only the displayed Banach rows and the later completion boundary of Definition 4088.4;*
5. *nonescape from quotient completions, host infima, selected decompositions, cofinal choice, and ambient operator-space equality.*

Lean4 ✓ `BEDC.Derived.ProjectiveTensorNormUp.TasteGate.ProjectiveTensorNormTasteGate single carrier alignment`

Proof. Project the carrier of Definition 4088.1. The endpoint rows E, F, the tensor-product row T, the decomposition ledger D, and the bound ledger B are visible before any projective-norm read is public.

The crossnorm obligation is finite. An elementary tensor estimate reads the two source norms from E and F, and a general displayed tensor estimate reads the finite list in D together with the scalar comparison rows stored in B.

The quotient-facing and completion-facing material is boundary data. The row Q permits only classifier readback for representatives already displayed by T and D, while O supplies the bounded-operator handoff without adding a completed quotient object.

Finally H, C, P, N transport, replay, source, and name only these rows. Since no carrier coordinate stores a host infimum, a selected optimizing decomposition, a quotient completion, cofinal choice, or ambient operator equality, the listed rows exhaust the local NameCert surface. □

Theorem 4088.3 (Projective tensor norm crossnorm boundary)**.** *Every elementary tensor read accepted by a ?? packet exposes the route*

$$\mathsf{Banach}^{\uparrow}, \mathsf{Norm}^{\uparrow}, \mathsf{TensorProduct}^{\uparrow} \longmapsto E, F, T, D, B$$

before a scalar bound is exported. The boundary identifies the displayed projective-norm estimate with finite source-norm products from E and F, not with a host infimum, a quotient representative, or a selected decomposition of minimal value.

Proof. Start with an elementary tensor request. The carrier of Definition 4088.1 forces the request to read the Banach endpoint rows E, F and the tensor-product row T before the decomposition ledger is inspected.

For elementary tensors the relevant ledger entry in D is a singleton decomposition, and B records the displayed product of the two source norm reads. For finite sums, the same rows are read entry by entry and then combined by the finite scalar comparison stored in B.

No additional optimization step is available. The packet has no coordinate for a host infimum over all decompositions, no quotient representative selector, and no choice row that could pick a preferred decomposition. □

Theorem 4088.4 (Projective tensor norm Banach completion handoff)**.** *Every Banach-completion or bounded-operator consumer of an accepted ?? packet factors through the displayed route*

$$E, F, T, D, B, Q, O, H, C, P, N.$$

It may use the finite projective-bound ledger as input to later $\mathsf{Banach}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, *or* $\mathsf{BanachAlgebra}^{\uparrow}$ *rows, but it receives no completed quotient tensor product, no universal completion object, no selected Cauchy representative, and no ambient completeness theorem.*

Proof. Use the obligation surface of Definition 4088.2. It places every completion-facing read after carrier admission, finite decomposition admission, crossnorm-bound admission, and quotient-boundary readback.

The bounded-operator handoff is exactly the row O. It can route bilinear or operator consumers through the displayed tensor and bound ledgers, but it does not add a separate operator-space quotient or a hidden complete tensor product.

Completion-facing consumers therefore receive only the finite data that the later Banach or operator packet can cite: endpoint Banach rows, tensor-product rows, finite decomposition rows, scalar bound rows, transport, replay, provenance, and local naming. The excluded completion and selection principles have no source coordinate in Π. □

Falsifiable prediction: Every accepted **??** packet must expose Banach endpoints, a TensorProductUp row, a finite decomposition ledger, a crossnorm-bound ledger, a quotient-boundary row, a bounded-operator handoff row, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before any projective tensor norm read is public.

Independence witness: tensorproduct, norm, banach, boundedlinearoperator, banachalgebra: **??** is not bijective to any listed sibling because it jointly carries finite tensor decompositions, crossnorm-bound ledgers, quotient-boundary readback, Banach-completion handoff, componentwise transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{??}$**.**

Constructive story: A **??** packet is generated from displayed Banach endpoint rows, a TensorProductUp source row, finite decomposition ledgers, crossnorm-bound ledgers, quotient-boundary rows, bounded-operator handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{??}$, seed)

Scope closed: Definition 4088.1, Definition 4088.2, Definition 4088.3, and Definition 4088.4 seed the finite projective tensor norm surface over tensor-product, norm, Banach, bounded-operator, and Banach-algebra rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{??}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, completed projective tensor products, host infima over all decompositions, selected optimizing decompositions, quotient completions, cofinal choice, or ambient operator-space equality.

Upgrade path: Obligation closure requires checked carrier admission, crossnorm-bound exactness, finite decomposition ledger coverage, Banach-completion handoff, quotient-boundary readback, transport, replay, provenance, and local naming for BEDC.Derived.ProjectiveTensorNormUp.

Chapter 4089

A Concrete Naming Certificate for $\mathsf{MetricSeparationReflector}^{\uparrow}$

Following Bishop–Bridges constructive metric separation and Kelley-style uniform separation, the $\mathsf{MetricSeparationReflector}^{\uparrow}$ packet records the finite reflector that turns pseudometric zero-distance evidence into separated metric identity without quotient primitives. It sits after the pseudometric carrier of chapter 1614, the separated metric classifier of chapter 1411, and the metric surface of chapter 57. Its completion handoff is read only through chapter 95 and the L10 real-name spine of chapter 291, chapter 126, chapter 301, and chapter 38.

Definition 4089.1 (Metric separation reflector carrier)**.** *A* $\mathsf{MetricSeparationReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (P, Z, S, M, C, D, W, Q, A, H, K, G, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{Pseudometric}^{\uparrow}$ *source row, carrying point observations, finite distance comparisons, and zero-distance witnesses.*
2. *Z is the zero-distance kernel row, recording exactly which displayed pairs of P are admitted as indistinguishable by the pseudometric evidence.*
3. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *identity row, consuming Z before any point classifier is allowed to identify two observations.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *handoff row, exposing the separated metric consumer surface reached after S.*
5. *C is the* $\mathsf{Completion}^{\uparrow}$ *route row for completion-facing consumers.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to inspect finite zero-distance budgets.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule attached to the same finite tolerance requests.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from D and W.*
9. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal through which numerical zero-distance evidence is read.*
10. *H records componentwise* hsame *transport for source rows, kernel rows, separated identity rows, metric handoffs, completion handoffs, tolerance ledgers, stream observations, regular rational readbacks, Real seals, replay data, provenance, and local naming.*
11. *K records displayed* Cont *replay along the same route.*

12. *G is the* Pkg *provenance over* $\mathsf{MetricSeparationReflector}^{\uparrow}$, $\mathsf{Pseudometric}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricSeparationReflector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, Z, S, M, C, D, W, Q, A, H, K, G, N$. It has no coordinate for quotient classes, selected representatives, host equality of points, countable choice, ambient completion, or an external real-line equality oracle.

Lean4 ✓ `BEDC.Derived.MetricSeparationReflectorUp.MetricSeparationReflectorTasteGate single carrier alignment`

Theorem 4089.2 (Metric separation reflector NameCert obligations)**.** *For every accepted* MetricSeparationReflector *carrier $R = (P, Z, S, M, C, D, W, Q, A, H, K, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricSeparationReflector}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the pseudometric source, zero-distance kernel, separated identity, metric handoff, completion route, dyadic tolerance, stream observation, regular rational readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *kernel exposure, requiring every identity-facing request to display the Z row before it can reach the separated metric row S;*
3. *reflector exactness, requiring S to identify precisely the displayed zero-distance pairs admitted by Z and no point pairs outside that row;*
4. *metric and completion handoff, requiring M before metric consumers and C before completion consumers inspect the separated result;*
5. *numerical readback discipline, requiring D, W, Q, A in that order for any finite tolerance or Real-facing zero-distance read;*
6. *structural preservation through H, K, G, N;*
7. *ledger non-escape, excluding quotient classes, selected representatives, host point equality, countable choice, hidden ambient completion, and external Real equality.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4089.1. The accepted packet exposes the pseudometric source, zero-distance kernel, separated identity, metric and completion handoffs, numerical readback rows, and structural rows.

The reflector clause is forced by the route through Z and S. A pseudometric comparison can become point identity only after the corresponding zero-distance pair has appeared in Z, and S is the only displayed row that exports separated identity.

Metric and completion consumers are downstream of that separated identity row. The metric handoff M and completion row C receive only the reflected classifier, while D, W, Q, A expose the finite tolerance and Real-facing readback route used to inspect zero distance.

Finally H, K, G, N preserve, replay, source, and name exactly these displayed rows. Since no excluded object appears as a carrier coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 4089.3 (Metric separation reflector zero-distance kernel)**.** *Let $R = (P, Z, S, M, C, D, W, Q, A, H, K, G, N$ be an accepted* $\mathsf{MetricSeparationReflector}^{\uparrow}$ *carrier. Every identity exported to a* $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *or* $\mathsf{Completion}^{\uparrow}$ *consumer factors through the finite route*

$$\mathsf{Pseudometric}^{\uparrow} \longmapsto Z \longmapsto \mathsf{SeparatedMetric}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{Completion}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqR}$$

Thus zero distance is the displayed kernel of the reflector. The packet exports separated classifier identity, not quotient equality, selected representatives, host point equality, countable choice, or an ambient completion theorem.

Proof. Start with an identity-facing consumer of an accepted packet. The carrier definition gives P as the only pseudometric source row and Z as the only zero-distance kernel row, so the request must first expose the displayed kernel evidence.

The separated identity row S consumes that kernel evidence before any metric or completion consumer can inspect the result. Rows M and C then carry the separated classifier into the metric and completion surfaces.

The numerical route is also explicit. A zero-distance tolerance read passes through D, the finite observation schedule W, the regular rational readback Q, and the terminal Real seal A.

Transport, replay, provenance, and local naming in H, K, G, N preserve this route componentwise. No quotient class, selected representative, host equality proof, choice schedule, or ambient completion coordinate is available to bypass the displayed kernel. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricSeparationReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricSeparationReflector}^{\uparrow}$ packet is generated from PseudometricUp source evidence, a zero-distance kernel row, a SeparatedMetricUp identity row, MetricSpaceUp and CompletionUp handoffs, DyadicRatCoreUp tolerances, StreamNameUp observations, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricSeparationReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4089.1, Definition 4089.2, and Definition 4089.3 seed the finite reflector from pseudometric zero-distance evidence to separated metric identity.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricSeparationReflector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient primitives, selected representatives, host point equality, countable choice, ambient completion, or external Real equality.

Upgrade path: Obligation closure requires checked carrier admission, zero-distance kernel exposure, separated identity exactness, metric and completion handoff, numerical readback, transport preservation, replay, provenance, and non-escape for BEDC.Derived.MetricSeparationReflectorUp.

Chapter 4090

A Concrete Naming Certificate for ??

The **??** packet realizes the local suffix-support rank theorem of Definition 9462.1756 and Definition 9462.1757 as finite BEDC NameCert data. It consumes the six-coordinate codon source of chapter 2234, the boundary classifier of chapter 3393, the coverage-rank surface of chapter 3470, and the codon lift-orbit classifier of chapter 4059. The packet records the stop/Trp face as the local two-coordinate square whose proper-support vertices are the stop row and whose full-support corner is the retained Trp row; it is not a biological mechanism, stochastic fitness model, quotient codon semantics, or hidden global translation table.

Definition 4090.1 (Stop/Trp face rank-deficiency carrier)**.** *A **??** carrier is a finite* BHist *packet*

$$F = (W, B, C, O, S, R, L, H, K, P, N)$$

with the following displayed rows:

1. *W is the* CodonSixBitWindow$^{\uparrow}$ *source-window row exposing the six-bit codon coordinates.*
2. *B is the* DnaWindowSixBoundaryTile$^{\uparrow}$ *stop/Trp boundary row, selecting the* U+RR *face* $\{\mathrm{UAA}, \mathrm{UAG}, \mathrm{UGA}, \mathrm{UGG}$
3. *C is the* SixBoundaryTileCoverage$^{\uparrow}$ *coverage row that keeps the visible boundary support inside the displayed tile surface.*
4. *O is the* CodonLiftOrbitClassifier$^{\uparrow}$ *row that records the finite orbit-readback context for the same codon window.*
5. *S is the local suffix-support table row based at* UAA*, with supports $\varnothing$, $\{f_3\}$, $\{f_2\}$, and $\{f_2, f_3\}$.*
6. *R is the rank-deficiency row, recording that stop vertices are exactly the rows whose support is a proper subset of $\{f_2, f_3\}$.*
7. *L is the ledger row separating the full-support* UGG *corner from the three proper-support stop vertices.*
8. *H records componentwise* hsame *transport for source windows, boundary tiles, coverage rows, orbit-classifier rows, suffix-support rows, rank rows, ledger rows, replay, provenance, and local naming.*
9. *K records displayed* Cont *replay from a stop-face query through W, B, C, O, S, R, L, H.*
10. *P is the* Pkg *provenance over **??**,* CodonSixBitWindow$^{\uparrow}$, DnaWindowSixBoundaryTile$^{\uparrow}$, SixBoundaryTileCoverage$^{\uparrow}$ CodonLiftOrbitClassifier$^{\uparrow}$, *Definition 9462.1757,* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{??}$ *row.*

The classifier accepts a stop-face rank read only through $W, B, C, O, S, R, L, H, K, P, N$. It has no coordinate for a hidden genetic-code table, probabilistic dynamics, quotient codon equality, biological causation, or a global semantic equivalence.

Lean4 ✓ `BEDC.Derived.StopTrpFaceRankDeficiencyUp.StopTrpFaceRankDeficiencyTasteGate single carrier alignment`

Theorem 4090.2 (Stop/Trp face rank-deficiency NameCert obligations)**.** *For every accepted ?? carrier $F = (W, B, C, O, S, R, L, H, K, P, N)$, the local* NameCert$_{??}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the codon-window, boundary-tile, coverage, lift-orbit, suffix-support, rank-deficiency, ledger, transport, replay, provenance, and local naming rows;*
2. *face exposure, requiring the stop/Trp read to pass through W and B before any support rank is inspected;*
3. *coverage and orbit compatibility, requiring C and O to preserve the same displayed codon-window context as W and B;*
4. *suffix-rank exactness, requiring S and R to classify* UAA, UAG, *and* UGA *as proper-support rows and* UGG *as the unique full-support row;*
5. *separated ledger discipline, requiring L to keep stop legality and Trp retention as different displayed rows;*
6. *structural preservation through H, K, P, N;*
7. *ledger non-escape, excluding hidden biological tables, stochastic mechanisms, quotient codon equality, global semantics, and external translation classifiers.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4090.1. The accepted packet displays the codon-window source, boundary-tile classifier, coverage route, lift-orbit context, suffix-support table, rank-deficiency row, ledger row, and structural rows.

The face exposure clause forces the local read to begin with W and B. Thus the rank table is attached to the displayed stop/Trp face, not to an unrecorded biological table.

Coverage and orbit compatibility are downstream checks on the same finite window. The rows C and O preserve the boundary support and orbit-readback context before S and R classify local suffix support.

The rank exactness row is the finite table of Definition 9462.1756. Proper subsets of $\{f_2, f_3\}$ give UAA, UAG, and UGA, while the full support gives UGG. The ledger row L records this separation without collapsing the full-support corner into the stop row.

Finally H, K, P, N preserve, replay, source, and name only these displayed rows. Since no excluded object is a carrier coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 4090.3 (Rank-deficiency prototype obligation surface)**.** *Every accepted ?? packet realizes the local rank-deficiency prototype of Definition 9462.1756 and Definition 9462.1757 only through the displayed route*

$$W, B, C, O, S, R, L, H, K, P, N.$$

Equivalently, the prototype is available only through the CodonSixBitWindow$^{\uparrow}$ *source window,* DnaWindowSixBounda *boundary tile,* SixBoundaryTileCoverage$^{\uparrow}$ *coverage row,* CodonLiftOrbitClassifier$^{\uparrow}$ *orbit classifier,*

suffix-support rows, rank-deficiency rows, separated ledger rows, transport, replay, provenance, and local NameCert rows. The packet exports no hidden genetic-code table, quotient codon equality, biological causation, or global semantic equivalence.

Proof. Project the carrier of Definition 4090.1. The displayed rows $W, B, C, O, S, R, L, H, K, P, N$ are the whole accepted packet.

The prototype begins with the six-bit window W and boundary tile B. Coverage C and orbit classification O keep that same finite window visible before any suffix-support or rank-deficiency row is read.

The rows S and R are exactly the local support and rank rows, and L keeps the stop vertices separated from the retained Trp corner. Thus the prototype route is a finite BEDC packet route, not a quotient of codons and not an external genetic-code table.

Finally H, K, P, N transport, replay, source, and name only the displayed rows. Since hidden code tables, biological causation, quotient codon equality, and global semantic equivalence are absent from the carrier, no accepted prototype obligation can pass through them. □

Theorem 4090.4 (Stop/Trp face local rank-deficiency route)**.** *Let $F = (W, B, C, O, S, R, L, H, K, P, N)$ be an accepted **??** carrier. Every accepted stop-face rank read factors through the finite route*

$$\mathsf{CodonSixBitWindow}^{\uparrow} \longmapsto \mathsf{DnaWindowSixBoundaryTile}^{\uparrow} \longmapsto \mathsf{SixBoundaryTileCoverage}^{\uparrow} \longmapsto \mathsf{CodonLiftOrbitClassifier}^{\uparrow}$$

Along this route the vertices UAA, UAG, *and* UGA *are exactly the proper-support rows of $\{f_2, f_3\}$, while* UGG *is the unique full-support corner. The packet exports no hidden code table, stochastic mechanism, quotient codon semantics, or global translation classifier.*

Proof. Start with an accepted stop-face rank read. The carrier requires the read to consume the source window W and the boundary tile B, so the four codons are the displayed $\mathrm{U} + \mathrm{RR}$ face.

The coverage row C and lift-orbit row O keep the same finite codon-window context visible. They do not replace the local face by a global biological semantics.

Now read S and R. By Definition 9462.1757, the proper-support vertices in the two suffix coordinates are precisely UAA, UAG, and UGA, and the remaining UGG corner has full support.

The ledger row L records that separation, and H, K, P, N transport, replay, source, and name the route. No excluded semantic or quotient object appears in the carrier, so the read cannot escape the displayed rank-deficiency packet. □

Falsifiable prediction: A **??** consumer that classifies UAA, UAG, or UGA without displaying the suffix-support row S and rank row R is not reading an accepted packet of this chapter.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, six-boundary-tile-coverage, codon-lift-orbit-classifier: **??** is not bijective to any listed sibling because it jointly carries the source window, stop/Trp boundary face, coverage row, orbit-readback context, suffix-support table, rank-deficiency classifier, separated ledger, transport, replay, provenance, and local naming.

The Lean TasteGate route for `BEDC.Derived.StopTrpFaceRankDeficiencyUp.TasteGate` must provide explicit Nontrivial **??** and FieldFaithful **??** instances preserving $W, B, C, O, S, R, L, H, K, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{??}$**.**

Constructive story: A **??** packet is generated from CodonSixBitWindowUp source rows, DnaWindowSixBoundaryTileUp stop/Trp boundary rows, SixBoundaryTileCoverageUp coverage rows, CodonLiftOrbitClassifierUp orbit rows, suffix-support rows, rank-deficiency rows, a separated ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{??}$, seed)

Scope closed: Definition 4090.1, Definition 4090.2, and Definition 4090.4 seed the finite stop/Trp face rank-deficiency packet over the local suffix-support theorem.

Formal verification: FormalStatus(NameCert$_{??}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, biological causation, stochastic fitness modeling, quotient codon equality, hidden translation tables, or global semantics.

Upgrade path: Obligation closure requires checked carrier admission, face exposure, coverage and orbit compatibility, suffix-rank exactness, separated ledger discipline, Nontrivial StopTrpFaceRankDeficiencyUp, and FieldFaithful StopTrpFaceRankDeficiencyUp for BEDC.Derived.StopTrpFaceRankDeficiencyUp.

Chapter 4091

A Concrete Naming Certificate for ??

Following Bourbaki/Kelley-style bornology plus Bishop–Bridges metric boundedness, the **??** packet records the metric bornology generated by displayed center-radius bounded-set data. It sits between the bounded-subset carrier of chapter 1757, the center-radius row of chapter 1450, the metric carrier of chapter 57, the radius comparison surfaces of chapter 38 and chapter 766, the ordinary bounded-family closure of chapter 3370, and the completion-facing specialization of chapter 1896. The packet turns metric ball containment and bounded subset evidence into a reusable bornology surface without introducing host suprema, compactness, selected bounds, quotient families, trichotomy, or ambient real completeness.

Definition 4091.1 (MetricBornology carrier)**.** *A **??** carrier is a finite* BHist *packet*

$$M = (X, S, c, r, B, U, E, D, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *carrier whose distance and point-classifier rows are the only metric data available to the packet.*
2. *S is the bounded-subset classifier row read through the* $\mathsf{BoundedSet}^{\uparrow}$ *packet.*
3. *c is the displayed center or witness row for the metric bound.*
4. *r is the radius row, read through* $\mathsf{Real}^{\uparrow}$ *and the ordered comparison surface of* $\mathsf{RealAlgOrder}^{\uparrow}$*.*
5. *B is the* $\mathsf{MetricBall}^{\uparrow}$ *containment ledger connecting accepted membership reads of S to the displayed ball with center c and radius r.*
6. *U is the finite-union bornology ledger, recording union requests only over previously accepted metric-bounded families.*
7. *E is the hereditary bounded-family ledger, recording subfamily requests only through a displayed parent family already accepted by S or U.*
8. *D is the consumer handoff row for* $\mathsf{Bornology}^{\uparrow}$ *and* $\mathsf{CauchyBornology}^{\uparrow}$ *readers.*
9. *H records componentwise* hsame *transport for $X, S, c, r, B, U, E, D, C, P, N$.*
10. *C records displayed* Cont *replay from a bounded-family request through metric carrier, classifier, center, radius, ball containment, hereditary closure, finite union, handoff, provenance, and local naming.*

11. *P is the* Pkg *provenance over* ??, $\mathsf{Met}^{\uparrow}$, $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Bornology}^{\uparrow}$, $\mathsf{CauchyBornology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{??}$ *row.*

The carrier compares metric-bounded families only through these rows. It has no coordinate for a host supremum, selected bound, compactness proof, open-cover compactness, quotient family, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MetricBornologyUp.MetricBornologyTasteGate single carrier alignment`

Theorem 4091.2 (MetricBornology NameCert obligations)**.** *For every accepted ?? carrier $M = (X, S, c, r, B, U, E, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{??}$ *surface consists exactly of carrier admission for the metric row, bounded-subset classifier, center or witness row, radius row, metric-ball containment ledger, finite-union ledger, hereditary ledger, consumer handoff, componentwise transport, displayed replay, provenance, and local naming rows.*

Every accepted bounded-family read must first expose the $\mathsf{Met}^{\uparrow}$ *row X, the* $\mathsf{BoundedSet}^{\uparrow}$ *classifier S, the center-radius data c, r, and the* $\mathsf{MetricBall}^{\uparrow}$ *ledger B. Hereditary and finite-union bornology reads may then consume only E and U, and downstream* $\mathsf{Bornology}^{\uparrow}$ *or* $\mathsf{CauchyBornology}^{\uparrow}$ *consumers may read the packet only through D, H, C, P, N.*

Proof. Project the carrier of Definition 4091.1. The metric rows are X, S, c, r, B, and the bornology rows are U, E, D; the remaining rows only transport, replay, source, and name the same packet.

Carrier admission and boundedness are forced by the sibling routes. The bounded-subset packet supplies S, c, r, B, while the metric-ball packet supplies the center-radius comparison over the same metric row X and radius row r.

Hereditary and finite-union reads are then confined to E and U. Since neither row stores a host powerset, selected bound, supremum, compactness proof, quotient family, or choice schedule, the local NameCert obligations are exactly the displayed metric-bounded-family rows. □

Theorem 4091.3 (MetricBornology bounded-set radius handoff)**.** *Let $M = (X, S, c, r, B, U, E, D, H, C, P, N)$ be an accepted ?? carrier. Every* $\mathsf{BoundedSet}^{\uparrow}$ *or* $\mathsf{MetricBall}^{\uparrow}$ *read exported from M follows the route*

$$X, S, c, r, B \longmapsto U, E \longmapsto D, H, C, P, N.$$

The radius row r is read only through $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RealAlgOrder}^{\uparrow}$*, the containment row B is read only as a* $\mathsf{MetricBall}^{\uparrow}$ *ledger, and the resulting bounded-family surface is handed to* $\mathsf{Bornology}^{\uparrow}$ *and* $\mathsf{CauchyBornology}^{\uparrow}$ *consumers before hereditary or finite-union bornology closure can be used downstream.*

Proof. Start with a bounded-set request. By Definition 4091.1, it must name the metric carrier X, the bounded-subset classifier S, the center or witness c, the radius row r, and the metric-ball containment ledger B.

Use the radius anchors next. The row r is available only through the $\mathsf{Real}^{\uparrow}$ and $\mathsf{RealAlgOrder}^{\uparrow}$ comparison surfaces, and B is available only through the $\mathsf{MetricBall}^{\uparrow}$ center-radius ledger. Thus the request cannot replace the displayed radius by a selected supremum or by a compactness argument.

Finally pass to the bornology rows. The hereditary row E and finite-union row U consume the already displayed metric-bounded families, while D, H, C, P, N export the same surface to $\mathsf{Bornology}^{\uparrow}$ and $\mathsf{CauchyBornology}^{\uparrow}$ readers. No downstream consumer receives a host family, quotient family, selected bound, trichotomy proof, or ambient real completeness datum. □

Closure status for NameCert$_{??}$**.**

Theory closure: TheoryGate(NameCert$_{??}$, seed)

Scope closed: Definition 4091.1, Definition 4091.2, and Definition 4091.3 seed the finite metric bornology surface over bounded-set, metric-ball, real-radius, general-bornology, and Cauchy-bornology consumers.

Formal verification: FormalStatus(NameCert$_{??}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host suprema, selected bounds, quotient families, compactness, open-cover compactness, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked metric carrier admission, bounded-subset classifier exposure, radius comparison, metric-ball containment, hereditary and finite-union ledgers, bornology handoff, transport, replay, provenance, and local naming for BEDC.Derived.MetricBornologyUp.

Constructive story: A **??** packet is generated from a MetricSpaceUp carrier, a BoundedSetUp classifier, a displayed center or witness, a RealUp radius read through RealAlgOrderUp, a MetricBallUp containment ledger, hereditary and finite-union bornology ledgers, BornologyUp and CauchyBornologyUp handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4092

A Concrete Naming Certificate for $\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley's treatment of completion by universal comparison, the $\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}$ packet records the finite BEDC surface on which several constructive completion presentations can be read through one comparison certificate. It sits after the Cauchy-comparison route of chapter 1954, the Bishop completion comparison of chapter 1508, the separated uniqueness ledger of chapter 1463, and the metric uniqueness boundary of chapter 1796. The packet also reads the finite observation spine of chapter 126, chapter 291, chapter 301, and chapter 38. It compares displayed constructive completion routes only; it is not quotient-completion equality, not selected representative equality, and not a proof that $\mathsf{Real}^{\uparrow}$ is ambiently complete.

Definition 4092.1 (Constructive completion equivalence carrier)**.** *A* $\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (C, B, U, M, S, D, R, A, H, K, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CauchyCompletionComparison}^{\uparrow}$ *row, comparing unit, universal-property, functorial, and metric-completion presentations by finite observation data.*
2. *B is the* $\mathsf{BishopCompletionComparison}^{\uparrow}$ *row, comparing regular located Cauchy data with the completion-facing real-name seal.*
3. *U is the* $\mathsf{CompletionUniqueness}^{\uparrow}$ *row, recording the separated uniqueness ledger available to completion consumers.*
4. *M is the* $\mathsf{MetricCompletionUniqueness}^{\uparrow}$ *row, recording the metric completion comparison boundary over a common metric source.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row common to the completion observations.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same windows and comparison requests.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the windows and dyadic ledger.*
8. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the comparison, window, tolerance, and readback rows have been displayed.*

9. *H records componentwise* hsame *transport for C, B, U, M, S, D, R, A and the local naming row.*
10. *K records displayed* Cont *replay through the comparison rows, observation spine, transport, provenance, and local naming rows.*
11. *P is the* Pkg *provenance over* $\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}$, $\mathsf{CauchyCompletionComparison}^{\uparrow}$, $\mathsf{BishopCompletionComparison}^{\uparrow}$, $\mathsf{CompletionUniqueness}^{\uparrow}$, $\mathsf{MetricCompletionUniqueness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $C, B, U, M, S, D, R, A, H, K, P, N$. It has no coordinate for quotient completion equality, selected representatives, host equality of completed objects, countable choice, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.ConstructiveCompletionEquivalenceUp.ConstructiveCompletionEquivalenceTasteGate`
`single carrier alignment`

Theorem 4092.2 (Constructive completion equivalence NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}$ *carrier*

$$E = (C, B, U, M, S, D, R, A, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}}$ *surface consists exactly of Cauchy-comparison exposure through C, Bishop-comparison exposure through B, separated uniqueness exposure through U, metric uniqueness exposure through M, finite-window exposure through S, dyadic tolerance exposure through D, regular rational readback through R, terminal real-name sealing through A, componentwise transport through H, displayed replay through K, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4092.1. The four comparison rows C, B, U, M are the only completion-presentation coordinates, while S, D, R, A are the shared finite observation spine.

The observation spine is read after the comparison rows have been named. Finite windows, dyadic tolerances, and regular rational readback provide the data by which the terminal $\mathsf{Real}^{\uparrow}$ seal is reached.

Finally H, K, P, N transport, replay, source, and name the same packet. Since no quotient completion equality, selected representative, host equality, countable-choice schedule, open-cover compactness row, or ambient real-completeness theorem occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 4092.3 (Constructive completion equivalence comparison route)**.** *Every completion-equivalence consumer of an accepted* $\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}$ *carrier factors through*

$\mathsf{CauchyCompletionComparison}^{\uparrow}$, $\mathsf{BishopCompletionComparison}^{\uparrow}$, $\mathsf{CompletionUniqueness}^{\uparrow}$, $\mathsf{MetricCompletionUniquenes}$

as displayed rows before it may compare constructive completion presentations. The route exports only the finite comparison certificate $E = (C, B, U, M, S, D, R, A, H, K, P, N)$ and does not identify quotient completions or assert ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Begin with the obligation surface of Definition 4092.2. Any consumer must first expose the Cauchy-comparison, Bishop-comparison, separated uniqueness, and metric uniqueness rows.

The shared observation spine is then consumed through S, D, R, A. These rows give finite windows, tolerance ledgers, regular rational readback, and a terminal real-name seal, so the comparison remains a displayed certificate rather than a quotient completion object.

The structural rows H, K, P, N preserve the same route under transport and replay. Therefore no consumer can bypass the finite comparison packet by citing selected representatives, host equality of completed points, countable choice, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$. □

Falsifiable prediction: Every accepted $\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}$ read exposes the CauchyCompletionComparison, BishopCompletionComparison, CompletionUniqueness, MetricCompletionUniqueness, StreamName, DyadicRatCore, RegSeqRat, RealUp, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before any constructive-completion comparison is consumed.

Independence witness: cauchy-completion-comparison, bishopcompletioncomparison, completion-uniqueness, metric-completion-uniqueness, streamname, dyadicratcore, regseqrat, real: none is bijective with $\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}$ because this carrier alone binds the four comparison surfaces to one shared finite observation spine and one local NameCert row without quotient-completion equality or ambient RealUp completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}$ packet is generated from CauchyCompletionComparison, BishopCompletionComparison, CompletionUniqueness, MetricCompletionUniqueness, StreamName, DyadicRatCore, RegSeqRat, RealUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4092.1, Definition 4092.2, and Definition 4092.3 seed the finite comparison certificate for constructive completion presentations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveCompletionEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, host equality of completed objects, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, comparison-row exposure, shared-window coverage, dyadic tolerance exactness, regular readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveCompletionEquivalenceUp.

Chapter 4093

A Concrete Naming Certificate for $\mathsf{EffectiveModulus}^{\uparrow}$

Following Bishop-style effective convergence, the $\mathsf{EffectiveModulus}^{\uparrow}$ packet records the finite threshold data by which a regular rational Cauchy name answers a dyadic tolerance request before any $\mathsf{Real}^{\uparrow}$ or completion-facing consumer reads the terminal seal. It sits over the regular rational source of chapter 301, the finite observation windows of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the modulus surface of chapter 292. The packet exposes a finite effective-modulus row, not a host function from tolerances to thresholds.

Definition 4093.1 (EffectiveModulus carrier)**.** *An* $\mathsf{EffectiveModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R, S, D, u, L, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose rational observations are being controlled.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation-window family through which R is inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row carrying the requested dyadic precision, comparison cells, and halving ledger.*
4. *u is the unary tolerance-index row naming the finite precision request inside the same history.*
5. *L is the modulus witness ledger. It records a threshold row saying that all inspected tails of R beyond u remain inside the tolerance read from D.*
6. *H records componentwise* hsame *transport for the regular source, stream windows, dyadic tolerance, unary index, witness ledger, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a dyadic tolerance request through S and R to the witness ledger L.*
8. *P is the* Pkg *provenance over* $\mathsf{EffectiveModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveModulus}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient equality of real names, selected limits, countable choice, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.EffectiveModulusUp.EffectiveModulusTasteGate single carrier alignment`

Theorem 4093.2 (EffectiveModulus NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveModulus}^{\uparrow}$ *carrier*

$$M = (R, S, D, u, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, source-window exposure, dyadic tolerance accounting, unary tolerance-index admission, modulus witness readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted read must display the route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the rows $R, S, D, u, L, H, C, P, N$*.*

Proof. Project the carrier of Definition 4093.1. Its public rows are exactly the regular rational source, stream-window family, dyadic tolerance, unary index, modulus witness ledger, transport, replay, provenance, and local name.

The source-window exposure and tolerance clauses are read through S and D. A tolerance request cannot reach the witness ledger until the same finite observation windows and dyadic comparison cells have been displayed.

The unary index row u supplies the finite threshold coordinate, while L records the corresponding tail-control witness for R. Transport through H and replay through C preserve that source route without adding a second threshold selector.

Finally P and N source and name only the displayed packet. Since the carrier has no quotient, selected-limit, choice, host-equality, or completeness coordinate, the listed rows exhaust the local certificate surface. □

Theorem 4093.3 (EffectiveModulus regular Cauchy handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{EffectiveModulus}^{\uparrow}$ *packet reads the modulus witness ledger only after the regular source row* R*, stream-window family* S*, dyadic tolerance ledger* D*, and unary tolerance index* u *have been exposed. The handoff supplies the displayed* $\mathsf{CauchyModulus}^{\uparrow}$*-compatible threshold row* L *together with* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *structural rows, and it supplies no quotient real equality, selected representative, countable-choice functional, host real equality, or ambient completeness principle.*

Proof. Begin with an accepted carrier $M = (R, S, D, u, L, H, C, P, N)$. The regular rational readback is the row R, and all admissible observations of it pass through the finite windows S.

Read the dyadic request next. The tolerance row D fixes the comparison scale, and the unary row u names the finite threshold request attached to that scale.

The witness ledger L is then the only modulus-facing handoff row. It is transported through H and replayed through C, while P and N preserve the same provenance and local name.

Thus any regular-Cauchy or real-seal consumer receives a finite threshold surface over $R, S, D, u, L, H, C, P, N$. The excluded quotient, representative-selection, choice, host-equality, and completeness objects are absent from the packet, so they cannot enter the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveModulus}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EffectiveModulus}^{\uparrow}$ packet is generated from a RegSeqRat source row, finite StreamName observation windows, a DyadicRatCore tolerance row, a unary tolerance index, a modulus witness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EffectiveModulus}^{\uparrow}}$, seed)

Scope closed: Definition 4093.1, Definition 4093.2, and Definition 4093.3 seed the finite effective-modulus route for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{EffectiveModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, selected representatives, countable choice, host real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-window exposure, dyadic tolerance accounting, unary threshold admission, modulus witness readback, regular-Cauchy handoff stability, and RealUp seal non-escape for BEDC.Derived.EffectiveModu

Chapter 4094

A Concrete Naming Certificate for ??

Following Bishop and Bridges and Mac Lane, the **??** packet records the functoriality certificate for separated completion as finite BEDC NameCert data. It sits after the separated-completion surface of chapter 1612, the public Cauchy reflector of chapter 1585, the metric-completion handoff of chapter 1506, and the L10 finite-name route through chapter 126, chapter 301, and chapter 38. The packet names the source-to-target transport of a uniformly continuous map through separated completion without importing quotient completions, chosen limits, host function extensionality, countable choice, ambient completeness, or bridge checking.

Definition 4094.1 (Separated completion functor carrier)**.** *A **??** carrier is a finite* BHist *packet*

$$F = (M, N, f, S, T, R, L, W, Q, A, H, C, P, E)$$

with the following displayed rows:

1. *M is the source metric row, naming the source carrier, metric comparison surface, and finite Cauchy-input budget.*
2. *N is the target metric row, naming the target carrier, metric comparison surface, and completion-facing output budget.*
3. *f is the source map row, recording the displayed uniformly continuous map data consumed by the completion route.*
4. *S is the source* $\mathsf{SeparatedCompletion}^{\uparrow}$ *row, read from the source metric before any completed source name is transported.*
5. *T is the target* $\mathsf{SeparatedCompletion}^{\uparrow}$ *row, read from the target metric before any completed target name is exposed.*
6. *R is the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *row, recording the reflector handoff that turns source Cauchy data into a completion-facing read.*
7. *L is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row, recording the metric-completion consumer surface through which the target completion read is delivered.*
8. *W is the* $\mathsf{StreamName}^{\uparrow}$ *local observation row attached to source and target completion names.*
9. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *local tolerance row consumed after W and before any terminal real-name seal.*
10. *A is the* $\mathsf{Real}^{\uparrow}$ *local seal row reached only through W, Q and the displayed separated-completion rows.*

11. *H records componentwise* hsame *transport for source metric data, target metric data, the source map, separated-completion rows, reflector and metric-completion rows, local L10 rows, replay, provenance, and naming.*
12. *C records displayed* Cont *replay from a source completion request through $M, N, f, S, T, R, L, W, Q, A, H, P, E$.*
13. *P is the* Pkg *provenance over* **??**, SeparatedCompletion$^{\uparrow}$, CauchyCompletionReflector$^{\uparrow}$, MetricCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *E is the local* NameCert$_{??}$ *row.*

The classifier compares accepted packets only through $M, N, f, S, T, R, L, W, Q, A, H, C, P, E$. It has no coordinate for quotient completion equality, selected limit representatives, host function extensionality, countable choice, ambient completeness of either completed metric, or a standard bridge.

Lean4 ✓ `BEDC.Derived.SeparatedCompletionFunctorUp.SeparatedCompletionFunctorTasteGate single carrier alignment`

Theorem 4094.2 (Separated completion functor NameCert obligations)**.** *For every accepted* **??** *carrier*

$$F = (M, N, f, S, T, R, L, W, Q, A, H, C, P, E),$$

the local NameCert$_{??}$ *surface consists exactly of source metric admission, target metric admission, source map admission, separated-completion exposure on both sides, Cauchy-reflector exposure, metric-completion exposure, StreamName observation, RegSeqRat tolerance readback, Real seal readback, componentwise transport, displayed replay, package provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.SeparatedCompletionFunctorUp.SeparatedCompletionFunctorCarrier namecert obligations`

Proof. Project the carrier of Definition 4094.1. The rows M, N, f expose the source metric, target metric, and map data before any completion-facing consumer reads the packet.

The separated-completion rows come next. Rows S and T keep the source and target completion surfaces separated before the reflector row R and the metric-completion row L are consumed.

The local numerical route is finite. The StreamName row W, RegSeqRat row Q, and Real row A display the L10 readback used by completion consumers, while H, C, P, E transport, replay, source, and name the same route.

Since no carrier coordinate contains quotient completion equality, a chosen limit representative, host function extensionality, countable choice, ambient completeness, or a bridge theorem, the listed rows exhaust the local NameCert surface. □

Theorem 4094.3 (Separated completion functor Cauchy-reflector route)**.** *Let $F = (M, N, f, S, T, R, L, W, Q, A, H,$ be an accepted* **??** *carrier. Every completion-facing read of the transported map factors through the route*

$$M, N, f, S, T, R, L, W, Q, A, H, C, P, E$$

before a target completion name is exported. In particular, the Cauchy-reflector row R and metric-completion row L are read only after both separated-completion rows S, T have been displayed, and the local StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows are read only as the terminal L10 route of that same packet.*

Proof. Start with a transported-map request for an accepted carrier. The source and target metric rows M, N and the source map row f are the only input coordinates available to the request.

Read the separated-completion rows S, T before any completion-facing handoff. This forces equality-facing and completion-facing consumers to remain on the separated surfaces carried by the packet.

The Cauchy reflector and metric completion handoffs are then R and L. Their consumers receive the local L10 route only through W, Q, A, so the exported target completion name remains attached to the displayed source map, separated-completion rows, transport, replay, provenance, and local naming.

Because the carrier contains no quotient completion class, selected limit, host function-extensionality proof, countable-choice selector, ambient-completeness row, or bridge theorem, no completion-facing read can bypass the named route. □

Falsifiable prediction: Every accepted **??** transport read displays source metric, target metric, source map, source separated-completion, target separated-completion, CauchyCompletionReflector, MetricCompletion, StreamName, RegSeqRat, Real, transport, replay, provenance, and local NameCert rows before a target completion name is exported.

Independence witness: separatedcompletion, cauchycompletionreflector, metriccompletion, streamname, regseqrat, real: the separated completion functor packet is not bijective to any listed sibling because it jointly carries a source metric row, target metric row, source map row, separated-completion rows on both sides, reflector and metric-completion handoffs, the local L10 readback route, transport, replay, provenance, and local naming.

Closure status for NameCert$_{??}$**.**

Constructive story: A **??** packet is generated from source metric data, target metric data, a source map row, separated-completion rows on both sides, CauchyCompletionReflectorUp and MetricCompletionUp handoffs, StreamNameUp observations, RegSeqRatUp tolerance readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{??}$, seed)

Scope closed: Definition 4094.1, Definition 4094.2, and Definition 4094.3 seed the finite functorial separated-completion route from a source map through separated completions and the L10 completion readback.

Formal verification: FormalStatus(NameCert$_{??}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host function extensionality, countable choice, ambient completeness, or bridge checking.

Upgrade path: Obligation closure requires checked source metric admission, target metric admission, source map admission, separated-completion exposure on both sides, Cauchy-reflector handoff, metric-completion handoff, StreamName observation, RegSeqRat tolerance readback, Real seal readback, transport, replay, provenance, and local naming for BEDC.Derived.SeparatedCompletionFunctorUp.

Chapter 4095

A Concrete Naming Certificate for EffectiveCauchySequenceSpace$^{\uparrow}$

Following Bishop and Bridges, the EffectiveCauchySequenceSpace$^{\uparrow}$ packet records the finite effective Cauchy-sequence surface used by Real and Completion consumers before any quotient of Cauchy names is formed. It reads the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the comparison boundary of chapter 1820, and the terminal real-name seal of chapter 38. The packet is a displayed sequence-space carrier with a replayable effective route, not a selected representative, not a host sequence type, and not ambient completeness of Real$^{\uparrow}$.

Definition 4095.1 (EffectiveCauchySequenceSpace carrier)**.** *An* EffectiveCauchySequenceSpace$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, R, D, Q, A, T, K, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite* StreamName$^{\uparrow}$ *window family through which sequence observations are requested.*
2. *R is the* RegSeqRat$^{\uparrow}$ *readback row exposing regular rational values on those windows.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger naming the dyadic request, halving data, and comparison cells.*
4. *Q is the* CauchyEquivalenceSetoid$^{\uparrow}$ *comparison row. It records equality-facing comparison only after the windows, regular readback, and dyadic tolerance rows have been displayed.*
5. *A is the terminal* Real$^{\uparrow}$ *seal row reached by the effective Cauchy route.*
6. *T records transport from the displayed stream windows and regular rational rows to the comparison and real-seal rows.*
7. *K records replay of the same route for downstream completion consumers.*
8. *H records componentwise* hsame *transport for S, R, D, Q, A, T, K and the local naming row.*
9. *C records displayed* Cont *replay from finite tolerance requests through $S, R, D, Q, A, T, K, H, P, N$.*
10. *P is the* Pkg *provenance over* EffectiveCauchySequenceSpace$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* CauchyEquivalenceSetoid$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveCauchySequenceSpace}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, R, D, Q, A, T, K, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EffectiveCauchySequenceSpaceUp.EffectiveCauchySequenceSpaceTasteGate`
`single carrier alignment`

Theorem 4095.2 (EffectiveCauchySequenceSpace NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveCauchySequenceSpace}^{\uparrow}$ *carrier*

$$E = (S, R, D, Q, A, T, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveCauchySequenceSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, finite StreamName window exposure, RegSeqRat readback, DyadicRatCore tolerance accounting, CauchyEquivalenceSetoid comparison routing, Real seal admission, transport, replay, componentwise* hsame *stability, displayed* Cont *continuation,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 4095.1. Its public rows are precisely the stream windows, regular rational readback, dyadic tolerance, setoid comparison, real seal, transport, replay, stability, continuation, provenance, and local name.

The comparison row Q can be read only after S, R, D have been displayed. Thus equality-facing consumers first consume finite windows, rational observations, and dyadic tolerance data before they see the setoid boundary.

The terminal seal A is downstream of the same route and is preserved only through T, K, H, C, P, N. Since quotient stream equality, selected representatives, countable choice, host real equality, and ambient completeness are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 4095.3 (EffectiveCauchySequenceSpace regular readback route)**.** *Every regular readback exported by an accepted* $\mathsf{EffectiveCauchySequenceSpace}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyEquivalenceSetoid}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

inside $S, R, D, Q, A, T, K, H, C, P, N$. The route exports finite observation and tolerance data for completion-facing consumers and does not export quotient equality of streams, a selected limiting representative, countable choice, or host real equality.

Proof. Start with Definition 4095.2. It forces a consumer to read the StreamName windows S before using the RegSeqRat row R.

The dyadic ledger D supplies the requested tolerance for that readback, and the comparison row Q consumes the same S, R, D data before any equality-facing statement is visible.

Finally the Real seal A is reached only after the comparison route has been displayed. Transport and replay through T, K, H, C, P, N preserve the same row order, so no quotient, selected representative, choice functional, or host equality can be inserted into the readback route. □

Theorem 4095.4 (EffectiveCauchySequenceSpace Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{EffectiveCauchySequenceSpace}^{\uparrow}$ *carrier must read the real seal as the terminal row of $S, R, D, Q, A, T, K, H, C, P, N$. The seal records that the displayed effective Cauchy route may be consumed by Real and Completion chapters; it does not assert that* $\mathsf{Real}^{\uparrow}$ *is ambiently complete, that all Cauchy streams have selected limits, or that Cauchy-equivalent streams are identified by host equality.*

Proof. Project A from the carrier. The definition places A after the StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, and CauchyEquivalenceSetoid comparison row.

Apply the regular readback route of Definition 4095.3. It binds every Real-facing read to the same finite observation and tolerance route before the terminal seal is consumed.

The remaining rows T, K, H, C, P, N transport, replay, source, and name that route. Because the carrier has no coordinate for ambient completeness, selected limits, quotient equality, or host equality, the Real seal remains a boundary row rather than a completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveCauchySequenceSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveCauchySequenceSpace}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback rows, a DyadicRatCore tolerance ledger, a CauchyEquivalenceSetoid comparison row, a terminal RealUp seal, transport, replay, componentwise hsame stability, displayed Cont continuation, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveCauchySequenceSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4095.1, Definition 4095.2, Definition 4095.3, and Definition 4095.4 seed the finite effective Cauchy-sequence-space route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveCauchySequenceSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient equality of Cauchy streams, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, StreamName window exposure, RegSeqRat readback, DyadicRatCore tolerance accounting, CauchyEquivalenceSetoid comparison routing, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.EffectiveCauchySequenceSpaceUp.

Chapter 4096

A Concrete Naming Certificate for $\mathsf{FiniteLowerBoundFold}^{\uparrow}$

Following the finite-cover proof of Heine–Cantor in chapter 9237, the $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ packet records the rational lower-bound fold that turns finitely many local continuity radii into one uniform precision row. It sits over compact finite coverage from chapter 60, the metric source of chapter 57, pointwise continuity rows from chapter 59, rational positivity from chapter 37, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer of chapter 369. The packet makes the finite $\mathsf{ProbeBundle}$ fold an explicit NameCert object.

Definition 4096.1 (FiniteLowerBoundFold carrier)**.** *A* $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, \mathcal{P}, R, A, B, L, H, C, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *source row carrying the finite coverage witness.*
2. *$\mathcal{P}$ is the nonempty* $\mathsf{ProbeBundle}$ *spine indexing the bundled centers.*
3. *R is the finite family of positive* $\mathsf{Rat}^{\uparrow}$ *lower-bound candidates, one row for each bundled probe.*
4. *A is the accumulator ledger produced by primitive recursion over $\mathcal{P}$.*
5. *B is the certified lower-bound row saying that the accumulator is below every displayed candidate in R.*
6. *L is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row that receives the accumulator as the tolerance-only precision.*
7. *H records componentwise* hsame *transport for the compact source, bundle spine, rational candidates, accumulator, lower-bound certificate, handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the fold over the finite bundle.*
9. *Q is the* Pkg *provenance over* $\mathsf{FiniteLowerBoundFold}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{ProbeBundle}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteLowerBoundFold}^{\uparrow}}$ *row.*

The carrier contains no host minimum, selected center outside $\mathcal{P}$, open-cover compactness object, quotient point equality, external modulus function, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 ✓ `BEDC.Derived.FiniteLowerBoundFoldUp.FiniteLowerBoundFoldTasteGate single carrier alignment`

Theorem 4096.2 (FiniteLowerBoundFold NameCert obligations)**.** *For every accepted* $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ *carrier*

$$F = (K, \mathcal{P}, R, A, B, L, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteLowerBoundFold}^{\uparrow}}$ *surface consists exactly of compact source exposure,* $\mathsf{ProbeBundle}$ *spine admission, positive* $\mathsf{Rat}^{\uparrow}$ *candidate admission, accumulator recursion, certified lower-bound readback,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, componentwise transport, displayed replay, provenance, and local naming. The fold route is confined to*

$$\mathsf{Compact}^{\uparrow}, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{Continuous}^{\uparrow}, \quad \mathsf{Rat}^{\uparrow}, \quad \mathsf{UniformModulus}^{\uparrow}.$$

Proof. Project the carrier in Definition 4096.1. The only rows visible to a consumer are the compact source, finite bundle, rational candidate family, accumulator, lower-bound certificate, handoff, and structural rows.

The bundle spine $\mathcal{P}$ supplies the induction domain. At each finite step the fold reads one positive rational candidate from R and updates the accumulator row A through the displayed replay route C.

The lower-bound certificate B is attached to the same finite recursion. It states that the final accumulator is below every candidate in R, so a downstream read of L receives a classifier-stable precision row rather than a host minimum.

Transport, provenance, and local naming are supplied by H, Q, N. Since none of the excluded host, open-cover, quotient, external-modulus, or completeness objects occurs in the carrier, the listed obligations exhaust the local certificate surface. □

Lean4 ✓ `BEDC.Derived.FiniteLowerBoundFoldUp.FiniteLowerBoundFoldCarrier namecert obligations`

Theorem 4096.3 (FiniteLowerBoundFold uniform-modulus handoff)**.** *Every compact-uniform-continuity consumer that reads a* $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ *packet obtains its* $\mathsf{UniformModulus}^{\uparrow}$ *precision row only through the finite* $\mathsf{ProbeBundle}$ *spine* $\mathcal{P}$*, the positive* $\mathsf{Rat}^{\uparrow}$ *candidate ledger* R*, the accumulator row* A*, the lower-bound certificate* B*, and the structural rows* H, C, Q, N*. The consumer receives no host finite minimum, selected center outside the bundle, open-cover compactness object, quotient point equality, external modulus selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Lean4 ✓ `BEDC.Derived.FiniteLowerBoundFoldUp.FiniteLowerBoundFoldCarrier uniform modulus handoff`

Proof. Start with an accepted carrier $F = (K, \mathcal{P}, R, A, B, L, H, C, Q, N)$. The compact source row K and the finite bundle $\mathcal{P}$ are the only coverage rows available.

Read the candidate family R. Each candidate is a positive $\mathsf{Rat}^{\uparrow}$ row attached to a bundled probe, so the fold cannot inspect an infinite cover or a center outside the displayed bundle.

The accumulator row A and certificate row B provide the lower-bound fold. They are transported and replayed by H and C, and then sourced and named by Q and N.

The handoff row L is therefore a $\mathsf{UniformModulus}^{\uparrow}$ precision read over that finite packet. Since no excluded host or compactness coordinate is present, every uniform-modulus consumer remains inside the displayed fold route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteLowerBoundFold}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ packet is generated from a CompactUp finite coverage row, a nonempty ProbeBundle spine, positive RatUp candidate rows, an accumulator ledger, a certified lower-bound row, a UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteLowerBoundFold}\uparrow}$, seed)

Scope closed: Definition 4096.1, Definition 4096.2, and Definition 4096.3 seed the finite ProbeBundle rational lower-bound fold used by compact-uniform-modulus consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteLowerBoundFold}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host finite minima, selected centers outside the bundle, open-cover compactness, quotient point equality, external modulus selectors, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked bundle admission, rational candidate positivity, accumulator recursion, lower-bound certificate stability, uniform-modulus handoff, and ledger non-escape for BEDC.Derived.FiniteLowerBoundFoldUp.

DNA hash: `aggregate=sha256:382cef63d1023f0ab10fc718fdae684b2ab03e53b1409d98cb6368e9134a7148;statement=sha256:cf`

Chapter 4097

A Concrete Naming Certificate for MetaCICDecidableConversionFrontier$^{\uparrow}$

The MetaCICDecidableConversionFrontier$^{\uparrow}$ packet realizes the bounded conversion boundary in chapter 9379 as finite NameCert data. It sits beside the decidability boundary of chapter 749, the normalization frontier of chapter 892, the bounded normal-conversion bridge of chapter 3439, the normal-form consistency seal of chapter 740, and the critical-path packet of chapter 765. The packet names the exact point where bounded normal equality may be consumed by a conversion-facing checker while the unrestricted closed-term conversion theorem remains outside the carrier.

Falsifiable prediction: Every accepted MetaCICDecidableConversionFrontier$^{\uparrow}$ read exposes metacicdecidableboundary, metacicnormalizationfrontier, bounded-normal-conversion-bridge, normal-form-consistency-seal, metaciccriticalpath, bounded-checker, finished-normal, obstruction, transport, replay, provenance, and local NameCert rows before any conversion-frontier handoff is consumed.

Independence witness: metacicdecidableboundary, metacicnormalizationfrontier, bounded-normal-conversion-bridge, normal-form-consistency-seal, metaciccriticalpath: the decidability boundary records checker limits without the normal endpoint row; the normalization frontier records candidate and endpoint evidence without the conversion checker; the bridge records bounded normal comparison without the full audit map; the consistency seal records closed normal-form safety without conversion completeness; and the critical path records dependency pressure without this finite conversion-frontier carrier. None is bijective to MetaCICDecidableConversionFrontier$^{\uparrow}$.

Definition 4097.1 (MetaCIC decidable conversion frontier carrier)**.** *A* MetaCICDecidableConversionFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, N, B, S, K, Q, O, H, C, P, L)$$

with the following displayed rows:

1. *D is the* MetaCICDecidableBoundary$^{\uparrow}$ *row, recording the typing-checker and same-term decision surface available to the audit map.*
2. *N is the* MetaCICNormalizationFrontier$^{\uparrow}$ *row, recording candidate evidence, finished-normal evidence, endpoint use, and retained obstruction data.*
3. *B is the* BoundedNormalConversionBridge$^{\uparrow}$ *row, comparing bounded normalizer outputs under the displayed finished-normal boundary.*

4. *S is the* NormalFormConsistencySeal$^{\uparrow}$ *row, recording the closed normal-form consistency seal consumed by conversion-facing checks.*
5. *K is the* MetaCICCriticalPath$^{\uparrow}$ *row, retaining the dependency-pressure ledger for conversion, normalization, confluence, and subject-reduction consumers.*
6. *Q is the bounded equality-checker row, recording the compared normal forms, finite fuel budget, and Boolean equality output.*
7. *O is the obstruction row, naming the excluded endpoints: unrestricted closed-term beta-conversion, arbitrary-fuel completeness, evaluator equality, quotient syntax equality, and kernel consistency.*
8. *H records componentwise* hsame *transport for D, N, B, S, K, Q, O and the local naming row.*
9. *C records displayed* Cont *replay from a conversion query through $D, N, B, S, K, Q, O, H, P, L$.*
10. *P is the* Pkg *provenance over* MetaCICDecidableConversionFrontier$^{\uparrow}$, MetaCICDecidableBoundary$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, BoundedNormalConversionBridge$^{\uparrow}$, NormalFormConsistencySeal$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* NameCert$_{\text{MetaCICDecidableConversionFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, N, B, S, K, Q, O, H, C, P, L$. It has no coordinate for unrestricted closed-term beta-conversion, arbitrary-fuel completeness, evaluator equality, quotient syntax equality, subject reduction, confluence, or kernel consistency.

Lean4 ✓ `BEDC.Derived.MetaCICDecidableConversionFrontierUp.MetaCICDecidableConversionFrontierTasteGate`
`single carrier alignment`

Theorem 4097.2 (MetaCIC decidable conversion frontier NameCert obligations)**.** *For every accepted* MetaCICDecidableConversionFrontier$^{\uparrow}$ *carrier*

$$F = (D, N, B, S, K, Q, O, H, C, P, L),$$

the local NameCert$_{\text{MetaCICDecidableConversionFrontier}^{\uparrow}}$ *surface consists exactly of decidability-boundary exposure through D, normalization-frontier exposure through N, bounded normal-conversion bridge exposure through B, normal-form seal exposure through S, critical-path exposure through K, bounded equality-checker exposure through Q, obstruction retention through O, componentwise transport through H, displayed replay through C, provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 4097.1. Rows D, N, B, S, K are the sibling audit and bridge surfaces, while Q is the local bounded checker row and O keeps the excluded endpoints visible.

The conversion-facing read must pass through the bounded bridge and the normal-form seal together. The bridge supplies only bounded normal comparison, and the seal supplies the closed normal-form safety row; neither row contains arbitrary-fuel completeness or unrestricted beta-conversion.

Finally H, C, P, L transport, replay, source, and name the same packet. Since no carrier coordinate contains evaluator equality, quotient syntax equality, subject reduction, confluence, or kernel consistency, the listed rows exhaust the local NameCert obligations. □

Theorem 4097.3 (MetaCIC decidable conversion frontier bounded route)**.** *Every conversion-facing consumer of an accepted* MetaCICDecidableConversionFrontier$^{\uparrow}$ *carrier factors through*

MetaCICDecidableBoundary$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, BoundedNormalConversionBridge$^{\uparrow}$, NormalFormConsi

and then through the local bounded equality-checker row Q with obstruction retention O. The route exports a bounded conversion frontier only; it does not prove unrestricted closed-term beta-conversion or arbitrary-fuel completeness.

Proof. Start with Definition 4097.2. It forces the consumer to read the decidability boundary, normalization frontier, bounded conversion bridge, consistency seal, and critical-path rows before using the local checker row.

The local checker row Q is interpreted under the obstruction row O. Thus a positive bounded comparison can be replayed as finite NameCert data, but the retained obstruction prevents it from being cited as an unrestricted conversion theorem.

Transport and replay through H and C, with provenance and naming through P and L, preserve that boundary. No sibling route adds arbitrary-fuel completeness, evaluator equality, quotient syntax equality, subject reduction, confluence, or kernel consistency to the carrier. □

Theorem 4097.4 (MetaCIC decidable conversion frontier bounded search)**.** *Every positive conversion-frontier read exported by an accepted* $\mathsf{MetaCICDecidableConversionFrontier}^{\uparrow}$ *carrier factors through the displayed finite fuel budget in Q, the bounded normalizer surface in N, the* $\mathsf{Term}.eq$ *comparison encoded by the bounded equality-checker row, the* $\mathsf{BoundedNormalConversionBridge}^{\uparrow}$ *row B, and the* $\mathsf{NormalFormConsistencySeal}^{\uparrow}$ *row S. The read is therefore a finite search certificate, not an unrestricted conversion theorem.*

Proof. Project the carrier of Definition 4097.1. The only local row that can report a positive comparison is Q, and that row stores the compared normal forms, finite fuel budget, and Boolean equality output.

Apply the NameCert obligations of Definition 4097.2. They force every conversion-facing read to expose the decidability boundary, normalization frontier, bounded bridge, normal-form seal, critical-path row, checker row, and obstruction row together.

Use the bounded route theorem Definition 4097.3. It places the positive read behind D, N, B, S, K and then behind Q, so the equality output is interpreted only through bounded normalization, $\mathsf{Term}.eq$ comparison, the bridge row, and the consistency seal.

The obstruction row O remains part of the same packet. Since unrestricted closed beta-conversion, arbitrary-fuel completeness, evaluator equality, quotient syntax equality, subject reduction, confluence, and kernel consistency are not carrier coordinates, a positive bounded read cannot be promoted to any of them. □

Theorem 4097.5 (MetaCIC decidable conversion frontier refusal)**.** *The same* $\mathsf{MetaCICDecidableConversionFrontier}$ *carrier refuses unrestricted closed beta-conversion, arbitrary-fuel completeness, evaluator equality, quotient syntax equality, subject reduction, confluence, and kernel consistency. Any consumer claiming one of those endpoints must supply data outside the displayed rows $D, N, B, S, K, Q, O, H, C, P, L$.*

Proof. Read the obstruction row O from Definition 4097.1. It explicitly names unrestricted closed-term beta-conversion, arbitrary-fuel completeness, evaluator equality, quotient syntax equality, and kernel consistency as excluded endpoints, while the classifier also omits subject reduction and confluence.

Apply Definition 4097.4. A positive conversion-frontier read is only a bounded search certificate passing through finite fuel, bounded normalization, checker comparison, bridge, and seal rows.

Now use Definition 4097.3. The route preserves obstruction retention through O and structural replay through H, C, P, L, so no later consumer can erase the finite-search boundary inside this packet.

Thus the refused endpoints require additional carriers or theorems not present here. The local NameCert surface exports a bounded decidability frontier only. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICDecidableConversionFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICDecidableConversionFrontier}^{\uparrow}$ packet is generated from MetaCICDecidableBoundary, MetaCICNormalizationFrontier, BoundedNormalConversionBridge, NormalFormConsistencySeal, MetaCICCriticalPath, bounded equality-checker, obstruction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICDecidableConversionFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4097.1, Definition 4097.2, and Definition 4097.3 seed the finite bounded-conversion frontier for MetaCIC decidability consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICDecidableConversionFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unrestricted closed-term beta-conversion, arbitrary-fuel completeness, evaluator equality, quotient syntax equality, subject reduction, confluence, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-checker exposure, normalization-frontier coverage, bounded bridge exactness, normal-form seal compatibility, critical-path retention, obstruction nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICDecidableConversionFrontierUp.

Chapter 4098

A Concrete Naming Certificate for MetaCICClosednessDecisionBoundary$^{\uparrow}$

The MetaCICClosednessDecisionBoundary$^{\uparrow}$ packet realizes the closedness-decision warning of chapter 9379 as finite NameCert data. It sits beside the decidability audit packet of chapter 746, the bounded normal-equality checker of chapter 752, the bounded fuel trace of chapter 3889, and the closed type-checker seal of chapter 2182. The packet names the boundary where closedness evidence can be consumed without exporting a theorem of the form `Decidable (ClosedAt n t)` or unrestricted closed-term beta-conversion decidability.

Falsifiable prediction: A consumer of MetaCICClosednessDecisionBoundary$^{\uparrow}$ cannot derive unrestricted closed-term beta-conversion decidability from this packet alone; every accepted read exposes decidability-audit, bounded-normal-equality, fuel-trace, closed-type-checker, closedness-boundary, refusal, transport, replay, provenance, and local NameCert rows before any conversion-facing handoff.

Independence witness: metacicdecidableauditpacket, boundednormalequalitychecker, metacicfueltrace, closedtypecheckerseal: the audit packet records checker scope without this closedness boundary row; the bounded normal-equality checker records finite fuel comparison without a global closedness decision; the fuel trace records bounded normalizer fuel without unrestricted conversion completeness; and the closed type-checker seal records checked typing without a standalone closedness decider. None is bijective to MetaCICClosednessDecisionBoundary$^{\uparrow}$.

Definition 4098.1 (MetaCIC closedness decision boundary carrier)**.** *A* MetaCICClosednessDecisionBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A, Q, F, S, Z, O, H, C, P, N)$$

with the following displayed rows:

1. *A is the* MetaCICDecidableAuditPacket$^{\uparrow}$ *row exposing the checked typing and bounded conversion audit surface.*
2. *Q is the* BoundedNormalEqualityChecker$^{\uparrow}$ *row exposing bounded normal-form comparison.*
3. *F is the* MetaCICFuelTrace$^{\uparrow}$ *row exposing the finite fuel budget and bounded normalizer endpoint data.*
4. *S is the* ClosedTypeCheckerSeal$^{\uparrow}$ *row exposing closed typing-checker reads.*

5. *Z is the closedness-boundary row naming the available finite closedness evidence and the absence of a global* `Decidable (ClosedAt n t)` *export.*
6. *O is the refusal row for unrestricted closed-term beta-conversion decidability, arbitrary-fuel completeness, evaluator equality, quotient syntax equality, subject reduction, confluence, and kernel consistency.*
7. *H records componentwise* hsame *transport for A, Q, F, S, Z, O and the local naming row.*
8. *C records displayed* Cont *replay from a closedness-facing query through $A, Q, F, S, Z, O, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{MetaCICClosednessDecisionBoundary}^{\uparrow}$, $\mathsf{MetaCICDecidableAuditPacket}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{MetaCICFuelTrace}^{\uparrow}$, $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICClosednessDecisionBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, Q, F, S, Z, O, H, C, P, N$. It has no coordinate for unrestricted closed-term beta-conversion decidability, arbitrary-fuel completeness, evaluator equality, quotient syntax equality, subject reduction, confluence, or kernel consistency.

Lean4 ✓ `BEDC.Derived.MetaCICClosednessDecisionBoundaryUp.MetaCICClosednessDecisionBoundaryTasteGate single carrier alignment`

Theorem 4098.2 (MetaCIC closedness decision boundary NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICClosednessDecisionBoundary}^{\uparrow}$ *carrier*

$$B = (A, Q, F, S, Z, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICClosednessDecisionBoundary}^{\uparrow}}$ *surface consists exactly of decidability-audit exposure through A, bounded normal-equality exposure through Q, finite fuel-trace exposure through F, closed type-checker seal exposure through S, closedness-boundary exposure through Z, refusal retention through O, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4098.1. Rows A, Q, F, S are the sibling checker and bounded-computation surfaces, while Z records the closedness boundary and O records the refused endpoints.

A closedness-facing read must pass through the audit packet, bounded checker, fuel trace, and closed type-checker seal before it can use Z. These rows provide finite checker evidence, but none contains a global `Decidable (ClosedAt n t)` theorem.

Finally H, C, P, N transport, replay, source, and name the same boundary packet. Since no carrier coordinate contains unrestricted beta-conversion decidability, arbitrary-fuel completeness, evaluator equality, quotient syntax equality, subject reduction, confluence, or kernel consistency, the listed rows exhaust the local NameCert obligations. □

Theorem 4098.3 (MetaCIC closedness decision boundary non-escape)**.** *Every consumer of an accepted* $\mathsf{MetaCICClosednessDecisionBoundary}^{\uparrow}$ *carrier can cite only the finite route*

$$\mathsf{MetaCICDecidableAuditPacket}^{\uparrow},\ \mathsf{BoundedNormalEqualityChecker}^{\uparrow},\ \mathsf{MetaCICFuelTrace}^{\uparrow},\ \mathsf{ClosedTypeCheckerSeal}^{\uparrow},\ Z,$$

The route preserves checked typing, bounded normal comparison, finite fuel tracing, and closed type-checker sealing while refusing unrestricted closed-term beta-conversion decidability and a standalone global closedness decision.

Proof. Apply Definition 4098.2. It forces every consumer to read the audit, bounded-checker, fuel-trace, and closed-type-checker rows before reading the local closedness-boundary row.

The refusal row O is part of the same carrier. It records that the packet does not export unrestricted closed-term beta-conversion decidability, arbitrary-fuel completeness, evaluator equality, quotient syntax equality, subject reduction, confluence, or kernel consistency.

Transport and replay through H and C, with provenance and naming through P and N, preserve that boundary. The consumer therefore receives a finite closedness-decision boundary packet, not a global decision theorem. □

The Lean follow-up supplies Nontrivial and FieldFaithful instances in `lean4/BEDC/Derived/MetaCICClosedness` by exhibiting distinct accepted and refused boundary packets and by matching on the rows $A, Q, F, S, Z, O, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICClosednessDecisionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICClosednessDecisionBoundary}^{\uparrow}$ packet is generated from MetaCICDecidableAuditPacket, BoundedNormalEqualityChecker, MetaCICFuelTrace, ClosedTypeCheckerSeal, closedness-boundary, refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICClosednessDecisionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4098.1, Definition 4098.2, and Definition 4098.3 seed the finite closedness-decision boundary for MetaCIC decidability consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICClosednessDecisionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unrestricted closed-term beta-conversion decidability, a global `Decidable (ClosedAt n t)` theorem, arbitrary-fuel completeness, evaluator equality, quotient syntax equality, subject reduction, confluence, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, audit-packet exposure, bounded-normal checker exposure, fuel-trace exposure, closed-type-checker seal compatibility, closedness-boundary nonescape, refusal retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICClosednessDecisionBoundaryUp.

Chapter 4099

A Concrete Naming Certificate for $\mathsf{EffectiveCauchySpace}^{\uparrow}$

Following Bishop–Bridges constructive analysis and represented-space computable analysis, the $\mathsf{EffectiveCauchySpace}^{\uparrow}$ packet records a represented metric source whose Cauchy access is mediated by displayed moduli and finite observation windows. It sits after the represented-space source of chapter 1494, the metric carrier of chapter 57, the effective modulus surface of chapter 3518, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the unit handoff of chapter 1527. The chapter gives Real and Completion consumers a finite route from represented names and effective Cauchy moduli to the current L10 completion boundary; it is not quotient completion equality, a selected limit, countable choice, host equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 4099.1 (Effective Cauchy space carrier)**.** *An* $\mathsf{EffectiveCauchySpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (A, M, E, S, R, D, L, U, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{RepresentedSpace}^{\uparrow}$ *source row, naming the represented input surface and the representation-mediated observations available to the packet.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *row, recording the point classifier, distance requests, and metric comparison data read over the same represented source.*
3. *E is the* $\mathsf{EffectiveCauchyModulus}^{\uparrow}$ *row, supplying the finite stage schedule by which metric tolerance requests become Cauchy-window requests.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, displaying the finite observation windows opened by the represented source and the effective modulus.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows after the metric and modulus rows have fixed the tolerance request.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing dyadic radii, slack, comparison budgets, and tolerance conversions used by E, S, R.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the represented source, metric row, effective modulus, stream schedule, regular readback, and dyadic ledger have been displayed.*

8. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *handoff row admitting the same represented Cauchy data into the completion-facing unit route.*
9. *H records componentwise* hsame *transport for A, M, E, S, R, D, L, U and the local naming row.*
10. *C records displayed* Cont *replay from a Real or Completion request through the represented source, metric row, modulus, finite windows, readback, tolerance ledger, seal, unit handoff, transport, provenance, and local naming rows.*
11. *P is the* Pkg *provenance over* $\mathsf{EffectiveCauchySpace}^{\uparrow}$, $\mathsf{RepresentedSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{EffectiveCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveCauchySpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, M, E, S, R, D, L, U, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, trichotomy, host equality of completed objects, ambient completeness of $\mathsf{Real}^{\uparrow}$*, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.EffectiveCauchySpaceUp.EffectiveCauchySpaceTasteGate single carrier alignment`

Theorem 4099.2 (Effective Cauchy space NameCert obligations)**.** *For every accepted* $\mathsf{EffectiveCauchySpace}^{\uparrow}$ *carrier*

$$X = (A, M, E, S, R, D, L, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveCauchySpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *represented-source admission through A and metric-source admission through M over the same displayed carrier;*
2. *effective-modulus exposure through E before any finite stream window is opened;*
3. *StreamName schedule exactness through S, requiring every inspected name window to be one of the displayed finite windows;*
4. *regular rational readback through R only after the represented source, metric row, modulus, stream schedule, and dyadic ledger have been displayed;*
5. *dyadic tolerance accounting through D for every radius, slack, comparison budget, and tolerance conversion consumed by E, S, R;*
6. *terminal Real sealing through L and completion-unit handoff through U, both downstream of A, M, E, S, R, D;*
7. *transport, replay, provenance, and local naming through H, C, P, N without adding a second classifier or hidden completion coordinate.*

No effective-Cauchy-space obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4099.1. The represented source row A and the metric row M are the only source coordinates, so every downstream read is tied to the same represented metric carrier.

The effective modulus row E mediates every tolerance request before the finite stream schedule S is opened. The dyadic ledger D supplies the radius and slack accounting needed by the modulus and schedule rows, and the regular rational readback R is downstream of those displayed data.

The terminal routes L and U are read only after A, M, E, S, R, D have been exposed. Thus the Real seal and the CauchyCompletionUnit handoff consume the same finite represented-Cauchy route rather than a quotient completion, selected limit, or host equality datum.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no row for countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 4099.3 (Effective Cauchy space completion handoff)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{EffectiveCauchySpace}^{\uparrow}$ *carrier*

$$X = (A, M, E, S, R, D, L, U, H, C, P, N)$$

factors through the displayed route

$$\mathsf{RepresentedSpace}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{EffectiveCauchyModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{CauchyCo}$$

with transport, replay, provenance, and local naming supplied only by H, C, P, N*. The consumer receives no quotient completion equality, selected limit, countable-choice selector, host equality, trichotomy branch, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Fix a Real-facing or completion-facing consumer of X. The carrier exposes the represented source, metric row, effective modulus, stream schedule, dyadic ledger, regular readback, Real seal, and completion-unit handoff as the only analytic coordinates.

The consumer first reads A and M, then obtains the tolerance stage from E. The corresponding finite windows are displayed in S, with all radius and slack conversions accounted for in D.

Only after that finite observation route is fixed can the readback row R be consumed. The Real seal L and the CauchyCompletionUnit handoff U are downstream of the same readback and ledger, so both terminal routes inherit the represented Cauchy data rather than selecting an external limit.

The structural rows H, C, P, N preserve the route and introduce no additional analytic coordinate. Therefore every allowed consumer factors through the displayed completion handoff and cannot extract any of the excluded quotient, choice, equality, trichotomy, or ambient-completeness data. □

Falsifiable prediction: Every accepted $\mathsf{EffectiveCauchySpace}^{\uparrow}$ Real or Completion read exposes the RepresentedSpace source, MetricSpace row, EffectiveCauchyModulus row, StreamName schedule, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, CauchyCompletionUnit handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows before the terminal handoff is consumed.

Independence witness: representedspace, metric, effective-cauchy-modulus, streamname, regseqrat, dyadicratcore, real, cauchycompletionunit: $\mathsf{EffectiveCauchySpace}^{\uparrow}$ is not bijective to any listed sibling because it binds a represented metric source, effective Cauchy modulus, finite schedule, tolerance ledger, regular readback, Real seal, completion-unit handoff, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveCauchySpace}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveCauchySpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4099.1, Definition 4099.2, and Definition 4099.3 seed the finite represented-metric Cauchy route from effective modulus data to Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveCauchySpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, countable choice, host equality, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, represented-source and metric-source agreement, effective-modulus exposure, finite-window exactness, dyadic tolerance accounting, regular readback, Real seal boundary, completion-unit handoff, transport, replay, provenance, and local naming for BEDC.Derived.EffectiveCauchySpaceUp.

Constructive story: An EffectiveCauchySpace$^{\uparrow}$ packet is generated from a represented-space source, a metric row, an effective Cauchy modulus, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, a CauchyCompletionUnit handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4100

A Concrete Naming Certificate for $\mathsf{RegularCauchyRegularization}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyRegularization}^{\uparrow}$ packet records the finite BEDC route by which arbitrary Cauchy data are tightened into the regular-rational route used by $\mathsf{RegSeqRat}^{\uparrow}$ and the terminal $\mathsf{Real}^{\uparrow}$ seal. It sits between chapter 291, chapter 126, chapter 301, chapter 38, and the Cauchy-criterion surfaces such as chapter 392. The packet is a regularization service over displayed finite rows; it is not quotient stream equality, a selected limit, trichotomy, countable choice, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 4100.1 (Regular Cauchy regularization carrier)**.** *A* $\mathsf{RegularCauchyRegularization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (Q, D, S, A, E, H, C, P, N)$$

with the following rows:

1. *Q is the raw Cauchy source row, naming the displayed rational data and its Cauchy-window evidence through a local Cauchy-criterion certificate;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tightening ledger, recording the dyadic precision scale used to replace arbitrary Cauchy requests by nested regular tolerances;*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that lists the finite read windows consumed by the regularization;*
4. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the tightened schedule and dyadic ledger;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after the regular readback row has been displayed;*
6. *H records componentwise* hsame *transport for the source, dyadic ledger, schedule, regular readback, terminal seal, replay, provenance, and naming rows;*
7. *C records the displayed* Cont *replay from Q through D, S, A to E;*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRegularization}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotienting Cauchy streams, selecting a host limit, comparing host real values by trichotomy, or importing completed-real closure.

Lean4 ✓ `BEDC.Derived.RegularCauchyRegularizationUp.RegularCauchyRegularizationTasteGate single carrier alignment`

Theorem 4100.2 (Regular Cauchy NameCert obligations)**.** *For the carrier of Definition 4100.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRegularization}^{\uparrow}}$ *surface consists exactly of carrier admission for* $R = (Q, D, S, A, E, H, C, P, N)$*, dyadic tightening from the raw Cauchy source row to the scheduled regular windows,* $\mathsf{StreamName}^{\uparrow}$ *schedule stability,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exactness,* $\mathsf{Real}^{\uparrow}$ *terminal-seal exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and nonescape for quotient stream equality, selected host limits, trichotomy, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the finite packet. The rows $Q, D, S, A, E, H, C, P, N$ are the whole carrier, so the admitted regularization service must expose the raw Cauchy source, the dyadic tightening ledger, the stream schedule, the regular rational readback, and the terminal seal as displayed data.

The Cauchy source is consumed through the local Cauchy-criterion row, while D chooses the dyadic precision budget used for each scheduled request. The schedule row S then records only finitely many read windows, and A packages those windows as the regular rational readback used by $\mathsf{RegSeqRat}^{\uparrow}$.

Transport and replay are componentwise. The hsame row H preserves the source, ledger, schedule, readback, seal, route, provenance, and local name together, while the Cont row C forces every consumer to traverse Q then D, S, A before reaching E.

Since the packet contains no quotient-stream coordinate, selected host limit, trichotomy row, choice row, or ambient completeness row, no such datum can be projected from the local NameCert surface. □

Theorem 4100.3 (Regular Cauchy modulus route)**.** *Every accepted* $\mathsf{RegularCauchyRegularization}^{\uparrow}$ *carrier turns a raw Cauchy source row into a* $\mathsf{RegSeqRat}^{\uparrow}$ *route by first tightening the source through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, then scheduling the required windows through* $\mathsf{StreamName}^{\uparrow}$*, then reading the scheduled rational data as the regular row* A*. The* $\mathsf{Real}^{\uparrow}$ *seal* E *is available only through that displayed route, and no consumer may replace the route by quotient stream equality, a selected limit, trichotomy, countable choice, or ambient completeness.*

Proof. Begin with the carrier inventory of Definition 4100.1. The only source of tolerance control is D, and the only source of read order is S. Thus the raw Cauchy row cannot be consumed as a regular sequence until the dyadic ledger and the stream schedule have both been displayed.

Next read the regular row. The packet places A after D and S, so the $\mathsf{RegSeqRat}^{\uparrow}$ consumer sees regular rational data only through the tightened windows. The terminal $\mathsf{Real}^{\uparrow}$ seal E is reached after this readback, not directly from the raw source row.

Finally apply the nonescape clauses from the NameCert obligations. Because no quotient stream, selected host limit, trichotomy, countable-choice coordinate, or ambient completeness row occurs in R, the modulus route is the displayed finite route through $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRegularization}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyRegularization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4100.1, Definition 4100.2, and Definition 4100.3 seed the finite regularization surface from raw Cauchy source rows through dyadic tightening, StreamName scheduling, RegSeqRat readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyRegularization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient stream equality, selected host limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tightening exactness, schedule stability, regular readback exactness, Real seal exposure, and nonescape for BEDC.Derived.RegularCauchyRegularizationUp.

Constructive story: A RegularCauchyRegularization$^{\uparrow}$ packet is generated from a raw Cauchy source row, a DyadicRatCore$^{\uparrow}$ tightening ledger, a StreamName$^{\uparrow}$ schedule, a RegSeqRat$^{\uparrow}$ readback row, a Real$^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4101

A Concrete Naming Certificate for $\mathsf{ReflexiveBanach}^{\uparrow}$

Following Banach and Alaoglu, the $\mathsf{ReflexiveBanach}^{\uparrow}$ packet records the finite double-dual evaluation window that functional-analysis consumers may inspect before any weak compactness conclusion is read. It sits beside the finite weak-star dual-ball route of chapter 3420, the weak observation surface of chapter 3597, the norm ledger of chapter 89, the Hilbert comparison surface of chapter 91, and the functional-analysis carrier of chapter 94. The packet names only displayed Banach, norm, dual-window, double-dual evaluation, weak-topology, bounded-ball, transport, replay, provenance, and local naming rows; it does not assert full Eberlein–Smulian, select weak cluster points, import quotient dual equality, or use choice over all bounded nets.

Definition 4101.1 (ReflexiveBanach finite double-dual carrier)**.** *A* $\mathsf{ReflexiveBanach}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, N, D, E, W, A, H, C, P, L)$$

with the following displayed rows:

1. *B is the Banach carrier row, read through the displayed* $\mathsf{Banach}^{\uparrow}$ *and* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *surfaces.*
2. *N is the norm row, recording the finite norm estimates used by source, dual, and ball consumers through* $\mathsf{Norm}^{\uparrow}$*.*
3. *D is the dual-window row, listing the finitely many bounded-linear-functional observations allowed in the current packet.*
4. *E is the double-dual evaluation row, recording the canonical evaluation of displayed source endpoints against the functionals named by D.*
5. *W is the weak-topology readback row, sending those finite scalar evaluations to the* $\mathsf{WeakTopology}^{\uparrow}$ *observation surface.*
6. *A is the bounded-ball ledger, recording the finite norm-bound rows whose weak-compactness handoff is visible to later consumers.*
7. *H records componentwise* hsame *transport for the Banach carrier, norm row, dual windows, double-dual evaluations, weak readbacks, bounded-ball ledgers, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from Banach admission through norm control, dual-window evaluation, weak readback, and bounded-ball handoff.*
9. *P is the* Pkg *provenance over* ReflexiveBanach$^\uparrow$, Banach$^\uparrow$, Norm$^\uparrow$, WeakTopology$^\uparrow$, BanachAlaoglu$^\uparrow$, Hilbert$^\uparrow$, FunctionalAnalysis$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* NameCert$_{\text{ReflexiveBanach}^\uparrow}$ *row.*

The carrier has no coordinate for a completed host double dual, quotient equality of dual functionals, a selected weak cluster point, a countable-choice family of balls, or an unrestricted compactness theorem.

Theorem 4101.2 (ReflexiveBanach NameCert obligations)**.** *For every accepted* ReflexiveBanach$^\uparrow$ *carrier $R = (B, N, D, E, W, A, H, C, P, L)$, the local* NameCert$_{\text{ReflexiveBanach}^\uparrow}$ *surface consists exactly of carrier admission for B, double-dual evaluation stability for E, weak topology compatibility for W, bounded-ball readback for A, and no-choice ledger nonescape for the structural rows H, C, P, L. Every accepted read must expose the Banach carrier, norm row, finite dual window, evaluation row, weak readback row, and bounded-ball ledger before local naming is consumed.*

Lean4 ✓ `BEDC.Derived.ReflexiveBanachUp.ReflexiveBanachTasteGate single carrier alignment`

Proof. Project the carrier of Definition 4101.1. The rows $B, N, D, E, W, A, H, C, P, L$ are the complete visible inventory, so carrier admission and local naming can only use those coordinates.

The double-dual evaluation obligation is finite. Each evaluation in E is tied to a source endpoint from B and a bounded functional from D, with norm control read through N; componentwise transport through H preserves the same displayed evaluation row.

Weak topology compatibility follows by reading W through the finite scalar observation surface of chapter 3597. The bounded-ball ledger A is downstream of the same norm and evaluation rows, and the Banach–Alaoglu sibling supplies only the finite dual-ball window cited in the provenance row.

Finally C, P, L replay, source, and name that same packet. Since no row stores a selected cluster point, quotient dual equality, host double-dual equality, or a choice family over all bounded balls, the no-choice ledger cannot escape the displayed finite route. □

Theorem 4101.3 (ReflexiveBanach weak compactness handoff)**.** *Every weak-compactness-facing consumer of an accepted* ReflexiveBanach$^\uparrow$ *packet must factor through the finite route*

$$B, N, D, E, W, A \longmapsto H, C, P, L.$$

The consumer may cite BanachAlaoglu$^\uparrow$ *only through the finite dual-window provenance, may cite* WeakTopology$^\uparrow$ *only through the scalar readback row W, and may cite* Hilbert$^\uparrow$ *or* FunctionalAnalysis$^\uparrow$ *only through the displayed source and norm rows. It receives no selected weakly convergent subnet, no quotient dual-space equality, no host compactness theorem, and no choice-based traversal of the bounded ball.*

Proof. Begin with the bounded-ball ledger. The row A is read after the Banach carrier B and norm row N, so every ball-facing request is already confined to displayed norm estimates over the accepted carrier.

Next expose the dual-window and evaluation rows. The row D lists only finitely many bounded-functional observations, and E evaluates displayed source endpoints against those observations before the weak-topology row W can be consumed.

The weak readback is therefore a finite scalar route. By chapter 3597 and chapter 3420, downstream compactness vocabulary can only repackage the finite weak and weak-star windows already present in D, E, W, A.

Transport, replay, provenance, and local naming preserve this route through H, C, P, L. The absence of selector, quotient, host compactness, and choice-family coordinates prevents the handoff from becoming a nonconstructive weak compactness principle. □

Falsifiable prediction: Every accepted $\mathsf{ReflexiveBanach}^{\uparrow}$ packet exposes a Banach carrier, norm row, finite dual-window row, double-dual evaluation row, weak-topology readback row, bounded-ball ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before any weak compactness consumer can read the packet.

Independence witness: banach-alaoglu, weak-topology, norm, hilbert, functionalanalysis: $\mathsf{ReflexiveBanach}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries double-dual evaluation rows and bounded-ball weak-readback ledgers over a Banach source while refusing selected weak cluster points and quotient dual equality.

Closure status for $\mathsf{NameCert}_{\mathsf{ReflexiveBanach}^{\uparrow}}$.

Constructive story: A $\mathsf{ReflexiveBanach}^{\uparrow}$ packet is generated from a Banach carrier, norm row, finite dual-window row, double-dual evaluation row, weak-topology readback row, bounded-ball ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ReflexiveBanach}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4101.1, Definition 4101.2, and Definition 4101.3 seed the finite double-dual and bounded-ball weak-readback certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ReflexiveBanach}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Eberlein–Smulian, selected weak cluster points, quotient dual equality, host double-dual equality, full weak compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, double-dual evaluation stability, weak topology compatibility, bounded-ball readback, no-choice ledger nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ReflexiveBanachUp.

Chapter 4102

A Concrete Naming Certificate for $\mathsf{RegularCauchyFilterSpace}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{RegularCauchyFilterSpace}^{\uparrow}$ packet records a regular Cauchy filter space as finite NameCert data for the L10 completion route. It sits between the Cauchy filter carrier of chapter 333, the regular Cauchy filter rows of chapter 1445, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the real seal of chapter 38. The packet feeds completion consumers by displaying regular filter-space rows before any quotient of filters, selected limit, or countable-choice principle can be invoked.

Definition 4102.1 (Regular Cauchy filter space carrier)**.** *A* $\mathsf{RegularCauchyFilterSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, B, W, Q, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the admitted point and basic-filter carrier row, retaining classifier-distinct point and filter names without quotienting them by convergence or equality;*
2. *B is the* $\mathsf{CauchyFilter}^{\uparrow}$ *basis row, exposing the finite filter-membership and directedness observations consumed by the packet;*
3. *W is the* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *regularity window, recording the shrinking, containment, and Cauchy-modulus rows used to read the filter as regular;*
4. *Q is the classifier/window exactness row, tying every accepted window request to the same point and filter classifier rows in X, B, W;*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *inspection row for finite request windows;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row for regular window moduli and Cauchy bounds;*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *sealing row reached only after S, R, W have displayed the finite regular-filter readback;*
8. *H records componentwise* hsame *transport for all carrier, basis, regularity, exactness, window, readback, seal, replay, provenance, and local naming rows;*
9. *C records displayed* Cont *replay through the same finite route;*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyFilterSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filter equality, a selected representative filter, a selected limit point, countable choice, ambient separated completion, or host equality of point names.

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterSpaceUp.RegularCauchyFilterSpaceTasteGate single carrier alignment`

Theorem 4102.2 (Regular Cauchy filter space NameCert obligations)**.** *For every accepted* RegularCauchyFilterSpac *carrier*

$$F = (X, B, W, Q, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterSpace}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the point/filter carrier X, Cauchy filter basis B, regularity window W, classifier/window exactness row Q, stream windows S, regular rational readback R, real seal E, transport H, replay C, provenance P, and local naming N;*
2. *classifier/window exactness, requiring every filter-space read to use the displayed classifier rows of X, B, W and the same finite request windows recorded in Q, S;*
3. *stability and transport, requiring regularity, Cauchy bounds, rational readback, and real sealing to move only componentwise through H and to replay through C;*
4. *ledger nonescape, excluding quotient filters, host equality, selected representatives, selected limits, countable choice, and ambient separated completion from the packet;*
5. *completion-consumer handoff, exporting only $X, B, W, Q, S, R, E, H, C, P, N$ to a* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumer before that consumer adds its own completion rows.*

No other NameCert obligation is available from the regular Cauchy filter space packet.

Proof. Carrier admission is the projection of Definition 4102.1. The tuple lists the point/filter carrier, Cauchy filter basis, regularity window, exactness row, finite stream windows, regular rational readback, Real seal, transport, replay, provenance, and local naming rows.

Classifier/window exactness is carried by Q and S. A consumer first fixes the point and filter classifiers in X, B, W, then reads the finite request windows through Q, S before asking for rational or real data.

Stability and transport are componentwise. The row H transports the displayed coordinates, and the row C replays the same route for consumers, so regularity and Cauchy bounds cannot be replaced by host equality or by a detached separated-completion fact.

Ledger nonescape follows from the carrier inventory. There is no coordinate for quotient filter equality, selected representatives, selected limits, countable choice, or ambient separated completion.

Finally the completion handoff is only the displayed tuple $X, B, W, Q, S, R, E, H, C, P, N$. A $\mathsf{CauchyFilterCompletion}^{\uparrow}$ consumer may use that finite regular-filter-space surface as input, but any completion object, quotient, or limit belongs to the consumer packet rather than to this carrier. □

Falsifiable prediction: A consumer that claims a $\mathsf{RegularCauchyFilterSpace}^{\uparrow}$ handoff while omitting the Cauchy filter basis, regularity window, classifier/window exactness row, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, hsame, Cont, Pkg, or NameCert rows refutes the carrier of Definition 4102.1.

Independence witness: cauchyfilter, regularcauchyfilter, streamname, regseqrat, real: $\mathsf{RegularCauchyFilterSpace}^{\uparrow}$ binds the filter basis, regularity window, finite request windows, rational readback, real sealing,

transport, replay, provenance, and local naming rows in one completion-facing packet; each named sibling lacks at least one of these rows as a local filter-space coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyFilterSpace}^{\uparrow}$ packet is generated from a point/filter carrier, CauchyFilter basis row, RegularCauchyFilter regularity window, classifier/window exactness row, StreamName finite windows, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4102.1 and Definition 4102.2 seed the finite regular-filter-space surface that can feed Cauchy filter completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filter equality, selected representatives, selected limits, countable choice, ambient separated completion, Lean verification, bridge checking, or host equality of point names.

Upgrade path: Obligation closure requires checked carrier admission, classifier/window exactness, componentwise stability, ledger nonescape, and completion-consumer handoff for BEDC.Derived.RegularCauchyFilterSpaceUp.

Chapter 4103

A Concrete Naming Certificate for $\mathsf{CauchyRealLimit}^{\uparrow}$

Following Bishop and Bridges, a Cauchy real limit is treated here as the finite handoff from a regular Cauchy presentation to a sealed real name. The $\mathsf{CauchyRealLimit}^{\uparrow}$ packet sits after the regular rational readback surface of chapter 301, the stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the filter-facing limit route of chapter 1558. Its role is to expose the L10 real-completion limit handoff without importing quotient streams, selected representatives, host limits, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4103.1 (Cauchy-real-limit carrier)**.** *A* $\mathsf{CauchyRealLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the Cauchy-modulus row that assigns each requested tolerance to a finite tail-window obligation.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row displaying the inspected windows of the Cauchy presentation.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational approximants observed through S.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the observed windows with the requested modulus budget.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular readback and dyadic tolerance rows have been displayed.*
6. *H records componentwise* hsame *transport for the modulus, stream, regular readback, dyadic tolerance, real seal, and local certificate rows.*
7. *C records displayed* Cont *replay from a tolerance request through M, S, R, D to the* $\mathsf{Real}^{\uparrow}$ *seal E.*
8. *P records* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealLimit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, an externally selected limit, host real convergence, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.CauchyRealLimitUp.CauchyRealLimitTasteGate single carrier alignment`

Theorem 4103.2 (Cauchy-real-limit NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealLimit}^{\uparrow}$ *carrier*

$$L = (M, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealLimit}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the displayed Cauchy modulus, stream windows, regular rational readback, dyadic tolerance ledger, real seal, transport, replay, provenance, and local naming rows;*
2. *tail-window coverage, requiring every tolerance request admitted by* M *to name a finite window in* S *before a limit read is exported;*
3. *dyadic tolerance exactness, requiring every comparison used by the handoff to read exactly the row* D *beside the* $\mathsf{RegSeqRat}^{\uparrow}$ *observations in* R*;*
4. *real-seal handoff, requiring the* $\mathsf{Real}^{\uparrow}$ *seal* E *to be consumed only after* M, S, R, D *have been displayed;*
5. *ledger non-escape, excluding quotient streams, selected limits, host convergence, choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Proof. Project the carrier coordinates. The rows M, S, R, D, E display the Cauchy modulus, finite stream windows, regular rational observations, dyadic tolerance ledger, and terminal real seal before any limit-facing consumer can read the packet.

The tail-window and tolerance clauses are finite. A tolerance request first consults M, then reads the scheduled window in S, observes the regular rational data in R, and checks the dyadic budget in D.

Finally attach the seal and structural rows. The row E is reachable only after the displayed readback route, while H, C, P, N transport, replay, source, and name that same route. Since no further coordinate is present, the carrier cannot export quotient stream equality, a selected limit, host convergence, choice, or ambient real completeness. □

Falsifiable prediction: A $\mathsf{CauchyRealLimit}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ limit seal without reading the displayed Cauchy modulus, StreamName windows, RegSeqRat observations, DyadicRatCore tolerance ledger, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row refutes the carrier surface.

Independence witness: regseqrat, streamname, dyadicratcore, real, cauchyfilterlimit: no listed sibling supplies the whole Cauchy-real-limit packet because each sibling contributes only readback, windowing, tolerance, sealing, or filter-facing limit data while this chapter binds the finite handoff route.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyRealLimit}^{\uparrow}$ packet is generated from a Cauchy modulus row, StreamName windows, RegSeqRat regular rational readbacks, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyRealLimit}^{\uparrow}}$, seed)

Scope closed: Definition 4103.1 and Definition 4103.2 seed the finite real-limit handoff over Cauchy modulus, stream-window, regular-readback, dyadic-tolerance, and Real seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyRealLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real convergence, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove carrier admission, tail-window coverage, dyadic tolerance exactness, Real seal handoff, and ledger non-escape.

Chapter 4104

A Concrete Naming Certificate for $\mathsf{PolishBaireFixedPoint}^{\uparrow}$

Following Banach's fixed-point theorem and Baire's complete-metric category theorem, the $\mathsf{PolishBaireFixedPoint}^{\uparrow}$ packet records the finite route by which a complete separable metric carrier, a Baire surface, and a contraction-iteration ledger are read together before any endpoint is treated as a host object. It routes through the complete-separable carrier of chapter 1490, the ultrametric Baire window of chapter 3485, the complete-metric Baire surface of chapter 3535, the Picard step route of chapter 395, and the finite iteration packet of chapter 2383. The chapter names the displayed fixed-point route without claiming open-cover compactness, countable choice, a selected host fixed point, or any fixed-point primitive outside the carried rows.

Definition 4104.1 (Polish-Baire fixed-point carrier)**.** *A* $\mathsf{PolishBaireFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (P, B, U, C, I, E, H, R, G, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{PolishSpace}^{\uparrow}$ *row exposing the complete separable metric carrier, stream-name schedule, regular rational readback, observation ledger, transport, replay, provenance, and local name.*
2. *B is the* $\mathsf{BaireUltrametric}^{\uparrow}$ *row that records the finite nested-window Baire route consumed by the packet.*
3. *U is the* $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ *row joining a dense-open schedule, complete-metric Cauchy thread, metric carrier, finite windows, rational readback, and terminal real seal.*
4. *C is the* $\mathsf{PicardContraction}^{\uparrow}$ *row carrying the one-step contraction route over the displayed metric source.*
5. *I is the* $\mathsf{FixedPointIteration}^{\uparrow}$ *row carrying the finite orbit ledger, residual budget, completion handoff, transport, replay, provenance, and local name for the same route.*
6. *E is the endpoint-candidate seal row. It is readable only after P, B, U, C, I have been displayed, and it records no selected host point or host fixed-point equality.*
7. *H records componentwise* hsame *transport for the Polish-space, Baire-ultrametric, complete-metric Baire, Picard-contraction, iteration, endpoint-seal, replay, provenance, and local naming rows.*

8. *R records displayed* Cont *replay from a contraction request through the Baire windows, complete-metric surface, Picard step, finite iteration ledger, residual budget, and endpoint-candidate seal.*
9. *G is the* Pkg *provenance over* $\mathsf{PolishBaireFixedPoint}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{BaireUltrametric}^{\uparrow}$, $\mathsf{CompleteMetricBaireSurfac}$ $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{FixedPointIteration}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PolishBaireFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for open-cover compactness, countable-choice selection, quotient completion equality, host fixed-point equality, or a primitive fixed-point theorem.

Theorem 4104.2 (Polish-Baire fixed-point NameCert obligations)**.** *For every accepted* $\mathsf{PolishBaireFixedPoint}^{\uparrow}$ *carrier*

$$F = (P, B, U, C, I, E, H, R, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{PolishBaireFixedPoint}^{\uparrow}}$ *surface consists exactly of carrier admission, Polish complete-separable source exposure, Baire-ultrametric window exposure, complete-metric Baire-surface routing, Picard one-step readability, finite fixed-point iteration ledger exposure, endpoint-candidate sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation is stored outside the rows of Definition 4104.1.*

Lean4 ✓ `BEDC.Derived.PolishBaireFixedPointUp.PolishBaireFixedPointTasteGate single carrier alignment`

Proof. Project the accepted carrier. The rows P, B, U, C, I, E are the only analytic rows available to the local certificate: complete separable source, Baire window, complete-metric Baire surface, Picard step, finite iteration ledger, and endpoint-candidate seal.

The source and Baire obligations are read before any endpoint row. The Polish row supplies the common complete-separable metric surface, while the two Baire rows expose only finite nested-window and complete-metric schedule data.

The fixed-point route is then read through C and I. The Picard row supplies the one-step contraction route, and the iteration row supplies the finite orbit ledger and residual budget without selecting a completed fixed point.

Finally H, R, G, N transport, replay, source, and name the same finite route. Since the carrier contains no coordinate beyond these rows, the listed surface exhausts the local NameCert obligations. □

Theorem 4104.3 (Polish-Baire fixed-point iteration nonescape)**.** *Every fixed-point-facing read from an accepted* $\mathsf{PolishBaireFixedPoint}^{\uparrow}$ *carrier must pass through*

$\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{BaireUltrametric}^{\uparrow}$, $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, $\mathsf{FixedPointIteration}^{\uparrow}$, BHist, hsa

In particular, the endpoint-candidate row E is consumable only after the complete-separable source, Baire windows, complete-metric Baire surface, Picard step, finite orbit ledger, transport, replay, provenance, and local naming rows have been displayed.

Proof. Start from the carrier definition. The endpoint-candidate seal E is stored after the Polish source P, Baire rows B, U, Picard route C, and finite iteration ledger I.

Apply the NameCert obligation theorem. It makes the complete-separable source, Baire schedule, Picard step, finite orbit ledger, and residual budget part of the public local surface before the endpoint-candidate seal can be read.

The structural rows H, R, G, N then preserve the same route under transport, replay it for downstream consumers, record provenance, and attach the local name. Because no separate coordinate stores open-cover compactness, countable choice, host fixed-point equality, or a fixed-point primitive, any fixed-point-facing read remains inside the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PolishBaireFixedPoint}\uparrow}$.

Constructive story: A $\mathsf{PolishBaireFixedPoint}^{\uparrow}$ packet is generated from a PolishSpace complete-separable carrier, BaireUltrametric finite window route, CompleteMetricBaireSurface schedule, PicardContraction step, FixedPointIteration ledger, endpoint-candidate seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PolishBaireFixedPoint}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4104.1, Definition 4104.2, and Definition 4104.3 seed the finite Polish/Baire fixed-point route over complete-separable, Baire-window, complete-metric Baire, Picard, iteration, endpoint-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PolishBaireFixedPoint}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected host fixed points, quotient completion equality, host fixed-point equality, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, Baire-window exposure, complete-metric Baire routing, Picard-step readability, finite iteration ledger exactness, endpoint-candidate nonescape, transport stability, replay stability, provenance stability, and local naming for BEDC.Derived.PolishBaireFixedPointUp.

Chapter 4105

A Concrete Naming Certificate for $\mathsf{CompactModulusSelector}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Heine–Cantor finite-net proof, the CompactModulusSelector packet records the finite selector route that turns compact-metric total boundedness and pointwise continuity data into a reusable uniform-modulus certificate. It sits over the compact metric source of chapter 129, the total-boundedness finite-net interface of chapter 127, the continuous-map row of chapter 130, and the uniform-modulus consumer of chapter 369. Its L10 real-facing reads pass through the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal seal of chapter 38. The packet names finite-net modulus selection as displayed BEDC data; it does not assert open-cover compactness, countable choice, a selected infinite net, host function equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4105.1 (CompactModulusSelector carrier)**.** *A* $\mathsf{CompactModulusSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, T, F, U, D, W, R, A, H, C, P, N)$$

with the following displayed rows:

1. *K is the accepted* $\mathsf{CompactMetric}^{\uparrow}$ *source row. It records the compact metric carrier and its displayed metric observation surface.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row read from K at the requested dyadic tolerance scale.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise-continuity row whose local moduli are inspected only at the displayed net centers.*
4. *U is the candidate* $\mathsf{UniformModulus}^{\uparrow}$ *row exported to downstream uniform-continuity consumers.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling the source mesh, target error budget, and triangle comparison.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected net-center and point-name windows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the finite metric and image-distance observations.*
8. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, W, R have displayed the requested estimates.*

9. *H records componentwise* hsame *transport for compact metric, total-boundedness, continuous-map, uniform-modulus, dyadic, window, readback, seal, continuation, provenance, and naming rows.*
10. *C records displayed* Cont *replay from a uniform-modulus request through the compact finite-net selection route and then into the exported modulus row.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactModulusSelector}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, a choice function over all covers, selected infinite subnet data, host equality of maps, trichotomy, quotient completion, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CompactModulusSelectorUp.CompactModulusSelectorTasteGate single carrier alignment`

Theorem 4105.2 (CompactModulusSelector NameCert obligations)**.** *For every accepted* $\mathsf{CompactModulusSelector}^{\uparrow}$ *carrier* $S = (K, T, F, U, D, W, R, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactModulusSelector}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, total-bounded finite net, continuous-map row, uniform-modulus export, dyadic tolerance ledger, finite windows, regular readback, Real seal, transport, continuation, provenance, and local naming rows. Any consumer that reads the exported modulus must consume the finite-net row T, the pointwise continuity row F, and the dyadic comparison row D before U is visible. The packet exports no open-cover compactness, countable choice, host map equality, selected infinite net, trichotomy, quotient completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4105.1. The listed coordinates are exactly the compact metric, total-boundedness, continuous-map, uniform-modulus, dyadic, window, readback, Real-seal, transport, replay, provenance, and local naming rows.

Replay C. A modulus request first reads the compact metric source K, then the finite-net row T, then the continuous-map row F at the displayed net centers. The dyadic ledger D, finite windows W, and regular readback R provide the requested source and target estimates before the terminal seal A is consumed.

The exported row U is therefore a finite-net modulus row. Transport by H preserves only the displayed coordinates, while P and N package and name the same route, so none of the excluded principles appears as a hidden obligation. □

Theorem 4105.3 (CompactModulusSelector finite-net selection)**.** *Let $S = (K, T, F, U, D, W, R, A, H, C, P, N)$ be an accepted* $\mathsf{CompactModulusSelector}^{\uparrow}$ *packet. Every exported* $\mathsf{UniformModulus}^{\uparrow}$ *read factors through the finite route*

$$K, T, F, D, W, R, A \longmapsto U, H, C, P, N.$$

The finite net is read from $\mathsf{TotallyBounded}^{\uparrow}$ *inside the* $\mathsf{CompactMetric}^{\uparrow}$ *source, the local continuity data are read from* $\mathsf{ContinuousMap}^{\uparrow}$ *at the displayed net centers, and the dyadic tolerance ledger supplies the comparison budget. The route preserves all rows $K, T, F, U, D, W, R, A, H, C, P, N$ and exports no open-cover compactness, countable choice, selected infinite net, host equality of functions, trichotomy, quotient completion, or ambient real completeness.*

Proof. Start from a consumer of the uniform-modulus row. Carrier admission exposes U only as a row of the packet named in Definition 4105.1.

Use the continuation row C to replay the finite selection route. The compact metric source K supplies the ambient metric data, T supplies the finite net, and F supplies the local continuity data at the displayed centers.

The tolerance and readback rows D, W, R, A then certify the comparison budget before U is exported. Since transport, provenance, and naming are confined to H, C, P, N, the handoff preserves the listed rows and cannot export any of the excluded choice, open-cover, equality, or completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusSelector}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactModulusSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4105.1, Definition 4105.2, and Definition 4105.3 seed the finite-net modulus selector route over compact metric, total-bounded, continuous-map, uniform-modulus, dyadic, window, readback, Real-seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactModulusSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected infinite nets, host function equality, trichotomy, quotient completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net selection, pointwise-continuity inspection, dyadic tolerance comparison, uniform-modulus export, and structural nonescape for BEDC.Derived.CompactModulusSelectorUp.

Constructive story: A $\mathsf{CompactModulusSelector}^{\uparrow}$ packet is generated from a CompactMetric row, a TotallyBounded finite-net row, a ContinuousMap pointwise-continuity row, a UniformModulus export row, dyadic tolerance data, finite windows, regular readback, a Real seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 4106

A Concrete Naming Certificate for $\mathsf{TypeCheckingClassifier}^{\uparrow}$

The $\mathsf{TypeCheckingClassifier}^{\uparrow}$ packet realizes the type-checking-as-Ext-membership vision of chapter 9367 as one finite NameCert carrier. It sits beside the classifier-membership packet of chapter 476, the typing-classifier route of chapter 489, the subject-reduction surface of chapter 483, the derivation-trace packet of chapter 598, and the proof-erasure route of chapter 642. The packet records type checking as finite membership data: it does not export a host conversion oracle, semantic equality of terms, normalization theorem, hidden proof object, quotient syntax, or ambient metatheory.

Definition 4106.1 (TypeCheckingClassifier carrier)**.** *A* $\mathsf{TypeCheckingClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, J, E, D, S, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite term row. It names the inspected term histories and their syntactic classifier.*
2. *J is the typing-ledger row. It records the finite judgment entries used by the checker.*
3. *E is the* Ext*-membership row, identifying accepted typed terms as classifier members.*
4. *D is the derivation-trace row linking each accepted membership read to a displayed typing derivation.*
5. *S is the subject-reduction row, routing accepted* Ext *membership through displayed* Cont *steps.*
6. *R is the erasure row, separating proof-term content from the erased computational term while preserving the displayed membership route.*
7. *H records componentwise* hsame *transport for term, typing-ledger,* Ext*-membership, derivation-trace, subject-reduction, erasure, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a type-checking request through membership, derivation, subject-reduction, and erasure rows.*
9. *P is the* Pkg *provenance over* $\mathsf{TypeCheckingClassifier}^{\uparrow}$, $\mathsf{TypeClassifierMembership}^{\uparrow}$, $\mathsf{ClassifierTyping}^{\uparrow}$, $\mathsf{SubjectReduction}^{\uparrow}$, $\mathsf{TypeCheckingDerivationTrace}^{\uparrow}$, $\mathsf{ProofTermErasureTrace}^{\uparrow}$, BHist, Ext, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TypeCheckingClassifier}^{\uparrow}}$ *row.*

The carrier has no coordinate for host conversion, semantic equality of terms, an ambient normalization theorem, hidden proof objects, quotient syntax, or external metatheoretic consistency.

Lean4 (definition) `BEDC.Derived.TypeCheckingClassifierUp.TypeCheckingClassifierUp`
Lean4 ✓ `BEDC.Derived.TypeCheckingClassifierUp.TypeCheckingClassifierTasteGate single carrier alignment`

Theorem 4106.2 (TypeCheckingClassifier NameCert obligations)**.** *For every accepted* $\mathsf{TypeCheckingClassifier}^{\uparrow}$ *carrier* $Q = (T, J, E, D, S, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TypeCheckingClassifier}^{\uparrow}}$ *surface consists exactly of carrier admission for the term row, typing ledger,* Ext*-membership row, derivation trace, subject-reduction row, erasure row, componentwise transport, continuation replay, provenance, and local naming. Every accepted type-checking read must expose membership through* E*, derivation through* D*, subject reduction through* S*, and erasure separation through* R *before* H, C, P, N *package the row. No obligation is stored in host conversion, semantic equality of terms, normalization, quotient syntax, hidden proof objects, or ambient metatheory.*

Proof. Project the carrier of Definition 4106.1. The tuple lists exactly the term, judgment, membership, derivation, subject-reduction, erasure, transport, replay, provenance, and local naming rows.

Replay the continuation row C. A type-checking request first reads the finite term row T and typing ledger J, then the Ext-membership row E and derivation trace D. Subject reduction is read from S, and proof-term erasure is kept in the displayed row R.

Transport by H is componentwise over those rows. The provenance and naming rows P, N therefore package only the finite classifier route, leaving no coordinate from which a host oracle, quotient syntax, hidden proof object, or ambient metatheorem could be exported. □

Theorem 4106.3 (TypeCheckingClassifier membership soundness)**.** *Let* $Q = (T, J, E, D, S, R, H, C, P, N)$ *be an accepted* $\mathsf{TypeCheckingClassifier}^{\uparrow}$ *packet. Every successful type-checking answer exported by* Q *is an* Ext*-membership read supported by the displayed typing ledger and derivation trace:*

$$T, J \longmapsto E, D \longmapsto S, R, H, C, P, N.$$

The subject-reduction row preserves the membership read along displayed Cont *replay, and the erasure row separates proof-term evidence from erased computational content. The handoff preserves* $T, J, E, D, S, R, H, C, P, N$ *and exports no host conversion oracle, semantic term equality, normalization theorem, hidden proof object, quotient syntax, or ambient consistency principle.*

Proof. Begin with a successful type-checking answer. By carrier admission, the answer can only be read through the rows of Definition 4106.1.

The finite term row T and typing ledger J provide the displayed input to the classifier. The Ext row E records membership, and the derivation trace D records the finite route witnessing the accepted judgment.

Subject reduction is then read as the displayed row S along Cont replay, while R keeps proof-term erasure separate from the erased computational term. Componentwise transport, provenance, and naming preserve this route through H, C, P, N without adding the excluded host-level principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{TypeCheckingClassifier}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TypeCheckingClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4106.1, Definition 4106.2, and Definition 4106.3 seed the finite term, typing-ledger, Ext-membership, derivation-trace, subject-reduction, erasure, transport, replay, provenance, and naming route.

Formal verification: FormalStatus(NameCert$_{\mathsf{TypeCheckingClassifier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host conversion, semantic equality of terms, normalization, hidden proof objects, quotient syntax, ambient metatheoretic consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Ext-membership soundness, derivation-trace support, subject-reduction replay, erasure separation, and structural nonescape for BEDC.Derived.TypeCheckingClassifierUp.

Constructive story: A TypeCheckingClassifier$^{\uparrow}$ packet is generated from term rows, a finite typing ledger, Ext-membership data, derivation traces, subject-reduction replay, erasure separation, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Chapter 4107

A Concrete Naming Certificate for $\mathsf{MengerNobelingEmbedding}^{\uparrow}$

Following Menger and Nobeling, the $\mathsf{MengerNobelingEmbedding}^{\uparrow}$ packet records a finite-dimensional metric embedding handoff as BEDC NameCert data. It sits after the metric carrier of chapter 57, the compact finite-net surface of chapter 129, the distance-function route of chapter 7569, the tolerance-indexed net row of chapter 1767, and the terminal real-name boundary of chapter 38. The packet names the finite coordinate route needed by embedding consumers; it is not a host Euclidean space, not a selected infinite coordinate family, not a quotient completion, and not an ambient dimension theorem.

Definition 4107.1 (Menger–Nobeling embedding carrier)**.** *A* $\mathsf{MengerNobelingEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, K, Q, F, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row whose point classifier and distance classifier are read by the embedding packet.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *or compact finite-metric handoff row supplying the finite cover and compact inspection data used by the coordinate budget.*
3. *Q is the* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *distance-function row that turns source-distance observations into displayed real-valued coordinate observations.*
4. *F is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row that records the inspected center bundle, tolerance, and coverage witnesses used to choose a finite coordinate window.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row for the displayed coordinate values and finite separation inequalities.*
6. *H records componentwise* hsame *transport for the metric source, compact handoff, Kuratowski row, finite-net row, real readbacks, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from metric-distance reads through K, Q, F, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MengerNobelingEmbedding}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{KuratowskiEmbedding}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MengerNobelingEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, K, Q, F, R, H, C, P, N$. It has no coordinate for a host Euclidean carrier, a selected infinite coordinate family, quotient completion, open-cover compactness, countable choice, or an ambient dimension principle.

Lean4 ✓ `BEDC.Derived.MengerNobelingEmbeddingUp.MengerNobelingEmbeddingTasteGate single carrier alignment`

Theorem 4107.2 (Menger–Nobeling embedding NameCert obligations)**.** *For every accepted* MengerNobelingEmbe *carrier $E = (M, K, Q, F, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MengerNobelingEmbedding}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed metric source, compact handoff, Kuratowski distance-function row, finite epsilon-net row, real coordinate readback, transport, replay, provenance, and local naming row;*
2. *metric-source exposure, requiring every source point and distance read to enter through M;*
3. *compact finite-net exposure, requiring every finite coordinate budget to be read through the compact row K and the finite-net row F;*
4. *Kuratowski coordinate handoff, requiring every displayed coordinate observation to pass through Q before its* $\mathsf{Real}^{\uparrow}$ *readback in R is consumed;*
5. *finite separation stability, requiring the same F, Q, R rows to witness the finite coordinate separation read under componentwise transport H;*
6. *non-escape, excluding host Euclidean carriers, selected infinite coordinate families, quotient completions, open-cover compactness, countable choice, and ambient dimension principles from the local certificate.*

No Menger–Nobeling embedding obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 4107.1. The only analytic rows are the metric source M, the compact handoff K, the Kuratowski distance-function row Q, the finite-net row F, and the real coordinate readback row R.

The compact coordinate budget is finite because it is read through K and F. The compact row supplies the finite inspection context, while the finite epsilon-net row supplies the displayed center bundle, tolerance, and coverage witnesses used by the coordinate window.

The coordinate values are then forced through the Kuratowski route. The row Q exposes distance-function observations, and R reads those observations through the terminal Real boundary before any separation claim is exported.

Finally, H, C, P, N preserve and name the same route. Since the carrier has no Euclidean host, infinite coordinate-family selector, quotient-completion row, open-cover compactness row, choice schedule, or ambient dimension row, none of those objects can become a local NameCert obligation. □

Theorem 4107.3 (Menger–Nobeling embedding finite coordinate handoff)**.** *Every* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{KuratowskiEmbedding}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{MengerNobelingEmbedding}^{\uparrow}$ *carrier must read the finite route*

$$M, K, Q, F, R, H, C, P, N.$$

Thus a finite-dimensional embedding request reaches coordinate data only after the metric source, compact finite-net budget, Kuratowski distance-function observations, and real readbacks are visible. The handoff exports no host Euclidean carrier, selected infinite coordinate family, quotient completion, open-cover compactness, countable choice, or ambient dimension principle.

Proof. Begin with an accepted carrier $E = (M, K, Q, F, R, H, C, P, N)$. A consumer can enter the packet only through the metric source M and the compact handoff K.

The finite coordinate window is opened next. The Kuratowski row Q supplies distance-function observations, the finite epsilon-net row F supplies the displayed center and coverage budget, and the Real row R supplies the coordinate readbacks.

The structural rows then package exactly that handoff. Componentwise transport H preserves the same finite route, replay C exposes it to downstream consumers, provenance P records the package lineage, and N names the local certificate. Therefore the embedding consumer receives only the displayed finite coordinate handoff and not any hidden host embedding principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{MengerNobelingEmbedding}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MengerNobelingEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4107.1, Definition 4107.2, and Definition 4107.3 seed the finite coordinate embedding route over MetricUp, CompactMetricUp, KuratowskiEmbeddingUp, FiniteEpsilonNetUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MengerNobelingEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host Euclidean embedding, selected infinite coordinate families, quotient completion, open-cover compactness, countable choice, ambient dimension principles, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, Kuratowski coordinate handoff, finite separation stability, Real readback, transport, replay, provenance, and local naming for BEDC.Derived.MengerNobelingEmbe

Constructive story: A $\mathsf{MengerNobelingEmbedding}^{\uparrow}$ packet is generated from a MetricUp source row, a CompactMetricUp handoff, a KuratowskiEmbeddingUp distance-function row, a FiniteEpsilonNetUp coordinate budget, a RealUp readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4108

A Concrete Naming Certificate for $\mathsf{UniformSpaceCompletionFilter}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{UniformSpaceCompletionFilter}^{\uparrow}$ packet records the completion route in which a displayed Cauchy filter is read through a uniform-space entourage basis before any quotient completion or selected limit is available. It sits after the uniform-space surface of chapter 339, the filter-basis generator of chapter 1501, the saturated Cauchy-filter packet of chapter 333, and the completion boundary of chapter 95. Its finite readback route uses the stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38.

Definition 4108.1 (Uniform-space completion-filter carrier)**.** *A* $\mathsf{UniformSpaceCompletionFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (U, B, F, S, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, including the finite diagonal, refinement, symmetry, and composition data visible to the packet.*
2. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *generator row, listing the basis elements and common-refinement witnesses read from U.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *saturated filter row generated from B.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule controlling which filter and entourage reads may be inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed windows and tolerance requests.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for entourage shrinkage, Cauchy refinement, and completion-radius comparison.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *completion-admission seal reached only after U, B, F, S, R, D have been displayed.*
8. *H records componentwise* hsame *transport for all displayed rows.*
9. *C records displayed* Cont *replay from a completion request through the uniform, basis, filter, window, readback, tolerance, and Real-seal rows.*

10. *P is the* Pkg *provenance over* $\mathsf{UniformSpaceCompletionFilter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformSpaceCompletionFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, B, F, S, R, D, A, H, C, P, N$. It has no coordinate for quotient filters, host equality of filters, selected representatives, countable choice, a chosen completion point, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformSpaceCompletionFilterUp.UniformSpaceCompletionFilterTasteGate`
`single carrier alignment`

Theorem 4108.2 (Uniform-space completion-filter NameCert obligations)**.** *For every accepted* $\mathsf{UniformSpaceCompletionFilter}^{\uparrow}$ *carrier $Q = (U, B, F, S, R, D, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformSpaceCompletionF}}$ *surface consists exactly of carrier admission for the displayed uniform-space entourage row, Cauchy-filter basis row, saturated Cauchy-filter row, stream-window row, regular-rational readback row, dyadic tolerance ledger, Real completion-admission seal, componentwise transport, continuation replay, package provenance, and local naming row. Every completion-facing read of Q must pass through*

$$\mathsf{UniformSpace}^{\uparrow} \longmapsto \mathsf{CauchyFilterBasis}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto$$

before the completion boundary of $\mathsf{Completion}^{\uparrow}$ *may consume the packet.*

Proof. Project the carrier of Definition 4108.1. The coordinates list exactly the uniform, basis, filter, window, readback, tolerance, Real-seal, transport, replay, provenance, and local naming rows.

The completion-facing order is forced by C. A consumer first reads the entourage data U, then the basis row B and saturated filter row F, and only then inspects the finite windows S, dyadic ledger D, regular rational readback R, and Real seal A.

The structural rows do not add a second source. The transport row H moves only the displayed coordinates componentwise, while P and N name the same finite packet as provenance and local certificate data.

Since no coordinate of Q names quotient filters, host filter equality, selected representatives, countable choice, a chosen completion point, or ambient $\mathsf{Real}^{\uparrow}$ completeness, those objects cannot be exported by the local NameCert surface. The listed rows therefore exhaust the obligations. □

Theorem 4108.3 (Uniform-space completion-filter boundary)**.** *Let $Q = (U, B, F, S, R, D, A, H, C, P, N)$ be an accepted* $\mathsf{UniformSpaceCompletionFilter}^{\uparrow}$ *packet. Any* $\mathsf{Completion}^{\uparrow}$ *consumer of Q receives a finite filter-completion route through the displayed rows $U, B, F, S, R, D, A, H, C, P, N$ and receives no quotient-filter class, selected completion point, host filter equality, countable-choice selector, hidden cofinal subfilter, or ambient completeness theorem.*

Proof. Begin with the NameCert obligation theorem, Definition 4108.2. It routes completion-facing reads through the uniform row, Cauchy-filter basis, Cauchy filter, finite windows, dyadic tolerance ledger, regular readback, and Real seal before the completion boundary consumes the packet.

The replay and transport rows preserve the same route. They do not add representatives, quotient classes, hidden cofinal filters, or selected limits; they only replay and transport the displayed coordinates.

Finally inspect the carrier definition. The excluded objects are absent from Q, so a $\mathsf{Completion}^{\uparrow}$ consumer cannot extract them from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformSpaceCompletionFilter}\uparrow}$.

Constructive story: A $\mathsf{UniformSpaceCompletionFilter}^{\uparrow}$ packet is generated from a UniformSpace entourage row, CauchyFilterBasis generator row, CauchyFilter saturation row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, a RealUp completion-admission seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformSpaceCompletionFilter}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4108.1, Definition 4108.2, and Definition 4108.3 seed the non-quotient filter-completion route for UniformSpaceUp, CauchyFilterBasisUp, CauchyFilterUp, CompletionUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, and RealUp consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformSpaceCompletionFilter}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filter completion, selected completion points, host filter equality, countable choice, hidden cofinal subfilters, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, basis-to-filter saturation, completion-facing replay, Real-seal handoff, and refusal of quotient-filter and selected-limit escapes for BEDC.Derived.UniformSpaceCompletionFilterUp.

Chapter 4109

A Concrete Naming Certificate for $\mathsf{RegularCauchyFilterCompletion}^{\uparrow}$

Following Bishop–Bridges regular Cauchy real names and Kelley filter terminology, the RegularCauchyFilterCompleti packet records the L10 route by which a regular Cauchy name is read as a Cauchy-filter completion object through finite BEDC rows. It sits after the filter-limit boundary of chapter 1558, the completion-facing filter surface of chapter 1569, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives filter-completion consumers a canonical regular-name bridge without quotient filters, selected representatives, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4109.1 (Regular Cauchy filter completion carrier)**.** *A* $\mathsf{RegularCauchyFilterCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, F, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *boundary row available only after the source filter and regular-name requests have been replayed.*
2. *F is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *completion-facing row whose consumers may read only the displayed filter route.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule opened for regular Cauchy tail requests and filter-completion reads.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling the requested windows, comparison radius, and filter limit slack.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and dyadic tolerance ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after L, F, S, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the limit, completion, window, tolerance, readback, seal, replay, provenance, and local-name rows.*
8. *C records displayed* Cont *replay from a regular Cauchy filter-completion request through $L, F, S, D, R, E, H, P, N$.*

9. *P records* Pkg *provenance over* $\mathsf{RegularCauchyFilterCompletion}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $L, F, S, D, R, E, H, C, P, N$. It stores no quotient filter, selected completion point, hidden cofinal sequence, host real equality, countable-choice schedule, or ambient completeness coordinate.

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterCompletionUp.RegularCauchyFilterCompletionTasteGate`
`single carrier alignment`

Theorem 4109.2 (Regular Cauchy filter completion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFilterCompletion}^{\uparrow}$ *carrier*

$$Q = (L, F, S, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *boundary exposure through L,* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumer exposure through F, finite* $\mathsf{StreamName}^{\uparrow}$ *window inspection through S,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting through D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *seal discipline through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4109.1. The tuple displays the filter-limit boundary, completion-facing row, window schedule, dyadic tolerance ledger, regular rational readback, terminal real seal, and structural rows.

Read the analytic route in order. The limit row L and completion row F place the request inside the Cauchy-filter completion surface before any finite regular-name data are inspected.

The regular-name data are then exhausted by S, D, R, E. The stream windows in S are measured by the dyadic ledger D, the regular rational row R is read from that displayed data, and the real seal E appears only after those rows have been exposed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. No remaining coordinate can supply quotient filters, selected representatives, hidden cofinal choices, host equality, or ambient completeness, so the listed rows are exactly the local NameCert obligations. □

Theorem 4109.3 (Regular Cauchy filter completion seal handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{RegularCauchyFilterCompletion}^{\uparrow}$ *packet receives the* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$\mathsf{CauchyFilterLimit}^{\uparrow} \longmapsto \mathsf{CauchyFilterCompletion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff is a filter-completion reading of a regular Cauchy name, not a quotient filter construction, selected completion point, host real equality, or ambient completeness principle.

Proof. Apply Definition 4109.2. It orders the completion-facing read through L, F, S, D, R, E before the terminal seal is visible.

The first two rows bind the filter-completion side. The $\mathsf{CauchyFilterLimit}^{\uparrow}$ row records the limit-facing boundary, and the $\mathsf{CauchyFilterCompletion}^{\uparrow}$ row records the completion consumer that may inspect the same displayed route.

The remaining rows bind the regular-name side. The finite windows, dyadic ledger, and regular rational readback feed the terminal real seal, while H, C, P, N only preserve and name that route.

Thus any consumer that reaches $\mathsf{Real}^{\uparrow}$ without passing through the listed route leaves the carrier. The handoff supplies a finite regular Cauchy filter-completion bridge and no hidden completion object. □

Theorem 4109.4 (Regular Cauchy filter completion nonescape)**.** *No accepted* $\mathsf{RegularCauchyFilterCompletion}^{\uparrow}$ *packet exports quotient filter equality, a selected representative, a chosen cofinal tail, host real equality, countable choice, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*. Every exported completion or real-facing read is confined to the rows* $L, F, S, D, R, E, H, C, P, N$*.*

Proof. Inspect the carrier definition. Its non-structural rows are exactly the filter-limit boundary L, completion row F, stream windows S, dyadic tolerance ledger D, regular rational readback R, and real seal E.

The structural rows add no analytic principle. Transport through H, replay through C, provenance through P, and local naming through N preserve the displayed packet rather than adding quotient filters, selected representatives, cofinal choices, or host equality.

Use the seal handoff of Definition 4109.3. Every completion or real-facing read must pass through the displayed finite route, so none of the excluded data can escape from the packet. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyFilterCompletion}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row refutes the packet surface.

Independence witness: cauchyfilterlimit, cauchyfiltercompletion, streamname, dyadicratcore, regseqrat, real: no listed sibling is bijective to $\mathsf{RegularCauchyFilterCompletion}^{\uparrow}$ because this packet binds the filter-limit boundary, completion-facing row, finite windows, tolerance ledger, regular readback, terminal seal, transport, replay, provenance, and local naming as one L10 route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyFilterCompletion}^{\uparrow}$ packet is generated from a CauchyFilterLimit boundary row, CauchyFilterCompletion consumer row, StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyFilterCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 4109.1, Definition 4109.2, Definition 4109.3, and Definition 4109.4 seed the L10 regular Cauchy filter-completion route over CauchyFilterLimitUp, CauchyFilterCompletionUp, StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyFilterCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected representatives, hidden cofinal choices, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove carrier admission, filter-limit exposure, completion-facing exposure, window exactness, tolerance exactness, RegSeqRat readback, Real seal handoff, transport, replay, provenance, and ledger nonescape for BEDC.Derived.RegularCauchyFilterCompletionUp.

Chapter 4110

A Concrete Naming Certificate for $\mathsf{CauchyFilterRegularization}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{CauchyFilterRegularization}^{\uparrow}$ packet records the L10 handoff that turns a displayed Cauchy-filter completion route into a regular Cauchy real-name route through finite BEDC rows. It sits after the Cauchy-filter surface of chapter 333, the completion boundary of chapter 1569, the Polish carrier discipline of chapter 1490, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the finite regularization handoff; it does not quotient filters, select representatives, import countable choice, assert host equality of limits, or use ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4110.1 (Cauchy-filter regularization carrier)**.** *A* $\mathsf{CauchyFilterRegularization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, W, D, R, L, H, C, P, N)$$

with the following displayed rows:

1. *F is the source* $\mathsf{CauchyFilter}^{\uparrow}/\mathsf{CauchyFilterCompletion}^{\uparrow}$ *row, naming the finite filter observations and the completion-facing boundary they expose.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule opened for regularization requests and tail comparisons.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same windows, comparison radii, and completion requests.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the displayed windows and dyadic tolerance data.*
5. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, W, D, R have been displayed.*
6. *H records componentwise* hsame *transport for the filter-completion source, stream windows, dyadic ledger, regular readback, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a regularization request through F, W, D, R, L, H, P, N.*
8. *P records* Pkg *provenance over* $\mathsf{CauchyFilterRegularization}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterRegularization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, W, D, R, L, H, C, P, N$. It stores no quotient filter, selected completion point, hidden cofinal subsequence, host real equality, countable-choice schedule, or ambient completeness coordinate.

Lean4 ✓ BEDC.Derived.CauchyFilterRegularizationUp.CauchyFilterRegularizationTasteGate single carrier alignment

Theorem 4110.2 (Cauchy-filter regularization NameCert obligations)**.** *For every accepted* CauchyFilterRegularizati *carrier*

$$G = (F, W, D, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyFilterRegularization}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed source, window, tolerance, readback, seal, transport, replay, provenance, and local-name rows;*
2. *filter exposure, requiring every regularization read to expose the* $\mathsf{CauchyFilter}^{\uparrow}/\mathsf{CauchyFilterCompletion}^{\uparrow}$ *row F before a stream window is inspected;*
3. *window and tolerance exactness, requiring the* $\mathsf{StreamName}^{\uparrow}$ *row W and* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D to determine every finite comparison used by the handoff;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring the regular rational row R to be read from the displayed W, D data and not from a hidden representative;*
5. $\mathsf{Real}^{\uparrow}$*-seal nonescape, requiring the terminal row L to be consumed only after F, W, D, R have been displayed;*
6. *provenance, requiring H, C, P, N to transport, replay, source, and name the same finite packet without adding quotient filters, selected limits, choice, host equality, or ambient completeness.*

Proof. Project the carrier of Definition 4110.1. The source row F exposes the Cauchy-filter completion boundary, and the rows W, D, R, L are the only non-structural regularization rows downstream from that boundary.

The window and tolerance part is finite. A regularization request opens the listed $\mathsf{StreamName}^{\uparrow}$ windows in W, reads the dyadic tolerance budget in D, and then obtains the $\mathsf{RegSeqRat}^{\uparrow}$ row R from those displayed observations.

The real-seal handoff is last. The terminal row L is reachable only after F, W, D, R have been exposed, while H, C, P, N only transport, replay, source, and name the same packet. Since no remaining coordinate stores quotient filters, selected representatives, hidden cofinal choices, host real equality, or ambient completeness, the listed clauses exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{CauchyFilterRegularization}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading the displayed CauchyFilter and CauchyFilterCompletion source, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row refutes the packet surface.

Independence witness: cauchyfiltercompletion, polishspace, streamname, dyadicratcore, regseqrat, real: $\mathsf{CauchyFilterRegularization}^{\uparrow}$ is not bijective to any listed sibling because it binds a Cauchy-filter completion boundary, finite window schedule, dyadic tolerance ledger, regular rational handoff, Real seal, transport, replay, provenance, and local naming into one L10 regularization certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterRegularization}^{\uparrow}}$.

Constructive story: A CauchyFilterRegularization$^{\uparrow}$ packet is generated from a CauchyFilter/CauchyFilterCompletion source row, StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyFilterRegularization}^{\uparrow}}$, seed)

Scope closed: Definition 4110.1 and Definition 4110.2 seed the L10 Cauchy-filter regularization handoff over CauchyFilterUp, CauchyFilterCompletionUp, StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchyFilterRegularization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected representatives, hidden cofinal choices, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove carrier admission, filter exposure, window exactness, tolerance exactness, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFilterRegularizationUp.

Chapter 4111

A Concrete Naming Certificate for $\mathsf{RealInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealInterval}^{\uparrow}$ packet records displayed real interval endpoints and finite enclosure rows for the L10 Real and Completion route. It sits after the located interval surface of chapter 394, the rational interval surface of chapter 354, and the dyadic-to-real spine of chapter 291, chapter 126, chapter 301, and chapter 38. The chapter gives interval-completion and real-enclosure consumers one named endpoint-and-enclosure packet; it is not a host closed interval, selected endpoint representatives, trichotomy, compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4111.1 (RealInterval carrier)**.** *A* $\mathsf{RealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, E, D, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower endpoint* $\mathsf{Real}^{\uparrow}$ *row, read through the displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *seal discipline.*
2. *U is the upper endpoint* $\mathsf{Real}^{\uparrow}$ *row, read through the same finite real-name seal discipline.*
3. *E is the enclosure and order row, binding the lower endpoint, upper endpoint, rational interval enclosure, and endpoint-order evidence without replacing the endpoints by host representatives.*
4. *D is the dyadic tolerance row supplied by* $\mathsf{DyadicRatCore}^{\uparrow}$*; it records positive precision requests, outward rounding budgets, and finite endpoint comparison tolerances.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the two endpoint streams and the interval enclosure reads visible at the requested tolerance.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the endpoint windows and dyadic tolerance budget into regular rational observations.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for endpoint and enclosure consumers; every Real-facing output must pass through this row after D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for endpoints, enclosure and order data, dyadic tolerance, windows, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from interval membership, enclosure, refinement, or completion-facing requests through $L, U, E, D, W, R, S, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{RealInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RealIntervalEnclosure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealInterval}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one displayed real interval endpoint-and-enclosure history. It has no coordinate for host interval equality, selected quotient representatives, real-order trichotomy, countable choice, compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalTasteGate single carrier alignment`

Theorem 4111.2 (RealInterval NameCert obligations)**.** *For every accepted* $\mathsf{RealInterval}^{\uparrow}$ *carrier* $I = (L, U, E, D, W, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the lower endpoint, upper endpoint, enclosure and order row, dyadic tolerance row, stream windows, regular rational readback, Real seal, transport, replay, provenance, and local name;*
2. *endpoint order, requiring E to bind L and U before any interval read can be treated as an enclosure;*
3. *enclosure stability, requiring every containment, refinement, and endpoint-bound read to pass through E together with the displayed tolerance and window rows;*
4. *dyadic tolerance handoff, requiring D to precede the* $\mathsf{StreamName}^{\uparrow}$ *windows W and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R;*
5. *Real seal non-escape, requiring every Real-facing endpoint or enclosure output to reach S only after L, U, E, D, W, R have been displayed;*
6. *ledger refusal, excluding host interval equality, selected endpoint representatives, real-order trichotomy, countable choice, compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No real interval obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4111.1. The projection exposes exactly the two endpoint rows, enclosure and order row, dyadic tolerance row, stream windows, regular rational readback, Real seal, and structural rows.

Endpoint order and enclosure stability are read from E. That row is the only coordinate joining L and U into an interval boundary, so containment, refinement, and endpoint-bound requests cannot bypass it.

The dyadic tolerance handoff is the route $D \mapsto W \mapsto R$. A positive precision request first enters the dyadic budget, then selects finite stream windows, and only then produces regular rational readback.

The Real seal row S is downstream of that route. The remaining rows H, C, P, N transport, replay, package, and name the same endpoint-and-enclosure history, while the excluded host interval, choice, compactness, and completeness objects have no coordinate in the carrier. □

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalCarrier namecert obligations`

Theorem 4111.3 (RealInterval seal enclosure route)**.** *Every endpoint, enclosure, refinement, or completion-facing read of an accepted* $\mathsf{RealInterval}^{\uparrow}$ *carrier reaches the* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed route*

$$L, U, E \longmapsto D, W, R \longmapsto S, H, C, P, N.$$

Consequently every interval consumer receives endpoint order, finite enclosure data, dyadic tolerance, stream windows, and regular rational readback before any Real-facing seal is visible. The route exports no host interval equality, selected endpoint representative, real-order trichotomy, countable-choice schedule, compactness theorem, hidden complete space, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with an accepted carrier $I = (L, U, E, D, W, R, S, H, C, P, N)$. The endpoint rows L and U are the only Real endpoints in the packet, and E is the only row that binds them as an ordered enclosure.

Read the dyadic tolerance handoff next. The row D supplies the finite precision and outward-rounding budget, W exposes the endpoint stream windows visible at that budget, and R turns those windows into regular rational readback.

Only after this handoff may the Real-facing seal S be consumed. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve the same route. Since none of the excluded host interval or completeness objects is a carrier coordinate, every interval read reaches the seal only through the displayed rows. □

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalSealEnclosureRoute`

Theorem 4111.4 (RealInterval endpoint-order obligation)**.** *Let* $I = (L, U, E, D, W, R, S, H, C, P, N)$ *be an accepted* $\mathsf{RealInterval}^{\uparrow}$ *carrier. Any consumer that treats* L *and* U *as an interval must first read the endpoint-order row* E*; the two endpoint rows alone do not authorize an interval enclosure.*

Proof. Project the carrier of Definition 4111.1. The rows L and U name the two endpoint Real rows, while E is the only displayed row that binds them as an ordered enclosure.

Now apply the local obligations of Definition 4111.2. The endpoint-order obligation explicitly requires E to bind L and U before any interval read can be treated as an enclosure.

The seal route of Definition 4111.3 preserves the same order, since every endpoint or enclosure read begins with L, U, E before entering the dyadic handoff. Thus an interval consumer cannot bypass E by reading the endpoint rows alone. □

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalEndpointOrderObligation`

Theorem 4111.5 (RealInterval classifier transport)**.** *Let* $I = (L, U, E, D, W, R, S, H, C, P, N)$ *and* $I' = (L', U', E', D', W', R', S', H', C', P', N')$ *be accepted* $\mathsf{RealInterval}^{\uparrow}$ *carriers. If the accepted interval classifier identifies the endpoint and enclosure rows of* I *with those of* I'*, then carrier admission transports from* I *to* I' *only through the displayed endpoint, locatedness, dyadic-window,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. In particular, classifier equality cannot replace the rows supplied by chapter 291, chapter 394, chapter 301, chapter 126, or chapter 38.*

Proof. Project both carriers through Definition 4111.1. The endpoint rows L, U, L', U' and enclosure rows E, E' are the only rows on which the interval classifier can act.

Use the endpoint-order obligation Definition 4111.4. It forces every interval read to keep the endpoint order row visible, so classifier equality must transport the ordered enclosure rather than only the two endpoints.

The seal route of Definition 4111.3 then carries the transported enclosure through the dyadic tolerance, stream-window, regular-rational, and Real-seal rows. The structural rows H', C', P', N' name the transported packet, so carrier admission moves only along the displayed BEDC rows. □

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalClassifierTransport`

Theorem 4111.6 (RealInterval endpoint refinement stability)**.** *For every accepted* $\mathsf{RealInterval}^{\uparrow}$ *carrier* $I = (L, U, E, D, W, R, S, H, C, P, N)$*, any dyadic refinement of the endpoint enclosure that preserves the displayed endpoint order and locatedness rows preserves the* $\mathsf{RealInterval}^{\uparrow}$ *NameCert surface before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is read. The refinement may change the finite dyadic tolerance and window rows* D, W, R*, but it must keep the endpoint, locatedness, transport, replay, provenance, and local naming rows visible before* S *is consumed.*

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalEndpointRefinementStability`

Proof. Read the carrier rows of Definition 4111.1. A dyadic endpoint refinement changes only the tolerance, window, and regular-rational observations recorded in D, W, R.

Apply Definition 4111.2. Its endpoint order and enclosure stability clauses keep L, U, E visible, while its dyadic tolerance handoff clause keeps every refinement inside the $D \mapsto W \mapsto R$ route.

Finally use the seal enclosure route Definition 4111.3. Since S is terminal, the refined endpoint surface must already have passed through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the displayed structural rows before any $\mathsf{Real}^{\uparrow}$ seal is available. □

Theorem 4111.7 (RealInterval dyadic-window handoff)**.** *For every accepted* $\mathsf{RealInterval}^{\uparrow}$ *carrier* $I = (L, U, E, D, W, R, S, H, C, P, N)$*, the displayed route*

$$D \longmapsto W \longmapsto R$$

is the only tolerance-to-readback handoff supplied by the packet.

Proof. Project Definition 4111.1. The tolerance coordinate is D, the finite endpoint-window coordinate is W, and the regular rational readback coordinate is R.

Use Definition 4111.2. Its dyadic tolerance handoff row requires D to precede the $\mathsf{StreamName}^{\uparrow}$ windows W and the $\mathsf{RegSeqRat}^{\uparrow}$ readback R.

Finally apply Definition 4111.3. The route displays no second tolerance-to-readback path; every enclosure read moves from D to W to R before any seal or structural row is public. □

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalDyadicWindowHandoff`

Theorem 4111.8 (RealInterval Real-seal nonescape)**.** *Let* $I = (L, U, E, D, W, R, S, H, C, P, N)$ *be an accepted* $\mathsf{RealInterval}^{\uparrow}$ *carrier. Every Real-facing enclosure read reaches the seal row* S *only after the endpoint rows, endpoint-order row, dyadic tolerance row, stream-window row, and regular readback row* L, U, E, D, W, R *have all been displayed.*

Proof. Start from the carrier of Definition 4111.1. The seal row S is not an independent endpoint; it is the terminal Real-facing row for endpoint and enclosure consumers.

The obligations of Definition 4111.2 make Real seal non-escape explicit. They require every Real-facing endpoint or enclosure output to reach S only after L, U, E, D, W, R have been displayed.

The route theorem Definition 4111.3 gives the same ordering as a displayed path. Therefore a Real-facing enclosure read cannot reach S while omitting any of the endpoint, order, tolerance, window, or readback rows. □

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalRealSealNonescape`

Theorem 4111.9 (RealInterval obligation-closure route)**.** *Every accepted* $\mathsf{RealInterval}^{\uparrow}$ *carrier* $I = (L, U, E, D, W, R, S, H, C, P, N)$ *routes endpoint admission, endpoint order, enclosure stability, dyadic-window handoff, Real-seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *through the displayed rows* $L, U, E, D, W, R, S, H, C, P, N$*.*

The route supplies no host interval equality, selected endpoint representative, trichotomy, countable choice, compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalCarrier obligation closure route`

Proof. First read the local obligation surface from Definition 4111.2. It exposes carrier admission, endpoint order, enclosure stability, dyadic tolerance handoff, Real seal non-escape, transport, replay, provenance, and local naming as finite rows of the accepted carrier.

Next use the route theorems that keep these rows in order. The seal enclosure route of Definition 4111.3, the endpoint-order obligation of Definition 4111.4, and the dyadic-window handoff of Definition 4111.7 force every interval read through L, U, E, D, W, R, S before the structural rows are consumed.

Finally apply Real-seal nonescape from Definition 4111.8. Since every Real-facing enclosure read reaches S only after L, U, E, D, W, R have been displayed, and since H, C, P, N only transport, replay, package, and name that same route, the carrier closes exactly the obligation route stated above while leaving the refused global principles outside the packet. □

Theorem 4111.10 (RealInterval public NameCert export)**.** *The public* $\mathsf{RealInterval}^{\uparrow}$ *export is exactly the endpoint-pair carrier together with endpoint order, classifier transport, endpoint-refinement stability, dyadic-window handoff, and Real-seal nonescape rows. A public interval consumer may cite the ordered surface*

$$L, U, E, D, W, R, S, H, C, P, N$$

only as the endpoint-and-enclosure packet of Definition 4111.1; it may not add host interval equality, selected endpoint representatives, trichotomy, countable choice, compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalPublicNameCertExport`

Proof. Start from the carrier and obligation route. Theorems 4111.1 and 4111.9 identify the complete endpoint-and-enclosure packet as the rows $L, U, E, D, W, R, S, H, C, P, N$.

The public surface is determined by the interval-facing route theorems. Endpoint order is supplied by Definition 4111.4, classifier transport by Definition 4111.5, endpoint-refinement stability by Definition 4111.6, dyadic-window handoff by Definition 4111.7, and Real-seal nonescape by Definition 4111.8.

These theorems cite the same displayed rows and no additional host object. Therefore the reusable public export is precisely the endpoint-pair carrier with its order, transport, refinement, dyadic-window, and seal rows, while the refused global principles remain outside the packet. □

Theorem 4111.11 (RealInterval finite-net consumer)**.** *Every finite-net or density-net consumer of an accepted* $\mathsf{RealInterval}^{\uparrow}$ *packet must read the endpoint order row* E*, dyadic tolerance row* D*,* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row* S *before passing interval data into chapter 5966 or chapter 6003. The consumer route is the displayed packet*

$$L, U, E, D, W, R, S, H, C, P, N,$$

not a host interval equality, selected endpoint representative, compactness theorem, countable-choice net, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalFiniteNetConsumer`

Proof. Start with endpoint order. By Definition 4111.4, a consumer cannot treat L and U as an interval until it has read the order and enclosure row E.

Next apply the dyadic-window handoff of Definition 4111.7. It forces the requested tolerance through D, then the finite StreamName windows W, and only then the regular rational readback row R used by dyadic interval cells or finite density rows.

Now use Real-seal nonescape and the public NameCert export, Definition 4111.8 and Definition 4111.10. The seal row S is available only after L, U, E, D, W, R have been displayed, and the public export keeps H, C, P, N attached to that same endpoint-and-enclosure packet.

Finally route the displayed interval data to the dyadic interval-net and finite density-net sibling chapters. Since Definition 4111.1 contains no coordinate for host interval equality, selected endpoint representatives, compactness, countable choice, or ambient completeness, those siblings receive only the finite displayed route stated above. □

Theorem 4111.12 (RealInterval bridged NameCert route)**.** *Every bridge-facing* $\mathsf{RealInterval}^{\uparrow}$ *consumer routes through the displayed endpoint-and-enclosure packet*

$$L, U, E, D, W, R, S, H, C, P, N.$$

The route first reads the $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger* D*, then the* $\mathsf{LocatedInterval}^{\uparrow}$ *and* $\mathsf{RealIntervalEnclosure}^{\uparrow}$ *rows carried by* E*, then the* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and finally the* $\mathsf{Real}^{\uparrow}$ *seal* S *with transport, replay, provenance, and local naming still visible.*

Proof. Project the accepted carrier of Definition 4111.1. The endpoint rows, enclosure row, tolerance ledger, windows, readback, seal, and structural rows are all coordinates of one packet.

Use the NameCert obligations and public export, Definition 4111.2 and Definition 4111.10. They keep endpoint order, enclosure stability, dyadic-window handoff, Real-seal nonescape, transport, replay, provenance, and local naming attached to the displayed rows.

Finally apply the finite-net consumer route of Definition 4111.11. It shows that downstream interval data reaches finite cell and density consumers only through the dyadic, located-enclosure, StreamName, RegSeqRat, and Real-seal route. Hence the bridge-facing NameCert route is the displayed packet above. □

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalBridgedNameCertRoute`

Theorem 4111.13 (RealInterval finite endpoint-envelope route)**.** *Every* $\mathsf{RealInterval}^{\uparrow}$ *endpoint consumer that exports interval membership must first factor through the displayed finite endpoint envelope*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealIntervalEnclosure}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The dyadic endpoint arithmetic is read from D*, the finite endpoint windows from* W*, the regular readback from* R*, the enclosure row from* E*, and the terminal value seal from* S *before membership is public. The envelope exports no quotient stream equality, selected endpoints, host interval equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, compactness, or countable-choice schedule.*

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalFiniteEndpointEnvelopeRoute`

Proof. Start with the endpoint-order obligation of Definition 4111.4. It keeps the enclosure and order row E visible whenever a consumer treats L and U as interval endpoints.

Next apply the dyadic-window handoff Definition 4111.7. The endpoint arithmetic enters through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ row D, then exposes only finite $\mathsf{StreamName}^{\uparrow}$ windows W, and only then produces the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Use the bridged NameCert route Definition 4111.12. It inserts the $\mathsf{LocatedInterval}^{\uparrow}$ and $\mathsf{RealIntervalEnclosure}^{\uparrow}$ rows carried by E between the endpoint ledger and the terminal $\mathsf{Real}^{\uparrow}$ seal S, while H, C, P, N transport, replay, package, and name the same displayed route.

Finally read Real-seal nonescape from Definition 4111.8. Since S is available only after L, U, E, D, W, R have been displayed, interval membership cannot be exported from quotient stream equality, selected endpoints, host interval equality, ambient completeness, trichotomy, compactness, or countable choice. □

Theorem 4111.14 (RealInterval endpoint enclosure transport)**.** *For accepted* $\mathsf{RealInterval}^{\uparrow}$ *carriers* $I = (L, U, E, D, W, R, S, H, C, P, N)$ *and* $I' = (L', U', E', D', W', R', S', H', C', P', N')$*, componentwise* hsame *transport preserves both endpoint enclosure rows before interval membership is public. In particular, a consumer that transports* L *to* L' *and* U *to* U' *must also transport the enclosure-and-order row* E *to* E' *and the dyadic-window-readback route* D, W, R *to* D', W', R' *before it may read the terminal seal.*

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalEndpointEnclosureTransport`

Proof. Start with classifier transport, Definition 4111.5. It allows carrier admission to move only through the displayed endpoint, enclosure, dyadic-window, hsame, Cont, Pkg, and NameCert rows.

Endpoint order then fixes the enclosure boundary. By Definition 4111.4, the two endpoint rows alone do not authorize interval membership; the row E must remain visible as the ordered enclosure.

Finally use endpoint-refinement stability and the dyadic-window handoff, Definition 4111.6 and Definition 4111.7. These rows keep D, W, R attached to the transported enclosure before S is consumed, so componentwise transport preserves both endpoint enclosure rows before membership becomes public. □

Theorem 4111.15 (RealInterval StreamName Real-seal nonescape)**.** *No* $\mathsf{RealInterval}^{\uparrow}$ *read that passes through* $\mathsf{StreamName}^{\uparrow}$ *windows and a* $\mathsf{Real}^{\uparrow}$ *seal exports open-cover compactness, quotient real equality, choice-selected endpoints, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness. The only public route is*

$$L, U, E, D, W, R, S, H, C, P, N,$$

with W *and* R *displayed before* S *and with the refusal boundary preserved by the local NameCert rows.*

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalStreamRealSealNonescape`

Proof. Read the Real-seal nonescape theorem Definition 4111.8. It places the seal row S strictly after the endpoint, order, tolerance, window, and readback rows L, U, E, D, W, R.

Use the obligation-closure route and public NameCert export, Definition 4111.9 and Definition 4111.10. They state that H, C, P, N only transport, replay, package, and name the same displayed packet.

The finite-net consumer theorem Definition 4111.11 keeps downstream interval reads inside the same route. Since none of the carrier coordinates names open-cover compactness, quotient equality, selected endpoints, trichotomy, or ambient completeness, the StreamName-to-Real-seal read cannot export those objects. □

Theorem 4111.16 (RealInterval bridge scope)**.** *Every bridge-facing* $\mathsf{RealInterval}^{\uparrow}$ *read factors through the finite endpoint-and-enclosure rows*

$$L, U, E, D, W, R, S, H, C, P, N$$

and by the sibling surfaces $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *only as endpoint-enclosure readback. The bridge-scope packet cannot be read as host interval equality, selected endpoint representatives, trichotomy, countable choice, compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the public export of Definition 4111.10. It binds public interval reads to the endpoint, enclosure, tolerance, window, readback, seal, transport, replay, provenance, and local naming rows of the displayed carrier.

Next use the bridged route and endpoint-enclosure transport, Definition 4111.12 and Definition 4111.14. These results keep the bridge-facing read on the located endpoint row, dyadic interval envelope, finite stream windows, regular rational readback, and terminal Real seal before any interval membership is public.

Finally apply the StreamName Real-seal nonescape theorem, Definition 4111.15. The seal row S remains downstream of L, U, E, D, W, R and upstream of no additional host principle, so the bridge scope is exactly the displayed endpoint-enclosure packet. Compactness, selected endpoint representatives, trichotomy, countable choice, and ambient completeness have no row in this factorization. □

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalBridgeScope`

Theorem 4111.17 (RealInterval formal target handoff)**.** *Any future Lean target that advances the formal status of* $\mathsf{RealInterval}^{\uparrow}$ *must expose the endpoint carrier rows* L, U*, the dyadic-window handoff rows* D, W, R*, the endpoint-order obligation* E*, the Real-seal nonescape row* S*, and the bridge-scope rows* H, C, P, N *before it may claim a checked public interval surface. In particular, the target must route through the carrier of Definition 4111.1, the finite-net consumer of Definition 4111.11, the finite endpoint envelope of Definition 4111.14, the StreamName Real-seal nonescape theorem of Definition 4111.15, and the bridge scope of Definition 4111.16.*

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalFormalTargetHandoff`

Proof. Start with the carrier definition. It presents the endpoint rows L, U, the endpoint-order and enclosure row E, the dyadic tolerance row D, the $\mathsf{StreamName}^{\uparrow}$ window row W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, the $\mathsf{Real}^{\uparrow}$ seal row S, and the structural rows H, C, P, N in one accepted packet.

Use the dyadic-window handoff and finite-net consumer theorems. They keep downstream real-completion and net reads on D, W, R before the seal row is consumed, so a formal target cannot replace those rows by an ambient interval object.

Apply endpoint-enclosure transport and StreamName Real-seal nonescape. The endpoint envelope must transport both endpoints together with E, while the seal theorem keeps S from exporting quotient real equality, selected endpoints, trichotomy, compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Finally read the bridge-scope theorem. It leaves only H, C, P, N as transport, replay, provenance, and local naming for the same packet, so any checked Lean target must display exactly these handoff rows before the formal status can advance. □

Theorem 4111.18 (RealInterval mature consumer route)**.** *Every mature* $\mathsf{RealInterval}^{\uparrow}$ *consumer read factors through the endpoint-and-enclosure route already displayed by* $\mathsf{DyadicIntervalNet}^{\uparrow}$*,* FiniteCauchyDensityN

$\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The route exposes lower endpoint L, upper endpoint U, enclosure and order row E, dyadic tolerance row D, finite window row W, regular-rational readback row R, terminal real seal S, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N before any downstream interval read is accepted. It does not export open-cover compactness, quotient real equality, selected endpoint representatives, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealIntervalUp.RealIntervalMatureConsumerRoute`

Proof. Start with the endpoint carrier and finite-net consumer theorems. The carrier displays $L, U, E, D, W, R, S, H, C, P, N$, while Definition 4111.11 routes net-facing reads through the dyadic and finite Cauchy density surfaces before any public interval endpoint is consumed.

Next apply the endpoint-enclosure and StreamName Real-seal results. By Definition 4111.14, endpoint transport keeps E attached to L and U; by Definition 4111.15, the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows feed the terminal $\mathsf{Real}^{\uparrow}$ seal without adding quotient equality or completeness.

Finally use the bridge-scope and formal-target handoff theorems. They identify $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as readback surfaces for the same displayed packet. The density and interval-net consumers therefore see only the endpoint-and-enclosure route, so the mature route closes without importing compactness, selected endpoints, trichotomy, countable choice, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealInterval}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealInterval}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 4111.1, Definition 4111.2, Definition 4111.3, Definition 4111.4, Definition 4111.7, Definition 4111.8, Definition 4111.9, Definition 4111.10, Definition 4111.16, and Definition 4111.18 bind endpoint admission, endpoint order, enclosure stability, dyadic-window handoff, finite net readback, Real-seal nonescape, hsame transport, Cont replay, Pkg provenance, and local NameCert to the displayed mature $\mathsf{RealInterval}^{\uparrow}$ rows over $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{RealIntervalEnclosure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host interval equality, selected endpoint representatives, trichotomy, countable choice, compactness, ambient RealUp completeness, Lean verification, or a public standard bridge.

Upgrade path: Verification closure requires checked carrier admission, endpoint enclosure, dyadic-window handoff, finite-net consumer routing, Real-seal nonescape, transport, replay, provenance, local naming, and bridge interpretation for BEDC.Derived.RealIntervalUp.

Constructive story: A $\mathsf{RealInterval}^{\uparrow}$ packet is generated from lower and upper RealUp endpoint rows, an enclosure and order row, a DyadicRatCoreUp tolerance row, StreamNameUp finite windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4112

A Concrete Naming Certificate for $\mathsf{SequentialSpace}^{\uparrow}$

Following Franklin and Engelking on sequential spaces, the $\mathsf{SequentialSpace}^{\uparrow}$ packet records the finite convergence interface by which sequence-indexed observations may be consumed as topological data without importing open-cover compactness, quotient point equality, or a selected subsequence principle. It sits beside the limit carrier of chapter 3845, the Cauchy source interface of chapter 1847, the finite windows of chapter 126, the indexed-open topology surface of chapter 88, and the terminal real seal of chapter 38. Later completion and compactness consumers may read sequential convergence only through this displayed packet.

Definition 4112.1 (SequentialSpace carrier)**.** *A* $\mathsf{SequentialSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, W, L, T, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the sequence-index row, naming the finite initial segment, tail request, and comparison scale read by the consumer.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing only the finite observations of the sequence at the requested indices.*
3. *L is the* $\mathsf{LimitSpace}^{\uparrow}$ *convergence row, recording the limit-facing test supplied by chapter 3845.*
4. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-test row, recording the indexed open neighbourhood test through which sequential convergence is observed.*
5. *Q is the* $\mathsf{CauchySpace}^{\uparrow}$ *comparison row when the sequence is also read by a completion or Cauchy consumer.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint row when the displayed observations are regular real-name reads.*
7. *H records componentwise* hsame *transport for the sequence index, StreamName window, limit row, topology row, Cauchy comparison row, Real endpoint row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a sequential-convergence request through $I, W, L, T, Q, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SequentialSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{LimitSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{CauchySpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{SequentialSpace}^\uparrow}$ *row.*
The carrier has no coordinate for open-cover compactness, quotient point equality, selected subsequences, countable-choice selectors, host topological closure, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentialSpaceUp.SequentialSpaceTasteGate single carrier alignment`

Theorem 4112.2 (SequentialSpace NameCert obligations)**.** *For every accepted* $\mathsf{SequentialSpace}^\uparrow$ *carrier*

$$S = (I, W, L, T, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialSpace}^\uparrow}$ *surface consists exactly of sequence-index admission through I, finite observation through W, limit-space convergence through L, topology open-test exposure through T, Cauchy comparison through Q when present, Real endpoint exposure through R when present, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.SequentialSpaceUp.SequentialSpaceCarrier namecert obligations`

Proof. Project the carrier of Definition 4112.1. The sequence-facing side is exhausted by I and W, so a consumer can inspect only displayed finite StreamName windows at displayed indices.

The convergence-facing side is exhausted by L, T, Q, R. The limit row supplies the sequential convergence request, the topology row supplies the open-test interface, and the Cauchy and Real rows are available only when the same packet displays those comparison surfaces.

The rows H, C, P, N transport, replay, source, and name exactly this data. Since the carrier has no coordinate for open-cover compactness, quotient point equality, selected subsequences, countable choice, host closure, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 4112.3 (SequentialSpace completion-facing route)**.** *Every completion-facing consumer of an accepted* $\mathsf{SequentialSpace}^\uparrow$ *packet reads sequential convergence through the finite route*

$$\mathsf{StreamName}^\uparrow,\ \mathsf{LimitSpace}^\uparrow,\ \mathsf{Topology}^\uparrow,\ \mathsf{CauchySpace}^\uparrow,\ \mathsf{Real}^\uparrow.$$

The route exposes finite sequence windows, a displayed limit test, an indexed-open neighbourhood test, a Cauchy comparison surface when relevant, and a terminal Real endpoint row; it exports no open-cover compactness, selected subsequence, quotient point equality, countable-choice selector, or ambient Real completeness principle.

Proof. Start with the NameCert obligations of Definition 4112.2. A completion-facing read must first inspect the sequence index and finite StreamName window rows.

The limit request then passes through the $\mathsf{LimitSpace}^\uparrow$ row and the $\mathsf{Topology}^\uparrow$ open-test row. If the consumer is a completion or Cauchy consumer, the same route displays the $\mathsf{CauchySpace}^\uparrow$ comparison row before any $\mathsf{Real}^\uparrow$ endpoint row is read.

Transport, replay, provenance, and naming preserve this order. The excluded principles are not carrier coordinates, so no consumer can extract them from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialSpace}^\uparrow}$.
Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SequentialSpace}^\uparrow}$, seed)
Scope closed: Definition 4112.1, Definition 4112.2, and Definition 4112.3 seed the finite sequential-convergence interface over StreamName, LimitSpace, Topology, CauchySpace, and Real rows.
Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SequentialSpace}^\uparrow}$, unformalized)
Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient point equality, selected subsequences, countable-choice selectors, host topological closure, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sequence-index exactness, StreamName window coverage, LimitSpace convergence routing, Topology open-test exposure, Cauchy comparison compatibility, Real endpoint nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SequentialSpaceUp.

Constructive story: A SequentialSpace$^{\uparrow}$ packet is generated from sequence-index rows, StreamName windows, LimitSpace convergence rows, Topology open-test rows, CauchySpace comparison rows where relevant, Real endpoint rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4113

A Concrete Naming Certificate for MetaCICConversionEndpointSeal$^{\uparrow}$

The MetaCICConversionEndpointSeal$^{\uparrow}$ packet realizes the endpoint question isolated in chapter 9386. It sits after the bounded normal-conversion bridge of chapter 3439, the finite fuel trace of chapter 3889, and the typed normal-form decider of chapter 3714. The packet names the exact surface where bounded normal computation may be sealed as finished normal-form data for the closed typed terms under discussion, while leaving unrestricted closed beta-conversion outside the carrier.

Falsifiable prediction: Every accepted MetaCICConversionEndpointSeal$^{\uparrow}$ read exposes bounded-normal-conversion bridge, MetaCIC fuel trace, typed normal-form decider, finished endpoint, closed typed term, obstruction, transport, replay, provenance, and local NameCert rows before any conversion endpoint handoff is consumed.

Independence witness: bounded-normal-conversion-bridge, metacic-fuel-trace, typed-normal-form-decider, metacic-decidable-conversion-frontier: the bridge records bounded comparison with endpoint evidence, the fuel trace records bounded computation, the typed decider records typed comparison, and the frontier records the broader decidability boundary. None is bijective to the endpoint seal because this packet binds those rows into one finished-normal endpoint handoff.

Definition 4113.1 (MetaCIC conversion endpoint seal carrier)**.** *A* MetaCICConversionEndpointSeal$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (B, F, D, T, O, H, C, P, N)$$

with the following displayed rows:

1. *B is the* BoundedNormalConversionBridge$^{\uparrow}$ *row, recording bounded normal comparison under displayed endpoint evidence.*
2. *F is the* MetaCICFuelTrace$^{\uparrow}$ *row, recording finite fuel, input, bounded output, finished-normalization evidence or its explicit absence, and bounded readback.*
3. *D is the* TypedNormalFormDecider$^{\uparrow}$ *row, recording the typed checker surface for the compared closed terms.*
4. *T is the closed typed-term row, recording the context, terms, inferred type status, and closedness window admitted by the decider surface.*

5. *O is the obstruction row, excluding unrestricted closed beta-conversion, arbitrary-fuel completeness, host evaluator equality, quotient syntax equality, subject reduction, confluence, and kernel consistency.*
6. *H records componentwise* hsame *transport for B, F, D, T, O and the local naming row.*
7. *C records displayed* Cont *replay from a conversion endpoint request through B, F, D, T, O, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MetaCICConversionEndpointSeal}^{\uparrow}$, $\mathsf{BoundedNormalConversionBridge}^{\uparrow}$, $\mathsf{MetaCICFuelTrace}^{\uparrow}$, $\mathsf{TypedNormalFormDecider}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICConversionEndpointSeal}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, F, D, T, O, H, C, P, N$. It has no coordinate for unrestricted closed beta-conversion, arbitrary-fuel completeness, host evaluator equality, quotient syntax equality, subject reduction, confluence, or kernel consistency.

Lean4 ✓ `BEDC.Derived.MetaCICConversionEndpointSealUp.MetaCICConversionEndpointSealTasteGate`
`single carrier alignment`

Theorem 4113.2 (MetaCIC conversion endpoint seal obligations)**.** *For every accepted* MetaCICConversionEndpoint *carrier*

$$E = (B, F, D, T, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICConversionEndpointSeal}^{\uparrow}}$ *surface consists exactly of bounded bridge exposure through B, finite fuel-trace exposure through F, typed normal-form decider exposure through D, closed typed-term endpoint exposure through T, obstruction retention through O, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4113.1. Rows B, F, D are the three sibling surfaces: bounded comparison, finite fuel trace, and typed normal-form decision.

The endpoint row T is read only after those sibling rows are displayed. It records the closed typed-term boundary under which bounded normal computation can be treated as a finished normal-form endpoint.

The obstruction row O remains part of the same packet. It blocks rereading the endpoint as unrestricted closed beta-conversion, arbitrary-fuel completeness, host evaluator equality, quotient syntax equality, subject reduction, confluence, or kernel consistency.

Finally H, C, P, N transport, replay, source, and name exactly the same finite route. No carrier coordinate stores a stronger global metatheorem. □

Theorem 4113.3 (MetaCIC conversion endpoint seal handoff)**.** *Every endpoint-facing consumer of an accepted* $\mathsf{MetaCICConversionEndpointSeal}^{\uparrow}$ *carrier factors through*

$$\mathsf{BoundedNormalConversionBridge}^{\uparrow},\ \mathsf{MetaCICFuelTrace}^{\uparrow},\ \mathsf{TypedNormalFormDecider}^{\uparrow}$$

before it may read the closed typed-term endpoint row. The handoff exports a finite endpoint seal for bounded normal computation, not an unrestricted conversion decider.

Proof. Use Definition 4113.2. The bounded bridge row supplies the comparison boundary, the fuel-trace row supplies the finite computation trace, and the typed decider row supplies the typing-facing comparison surface.

Only after these rows are present can the endpoint row T be consumed. This makes the endpoint a replayable finite seal rather than a theorem erasing the fuel and typed-side hypotheses.

The obstruction, transport, replay, provenance, and naming rows preserve the same boundary. Thus the packet gives the decidability frontier a concrete endpoint landing while refusing the stronger global conversion claims. □

The Lean TasteGate follow-up for this chapter must provide explicit Nontrivial MetaCICConversionEndpointSeal$^{\uparrow}$ and FieldFaithful MetaCICConversionEndpointSeal$^{\uparrow}$ instances preserving $B, F, D, T, O, H, C, P, N$ as separate displayed rows.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICConversionEndpointSeal}^{\uparrow}}$, seed)

Scope closed: Definition 4113.1, Definition 4113.2, and Definition 4113.3 seed the finite endpoint seal connecting bounded normal computation to finished normal-form data for closed typed terms.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICConversionEndpointSeal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unrestricted closed beta-conversion, arbitrary-fuel completeness, host evaluator equality, quotient syntax equality, subject reduction, confluence, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded bridge exposure, fuel-trace exactness, typed normal-form decider compatibility, closed endpoint exposure, obstruction nonescape, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICConversionEndpointSealUp.

Constructive story: A MetaCICConversionEndpointSeal$^{\uparrow}$ packet is generated from BoundedNormalConversionBridge, MetaCICFuelTrace, TypedNormalFormDecider, closed typed-term endpoint, obstruction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4114

A Concrete Naming Certificate for $\mathsf{BishopLocatedCompletionComparison}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopLocatedCompletionComparison}^{\uparrow}$ packet records the finite comparison route between located metric completion, Bishop metric completion, constructive metric completion, and the general metric-completion comparison surface. It sits after chapter 2114, chapter 4023, chapter 1556, chapter 3553, chapter 301, chapter 126, chapter 291, and chapter 38. The chapter names one located completion route through displayed finite rows; it does not assert quotient completion equality, selected representatives, countable choice, host equality of completion classes, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4114.1 (Bishop located-completion comparison carrier)**.** *A* $\mathsf{BishopLocatedCompletionComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, B, Q, M, R, S, D, A, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedMetricCompletion}^{\uparrow}$ *route, carrying the located source and the displayed completion-facing windows.*
2. *B is the* $\mathsf{BishopMetricCompletion}^{\uparrow}$ *route, carrying the Bishop regular Cauchy presentation of the same located source.*
3. *Q is the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *route, carrying the constructive metric completion packet over located metrics, regular Cauchy names, dyadic tolerances, and separated comparison.*
4. *M is the* $\mathsf{MetricCompletionComparison}^{\uparrow}$ *row comparing the visible completion presentations through paired dense embeddings, a common dense source, and finite round-trip reads.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row shared by the Bishop and constructive routes.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected before any regular rational readback or comparison map is named.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the located, Bishop, constructive, and metric-comparison windows at finite precision.*
8. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, B, Q, M, R, S, D have been displayed.*
9. *H records componentwise* hsame *transport for the four completion routes, readback, window, tolerance, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a located completion request through the Bishop and constructive presentations, the metric-comparison row, the shared readback rows, and then the Real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCompletionComparison}^{\uparrow}$*, the eight sibling chapters named above,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionComparison}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completions, selected representatives, countable choice, host equality of completion classes, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionComparisonUp.BishopLocatedCompletionComparisonTasteGate`
`single carrier alignment`

Theorem 4114.2 (BishopLocatedCompletionComparison NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedCompletionComparison}^{\uparrow}$ *carrier* $K = (L, B, Q, M, R, S, D, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionComparison}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the located completion route, Bishop metric completion route, constructive metric completion route, metric-completion comparison row, regular rational readback, stream windows, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming row;*

2. *located route comparison, requiring L, B, Q, M to share the same displayed located source before any completion-facing comparison is exported;*

3. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *readback compatibility, requiring S to be read before R and requiring both rows to be replayed through C before the comparison row M reaches the seal;*

4. *Real seal handoff, requiring A to remain downstream of L, B, Q, M, R, S, D;*

5. *ledger refusal for quotient completions, selected representatives, countable choice, host equality of completion classes, and ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

No obligation is stored outside these finite rows.

Proof. Project the carrier of Definition 4114.1. The projection exposes exactly the located, Bishop, constructive, and metric-comparison routes, together with the shared regular readback, stream-window, dyadic-tolerance, Real-seal, transport, replay, provenance, and naming rows.

Use the located route as the common source. The rows L, B, Q, M can be compared only after the located metric completion route has been displayed, so the Bishop and constructive presentations are read as finite routes over the same located completion request.

Next read the shared observation rows. The stream row S supplies the inspected finite windows, R reads them as regular rational data, and D records the tolerance ledger used by the comparison row. Replay by C preserves this order before the seal row A can be consumed.

Finally attach H, P, N. Componentwise transport, provenance, and local naming preserve the same finite route and add no coordinate for quotient completions, selected representatives, countable choice, host equality, or ambient Real completeness. Hence the listed rows exhaust the NameCert obligations. □

Falsifiable prediction: A $\mathsf{BishopLocatedCompletionComparison}^{\uparrow}$ consumer that reaches a comparison map or $\mathsf{Real}^{\uparrow}$ seal while omitting the located completion row, Bishop completion row,

constructive completion row, metric-comparison row, RegSeqRat readback, StreamName windows, DyadicRatCore tolerance ledger, componentwise hsame transport, Cont replay, Pkg provenance, or local NameCert row refutes the packet.

Independence witness: located-metric-completion, bishop-metric-completion, constructive-metric-completion, metric-completion-comparison, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the whole comparison packet because each contributes only a completion presentation, comparison surface, readback row, window row, tolerance ledger, or seal, while this chapter binds them into one located completion route.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedCompletionComparison}^{\uparrow}$ packet is generated from LocatedMetricCompletion, BishopMetricCompletion, ConstructiveMetricCompletion, MetricCompletionComparison, RegSeqRat, StreamName, DyadicRatCore, Real, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4114.1 and Definition 4114.2 seed the finite located completion comparison route over Bishop, constructive, metric-comparison, readback, tolerance, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, countable choice, host equality of completion classes, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located route comparison, RegSeqRat and StreamName readback compatibility, Real seal handoff, transport replay, provenance non-escape, and ledger refusals for BEDC.Derived.BishopLocatedCompletionComparisonUp.

Chapter 4115

A Concrete Naming Certificate for $\mathsf{RiemannSumGauge}^{\uparrow}$

Following Bishop and Bridges on Riemann integration, the $\mathsf{RiemannSumGauge}^{\uparrow}$ packet records the finite tagged-gauge data visible before an integration consumer reads a Riemann-sum or Darboux-sum handoff. It sits after the real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the finite window surface of chapter 126, the upper Darboux-sum boundary of chapter 4083, and the closed bounded interval Darboux-partition surface of chapter 3429. The packet names a finite gauge-and-tag carrier for later $\mathsf{Calculus}^{\uparrow}$ and $\mathsf{Integral}^{\uparrow}$ consumers; it does not import host real functions, selected tags, quotient equality of partitions, choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4115.1 (Riemann sum gauge carrier)**.** *A* $\mathsf{RiemannSumGauge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, T, Q, M, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the closed bounded* $\mathsf{Real}^{\uparrow}$ *interval row, including endpoint seals and the finite interval enclosure visible to the consumer.*
2. *T is the tagged finite partition row, recording cells, tags, endpoint reads, and the local tag-in-cell classifier.*
3. *Q is the positive rational gauge-radius row, read as displayed rational data rather than as an ambient open cover.*
4. *M is the mesh ledger, binding the tagged partition to the gauge-radius row and recording the visible mesh comparisons.*
5. *D is the Darboux/Riemann sum row, carrying the finite weighted values and the handoff to* **??** *and the displayed Darboux-partition surface.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for endpoint, tag, mesh, and value observations at the requested finite windows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same windows and rational gauge data.*
8. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger and terminal* $\mathsf{Real}^{\uparrow}$ *seal row for every real-facing value or interval read.*

9. *H records componentwise* hsame *transport for interval, tagged partition, gauge, mesh, sum, window, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from gauge requests, tagged-sum reads, Darboux handoffs, or real-facing consumers through $I, T, Q, M, D, W, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{RiemannSumGauge}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalDarbouxPartition}^{\uparrow}$, ***??***, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannSumGauge}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one displayed finite tagged-gauge Riemann-sum history. It has no coordinate for a host function space, selected open cover, quotient equality of partitions, chosen limiting mesh, choice principle, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4115.2 (Riemann sum gauge NameCert obligations)**.** *For every accepted* $\mathsf{RiemannSumGauge}^{\uparrow}$ *carrier $G = (I, T, Q, M, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannSumGauge}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the closed bounded interval, tagged finite partition, positive rational gauge-radius row, mesh ledger, Darboux/Riemann sum row, stream windows, regular rational readback, dyadic tolerance and Real seal row, transport, replay, provenance, and local name;*
2. *classifier transport, requiring tags, cells, endpoint observations, and gauge-radius comparisons to move only by the componentwise* hsame *row H;*
3. *mesh-gauge exactness, requiring M to bind the tagged partition T to the positive rational gauge-radius row Q before any tagged-sum consumer reads the mesh;*
4. *Darboux-sum handoff, requiring the finite sum row D to expose only the displayed* ***??*** *and* $\mathsf{ClosedBoundedIntervalDarbouxPartition}^{\uparrow}$ *routes;*
5. *Real seal nonescape, requiring every Real-facing value, endpoint, or interval read to pass through W, R, E after I, T, Q, M, D have been displayed;*
6. *transport and replay, requiring H and C to preserve the same finite tagged-gauge history;*
7. *provenance and naming, requiring P and N to package and name exactly the displayed rows;*
8. *ledger refusal, excluding host real functions, quotient equality of partitions, selected limiting meshes, choice, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No Riemann-sum gauge obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RiemannSumGaugeUp.RiemannSumGaugeTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 4115.1. The projection exposes exactly the interval, tagged partition, gauge-radius, mesh, finite sum, window, readback, seal, and structural rows.

The mesh-gauge route is $T, Q \mapsto M \mapsto D$. A tag or cell may be consumed by the sum row only after the mesh ledger has related that tagged partition to the displayed positive rational gauge-radius row.

The Darboux handoff is then read from D. Since D only names the finite **??** and ClosedBoundedIntervalDarbouxP routes, it cannot add a host supremum, hidden function equality, or selected limiting mesh.

Finally, W, R, E supply finite window, regular rational readback, dyadic tolerance, and Real seal data, while H, C, P, N transport, replay, package, and name the same history. The excluded host objects have no carrier coordinate, so the listed obligations exhaust the local NameCert surface. □

Theorem 4115.3 (Riemann sum gauge tagged-real-partition source lock)**.** *For every accepted* $\mathsf{RiemannSumGauge}^{\uparrow}$ *carrier* $G = (I, T, Q, M, D, W, R, E, H, C, P, N)$*, the mesh ledger* M *is readable only after the tagged partition row* T *supplied by chapter 4296 has displayed its cells, tags, endpoint reads, and local tag-in-cell classifier. Every Darboux or gauge-integral consumer therefore receives the mesh route*

$$T, Q \longmapsto M \longmapsto D \longmapsto W, R, E, H, C, P, N$$

and cannot replace it with host partitions, selected mesh limits, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4115.1. The tagged partition coordinate T is listed before the mesh ledger M, and M is the first row that binds the tagged cells to the positive rational gauge-radius row Q.

Apply Definition 4115.2. Its mesh-gauge exactness clause requires M to bind T and Q before any tagged-sum consumer reads the mesh.

The tagged partition source itself is the carrier of chapter 4296, where cells, tags, endpoint observations, containment rows, window reads, and mesh exactness are displayed as finite rows. Reading M without that source row is therefore outside the accepted $\mathsf{RiemannSumGauge}^{\uparrow}$ packet.

Finally the Darboux/Riemann sum row D and the structural rows W, R, E, H, C, P, N preserve the same route. None of these rows adds host partitions, selected mesh limits, quotient function equality, or ambient Real completeness, so every downstream consumer remains locked to the tagged-real-partition source. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannSumGauge}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannSumGauge}^{\uparrow}$ packet is generated from a closed bounded RealUp interval row, tagged finite partition row, positive rational gauge-radius row, mesh ledger, Darboux/Riemann sum row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RiemannSumGauge}^{\uparrow}}$, seed)

Scope closed: Definition 4115.1 and Definition 4115.2 seed the finite tagged-gauge Riemann-sum surface over $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalDarbouxPartition}^{\uparrow}$, **??**, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RiemannSumGauge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host real functions, quotient equality of partitions, selected limiting meshes, choice, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, mesh-gauge exactness, Darboux-sum handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RiemannSumGaugeUp.

Chapter 4116

A Concrete Naming Certificate for $\mathsf{RegularCauchyTransform}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyTransform}^{\uparrow}$ packet records the finite transform route between regular Cauchy names without committing to a map-specific analytic hypothesis. It sits over the regular rational readback of chapter 301, the finite observation windows of chapter 126, the dyadic tolerance ledger of chapter 291, the explicit modulus surface of chapter 3768, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a displayed transform certificate; it is not a quotient stream operation, selected representative, host function equality, countable-choice schedule, or ambient completeness principle.

Definition 4116.1 (Regular Cauchy transform carrier)**.** *A* $\mathsf{RegularCauchyTransform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, R, M, D, U, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *finite-window row.*
2. *R is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy readback row attached to those windows.*
3. *M is the transform modulus row, assigning each requested output tolerance to a finite source-window obligation.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the requested output radius, source radius, and slack comparisons used by M.*
5. *U is the output* $\mathsf{StreamName}^{\uparrow}$ *finite-window row produced by the displayed transform route.*
6. *Q is the output* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to U and D.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the output regular readback row has been displayed.*
8. *H records componentwise* hsame *transport for the source windows, source readback, transform modulus, dyadic ledger, output windows, output readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the route*

$$S, R, M, D \longmapsto U, Q \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTransform}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTransform}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, a selected Cauchy representative, host function extensionality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached output seal.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTransformUp.RegularCauchyTransformTasteGate single carrier alignment`

Definition 4116.2 (Regular Cauchy transform classifier)**.** *The* $\mathsf{RegularCauchyTransform}^{\uparrow}$ *classifier compares accepted carriers only through componentwise* hsame *transport of*

$$S, R, M, D, U, Q, E, H, C, P, N.$$

Thus source windows, source regular readback, transform modulus, dyadic tolerance accounting, output windows, output regular readback, terminal Real seal, replay, provenance, and local naming are all visible comparison data. No classifier clause compares hidden host functions, quotient streams, selected limits, or unrecorded completion witnesses.

Theorem 4116.3 (Regular Cauchy transform NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTransform}^{\uparrow}$ *carrier*

$$T = (S, R, M, D, U, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTransform}^{\uparrow}}$ *surface consists exactly of carrier admission, source-window exposure, source regular readback, transform-modulus routing, dyadic tolerance accounting, output-window production, output regular readback, terminal Real-seal handoff, componentwise transport, displayed replay, provenance, and local naming through the displayed rows* $S, R, M, D, U, Q, E, H, C, P, N$.

Proof. Project the carrier of Definition 4116.1. The source side is visible as S, R, the tolerance route is visible as M, D, the output side is visible as U, Q, E, and the structural rows are visible as H, C, P, N.

Read the transform route in displayed order. A consumer first opens finite source windows, attaches them to the regular rational readback, reads the transform modulus and dyadic tolerance ledger, and only then obtains output windows and output regular readback.

Finally attach the terminal and structural rows. The Real seal E is downstream of Q, while H, C, P, N transport, replay, source, and name the same finite route. Because the carrier has no hidden host map, quotient stream equality, selected representative, choice schedule, or ambient completeness row, the listed obligations exhaust the local NameCert surface. □

Theorem 4116.4 (Regular Cauchy transform modulus route)**.** *Every output window admitted by a* $\mathsf{RegularCauchyTransform}^{\uparrow}$ *packet is backed by the transform modulus row M, the dyadic tolerance ledger D, a finite source* $\mathsf{StreamName}^{\uparrow}$ *window S, and source* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R. Hence a Real or Completion consumer cannot read the output regular name through U, Q without first displaying the modulus-controlled source route.*

Proof. Begin with an admitted output window. Carrier projection exposes U as an output $\mathsf{StreamName}^{\uparrow}$ row, but U is downstream of the transform route rather than an independent stream source.

Trace the request through M and D. The modulus row names the source-window obligation for the requested output tolerance, and the dyadic ledger records the radii and slack comparisons needed to serve that obligation.

The source evidence is then S, R. The finite windows in S are attached to regular rational readback by R, so the output route cannot be justified by a selected limit or host convergence witness.

After U is produced, the output readback Q and terminal seal E remain downstream of the same route. The structural rows H, C, P, N preserve this order under transport and replay. □

Theorem 4116.5 (Regular Cauchy transform Real-seal nonescape)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *read accepted by a* $\mathsf{RegularCauchyTransform}^{\uparrow}$ *carrier factors through*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{RegularModulus}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{C}$$

No accepted read bypasses the source regular name, transform modulus, dyadic tolerance ledger, output regular readback, componentwise transport, replay, provenance, or local naming rows.

Proof. Start with the terminal seal row E. In the carrier definition, E is reachable only after the output readback row Q, and Q is attached to the output finite-window row U.

Use the modulus-route theorem. The output window U is produced only after the source windows S, source readback R, transform modulus M, and dyadic ledger D have been displayed.

Finally read the structural rows. The hsame transport, Cont replay, Pkg provenance, and local NameCert preserve the same finite chain; they do not add a quotient stream, selected host representative, ambient completeness theorem, or second seal route. □

Falsifiable prediction: A $\mathsf{RegularCauchyTransform}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal without first displaying source windows, source RegSeqRat readback, a transform modulus row, dyadic tolerance accounting, output windows, output RegSeqRat readback, transport, replay, provenance, and local naming is not reading this packet.

Independence witness: regseqrat, streamname, dyadicratcore, regular-modulus, real: no listed sibling supplies the whole transform packet because each contributes only readback, windowing, tolerance, modulus, or sealing data while this chapter binds the finite source-to-output route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTransform}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTransform}^{\uparrow}$ packet is generated from source StreamName windows, source RegSeqRat readback, a transform modulus row, DyadicRatCore tolerance accounting, output StreamName windows, output RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTransform}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4116.1, Definition 4116.2, Definition 4116.3, Definition 4116.4, and Definition 4116.5 seed the finite transform route between regular Cauchy names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTransform}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host function equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove carrier admission, classifier transport, modulus routing, output-window production, Real-seal handoff, and ledger non-escape for BEDC.Derived.RegularCauchyTransformUp.

Chapter 4117

A Concrete Naming Certificate for $\mathsf{PoincareDiskDynamics}^{\uparrow}$

The $\mathsf{PoincareDiskDynamics}^{\uparrow}$ packet realizes the disk-dynamics fixed-end reading of section 9463.5 as finite BEDC data. It consumes the phase-transport route of chapter 3455, the metric surface of chapter 3474, disk coordinates from chapter 377, finite evolution rows from chapter 195, and boundary-circle consumers from chapter 58. Its distinguishing carrier binds disk-map evolution to a preserved far-end boundary row; it is not a completed hyperbolic plane, physical cosmology, global clock, quotient boundary, or internal object named T.

Definition 4117.1 (Poincare disk dynamics carrier)**.** *A* $\mathsf{PoincareDiskDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (U, \Phi, G, B, F, V, A, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UnitDisk}^{\uparrow}$ *coordinate row for the inspected disk points.*
2. *Φ is the disk-map row, recording the finite boundary-preserving transport applied to those points.*
3. *G is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row used only as displayed four-point or distance-comparison data.*
4. *B is the* $\mathsf{S}^{1\uparrow}$ *boundary-consumer row naming the fixed far-end commitment.*
5. *F is the* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$ *provenance row linking visible phase movement, disk coordinates, reversible transport, fiber provenance, and refusal data.*
6. *V is the* $\mathsf{DynSystem}^{\uparrow}$ *finite-evolution row for replaying the disk-map orbit.*
7. *A is the audit-refusal row excluding an interior fixed point requirement, host hyperbolic geometry, physical light-speed derivation, global observer time, subject-substance, and an internal* T *object.*
8. *H records componentwise* hsame *transport for the disk, map, metric, boundary, phase-provenance, dynamics, refusal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through disk coordinates, disk-map evolution, metric readback, boundary preservation, phase provenance, and refusal.*
10. *P is the* Pkg *provenance over* $\mathsf{PoincareDiskDynamics}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PoincareDiskDynamics}^{\uparrow}}$ *row.*

The carrier compares packets only through these rows. It has no coordinate for a host Poincare disk model, quotient ideal boundary, global physical evolution law, completed metric geometry, or object-level T*.*

Lean4 ✓ `BEDC.Derived.PoincareDiskDynamicsUp.PoincareDiskDynamicsTasteGate single carrier alignment`

Theorem 4117.2 (Poincare disk dynamics NameCert obligations)**.** *For every accepted* $\mathsf{PoincareDiskDynamics}^{\uparrow}$ *carrier*

$$D = (U, \Phi, G, B, F, V, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PoincareDiskDynamics}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission, disk-map exposure, hyperbolic metric readback, fixed far-end boundary preservation, phase-transport provenance, finite dynamic replay, refusal exactness, componentwise transport, displayed continuation, package provenance, and local naming through the rows* $U, \Phi, G, B, F, V, A, H, C, P, N$*.*

Proof. Project the carrier of Definition 4117.1. The visible geometric data are the disk coordinates U, disk-map row Φ, metric-read row G, boundary row B, phase-provenance row F, and finite-evolution row V.

Read the fixed-end condition next. The boundary row B is preserved by the displayed disk-map route, while F records the phase-transport provenance that keeps visible movement distinct from source collapse or an internal T object.

The dynamic replay is finite. The row V supplies only the inspected orbit cells, and C replays those cells together with the disk, map, metric, boundary, and refusal rows.

Finally attach H, P, N. Componentwise transport, provenance, and local naming preserve exactly the displayed rows, so the NameCert surface cannot export host hyperbolic geometry, a quotient boundary, global time, physical constants, or subject-substance. □

Falsifiable prediction: If a disk-dynamics consumer preserves visible disk coordinates but drops either the boundary row, the phase-transport provenance row, or the refusal row, it is not reading a $\mathsf{PoincareDiskDynamics}^{\uparrow}$ packet.

Independence witness: poincare-disk-phase-transport, hyperbolic-metric, unitdisk, dynsystem, s1: no listed sibling is bijective to $\mathsf{PoincareDiskDynamics}^{\uparrow}$ because this packet jointly carries disk coordinates, disk-map evolution, metric readback, fixed far-end boundary preservation, phase provenance, dynamic replay, refusal, transport, provenance, and local naming.

The Lean follow-up for this packet must provide explicit $\mathsf{Nontrivial}\ \mathsf{PoincareDiskDynamics}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{PoincareDiskDynamics}^{\uparrow}$ TasteGate instances. Those instances must keep $U, \Phi, G, B, F, V, A, H, C, P, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareDiskDynamics}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PoincareDiskDynamics}^{\uparrow}$ packet is generated from UnitDisk coordinates, a disk-map row, HyperbolicMetric readback, SOne boundary consumption, PoincareDiskPhaseTransport provenance, DynSystem finite evolution, refusal exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareDiskDynamics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4117.1 and Definition 4117.2 seed the finite disk-map, metric, fixed-boundary, phase-provenance, and dynamic-replay route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareDiskDynamics}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed Poincare disk geometry, host hyperbolic metric models, quotient boundary equality, global observer time, physical light-speed derivation, internal T, subject-substance, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, disk-map exposure, metric readback, fixed-boundary preservation, phase-provenance routing, dynamic replay, TasteGate nontriviality, field faithfulness, and local naming for BEDC.Derived.PoincareDiskDynamicsUp.

Chapter 4118

A Concrete Naming Certificate for $\mathsf{ProbeBundleFiniteMinimumFold}^{\uparrow}$

Following the finite minimum step in the Heine–Cantor proof of chapter 9237, the $\mathsf{ProbeBundleFiniteMinimumFold}^{\uparrow}$ packet records the compact-net lower-bound fold as a finite BEDC carrier. It reads the $\mathsf{ProbeBundle}$ spine supplied by compactness, the $\mathsf{Rat}^{\uparrow}$ radius histories attached to bundled centers, the order readback exposed through $\mathsf{TotalOrder}^{\uparrow}$, the source rows of $\mathsf{Compact}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$, the pointwise graph rows of $\mathsf{ContinuousMap}^{\uparrow}$, and the downstream $\mathsf{UniformContinuityModulus}^{\uparrow}$ consumer. The packet names the fold as finite induction over displayed probes, not as a host minimum over a semantic finite set.

The fold is the finite lower-bound row consumed by chapter 388 and by the uniform-modulus handoff, while remaining only a $\mathsf{ProbeBundle}$ and $\mathsf{Rat}^{\uparrow}$ finite induction surface.

Definition 4118.1 (ProbeBundleFiniteMinimumFold carrier)**.** *A* $\mathsf{ProbeBundleFiniteMinimumFold}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, M, G, \mathcal{P}, R, O, A, B, U, H, C, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *source row carrying the finite-net witness.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *source-distance row used by the compact-uniform-continuity argument.*
3. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row attached to the displayed graph.*
4. *$\mathcal{P}$ is the nonempty* $\mathsf{ProbeBundle}$ *spine indexing the compact-net centers.*
5. *R is the finite family of positive* $\mathsf{Rat}^{\uparrow}$ *radius histories, one for each bundled probe.*
6. *O is the* $\mathsf{TotalOrder}^{\uparrow}$ *readback row used to compare the positive rational radius histories.*
7. *A is the accumulator ledger produced by primitive recursion over $\mathcal{P}$.*
8. *B is the certified lower-bound row saying that the final accumulator is below every displayed radius history in R.*
9. *U is the* $\mathsf{UniformContinuityModulus}^{\uparrow}$ *handoff row that receives the accumulator as the tolerance-only precision.*
10. *H records componentwise* hsame *transport for the compact source, metric source, continuous-map row, bundle spine, rational candidates, order readback, accumulator, lower-bound certificate, handoff, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the finite fold from the bundle spine to the handoff row.*
12. *Q records* Pkg *provenance over* $\mathsf{ProbeBundleFiniteMinimumFold}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, $\mathsf{UniformContinuityModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{ProbeBundleFiniteMinimumFold}^{\uparrow}}$ *row.*

The carrier contains no host finite minimum, escaped probe outside $\mathcal{P}$, open-cover compactness object, quotient point equality, external modulus selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

```
Lean4 ✓  BEDC.Derived.ProbeBundleFiniteMinimumFoldUp.ProbeBundleFiniteMinimumFoldTasteGate
single carrier alignment
```

Theorem 4118.2 (ProbeBundleFiniteMinimumFold NameCert obligations)**.** *For every accepted* $\mathsf{ProbeBundleFiniteMinimumFold}^{\uparrow}$ *carrier*

$$F = (K, M, G, \mathcal{P}, R, O, A, B, U, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{ProbeBundleFiniteMinimumFold}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *compact, metric, and continuous-map source admission through K, M, G;*
2. *nonempty* ProbeBundle *spine admission for $\mathcal{P}$;*
3. *positive* $\mathsf{Rat}^{\uparrow}$ *radius admission for each bundled row of R;*
4. $\mathsf{TotalOrder}^{\uparrow}$ *comparison readback through O at each successor step of the fold;*
5. *finite-spine induction producing the accumulator row A from the rows of R;*
6. *lower-bound exactness, requiring B to certify that the accumulator is below every displayed radius history and to read no radius outside R;*
7. $\mathsf{UniformContinuityModulus}^{\uparrow}$ *handoff through U;*
8. *ledger non-escape, excluding host minima, escaped probes, open-cover compactness, quotient point equality, external modulus selectors, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier in Definition 4118.1. The compact, metric, and continuous-map rows expose the source of the compact-uniform-continuity argument, while $\mathcal{P}$ is the only induction spine available to the fold.

Use primitive recursion over $\mathcal{P}$. At the initial row the accumulator reads the first positive $\mathsf{Rat}^{\uparrow}$ radius history in R; at each successor step the fold compares the accumulator with the next radius through the displayed $\mathsf{TotalOrder}^{\uparrow}$ row O and writes the retained lower row into A.

The lower-bound certificate B is attached to the same recursion. It records that the final accumulator is classifier-stably below every radius row already inspected in R, and it has no coordinate from which a radius outside the bundle can be read.

Finally the handoff row U gives the compact-uniform-continuity consumer a tolerance-only precision history. The structural rows H, C, Q, N transport, replay, source, and name the same finite route, so no host finite minimum, escaped probe, open-cover compactness object, quotient point equality, external modulus selector, or ambient real-completeness object can enter the certificate. □

Falsifiable prediction: A $\mathsf{ProbeBundleFiniteMinimumFold}^{\uparrow}$ consumer that obtains a UniformContinuityModulusUp precision without reading the displayed CompactUp source, MetricUp source, ContinuousMapUp row, ProbeBundle spine, RatUp radius histories, TotalOrderUp comparison row, accumulator ledger, lower-bound certificate, hsame transport, Cont replay, Pkg provenance, and local NameCert row refutes the carrier surface.

Independence witness: compact, metric, continuousmap, rat, totalorder, uniformcontinuitymodulus: no listed sibling supplies the whole ProbeBundle finite minimum fold because each sibling contributes only compact source data, metric rows, graph rows, rational order data, or modulus handoff rows while this chapter binds the finite-spine induction surface.

Closure status for $\mathsf{NameCert}_{\mathsf{ProbeBundleFiniteMinimumFold}^{\uparrow}}$.

Constructive story: A $\mathsf{ProbeBundleFiniteMinimumFold}^{\uparrow}$ packet is generated from CompactUp finite-net rows, MetricUp source rows, ContinuousMapUp pointwise-modulus rows, a nonempty ProbeBundle spine, positive RatUp radius histories, a TotalOrderUp comparison readback row, an accumulator ledger, a lower-bound certificate, a UniformContinuityModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProbeBundleFiniteMinimumFold}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4118.1 and Definition 4118.2 seed the finite ProbeBundle minimum fold required by the compact-uniform-continuity lower-bound route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProbeBundleFiniteMinimumFold}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host finite minima, probes outside the displayed bundle, open-cover compactness, quotient point equality, external modulus selectors, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove source admission, bundle spine admission, positive rational admission, order readback, finite-spine induction, lower-bound exactness, modulus handoff, and ledger non-escape.

Chapter 4119

A Concrete Naming Certificate for $\mathsf{HausdorffDimension}^{\uparrow}$

Following Hausdorff and Falconer, the $\mathsf{HausdorffDimension}^{\uparrow}$ packet records the BEDC surface at which gauge-weighted finite and countable-looking cover data become a named scale-cover dimension read. It sits beside the scale counting route of chapter 3877, the finite refinement route of chapter 1853, the compact source boundary of chapter 129, and the dense Real-facing route of chapter 1809. The chapter names a gauge-cover packet; it does not overload $\mathsf{BoxDimension}^{\uparrow}$ with Hausdorff-measure obligations and does not assert a host measure theorem.

Definition 4119.1 (Hausdorff dimension gauge-cover carrier)**.** *A* $\mathsf{HausdorffDimension}^{\uparrow}$ *carrier over a compact metric source* X *is a finite* BHist *packet*

$$H = (M, K, G, C, W, R, S, D, T, P, N)$$

with the following displayed rows:

1. M *is the inherited* $\mathsf{Met}^{\uparrow}$ *row on* X*, including the visible distance classifier used to read ball diameters.*
2. K *is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing finite-net and complete-limit data before any gauge cover is inspected.*
3. G *is the gauge row. It records the dyadic scale exponent, positive radius bound, and rational weight expression used by the Hausdorff gauge read.*
4. C *is the finite visible cover row. Each cover member carries a center history, a radius history, membership evidence, and a diameter bound readable through* M *and* K*.*
5. W *is the gauge-weight ledger. It assigns to each displayed cover member its rational gauge contribution and records the finite partial sum.*
6. R *is the refinement route. It records how a smaller visible gauge cover refines the previous one without choosing a host-minimal cover.*
7. S *is the separability route through* $\mathsf{RealSeparability}^{\uparrow}$*, used when the compact metric source is Real-facing and cover centers must be read from dense windows.*
8. D *is the dimension-threshold ledger. It records rational lower and upper threshold comparisons for gauge-weight decay across displayed scales.*

9. *T stores componentwise* hsame *transport and displayed* Cont *replay for metric points, gauge scales, cover members, gauge weights, refinement rows, dense-route data, and threshold comparisons.*

10. *P is the* Pkg *provenance over* $\mathsf{HausdorffDimension}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CoveringDimension}^{\uparrow}$, $\mathsf{BoxDimension}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffDimension}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary outer measure, a selected optimal cover, countable choice over covers, host logarithms, quotient compacta, ambient Euclidean embeddings, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.HausdorffDimensionUp.HausdorffDimensionTasteGate single carrier alignment`

Theorem 4119.2 (Hausdorff dimension NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffDimension}^{\uparrow}$ *carrier*

$$H = (M, K, G, C, W, R, S, D, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HausdorffDimension}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric and compact rows, gauge positivity and scale exposure, finite cover membership, diameter comparison, gauge-weight summation, refinement transport, dense Real-facing routing when present, threshold comparison, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside $M, K, G, C, W, R, S, D, T, P, N$.*

Proof. Project the carrier of Definition 4119.1. The source rows M and K provide the metric and compact finite-net surface, while G supplies the positive gauge scale and the rational exponent data used by the dimension read.

For a fixed gauge, C displays the cover members and W displays their gauge contributions. The finite sum is therefore a packet row, not an invocation of an ambient outer-measure construction.

The row R is the only refinement route between gauges. It transports displayed covers to smaller displayed covers and keeps the weight ledger attached to the same finite source surface.

The dense-source route S, threshold ledger D, transport and replay row T, provenance row P, and naming row N preserve the same visible data. Since the carrier contains no coordinate for selected optimal covers, countable choice, host logarithms, outer measures, quotient compacta, Lean verification, or bridge checking, the listed rows exhaust the local NameCert obligations. □

Theorem 4119.3 (Hausdorff dimension scale-cover route)**.** *Every scale-cover read exported by an accepted* $\mathsf{HausdorffDimension}^{\uparrow}$ *packet factors through*

$$\mathsf{Met}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow} \longmapsto G, C, W, R \longmapsto S, D, T, P, N.$$

The route may be compared with $\mathsf{BoxDimension}^{\uparrow}$ *only at the shared metric, compact, dyadic-scale, finite-cover, refinement, counting, and dense-route rows, and with* $\mathsf{CoveringDimension}^{\uparrow}$ *only at the finite cover-refinement surface. It does not identify Hausdorff gauge weights with box cover counts, does not turn covering dimension into a gauge measure, and does not import open-cover compactness or selected subcovers.*

Proof. Start from the metric and compact source rows. A scale-cover consumer must first read M and K, so the cover is anchored in the same compact metric finite-net boundary used by chapter 129.

Open the gauge-cover rows. The gauge row G, visible cover row C, and gauge-weight ledger W provide the Hausdorff-specific data; the refinement row R records how these rows persist as the scale decreases.

Compare only along shared surfaces. The $\mathsf{BoxDimension}^{\uparrow}$ sibling shares finite scale-cover and counting language but lacks the gauge-weight ledger, while $\mathsf{CoveringDimension}^{\uparrow}$ shares finite refinement language but lacks the gauge-threshold comparison row.

Finally route Real-facing centers through S and close the threshold read through D, T, P, N. The packet therefore exports a concrete gauge-cover dimension route without adding host outer measures, selected cover families, open-cover compactness, quotient equality, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffDimension}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffDimension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4119.1, Definition 4119.2, and Definition 4119.3 seed the gauge-cover dimension packet over compact metric sources, finite refinement rows, RealSeparability dense routes, and box-dimension comparison surfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffDimension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Hausdorff measure existence, exact numerical dimension values, countable cover choice, selected optimal covers, host logarithm analysis, ambient Euclidean embeddings, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, gauge positivity, finite cover membership, diameter comparison, gauge-weight summation, refinement routing, threshold comparison, and RealSeparability dense-route coverage for BEDC.Derived.HausdorffDimensionUp.

Constructive story: A $\mathsf{HausdorffDimension}^{\uparrow}$ packet is generated from a metric row, compact metric source row, gauge row, visible cover row, gauge-weight ledger, refinement route, dense Real-facing route, threshold ledger, componentwise transport and replay, provenance, and a local NameCert row.

Chapter 4120

A Concrete Naming Certificate for $\mathsf{EffectiveLimitOperator}^{\uparrow}$

Following Weihrauch computable analysis, the $\mathsf{EffectiveLimitOperator}^{\uparrow}$ packet records the represented-space limit operation as a finite BEDC handoff from Cauchy names to a sealed represented output. It sits over represented-space source rows from chapter 1494, Cauchy representation rows from chapter 1680, stream-window observations from chapter 126, regular rational readback from chapter 301, dyadic tolerance control from chapter 291, and the terminal real-name seal of chapter 38. The packet makes the limit operator visible as displayed finite convergence data, not as an ambient completeness principle.

Definition 4120.1 (EffectiveLimitOperator carrier)**.** *An* $\mathsf{EffectiveLimitOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, A, S, M, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the represented-space source row, including the representation interface through which names are read.*
2. *A is the* $\mathsf{CauchyRepresentation}^{\uparrow}$ *source row presenting the input name as a Cauchy object over X.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row of inspected name windows.*
4. *M is the effective convergence and modulus ledger assigning each requested tolerance to a finite tail-window obligation.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational observations made through the windows in S.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the requested precision with the displayed tail budget.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the represented source, Cauchy representation, stream windows, modulus ledger, regular readback, and dyadic tolerance rows have been displayed.*
8. *H records componentwise* hsame *transport for the represented source, Cauchy source, stream windows, modulus ledger, readback, tolerance, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a tolerance request through A, S, M, R, D to the sealed output row E.*

10. *P records* Pkg *provenance over* EffectiveLimitOperator$^{\uparrow}$, RepresentedSpace$^{\uparrow}$, CauchyRepresentation$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{EffectiveLimitOperator}^{\uparrow}}$ *row.*

The carrier contains no selected limit, quotient stream equality, countable-choice selector, host real equality, or ambient completeness row for Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.EffectiveLimitOperatorUp.EffectiveLimitOperatorTasteGate single carrier alignment`

Theorem 4120.2 (EffectiveLimitOperator NameCert obligations)**.** *For every accepted* EffectiveLimitOperator$^{\uparrow}$ *carrier*

$$L = (X, A, S, M, R, D, E, H, C, P, N),$$

the local NameCert$_{\text{EffectiveLimitOperator}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *represented-source admission for the displayed* RepresentedSpace$^{\uparrow}$ *and* CauchyRepresentation$^{\uparrow}$ *rows;*
2. *stream-window coverage, requiring every tolerance request admitted by M to name a finite inspected window in S;*
3. *effective-modulus replay, requiring the convergence ledger M to route each requested tolerance to the displayed regular rational readback R;*
4. *dyadic tolerance exactness, requiring every comparison used by the limit handoff to read exactly the row D beside R;*
5. *real-seal handoff, requiring the* Real$^{\uparrow}$ *seal E to be consumed only after X, A, S, M, R, D have been displayed;*
6. *structural stability through the componentwise* hsame, *displayed* Cont, Pkg, *and local* NameCert *rows;*
7. *ledger non-escape, excluding selected limits, quotient stream equality, countable choice, host real equality, and ambient* Real$^{\uparrow}$ *completeness from the packet.*

Proof. Project the carrier in Definition 4120.1. The rows X, A, S, M, R, D, E display the represented source, Cauchy presentation, stream windows, effective convergence ledger, regular rational readback, dyadic tolerance comparison, and terminal real seal.

A tolerance request first reads the ledger M. The ledger names a finite window in S, sends the observed entries through the regular readback row R, and compares the requested budget against the dyadic tolerance row D.

The seal row E is therefore reachable only after this displayed route has been followed. The transport, replay, provenance, and local naming rows H, C, P, N attach the same route to classifier-stable BEDC data.

Since the carrier has no coordinate for a selected limit, quotient stream equality, countable-choice selector, host real equality, or ambient completeness of Real$^{\uparrow}$, a consumer cannot obtain any of those objects from the local certificate surface. □

Falsifiable prediction: A EffectiveLimitOperator$^{\uparrow}$ consumer that reaches a Real$^{\uparrow}$ limit seal without reading the displayed represented-space source, CauchyRepresentation source, StreamName

windows, effective modulus ledger, RegSeqRat readback, DyadicRatCore tolerance row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row refutes the carrier surface.

Independence witness: representedspace, cauchyrepresentation, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the whole effective-limit-operator packet because each sibling contributes only source representation, Cauchy naming, windowing, readback, tolerance, or sealing data while this chapter binds the finite operator handoff route.

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveLimitOperator}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveLimitOperator}^{\uparrow}$ packet is generated from a RepresentedSpace source row, a CauchyRepresentation source row, StreamName windows, an effective convergence and modulus ledger, RegSeqRat regular rational readbacks, a DyadicRatCore tolerance row, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveLimitOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4120.1 and Definition 4120.2 seed the finite represented-space limit-operator handoff over Cauchy names, stream windows, regular readback, dyadic tolerance, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveLimitOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient stream equality, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove represented-source admission, stream-window coverage, effective-modulus replay, dyadic tolerance exactness, Real seal handoff, structural stability, and ledger non-escape.

Chapter 4121

A Concrete Naming Certificate for LocatedCauchyFilterLimit$^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Bourbaki–Kelley terminology of filters and filter bases, the LocatedCauchyFilterLimit$^{\uparrow}$ packet records the localized L10 limit route in which a located filter-basis row feeds the existing CauchyFilterLimit$^{\uparrow}$ and CauchyFilterRegularization$^{\uparrow}$ packets before any Real$^{\uparrow}$ seal is read. It sits after chapter 1558, chapter 4110, chapter 126, chapter 301, chapter 291, and chapter 38. The chapter names the finite located completion-filter route, not quotient equality of filters, selected representatives, host real equality, countable choice, or ambient completeness.

Definition 4121.1 (LocatedCauchyFilterLimit carrier)**.** *A* LocatedCauchyFilterLimit$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, F, G, S, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *B is the located filter-basis row, naming the finite located neighborhoods and common-refinement data used by the completion-filter request.*
2. *F is the* CauchyFilterLimit$^{\uparrow}$ *row, consuming the displayed basis route before a limit-facing seal is read.*
3. *G is the* CauchyFilterRegularization$^{\uparrow}$ *row, regularizing the same filter route into finite stream, rational, dyadic, and seal data.*
4. *S is the* StreamName$^{\uparrow}$ *finite-window row inspected by the located request.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to those windows.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger for located comparison and limit-scale accounting.*
7. *A is the* Real$^{\uparrow}$ *seal row reached only after B, F, G, S, R, D have been replayed.*
8. *H records componentwise* hsame *transport for the located basis, limit, regularization, window, readback, tolerance, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a located completion-filter request through $B, F, G, S, R, D, A, H, P, N$.*
10. *P is the* Pkg *provenance over* LocatedCauchyFilterLimit$^{\uparrow}$, CauchyFilterLimit$^{\uparrow}$, CauchyFilterRegularization$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterLimit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filters, selected limit representatives, host real equality, countable-choice locators, hidden cofinal subsequences, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.LocatedCauchyFilterLimitUp.LocatedCauchyFilterLimitUp`
Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterLimitUp.LocatedCauchyFilterLimitTasteGate single carrier alignment`

Theorem 4121.2 (LocatedCauchyFilterLimit NameCert obligations)**.** *For every accepted* LocatedCauchyFilterLimi *carrier*

$$L = (B, F, G, S, R, D, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterLimit}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the located filter-basis row,* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *row,* $\mathsf{CauchyFilterRegularization}^{\uparrow}$ *row, finite stream windows, regular rational readback, dyadic tolerance ledger, Real seal, transport, continuation, provenance, and local naming row;*
2. *located-basis exposure, requiring B to be displayed before the limit row F or the regularization row G can be consumed;*
3. *completion-filter compatibility, requiring F and G to read the same finite* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows before the* $\mathsf{Real}^{\uparrow}$ *seal is reached;*
4. *seal non-escape, requiring A to remain downstream of B, F, G, S, R, D;*
5. *ledger refusal for quotient filters, selected representatives, hidden cofinal choices, countable choice, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No obligation is stored outside these finite rows.

Proof. Project the carrier of Definition 4121.1. The projection exposes the located basis row B, the limit row F, the regularization row G, the shared observation rows S, R, D, the seal row A, and the structural rows H, C, P, N.

The located row is read first. The continuation row C sends any completion-filter request through the displayed located neighborhoods and common refinements before the request can inspect the $\mathsf{CauchyFilterLimit}^{\uparrow}$ or $\mathsf{CauchyFilterRegularization}^{\uparrow}$ surfaces.

The shared observation rows bind the two sibling packets. Both the limit row and the regularization row consume the same finite stream windows, regular rational readbacks, and dyadic tolerance ledger before reaching A.

Finally attach transport, provenance, and local naming. The rows H, P, N preserve only the displayed route, so the carrier has no coordinate for quotient filters, selected representatives, hidden cofinal schedules, countable choice, host equality, or ambient completeness. □

Falsifiable prediction: A $\mathsf{LocatedCauchyFilterLimit}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal while omitting the located filter-basis row, CauchyFilterLimit row, CauchyFilterRegularization row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, componentwise hsame transport, Cont replay, Pkg provenance, or local NameCert row refutes the packet.

Independence witness: cauchyfilterlimit, cauchy-filter-regularization, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the whole located completion-filter packet because each contributes only a limit row, regularization row, window row, rational readback, tolerance ledger, or seal, while this chapter binds them to a located filter-basis route.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCauchyFilterLimit}^{\uparrow}$ packet is generated from a located filter-basis row, CauchyFilterLimit row, CauchyFilterRegularization row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4121.1 and Definition 4121.2 seed the finite located Cauchy-filter limit route over limit, regularization, stream, rational, tolerance, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filter equality, selected representatives, hidden cofinal choices, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-basis exposure, completion-filter compatibility, Real seal nonescape, transport replay, provenance nonescape, and ledger refusals for BEDC.Derived.LocatedCauchyFilterLimitUp.

This hub routes the pre-separated universal-property packet through chapter 1614, chapter 2237, chapter 1506, chapter 397, and chapter 3351.

Chapter 4122

A Concrete Naming Certificate for PseudometricCompletionUniversalProperty$^{\uparrow}$

Following Bishop and Bridges and Bourbaki–Kelley completion terminology, the PseudometricCompletionUniversalPr packet records the finite universal-property route for completing a pre-separated distance surface. It sits after the Pseudometric$^{\uparrow}$ carrier of chapter 1614, the separated classifier route of chapter 2004, the separated-completion handoff of chapter 2237, the metric-completion surface of chapter 1506, and the extension ledger of chapter 397. Its finite observations are read through chapter 126, chapter 301, chapter 291, and the terminal seal of chapter 38. The dense-source map row is the forward-facing consumer of chapter 3351, because extension existence and uniqueness must read dense embedding data before the completion-facing map row is compared. The chapter supplies the L10 bridge from pre-separated distance data to extension uniqueness without quotient completions, selected representatives, selected limits, host function equality, or countable choice.

Definition 4122.1 (PseudometricCompletionUniversalProperty carrier)**.** *A* PseudometricCompletionUniversalProp *carrier is a finite* BHist *packet*

$$U = (P, Q, S, M, V, W, R, D, A, F, E, L, H, C, N)$$

with the following displayed rows:

1. *P is the source* Pseudometric$^{\uparrow}$ *packet, carrying the point rows, displayed distance witness, zero-distance boundary, dyadic tolerance ledger, finite windows, regular rational readback, and terminal real distance seal.*
2. *Q is the* SeparatedQuotientMetric$^{\uparrow}$ *classifier row that consumes zero-distance evidence from P before any separated metric read is exposed.*
3. *S is the* SeparatedPseudometricCompletion$^{\uparrow}$ *handoff row that routes the source pseudometric through separated completion data while keeping the pre-separated source visible.*
4. *M is the* MetricCompletion$^{\uparrow}$ *row naming the completion-facing separated metric packet consumed by extension readers.*
5. *V is the* CompletionUniversalProperty$^{\uparrow}$ *row that supplies the finite extension-existence and uniqueness ledgers over completion data.*
6. *W is the* StreamName$^{\uparrow}$ *finite-window schedule through which source points, distance approximants, and dense observations are inspected.*

7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in W and to the dense source observations used by the extension route.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for zero-distance, triangle, and extension-precision comparisons before the real seal is read.*
9. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after W, R, D display the requested approximation data.*
10. *F is the dense-source map row whose finite graph and modulus reads are to be extended from the pseudometric source.*
11. *E is the extension-existence ledger, a displayed route from $P, Q, S, M, V, W, R, D, A, F$ to a completion-facing map row.*
12. *L is the uniqueness ledger comparing two extension rows whenever they agree on the same separated classifier, dense-source windows, regular readback, dyadic tolerance, real seal, and dense map rows.*
13. *H records componentwise* hsame *transport for the source pseudometric, separated classifier, separated completion, metric completion, universal-property row, window schedule, regular readback, dyadic tolerance, real seal, map row, extension ledger, uniqueness ledger, continuation, provenance, and local naming rows.*
14. *C records displayed* Cont *replay of the route*
$$P, Q, S, M, V, W, R, D, A, F \longmapsto E \longmapsto L.$$
15. *N is both the* Pkg *provenance over* $\mathsf{Pseudometric}^{\uparrow}$, $\mathsf{SeparatedQuotientMetric}^{\uparrow}$, $\mathsf{SeparatedPseudometricCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows and the local* $\mathsf{NameCert}_{\mathsf{PseudometricCompletionUniversalProperty}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion classes, selected representatives, selected limits, host function equality, countable-choice schedules, trichotomy, or ambient completeness.

Theorem 4122.2 (PseudometricCompletionUniversalProperty NameCert obligations)**.** *For every accepted* $\mathsf{PseudometricCompletionUniversalProperty}^{\uparrow}$ *carrier $U = (P, Q, S, M, V, W, R, D, A, F, E, L, H, C, N)$, the local* $\mathsf{NameCert}_{\mathsf{PseudometricCompletionUniversalProperty}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source pseudometric, separated classifier, separated completion handoff, metric completion row, universal-property row, finite windows, regular readback, dyadic tolerance, real seal, dense map, extension ledger, uniqueness ledger, transport, replay, provenance, and local naming rows;*
2. *separated-source exposure, requiring zero-distance evidence from P to pass through Q and S before the metric-completion row M is read;*
3. *dense-readback exposure, requiring every extension request to display W, R, D, A before the dense map row F is repacked as an extension;*
4. *extension existence, requiring E to be read only after $P, Q, S, M, V, W, R, D, A, F$ have been displayed;*
5. *extension uniqueness, requiring L to compare candidate extension rows over the same separated source, dense windows, readback rows, real seal, and dense map data;*

6. *non-escape, excluding quotient completions, selected representatives, selected host limits, host function equality, countable choice, trichotomy, and ambient completeness from every exported consumer route.*

No pseudometric-completion universal-property obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4122.1. The accepted packet lists the source pseudometric, separated classifier, separated completion handoff, completion row, universal-property row, dense readback rows, extension and uniqueness ledgers, and structural support rows.

Separated-source exposure follows from the order P, Q, S, M. The source distance surface remains pre-separated in P until the zero-distance evidence is consumed by Q and the separated-completion handoff S.

Dense-readback exposure follows from W, R, D, A, F. The stream schedule, regular rational row, dyadic tolerance row, and real seal are displayed before the dense map row is used by an extension request.

Extension existence is the role of E, and uniqueness is the role of L. The replay row C places those ledgers after the same source, separated, completion, dense-readback, and map rows, while H transports only the displayed coordinates.

The non-escape clause is an inventory check on the carrier. Since no quotient completion class, selected representative, selected host limit, host function equality, countable-choice schedule, trichotomy row, or ambient completeness theorem appears among the coordinates, none can be exported by the local naming certificate. □

Theorem 4122.3 (PseudometricCompletionUniversalProperty extension uniqueness)**.** *Let* $U = (P, Q, S, M, V, W, R, D, A, F, E, L, H, C, N)$ *and* $U' = (P, Q, S, M, V, W, R, D, A, F, E', L', H', C', N')$ *be accepted* $\mathsf{PseudometricCompletionUniversalProperty}^{\uparrow}$ *carriers with the same source pseudometric, separated classifier, separated completion handoff, metric completion row, universal-property row, finite windows, regular readback, dyadic tolerance, real seal, dense map row, and package provenance. If* E *and* E' *agree on every displayed finite read from* W, R, D, A *after the separated-source route* P, Q, S *has been consumed, then the two completion-facing extension rows are compared by the uniqueness ledgers* L *and* L'*.*

The comparison is a displayed hsame *ledger over the finite carrier rows. It is not host equality of maps, not equality of quotient-completion representatives, and not a selected-limit principle.*

Proof. Read the common source coordinates from the two accepted packets. The rows P, Q, S fix the pre-separated distance surface, the separated classifier, and the separated-completion handoff available to both extensions.

Next read the common completion and dense-source coordinates. The rows M, V, W, R, D, A, F fix the completion-facing target, the universal-property ledger, the finite window schedule, regular rational readback, dyadic tolerances, real seal, and dense map data.

The hypothesis compares E and E' on the displayed finite reads from W, R, D, A after the separated-source route has been consumed. Transport those reads through H, H' and replay them through C, C' so both extension rows are presented over the same source, completion, dense-readback, real-seal, and dense-map coordinates.

The uniqueness coordinates are exactly L and L'. Applying them gives the required displayed comparison of extension rows, with no appeal to host function equality, quotient representatives, selected limits, or countable choice. □

Theorem 4122.4 (PseudometricCompletionUniversalProperty non-escape)**.** *Every consumer read exported by an accepted* PseudometricCompletionUniversalProperty$^{\uparrow}$ *carrier factors through the finite route*

Pseudometric$^{\uparrow}$, SeparatedQuotientMetric$^{\uparrow}$, SeparatedPseudometricCompletion$^{\uparrow}$, MetricCompletion$^{\uparrow}$, CompletionUnivers

The packet exposes extension existence through E and extension uniqueness through L only after that route has been displayed. It exports no quotient completion class, selected representative, selected host limit, countable-choice schedule, host function equality, trichotomy decision, or ambient completeness theorem.

Proof. Project the carrier of Definition 4122.1. Its source and completion rows are P, Q, S, M, V, and its dense-readback rows are W, R, D, A.

Apply Definition 4122.2. The separated-source obligation forces a consumer through P, Q, S before M is read, and the dense-readback obligation forces a consumer through W, R, D, A before F, E, L are read.

Extension existence is then confined to the ledger E, while extension uniqueness is confined to L. The transport and replay rows H, C move only the displayed coordinates and preserve the same order.

The exclusions follow from the carrier inventory. Since the packet contains no coordinate for quotient completion classes, selected representatives, selected host limits, countable-choice schedules, host function equality, trichotomy, or ambient completeness, none of those objects can escape along a consumer route. □

Theorem 4122.5 (Pseudometric completion sibling route)**.** *Any accepted* PseudometricCompletionUniversalProperty *packet that exposes a universal readback must first route through* MetricCompletion$^{\uparrow}$, CauchyEquivalenceSetoid$^{\uparrow}$, *and* SeparatedCompletion$^{\uparrow}$. *The universal readback first consumes the Cauchy-equivalence setoid route of chapter 1820, then the metric completion route of chapter 1506, before extension existence or uniqueness can be read. The readback may then consume the displayed extension and uniqueness ledgers of the carrier, but it may not replace those sibling rows by quotient representatives, selected limits, host function equality, countable-choice schedules, trichotomy, or ambient completeness.*

Proof. Project the carrier of Definition 4122.1. The rows $P, Q, S, M, V, W, R, D, A, F, E, L, H, C, N$ already place the source pseudometric before the separated classifier, separated-completion handoff, metric-completion row, and universal-property ledger.

Read the equality-facing route next. The CauchyEquivalenceSetoid$^{\uparrow}$ comparison is the visible setoid boundary for regular Cauchy data, and the sibling route of chapter 1820 must be consumed before the metric-completion route of chapter 1506. The SeparatedCompletion$^{\uparrow}$ row records the separated completion route before the metric-completion consumer reads M.

Finally apply the non-escape theorem, Definition 4122.4. Since the carrier exports only extension and uniqueness ledgers after those displayed sibling rows, a universal readback cannot be retyped as quotient representatives, selected limits, host map equality, countable choice, trichotomy, or ambient completeness. □

Closure status for NameCert$_{\text{PseudometricCompletionUniversalProperty}^{\uparrow}}$.

Constructive story: A PseudometricCompletionUniversalProperty$^{\uparrow}$ packet is generated from a source Pseudometric$^{\uparrow}$ row, a SeparatedQuotientMetric$^{\uparrow}$ classifier, a SeparatedPseudometricCompletion$^{\uparrow}$ handoff, a MetricCompletion$^{\uparrow}$ completion row, a CompletionUniversalProperty$^{\uparrow}$ extension surface, finite StreamName$^{\uparrow}$ windows, RegSeqRat$^{\uparrow}$ readback, DyadicRatCore$^{\uparrow}$ tolerance rows, a Real$^{\uparrow}$ seal, a dense map row, extension and uniqueness ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PseudometricCompletionUniversalProperty}\uparrow}$, seed)

Scope closed: Definition 4122.1, Definition 4122.2, Definition 4122.3, Definition 4122.4, and Definition 4122.5 seed the finite universal-property route from pre-separated distance data to extension uniqueness through the sibling completion rows.

Formal verification: FormalStatus(NameCert$_{\text{PseudometricCompletionUniversalProperty}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion construction, selected representatives, selected host limits, countable choice, host function equality, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated-source exposure, dense-readback exposure, extension existence, extension uniqueness, and non-escape for BEDC.Derived.PseudometricCompletionUniversalPropertyUp.

Chapter 4123

A Concrete Naming Certificate for $\mathsf{BaireCategoryChoiceFree}^{\uparrow}$

Following Baire and Bishop–Bridges constructive analysis, the $\mathsf{BaireCategoryChoiceFree}^{\uparrow}$ packet records the finite choice-free boundary that Real and Completion consumers may use before any dense-open or Baire-style argument reaches a sealed real name. It sits between the dense-open packet of chapter 1542, the complete metric source of chapter 128, the finite window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Specker obstruction surface of chapter 1406. The packet exposes a displayed finite thread through those rows; it does not assert a host Baire theorem, countable choice, quotient stream equality, selected limits, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 4123.1 (BaireCategoryChoiceFree carrier)**.** *A* $\mathsf{BaireCategoryChoiceFree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, M, W, R, S, K, H, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BaireCategory}^{\uparrow}$ *dense-open boundary row, read only through the finite schedule and nested-ball thread already named in chapter 1542.*
2. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row supplying the displayed complete-metric carrier, ball classifier, Cauchy-thread route, and limit-witness boundary.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the inspected dense-open requests, metric balls, and terminal real-name observations before any consumer reads the boundary.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row converting the displayed windows into regular-rational tolerance data.*
5. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, M, W, R have been displayed.*
6. *K is the Specker boundary row. It records that nonconstructive selection or completeness requests are refused by comparison with the finite Specker-style obstruction surface, rather than discharged by countable choice.*
7. *H records componentwise* hsame *transport for B, M, W, R, S, K and the structural rows.*
8. *C records displayed* Cont *replay from dense-open requests through finite windows, regular-rational readback, the real seal, and the refusal row.*

9. *P is the* Pkg *provenance over* $\mathsf{BaireCategoryChoiceFree}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireCategoryChoiceFree}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $B, M, W, R, S, K, H, C, P, N$. It has no coordinate for countable choice, an infinite selector, host set intersection, quotient stream equality, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4123.2 (BaireCategoryChoiceFree NameCert obligations)**.** *For every accepted* $\mathsf{BaireCategoryChoiceFree}^{\uparrow}$ *carrier $Q = (B, M, W, R, S, K, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireCategoryChoiceFree}^{\uparrow}}$ *surface consists exactly of the finite obligations:*

1. *carrier admission for the dense-open Baire row, complete-metric source row, finite windows, regular-rational readback, real seal, Specker refusal row, transport, replay, provenance, and local naming;*
2. *window coherence, requiring every dense-open request consumed from B to pass through the same* $\mathsf{StreamName}^{\uparrow}$ *window row W before the readback row R is visible;*
3. *metric-source coherence, requiring the complete-metric row M to supply the only Cauchy-thread and limit-witness route available to the packet;*
4. *real-seal exactness, requiring S to be downstream of B, M, W, R and not a detached host real object;*
5. *choice-free refusal, requiring K to block countable choice, hidden selectors, quotient stream equality, selected limits, and ambient completeness as local certificate data.*

Lean4 ✓ `BEDC.Derived.BaireCategoryChoiceFreeUp.TasteGate.BaireCategoryChoiceFreeTasteGate single carrier alignment`

Proof. Project the carrier of Definition 4123.1. Its rows list the dense-open Baire boundary, complete metric source, finite windows, readback, real seal, Specker refusal row, transport, replay, provenance, and local naming, and no other row is available to the local certificate.

Window coherence follows by reading the $\mathsf{BaireCategory}^{\uparrow}$ schedule only through W. The regular-rational row R is downstream of that same finite window surface, so the carrier cannot replace it with an unlisted stream representative or a selector over all dense-open requests.

Metric-source coherence is supplied by the complete-metric row M. The Cauchy thread and limit-witness route are the displayed rows consumed from M, and the transport and replay rows H, C preserve that source without creating a second completeness datum.

Finally read the seal and refusal rows. The $\mathsf{Real}^{\uparrow}$ row S is exposed only after B, M, W, R, while K records the Specker-style obstruction to turning the packet into countable choice, quotient equality, a selected limit, or ambient completeness. Thus the five obligations exhaust the local NameCert surface. □

Theorem 4123.3 (BaireCategoryChoiceFree ProbeBundle induction)**.** *Every accepted probe-bundle consumer of a* $\mathsf{BaireCategoryChoiceFree}^{\uparrow}$ *packet advances by finite induction over the displayed window row W. At each step the consumer reads the current dense-open request from B, the complete-metric source row M, the regular-rational tolerance row R, and the structural rows H, C, P, N before it may inspect the next request. The induction has no branch that selects an infinite sequence of witnesses, identifies quotient streams, chooses a host limit, or invokes ambient completeness.*

Proof. Start with the finite window row W. It is the only row listing the requests visible to the consumer, so the induction domain is a displayed finite packet rather than a countable family.

For the base step, the consumer reads the initial dense-open and metric rows through B and M. The readback row R supplies the tolerance data for the inspected window, and H, C, P, N carry only transport, replay, provenance, and local naming.

For the inductive step, the next request is another entry of the same finite W row. The same B, M, R, H, C, P, N route is replayed for that entry, and the refusal row K prevents the step from being interpreted as a hidden selector or a host completeness argument.

Since every step is indexed by an entry already displayed in W, the probe-bundle induction remains finite and choice-free. The excluded analytic alternatives have no coordinate in the carrier. □

Theorem 4123.4 (BaireCategoryChoiceFree Real and Completion boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{BaireCategoryChoiceFree}^{\uparrow}$ *packet must pass through the displayed route*

$$B, M, W, R, S, K, H, C, P, N$$

before reading any local NameCert surface. The route uses the $\mathsf{BaireCategory}^{\uparrow}$ *dense-open packet, the* $\mathsf{CompleteMetric}^{\uparrow}$ *source, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback, the* $\mathsf{Real}^{\uparrow}$ *seal, and the* $\mathsf{SpeckerSequence}^{\uparrow}$ *refusal boundary. It exports no countable choice principle, quotient stream, selected limit, host equality test, or ambient Real completeness theorem.*

Proof. Read the carrier first. The only Real-facing endpoint is the row S, and S is downstream of the Baire boundary B, complete metric row M, finite windows W, and regular-rational readback R.

Apply the NameCert obligations. They force every local naming read through the same carrier, window, metric-source, real-seal, and refusal rows, so a Completion-facing consumer cannot bypass the finite route by citing an ambient completed object.

Use the probe-bundle induction for consumers that inspect several dense-open requests. The induction is finite over W and reuses the same B, M, R, H, C, P, N route at every inspected entry.

The Specker refusal row closes the boundary. It records that requests for countable choice, quotient stream equality, selected limits, host equality, or ambient Real completeness remain outside the packet. Therefore every Real or Completion consumer reads exactly the displayed finite choice-free route before the local NameCert is available. □

Theorem 4123.5 (BaireCategoryChoiceFree complete-metric handoff)**.** *Every Completion-facing consumer of an accepted* $\mathsf{BaireCategoryChoiceFree}^{\uparrow}$ *packet must read the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row* M *together with*

$$B, W, R, S, K, H, C, P, N$$

before it may use the choice-free Baire packet. The handoff makes the complete-metric carrier, ball classifier, Cauchy-thread route, and limit-witness boundary visible as source data inside the same finite packet; it does not allow the consumer to replace M *by countable choice, a hidden selector, quotient stream equality, a selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4123.1. The only complete-metric source is the row M, and it is displayed alongside the dense-open Baire row B, finite windows W, regular-rational readback R, Real seal S, refusal row K, and structural rows H, C, P, N.

Use the NameCert obligations of Definition 4123.2. Their metric-source coherence row requires the Cauchy thread and limit-witness route to be consumed from M, while their window and real-seal rows keep M tied to the same $B, W, R, S, K, H, C, P, N$ packet.

Finally apply the Real and Completion boundary theorem, Definition 4123.4. A Completion-facing consumer must traverse the displayed finite route before any local certificate is available, so the complete-metric handoff is exactly the source row M read together with the remaining packet rows and not an ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireCategoryChoiceFree}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireCategoryChoiceFree}^{\uparrow}$ packet is generated from a BaireCategoryUp dense-open boundary row, a CompleteMetricUp source row, finite StreamNameUp windows, RegSeqRatUp readback, a RealUp seal, a SpeckerSequenceUp refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireCategoryChoiceFree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4123.1, Definition 4123.2, Definition 4123.3, and Definition 4123.4 seed the finite choice-free Baire boundary for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireCategoryChoiceFree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim the full classical Baire category theorem, countable choice, quotient stream equality, selected limits, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window coherence, complete-metric source coherence, real-seal exactness, Specker refusal, transport, provenance, and local naming for BEDC.Derived.BaireCategoryChoiceFreeUp.

Chapter 4124

A Concrete Naming Certificate for $\mathsf{RiemannIntegrabilityModulus}^{\uparrow}$

Following Riemann–Darboux integration and Bishop–Bridges constructive analysis, the RiemannIntegrabilityModulu packet records the finite modulus data that turns a Darboux gap estimate into a Cauchy route for integral names. It sits after the equal-mesh surface of chapter 2033, the Darboux finite-sum carrier of chapter 1880, the integrability carrier of chapter 1960, the real seal of chapter 38, the regular rational readback of chapter 301, and the dyadic tolerance ledger of chapter 291. The packet gives later integration chapters a displayed finite handoff from upper-lower Darboux gaps to Cauchy integral windows without importing selected integrals, quotient functions, open-cover compactness, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4124.1 (Riemann integrability modulus carrier)**.** *A* $\mathsf{RiemannIntegrabilityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, U, L, G, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the closed bounded* $\mathsf{Real}^{\uparrow}$ *interval and bounded-function observation row consumed by the Darboux and Riemann-integrable surfaces.*
2. *U is the* $\mathsf{UniformPartition}^{\uparrow}$ *row selecting an equal-mesh finite partition at a requested dyadic tolerance scale.*
3. *L is the lower Darboux finite-sum row read over the same interval and partition windows.*
4. *G is the upper Darboux finite-sum row read over the same interval and partition windows.*
5. *D is the Darboux-gap ledger, recording a positive dyadic tolerance request and the displayed comparison $G - L$ below that request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the Darboux-gap ledger into a regular rational Cauchy window for the integral name.*
7. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and terminal* $\mathsf{Real}^{\uparrow}$ *seal row for every endpoint, sum, gap, and integral-window read.*
8. *H records componentwise* hsame *transport for interval, partition, lower sum, upper sum, gap, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from Darboux-gap requests, Riemann-integrable reads, or integral-window consumers through $I, U, L, G, D, R, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{RiemannIntegrabilityModulus}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{UniformPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityModulus}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite constructive Darboux-to-Cauchy modulus history. It has no coordinate for a selected integral value, host function quotient, open cover of the interval, measure-completion object, choice principle, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.RiemannIntegrabilityModulusUp.TasteGate.RiemannIntegrabilityModulusTasteGate`
`single carrier alignment`

Theorem 4124.2 (Riemann integrability modulus NameCert obligations)**.** *For every accepted* $\mathsf{RiemannIntegrabilityModulus}^{\uparrow}$ *carrier $M = (I, U, L, G, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityModulu}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the interval, equal-mesh partition, lower Darboux sum, upper Darboux sum, gap ledger, regular rational readback, dyadic tolerance and Real seal, transport, replay, provenance, and local name;*

2. *partition coherence, requiring L and G to read the same I and U rows before the gap ledger D can be consumed;*

3. *Darboux-gap exactness, requiring D to expose only the displayed comparison between the upper and lower finite sums at the requested dyadic tolerance;*

4. *Cauchy-window readiness, requiring R to be read from D and E before any integral-window consumer receives a regular rational name;*

5. *Real seal nonescape, requiring every endpoint, sum, gap, or integral-window read to pass through E after the displayed finite Darboux rows have been exposed;*

6. *transport and replay, requiring H and C to preserve the same finite modulus history;*

7. *provenance and naming, requiring P and N to package and name exactly the displayed rows;*

8. *ledger refusal, excluding selected integrals, quotient functions, open-cover compactness, measure completion, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No Riemann-integrability modulus obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4124.1. The projection exposes exactly the interval, partition, lower-sum, upper-sum, gap, readback, seal, and structural rows.

The Darboux route is $I, U \mapsto L, G \mapsto D$. Since L and G read the same interval and partition rows, the comparison in D is a comparison between two finite Darboux sums attached to one displayed partition history.

The Cauchy handoff is then read from D, R, E. The gap ledger supplies the dyadic tolerance comparison, the regular rational readback turns that comparison into a Cauchy window, and the Real seal records only the resulting finite read.

Finally, H, C, P, N transport, replay, package, and name the same history. The excluded host objects have no carrier coordinate, so the listed obligations exhaust the local NameCert surface. □

Theorem 4124.3 (Darboux-to-Cauchy handoff)**.** *Every accepted* $\mathsf{RiemannIntegrabilityModulus}^{\uparrow}$ *carrier* $M = (I, U, L, G, D, R, E, H, C, P, N)$ *exports a finite route*

$$\mathsf{UniformPartition}^{\uparrow} \longmapsto \mathsf{DarbouxSum}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

in which a Darboux-gap request first reads the common partition row U*, then the paired lower and upper finite-sum rows* L, G*, then the gap ledger* D*, and only then the regular rational readback* R *and Real seal* E*. Any later Riemann-integral or completion-facing consumer of the integral name factors through this route and cannot bypass it by selecting an ambient integral value, quotienting functions, invoking an open-cover compactness theorem, completing a measure space, or using ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier through Definition 4124.1. The only partition coordinate is U, and the only Darboux-sum coordinates are the paired lower and upper rows L and G.

The gap ledger D is defined after those rows, so any gap request must pass through the common partition and the paired finite sums before the tolerance comparison is available. The readback row R and the seal row E occur after D, hence the Cauchy-window read cannot precede the Darboux comparison.

The replay row C preserves that order for downstream consumers, while H, P, N preserve transport, provenance, and naming. Since no selected integral, quotient-function, open-cover, measure-completion, or ambient-completeness coordinate is present in the carrier, none can be used as an alternate route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RiemannIntegrabilityModulus}^{\uparrow}$ packet is generated from a closed bounded RealUp interval row, UniformPartitionUp equal-mesh row, paired DarbouxSumUp lower and upper finite sums, Darboux-gap ledger, RegSeqRatUp readback, DyadicRatCoreUp tolerance ledger, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4124.1, Definition 4124.2, and Definition 4124.3 seed the finite constructive Darboux-to-Cauchy modulus route over $\mathsf{UniformPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected integrals, quotient functions, open-cover compactness, measure completion, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition coherence, Darboux-gap exactness, Cauchy-window readiness, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RiemannIntegrabilityModulu

Chapter 4125

A Concrete Naming Certificate for $\mathsf{SequentialRealCompletion}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley's completion route, the $\mathsf{SequentialRealCompletion}^{\uparrow}$ packet records the standard sequential completion path from regular Cauchy names to the $\mathsf{Real}^{\uparrow}$ seal as finite BEDC data. It sits after the stream-window carrier of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the real-name seal of chapter 38, the completion interface of chapter 95, and the Cauchy-limit sealing routes used by $\mathsf{CauchyLimitSeal}^{\uparrow}$ consumers. The packet is finite regular-Cauchy completion data: it is not a quotient representative, not host equality of completed objects, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4125.1 (Sequential real completion carrier)**.** *A* $\mathsf{SequentialRealCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, R, D, Q, E, L, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected observations of the candidate regular Cauchy name.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row naming the regular rational approximants visible in those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare window observations against the requested precision.*
4. *Q is the regular-Cauchy coherence row, recording tail agreement and modulus coverage only through displayed finite windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after W, R, D, Q have been displayed.*
6. *L is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *handoff row, recording that the same regular route is available to completion-facing consumers.*
7. *H records componentwise* hsame *transport for the stream windows, regular readback, dyadic ledger, coherence row, real seal, limit seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a precision request through $W, R, D, Q, E, L, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SequentialRealCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SequentialRealCompletion}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $W, R, D, Q, E, L, H, C, P, N$. It has no coordinate for quotient representatives of Cauchy sequences, host equality of completed objects, countable choice over tails, an external limit selector, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.SequentialRealCompletionUp.TasteGate.SequentialRealCompletionTasteGate single carrier alignment`

Theorem 4125.2 (Sequential real completion NameCert obligations)**.** *For every accepted* SequentialRealCompletion *carrier*

$$S = (W, R, D, Q, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialRealCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, StreamName window admission through W, RegSeqRat readback through R, DyadicRatCore tolerance admission through D, regular-Cauchy coherence through Q, RealUp seal admission through E, CauchyLimitSeal handoff through L, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4125.1. The rows W, R, D, Q are the regular Cauchy source route, while E and L are the only real-facing and completion-facing endpoints.

The finite route starts with windows. A precision request reads the displayed $\mathsf{StreamName}^{\uparrow}$ row W, extracts the regular rational observations through R, and checks the dyadic tolerance data through D before the coherence row Q may be consumed.

The endpoint rows are downstream of that same route. The $\mathsf{Real}^{\uparrow}$ seal E and the $\mathsf{CauchyLimitSeal}^{\uparrow}$ handoff L read only the displayed regular-Cauchy packet, and the structural rows H, C, P, N preserve the same packet under transport, replay, source, and naming.

Since no carrier coordinate contains quotient representatives, host equality, countable-choice schedules, external limit selectors, or ambient real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 4125.3 (Sequential real completion Cauchy-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of an accepted* $\mathsf{SequentialRealCompletion}^{\uparrow}$ *carrier factors through the finite chain*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{CauchyLimitSeal}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

as displayed by W, R, D, L, E and preserved by Q, H, C, P, N. The route exports a sealed regular-Cauchy completion packet only; it does not export quotient stream equality, a selected host real, countable choice, host equality of completions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Apply the obligation surface of Definition 4125.2. Any real-facing or completion-facing read must first expose the finite stream windows, regular rational readback, dyadic tolerance ledger, and coherence row.

The limit-seal row L is then read on the same route. It cannot be detached from W, R, D, Q, because its provenance and replay coordinates are the same H, C, P, N rows already attached to the carrier.

Finally the $\mathsf{Real}^{\uparrow}$ seal E is reached only after that limit-seal route is visible. Thus the consumer receives a finite regular-Cauchy completion packet and no quotient representative, selected host limit, countable-choice schedule, host equality, or ambient real-completeness coordinate. □

Falsifiable prediction: A $\mathsf{SequentialRealCompletion}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ endpoint without reading the displayed StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, regular-Cauchy coherence row, CauchyLimitSeal handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real, completion, cauchylimitseal: no listed sibling supplies the whole sequential real completion packet because each sibling contributes only windowing, regular readback, dyadic tolerance, real sealing, completion consumption, or limit-seal handoff while this chapter binds them into one finite regular-Cauchy completion route.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialRealCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialRealCompletion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat regular rational readback, DyadicRatCore tolerance ledgers, regular-Cauchy coherence rows, a RealUp seal, a CauchyLimitSeal handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialRealCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4125.1, Definition 4125.2, and Definition 4125.3 seed the finite regular-Cauchy completion route from sequential names to the RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialRealCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient representatives, host equality of completed objects, countable choice, selected host limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, StreamName window coverage, RegSeqRat readback, DyadicRatCore tolerance exactness, regular-Cauchy coherence, CauchyLimitSeal handoff, RealUp seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.SequentialRealCompletionUp.

Chapter 4126

A Concrete Naming Certificate for MetaCICLocalJoinLedger$^{\uparrow}$

The MetaCICLocalJoinLedger$^{\uparrow}$ packet realizes the residual-substitution boundary of chapter 9378 as finite local-join data. It sits beside the local diamond witness of chapter 3595, the residual checker of chapter 3827, the confluence substitution boundary of chapter 3791, the confluence diamond boundary of chapter 4082, and the subject-reduction discharge socket of chapter 719. The carrier records local peaks, candidate joins, bounded checker handoffs, residual-substitution frontiers, obstruction-preserving readback, and TasteGate readiness without claiming full confluence, unrestricted substitution compatibility, subject reduction, evaluator equality, or kernel consistency.

Definition 4126.1 (MetaCIC local join ledger carrier)**.** *A* MetaCICLocalJoinLedger$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (K, A, B, R, S, O, G, H, C, P, N)$$

with the following displayed rows:

1. *K is the local peak row, naming the source term and the two outgoing reduction observations.*
2. *A is the candidate join row, recording the proposed common reduct and the two finite routes into it.*
3. *B is the bounded checker handoff row, exposing the closedness, support, branch compatibility, and variable-escape checks applied to the peak.*
4. *R is the residual frontier row, listing residual descendants and binder-depth data retained by the local join attempt.*
5. *S is the substitution-boundary row, recording the residual-substitution input that remains visible whenever the local join is conditional.*
6. *O is the obstruction readback row, naming the endpoints still outside the packet: unrestricted substitution compatibility, full closed Church–Rosser, arbitrary subject reduction, evaluator equality, and kernel consistency.*
7. *G is the* TasteGate *readiness row, reserving the later* Nontrivial *and* FieldFaithful *instance obligations for this finite carrier surface.*
8. *H records componentwise* hsame *transport for local peaks, candidate joins, bounded checks, residual frontiers, substitution boundaries, obstruction rows, TasteGate readiness, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a confluence-boundary query through $K, A, B, R, S, O, G, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$, $\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}$, MetaCICConfluenceResi MetaCICConfluenceSubstitutionBoundary$^{\uparrow}$, $\mathsf{MetaCICConfluenceDiamondBoundary}^{\uparrow}$, SubjectReductionDischargeSoc BHist, hsame, Cont, TasteGate, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICLocalJoinLedger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, A, B, R, S, O, G, H, C, P, N$. It contains no coordinate for a global confluence theorem, unrestricted substitution compatibility, subject reduction, quotient equality of terms, evaluator equality, or kernel consistency.

Theorem 4126.2 (MetaCIC local join ledger obligations)**.** *For every accepted* $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$ *carrier*

$$J = (K, A, B, R, S, O, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICLocalJoinLedger}^{\uparrow}}$ *surface consists exactly of local-peak exposure through K, candidate-join exposure through A, bounded-checker handoff through B, residual-frontier exposure through R, substitution-boundary retention through S, obstruction readback through O, TasteGate readiness through G, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4126.1. Rows K, A, B, R, S, O are the confluence-facing ledger data, and rows G, H, C, P, N are the structural certificate data.

The local join attempt first reads the peak and candidate join. Row K gives the finite source and branch observations, while A records only the proposed common reduct and its two routes.

The bounded checker and residual rows remain visible before the join can be consumed. Row B records the finite checks actually performed, R keeps residual descendants and binder-depth data, and S keeps the substitution-sensitive input that prevents the ledger from being read as an unconditional diamond.

Finally O preserves the open endpoints, while G, H, C, P, N reserve the TasteGate instance surface, transport the rows, replay the query, source the packet, and name it. Since no carrier coordinate contains full confluence, unrestricted substitution compatibility, subject reduction, evaluator equality, quotient equality, or kernel consistency, the listed rows exhaust the local NameCert obligations. □

Theorem 4126.3 (MetaCIC local join ledger bounded checker handoff)**.** *Every checker-facing consumer of an accepted* $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$ *carrier factors through*

$$K, A, B, R, S, O, G, H, C, P, N$$

before it may consume the local join ledger. The bounded checker row B is a finite handoff over the displayed peak and residual rows; it is not a global confluence checker, not a subject-reduction proof, and not an evaluator-equality decision.

Proof. Apply the obligation surface of Definition 4126.2. It forces a checker-facing read through the local peak, candidate join, bounded-checker handoff, residual frontier, substitution boundary, and obstruction row.

The handoff is therefore scoped by K, A, R, S, O. It can report the checks listed in B, but it has no coordinate from which to manufacture an unrestricted substitution theorem, a subject-reduction theorem, or a global Church–Rosser result.

The structural rows G, H, C, P, N preserve the same finite route under TasteGate readiness, transport, replay, provenance, and local naming. Hence the checker handoff remains bounded local-join data. □

Theorem 4126.4 (MetaCIC local join ledger obstruction-preserving readback)**.** *Every confluence-audit read exported by an accepted* $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$ *carrier preserves the obstruction row O beside the candidate join. A consumer may pass the local ledger to the local-diamond witness, residual checker, substitution-boundary packet, diamond-boundary packet, or subject-reduction discharge socket named above, but it cannot erase the residual-substitution boundary or reinterpret the ledger as full MetaCIC confluence.*

Proof. Start from the bounded checker handoff of Definition 4126.3. The local join is consumed only after the peak, join, checker, residual, substitution-boundary, and obstruction rows have been displayed together.

The sibling handoffs preserve that pairing. The local-diamond witness may read K and A, the residual checker may read B, R, S, O, the substitution-boundary and diamond-boundary packets may read the same residual-substitution interface, and the subject-reduction discharge socket may read the obstruction as a boundary rather than as a proof.

Since O is a carrier coordinate and no sibling handoff adds a hidden theorem row, every readback keeps the obstruction visible. The exported ledger is therefore finite local-join data, not unrestricted substitution compatibility, full confluence, subject reduction, evaluator equality, or kernel consistency. □

Theorem 4126.5 (MetaCIC local join ledger TasteGate readiness)**.** *The later Lean side must provide* Nontrivial *and* FieldFaithful TasteGate *instances for* $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$ *at the displayed finite carrier surface*

$$K, A, B, R, S, O, G, H, C, P, N.$$

Those instances must certify that the packet is neither empty nor field-forgetting: every accepted carrier visibly retains the local peak, candidate join, bounded checker handoff, residual frontier, substitution boundary, obstruction readback, transport, replay, provenance, and local NameCert data.

Lean4 ✓ `BEDC.Derived.MetaCICLocalJoinLedgerUp.MetaCICLocalJoinLedgerTasteGate single carrier alignment`

Proof. The readiness row G in Definition 4126.1 is tied to the whole local-join ledger rather than to a single obstruction field.

Nontriviality must exhibit an accepted packet with the displayed finite rows present. FieldFaithfulness must show that deleting any of $K, A, B, R, S, O, H, C, P, N$ changes the readable carrier surface. Thus the TasteGate burden remains at the same finite packet boundary as the NameCert obligations. □

Falsifiable prediction: A $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$ confluence-audit read factors through displayed local-peak rows, candidate-join rows, bounded-checker handoff rows, residual-frontier rows, substitution-boundary rows, obstruction readback rows, Nontrivial and FieldFaithful TasteGate readiness, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: metacic-local-diamond-witness, metacic-confluence-residual-checker, metacic-confluence-substitution-boundary, metacic-confluence-diamond-boundary, subject-reduction-discharge-socket: none is bijective with $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$ because this packet jointly carries a local peak, candidate join, bounded checker handoff, residual frontier, substitution boundary, obstruction-preserving readback, TasteGate readiness, replay, transport, provenance, and local naming as one ledger surface.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICLocalJoinLedger}^{\uparrow}}$ **·**

Constructive story: A $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$ packet is generated from local-peak rows, candidate-join rows, bounded-checker handoff rows, residual-frontier rows, substitution-boundary rows, obstruction readback rows, Nontrivial and FieldFaithful TasteGate readiness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICLocalJoinLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4126.1, Definition 4126.2, Definition 4126.3, Definition 4126.4, and Definition 4126.5 seed the finite local-join ledger for MetaCIC confluence audit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICLocalJoinLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full confluence, unrestricted substitution compatibility, arbitrary subject reduction, evaluator equality, quotient equality of terms, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local-peak exposure, candidate-join exactness, bounded-checker handoff, residual-frontier coverage, substitution-boundary retention, obstruction-preserving readback, TasteGate nontriviality, FieldFaithful coverage, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICLocalJoinLedgerUp.

Chapter 4127

A Concrete Naming Certificate for $\mathsf{HemicompactSpace}^{\uparrow}$

Following Kelley and Engelking on hemicompact spaces, the $\mathsf{HemicompactSpace}^{\uparrow}$ packet records compact exhaustion as explicit finite-name data. It sits over the metric carrier of chapter 57, the compact metric window surface of chapter 129, the finite stream schedule of chapter 126, the formal-ball neighborhood route of chapter 1510, and the real-radius seal of chapter 38. The carrier names a countable displayed exhaustion by compact windows; it does not infer open-cover compactness, select covers by choice, or assume that the whole host space is compact.

Definition 4127.1 (Hemicompact-space carrier)**.** *A* $\mathsf{HemicompactSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, K, S, F, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the ambient* $\mathsf{Met}^{\uparrow}$ *row, including the point classifier, distance readback, and finite observation histories used by the exhaustion.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *exhaustion-window row; its entries name compact metric windows K_i as finite BEDC data and expose their local compact certificates only when the corresponding index is displayed.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *index schedule recording the inspected exhaustion indices, monotone window requests, and replayed finite prefixes.*
4. *F is the* $\mathsf{FormalBall}^{\uparrow}$ *neighborhood-window row that reads local center-radius data inside a displayed compact window before any neighborhood consumer uses it.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *radius-seal row attached to the formal-ball windows and to the compact-window containment tests.*
6. *H records componentwise* hsame *transport for M, K, S, F, R, C, P, N and for the local classifier row.*
7. *C records displayed* Cont *replay from an index request through the compact window, formal-ball neighborhood window, real-radius seal, transport, provenance, and local name.*
8. *P is the* Pkg *provenance over* $\mathsf{HemicompactSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{HemicompactSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by replaying $M, K, S, F, R, H, C, P, N$. It has no coordinate for an open-cover compactness theorem, a choice-selected cover, a selected global compactification, host-space compactness, quotient equality of exhaustion sequences, or ambient completeness.

Lean4 ✓ `BEDC.Derived.HemicompactSpaceUp.HemicompactSpaceTasteGate single carrier alignment`

Theorem 4127.2 (HemicompactSpace NameCert obligations)**.** *For every accepted* $\mathsf{HemicompactSpace}^{\uparrow}$ *carrier $E = (M, K, S, F, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HemicompactSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed metric source, compact-window exhaustion, stream index schedule, formal-ball neighborhood windows, real-radius seals, transport, replay, provenance, and local name;*
2. *compact-window accountability, requiring every compactness read to pass through the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *row K at an index supplied by the schedule S;*
3. *neighborhood-window accountability, requiring every local neighborhood read to pass through the* $\mathsf{FormalBall}^{\uparrow}$ *row F and the* $\mathsf{Real}^{\uparrow}$ *radius seals R over the same metric source M;*
4. *componentwise* hsame *transport and* Cont *replay stability for the same finite rows;*
5. *ledger refusal, stating that open-cover compactness, choice-selected covers, host compactness, quotient equality of exhaustion sequences, and ambient completeness are not carrier coordinates.*

No local obligation is stored outside these rows.

Proof. Project the carrier in Definition 4127.1. The analytic rows are exactly the metric source, compact-window exhaustion, index schedule, formal-ball neighborhood row, and real-radius seals.

The compact and neighborhood obligations are ordered by the displayed schedule. A consumer first reads an index in S, then the compact metric window in K, and only then the formal-ball and real-radius rows F, R available over that window.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since the excluded compactness and choice principles are absent from the carrier, no NameCert obligation can export them. □

Theorem 4127.3 (Hemicompact exhaustion window)**.** *Every accepted* $\mathsf{HemicompactSpace}^{\uparrow}$ *read of a compact exhaustion window factors through*

$$M, S, K, F, R, H, C, P, N.$$

In particular, the consumer receives an index from the $\mathsf{StreamName}^{\uparrow}$ *schedule, the corresponding* $\mathsf{CompactMetric}^{\uparrow}$ *window, the local* $\mathsf{FormalBall}^{\uparrow}$ *neighborhood rows, and the* $\mathsf{Real}^{\uparrow}$ *radius seals over the same* $\mathsf{Met}^{\uparrow}$ *source before the local* NameCert *row is consumed. The route exports no open-cover compactness proof, selected cover family, host-space compactness witness, quotient exhaustion equality, or ambient completeness.*

Proof. Start with the index schedule. The row S is the only coordinate that can name which exhaustion window is being inspected, so a compact-window read cannot begin with an unindexed compact object.

Read K, F, R at the displayed index. The compact metric window comes from K, while formal-ball neighborhoods and radius seals are replayed through F and R over the same metric source M.

Finally attach H, C, P, N. These rows preserve the same finite route under transport and replay, and they contain no open-cover, choice-selected, quotient, host compactness, or ambient-completeness coordinate. □

Theorem 4127.4 (Hemicompact nonescape)**.** *Every neighborhood or compact-window consumer of an accepted* $\mathsf{HemicompactSpace}^{\uparrow}$ *carrier remains inside the finite route through* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. The consumer cannot escape to open-cover compactness, choice-selected finite subcovers, a compact host-space assertion, selected representatives of exhaustion windows, quotient equality, or ambient completeness.*

Proof. Project the accepted packet. The only analytic coordinates are M, K, S, F, R, and each is displayed before the local naming row is available.

Use the exhaustion-window theorem. It forces compact and neighborhood reads to pass through the scheduled compact metric window, formal-ball row, and real-radius seal rather than through an external compactness theorem.

The remaining rows are structural. Transport, replay, provenance, and local naming keep the read inside the displayed BHist packet, so there is no coordinate from which a consumer can obtain the excluded principles. □

Falsifiable prediction: Every $\mathsf{HemicompactSpace}^{\uparrow}$ consumer of a compact exhaustion window reads a MetricSpaceUp source, CompactMetricUp window, StreamNameUp index schedule, FormalBallUp neighborhood row, RealUp radius seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: metricspace, compactmetric, streamname, formalball, real: $\mathsf{HemicompactSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an indexed compact-exhaustion schedule, compact metric windows, formal-ball neighborhood windows, real-radius seals, transport, replay, provenance, and local NameCert rows as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HemicompactSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{HemicompactSpace}^{\uparrow}$ packet is generated from a MetricSpaceUp source, CompactMetricUp exhaustion windows, a StreamNameUp index schedule, FormalBallUp neighborhood windows, RealUp radius seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HemicompactSpace}^{\uparrow}}$, seed)

Scope closed: Definition 4127.1, Definition 4127.2, Definition 4127.3, and Definition 4127.4 seed the finite compact-exhaustion interface over scheduled compact metric windows and formal-ball neighborhoods.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HemicompactSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected finite subcovers, host-space compactness, quotient exhaustion equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-window accountability, index-schedule exactness, formal-ball and real-radius replay, transport stability, provenance, and local naming for BEDC.Derived.HemicompactSpaceUp.

Chapter 4128

A Concrete Naming Certificate for $\mathsf{DistanceFunctionCompletion}^{\uparrow}$

Following Bourbaki and Kelley on metric completion by distance functions, the $\mathsf{DistanceFunctionCompletion}^{\uparrow}$ packet records the L10 route where a metric source is read through its distance-to-source observations before later completion and separated-completion consumers inspect it. It sits after the metric carrier of chapter 57, the metric-completion boundary of chapter 1506, the Kuratowski embedding route of chapter 7569, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the distance-function completion route as finite BEDC data; it is not a quotient completion, selected representative, host equality of completed points, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 4128.1 (DistanceFunctionCompletion carrier)**.** *A* $\mathsf{DistanceFunctionCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, C, K, S, R, D, A, H, T, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose distances are observed.*
2. *C is the* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer row reached only after the source metric observations have been displayed.*
3. *K is the* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *distance-function handoff row from the source metric into the completion-facing observation space.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected distance observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational values exposed by those windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare requested distances and finite approximants.*
7. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for each displayed distance value.*
8. *H records componentwise* hsame *transport for the metric source, completion row, Kuratowski handoff, stream windows, regular readback, dyadic ledger, real seal, replay, provenance, and local naming rows.*

9. *T records displayed* Cont *replay of the route*

$$M, K, S, R, D \longmapsto A \longmapsto C \longmapsto H, P, N.$$

10. *P is the* Pkg *provenance over* DistanceFunctionCompletion$^{\uparrow}$, Met$^{\uparrow}$, MetricCompletion$^{\uparrow}$, KuratowskiEmbedding$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{DistanceFunctionCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, C, K, S, R, D, A, H, T, P, N$. It has no coordinate for quotient completion classes, selected completed points, host equality of distance functions, countable choice over source points, ambient completeness of Real$^{\uparrow}$*, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DistanceFunctionCompletionUp.DistanceFunctionCompletionTasteGate single carrier alignment`

Theorem 4128.2 (DistanceFunctionCompletion NameCert obligations)**.** *For every accepted* DistanceFunctionComp *carrier*

$$F = (M, C, K, S, R, D, A, H, T, P, N),$$

the local NameCert$_{\text{DistanceFunctionCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the metric source, metric-completion consumer, Kuratowski embedding, stream-window, regular-rational, dyadic-tolerance, real-seal, transport, replay, provenance, and local naming rows;*
2. *distance-function exposure, requiring every completion-facing read to pass through M and K before C may be consumed;*
3. *L10 readback, requiring each displayed distance observation to pass through S, R, D, A before it is available to a completion consumer;*
4. *transport stability, requiring* hsame *comparison to preserve the source metric, distance-function handoff, readback route, completion consumer, replay, provenance, and local naming rows componentwise;*
5. *replay locality, requiring* Cont *replay to use only the displayed route from M, K, S, R, D through A and C;*
6. *non-escape, excluding quotient completion classes, selected completed points, host equality of completed points or distance functions, countable choice, ambient* Real$^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 4128.1. The displayed packet supplies exactly the source metric row, the distance-function handoff, the finite observation route, the completion consumer, and the structural rows.

Distance-function exposure starts with M and K. A completion-facing read has no access to C until the source metric and its Kuratowski distance observations have both been displayed.

The L10 readback is the route S, R, D, A. Stream windows name the inspected observations, regular rational rows read them back, dyadic tolerance rows compare requested scales, and the real seal records the terminal value visible to completion consumers.

Finally H, T, P, N preserve and name the same route. Since no excluded quotient, selector, host-equality, choice, completeness, verification, or bridge object is a carrier row, the listed obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{DistanceFunctionCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{DistanceFunctionCompletion}^{\uparrow}$ packet is generated from a MetricUp source row, a MetricCompletionUp consumer row, a KuratowskiEmbeddingUp distance-function handoff, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DistanceFunctionCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4128.1 and Definition 4128.2 seed the finite distance-function completion route through metric source observations, Kuratowski embedding, L10 readback, and completion consumption.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DistanceFunctionCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion classes, selected completed points, host equality of completed points or distance functions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, bridge checking, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, distance-function exposure, L10 readback, transport stability, replay locality, provenance, and local naming for BEDC.Derived.DistanceFunctionCompletionUp.

Chapter 4129

A Concrete Naming Certificate for $\mathsf{MinimalTriggerLiftBundle}^{\uparrow}$

The $\mathsf{MinimalTriggerLiftBundle}^{\uparrow}$ packet realizes the lift-fiber decomposition of Definition 9462.1687 as finite BEDC NameCert data. It sits beside the codon-window carrier of chapter 2234, the lift-orbit classifier of chapter 4059, the DNA boundary-tile packet of chapter 3393, and the trigger-algebra surface of chapter 3478. The packet records quotient supports, binary lift choices, orbit fibers, and lift-flip ledgers as displayed finite rows; it is not biological mechanism, stochastic fitness, host quotient semantics, or an unrecorded enumeration oracle.

Definition 4129.1 (Minimal trigger lift-bundle carrier)**.** *A* $\mathsf{MinimalTriggerLiftBundle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, L, O, F, G, H, C, P, N)$$

with the following displayed rows:

1. *Q is the quotient-support row, listing a quotient-level minimal trigger and its displayed support cells.*
2. *L is the lift-choice row, recording one binary f_3 lift coordinate for each displayed quotient support.*
3. *O is the orbit-fiber row, naming the fiber dimension and orbit type read from the quotient minimal-trigger table.*
4. *F is the finite fiber-count row, displaying the Q_1, Q_2, Q_3, and Q_4 multiplicities and the codon count readback.*
5. *G is the lift-flip ledger, recording the within-fiber one-coordinate flip graph and its edge-count row.*
6. *H records componentwise* hsame *transport for quotient supports, lift choices, orbit fibers, fiber counts, lift-flip ledgers, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from a quotient support through lift choices, fiber counting, orbit labeling, and flip-ledger exposure.*
8. *P is the* Pkg *provenance over* $\mathsf{MinimalTriggerLiftBundle}^{\uparrow}$*, the source theorem Definition 9462.1687,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MinimalTriggerLiftBundle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, L, O, F, G, H, C, P, N$. It has no coordinate for hidden quotient semantics, empirical biology, probabilistic fitness, an unrestricted search space, or a lift choice detached from the displayed quotient support.

Lean4 ✓ `BEDC.Derived.MinimalTriggerLiftBundleUp.MinimalTriggerLiftBundleTasteGate single carrier alignment`

Theorem 4129.2 (Minimal trigger lift-bundle NameCert obligations)**.** *For every accepted* MinimalTriggerLiftBundle *carrier $B = (Q, L, O, F, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MinimalTriggerLiftBundle}^{\uparrow}}$ *surface consists exactly of quotient-support admission through Q, lift-choice admission through L, orbit-fiber readback through O, finite fiber-count preservation through F, lift-flip ledger exposure through G, componentwise* hsame *transport through H, displayed replay through C, provenance through P, and local naming through N. The carrier admits no read of a codon-level trigger before the quotient support and the matching lift-choice row have both been displayed.*

Proof. Project the carrier of Definition 4129.1. The quotient-support row Q fixes the base trigger, and the lift-choice row L records exactly one binary lift coordinate for each displayed support.

The orbit-fiber row O and count row F are read from the decomposition of Definition 9462.1687. The lift-flip row G records adjacency only inside the same displayed fiber, so no cross-fiber bijection is introduced.

Transport and replay preserve the rows componentwise, while provenance and local naming source the same finite packet. Therefore the listed rows exhaust the local NameCert obligations and prevent detached quotient semantics or hidden enumeration data. □

Theorem 4129.3 (Minimal trigger lift-bundle vision handoff)**.** *The decomposition*

$$\mathcal{T}_c = Q_1 \sqcup 25Q_2 \sqcup 22Q_3 \sqcup Q_4$$

is consumed by $\mathsf{MinimalTriggerLiftBundle}^{\uparrow}$ *only through the finite route*

$$Q, L \longmapsto O, F, G \longmapsto H, C, P, N.$$

Later Lean-facing TasteGate files for this packet must provide Nontrivial $\mathsf{MinimalTriggerLiftBundle}^{\uparrow}$ *and* FieldFaithful $\mathsf{MinimalTriggerLiftBundle}^{\uparrow}$ *instances before the packet can serve as a verified downstream trigger-lattice consumer.*

Proof. Read the source decomposition through its displayed finite rows. The quotient support gives Q, and the independent binary lift choices give L.

The fiber dimension, multiplicity, and codon count are then recorded by O and F. The lift-flip graph row G is internal to each fiber and does not identify different quotient supports.

The structural rows H, C, P, N transport, replay, source, and name exactly that finite route. The stated TasteGate obligations are therefore downstream instance requirements, not hidden assumptions inside the present paper carrier. □

Falsifiable prediction: For every accepted $\mathsf{MinimalTriggerLiftBundle}^{\uparrow}$ packet, replacing each displayed row by a componentwise hsame row preserves the finite fiber counts $1, 25, 22, 1$ over Q_1, Q_2, Q_3, Q_4 and the codon total 294.

Independence witness: codon-six-bit-window, codon-lift-orbit-classifier, dna-window-six-boundary-tile, window-coverage-trigger-algebra: none is bijective with $\mathsf{MinimalTriggerLiftBundle}^{\uparrow}$ because this

packet jointly carries quotient supports, lift-choice vectors, orbit fibers, finite fiber counts, lift-flip ledgers, componentwise transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MinimalTriggerLiftBundle}^{\uparrow}}$.

Constructive story: A $\mathsf{MinimalTriggerLiftBundle}^{\uparrow}$ packet is generated from quotient-support rows, binary lift-choice rows, orbit-fiber rows, finite fiber-count rows, lift-flip ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MinimalTriggerLiftBundle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4129.1, Definition 4129.2, and Definition 4129.3 seed the finite lift-fiber NameCert route over quotient supports, lift choices, orbit fibers, fiber counts, and flip ledgers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MinimalTriggerLiftBundle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic fitness, host quotient semantics, unrestricted trigger search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked quotient-support admission, lift-choice admission, orbit-fiber readback, finite fiber-count preservation, lift-flip ledger exposure, and TasteGate instances for BEDC.Derived.MinimalTriggerLiftBundleUp.

Chapter 4130

A Concrete Naming Certificate for $\mathsf{BishopUniformContinuityModulus}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{BishopUniformContinuityModulus}^{\uparrow}$ packet records an explicit tolerance-to-source-window modulus as finite BEDC NameCert data. It sits on the finite stream surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the metric source rows of chapter 57, the continuous-map graph of chapter 130, and the downstream modulus consumer of chapter 369. The packet names the constructive uniform-continuity modulus needed by the open L10 real and completion route; it does not import open-cover compactness, countable choice, quotient real equality, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4130.1 (Bishop uniform-continuity modulus carrier)**.** *A* $\mathsf{BishopUniformContinuityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, F, T, L, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source-window row naming the finite input observations that a tolerance request may inspect.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, including the displayed pointwise continuity data whose local bounds are eligible for uniform readback.*
3. *T is the tolerance-row carrier admission ledger, recording the requested target precision and the finite source-window budget produced for that request.*
4. *L is the pointwise-to-uniform modulus ledger, displaying the finite route from local continuity rows to one uniform source tolerance.*
5. *D is the dyadic lower-bound readback row, computed inside the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance discipline and exposed before any real-valued consumer reads the modulus.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the source and target estimates.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after S, F, T, L, D, R have been displayed.*
8. *H records componentwise* hsame *transport for source-window, continuous-map, tolerance, ledger, dyadic, regular-readback, real-seal, replay, provenance, and naming rows.*

9. *C records displayed* Cont *replay from a target-tolerance request through the same finite modulus route.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopUniformContinuityModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopUniformContinuityModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, F, T, L, D, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, countable choice, selected representatives, quotient equality of real names, a hidden host modulus, or ambient completion.

Lean4 ✓ `BEDC.Derived.BishopUniformContinuityModulusUp.TasteGate.BishopUniformContinuityModulusTasteGate`
`single carrier alignment`

Theorem 4130.2 (Bishop uniform-continuity modulus NameCert obligations)**.** *For every accepted* $\mathsf{BishopUniformContinuityModulus}^{\uparrow}$ *carrier $M = (S, F, T, L, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopUniformContinuityModulus}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *tolerance-row carrier admission through T;*

2. *pointwise-to-uniform modulus ledger exposure through L;*

3. *dyadic lower-bound readback through D;*

4. $\mathsf{Real}^{\uparrow}$ *seal nonescape through E;*

5. *provenance and name exhaustion through P, N together with transport and replay rows H, C.*

Every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of the packet must read those rows through the displayed carrier route, and no accepted read may project compactness, choice, quotient equality, selected representatives, or a host modulus.*

Proof. Project the carrier of Definition 4130.1. The source-window row S and continuous-map row F are visible before any tolerance output is read.

The tolerance row T and ledger row L record the constructive step from a requested target precision to a uniform source window. The dyadic row D supplies the finite lower-bound comparison, and the regular readback row R makes that comparison available to real-name consumers.

Finally the seal row E is downstream of the displayed route, while H, C, P, N transport, replay, source, and name the same finite packet. Since no other carrier coordinate exists, the listed five obligation rows exhaust the local NameCert surface. □

Theorem 4130.3 (Bishop uniform-continuity modulus compact handoff)**.** *Any compact-uniform-continuity, continuous-map, or* $\mathsf{Real}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{BishopUniformContinuityModulus}^{\uparrow}$ *packet must factor its read through*

$\mathsf{StreamName}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg,

Thus the packet supplies a finite constructive modulus object for later compact-uniform-continuity and completion-facing chapters without importing choice, open-cover compactness, selected representatives, quotient equality, or ambient real completeness.

Proof. Use Definition 4130.2. A downstream read first exposes the finite source window, the continuous-map row, the tolerance row, the pointwise-to-uniform ledger, and the dyadic lower-bound readback.

The regular rational row and real seal then pass the same displayed estimates to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers. The $\mathsf{UniformModulus}^{\uparrow}$ output is therefore a named row of the finite packet, not a hidden host function.

Transport, replay, provenance, and local naming preserve only the displayed coordinates. The compact handoff can cite the modulus object, but it receives no open-cover compactness, choice principle, quotient equality, selected representative, or ambient completeness theorem from this chapter. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopUniformContinuityModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopUniformContinuityModulus}^{\uparrow}$ packet is generated from source-window rows, continuous-map rows, tolerance rows, pointwise-to-uniform ledgers, dyadic lower-bound readback, regular rational readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopUniformContinuityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4130.1, Definition 4130.2, and Definition 4130.3 seed the finite Bishop uniform-continuity modulus route for L10 real and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopUniformContinuityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected representatives, quotient real equality, host modulus functions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-row admission, pointwise-to-uniform ledger exposure, dyadic lower-bound readback, Real seal nonescape, and provenance/name exhaustion for BEDC.Derived.BishopUniformContin

Chapter 4131

A Concrete Naming Certificate for $\mathsf{CompactContinuousInverse}^{\uparrow}$

Following Kelley and Bishop–Bridges on compact Hausdorff inverse-continuity arguments, the $\mathsf{CompactContinuousInverse}^{\uparrow}$ packet records the finite BEDC surface by which a continuous bijection from a compact finite-net source into a separated target receives a displayed inverse-continuity handoff. It sits over the compact carrier of chapter 60, the continuous-map graph of chapter 130, the separated target boundary of chapter 1411, and the uniform-homeomorphism consumer of chapter 1815. The packet names only finite-net inverse readback; it does not import open-cover compactness, quotient equality of maps, host inverse functions, ambient $\mathsf{Real}^{\uparrow}$ completeness, countable choice, or a global topological inverse theorem.

Definition 4131.1 (Compact continuous inverse carrier)**.** *A* $\mathsf{CompactContinuousInverse}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (K, F, B, S, G, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-net source row, exposing the compact packet only through named finite covers and source-window witnesses.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, recording the forward graph and its local continuity data over the displayed compact source.*
3. *B is the bijection ledger, recording graph-totality, graph-single-valuedness, target coverage, and source uniqueness for the same displayed map row.*
4. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *target-separation row, or the corresponding Hausdorff separation read when the target is supplied through* $\mathsf{HausdorffSpace}^{\uparrow}$*.*
5. *G is the inverse graph readback row: a target observation reads a unique source window only through B and then returns to the forward graph row F.*
6. *M is the finite-net modulus extraction row, turning the compact source row K, graph row F, bijection ledger B, and separation row S into a named inverse-continuity tolerance window.*
7. *H records componentwise* hsame *transport for the compact, graph, bijection, separation, inverse-readback, and modulus rows.*
8. *C records displayed* Cont *replay from a target-window request through G and M back to the same finite source-net route.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactContinuousInverse}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{UniformHomeomorphism}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactContinuousInverse}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient host inverse function, quotient equality of maps, open-cover compactness, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactContinuousInverseUp.CompactContinuousInverseTasteGate single carrier alignment`

Theorem 4131.2 (Compact continuous inverse NameCert obligations)**.** *For every accepted* CompactContinuousInve *carrier $I = (K, F, B, S, G, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactContinuousInverse}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact source, continuous graph, bijection ledger, separated target, inverse graph readback, finite-net modulus, hsame transport, Cont replay, provenance, and local naming rows. Every inverse-continuity read must inspect K, F, B, S before G and M are available, and every transport or replay read must preserve the same ordered route through H, C, P, N.*

Proof. Project the carrier of Definition 4131.1. The rows K, F, B, S display the compact source, forward graph, bijection data, and target separation before any inverse read is admitted.

The inverse graph row G is therefore a readback of the same graph through the bijection ledger, not a host inverse function. The finite-net modulus row M consumes the compact finite-net row and the separated target row after the graph has been fixed.

Finally H, C, P, N transport, replay, source, and name exactly that route. Since the carrier has no additional inverse, quotient-map equality, selected representative, choice, open-cover, or ambient-completeness coordinate, the stated rows exhaust the local NameCert obligations. □

Theorem 4131.3 (Compact continuous inverse uniform handoff)**.** *Any* $\mathsf{UniformHomeomorphism}^{\uparrow}$ *or inverse-continuity consumer that reads an accepted* $\mathsf{CompactContinuousInverse}^{\uparrow}$ *packet must factor its read through*

$$\mathsf{Compact}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The exported handoff is the finite-net modulus row M together with the inverse graph readback row G; it is not an open-cover compactness theorem, a quotient equality of functions, a selected host inverse, a countable-choice construction, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with an accepted consumer read. The carrier admits only $K, F, B, S, G, M, H, C, P, N$, so the source compactness and forward graph data must be visible before the inverse graph is read.

The row G turns target observations back into source windows through the bijection ledger. The row M then extracts the finite-net modulus from the compact source and separated target route.

Transport and replay preserve that same route through H and C, while P and N attach provenance and local naming. The consumer may use the resulting modulus as a uniform-homeomorphism handoff, but it receives no extra host inverse, quotient equality, open-cover compactness, choice, or real-completeness principle. □

Theorem 4131.4 (Compact continuous inverse finite-net readback)**.** *Let $I = (K, F, B, S, G, M, H, C, P, N)$ be an accepted* $\mathsf{CompactContinuousInverse}^{\uparrow}$ *carrier. Every target-neighbourhood request for inverse continuity is answered by first reading the inverse graph row G, then the finite-net modulus row M, and then replaying the answer through C over the same K, F, B, S dependency route.*

Proof. The request enters through the separated target row S and the inverse graph readback row G. The graph readback uses the bijection ledger B and the forward graph row F, so it cannot select a host inverse independently of the displayed map.

The finite-net modulus row M then uses the compact source row K to extract a finite source-window response. This is the only modulus coordinate in the packet.

The replay row C returns the answer along the same ordered rows, and H, P, N preserve the route under transport, provenance, and local naming. No open-cover, quotient-equality, selected-representative, choice, or ambient-completeness read is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactContinuousInverse}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactContinuousInverse}^{\uparrow}$ packet is generated from compact finite-net source rows, continuous-map graph rows, bijection ledgers, separated-target rows, inverse graph readback, finite-net modulus extraction, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactContinuousInverse}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4131.1, Definition 4131.2, Definition 4131.3, and Definition 4131.4 seed the finite inverse-continuity route from compact source data, a continuous bijection ledger, separated target data, inverse graph readback, and finite-net modulus extraction.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactContinuousInverse}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient map equality, host inverse functions, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, continuous-bijection ledger exactness, separated-target readback, inverse graph readback, finite-net modulus extraction, transport replay, provenance, and local NameCert rows for BEDC.Derived.CompactContinuousInverseUp.

Chapter 4132

A Concrete Naming Certificate for $\mathsf{HausdorffRealCompletion}^{\uparrow}$

Following Bishop–Bridges constructive real analysis and Bourbaki's separated completion discipline, the $\mathsf{HausdorffRealCompletion}^{\uparrow}$ packet records the route by which the separated Hausdorff completion surface is read through the displayed regular real-name faces. It sits after the separated completion carrier of chapter 402, the terminal real-name seal of chapter 38, and the regular rational readback of chapter 301. The packet gives completion-facing consumers a named separated Real-completion certificate without asserting quotient completion equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4132.1 (Hausdorff real completion carrier)**.** *A* $\mathsf{HausdorffRealCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, U, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separated-completion row that exposes the separated carrier and its local equality boundary.*
2. *U is the* $\mathsf{MetricCompletionUniqueness}^{\uparrow}$ *uniqueness row read only as separated limit uniqueness inside the displayed completion route.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule supplying the observable Cauchy-name requests.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling all finite radii and comparison slacks.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from S and D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached from the regular readback route.*
7. *H records componentwise* hsame *transport for the separated-completion, uniqueness, stream, dyadic, regular-rational, real-seal, replay, provenance, and local-name rows.*
8. *C records displayed* Cont *replay from a separated Real-completion request through $A, U, S, D, R, E, H, P, N$.*
9. *P records* Pkg *provenance over* $\mathsf{HausdorffRealCompletion}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{MetricCompletionUniqueness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffRealCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, U, S, D, R, E, H, C, P, N$. It stores no quotient completion equality, selected completion point, host real equality, countable-choice schedule, hidden Cauchy filter, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.HausdorffRealCompletionUp.HausdorffRealCompletionTasteGate single carrier alignment`

Theorem 4132.2 (Hausdorff real completion NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffRealCompletion}^{\uparrow}$ *carrier*

$$Q = (A, U, S, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HausdorffRealCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separated-completion exposure through A,* $\mathsf{MetricCompletionUniqueness}^{\uparrow}$ *separated uniqueness exposure through U, finite* $\mathsf{StreamName}^{\uparrow}$ *window inspection through S,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting through D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *seal discipline through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4132.1. The packet displays exactly the separated-completion row, uniqueness row, finite windows, dyadic tolerance ledger, regular rational readback, terminal real seal, and structural rows.

Read the separated-completion route first. The row A supplies only the Hausdorff completion surface, while U records the uniqueness boundary available inside that separated route.

Read the Real-name route next. The finite windows S are measured by the dyadic ledger D, the regular rational row R is read from those displayed requests, and the real seal E is reached only after the regular readback appears.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no further analytic coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 4132.3 (Hausdorff real completion separated limit uniqueness)**.** *Every completion-facing consumer of an accepted* $\mathsf{HausdorffRealCompletion}^{\uparrow}$ *packet receives separated limit uniqueness only through the finite route*

$$\mathsf{HausdorffCompletion}^{\uparrow} \longmapsto \mathsf{MetricCompletionUniqueness}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto$$

The route is a separated Real-completion readback certificate, not a quotient completion equality theorem, a selected representative, a hidden Cauchy-filter construction, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Apply Definition 4132.2. It orders every public completion-facing read through A, U, S, D, R, E before any separated uniqueness claim is visible.

The separated side is local to A and U. The Hausdorff completion row supplies the separated carrier boundary, and the metric-completion uniqueness row supplies only the uniqueness read available inside that displayed boundary.

The real-name side is local to S, D, R, E. Stream windows, dyadic tolerances, and regular rational readback must be displayed before the terminal $\mathsf{Real}^{\uparrow}$ seal can be consumed by the same route.

Thus a consumer cannot replace the route by quotient completion equality, selected representatives, hidden filters, host equality, or ambient completeness. The packet records separated limit uniqueness only as the displayed finite NameCert route. □

Theorem 4132.4 (Hausdorff real completion nonescape)**.** *No accepted* $\mathsf{HausdorffRealCompletion}^{\uparrow}$ *packet exports quotient completion equality, a selected completion representative, hidden Cauchy-filter data, countable choice, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*. Every exported separated-completion or Real-facing read is confined to the rows* $A, U, S, D, R, E, H, C, P, N$*.*

Proof. Inspect the carrier definition. Its analytic coordinates are exactly the separated-completion row A, uniqueness row U, stream windows S, dyadic tolerance ledger D, regular rational readback R, and real seal E.

The structural rows add no new analytic principle. Transport through H, replay through C, provenance through P, and local naming through N preserve the displayed packet rather than introducing quotient equalities, representative choices, hidden filters, host equality, or completeness.

Use the separated uniqueness theorem, Definition 4132.3. Every separated-completion or Real-facing consumer must pass through the displayed finite route, so none of the excluded data can escape from the packet. □

Falsifiable prediction: Every accepted $\mathsf{HausdorffRealCompletion}^{\uparrow}$ consumer that claims separated limit uniqueness without reading $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{MetricCompletionUniqueness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row refutes the packet surface.

Independence witness: hausdorffcompletion, metriccompletionuniqueness, streamname, dyadicratcore, regseqrat, real: no listed sibling is bijective to $\mathsf{HausdorffRealCompletion}^{\uparrow}$ because this packet binds separated completion, separated limit uniqueness, finite windows, tolerance accounting, regular readback, Real seal, transport, replay, provenance, and local naming as one L10 route.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffRealCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffRealCompletion}^{\uparrow}$ packet is generated from a HausdorffCompletion separated-completion row, MetricCompletionUniqueness separated uniqueness row, StreamName finite windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffRealCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4132.1, Definition 4132.2, Definition 4132.3, and Definition 4132.4 seed the separated Real-completion route over HausdorffCompletionUp, MetricCompletionUniquenessUp, StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffRealCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, hidden Cauchy filters, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove carrier admission, separated-completion exposure, uniqueness exposure, window exactness, tolerance exactness, RegSeqRat readback, Real seal handoff, transport, replay, provenance, and nonescape for BEDC.Derived.HausdorffRealCompletionUp.

Chapter 4133

A Concrete Naming Certificate for $\mathsf{NeighborhoodFilter}^{\uparrow}$

Following Kelley and Bourbaki, the $\mathsf{NeighborhoodFilter}^{\uparrow}$ packet records the local filter generated by displayed neighbourhood rows around a named point or finite source window. It sits between the finite directed basis interface of chapter 1601, the Cauchy-filter surface of chapter 333, the metric source of chapter 57, the open-neighbourhood discipline of chapter 88, and the completion handoff of chapter 1569. The packet names a local neighbourhood-filter interface; it does not quotient filters, select ultrafilters, choose limits, assert host point equality, or import ambient completeness.

Definition 4133.1 (NeighborhoodFilter carrier)**.** *A* $\mathsf{NeighborhoodFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, x, O, B, D, C, M, T, H, K, P, N)$$

with the following displayed rows:

1. *X is the source carrier row whose visible points are consumed through* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Topology}^{\uparrow}$ *data.*
2. *x is the focused point or source-window row around which the local filter is read.*
3. *O is the finite open-neighbourhood row, exposed through the* $\mathsf{Topology}^{\uparrow}$ *classifier.*
4. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *row generated by the displayed neighbourhood family.*
5. *D is the directed-refinement ledger: two displayed neighbourhood rows admit a smaller displayed neighbourhood row before any filter consumer reads downstream data.*
6. *C is the* $\mathsf{CauchyFilter}^{\uparrow}$ *compatibility row used when the local neighbourhood filter is consumed by completion routes.*
7. *M is the* $\mathsf{Met}^{\uparrow}$ *witness row when neighbourhoods are read as metric balls or radius windows.*
8. *T records the* $\mathsf{Topology}^{\uparrow}$ *provenance that the displayed open rows are local neighbourhoods of the same focused source.*
9. *H records componentwise* hsame *transport for source, point, open row, basis row, directed refinement, Cauchy compatibility, metric read, topology provenance, replay, package, and naming rows.*
10. *K records displayed* Cont *replay from a local-neighbourhood request through $X, x, O, B, D, C, M, T, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{NeighborhoodFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{NeighborhoodFilter}^{\uparrow}}$ *row.*
The carrier contains no coordinate for ultrafilters, quotient filters, selected cluster points, host equality of neighbourhood systems, countable-choice selectors, or ambient completion theorems.

Lean4 ✓ `BEDC.Derived.NeighborhoodFilterUp.NeighborhoodFilterTasteGate single carrier alignment`

Theorem 4133.2 (NeighborhoodFilter directed completion base)**.** *For every accepted* $\mathsf{NeighborhoodFilter}^{\uparrow}$ *carrier* $U = (X, x, O, B, D, C, M, T, H, K, P, N)$*, every completion-facing read of the local filter first traverses the directed* $\mathsf{FilterBase}^{\uparrow}$ *row* B *and its refinement ledger* D*. The* $\mathsf{CauchyFilter}^{\uparrow}$ *row* C *and the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *consumer may read only the route*

$$X, x, O \longmapsto B, D \longmapsto C, M, T, H, K, P, N.$$

Thus local-neighbourhood completion data are exported as finite basis rows rather than quotient filters, ultrafilters, selected limits, or hidden host neighbourhood equality.

Proof. Project the carrier of Definition 4133.1. The only basis-facing coordinates are the open-neighbourhood row O, the generated $\mathsf{FilterBase}^{\uparrow}$ row B, and the directed-refinement ledger D.

The completion side cannot bypass those rows. A $\mathsf{CauchyFilter}^{\uparrow}$ or $\mathsf{CauchyFilterCompletion}^{\uparrow}$ consumer reads C only after B and D have supplied the local directed base, while M and T record the metric and topological provenance of the same neighbourhood family.

Finally the structural rows H, K, P, N transport, replay, package, and name that route. Since ultrafilters, quotient filters, selected limits, host equality, and choice selectors are absent from the carrier, every completion-facing read is exhausted by the displayed basis route. □

Theorem 4133.3 (NeighborhoodFilter local Cauchy handoff)**.** *Let* $U = (X, x, O, B, D, C, M, T, H, K, P, N)$ *be an accepted* $\mathsf{NeighborhoodFilter}^{\uparrow}$ *carrier. Whenever a Cauchy-filter completion route consumes the local neighbourhood filter, the handoff factors through the same* $\mathsf{FilterBase}^{\uparrow}$ *row* B*, directed-refinement ledger* D*,* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Topology}^{\uparrow}$ *provenance rows* M, T*, and local* $\mathsf{NameCert}_{\mathsf{NeighborhoodFilter}^{\uparrow}}$ *row* N*. No consumer receives an independent filter object beyond the finite packet* U*.*

Proof. Begin with Definition 4133.2. It fixes the source-to-basis-to-completion route before any completion-facing read can inspect the Cauchy row C.

Use the metric and topological provenance rows next. The row M records ball-style local reads when available, while T records open-neighbourhood membership through the topology carrier; both are attached to the same focused source X, x, O.

The local NameCert row N closes the handoff by naming the visible packet U. Thus the Cauchy-filter completion route receives finite neighbourhood-filter data, not a detached filter, selected limit, ultrafilter, quotient, host equality witness, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{NeighborhoodFilter}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NeighborhoodFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4133.1, Definition 4133.2, and Definition 4133.3 seed the local neighbourhood-filter interface over FilterBaseUp, CauchyFilterUp, MetricUp, TopologyUp, CauchyFilterCompletionUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NeighborhoodFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, ultrafilters, quotient filters, selected limits, host equality of neighbourhood systems, countable choice, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, directed-refinement coverage, metric and topology provenance, Cauchy-filter handoff, completion nonescape, and local NameCert faithfulness for BEDC.Derived.NeighborhoodFilterUp.

Constructive story: A $\mathsf{NeighborhoodFilter}^{\uparrow}$ packet is generated from a source row, focused point row, finite open-neighbourhood row, FilterBase row, directed-refinement ledger, CauchyFilter compatibility row, metric and topology provenance rows, transport and replay, package provenance, and a local NameCert row.

Chapter 4134

A Concrete Naming Certificate for $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$

Following Busemann and Bridson–Haefliger, the $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ packet records the additive boundary cocycle read by comparing two displayed disk or geodesic positions toward the same boundary point. It sits after the metric-read surface of chapter 3474, the boundary-point carrier of chapter 3732, the visual comparison route of chapter 3866, the geodesic-flow carrier of chapter 3856, and the horocycle packet of chapter 3534. The packet names a finite boundary-point and metric-read cocycle route; it does not complete the hyperbolic boundary, quotient geodesic rays, choose global representatives, or import host curvature analysis.

Definition 4134.1 (HyperbolicBusemannCocycle carrier)**.** *A* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, \Xi, R_0, R_1, G, V, Q, E, H, K, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row on the visible disk or geodesic source.*
2. *Ξ is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *boundary-point row toward which the comparison is read.*
3. *R_0 and R_1 are geodesic-ray or disk-position rows with the same displayed boundary endpoint Ξ.*
4. *G is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *transport row used to compare positions along the same boundary-facing route.*
5. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *visibility row recording the boundary comparison window.*
6. *Q is the* $\mathsf{HyperbolicHorocycle}^{\uparrow}$ *horocycle row that records equal-level surfaces for the boundary point.*
7. *E is the additive cocycle ledger. It stores the signed metric-read difference and the concatenation rule for composable displayed positions.*
8. *H records componentwise* hsame *transport for metric, boundary, ray, flow, visual, horocycle, cocycle, replay, package, and naming rows.*
9. *K records displayed* Cont *replay from a boundary-cocycle request through $M, \Xi, R_0, R_1, G, V, Q, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicHorocycle}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicBusemannCocycle}^{\uparrow}}$ *row.*
The carrier contains no coordinate for a completed ideal-boundary quotient, selected geodesic representative, ambient horosphere foliation, global curvature theorem, or physical observer trajectory.

Lean4 ✓ `BEDC.Derived.HyperbolicBusemannCocycleUp.HyperbolicBusemannCocycleTasteGate single carrier alignment`

Theorem 4134.2 (HyperbolicBusemannCocycle boundary additivity)**.** *For every accepted* HyperbolicBusemannCo *carrier* $B = (M, \Xi, R_0, R_1, G, V, Q, E, H, K, P, N)$*, the additive boundary-cocycle read is exhausted by the visible route*

$$\mathsf{HyperbolicMetric}^{\uparrow}, \mathsf{HyperbolicBusemannBoundary}^{\uparrow} \longmapsto R_0, R_1, G, V, Q \longmapsto E, H, K, P, N.$$

If a third displayed position R_2 is admitted by the same boundary row Ξ, the cocycle ledger E records the composite read from R_0 to R_2 as the concatenation of the reads from R_0 to R_1 and from R_1 to R_2, with all equality understood through the displayed hsame *and* Cont *rows of the same packet.*

Proof. Project the carrier of Definition 4134.1. The metric row M and boundary row Ξ are the only source rows from which a Busemann-level comparison can be read.

Read the geometric comparison rows. The positions R_0, R_1, flow row G, visual row V, and horocycle row Q attach the comparison to one displayed boundary endpoint rather than to an ambient ideal-boundary quotient.

The additive statement is the content of the ledger E. Its concatenation rule is transported by H and replayed by K, while P and N package and name the same finite route. Since selected ray representatives, global horosphere foliations, host curvature theorems, and physical observer trajectories have no coordinate in B, the boundary additivity read is confined to the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBusemannCocycle}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicBusemannCocycle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4134.1 and Definition 4134.2 seed the finite boundary-point, geodesic-ray, visual-metric, horocycle, additive-ledger, transport, replay, provenance, and NameCert route for the Busemann cocycle.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicBusemannCocycle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, completed ideal-boundary quotients, selected geodesic representatives, global horosphere foliations, host curvature analysis, or physical observer dynamics.

Upgrade path: Obligation closure requires checked carrier admission, boundary endpoint coverage, metric-read exactness, horocycle compatibility, additive-ledger concatenation, and local NameCert faithfulness for BEDC.Derived.HyperbolicBusemannCocycleU

Constructive story: A $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ packet is generated from hyperbolic metric, Busemann boundary, geodesic-position, geodesic-flow, visual-metric, horocycle, additive-ledger, transport, replay, package, and local NameCert rows.

Chapter 4135

A Concrete Naming Certificate for $\mathsf{BishopRealConstruction}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopRealConstruction}^{\uparrow}$ packet records the regular-Cauchy construction of the real numbers as finite BEDC NameCert data. It sits over the dyadic tolerance rows of chapter 291, the finite stream windows of chapter 126, the regular rational readback route of chapter 301, the explicit convergence ledger of chapter 332, and the terminal real-name seal of chapter 38. The packet names the human-known Bishop real construction without quotient stream equality, selected host limits, countable choice, host real equality, Dedekind-cut replacement, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4135.1 (Bishop real construction carrier)**.** *A* $\mathsf{BishopRealConstruction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, S, Q, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii, slack comparisons, and endpoint bounds used by every inspected Cauchy window.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing the finite observation schedule for the rational approximants before any real-name seal is read.*
3. *Q is the regular-Cauchy source row, retaining the named rational stream together with its displayed regularity budget.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-readback row obtained from D, S, Q, and it is the only row through which rational approximants are exported to later consumers.*
5. *M is the* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *ledger row, recording the finite modulus entries that witness the regular-Cauchy estimates read by R.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the dyadic, stream, regular-readback, and convergence-ledger rows have all been displayed.*
7. *H records componentwise* hsame *transport for dyadic tolerances, finite windows, regular sources, readback rows, convergence ledgers, real seals, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a real-construction request through the same finite route D, S, Q, R, M, E.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopRealConstruction}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealModulusOfConvergence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealConstruction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, Q, R, M, E, H, C, P, N$. It has no coordinate for quotient equality of streams, a selected host limit, countable choice, host real equality, Dedekind-cut replacement, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.BishopRealConstructionUp.BishopRealConstructionTasteGate single carrier alignment`

Theorem 4135.2 (Bishop real construction NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealConstruction}^{\uparrow}$ *carrier*

$$B = (D, S, Q, R, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRealConstruction}^{\uparrow}}$ *surface consists exactly of the following six obligation rows:*

1. *carrier admission for the dyadic tolerance ledger D, finite stream windows S, regular-Cauchy source Q, regular readback R, convergence ledger M, real seal E, transport H, replay C, provenance P, and local naming N;*
2. *tolerance-window exactness, requiring every accepted read to pair the same dyadic budget in D with the same finite windows in S;*
3. *regular-Cauchy readback, requiring the rational approximants exported by the packet to pass through Q, R before any* $\mathsf{Real}^{\uparrow}$ *consumer reads them;*
4. *convergence-ledger exposure through M, so the construction records finite regularity evidence rather than a hidden host limit;*
5. *seal nonescape through E, which blocks quotient stream equality, selected host limits, host real equality, Dedekind-cut replacement, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness;*
6. *provenance and name exhaustion through P, N together with componentwise transport and replay rows H, C.*

No other NameCert obligation is available from the Bishop real construction packet.

Proof. Project the carrier of Definition 4135.1. The displayed tuple exposes the dyadic tolerance ledger, finite stream windows, regular-Cauchy source, regular rational readback, convergence ledger, real seal, transport, replay, provenance, and local naming rows.

The tolerance-window exactness row is read before any rational approximation is exported. A request first fixes the dyadic budget D and the finite windows S, then reads the regular source Q and the readback row R along that same displayed route.

The convergence ledger M records the finite regularity evidence used by the construction. The real seal E is downstream of D, S, Q, R, M, so a consumer cannot replace those rows by quotient stream equality, a selected host limit, host real equality, Dedekind cuts, countable choice, or ambient completeness.

Finally H, C, P, N transport, replay, source, and name exactly the same finite packet. Since the carrier has no additional coordinate, the six listed rows exhaust the local NameCert surface. □

Theorem 4135.3 (Regular-Cauchy readback route)**.** *For every accepted* $\mathsf{BishopRealConstruction}^{\uparrow}$ *carrier*

$$B = (D, S, Q, R, M, E, H, C, P, N),$$

every rational approximant exported by B is read along the displayed route

$$D, S \longrightarrow Q \longrightarrow R \longrightarrow M.$$

In particular, the approximant first uses the dyadic tolerance ledger D and finite stream windows S, then passes through the regular-Cauchy source Q, the $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the convergence ledger M before it is available to any later row of the packet.*

Proof. Project the carrier of Definition 4135.1. Its only rows capable of naming rational approximants are the finite windows S, the regular-Cauchy source Q, and the regular readback row R, all measured against the dyadic budget D.

Apply Definition 4135.2. The regular-Cauchy readback obligation requires exported rational approximants to pass through Q, R, while the convergence-ledger exposure obligation records the finite regularity evidence in M. Since the classifier compares packets only through $D, S, Q, R, M, E, H, C, P, N$, no alternate approximant coordinate is available. □

Theorem 4135.4 (Real seal handoff)**.** *For every accepted* $\mathsf{BishopRealConstruction}^{\uparrow}$ *carrier*

$$B = (D, S, Q, R, M, E, H, C, P, N),$$

every $\mathsf{Real}^{\uparrow}$ *consumer reaches the seal row E only after the dyadic ledger D, finite stream windows S, regular-Cauchy source Q, regular readback R, and convergence ledger M have been displayed, and only through the transport, replay, provenance, and local naming rows H, C, P, N.*

Proof. Project the displayed tuple in Definition 4135.1. The seal row E is declared downstream of D, S, Q, R, M, and the remaining public movement of the packet is carried by componentwise hsame transport H, Cont replay C, provenance P, and local naming N.

Apply the seal nonescape and provenance-name exhaustion clauses of Definition 4135.2. They force the $\mathsf{Real}^{\uparrow}$ seal to remain attached to the same finite route, so a consumer can reach E only through the displayed handoff rows rather than through a hidden host-side real object. □

Theorem 4135.5 (Ledger nonescape)**.** *For every accepted* $\mathsf{BishopRealConstruction}^{\uparrow}$ *carrier*

$$B = (D, S, Q, R, M, E, H, C, P, N),$$

the packet contains no coordinate for quotient stream equality, selected host limits, countable choice, host real equality, Dedekind-cut substitution, or ambient $\mathsf{Real}^{\uparrow}$ *completeness. Any accepted comparison or consumer read must therefore be witnessed inside the rows $D, S, Q, R, M, E, H, C, P, N$.*

Proof. Project the carrier definition. The classifier is explicitly restricted to the displayed rows $D, S, Q, R, M, E, H, C, P, N$, and the definition states that the excluded principles have no coordinate in the packet.

Apply the seal nonescape clause of Definition 4135.2. It blocks the listed host-side or quotient-side replacements at the NameCert surface. The exhaustion clause then shows that H, C, P, N only transport, replay, source, and name the same finite packet, so they cannot introduce a new equality, limit, choice, cut, or completeness row. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealConstruction}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealConstruction}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName finite-window rows, RegSeqRat regular-readback rows, RealModulusOfConvergence ledger rows, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealConstruction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4135.1 and Definition 4135.2 seed the finite Bishop–Bridges regular-Cauchy construction route for Real and completion-facing consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopRealConstruction}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected host limits, countable choice, host real equality, Dedekind-cut replacement, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular-Cauchy readback, Real seal handoff, convergence-ledger refusal, transport, replay, provenance, and local naming for BEDC.Derived.BishopRealConstructionUp.BishopRealConstruct

Chapter 4136

A Concrete Naming Certificate for $\mathsf{CauchyIntegralFormula}^{\uparrow}$

Following Cauchy and Bishop–Bridges constructive complex analysis, the $\mathsf{CauchyIntegralFormula}^{\uparrow}$ packet names the finite contour-evaluation theorem surface that lets a holomorphic local datum be read at an interior point through an explicit contour integral. It sits above the holomorphic predicate of chapter 68, the complex carrier of chapter 39, the complex series modulus rows of chapter 69, the operation socket of chapter 583, and the triangle-to-polygon null-integral route of chapter 2098. The chapter names the Cauchy integral formula as a BEDC NameCert dependency for residue, maximum-modulus, and analytic-continuation consumers; it does not introduce a host contour integral, quotient path space, classical compactness principle, or unrecorded branch-selection oracle.

Definition 4136.1 (Cauchy integral formula carrier)**.** *A* $\mathsf{CauchyIntegralFormula}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, Z, R, H, C, S, G, L, T, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{Holomorphic}^{\uparrow}$ *domain row, displaying the holomorphic function, its complex neighbourhood, and the interior point whose value is to be read.*
2. *Z is the* $\mathsf{Complex}^{\uparrow}$ *point row, carrying the point coordinate and the complex arithmetic rows used by the evaluation denominator.*
3. *R is the radius and contour row, naming a rational circle or polygonal contour around Z whose image remains inside the displayed holomorphic neighbourhood.*
4. *H is the* $\mathsf{ContourIntegralSocket}^{\uparrow}$ *row, exposing the piecewise-linear contour, holomorphic input, Riemann-sum modulus, complex output, operation-law ledger, transport, replay, provenance, and local naming rows.*
5. *C is the* $\mathsf{CplxSer}^{\uparrow}$ *local expansion row, recording the finite read of the convergent power-series data needed to identify the residue coefficient at the point.*
6. *S is the singular-kernel exclusion row, displaying that the contour avoids the evaluation point in the denominator while the point remains inside the contour.*
7. *G is the* $\mathsf{Goursat}^{\uparrow}$ *null-triangle ledger row, routing contour deformation and polygon subdivision through the already named null-integral packet.*

8. *L is the formula ledger row, recording the equality between the point value and the contour integral of the Cauchy kernel over the displayed contour.*
9. *T records componentwise* hsame *transport for the holomorphic, complex, contour, socket, series, exclusion, Goursat, formula, replay, provenance, and local naming rows.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyIntegralFormula}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{CplxSer}^{\uparrow}$, $\mathsf{ContourIntegralSocket}^{\uparrow}$ $\mathsf{Goursat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyIntegralFormula}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, Z, R, H, C, S, G, L, T, P, N$. It has no coordinate for a host analytic theorem, selected branch, quotient path equality, or classical integral representation outside the displayed contour socket.

Lean4 ✓ `BEDC.Derived.CauchyIntegralFormulaUp.CauchyIntegralFormulaTasteGate single carrier alignment`

Theorem 4136.2 (Cauchy integral formula NameCert obligations)**.** *For every accepted* $\mathsf{CauchyIntegralFormula}^{\uparrow}$ *carrier $F = (D, Z, R, H, C, S, G, L, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyIntegralFormula}^{\uparrow}}$ *surface consists exactly of holomorphic-domain admission through D, complex point and arithmetic admission through Z, contour containment through R, contour-socket admission through H, complex-series local expansion through C, singular-kernel exclusion through S, Goursat deformation through G, formula-ledger exactness through L, componentwise transport through T, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.CauchyIntegralFormulaUp.CauchyIntegralFormulaCarrier namecert obligations`

Proof. Project the carrier. The holomorphic source D and point row Z fix the only domain and evaluation data that the packet may read.

The contour row R and socket row H provide the finite operation surface. They determine the contour-integral value through displayed piecewise-linear, Riemann-sum, complex-output, and operation-law rows.

The series row C, exclusion row S, and Goursat row G identify the Cauchy kernel computation and the allowed contour deformations. The formula ledger L then records the point-evaluation equality inside the same packet.

Finally T, P, N transport, source, and name the same finite route. Since no carrier coordinate stores a host contour theorem, branch selection, quotient path equality, or classical integral representation, the listed rows exhaust the NameCert obligations. □

Theorem 4136.3 (Cauchy integral formula contour-socket route)**.** *Every point-evaluation read exported by an accepted* $\mathsf{CauchyIntegralFormula}^{\uparrow}$ *carrier factors through the finite route*

$$D, Z, R \longmapsto H \longmapsto C, S, G, L \longmapsto T, P, N.$$

In particular, the read must pass through the $\mathsf{ContourIntegralSocket}^{\uparrow}$ *row before the formula ledger can be consumed, and it cannot bypass the contour socket by citing a host Cauchy theorem, quotient path identity, selected branch, or undisplayed completeness object.*

Proof. Start with a point-evaluation request. The rows D, Z, R display the holomorphic input, complex point, and contour containment data, but none of them alone stores the contour integral or the formula equality.

The request must next pass through H. By chapter 583, the socket exposes the contour, input, modulus, complex output, operation ledger, transport, replay, provenance, and local naming rows needed by a contour-integral consumer.

The rows C, S, G, L then attach local series computation, denominator exclusion, Goursat deformation, and formula equality to that same socket route. Transport and provenance through T, P, N preserve the displayed route without adding a second source of analytic equality.

Therefore every exported Cauchy integral formula read is socket-mediated and finite-row visible. The absent host theorem, quotient path identity, branch selection, and completeness oracle have no coordinate in the carrier. □

Falsifiable prediction: Every residue, maximum-modulus, or analytic-continuation consumer that cites $\mathsf{CauchyIntegralFormula}^{\uparrow}$ must expose holomorphic-domain data, complex point data, contour containment, contour-socket rows, local complex-series data, singular-kernel exclusion, Goursat deformation, formula ledger, componentwise hsame transport, Pkg provenance, and local NameCert evidence.

Independence witness: holomorphic, complex-series, contourintegralsocket, goursat: none is bijective with $\mathsf{CauchyIntegralFormula}^{\uparrow}$ because this packet jointly carries point-evaluation data, contour containment, socket-mediated integral rows, kernel exclusion, deformation ledger, formula equality, transport, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyIntegralFormula}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyIntegralFormula}^{\uparrow}$ packet is generated from holomorphic-domain rows, complex point rows, contour-containment rows, contour-socket rows, local complex-series rows, singular-kernel exclusion rows, Goursat deformation rows, formula-ledger rows, componentwise hsame transport, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyIntegralFormula}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4136.1, Definition 4136.2, and Definition 4136.3 seed the finite contour-mediated point-evaluation packet over holomorphic, complex, complex-series, contour-socket, Goursat, transport, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyIntegralFormula}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close residue calculus, maximum-modulus consequences, host contour integration, quotient path spaces, global analytic continuation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, holomorphic source lock, contour containment, contour-socket handoff, local series exactness, singular-kernel exclusion, Goursat deformation, formula-ledger exactness, and non-escape for BEDC.Derived.CauchyIntegralFormulaUp.

Chapter 4137

A Concrete Naming Certificate for $\mathsf{MinimalTriggerHomologyCore}^{\uparrow}$

The $\mathsf{MinimalTriggerHomologyCore}^{\uparrow}$ packet realizes the zero-marker support-nerve sphere core of Definition 9462.1665 and the finite count table of Definition 9462.1668 as finite BEDC NameCert data. It sits beside the support-nerve realization of chapter 4079, the support-nerve census of chapter 4048, the codon lift packet of chapter 4129, and the boundary-tile packet of chapter 3393. The packet names the quotient trigger, complement simplex cover, boundary-simplex nerve, reduced homology degree, finite count table, TasteGate admission boundary, transport, replay, provenance, and local naming rows; it is not a biological mechanism, stochastic selection claim, or unbounded enumeration oracle.

Definition 4137.1 (Minimal trigger homology-core carrier)**.** *A* $\mathsf{MinimalTriggerHomologyCore}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, F, N, R, B, K, T, H, C, P, L)$$

with the following displayed rows:

1. *Q is the quotient-level minimal full-trigger row, displaying $A = \{S_1, \ldots, S_m\}$ and its finite support cells.*
2. *F is the complement-simplex row, recording $F_i = \Omega \setminus S_i$ and the finite simplices 2^{F_i}.*
3. *N is the support-nerve row, identifying the union $\bigcup_i 2^{F_i}$ as the displayed support nerve.*
4. *R is the boundary-simplex route row, recording that the cover nerve is $\partial\Delta^{m-1}$ because every proper complement intersection is inhabited and the full intersection is empty.*
5. *B is the reduced-homology row, naming the sphere type S^{m-2} and the corresponding one-dimensional reduced homology witness.*
6. *K is the finite count row, displaying the quotient and codon count table for trigger sizes $1, 2, 3, 4$.*
7. *T is the TasteGate obligation row, requiring later* $\mathsf{Nontrivial\ MinimalTriggerHomologyCore}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ MinimalTriggerHomologyCore}^{\uparrow}$ *instances to preserve Q, F, N, R, B, K before downstream consumers may use the packet as a stable AI-origin chapter surface.*
8. *H records componentwise* hsame *transport for quotient triggers, complement simplices, support nerves, boundary-simplex routes, homology rows, count rows, TasteGate rows, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a quotient trigger through complement simplices, support nerves, boundary-simplex routing, homology readback, and finite count exposure.*

10. *P is the* Pkg *provenance over* $\mathsf{MinimalTriggerHomologyCore}^{\uparrow}$*, Definition 9462.1665, Definition 9462.1668,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *L is the local* $\mathsf{NameCert}_{\mathsf{MinimalTriggerHomologyCore}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, F, N, R, B, K, T, H, C, P, L$. It has no coordinate for empirical biology, stochastic fitness, a host simplicial-complex library, or an unrestricted search over supports.

Theorem 4137.2 (Minimal trigger homology-core NameCert obligations)**.** *For every accepted* $\mathsf{MinimalTriggerHomologyCore}^{\uparrow}$ *carrier $M = (Q, F, N, R, B, K, T, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{MinimalTriggerHomologyC}}$ *surface consists exactly of quotient-trigger admission through Q, complement-simplex admission through F, support-nerve construction through N, boundary-simplex routing through R, reduced-homology readback through B, finite count preservation through K, TasteGate obligation exposure through T, componentwise transport through H, replay through C, provenance through P, and local naming through L.*

Lean4 ✓ `BEDC.Derived.MinimalTriggerHomologyCoreUp.MinimalTriggerHomologyCoreNamecertObligations`

Proof. Project the carrier. The quotient trigger row Q fixes the finite support family, and the complement row F records the finite simplices that generate the support nerve.

The support-nerve row N and boundary-simplex route R encode the nerve-theorem calculation from Definition 9462.1665. The reduced-homology row B reads the displayed sphere degree, and the count row K records the quotient and codon tables from Definition 9462.1668.

The TasteGate row T is an explicit downstream obligation: later Nontrivial and FieldFaithful instances must preserve the carrier rows, but those instances are not hidden assumptions in the present packet. The rows H, C, P, L transport, replay, source, and name the same finite data. □

Theorem 4137.3 (Minimal trigger homology-core support-nerve route)**.** *Every homology-core read exported by an accepted* $\mathsf{MinimalTriggerHomologyCore}^{\uparrow}$ *carrier factors through the finite route*

$$Q, F \longmapsto N, R \longmapsto B, K \longmapsto T, H, C, P, L.$$

The route requires the quotient minimal-trigger row and complement-simplex row before the support nerve, boundary-simplex route, homology witness, count table, TasteGate obligation, transport, replay, provenance, and local naming rows can be consumed.

Proof. Start with a homology-core read. The row Q displays the quotient-level minimal full trigger, while F displays its complement simplices; neither row by itself stores a homology conclusion.

The read must pass through N and R. These rows expose the support nerve and the boundary-simplex route that turns minimal full-trigger data into the sphere core.

The rows B and K then read the reduced homology degree and the finite count table. The TasteGate row T keeps the future nontriviality and field-faithfulness requirements attached to the same carrier rather than replacing the packet by a detached classifier.

Finally H, C, P, L preserve the route by componentwise transport, replay, provenance, and local naming. Since the carrier has no row for a host simplicial-complex library, stochastic fitness model, or unbounded support search, every exported read is exhausted by the displayed finite route. □

Falsifiable prediction: Every accepted $\mathsf{MinimalTriggerHomologyCore}^{\uparrow}$ packet exposes quotient-trigger data, complement-simplex data, support-nerve data, boundary-simplex routing, reduced homology readback, finite count rows, TasteGate obligations, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert evidence before any downstream trigger-lattice consumer may cite the sphere-core result.

Independence witness: support-nerve-realization, support-nerve-census, minimal-trigger-lift-bundle, dna-window-six-boundary-tile: none is bijective with $\mathsf{MinimalTriggerHomologyCore}^{\uparrow}$ because this packet jointly carries quotient minimal-trigger rows, complement simplices, support-nerve routing, reduced homology, finite counts, TasteGate obligations, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MinimalTriggerHomologyCore}^{\uparrow}}$.

Constructive story: A $\mathsf{MinimalTriggerHomologyCore}^{\uparrow}$ packet is generated from quotient minimal-trigger rows, complement-simplex rows, support-nerve rows, boundary-simplex route rows, reduced-homology rows, finite count rows, TasteGate obligation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MinimalTriggerHomologyCore}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4137.1, Definition 4137.2, and Definition 4137.3 seed the finite support-nerve sphere-core packet over quotient triggers, complement simplices, boundary-simplex routes, reduced homology, count rows, TasteGate obligations, transport, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MinimalTriggerHomologyCore}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic fitness, host simplicial-complex libraries, unrestricted trigger search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked quotient-trigger admission, complement-simplex admission, support-nerve construction, boundary-simplex route exactness, homology readback, finite count preservation, and TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.MinimalTriggerHomologyCoreUp.

Chapter 4138

A Concrete Naming Certificate for $\mathsf{CompactOpenTopology}^{\uparrow}$

Following Kelley and Bourbaki on compact-open topologies, the $\mathsf{CompactOpenTopology}^{\uparrow}$ packet names the finite subbasic topology surface carried by compact-domain windows and open-target tests. It sits next to the compact-open metric packet of chapter 1903, the compact-open function-space carrier of chapter 2221, the continuous-map graph route of chapter 130, the compact-metric source surface of chapter 129, and the compact-window convergence route of chapter 4022. The packet records compact-domain rows, open-target rows, finite window rows, componentwise transport, displayed replay, provenance, and local naming; it does not install a host topology on all functions.

Definition 4138.1 (Compact-open topology carrier)**.** *A* $\mathsf{CompactOpenTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, O, W, F, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact-domain row. It records the retained* $\mathsf{CompactMetric}^{\uparrow}$ *source windows and the compact subobjects whose images are tested.*
2. *O is the open-target row. It records the displayed target-open tests used by the subbasic condition.*
3. *W is the finite window row. Each entry pairs one compact-domain entry from K with one open-target entry from O.*
4. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row whose displayed values are inspected only on the windows listed by W.*
5. *S is the subbasic membership ledger. It records that the displayed map sends the retained compact-domain window into the corresponding open-target row.*
6. *H records componentwise* hsame *transport for compact-domain rows, open-target rows, finite windows, continuous-map graph rows, subbasic membership ledgers, replay rows, provenance, and local naming.*
7. *C records displayed* Cont *replay from a compact-open topology request through compact-domain inspection, open-target inspection, graph evaluation, and subbasic membership.*
8. *P is the* Pkg *provenance over* $\mathsf{CompactOpenTopology}^{\uparrow}$, $\mathsf{CompactOpenMetric}^{\uparrow}$, $\mathsf{CompactOpenFunctionSpace}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocallyUniformConvergence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CompactOpenTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, O, W, F, S, H, C, P, N$. There is no coordinate for open-cover compactness, choice-selected compact witnesses, quotient equality of host functions, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompactOpenTopologyUp.CompactOpenTopologyTasteGate single carrier alignment`

Theorem 4138.2 (Compact-open topology NameCert obligations)**.** *For every accepted* $\mathsf{CompactOpenTopology}^{\uparrow}$ *carrier $T = (K, O, W, F, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactOpenTopology}^{\uparrow}}$ *surface consists exactly of these obligation rows:*

1. *carrier admission for compact-domain rows, open-target rows, finite windows, continuous-map graph rows, subbasic membership ledgers, transport, replay, provenance, and local naming;*
2. *compact-domain visibility, requiring every domain side of a subbasic request to read through the retained* $\mathsf{CompactMetric}^{\uparrow}$ *rows in K;*
3. *open-target visibility, requiring every target side of a subbasic request to read through the displayed open-target row O;*
4. *finite-window stability, requiring membership checks to use the paired rows in W and the subbasic ledger S before any consumer reads the topology packet;*
5. *non-escape, requiring H, C, P, N to preserve the same displayed rows and to export no open-cover compactness, choice-selected compact witness, host function-space equality, or ambient completeness.*

No compact-open topology obligation is stored outside those rows.

Proof. Project the carrier in Definition 4138.1. The visible topology coordinates are exactly the compact-domain row, open-target row, finite window row, continuous-map graph row, subbasic membership ledger, and the structural rows H, C, P, N.

The compact-domain side is forced by K. Its reads are the same finite compact-source surface used by chapter 129 and by the compact-open metric route of chapter 1903.

The function side is forced by F and S. A subbasic membership request must inspect displayed graph values through chapter 130 and then record the result in the finite membership ledger attached to the paired window in W.

The provenance row places the packet beside chapter 2221 and chapter 4022. Those siblings may consume the displayed subbasic surface, but the carrier has no row for host function-space equality, open-cover compactness, choice-selected compact witnesses, or ambient completeness. □

Theorem 4138.3 (Compact-open topology finite subbase stability)**.** *Let $T = (K, O, W, F, S, H, C, P, N)$ be an accepted* $\mathsf{CompactOpenTopology}^{\uparrow}$ *carrier. Every finite family of displayed compact-open subbasic requests admitted through W remains a request on the same compact-domain, open-target, continuous-map, and membership rows after componentwise* hsame *transport by H and displayed* Cont *replay by C. Thus finite subbase stability is internal to $K, O, W, F, S, H, C, P, N$ and cannot be replaced by open-cover compactness, choice-selected compact witnesses, host function-space equality, or ambient completeness.*

Proof. Start with a finite list of subbasic requests. Each request is already an entry of W, so it names one compact-domain row from K and one open-target row from O before it can inspect a function.

Read the continuous-map data through F and the membership row through S. The compact-open metric and compact-open function-space siblings may reuse this windowed read, but they receive only the displayed graph and membership coordinates.

Transport by H is componentwise on the listed rows. Replay by C repeats the same compact-domain, open-target, graph, and membership route, so finite intersections of displayed subbasic requests remain inside the same carrier.

Since the carrier has no row for open-cover compactness, selected compact witnesses, host function equality, or ambient completeness, none of those principles can be introduced by finite subbase stability. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOpenTopology}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOpenTopology}^{\uparrow}$ packet is generated from compact-domain rows, open-target rows, finite compact-open windows, ContinuousMap graph rows, subbasic membership ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOpenTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4138.1, Definition 4138.2, and Definition 4138.3 seed the finite subbasic compact-open topology surface for compact-domain and open-target requests.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactOpenTopology}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CompactOpenTopologyUp.CompactOpenTopologyTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected compact witnesses, host function-space equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires binding compact-domain visibility, open-target visibility, finite-window stability, graph membership, componentwise transport, replay, provenance, and local naming explicitly to the finite carrier rows.

The $\mathsf{PointwiseStreamMetric}^{\uparrow}$ hub reads pointwise stream windows through chapter 126, the metric comparison route through chapter 57, and terminal real seals through chapter 38.

Chapter 4139

A Concrete Naming Certificate for $\mathsf{PointwiseStreamMetric}^{\uparrow}$

Following Bishop and Bridges' constructive metric-space treatment, the $\mathsf{PointwiseStreamMetric}^{\uparrow}$ packet records the standard pointwise distance interface for certified streams as finite BEDC data. It sits after the stream-name surface of chapter 126, the regular-rational readback of chapter 301, the terminal real-name seal of chapter 38, and the metric-space carrier discipline of chapter 57. The packet exposes pointwise metric data for completion and continuous-map consumers without host functions, quotient stream equality, selected representatives, or choice.

Definition 4139.1 (Pointwise stream metric carrier)**.** *A* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, W, D, R, E, M, H, C, P, N)$$

with the following displayed coordinates:

1. *S is the certified stream source row, read through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window interface.*
2. *W records the finite pointwise window schedule used when two certified streams are compared at a displayed index.*
3. *D is the dyadic tolerance and triangle ledger governing the finite comparisons of pointwise observations.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that converts the finite rational comparison stream into a regular rational name.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the distance value obtained from the displayed pointwise route.*
6. *M is the* $\mathsf{Met}^{\uparrow}$ *metric-structure row, used only after the pointwise stream route has displayed S, W, D, R, E.*
7. *H stores componentwise* hsame *transport for stream names, window schedules, dyadic ledgers, regular readbacks, real seals, metric rows, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a consumer request through $S, W, D, R, E, M, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PointwiseStreamMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these coordinates. It contains no host function equality, quotient stream object, selected stream representative, countable-choice schedule, or ambient completeness assertion.

Theorem 4139.2 (Pointwise stream metric pointwise classifier)**.** *For an accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *carrier* $Q = (S, W, D, R, E, M, H, C, P, N)$*, every pointwise distance classifier read factors through the certified stream source* S*, the finite window schedule* W*, the dyadic tolerance ledger* D*, the regular-rational readback* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *before the* $\mathsf{Met}^{\uparrow}$ *row* M *may be inspected. The classifier therefore names a pointwise metric route on certified streams and does not read host functions, quotient streams, selected representatives, countable choice, or an ambient completion theorem.*

Lean4 ✓ `BEDC.Derived.PointwiseStreamMetricUp.PointwiseStreamMetricPointwiseClassifier`

Proof. Project the carrier of Definition 4139.1. The source stream, window schedule, dyadic ledger, regular readback, Real seal, metric row, transport, replay, provenance, and local naming row are all displayed coordinates.

The pointwise route begins with S and W. A consumer must name the stream source and the finite observation windows before any rational readback or metric row can be inspected.

The distance read then passes through D, R, E. The dyadic ledger bounds the finite comparisons, the regular-rational row gives the readback discipline, and the Real seal is the terminal distance value. Since no coordinate stores a host function or quotient stream, the classifier cannot export one. □

Theorem 4139.3 (Pointwise stream metric constant stream)**.** *Let* $Q = (S, W, D, R, E, M, H, C, P, N)$ *be an accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *carrier whose stream source row* S *is displayed as a constant certified stream. Then every distance read between two displayed copies of that source is routed through the same finite window schedule* W*, dyadic zero-tolerance ledger* D*, regular-rational readback* R*, terminal Real seal* E*, and metric row* M*. The packet records the constant-stream zero-distance route as displayed NameCert data, not as host equality of functions or quotient stream identity.*

Proof. Start with the displayed constant stream row in S. Because the stream is certified by its $\mathsf{StreamName}^{\uparrow}$ windows, the two copies are compared only through the finite schedule W.

Use the dyadic ledger D for the zero-tolerance comparison. The readback row R and the terminal seal E record the regular-rational and Real distance route generated by that finite ledger.

Finally inspect M only after the pointwise route has been displayed. The metric row reads the zero-distance route as finite certificate data, while host function equality and quotient stream identity are absent from the carrier. □

Theorem 4139.4 (Pointwise stream metric reindexing stability)**.** *Let* $Q = (S, W, D, R, E, M, H, C, P, N)$ *be an accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *carrier. Any accepted finite reindexing of the certified stream windows transports the pointwise metric classifier only through the displayed* hsame *rows* H *and the replay row* C*: the reindexed route must preserve the stream source row, window schedule, dyadic ledger, regular-rational readback, Real seal, metric row, provenance, and local naming row. It cannot add a hidden stream quotient, selected representative, or host-level function extensionality principle.*

Proof. Read the transport coordinate H. It is componentwise: stream sources, window schedules, dyadic ledgers, readback rows, Real seals, metric rows, replay, provenance, and naming rows are transported as displayed rows.

Replay the reindexed request with C. Since C follows the same order $S, W, D, R, E, M, H, P, N$, the pointwise classifier is preserved only by the finite route already present in the carrier.

The exclusions are an inventory check. No coordinate of Q stores a stream quotient, selected representative, or host-level function extensionality principle, so reindexing stability cannot export such data. □

Theorem 4139.5 (Pointwise stream metric NameCert obligations)**.** *For an accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *carrier* $Q = (S, W, D, R, E, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PointwiseStreamMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the certified stream source, finite pointwise windows, dyadic tolerance ledger, regular-rational readback, Real seal, metric row, componentwise transport, continuation replay, provenance, and local naming row; pointwise classifier exposure; constant-stream zero-distance exposure; reindexing stability; and ledger non-escape for host functions, quotient streams, selected representatives, countable choice, and ambient completeness.*

Proof. Carrier admission is projection from Definition 4139.1. The accepted packet displays exactly the stream, window, tolerance, readback, Real, metric, transport, replay, provenance, and naming rows.

Pointwise classifier exposure is Definition 4139.2. Constant-stream zero-distance exposure is Definition 4139.3. Reindexing stability is Definition 4139.4.

The ledger non-escape clause follows from the same carrier inventory. Since no row stores host functions, quotient streams, selected representatives, countable-choice schedules, or ambient completeness, the local NameCert surface is exhausted by the displayed finite rows. □

Theorem 4139.6 (Pointwise stream metric sibling route)**.** *Every accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *consumer reaches pointwise distance data only after the certified* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and* $\mathsf{Met}^{\uparrow}$ *carrier rows named in the introduction have been displayed. The pointwise metric row is therefore a sibling route through the finite stream, regular-rational, Real-seal, and metric surfaces, not a host function metric, quotient stream comparison, selected representative, countable-choice schedule, or ambient completeness assertion.*

Proof. Apply Definition 4139.5. The obligation surface lists carrier admission for the certified stream source, finite pointwise windows, dyadic tolerance ledger, regular-rational readback, Real seal, metric row, componentwise transport, continuation replay, provenance, and local naming row.

The opening paragraph identifies the sibling chapters that supply those rows: chapter 126, chapter 301, chapter 38, and chapter 57. Reading the pointwise distance surface therefore requires the stream window before the regular readback, the regular readback before the Real seal, and the Real seal before the metric row may be used.

Since the same obligation theorem excludes host functions, quotient streams, selected representatives, countable choice, and ambient completeness, the sibling route is exhausted by the displayed finite packet. □

Theorem 4139.7 (Pointwise stream metric Real-completion anchor)**.** *Every completion-facing read of an accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *packet factors through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and the displayed* $\mathsf{Met}^{\uparrow}$ *row before it reaches any Real-completion consumer. The route exports the finite pointwise metric packet and excludes host functions, quotient streams, selected representatives, countable choice, and ambient completeness.*

Proof. Start with the pointwise classifier of Definition 4139.2. It forces a distance read to pass through the certified stream source, finite window schedule, dyadic tolerance ledger, regular-rational readback, and terminal $\mathsf{Real}^{\uparrow}$ seal before the metric row is inspected.

Use Definition 4139.4 to transport any completion-facing reindexing request. The transport coordinate H and replay coordinate C preserve the same stream windows, dyadic ledger, readback row, Real seal, metric row, provenance, and local naming row.

Apply Definition 4139.5 and then Definition 4139.6. The NameCert obligations exhaust the accepted packet, and the sibling route identifies the supplying chapters for $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Met}^{\uparrow}$; the dyadic ledger is already a displayed coordinate of the carrier and obligations.

Therefore a Real-completion consumer receives only the finite route

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{Met}^{\uparrow}.$$

Since none of the cited surfaces stores host functions, quotient streams, selected representatives, countable-choice schedules, or ambient completeness, the completion-facing read cannot acquire them. □

Theorem 4139.8 (Pointwise stream metric dossier lattice route)**.** *Every* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *carrier*

$$Q = (S, W, D, R, E, M, H, C, P, N)$$

must read the same finite pointwise window W, dyadic ledger D, $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and displayed* $\mathsf{Met}^{\uparrow}$ *row M before any completion-facing route is consumed. The downstream lattice is therefore the convergence-ledger route of chapter 2074 together with the completion route of chapter 1506, not an ambient completeness theorem, host function equality, quotient stream equality, selected representative, or countable-choice schedule.*

Proof. Project the carrier of Definition 4139.1. The only rows available before the structural data are the certified stream source S, finite window schedule W, dyadic ledger D, regular-rational readback R, terminal Real seal E, and metric row M.

Apply the Real-completion anchor Definition 4139.7. It already forces every completion-facing read through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the displayed $\mathsf{Met}^{\uparrow}$ row before a consumer receives the pointwise metric packet.

Now split the downstream request by destination. A $\mathsf{RealModulusOfConvergence}^{\uparrow}$ consumer reads the convergence ledger only through chapter 2074, so the same W, D, R, E, M rows remain visible before convergence data is public. A $\mathsf{MetricCompletion}^{\uparrow}$ consumer reads the completion route only through chapter 1506, so the same finite pointwise dossier is still the source of completion-facing distance data.

Because the carrier lacks coordinates for ambient completeness, host function equality, quotient stream equality, selected representatives, and countable-choice schedules, neither downstream route can acquire those objects from $\mathsf{PointwiseStreamMetric}^{\uparrow}$. □

The finite-window side of this lattice is consumed by chapter 5916 through its pointwise metric forward route. Thus a downstream $\mathsf{FiniteStream}^{\uparrow}$ reader receives the same $S, W, D, R, E, M, H, C, P, N$ packet as a finite-window metric read, not as an added completion principle or a hidden stream quotient.

The downstream completion lattice consumes this anchor through the convergence-ledger route of chapter 2074. Every $\mathsf{RealModulusOfConvergence}^{\uparrow}$ consumer of an accepted $\mathsf{PointwiseStreamMetric}^{\uparrow}$ packet must read the same finite windows W, dyadic ledger D, $\mathsf{RegSeqRat}^{\uparrow}$ readback R, terminal $\mathsf{Real}^{\uparrow}$ seal E, and displayed metric row M before any convergence ledger is public. The consumer therefore receives the pointwise stream metric only as the finite route already exposed by the carrier, not as a detached completion principle.

Theorem 4139.9 (Pointwise stream metric finite-window consumption)**.** *Every metric-distance read from an accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *packet first consumes the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the* $\mathsf{Met}^{\uparrow}$ *distance row. The consumed route is the finite packet*

$$S, W, D, R, E, M, H, C, P, N$$

of Definition 4139.1, with the dyadic ledger D bounding the window comparison before the Real seal and metric row are read.

The route is invariant under accepted scheduled window replacement transported by H and replayed by C. It exposes no quotient stream equality, selected stream representative, host function equality, countable-choice schedule, or ambient completeness principle.

Proof. Project the carrier of Definition 4139.1. The metric-distance read has only the stream source, finite window schedule, dyadic ledger, regular readback, Real seal, metric row, transport, replay, provenance, and local naming coordinates available.

Apply Definition 4139.6. It orders the reader through the $\mathsf{StreamName}^{\uparrow}$ finite window, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, the terminal $\mathsf{Real}^{\uparrow}$ seal, and then the $\mathsf{Met}^{\uparrow}$ row.

Use Definition 4139.7 to connect the same route to completion-facing consumers. The dyadic ledger remains a displayed coordinate of the packet, so the read cannot bypass the finite window and regular readback.

Finally invoke Definition 4139.4. Any scheduled replacement transported by H and replayed by C preserves the same stream windows, dyadic ledger, readback, Real seal, metric row, provenance, and local naming row. Since the carrier has no quotient stream, selected representative, host function equality, choice schedule, or ambient completeness coordinate, the finite-window consumption route is exhausted by the displayed packet. □

Theorem 4139.10 (Pointwise stream metric completion separation)**.** *Every completion-facing read of an accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *carrier*

$$Q = (S, W, D, R, E, M, H, C, P, N)$$

must expose $S, W, D, R, E, M, H, C, P, N$ before a completion consumer may inspect the metric-distance row. The read cannot infer ambient completeness, quotient stream equality, selected representatives, countable-choice schedules, or host function equality unless the displayed $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R and terminal* $\mathsf{Real}^{\uparrow}$ *seal row E are present in the same packet.*

Proof. Project the carrier of Definition 4139.1. The only available rows are the certified stream source, finite window schedule, dyadic tolerance ledger, regular-rational readback, terminal Real seal, metric row, transport, replay, provenance, and local naming row.

Apply the pointwise classifier theorem Definition 4139.2. It forces the distance read through S, W, D, R, E before M is inspected, so a completion consumer cannot start from an ambient completed stream space.

Use the Real-completion anchor Definition 4139.7 and the finite-window consumption theorem Definition 4139.9. Together they place every completion-facing request on the displayed stream-window, dyadic-ledger, RegSeqRat readback, Real-seal, and metric route.

The conclusion is the carrier inventory. Since no coordinate stores ambient completeness, quotient stream equality, selected representatives, countable choice, or host function equality, the completion-facing read can use such data only by leaving the accepted $\mathsf{PointwiseStreamMetric}^{\uparrow}$ packet. □

Theorem 4139.11 (Pointwise stream metric synchronized-window triangle route)**.** *Let $Q_{\mathrm{xy}}, Q_{\mathrm{yz}}, Q_{\mathrm{xz}}$ be accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *carriers for the displayed stream reads from x to y, from y to z, and from x to z. Suppose the three packets share the same certified* $\mathsf{StreamName}^{\uparrow}$ *window schedule W and the same displayed* $\mathsf{Met}^{\uparrow}$ *row M:*

$$\begin{aligned} Q_{\mathrm{xy}} &= (S_{\mathrm{xy}}, W, D_{\mathrm{xy}}, R_{\mathrm{xy}}, E_{\mathrm{xy}}, M, H_{\mathrm{xy}}, C_{\mathrm{xy}}, P_{\mathrm{xy}}, N_{\mathrm{xy}}), \\ Q_{\mathrm{yz}} &= (S_{\mathrm{yz}}, W, D_{\mathrm{yz}}, R_{\mathrm{yz}}, E_{\mathrm{yz}}, M, H_{\mathrm{yz}}, C_{\mathrm{yz}}, P_{\mathrm{yz}}, N_{\mathrm{yz}}), \\ Q_{\mathrm{xz}} &= (S_{\mathrm{xz}}, W, D_{\mathrm{xz}}, R_{\mathrm{xz}}, E_{\mathrm{xz}}, M, H_{\mathrm{xz}}, C_{\mathrm{xz}}, P_{\mathrm{xz}}, N_{\mathrm{xz}}). \end{aligned}$$

Then any two-leg distance read from x to z through y must consume, in the same synchronized order, the shared finite window W, the dyadic triangle ledgers $D_{\mathrm{xy}}, D_{\mathrm{yz}}, D_{\mathrm{xz}}$, the $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks $R_{\mathrm{xy}}, R_{\mathrm{yz}}, R_{\mathrm{xz}}$, the terminal* $\mathsf{Real}^{\uparrow}$ *seals $E_{\mathrm{xy}}, E_{\mathrm{yz}}, E_{\mathrm{xz}}$, and the displayed metric row M before any* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *consumer may use the composed distance. The route is a finite BEDC triangle ledger and not an ambient metric-space triangle proof over host functions, quotient streams, selected representatives, or countable-choice schedules.*

Proof. Project the three carriers. Each packet displays its stream source row, the shared finite window schedule, its dyadic ledger, its regular-rational readback, its Real seal, the shared metric row, transport, replay, provenance, and local naming row.

Apply the pointwise classifier theorem, Definition 4139.2, to the three legs. For Q_{xy}, Q_{yz}, and Q_{xz} the distance read must pass through the displayed window, dyadic ledger, readback, and Real seal before M is inspected.

Use finite-window consumption, Definition 4139.9, for each leg. The two-leg read may compose the x to y and y to z reads only after both have exposed the same window W, and it may compare them with the x to z read only through the displayed dyadic triangle ledger and readback rows.

Apply reindexing stability, Definition 4139.4, to any transported schedule request. The H_{xy}, H_{yz}, and H_{xz} rows, replayed by the corresponding C rows, preserve the shared window and metric row while keeping the three dyadic ledgers, readbacks, Real seals, provenance rows, and local names visible.

Finally invoke completion separation, Definition 4139.10. A completion or modulus consumer can use the composed distance only after the synchronized finite route has displayed all three pointwise packets. Since none of the carriers stores ambient completeness, quotient stream equality, selected representatives, host function equality, or countable choice, the triangle route remains a BEDC finite-window route. □

Theorem 4139.12 (Pointwise stream metric finite-window triangle budget)**.** *Let $Q_{\mathrm{xy}}, Q_{\mathrm{yz}}, Q_{\mathrm{xz}}$ be accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *packets sharing a* $\mathsf{StreamName}^{\uparrow}$ *window schedule W and a displayed* $\mathsf{Met}^{\uparrow}$ *row M. A completion-facing triangle-budget read for the three legs may export data only through the three displayed dyadic ledgers $D_{\mathrm{xy}}, D_{\mathrm{yz}}, D_{\mathrm{xz}}$, the three* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks $R_{\mathrm{xy}}, R_{\mathrm{yz}}, R_{\mathrm{xz}}$, the three terminal* $\mathsf{Real}^{\uparrow}$ *seals $E_{\mathrm{xy}}, E_{\mathrm{yz}}, E_{\mathrm{xz}}$, and the shared metric row M, with the source, transport, replay, provenance, and local naming rows of each packet still visible. The budget route has no coordinate for ambient completeness, quotient stream equality, selected representative, host function equality, or countable choice.*

Proof. Apply the synchronized-window triangle route, Definition 4139.11. It already forces the two-leg comparison and the direct comparison to share the same finite window W and metric row M before any completion-facing consumer can read the composed distance.

Use finite-window consumption, Definition 4139.9, on each of the three packets. This exposes the dyadic ledger, regular-rational readback, and Real seal of each leg as displayed finite-window data rather than as an ambient metric-space fact.

Finally apply the NameCert obligations, Definition 4139.5. They keep the source rows, componentwise hsame transports, displayed Cont replays, Pkg provenance, and local names in the exported packet. Since the carrier contains none of the excluded quotient, representative, host-equality, completeness, or choice coordinates, the triangle budget is exactly the listed finite BEDC route. □

Theorem 4139.13 (Pointwise stream metric source separation)**.** *Let* $Q = (S, W, D, R, E, M, H, C, P, N)$ *be an accepted* PointwiseStreamMetric$^{\uparrow}$ *carrier. If two completion-facing reads agree on the metric row* M *but differ in any of the source rows* S, W, D, R, E*, then the packet cannot identify them by* PointwiseStreamMetric$^{\uparrow}$*. Source separation requires the same* StreamName$^{\uparrow}$ *finite window, dyadic ledger,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *seal, and* Met$^{\uparrow}$ *row; no quotient stream equality or host function equality can collapse different source rows.*

Proof. Project the carrier of Definition 4139.1. A completion-facing read exposes the ordered packet $S, W, D, R, E, M, H, C, P, N$, so agreement of the metric row M alone does not determine the source route.

Apply the pointwise classifier theorem Definition 4139.2. It places the certified stream source, finite window schedule, dyadic ledger, regular readback, and Real seal before the metric row is inspected.

Use finite-window consumption, Definition 4139.9, and completion separation, Definition 4139.10. Together they require a completion-facing metric read to keep the same S, W, D, R, E rows in the packet, not merely the same metric row.

Finally apply reindexing stability, Definition 4139.4. Transport by H and replay by C preserve displayed rows componentwise, and the carrier has no quotient stream or host function equality coordinate. Therefore two reads differing in any of S, W, D, R, E remain source-separated inside PointwiseStreamMetric$^{\uparrow}$. □

Theorem 4139.14 (Pointwise stream metric modulus ledger pullback)**.** *Every* RealModulusOfConvergence$^{\uparrow}$ *consumer of an accepted* PointwiseStreamMetric$^{\uparrow}$ *carrier*

$$Q = (S, W, D, R, E, M, H, C, P, N)$$

must factor through the displayed certified stream source S*, finite pointwise window* W*, dyadic ledger* D*,* RegSeqRat$^{\uparrow}$ *readback* R*, terminal* Real$^{\uparrow}$ *seal* E*, and metric row* M *before it may read convergence data. The pullback reaches the convergence ledger only through the sibling route of chapter 2074; it exports no detached modulus, quotient stream equality, selected representative, countable-choice schedule, host function equality, or ambient completion principle.*

Proof. Project the carrier of Definition 4139.1. The only completion-facing analytic rows available before the structural data are S, W, D, R, E, M.

Apply the NameCert obligations, Definition 4139.5, together with completion separation, Definition 4139.10. These force any completion consumer to expose the certified stream source, finite windows, dyadic ledger, regular-rational readback, Real seal, metric row, transport, replay, provenance, and local naming before a metric-distance read is public.

Now use the sibling RealModulusOfConvergence$^{\uparrow}$ chapter. Its carrier and route theorems read convergence-modulus data only after the finite StreamName$^{\uparrow}$ window, DyadicRatCore$^{\uparrow}$ tolerance ledger, RegSeqRat$^{\uparrow}$ readback, and terminal Real$^{\uparrow}$ seal are displayed. Therefore the pointwise metric contribution enters the convergence ledger through the same S, W, D, R, E, M route.

Since neither carrier stores a detached modulus selector, quotient stream equality, selected representative, choice schedule, host function equality, or ambient completion theorem, the pullback is exhausted by the displayed rows. □

Theorem 4139.15 (Pointwise stream metric StreamName dependency)**.** *Every accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *packet consumes its pointwise metric rows only after the finite* $\mathsf{StreamName}^{\uparrow}$ *window route of chapter 126 has been displayed. Thus the metric comparison is a pointwise stream-window read through*

$$S, W, D, R, E, M, H, C, P, N$$

and not an external metric-space equality, quotient stream comparison, selected representative, countable-choice schedule, or quotient completion.

Proof. Project the carrier of Definition 4139.1. The source row S and window row W precede the dyadic ledger, regular readback, Real seal, and metric row in the accepted packet.

Use finite-window consumption, Definition 4139.9. It forces every completion-facing metric read to expose the certified $\mathsf{StreamName}^{\uparrow}$ window before any pointwise distance row can be consumed.

Apply synchronized-window triangle routing, Definition 4139.11, and source separation, Definition 4139.13. Together they make the metric comparison depend on the same finite stream-window route rather than on ambient metric equality or a quotient of stream sources.

Finally use modulus ledger pullback, Definition 4139.14. Any convergence-facing consumer reads the pointwise metric contribution through the displayed StreamName, DyadicRatCore, RegSeqRat, Real, and MetricSpace rows, so the dependency edge to chapter 126 is part of the finite BEDC ledger. □

Theorem 4139.16 (Pointwise stream metric regular Cauchy bridge)**.** *Let* $Q = (S, W, D, R, E, M, H, C, P, N)$ *be an accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *carrier. Any metric comparison over synchronized stream windows that reaches the terminal* $\mathsf{Real}^{\uparrow}$ *distance seal* E *must expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row* R *before the* $\mathsf{Met}^{\uparrow}$ *comparison row* M *can be consumed. Thus the comparison is routed through stream windows, dyadic ledgers, regular Cauchy readback, and the Real seal, not through ambient metric equality, quotient stream equality, selected representatives, countable choice, or host function equality.*

Proof. Start with finite-window consumption, Definition 4139.9. A distance read consumes the certified stream window, dyadic ledger, regular readback, Real seal, and metric row as the displayed packet $S, W, D, R, E, M, H, C, P, N$.

Apply synchronized-window triangle routing, Definition 4139.11. In a synchronized comparison, each leg keeps the shared window schedule visible while its dyadic ledger and readback rows are displayed before the Real distance seal is used.

Use source separation, Definition 4139.13. Agreement at the metric row alone cannot identify two reads; the source route still requires the same stream window, dyadic ledger, regular readback, and Real seal.

Finally invoke modulus ledger pullback, Definition 4139.14. Any convergence-facing or completion-facing consumer receives the pointwise metric contribution only after the $\mathsf{RegSeqRat}^{\uparrow}$ row has pulled the finite rational stream into the regular Cauchy readback surface. Therefore R is exposed before M is consumed. □

Theorem 4139.17 (Pointwise stream metric obligation scope)**.** *The carrier, pointwise classifier, constant-stream route, reindexing stability, NameCert obligations, sibling route, Real-completion anchor, finite-window consumption, completion separation, synchronized-window triangle route, source separation, modulus pullback, StreamName dependency, and regular-Cauchy bridge exhaust the obligation surface of* $\mathsf{PointwiseStreamMetric}^{\uparrow}$*. Any accepted metric read must therefore pass through the displayed stream source, finite windows, dyadic ledger, regular readback, Real seal,*

metric row, componentwise transport, displayed replay, provenance, and local naming before it is public.

Proof. The carrier and classifier results, Definition 4139.1, Definition 4139.2, Definition 4139.3, and Definition 4139.4, determine the packet rows and the basic stable reads.

The NameCert obligations and sibling route then expose the immediate obligation surface. The Real-completion anchor, finite-window consumption, and completion separation theorems force any completion-facing consumer through the same finite windows, dyadic ledger, regular readback, Real seal, and metric row.

The synchronized-window triangle route, source separation, modulus pullback, StreamName dependency, and regular-Cauchy bridge cover the remaining consumer paths. Since each path is routed through the displayed rows $S, W, D, R, E, M, H, C, P, N$, there is no further local obligation for host function equality, quotient stream equality, selected representatives, countable choice, or ambient completion. □

Closure status for $\mathsf{NameCert}_{\mathsf{PointwiseStreamMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{PointwiseStreamMetric}^{\uparrow}$ packet is generated from a certified stream source, finite pointwise windows, a dyadic tolerance ledger, regular-rational readback, a Real distance seal, a displayed metric-space row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointwiseStreamMetric}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 4139.17 exhausts the displayed obligation surface for certified pointwise stream metrics over StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, RealUp, MetricSpaceUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointwiseStreamMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient stream equality, selected representatives, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires binding these obligations to their exact primitive routes for stream sources, dyadic ledgers, regular readback, Real seals, metric rows, transport, replay, provenance, and local naming.

The $\mathsf{PointwiseStreamMetric}^{\uparrow}$ packet sits horizontally between the completion route of chapter 1506 and the convergence-budget route of chapter 2074. MetricCompletion consumers read pointwise distance through the certified stream-name rows of chapter 126, the dyadic ledger of chapter 291, the regular rational readback rows of chapter 301, the terminal real-name seal of chapter 38, and the displayed metric carrier rows of chapter 57. RealModulusOfConvergence consumers read the same finite window and dyadic ledger as a convergence budget before any pointwise stream metric row is available. The route exports no host function equality, quotient stream equality, selected representative, countable-choice schedule, or ambient completeness principle.

Theorem 4139.18 (PointwiseStreamMetric L10 dependency route)**.** *Every completion-facing* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *read consumes the certified* $\mathsf{StreamName}^{\uparrow}$ *pointwise windows of chapter 126, the displayed* $\mathsf{Met}^{\uparrow}$ *distance rows of chapter 57, the* $\mathsf{RealUniformStructure}^{\uparrow}$ *entourage reads of chapter 1624, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary of chapter 38 before it can expose a pointwise metric packet to a downstream Real or completion consumer.*

Proof. Start with the certified stream source and finite pointwise windows in the carrier of Definition 4139.1. These rows force every read to pass through $\mathsf{StreamName}^{\uparrow}$ before any distance datum is visible.

Next read the metric row and the Real-uniform entourage row. The sibling chapters cited above provide the displayed distance and entourage surfaces used by the pointwise packet; no host function equality, quotient stream equality, selected representative, or countable-choice schedule is available in the carrier.

Finally apply the Real-completion anchor theorem Definition 4139.7. It keeps the route inside the already displayed stream windows, metric rows, entourage reads, and terminal Real seal, so the L10 dependency route is exactly the concrete sibling route stated above. □

Theorem 4139.19 (Pointwise stream metric completion sibling anchor)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *packet must first read the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{Real}^{\uparrow}$ *seal, and the* $\mathsf{Met}^{\uparrow}$ *distance rows before any completion-facing convergence data are available. The forward lattice route exports only this displayed pointwise metric packet; it does not supply host stream equality, selected representatives, countable-choice schedules, or an ambient completion principle.*

Proof. Project the carrier of Definition 4139.1. The completion-facing analytic rows are the certified stream source S, finite pointwise windows W, dyadic tolerance ledger D, regular-rational readback R, terminal Real seal E, and displayed metric row M.

Apply the pointwise classifier and completion-separation routes in Definition 4139.2 and Definition 4139.10. They force a distance read to consume S, W, D, R, E before M is inspected, and they exclude completion data not carried by the same finite packet.

The $\mathsf{MetricCompletion}^{\uparrow}$ consumer therefore receives convergence-facing data only after the sibling chain

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{Met}^{\uparrow}$$

has been displayed. Since the packet contains no host stream equality, selected representative, choice schedule, or ambient completion coordinate, the forward lattice route is exhausted by those rows. □

Every finite-limit or completion-facing consumer of $\mathsf{PointwiseStreamMetric}^{\uparrow}$ must read the displayed $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, terminal $\mathsf{Real}^{\uparrow}$ seal, and $\mathsf{Met}^{\uparrow}$ row from Definition 4139.1 before entering the finite-limit seal route of chapter 5722 or the completion route of chapter 1506. Thus $\mathsf{FiniteLimitSeal}^{\uparrow}$ and $\mathsf{MetricCompletion}^{\uparrow}$ receive pointwise stream metric data only as the finite window route $S, W, D, R, E, M, H, C, P, N$, not as quotient stream equality, selected representatives, host function equality, countable choice, ambient Real completeness, or a detached completion object. Every $\mathsf{PointwiseStreamMetric}^{\uparrow}$ consumer reads pointwise metric data only after the finite-window source of chapter 126, the distance row of chapter 57, and the regular rational tolerance readback of chapter 301 are all visible. This route keeps the pointwise stream metric surface attached to displayed StreamName, Metric, and RegSeqRat rows before any downstream argument treats the stream as metric data.

Theorem 4139.20 (Pointwise stream metric sibling repair route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *consumer of* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *must first read the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{Met}^{\uparrow}$ *rows from Definition 4139.1 and Definition 4139.5. A completion-facing read also passes through the metric-generated uniformity route supplied by chapter 7788 when that chapter is present; before that named bridge is inspected, the dependency is the* $\mathsf{Met}^{\uparrow}$*-to-*$\mathsf{UniformSpace}^{\uparrow}$ *handoff through chapter 57 and chapter 339. Only then may the consumer enter the downstream completion ledgers of chapter 1506, the finite-window boundary of chapter 1559, and chapter 2074.*

Proof. Project the carrier. The stream source, dyadic tolerance ledger, regular-rational readback, terminal Real seal, and metric row are displayed before any completion-facing row can be consumed.

The $\mathsf{MetricCompletionFinite}^{\uparrow}$ packet is the finite-window boundary between the pointwise stream packet and the completion-facing readback.

The uniformity dependency is not a new carrier row. It is the displayed passage from the pointwise metric row to the uniform entourage reader, using the Metric-to-UniformSpace handoff and, when available, the $\mathsf{MetricUniformity}^{\uparrow}$ bridge that packages that route for completion consumers.

Read the obligation surface. It requires carrier admission, pointwise classifier exposure, constant-stream zero-distance exposure, reindexing stability, and ledger non-escape over the same finite rows.

The downstream references therefore consume the pointwise metric packet as a displayed BEDC route. No host completion theorem, quotient stream equality, selected representative, or countable-choice schedule is introduced. □

When a $\mathsf{PointwiseStreamMetric}^{\uparrow}$ distance read is used as a completion-facing convergence witness, the pointwise comparison stream leaves the carrier through the convergence ledger of chapter 2074. The route first projects the carrier of Definition 4139.1 and the obligation surface of Definition 4139.5: the certified stream source, finite pointwise windows, dyadic tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, terminal $\mathsf{Real}^{\uparrow}$ seal, and displayed metric row are consumed before the RealModulusOfConvergenceUp ledger may read the sequence as completion data. Every $\mathsf{PointwiseStreamMetric}^{\uparrow}$ consumer that reads a pointwise metric value must pass through the finite $\mathsf{StreamName}^{\uparrow}$ schedule of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38 before the metric comparison is public. The route exposes a finite stream, rational readback, and Real-facing seal boundary; it does not export quotient stream equality, a selected representative, countable choice, or ambient completeness for $\mathsf{Real}^{\uparrow}$. The $\mathsf{PointwiseStreamMetric}^{\uparrow}$ hub has a substantive horizontal dependency on chapter 129 and chapter 38: compact-metric finite-net rows and $\mathsf{Real}^{\uparrow}$ distance rows may enter the pointwise stream metric route only through the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ carriers already named by the packet. The dependency is therefore a finite stream-and-rational route, not ambient compactness, selected subsequences, quotient stream equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 4139.21 (Pointwise stream metric regular-Cauchy pruning route)**.** *Every completion-facing* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *read that prunes redundant pointwise observations must first expose the* $\mathsf{StreamName}^{\uparrow}$ *pointwise windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and terminal* $\mathsf{Real}^{\uparrow}$ *seal already carried by Definition 4139.1. The pruning handoff then factors through the* $\mathsf{RegularCauchyPruning}^{\uparrow}$ *certificate of chapter 7851 before any downstream metric or completion consumer reads the retained stream. The route exports no host stream equality, hidden infinite selector, quotient Real equality, or ambient completeness principle.*

Proof. Project the pointwise stream metric carrier. Its analytic rows expose the stream source, finite pointwise windows, dyadic tolerance ledger, regular rational readback, Real seal, and metric row before any completion-facing consumer has a pointwise distance packet to inspect.

Apply the regular-Cauchy pruning certificate of chapter 7851. That sibling consumes exactly the StreamName windows, retained schedule, dyadic ledger, RegSeqRat readback, and inherited Real seal needed to delete redundant observation requests as finite NameCert data.

Finally use the existing L10 route of Definition 4139.18. The retained stream remains inside the displayed pointwise windows and Real seal boundary before it reaches metric or completion consumers, so the horizontal edge is a concrete stream/pruning dependency rather than a kernel-only pointwise metric export. □

Theorem 4139.22 (Pointwise stream metric stream-metric sibling route)**.** *Every* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *consumer first reads the certified* $\mathsf{StreamName}^{\uparrow}$ *finite windows of chapter 126 and the displayed* $\mathsf{Met}^{\uparrow}$ *distance rows of chapter 57. The pointwise stream packet may then hand its finite distance surface to* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *consumers, but only after the stream windows, dyadic tolerance ledger, regular rational readback, terminal Real seal, and metric row have all been exposed.*

Proof. Project the carrier of Definition 4139.1. Its stream source row S, finite window row W, dyadic ledger D, regular readback row R, Real seal E, and metric row M are the only analytic rows available before transport, replay, provenance, and local naming.

Apply Definition 4139.2. It forces the pointwise distance read to pass through S, W, D, R, E before the metric row M can be inspected.

Finally use Definition 4139.7. Any completion-facing or convergence-facing consumer receives the same finite route before reaching $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{RealModulusOfConvergence}^{\uparrow}$. Since no carrier coordinate stores host stream equality, selected representatives, countable-choice schedules, or ambient completeness, the sibling route is exhausted by the displayed stream and metric surfaces. □

Theorem 4139.23 (Pointwise stream metric StreamName completion sibling route)**.** *Every* $\mathsf{PointwiseStreamMetric}$ *completion-facing consumer first reads the certified* $\mathsf{StreamName}^{\uparrow}$ *finite observations of chapter 126 and the* $\mathsf{MetricCompletion}^{\uparrow}$ *existence boundary of chapter 5721. The pointwise packet reaches that boundary only through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{Met}^{\uparrow} \longrightarrow \mathsf{MetricCompletion}^{\uparrow}.$$

Thus the completion read consumes pointwise stream observations, regular rational readback, the terminal Real classifier, and the metric row already displayed in $\mathsf{PointwiseStreamMetric}^{\uparrow}$*; it does not introduce host stream equality, a selected representative, quotient completion, countable-choice scheduling, or ambient completeness.*

Proof. Project the carrier of Definition 4139.1. The stream source S, finite window schedule W, dyadic ledger D, regular readback row R, terminal Real seal E, and metric row M are visible before any structural row can be consumed.

Apply the pointwise classifier and Real-completion anchor, Definition 4139.2 and Definition 4139.7. They force every distance read through the StreamName window, RegSeqRat readback, Real seal, and metric row before a completion-facing consumer receives the packet.

Finally read the completion existence boundary through chapter 5721. Since the incoming route has already exhausted $S, W, D, R, E, M, H, C, P, N$, the completion consumer receives only the displayed sibling dependency surface and cannot acquire host stream equality, quotient completion, selected representatives, countable-choice schedules, or ambient completeness from $\mathsf{PointwiseStreamMetric}^{\uparrow}$. □

The $\mathsf{PointwiseStreamMetric}^{\uparrow}$ route also admits located-real lower-cut rows as completion-facing input data. A metric comparison first reads the certified $\mathsf{StreamName}^{\uparrow}$ windows, passes the rational readback through $\mathsf{RegSeqRat}^{\uparrow}$, consumes the lower-cut row before the terminal $\mathsf{Real}^{\uparrow}$ consumer, and only then exposes the pointwise metric packet to Real and Completion dependents. The $\mathsf{PointwiseStreamMetric}^{\uparrow}$ packet depends substantively on the finite $\mathsf{StreamName}^{\uparrow}$ observation route of chapter 126, the $\mathsf{Met}^{\uparrow}$ distance-witness interface of chapter 57, and the terminal $\mathsf{Real}^{\uparrow}$ seal row of chapter 38. The pointwise metric route is not an isolated kernel float: it consumes stream

windows, metric distance rows, and Real-facing seal rows before any pointwise classifier read is public. The $\mathsf{PointwiseStreamMetric}^{\uparrow}$ route consumes the finite-window stream rows of chapter 126 and the distance rows of chapter 57 before any Real seal or completion-facing read is available. This dependency keeps pointwise stream metrics attached to the stream-name carrier and the metric carrier that their local classifier actually reads.

Proposition 4139.24 (Pointwise stream metric StreamName–Metric dependency)**.** *Every* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *consumer that reaches a Real seal, a* $\mathsf{MetricCompletion}^{\uparrow}$ *route, or another completion-facing read first factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite windows and the displayed* $\mathsf{Met}^{\uparrow}$ *distance rows. No completion-facing consumer can bypass those two carrier surfaces.*

Theorem 4139.25 (Pointwise stream metric coordinate extension stability)**.** *Let*

$$Q = (S, W, D, R, E, M, H, C, P, N)$$

be an accepted $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *carrier. Any accepted coordinate extension of* Q *preserves the route through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RealModulusOfConvergence}^{\uparrow}$, *and* $\mathsf{MetricCompletion}^{\uparrow}$*: the extended packet must keep the certified stream source, dyadic ledger, regular readback, terminal Real seal, displayed metric row, convergence ledger, and completion-facing dossier visible through the same finite NameCert route. The extension cannot identify quotient streams, select representatives, or replace the displayed rows by host function equality.*

Proof. Begin with the pointwise classifier of Definition 4139.2. It forces the read of Q through S, W, D, R, E before the displayed metric row M is inspected, so any coordinate extension starts from the same stream, dyadic, regular-rational, and Real-seal rows.

Next apply reindexing stability, Definition 4139.4. The transport row H and replay row C preserve the stream source, window schedule, dyadic ledger, regular readback, Real seal, metric row, provenance, and local naming rows under every accepted scheduled replacement.

Use the Real-completion anchor, Definition 4139.7. It routes completion-facing reads through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Met}^{\uparrow}$ before any downstream completion consumer receives the pointwise packet.

Finally invoke the dossier lattice route, Definition 4139.8. A $\mathsf{RealModulusOfConvergence}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ consumer reads the same finite dossier before convergence or completion data is public. Since none of the cited carrier rows stores quotient stream equality, selected representatives, or host function equality, coordinate extension cannot introduce them. □

Theorem 4139.26 (Pointwise stream metric orphan lattice route)**.** *Every* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *consumer of* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *must first expose the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{Met}^{\uparrow}$ *rows of Definition 4139.1 and Definition 4139.5. Only after those rows are visible may the consumer enter the finite-window completion boundary of chapter 1559. The route exports no quotient stream equality, no selected completion representative, no ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$*, and no host metric completion object.*

Proof. Project the pointwise stream metric carrier. The stream windows, dyadic tolerance ledger, regular rational readback, Real seal, and metric-space row are all displayed before a completion-facing read has a source.

Apply the NameCert obligations for the same packet. They assign the completion-facing dependency to the visible stream and metric rows rather than to an external completion object.

Thus a $\mathsf{MetricCompletionFinite}^{\uparrow}$ consumer can read only the finite row lattice already exposed by $\mathsf{PointwiseStreamMetric}^{\uparrow}$, and the refused quotient, representative, completeness, and host-completion objects remain outside the route. □

Theorem 4139.27 (Pointwise stream metric hub completion sibling route)**.** *Every hub-level* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *completion read first consumes the certified stream-name surface of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, the metric carrier surface of chapter 57, and the finite completion boundary of chapter 1559 before exporting the pointwise distance packet. The hub exports only the displayed stream, readback, Real, metric, and finite-completion lattice; it exports no detached stream quotient, selected representative, host function equality, countable-choice schedule, or ambient completeness principle.*

Proof. Read the hub through the body carrier and its existing sibling routes. The stream-name windows, regular rational readback, Real seal, and metric distance rows are visible before any pointwise distance packet is exported.

The finite completion boundary is then supplied by $\mathsf{MetricCompletionFinite}^{\uparrow}$. It consumes the same displayed rows as completion-facing data and adds no quotient stream equality, selected representative, countable-choice schedule, host function equality, or ambient completeness theorem.

Thus every hub-level completion read follows the stated sibling lattice before exporting the pointwise stream metric distance packet. □

Theorem 4139.28 (Pointwise stream metric top-level sibling lattice route)**.** *Every top-level read exported by the* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *hub first consumes the certified stream-name surface of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the metric carrier surface of chapter 57. Only after those sibling rows are visible may a pointwise stream metric read expose its local distance packet; the hub exports no detached stream quotient, selected representative, host function equality, countable-choice schedule, or ambient completeness principle.*

Proof. Read the hub through its body chapter, Definition 4139.6. That route already places $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{Met}^{\uparrow}$ before the pointwise metric row.

The present top-level route records the same dependency at the hub boundary. Since the hub has no substantive rows of its own, any exported pointwise stream metric read is exactly the sibling lattice route supplied by the body chapter and its Real-modulus dependency file. □

Theorem 4139.29 (Pointwise stream metric real-completion route)**.** *For every accepted* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *packet, each completion-facing read factors through finite* $\mathsf{StreamName}^{\uparrow}$ *coordinate windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows,* $\mathsf{Real}^{\uparrow}$ *distance seals,* $\mathsf{MetricCompletion}^{\uparrow}$ *limit witnesses, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. The route reads the coordinate windows before the rational readback, the rational readback before the Real distance seal, and the Real seal before any metric-completion handoff.*

The packet exports no quotient stream equality, no selected limit representative, and no ambient completeness theorem. It is the same finite L10 route used by the StreamName chapter of chapter 126, the RegSeqRat chapter of chapter 301, the Real chapter of chapter 38, and the metric-completion interface of chapter 1506.

Proof. Project the accepted $\mathsf{PointwiseStreamMetric}^{\uparrow}$ packet onto its coordinate-window, regular-rational readback, real-distance, completion-facing, transport, replay, provenance, and local naming rows. The coordinate windows are finite $\mathsf{StreamName}^{\uparrow}$ data, so a completion read cannot start from an ambient stream equality.

The $\mathsf{RegSeqRat}^{\uparrow}$ readback rows then expose the rational comparisons used by each displayed coordinate distance. The terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of those readbacks, not a host real equality detached from them.

Only after those rows are fixed may a $\mathsf{MetricCompletion}^{\uparrow}$ consumer inspect a limit witness. Componentwise hsame transport and Cont replay preserve the same displayed route, while Pkg provenance and local $\mathsf{NameCert}$ naming export no selected representative or ambient completeness principle. □

Chapter 4140

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailFilterCofinality}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completion and Frechet on cofinite filters, the $\mathsf{RegularCauchyTailFilterCofinality}^{\uparrow}$ packet records the finite route by which regular Cauchy tail evidence is read as a cofinal Frechet-filter schedule. It sits between the tail-filter certificate of chapter 1605, the finite-tail schedule of chapter 1119, and the Frechet cofinite filter interface of chapter 1564. The chapter contributes a NameCert landing for Real and Completion consumers; it does not select limits, quotient streams, host reals, or an ambient completeness theorem.

Definition 4140.1 (Regular Cauchy tail-filter cofinality carrier)**.** *A* $\mathsf{RegularCauchyTailFilterCofinality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, F, G, S, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ *source row, carrying the regular tail-filter evidence already displayed by the sibling tail-filter chapter.*
2. *F is the* $\mathsf{FiniteTailFilter}^{\uparrow}$ *cofinal schedule row, recording the finite tail windows through which later requests are admitted.*
3. *G is the* $\mathsf{FrechetFilter}^{\uparrow}$ *cofinite-filter row produced from the same finite tail schedule.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row whose inspected windows are exposed only after T, F, G have been replayed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled tail windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the same scheduled readback.*
7. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular tail, finite-tail, Frechet-filter, stream, readback, and dyadic rows have been displayed.*
8. *H records componentwise* hsame *transport for $T, F, G, S, R, D, A, C, P, N$.*
9. *C records displayed* Cont *replay from a cofinal-tail request through the regular tail-filter source, finite-tail schedule, Frechet-filter row, stream windows, regular rational readback, dyadic tolerances, and Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailFilter}^{\uparrow}$, $\mathsf{FiniteTailFilter}^{\uparrow}$, $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilterCofinality}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows and has no coordinate for quotient streams, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailFilterCofinalityUp.RegularCauchyTailFilterCofinalityTasteGate single carrier alignment`

Theorem 4140.2 (Regular Cauchy tail-filter cofinality NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailFilterCofinality}^{\uparrow}$ *carrier* $K = (T, F, G, S, R, D, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilterCofinality}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, cofinality of the finite-tail schedule between T and G, ordered exposure of* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation is stored outside $T, F, G, S, R, D, A, H, C, P, N$.*

Proof. Project the carrier of Definition 4140.1. The analytic rows are exactly the regular tail-filter source, finite-tail schedule, Frechet-filter route, stream windows, regular rational readback, dyadic tolerances, and terminal Real seal.

Cofinality is recorded by the row order T, F, G. A request reads the regular Cauchy tail-filter evidence first, then the finite schedule that witnesses cofinal tail access, and only then the Frechet cofinite-filter row.

The remaining rows preserve that route. The $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are downstream of the cofinal filter route, while H, C, P, N transport, replay, source, and name the same packet. Since the excluded quotient, selector, choice, host-equality, and completeness objects are absent, the listed rows exhaust the local obligations. □

Theorem 4140.3 (Regular Cauchy tail-filter cofinal Frechet route)**.** *Every Frechet-facing or Real-facing consumer of an accepted* $\mathsf{RegularCauchyTailFilterCofinality}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{RegularCauchyTailFilter}^{\uparrow} \longmapsto \mathsf{FiniteTailFilter}^{\uparrow} \longmapsto \mathsf{FrechetFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}$$

Thus the Frechet cofinite schedule is cofinal for the displayed regular Cauchy tail evidence before any stream, readback, dyadic, or Real-seal row is exported.

Proof. Start with a consumer of $K = (T, F, G, S, R, D, A, H, C, P, N)$. Carrier admission exposes G only as a row downstream of the regular tail-filter source T and the finite-tail schedule F.

Replay the continuation row C. The request consumes the tail evidence named by chapter 1605, then the finite-tail schedule of chapter 1119, and then the Frechet route of chapter 1564.

Only after that cofinal route is displayed can the stream windows S, readback row R, dyadic tolerance row D, and Real seal A be consumed. Componentwise transport and provenance preserve the same order, so the exported Frechet and Real-facing routes are exactly the displayed finite cofinal-tail route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailFilterCofinality}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyTailFilterCofinality}^{\uparrow}$ packet is generated from a RegularCauchyTailFilter source row, a FiniteTailFilter cofinal schedule, a FrechetFilter cofinite-filter row, StreamName windows, RegSeqRat readback,

DyadicRatCore tolerances, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyTailFilterCofinality}\uparrow}$, seed)

Scope closed: Definition 4140.1, Definition 4140.2, and Definition 4140.3 seed the finite cofinal route from regular Cauchy tail evidence through finite-tail schedules and Frechet cofinite filters to stream, readback, dyadic, and Real-seal rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyTailFilterCofinality}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.RegularCauchyTailFilterCofinalityUp.RegularCauchyTailFilterCofinalityTasteGate\_single\`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal finite-tail scheduling, Frechet-route exactness, stream-readback order, dyadic tolerance preservation, Real-seal boundary, and ledger refusal proofs for the same packet.

Chapter 4141

A Concrete Naming Certificate for $\mathsf{BishopRealPrecision}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopRealPrecision}^{\uparrow}$ packet records the finite precision budgets by which a real-number read is inspected before any completion-facing consumer may treat it as usable $\mathsf{Real}^{\uparrow}$ data. It sits over the dyadic tolerance rows of chapter 291, the finite stream windows of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names the visible precision route; it is not quotient equality of streams, a selected limit, a countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4141.1 (Bishop real precision carrier)**.** *A* $\mathsf{BishopRealPrecision}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (D, W, R, E, M, H, C, Q, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the requested dyadic radius, slack comparison, and endpoint budget for the inspected read.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, naming the finite observation schedule consumed by the precision request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular rational approximants visible through D and W.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the tolerance, window, and regular-readback rows have been displayed.*
5. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *handoff row, recording the finite modulus entry that justifies the requested precision budget for later Real and Completion consumers.*
6. *H records componentwise* hsame *transport for tolerance, window, readback, seal, modulus, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from a precision request through D, W, R, E, M.*
8. *Q is the* Pkg *provenance over* $\mathsf{BishopRealPrecision}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealPrecision}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, R, E, M, H, C, Q, N$. It has no coordinate for quotient stream equality, a selected host limit, a countable-choice schedule, host real equality, hidden precision repair, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopRealPrecisionUp.BishopRealPrecisionTasteGate single carrier alignment`

Theorem 4141.2 (Bishop real precision NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealPrecision}^{\uparrow}$ *carrier*

$$P = (D, W, R, E, M, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRealPrecision}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tolerance, window, readback, seal, modulus, transport, replay, provenance, and naming rows; tolerance-window exactness through D, W; regular rational readback through R; real-seal nonescape through E; modulus handoff through M; componentwise transport through H; displayed replay through C; package provenance through Q; and local naming through N.*

Proof. Project the carrier of Definition 4141.1. The rows $D, W, R, E, M, H, C, Q, N$ are the only coordinates exposed to a precision consumer.

The tolerance and window are fixed first. A request chooses the dyadic budget D and the finite stream schedule W, then reads the regular rational row R along that same displayed route.

The real seal E is downstream of the readback row, while the modulus handoff M records the finite Cauchy budget consumed by later Real and Completion packets. Transport, replay, provenance, and local naming preserve exactly those rows.

Since the carrier contains no further coordinate, the listed obligations exhaust the local NameCert surface and refuse quotient streams, selected limits, countable choice, host real equality, hidden precision repair, and ambient completeness. □

Theorem 4141.3 (Bishop real precision RegSeqRat handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *precision read exported by an accepted* $\mathsf{BishopRealPrecision}^{\uparrow}$ *carrier factors through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before use. Equivalently, a completion-facing consumer can read the requested precision only after the route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

has been replayed inside the same packet.

Proof. Begin with an accepted carrier $P = (D, W, R, E, M, H, C, Q, N)$. The finite stream window W determines which rational approximants may be inspected, and the dyadic tolerance row D determines the budget at which the inspection is valid.

The regular rational readback R is the only row that exports approximants to the precision request. The modulus handoff M records the finite Cauchy budget attached to that readback before the $\mathsf{Real}^{\uparrow}$ seal E is consumed.

Finally, H, C, Q, N transport, replay, source, and name the same route. Thus every accepted precision read reaches $\mathsf{Real}^{\uparrow}$ only through the displayed finite route, and no hidden limit, quotient equality, choice schedule, or ambient completeness principle can supply a bypass. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealPrecision}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopRealPrecision}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, a RealUp seal, a CauchyModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealPrecision}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4141.1, Definition 4141.2, and Definition 4141.3 seed the finite precision-budget route for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopRealPrecision}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected host limits, countable choice, host real equality, hidden precision repair, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-window exactness, RegSeqRat readback, Real seal handoff, CauchyModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopRealPrecisionUp.

Chapter 4142

A Concrete Naming Certificate for HyperbolicVisualShadowMetric$^{\uparrow}$

The HyperbolicVisualShadowMetric$^{\uparrow}$ packet realizes the boundary-shadow visual metric reading of section 9463.3 as finite NameCert data. It consumes disk coordinates from chapter 377, the metric-read surface of chapter 3474, the boundary-shadow packet of chapter 3813, the visual-metric packet of chapter 3866, and the Busemann-boundary route of chapter 3732. Its carrier binds those rows into one finite visual-shadow metric packet rather than a completed disk model, quotient boundary, global field instance, or host hyperbolic geometry.

Definition 4142.1 (Hyperbolic visual-shadow metric carrier)**.** *A* HyperbolicVisualShadowMetric$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (U, B, M, S, G, T, H, C, P, N)$$

with the following displayed rows:

1. *U is the* UnitDisk$^{\uparrow}$ *disk-carrier row for the inspected points and visible disk windows.*
2. *B is the boundary-shadow row, recording the displayed boundary projection or shadow comparison consumed by the read.*
3. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-read row on the displayed disk data.*
4. *S is the* HyperbolicVisualMetric$^{\uparrow}$ *visual-metric row, recording the finite visual comparison surface.*
5. *G is the* HyperbolicBusemannBoundary$^{\uparrow}$ *boundary row used to keep the shadow comparison attached to a displayed Busemann endpoint.*
6. *T is the phase-transport row, recording the displayed observer-expansion transport through which the visual-shadow read is replayed.*
7. *H records componentwise* hsame *transport for disk, boundary-shadow, metric, visual, Busemann, phase-transport, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a visual-shadow metric request through U, B, M, S, G, T.*
9. *P is the* Pkg *provenance over* HyperbolicVisualShadowMetric$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicBusemannBoundary$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $U, B, M, S, G, T, H, C, P, N$. It has no coordinate for a host Poincare disk, quotient ideal boundary, global geometry theorem, physical observer trajectory, or implicit field-faithfulness witness.

Lean4 (definition) `BEDC.Derived.HyperbolicVisualShadowMetricUp.HyperbolicVisualShadowMetricUp`

Theorem 4142.2 (Hyperbolic visual-shadow metric NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$ *carrier*

$$V = (U, B, M, S, G, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}}$ *surface consists exactly of disk-carrier admission, boundary-shadow exposure, hyperbolic metric readback, visual-metric readback, Busemann-boundary attachment, phase-transport replay, componentwise transport, displayed continuation, package provenance, and local naming through $U, B, M, S, G, T, H, C, P, N$.*

Proof. Project the carrier of Definition 4142.1. The rows $U, B, M, S, G, T, H, C, P, N$ are the whole visual-shadow metric packet.

The disk and boundary data are read first. The disk carrier U supplies the visible points, the boundary-shadow row B supplies the shadow comparison, and the metric row M supplies the hyperbolic readback attached to those points.

The visual and Busemann rows then bind the comparison to a displayed boundary-facing route. The phase-transport row T records how the observer-expansion reading is replayed without importing a completed geometry.

Finally H, C, P, N transport, replay, source, and name the same finite route. Therefore the listed rows exhaust the NameCert surface and leave host disk models, quotient boundaries, global geometry, physical trajectories, and implicit field-faithfulness outside the packet. □

Lean4 ✓ `BEDC.Derived.HyperbolicVisualShadowMetricUp.HyperbolicVisualShadowMetricNamecertObligations`

Theorem 4142.3 (Hyperbolic visual-shadow metric factorization)**.** *Every accepted visual-shadow metric read factors through the disk carrier, boundary-shadow row,* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row,* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *row,* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row, phase-transport row, displayed replay, package provenance, and local* $\mathsf{NameCert}$ *row before use.*

Proof. Begin with an accepted carrier $V = (U, B, M, S, G, T, H, C, P, N)$. A read first lands on the disk-carrier row U, then consumes the boundary-shadow row B and the hyperbolic metric row M.

The visual comparison row S and Busemann boundary row G attach that metric read to a displayed boundary-facing visual surface. The phase-transport row T records the route along which the observer-expansion packet replays the comparison.

Transport, continuation, provenance, and naming are then supplied by H, C, P, N. Since no further coordinate is present, every accepted read factors through the displayed rows and cannot bypass them through host geometry, quotient boundary data, or an implicit global field instance. □

Falsifiable prediction: Every accepted visual-shadow metric read factors through the disk carrier, boundary-shadow row, $\mathsf{HyperbolicMetric}^{\uparrow}$ row, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ row, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ row, phase-transport row, displayed replay, provenance, and local $\mathsf{NameCert}$ row.

Independence witness: unitdisk, hyperbolicmetric, hyperbolic-boundary-shadow, hyperbolic-visual-metric, hyperbolic-busemann-boundary: no listed sibling is bijective to $\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$ because this packet jointly carries disk windows, boundary shadows, metric readback, visual comparison, Busemann boundary attachment, phase transport, replay, provenance, and local naming.

The future `lean4/BEDC/Derived/HyperbolicVisualShadowMetricUp/TasteGate.lean` file supplies explicit $\mathsf{Nontrivial}\ \mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$ instances. Those instances must preserve $U, B, M, S, G, T, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve as a TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$ packet is generated from UnitDisk carrier rows, boundary-shadow rows, HyperbolicMetric readback, HyperbolicVisualMetric comparison, HyperbolicBusemannBoundary attachment, phase transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4142.1, Definition 4142.2, and Definition 4142.3 seed the finite boundary-shadow visual metric route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed Poincare disk geometry, quotient ideal boundary equality, global field instances, physical observer trajectories, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, disk readback, boundary-shadow exposure, metric readback, visual comparison, Busemann boundary attachment, phase transport, TasteGate nontriviality, field faithfulness, and local naming for BEDC.Derived.HyperbolicVisualShadowMetricUp.

Chapter 4143

A Concrete Naming Certificate for $\mathsf{LocatedCauchyExtraction}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedCauchyExtraction}^{\uparrow}$ packet records the finite extraction surface that turns located regular-Cauchy modulus evidence into a sealed real-name read. It sits after the dyadic rational ledger of chapter 291, the stream observation window of chapter 126, the regular rational readback of chapter 301, the located-modulus boundary of chapter 3655, the located comparison rows of chapter 1730, and the terminal real-name seal of chapter 38. The packet names the extraction route as displayed BEDC data; it does not quotient Cauchy names, select a limit, use trichotomy, import a host order, or appeal to ambient completeness.

4143.1 Located Cauchy extraction carrier

Definition 4143.1 (Located Cauchy extraction carrier)**.** *A* $\mathsf{LocatedCauchyExtraction}^{\uparrow}$ *carrier is a finite packet* $(D, S, Q, L, U, M, E, H, C, P, N)$ *with the following displayed rows:*

1. D*, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision ledger for the positive dyadic budgets used by the extraction;*
2. S*, a* $\mathsf{StreamName}^{\uparrow}$ *observation window for the rational name being read;*
3. Q*, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposing the regular Cauchy rational values visible on* S*;*
4. L *and* U*, lower and upper* $\mathsf{LocatedRealComparison}^{\uparrow}$ *rows tied to the same window and dyadic ledger;*
5. M*, the* $\mathsf{RegularCauchyLocatedModulus}^{\uparrow}$ *row assigning displayed precision budgets to finite window depths;*
6. E*, the* $\mathsf{Real}^{\uparrow}$ *seal row that receives only the extracted finite regular-Cauchy read;*
7. H*, the componentwise* hsame *transport rows for* D, S, Q, L, U, M, E*;*
8. C*, the displayed* Cont *replay routes preserving the extraction window, located brackets, modulus row, and real seal;*
9. P*, the* Pkg *provenance rows for the dyadic ledger, stream window, regular readback, located comparison evidence, located modulus, and real seal;*
10. N*, the local* $\mathsf{NameCert}$ *row binding these ten rows as one located Cauchy extraction certificate.*

The carrier contains no quotient equality of Cauchy names, no selected limit, no trichotomy, no host real order predicate, and no ambient completeness principle.

Lean4 ✓ `BEDC.Derived.LocatedCauchyExtractionUp.LocatedCauchyExtractionTasteGate single carrier alignment`

Theorem 4143.2 (Located Cauchy extraction NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyExtraction}^{\uparrow}}$ *surface for Definition 4143.1 consists of finite admission of the rows* $(D, S, Q, L, U, M, E, H, C, P, N)$*, shared-window alignment for* S*, dyadic precision exactness through* D*, regular readback confinement through* Q*, located bracket export through* L, U*, modulus handoff through* M*, real sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 4143.1. The projection exposes exactly the rows $D, S, Q, L, U, M, E, H, C, P,$

The extraction route is fixed by the shared window and ledger. Row S is the only observation window, row D is the only dyadic precision source, and row Q is the only regular rational readback exposed to the located comparison and modulus rows.

The located handoff is then forced through L, U, M before the real seal E is read. Componentwise transport and replay through H and C preserve those rows, while P and N record provenance and local naming.

No carrier coordinate names quotient equality, a selected limit, trichotomy, a host order predicate, or ambient completeness. Hence the stated obligations exhaust the local NameCert surface. □

Theorem 4143.3 (Located Cauchy extraction Real-seal route)**.** *Every accepted* $\mathsf{LocatedCauchyExtraction}^{\uparrow}$ *packet exports toward* $\mathsf{Real}^{\uparrow}$ *only the finite route*

$$D, S, Q, L, U, M \longmapsto E \longmapsto H, C, P, N.$$

Any $\mathsf{LocatedRealComparison}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of the accepted packet must read through the displayed dyadic ledger, stream window, regular rational readback, located comparison rows, located modulus row, transport, replay, provenance, and local NameCert rows. The route supplies no quotient Cauchy equality, selected limit, trichotomy, host order, or ambient completeness.*

Proof. Start with an accepted carrier and apply Definition 4143.2. The obligations pin the regular rational readback to Q over the displayed window S and dyadic ledger D.

The located comparison rows L, U and the located-modulus row M are the only rows that can be exported before the seal E. Therefore every Real-facing consumer reaches the seal by the displayed finite route and not by selecting a limit outside the packet.

Transport, replay, provenance, and local naming are exactly H, C, P, N. Since the refused objects are absent from the carrier coordinates, no downstream consumer can recover quotient equality, trichotomy, host order, or ambient completeness from the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCauchyExtraction}^{\uparrow}$ packet is generated from a dyadic precision ledger, a StreamName observation window, a RegSeqRat readback, lower and upper located comparison rows, a regular-Cauchy located modulus row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedCauchyExtraction}^{\uparrow}}$, seed)

Scope closed: Definition 4143.1, Definition 4143.2, and Definition 4143.3 seed the finite extraction route from located regular-Cauchy modulus evidence to the RealUp seal.

Formal verification: FormalStatus(NameCert$_{\text{LocatedCauchyExtraction}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.LocatedCauchyExtractionUp.LocatedCauchyExtractionTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient equality of Cauchy names, selected limits, trichotomy, host real order, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located modulus handoff, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCauchyExtractionUp.

Chapter 4144

A Concrete Naming Certificate for $\mathsf{BanachMazurGame}^{\uparrow}$

Following Banach and Mazur on nested-open games, the $\mathsf{BanachMazurGame}^{\uparrow}$ packet records the finite alternating-play route by which a Polish complete-metric Baire argument is inspected inside BEDC. It sits over the Polish-space synthesis of chapter 1490, the Baire-category surface of chapter 1542, the complete-metric handoff of chapter 128, the metric carrier of chapter 57, the finite schedule discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names the classical Banach–Mazur game interface as finite NameCert data without adding a selected winning strategy, a host intersection point, countable choice, quotient equality of plays, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4144.1 (Banach–Mazur game carrier)**.** *A* $\mathsf{BanachMazurGame}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (P, B, K, M, L, S, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{PolishSpace}^{\uparrow}$ *row naming the complete separable metric source over which the play is read.*
2. *B is the* $\mathsf{BaireCategory}^{\uparrow}$ *row exposing the dense-open and residual obligations visible to the game consumer.*
3. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row, including displayed Cauchy-window and nested-ball support.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *row carrying the distance classifier, metric-radius comparisons, and ball-inclusion checks.*
5. *L is the alternating legal-move ledger, recording each finite play prefix, player tag, chosen basic open or ball row, predecessor inclusion, and shrinking-radius evidence.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule listing the finite play prefixes, dense-open requests, ball observations, and Cauchy-window inspections visible to downstream consumers.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational centers, radius budgets, tolerance comparisons, and dense-window observations used by L and S.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the Polish, Baire-category, complete-metric, metric, legal-move, schedule, and readback rows have been displayed.*

9. *H records componentwise* hsame *transport for P, B, K, M, L, S, R, E and for the structural rows.*
10. *C records displayed* Cont *replay from a game request through the Polish source, Baire-category obligation, complete-metric handoff, metric-radius checks, legal-move ledger, finite schedule, regular readback, Real seal, transport, provenance, and local naming rows.*
11. *Q is the* Pkg *provenance over* $\mathsf{BanachMazurGame}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachMazurGame}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting these displayed rows to a common Polish, Baire-category, complete-metric, metric, play-ledger, stream, readback, and real-seal surface. It has no coordinate for a global winning strategy, a chosen play limit, an infinite intersection object, a quotient of plays, countable choice, or an ambient host topology.

Lean4 ✓ `BEDC.Derived.BanachMazurGameUp.TasteGate.BanachMazurGameTasteGate single carrier alignment`

Theorem 4144.2 (Banach–Mazur game NameCert obligations)**.** *For every accepted* $\mathsf{BanachMazurGame}^{\uparrow}$ *carrier $G = (P, B, K, M, L, S, R, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachMazurGame}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed Polish, Baire-category, complete-metric, metric, legal-move, stream, readback, real-seal, transport, replay, provenance, and local naming rows;*
2. *source compatibility, requiring P, K, M to expose one complete metric source before a legal move can be read;*
3. *Baire-category visibility, requiring each dense-open or residual request to pass through B and the finite schedule S before the play ledger is consumed;*
4. *legal-move exactness, requiring L to store only finite alternating prefixes, predecessor inclusions, and shrinking-radius evidence;*
5. *readback discipline, requiring S, R, E to be read in that order before any real-facing terminal observation is exported;*
6. *structural preservation, requiring H, C, Q, N to transport, replay, source, and name exactly the displayed game route;*
7. *nonescape, excluding global winning strategies, selected limit points, host intersections, quotient equality of plays, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and hidden dense-open oracles.*

No Banach–Mazur-game obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4144.1. The analytic rows are P, B, K, M, L, S, R, E, and the structural rows are H, C, Q, N.

The complete metric source is fixed before play begins. The rows P, K, M expose the Polish packet, complete-metric handoff, and metric-radius checks on one displayed carrier, so a move ledger cannot switch to a second metric source.

The Baire-category part is scheduled. A dense-open or residual request is first read through B and then through the finite stream row S, while L records only the finite legal prefix and the displayed inclusion evidence for the chosen successor.

The terminal read is downstream of regular rational observation. The row R supplies rational centers, radii, and tolerances before E is consumed, and H, C, Q, N preserve the same route. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4144.3 (Banach–Mazur Polish–Baire handoff)**.** *Every* $\mathsf{BaireCategory}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BanachMazurGame}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{PolishSpace}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{BaireCategory}^{\uparrow} \longmapsto \mathsf{BanachMazurGame}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{Re}$$

The route supplies the complete-metric Baire interface by exposing finite alternating play prefixes, dense-open requests, metric-ball inclusions, stream windows, regular rational readback, and the terminal real-name seal. It does not select a winning strategy, choose an intersection point, quotient plays, invoke countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the Polish source. The packet reads P, K, M as the complete separable metric carrier, complete-metric handoff, and metric-radius comparison surface before any game row is inspected.

Next expose the Baire-category request. The row B supplies the dense-open or residual obligation, and the finite schedule S records the play prefix and observation windows through which that request is visible.

The game ledger is then read as finite data. The row L records alternating legal moves, predecessor inclusions, and shrinking-radius evidence, while R supplies the regular rational observations needed to compare centers and radii.

Finally the terminal seal E is reached only after the route has passed through P, K, M, B, L, S, R. The structural rows H, C, Q, N transport, replay, source, and name the same handoff, so the consumer receives the displayed Polish–Baire game interface and no hidden strategy, selected point, quotient play, choice principle, or ambient completeness datum. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachMazurGame}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachMazurGame}^{\uparrow}$ packet is generated from a PolishSpace source, BaireCategory dense-open row, CompleteMetric handoff, MetricSpace radius checks, an alternating legal-move ledger, StreamName schedule, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BanachMazurGame}^{\uparrow}}$, seed)

Scope closed: Definition 4144.1, Definition 4144.2, and Definition 4144.3 seed the finite Banach–Mazur route over $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BanachMazurGame}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not claim selected winning strategies, host intersection points, quotient play equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, Baire-category visibility, legal-move exactness, readback discipline, structural preservation, and nonescape for BEDC.Derived.BanachMazurGameUp.

Chapter 4145

A Concrete Naming Certificate for $\mathsf{EffectiveMetricSpace}^{\uparrow}$

Following Bishop and Bridges constructive metric spaces and Weihrauch represented spaces, the $\mathsf{EffectiveMetricSpace}^{\uparrow}$ packet records the finite interface needed by completion consumers before any limit object is formed. It refines the represented-name surface of chapter 1494, the distance obligations of chapter 57, the dyadic tolerance arithmetic of chapter 291, the scheduled name windows of chapter 126, the regular rational readback route of chapter 301, and the terminal real seal of chapter 38.

Definition 4145.1 (EffectiveMetricSpace carrier)**.** *An* $\mathsf{EffectiveMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, S, W, \rho, D, R, \delta, \Sigma, \Delta, T, C, P, N)$$

with the following rows:

1. *a point-name row* X *and a represented-space schedule* S, W, ρ *for finite* $\mathsf{StreamName}^{\uparrow}$ *reads;*
2. *a dyadic tolerance row* D *and a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *for all inspected distance approximants;*
3. *a* $\mathsf{Real}^{\uparrow}$*-valued distance seal* δ *whose admitted reads pass through* D *and* R*;*
4. *symmetry and triangle replay rows* Σ, Δ *for the displayed distance seal;*
5. *componentwise transport* T*, replay* C*, provenance* P*, and a local* $\mathsf{NameCert}$ *row* N*.*

The carrier is accepted only when every distance request exposes a scheduled name window, a dyadic tolerance, a regular rational readback, and the resulting $\mathsf{Real}^{\uparrow}$ *seal before a completion-facing consumer can inspect it.*

Lean4 ✓ `BEDC.Derived.EffectiveMetricSpaceUp.EffectiveMetricSpaceTasteGate` single carrier alignment

Theorem 4145.2 (EffectiveMetricSpace NameCert obligations)**.** *Every accepted* $\mathsf{EffectiveMetricSpace}^{\uparrow}$ *carrier* $E = (X, S, W, \rho, D, R, \delta, \Sigma, \Delta, T, C, P, N)$ *supplies the finite NameCert obligations needed by an* $\mathsf{EffectiveMetricCompletion}^{\uparrow}$ *consumer: point-name admission, represented-space scheduling, dyadic tolerance tracking, regular rational readback, Real-valued distance sealing, symmetry replay, triangle replay, componentwise transport, provenance, and local naming.*

Proof. Project the carrier of Definition 4145.1. The only rows available to a completion-facing reader are the displayed point names, scheduled representation reads, tolerance ledger, rational readback, real seal, replay rows, transport, provenance, and local NameCert.

The represented-space part is sourced by chapter 1494. The tolerance and readback rows then pass through chapter 291 and chapter 301, so the distance seal cannot be opened without the finite arithmetic route.

Finally the symmetry and triangle rows replay only that displayed seal. Transport and provenance carry the same finite packet into the local NameCert row, excluding host equality of points, selected representatives, countable choice, and ambient completion data. □

Theorem 4145.3 (EffectiveMetricSpace distance readback)**.** *For any two accepted point names in an* $\mathsf{EffectiveMetricSpace}^{\uparrow}$ *carrier, each distance read available to a Real or completion consumer factors through*

$$S, W, \rho \longmapsto D \longmapsto R \longmapsto \delta \longmapsto \Sigma, \Delta, T, C, P, N.$$

The read is therefore a finite scheduled $\mathsf{Real}^{\uparrow}$ *seal assembled from* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *data, not a host metric value, quotient representative, selected Cauchy name, or pre-existing completion point.*

Proof. Start with the two point names and their represented-space schedule. The carrier exposes only the finite $\mathsf{StreamName}^{\uparrow}$ windows and representation relation before any distance request can be made.

Next consume the dyadic and regular-rational rows. They produce the tolerance-indexed readback that feeds the $\mathsf{Real}^{\uparrow}$ distance seal, so the downstream reader sees a certified real value rather than an ambient metric value.

The replay rows Σ and Δ preserve symmetry and triangle evidence for the same seal. The transport, replay, provenance, and local naming rows then package the read for Real and completion consumers without adding a quotient, a selected representative, a choice principle, or an already completed point. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveMetricSpace}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EffectiveMetricSpace}^{\uparrow}$ packet is generated from displayed point-name rows, a represented-space schedule, dyadic tolerance data, regular rational readback, a Real-valued distance seal, symmetry and triangle replay rows, componentwise transport, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4145.1, Definition 4145.2, and Definition 4145.3 seed the finite effective-metric source interface consumed by Real and completion chapters.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close metric completion, located limits, quotient metric spaces, selected representatives, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, represented-space scheduling, dyadic and regular-rational readback, Real seal stability, symmetry and triangle replay, transport, provenance, and local naming.

Chapter 4146

A Concrete Naming Certificate for $\mathsf{ComputablePolishSpace}^{\uparrow}$

Following Weihrauch and Alexandrov–Urysohn, the $\mathsf{ComputablePolishSpace}^{\uparrow}$ packet records the complete separable metric object whose dense names, Cauchy realizers, representation decoder, and terminal real seal are all visible before any computable-analysis consumer reads the space. It sits after the Polish-space boundary of chapter 1490, the effective complete-separable route of chapter 1706, and the represented-space interface of chapter 1494. The packet also consumes the Cauchy-representation surface of chapter 1680, the explicit-modulus Cauchy route of chapter 1705, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. It is a BEDC finite naming surface for computable Polish data, not a quotient of names, a selected dense family, host equality, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4146.1 (Computable Polish space carrier)**.** *A* $\mathsf{ComputablePolishSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (P, E, R, A, Q, S, G, D, L, H, K, U, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{PolishSpace}^{\uparrow}$ *row, carrying the complete separable metric boundary read by ordinary Polish-space consumers.*
2. *E is the* $\mathsf{EffectivePolishSpace}^{\uparrow}$ *row, exposing the indexed dense family, explicit realizer route, and effective complete-separable metric data.*
3. *R is the* $\mathsf{RepresentedSpace}^{\uparrow}$ *row, presenting the finite name interface through which computable names reach target objects.*
4. *A is the* $\mathsf{CauchyRepresentation}^{\uparrow}$ *decoder row, routing stream observations through regular rational readback, dyadic tolerances, and the represented-space boundary.*
5. *Q is the* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *row, carrying the explicit-modulus Cauchy sequence data used by the realizer route.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule shared by the representation decoder and the effective Cauchy route.*
7. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and Cauchy stages.*

8. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger used for the decoder, regular readback, effective Cauchy modulus, and Real seal thresholds.*
9. *L is the terminal* Real$^{\uparrow}$ *seal row reached only after A, Q, S, G, D have been displayed.*
10. *H records componentwise* hsame *transport for the Polish, effective Polish, represented-space, Cauchy-representation, effective Cauchy, stream-window, regular-readback, dyadic-ledger, Real-seal, replay, provenance, and local naming rows.*
11. *K records displayed* Cont *replay from a computable-name request through R, A, S, Q, G, D, L and back to the Polish and effective-Polish rows P, E.*
12. *U is the* Pkg *provenance over* ComputablePolishSpace$^{\uparrow}$, PolishSpace$^{\uparrow}$, EffectivePolishSpace$^{\uparrow}$, RepresentedSpace$^{\uparrow}$, CauchyRepresentation$^{\uparrow}$, EffectiveCauchySequence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{ComputablePolishSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting the displayed rows to a common complete-separable, represented, Cauchy-realizer, stream-window, regular-readback, dyadic-tolerance, and Real-seal surface. It has no coordinate for quotient names, selected dense points, host equality of represented objects, countable choice, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.ComputablePolishSpaceUp.ComputablePolishSpaceTasteGate single carrier alignment`

Theorem 4146.2 (Computable Polish space NameCert obligations)**.** *For every accepted* ComputablePolishSpace$^{\uparrow}$ *carrier $C = (P, E, R, A, Q, S, G, D, L, H, K, U, N)$, the local* NameCert$_{\text{ComputablePolishSpace}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed Polish, effective Polish, represented-space, Cauchy-representation, effective Cauchy, StreamName, RegSeqRat, DyadicRatCore, Real-seal, transport, replay, provenance, and local naming rows;*
2. *complete-separable compatibility, requiring P and E to expose the same complete separable metric object through the displayed dense-realizer route;*
3. *representation exactness, requiring every computable name to pass through the represented-space row R and Cauchy-representation decoder A before a target-facing read is available;*
4. *effective Cauchy exactness, requiring the explicit row Q and the finite stream windows S to precede the regular rational readback G, dyadic ledger D, and Real seal L;*
5. *componentwise transport, continuation replay, package provenance, and local naming through H, K, U, N for exactly the displayed rows;*
6. *ledger nonescape, excluding quotient names, selected dense points, host equality, countable choice, trichotomy, open-cover compactness, ambient* Real$^{\uparrow}$ *completeness, Lean verification, and bridge checking as local certificate data.*

No computable-Polish-space obligation is stored outside these rows.

Proof. Project the carrier of Definition 4146.1. The projection exposes the Polish row P, effective Polish row E, represented-space row R, Cauchy-representation decoder A, effective Cauchy row Q, stream windows S, regular readback G, dyadic ledger D, Real seal L, and structural rows H, K, U, N.

The complete-separable compatibility row reads the sibling surfaces of chapter 1490 and chapter 1706. Since P and E occur in the same finite packet, a consumer cannot replace the displayed dense-realizer route by a second dense family or a hidden completion equality.

The representation route is then forced through chapter 1494 and chapter 1680. A computable name first exposes R and A, then reads the finite stream windows rather than an unscheduled name oracle.

The effective Cauchy route uses chapter 1705, chapter 301, chapter 291, and chapter 38. These rows place Q, S, G, D before L, so the Real seal is downstream of the explicit modulus and tolerance ledger.

Finally, H, K, U, N transport, replay, source, and name only that displayed packet. They introduce no quotient names, selected dense points, host equality, countable choice, trichotomy, open-cover compactness, or ambient Real completeness, and the listed rows exhaust the local NameCert surface. □

Theorem 4146.3 (Computable Polish space realizer handoff)**.** *Every represented-space, Polish-space, or Real-facing consumer of an accepted* $\mathsf{ComputablePolishSpace}^{\uparrow}$ *carrier* $C = (P, E, R, A, Q, S, G, D, L, H, K,$ *factors through the displayed route*

$$R, A \longmapsto S \longmapsto Q \longmapsto G \longmapsto D \longmapsto L \longmapsto P, E, H, K, U, N.$$

Thus the consumer receives the represented-space name interface, Cauchy-representation decoder, finite StreamName windows, EffectiveCauchySequence modulus route, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, Polish row, effective Polish row, transport, replay, provenance, and local naming before it can inspect the completed computable Polish object.

Proof. Begin with a represented-space, Polish-space, or Real-facing read of the carrier. The only name-facing rows are R and A, so the read must expose the represented-space interface and the Cauchy-representation decoder before any target row can be consumed.

Next replay the finite observation route. The row S supplies the inspected stream windows, while the effective Cauchy row Q supplies the explicit modulus route attached to those windows.

The regular and Real-facing handoff is then fixed by G, D, L. The regular rational readback G is read from the displayed windows and effective Cauchy stages; the dyadic ledger D records the tolerance data; and the Real seal L is terminal for that route.

Only after this handoff can the Polish and effective Polish rows P, E be read as a completed computable Polish object. The structural rows H, K, U, N preserve and name the same route, so no consumer can bypass it through quotient names, selected dense points, host equality, countable choice, trichotomy, open-cover compactness, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{ComputablePolishSpace}^{\uparrow}$ represented-space, Polish-space, or Real-facing read factors through a represented-space row, CauchyRepresentation decoder, StreamName finite windows, EffectiveCauchySequence modulus route, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, PolishSpace row, EffectivePolishSpace row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: polishspace, effective-polish-space, representedspace, cauchy-representation, effective-cauchy-sequence, streamname, regseqrat, dyadicratcore, real: $\mathsf{ComputablePolishSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries all of their displayed rows as one computable complete-separable name interface.

Closure status for $\mathsf{NameCert}_{\mathsf{ComputablePolishSpace}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\mathsf{ComputablePolishSpace}^{\uparrow}}$, seed)

Scope closed: Definition 4146.1, Definition 4146.2, and Definition 4146.3 seed the finite computable Polish route over PolishSpaceUp, EffectivePolishSpaceUp, RepresentedSpaceUp, CauchyRepresentationUp, EffectiveCauchySequenceUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{ComputablePolishSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient names, selected dense points, host equality, countable choice, trichotomy, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, complete-separable compatibility, representation exactness, effective Cauchy exactness, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.ComputablePolishSpaceUp.

Constructive story: A ComputablePolishSpace$^{\uparrow}$ packet is generated from PolishSpace, EffectivePolishSpace, RepresentedSpace, CauchyRepresentation, EffectiveCauchySequence, StreamName, RegSeqRat, DyadicRatCore, RealUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4147

A Concrete Naming Certificate for $\mathsf{LusinApproximation}^{\uparrow}$

Following Lusin and Bishop–Bridges constructive measure theory, the $\mathsf{LusinApproximation}^{\uparrow}$ packet records the finite route by which a measurable real-valued row is approximated on a large displayed set by a continuous row. It sits after the measurable carrier of chapter 92, the continuous-map surface of chapter 130, the integral readback route of chapter 123, the terminal real-name seal of chapter 38, the finite exceptional-window route of chapter 2204, and the density ledger of chapter 3448. The carrier exposes the approximant, tolerance, large-set, integral, replay, and naming rows needed by later measure-analysis packets; it is not a host regularity theorem, selected null-set completion, quotient almost-everywhere equality, or countable-choice construction.

Definition 4147.1 (Lusin approximation carrier)**.** *A* $\mathsf{LusinApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, A, C, F, E, I, R, H, Q, P, N)$$

with the following displayed rows:

1. *M is the ambient finite* $\mathsf{Measure}^{\uparrow}$ *row, exposing the measurable-set ledger and the finite measure budget against which the exceptional set is read.*
2. *A is the finite large-set and exceptional-window row, carrying the measurable subset on which the approximation is certified and the displayed complement budget.*
3. *C is the* $\mathsf{ContinuousMap}^{\uparrow}$ *approximant row, naming the continuous candidate consumed by the public approximation read.*
4. *F is the measured function row, stored as finite measurable readback data rather than as an ambient almost-everywhere equivalence class.*
5. *E is the error-tolerance row, recording the requested* $\mathsf{Real}^{\uparrow}$ *tolerance, the pointwise comparison window, and the bound used outside the exceptional set.*
6. *I is the* $\mathsf{Integral}^{\uparrow}$ *readback row, exposing the finite integral or size comparisons used when a consumer asks for quantitative approximation data.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal that compares the measured function, continuous approximant, tolerance, and integral-facing reads through the displayed finite route.*
8. *H records componentwise* hsame *transport for the measure, large-set, continuous, function, error, integral, Real, replay, provenance, and naming rows.*

9. *Q records displayed* Cont *replay of the route*

$$M, A, C, F, E, I, R \longmapsto H, P, N.$$

10. *P is the* Pkg *provenance over* LusinApproximation$^{\uparrow}$, Measure$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Integral$^{\uparrow}$, Real$^{\uparrow}$, Egorov$^{\uparrow}$, RadonNikodym$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{LusinApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, A, C, F, E, I, R, H, Q, P, N$. It has no coordinate for a host Lusin theorem, completed measure algebras, selected null sets, quotient almost-everywhere equality, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LusinApproximationUp.TasteGate.LusinApproximationTasteGate single carrier alignment`

Theorem 4147.2 (Lusin approximation NameCert obligations)**.** *For every accepted* LusinApproximation$^{\uparrow}$ *carrier*

$$L = (M, A, C, F, E, I, R, H, Q, P, N),$$

the local NameCert$_{\text{LusinApproximation}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the finite* Measure$^{\uparrow}$ *row M, the measured function row F, and the continuous approximant row C;*
2. *large-set and exceptional-window exposure through A, with the finite complement budget read in the same measure ledger as M;*
3. *tolerance and comparison exactness through E and the* Real$^{\uparrow}$ *seal R, requiring each public approximation read to display its error budget;*
4. *quantitative readback through I, requiring integral-facing or size-facing consumers to remain on the same finite route;*
5. *structural stability through H, Q, P, N, requiring componentwise transport, displayed replay, provenance, and local naming to preserve exactly the rows M, A, C, F, E, I, R.*

No obligation may be discharged by importing a host Lusin theorem, completing the measure algebra, choosing null representatives, quotienting by almost-everywhere equality, or appealing to countable choice.

Proof. Project the carrier of Definition 4147.1. The measure-facing rows are M and A, the approximation-facing rows are C, F, E, R, and the quantitative readback row is I.

The large-set budget is visible before any approximation conclusion is named. This is the same finite exceptional-window discipline used by chapter 2204, but the public consumer here reads a continuous approximant row rather than a uniform convergence window.

The density and integral-facing dependency is also explicit. The route through I and R mirrors the eventwise readback discipline of chapter 3448, while refusing completed measure algebras and quotient almost-everywhere classes.

Finally H, Q, P, N transport, replay, source, and name only those displayed rows. Since the excluded host theorem, null-set selector, quotient, choice, and completeness coordinates are absent from the carrier, the five listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{LusinApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{LusinApproximation}^{\uparrow}$ packet is generated from finite Measure rows, large-set and exceptional-window ledgers, ContinuousMap approximants, measurable function readback, Real tolerance seals, Integral readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LusinApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4147.1 and Definition 4147.2 seed the finite large-set continuous-approximant route from Measure and Real tolerance rows to ContinuousMap and Integral consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LusinApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host Lusin theorem, completed measure algebra, selected null representatives, quotient almost-everywhere equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, large-set budget exactness, continuous approximant admission, function readback, tolerance sealing, integral readback, transport stability, and replay stability for BEDC.Derived.LusinApproximationUp.

Chapter 4148

A Concrete Naming Certificate for $\mathsf{StreamNameModulus}^{\uparrow}$

Following Bishop and Bridges, a constructive modulus is treated as displayed finite control on later observations rather than as a selected limit object. The $\mathsf{StreamNameModulus}^{\uparrow}$ packet sits between the stream-name observation surface of chapter 126, the dyadic readback rows of chapter 291, the regular rational consumer of chapter 301, and the real-seal boundary of chapter 38. It records the finite witness by which a StreamName observation budget can be handed to RegSeqRat and Real consumers without claiming a completed stream quotient, a host-selected tail, or equality of real representatives.

Definition 4148.1 (Stream-name modulus carrier)**.** *A* $\mathsf{StreamNameModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, R, E, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row, containing the requested stream name, observed positions, and local observation budget.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row for the inspected positions.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row that receives the finite dyadic windows and their regularity ledger.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-request row, recording only the downstream consumer boundary that may later consume R.*
5. *W is the modulus ledger: for each requested precision it displays a finite stream position, the associated dyadic readback, and the regular-rational handoff row visible at that position.*
6. *H records componentwise* hsame *transport for S, D, R, E, W and the local certificate data.*
7. *C records displayed* Cont *replay from a precision request to the stream position, from that position to the dyadic readback, and from the readback to the RegSeqRat handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{StreamNameModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for a completed stream quotient, an ambient limit selector, a host real equality proof, or a tail chosen outside the displayed observation ledger.

Lean4 ✓ `BEDC.Derived.StreamNameModulusUp.StreamNameModulusTasteGate single carrier alignment`

Theorem 4148.2 (Stream-name modulus pointwise stability)**.** *Let $U = (S, D, R, E, W, H, C, P, N)$ be an accepted* $\mathsf{StreamNameModulus}^{\uparrow}$ *carrier. If a downstream consumer transports the displayed stream, dyadic readback, RegSeqRat handoff, Real seal-request, and modulus ledger along the componentwise* hsame *rows in H, then each precision request reads the same finite position of S, the same dyadic row of D, and the same regular-rational handoff in R after replay through C.*

Lean4 ✓ `BEDC.Derived.StreamNameModulusUp.StreamNameModulusCarrier pointwise stability`

Proof. Project the carrier of Definition 4148.1. The only precision-facing data are the rows S, D, R, E, W together with transport, replay, provenance, and the local name.

The modulus ledger W binds each requested precision to one displayed stream position and one displayed dyadic readback. Componentwise transport through H moves those rows together, so a transported request cannot alter the position without also altering the visible ledger row.

Replay through C reconstructs the same path from the precision request to S, then to D, then to R. The rows P and N only source and name this finite route; they do not add an external tail or equality proof. □

Theorem 4148.3 (Stream-name modulus monotone reindex stability)**.** *Let $U = (S, D, R, E, W, H, C, P, N)$ be an accepted* $\mathsf{StreamNameModulus}^{\uparrow}$ *carrier. If a later finite-window request is transported through the modulus ledger W, then the transported request preserves the same* $\mathsf{StreamName}^{\uparrow}$ *point certificate, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, and the same downstream* $\mathsf{Real}^{\uparrow}$ *seal route before any consumer may read a Real-facing conclusion.*

Proof. Project the carrier of Definition 4148.1. The rows S, D, R, E, W display the source point certificate, dyadic readback, regular-rational handoff, Real seal request, and modulus ledger for every accepted precision request.

Apply Definition 4148.2. A transported later request may move along the ledger W, but the corresponding stream position, dyadic readback, and regular-rational handoff remain attached to the same componentwise transport and replay rows.

Finally apply Definition 4148.4. The later finite-window request reaches the RegSeqRat handoff only through S, D, W, H, C, P, N, and the Real seal row E is read only after that handoff. Thus monotone reindexing cannot detach a tail selector from the displayed StreamName point certificate or from the Real-facing route. □

Theorem 4148.4 (Stream-name modulus RegSeqRat readiness)**.** *An accepted* $\mathsf{StreamNameModulus}^{\uparrow}$ *packet can be consumed by a* $\mathsf{RegSeqRat}^{\uparrow}$ *row only as the finite route*

$$S, D, W \longmapsto R$$

together with H, C, P, N. The handoff supplies displayed stream positions, dyadic observations, and regularity ledger rows, but it does not supply a completed sequence quotient, a selected tail, a host convergence theorem, or a real-equality witness.

Proof. Begin with the carrier projection. The RegSeqRat row R is not independent; it is stored beside the stream source S, dyadic readback D, and modulus ledger W.

Use pointwise stability from Definition 4148.2. Every transported precision request still reaches R through the same visible stream position and dyadic observation.

The RegSeqRat consumer therefore receives only the displayed finite route and its support rows. Since the carrier has no coordinate for quotient sequences, selected tails, host convergence, or real equality, none of those objects can be exported at the RegSeqRat boundary. □

Theorem 4148.5 (Stream-name modulus Real handoff)**.** *A* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{StreamNameModulus}^{\uparrow}$ *packet may import only the RegSeqRat-facing handoff R, the Real seal-request row E, and the finite stream/dyadic modulus route S, D, W, H, C, P, N. The packet therefore prepares a RealUp handoff by finite observed windows and regular rational rows, without asserting completeness of* $\mathsf{Real}^{\uparrow}$*, equality of Real representatives, or convergence outside the carried ledger.*

Proof. Apply Definition 4148.4. It identifies R as the only regular-rational object exported by the packet and forces the route through S, D, W, H, C, P, N.

The Real-facing row E records only that this regular-rational handoff is the object a Real consumer may later inspect. It is a seal-request row, not a proof of Real completeness or equality.

Thus the Real consumer receives the same finite modulus route that the RegSeqRat consumer receives, together with the request row E. No ambient limit, quotient equality, or external convergence datum is available. □

Theorem 4148.6 (Stream-name modulus NameCert obligations)**.** *For every accepted* $\mathsf{StreamNameModulus}^{\uparrow}$ *carrier $U = (S, D, R, E, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{StreamNameModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, stream-position exposure, dyadic readback, RegSeqRat handoff, Real seal-request boundary, modulus-ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obligation is discharged inside the displayed finite route and no obligation is stored outside U.*

Proof. Carrier admission is the projection of the finite tuple in Definition 4148.1. The rows S, D, R, E, W expose the stream source, dyadic readback, regular-rational handoff, Real request, and modulus ledger.

Pointwise stability supplies the transport obligation. Theorem 4148.2 keeps precision requests attached to the same displayed stream and dyadic rows under hsame movement.

The RegSeqRat readiness and Real handoff theorems supply the consumer-facing obligations. They show that R and E can be read only through the carried finite route.

Finally C, P, N replay, source, and name the packet. Since no remaining carrier coordinate exists, the listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{StreamNameModulus}^{\uparrow}$ consumer that reads a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ handoff without first exposing the displayed $\mathsf{StreamName}^{\uparrow}$ positions, $\mathsf{DyadicRatCore}^{\uparrow}$ readbacks, modulus ledger, componentwise hsame rows, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row refutes the packet surface.

Independence witness: streamname, dyadicratcore, regseqrat, real: none of the listed sibling chapters supplies the whole modulus handoff $U = (S, D, R, E, W, H, C, P, N)$, because each sibling contributes only the source stream, dyadic readback, regular rational consumer, or Real seal boundary while this chapter binds them into one finite modulus route.

Closure status for $\mathsf{NameCert}_{\mathsf{StreamNameModulus}^{\uparrow}}$.

Constructive story: A StreamNameModulus$^{\uparrow}$ packet is generated from a StreamName$^{\uparrow}$ source row, DyadicRatCore$^{\uparrow}$ readbacks, a RegSeqRat$^{\uparrow}$ handoff, a Real$^{\uparrow}$ seal-request row, a modulus ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate(NameCert$_{\text{StreamNameModulus}^{\uparrow}}$, seed)

Scope closed: Definition 4148.1, Definition 4148.2, Definition 4148.4, Definition 4148.5, and Definition 4148.6 seed the finite modulus handoff from StreamName$^{\uparrow}$ observations to RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ consumers.

Formal verification: FormalStatus(NameCert$_{\text{StreamNameModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a completed stream quotient, selected tails, host convergence, Real equality, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove the finite modulus ledger, RegSeqRat readiness, and Real handoff obligations for BEDC.Derived.StreamNameModulusUp.

Chapter 4149

A Concrete Naming Certificate for $\mathsf{FiniteObservationTraceFilter}^{\uparrow}$

The $\mathsf{FiniteObservationTraceFilter}^{\uparrow}$ packet realizes the finite verification trace of Definition 9393.4 as a concrete NameCert surface. It sits beside the finite-trace GAP socket of chapter 504 and the closed observation ledger of chapter 616. Its role is to filter observed trace rows through finite kernel checks while keeping the universal-induction boundary visible as a GAP-facing refusal.

Definition 4149.1 (Finite observation trace filter carrier)**.** *A* $\mathsf{FiniteObservationTraceFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (O, T, K, A, G, H, C, P, N)$$

with the following displayed rows:

1. *O is the closed-observation source row containing the finite observed states and their monotone ledger.*
2. *T is the finite verification trace row, listing inspected indices, their predicates, and the closed-generation checks visible at those indices.*
3. *K is the kernel-filter row that records which trace entries are accepted by finite verification and which are rejected as outside the carried window.*
4. *A is the audit row for non-escape: it records that no universal quantifier, induction schema, future-observation oracle, or hidden host rule is imported by the filter.*
5. *G is the GAP-socket row exposed when a consumer asks the finite trace to act as a universal statement.*
6. *H records componentwise* hsame *transport for O, T, K, A, G and the local certificate data.*
7. *C records displayed* Cont *replay from an observation request to the trace row, from the trace row to the kernel filter, and from a universal request to the GAP row.*
8. *P is the* Pkg *provenance over* BHist*, closed observation, finite-trace rows, GAP sockets,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationTraceFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these rows. It has no coordinate for a future observation, a substrate-internal induction principle, a universal closure over all indices, or a host-level truth predicate.

Theorem 4149.2 (Finite trace filter acceptance boundary)**.** *For every accepted* $\mathsf{FiniteObservationTraceFilter}^{\uparrow}$ *carrier* $F = (O, T, K, A, G, H, C, P, N)$*, a trace entry is available to a downstream consumer only after it appears in the finite trace row* T*, is checked by the kernel-filter row* K*, and is replayed through* C *with provenance* P *and local name* N*. Entries outside the displayed trace are not refused as false; they are routed to the GAP row* G *when a consumer asks for universal closure.*

Proof. Project the carrier. The observed source is O, the trace is T, and the filter row is K; no other row stores accepted trace entries.

The replay row C makes the accepted route explicit. It starts from the observation request, reads the finite trace entry, and then checks that entry against K.

When the requested entry is not in the displayed trace, the packet exposes the GAP row G rather than converting absence into a universal claim. The audit row A records this non-escape boundary, while P, N source and name the finite route. □

Theorem 4149.3 (Finite trace filter NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{FiniteObservationTraceFilter}^{\uparrow}}$ *surface consists exactly of closed-observation source admission, finite trace exposure, kernel-filter acceptance, non-escape audit, GAP-socket routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. These obligations certify finite trace filtering only; they do not certify induction, field completeness, universal closure, or future-observation coverage.*

Proof. Carrier admission exposes the tuple

$$F = (O, T, K, A, G, H, C, P, N).$$

The source, trace, filter, audit, and GAP rows are the only content rows.

Apply the acceptance boundary of Definition 4149.2. It identifies the accepted route through T, K, C, P, N and routes universal requests to G.

Transport through H preserves this row structure componentwise. Since the carrier has no row for induction, field completeness, universal closure, or future observations, the listed rows exhaust the NameCert obligations. □

Theorem 4149.4 (Finite trace filter TasteGate worklist)**.** *Any Lean TasteGate implementation for* $\mathsf{FiniteObservationTraceFilter}^{\uparrow}$ *must separate finite trace acceptance from algebraic adequacy by carrying explicit* `Nontrivial` *and* `FieldFaithful` *instance obligations for the numeric side of the filter. The paper packet records the finite trace boundary only; those instances are downstream formal work and cannot be inferred from closed observation rows alone.*

Lean4 ✓ `BEDC.Derived.FiniteObservationTraceFilterUp.FiniteObservationTraceFilterTasteGate`
`single carrier alignment`

Proof. The filter carrier records finite observation, trace, kernel acceptance, audit, GAP, transport, replay, provenance, and naming rows. None of these rows asserts that a numeric carrier has more than one element or that field operations are faithful to the intended readback.

The acceptance boundary therefore cannot discharge `Nontrivial` or `FieldFaithful` by projection. Those obligations must be visible in the Lean TasteGate work for any numeric consumer of the filter.

This keeps the concrete packet honest: it certifies finite observation filtering, while algebraic adequacy remains a separate formal instance surface. □

Theorem 4149.5 (Finite trace filter GAP handoff)**.** *If a downstream consumer treats an accepted* $\mathsf{FiniteObservationTraceFilter}^{\uparrow}$ *packet as evidence for a universal statement, the packet exports only the finite accepted rows and the GAP socket G. It supplies no substrate-internal induction rule, no future-observation oracle, no total trace closure, and no host truth predicate.*

Proof. Start with the NameCert obligations. They expose finite source, trace, filter, audit, GAP, transport, replay, provenance, and naming rows.

A universal request is not one of the accepted trace entries. By the acceptance boundary, such a request is routed to G rather than accepted by K.

The non-escape audit row A records that this is a refusal boundary. Since the carrier has no row for induction, future observations, total closure, or a host truth predicate, the GAP handoff is the only universal-facing export. □

Falsifiable prediction: An accepted $\mathsf{FiniteObservationTraceFilter}^{\uparrow}$ consumer that obtains a universal statement, induction rule, future-observation value, or host truth predicate without passing through the displayed GAP row G refutes the filter surface.

Independence witness: finite-trace-gap-socket, closedobservationsystem: the GAP socket names the universal request boundary and the closed-observation chapter names monotone finite records, but neither chapter supplies the kernel-filter row K and audit row A that classify accepted finite trace entries.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteObservationTraceFilter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteObservationTraceFilter}^{\uparrow}$ packet is generated from closed-observation rows, finite verification trace rows, kernel-filter acceptance rows, audit rows, GAP socket rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteObservationTraceFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4149.1, Definition 4149.2, Definition 4149.3, Definition 4149.4, and Definition 4149.5 seed the finite trace filter boundary for closed observation.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteObservationTraceFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim induction, universal trace closure, future-observation coverage, field adequacy, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove finite trace acceptance, GAP handoff, and the TasteGate instance boundary for BEDC.Derived.FiniteObservationTraceFilterUp.

Chapter 4150

A Concrete Naming Certificate for $\mathsf{LocatedCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedCompletion}^{\uparrow}$ packet records the finite located completion surface used by the L10 Real and Completion route. It sits between the located metric source of chapter 1533, the separated completion boundary of chapter 1612, the dense completion entry of chapter 1512, and the located completion space interface of **??**. The packet is a displayed NameCert route for located completion data; it is not a quotient completion, a selected representative, a countable-choice schedule, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4150.1 (LocatedCompletion carrier)**.** *A* $\mathsf{LocatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, E, W, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{LocatedMetric}^{\uparrow}$ *source row, including the metric carrier, located distance comparison, and finite request discipline consumed before completion data are public.*
2. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row, read before completed names may be compared as separated.*
3. *E is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row by which source observations enter the completion-facing route.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposed before any regular rational readback.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed stream windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling located comparison, Cauchy tail requests, and zero-distance checks.*
7. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after M, S, E, W, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the located metric source, separated boundary, embedding, window, readback, tolerance, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a completion request through the same ordered rows.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedCompletion}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, CompletionEmbedding $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompletion}^\uparrow}$ *row.*
The classifier compares accepted carriers only through $M, S, E, W, R, D, A, H, C, P, N$. It has no coordinate for quotient completion equality, selected completed representatives, host equality, countable choice, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedCompletionUp.LocatedCompletionTasteGate single carrier alignment`

Theorem 4150.2 (LocatedCompletion NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompletion}^\uparrow$ *carrier $L = (M, S, E, W, R, D, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedCompletion}^\uparrow}$ *surface consists exactly of carrier admission, located metric source exposure, separated completion exposure, dense embedding coverage, finite stream-window exactness, regular rational readback, dyadic tolerance accounting, terminal Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or completion-facing consumer must read those rows in the displayed route before it can use the local name.*

Lean4 ✓ `BEDC.Derived.LocatedCompletionUp.LocatedCompletionCarrier namecert obligations`

Proof. Project the carrier of Definition 4150.1. The displayed analytic rows are the located metric source M, separated completion boundary S, completion embedding E, stream windows W, regular readback R, dyadic tolerance ledger D, and Real seal A.

Read the source and embedding side first. The $\mathsf{LocatedMetric}^\uparrow$ row supplies located distance data, the $\mathsf{CompletionEmbedding}^\uparrow$ row admits source observations, and the $\mathsf{SeparatedCompletion}^\uparrow$ row supplies the separated comparison boundary named in chapter 1612.

The numerical route is finite. The stream windows W and dyadic ledger D precede the $\mathsf{RegSeqRat}^\uparrow$ readback R, and R precedes the terminal $\mathsf{Real}^\uparrow$ seal A.

Finally attach H, C, P, N. These rows transport, replay, source, and name the same route, while the carrier lists no quotient completion, selected representative, host equality, choice schedule, or ambient completeness coordinate. Hence the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{LocatedCompletion}^\uparrow}$ obligations. □

Theorem 4150.3 (LocatedCompletion L10 handoff)**.** *Every* $\mathsf{LocatedCompletion}^\uparrow$ *consumer route factors through the finite L10 chain*

$$\mathsf{LocatedMetric}^\uparrow \longmapsto \mathsf{CompletionEmbedding}^\uparrow \longmapsto \mathsf{SeparatedCompletion}^\uparrow \longmapsto \mathsf{StreamName}^\uparrow, \mathsf{DyadicRatCore}^\uparrow \longmapsto \mathsf{RegS}$$

The handoff is the same route consumed by the located completion space chapter of **??***; it exports no quotient completion, selected completed point, host equality, countable-choice selector, or ambient completeness theorem.*

Proof. Use Definition 4150.2 to expose the full packet route. The located metric row, dense embedding, separated boundary, finite windows, tolerance ledger, readback, and Real seal must all be displayed before the local name is available.

Compare this route with **??**. The located completion space interface consumes the same sibling rows but packages them as a space-facing boundary, while the present chapter packages them as the local located completion object.

No additional completion principle remains. The structural rows H, C, P, N merely transport, replay, source, and name the displayed chain, and the refused quotient, selection, equality, choice, and ambient-completeness objects have no coordinate in the carrier. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCompletion}^{\uparrow}$ consumer displays a $\mathsf{LocatedMetric}^{\uparrow}$ source row, a $\mathsf{CompletionEmbedding}^{\uparrow}$ dense entry row, a $\mathsf{SeparatedCompletion}^{\uparrow}$ boundary row, $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: locatedmetric, separatedcompletion, completionembedding, streamname, regseqrat, dyadicratcore, real: $\mathsf{LocatedCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries located metric source data, dense entry, separated completion boundary, finite stream windows, dyadic tolerance, regular readback, Real sealing, transport, continuation, provenance, and local naming as one completion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4150.1, Definition 4150.2, and Definition 4150.3 seed the finite located completion surface over $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected completed representatives, host equality of completed points, countable choice, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, located source exposure, separated completion compatibility, embedding coverage, finite readback exactness, Real seal exactness, transport replay, and non-escape over the same displayed packet.

Constructive story: A $\mathsf{LocatedCompletion}^{\uparrow}$ packet is generated from a located metric source, a dense completion entry, a separated completion boundary, finite stream windows, dyadic tolerances, regular rational readback, a Real seal, and structural NameCert rows.

Chapter 4151

A Concrete Naming Certificate for $\mathsf{SeparatedReflection}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SeparatedReflection}^{\uparrow}$ packet records the boundary where a pseudometric source exposes zero-distance evidence before any consumer treats that evidence as point identity. It starts from the displayed source rows of chapter 1614, routes the zero-distance boundary through the separated classifier of chapter 1411, and hands only that routed surface to the completion consumer of chapter 1506. Its finite readback remains inside the stream windows of chapter 126, the regular rational route of chapter 301, and the terminal real-name seal of chapter 38. The packet therefore names the constructive pseudometric-to-separated boundary without quotient primitives, selected representatives, host equality, countable choice, trichotomy, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4151.1 (SeparatedReflection carrier)**.** *A* $\mathsf{SeparatedReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (P_0, Z, S, M, R, E, H, C, N)$$

with the following displayed rows:

1. *P_0 is the source* $\mathsf{Pseudometric}^{\uparrow}$ *packet, including point admission, displayed distance witnesses, dyadic tolerance and triangle ledgers, stream windows, regular rational readback, a real-distance seal, and the zero-distance boundary available before separation.*
2. *Z records the zero-distance boundary as evidence read from P_0. It does not identify source point rows and does not introduce a quotient class.*
3. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier handoff. It is the first row allowed to turn zero-distance evidence into separated point-classifier evidence.*
4. *M is the metric-completion readback row. It hands the separated classifier surface to* $\mathsf{MetricCompletion}^{\uparrow}$ *only after S has been displayed.*
5. *R is the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window route available to completion and real-readback consumers.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached from the displayed finite and regular rational rows.*
7. *H stores componentwise* hsame *transport for the pseudometric source, zero-distance boundary, separated classifier, completion readback, finite-window route, real seal, replay, provenance, and local naming rows.*

8. *C stores the displayed* Cont *replay from pseudometric inspection through zero-distance evidence, separated classifier handoff, completion readback, finite windows, regular rational readback, and real sealing.*

9. *N is both the* Pkg *provenance over* $\mathsf{Pseudometric}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows and the local* $\mathsf{NameCert}_{\mathsf{SeparatedReflection}^{\uparrow}}$ *row.*

The carrier is a finite reflection-boundary certificate. It has no quotient-completion coordinate, no host-equality coordinate, no selected representative, no countable-choice selector, no trichotomy row, no open-cover compactness principle, and no ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.SeparatedReflectionUp.SeparatedReflectionTasteGate single carrier alignment`

Theorem 4151.2 (SeparatedReflection NameCert obligations)**.** *For every accepted* $\mathsf{SeparatedReflection}^{\uparrow}$ *carrier* $P = (P_0, Z, S, M, R, E, H, C, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SeparatedReflection}^{\uparrow}}$ *surface consists exactly of the displayed rows for source pseudometric admission, zero-distance boundary exposure, separated carrier handoff, metric-completion readback, StreamName-RegSeqRat-Real sealing, componentwise transport, continuation replay, provenance, and local naming. No obligation may be discharged by a quotient completion, host equality, selected representative, countable-choice selector, trichotomy split, open-cover compactness datum, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification row, or bridge row.*

Proof. Project the carrier of Definition 4151.1. The tuple displays the source pseudometric packet, zero-distance row, separated classifier, completion readback, finite-window and regular-rational route, real seal, transport, replay, provenance, and naming rows.

The obligation order is the order of those displayed rows. The zero-distance evidence is first held in Z, the separated carrier handoff is S, and completion-facing readback is delayed until M reads the routed separated surface.

The finite numerical readback is confined to R and E, while H, C, N provide transport, replay, provenance, and local naming. Since none of the excluded principles is a field of the carrier, none can serve as a local NameCert obligation. □

Theorem 4151.3 (SeparatedReflection zero-distance boundary)**.** *Let* $P = (P_0, Z, S, M, R, E, H, C, N)$ *be an accepted* $\mathsf{SeparatedReflection}^{\uparrow}$ *packet. Every consumer that reads zero-distance evidence from the pseudometric source receives that evidence first as the displayed boundary row* Z*. If the consumer asks for point identity, the request must pass through the separated classifier row* S *before any metric, completion, regular-rational, or real-readback row can consume it.*

Proof. Start with the source row P_0. It supplies the pseudometric distance surface and exposes zero-distance evidence without identifying source point histories.

The boundary row Z records exactly that evidence. It is not a point-identity row, so a consumer that needs identity has no route inside P_0 or Z.

The first identity-facing coordinate is S. Therefore every downstream metric, completion, regular-rational, or real-readback consumer receives the zero-distance claim only after the separated classifier handoff has been displayed. □

Theorem 4151.4 (SeparatedReflection completion handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{SeparatedReflection}^{\uparrow}$ *packet reads the route*

$$\mathsf{Pseudometric}^{\uparrow} \to Z \to \mathsf{SeparatedMetric}^{\uparrow} \to \mathsf{MetricCompletion}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Thus completion consumers obtain only the separated carrier handoff and its finite readback; they do not obtain quotient completion, host equality, selected representatives, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness from the reflection packet.*

Proof. Read the displayed carrier order. The pseudometric source precedes the zero-distance row, the zero-distance row precedes the separated classifier, and the separated classifier precedes the completion readback.

The numerical part of the read is then forced through R and E. Stream windows and regular rational approximants are displayed before the real seal, so completion-facing consumers see a finite readback route rather than a detached real object.

The exclusions are inventory facts. No quotient completion, host-equality proof, selected representative, countable-choice selector, trichotomy split, open-cover compactness datum, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem is present in P, so no completion handoff can export one. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparatedReflection}^{\uparrow}$ packet is generated from a source $\mathsf{Pseudometric}^{\uparrow}$ packet, a displayed zero-distance boundary row, a $\mathsf{SeparatedMetric}^{\uparrow}$ classifier handoff, a $\mathsf{MetricCompletion}^{\uparrow}$ readback row, local StreamNameRegSeqRat-Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4151.1, Definition 4151.2, Definition 4151.3, and Definition 4151.4 seed the finite boundary between pseudometric zero-distance evidence and separated completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, host equality, selected representatives, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zero-distance boundary exposure, separated carrier handoff, completion readback, finite real sealing, transport replay, provenance visibility, and non-escape for BEDC.Derived.SeparatedReflecti

Chapter 4152

A Concrete Naming Certificate for $\mathsf{ConstructiveLipschitzFlow}^{\uparrow}$

Following Picard and Lindelof, local flow data are treated here as a finite constructive package: a metric phase row, a rational time-window row, a local Lipschitz budget, an Euler-style approximation schedule, and a replay ledger that records how each requested window is inspected. The $\mathsf{ConstructiveLipschitzFlow}^{\uparrow}$ packet names the local existence interface for ODE consumers without importing host flows, selected maximal intervals, ambient completeness, or global continuation. Its local-flow route consumes the Lipschitz budget surface of chapter 3724 together with the map boundary of chapter 410, the phase metric row of chapter 57, the regular time-window readback of chapter 301, and the finite schedule surface of chapter 126.

Definition 4152.1 (Constructive Lipschitz flow carrier)**.** *A* $\mathsf{ConstructiveLipschitzFlow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, T, L, E, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *phase row containing the point-history carrier, metric readbacks, distance classifier, and local metric* $\mathsf{NameCert}$*.*
2. *T is the rational time-window row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *windows and not through a host interval object.*
3. *L is the local Lipschitz budget row; it records the radius, time-length, and contraction budget inspected by the packet.*
4. *E is the finite approximation schedule, read as a* $\mathsf{StreamName}^{\uparrow}$ *sequence of local Euler windows.*
5. *W is the observation ledger joining metric-radius requests, time windows, Lipschitz-budget checks, and approximation-window readbacks.*
6. *H records componentwise* hsame *transport for M, T, L, E, W and the local certificate rows.*
7. *C records the displayed* Cont *replay from a requested local flow window to its metric, time, Lipschitz, and approximation rows.*
8. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveLipschitzFlow}^{\uparrow}}$ *row.*

The classifier compares two accepted carriers only by transporting these displayed rows to a common metric, time-window, Lipschitz-budget, and approximation-schedule surface. It has no coordinate for a selected host solution curve, maximal interval, quotient trajectory, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.ConstructiveLipschitzFlowUp.TasteGate.ConstructiveLipschitzFlowTasteGate`
`single carrier alignment`

Theorem 4152.2 (Constructive Lipschitz flow NameCert obligations)**.** *For every accepted* ConstructiveLipschitzFlo *carrier* $F = (M, T, L, E, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveLipschitzFlow}^{\uparrow}}$ *surface consists exactly of the carrier admission row, classifier-transport row, local Lipschitz-budget row, finite approximation-schedule row, observation-ledger exactness row, continuation-replay row, package-provenance row, and local naming row. These rows bind* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *as the whole public obligation surface.*

Proof. Project the carrier of Definition 4152.1. The projection displays the phase metric row M, time-window row T, Lipschitz budget L, approximation schedule E, observation ledger W, transport row H, continuation row C, provenance row P, and local name N.

Classifier transport uses H to keep all rows over one metric and one time-window surface. The Lipschitz budget is therefore read with the same metric-radius and rational time data as the approximation schedule.

The ledger exactness clause is exhausted by W. Every local-flow request must pass through the displayed metric, time, budget, and schedule windows before it reaches the Cont replay row.

Finally attach P and N. These rows source and name the displayed packet; they add no host solution curve, selected maximal interval, quotient trajectory, or ambient completeness principle. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 4152.3 (Constructive Lipschitz flow local-window boundary)**.** *Every downstream ODE consumer of an accepted* $\mathsf{ConstructiveLipschitzFlow}^{\uparrow}$ *carrier* $F = (M, T, L, E, W, H, C, P, N)$ *must read local flow data through the displayed metric row* M*, rational time-window row* T*, Lipschitz budget* L*, approximation schedule* E*, observation ledger* W*, componentwise transport* H*, continuation replay* C*, package provenance* P*, and local* NameCert *row* N*. The packet supplies no global flow, no selected maximal interval, no quotient trajectory equality, no closed completeness of the phase space, and no host-level uniqueness theorem.*

Proof. Start from the NameCert obligation surface of Definition 4152.2. It exposes only the metric, time, budget, schedule, ledger, transport, replay, provenance, and naming rows.

A local-window request first fixes its rational time window and its metric radius through T and M. The Lipschitz budget L and approximation schedule E can then be inspected only through the ledger W.

The continuation row C replays this finite inspection route, while H keeps the rows componentwise stable and P, N record provenance and naming. Since no carrier coordinate stores a host flow or maximal interval, the downstream consumer receives only the displayed local-window data. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveLipschitzFlow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ConstructiveLipschitzFlow}^{\uparrow}$ packet is generated from a phase metric row, rational time-window row, local Lipschitz budget, finite approximation schedule, observation ledger, componentwise transport, displayed continuation replay, package provenance, and local naming data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveLipschitzFlow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4152.1, Definition 4152.2, and Definition 4152.3 define the local flow carrier and seed the ODE-facing local-window route over $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\mathsf{ConstructiveLipschitzFlow}\uparrow}$, unformalized)
Bridge status: none
Origin: human
Not claimed: This chapter does not close a Lean target, global flows, selected maximal intervals, quotient trajectories, phase-space completeness, host uniqueness, or bridge checking.
Upgrade path: Obligation closure requires checked carrier admission, classifier transport, Lipschitz-budget exactness, approximation-schedule replay, and local-window non-escape for the same packet.

Chapter 4153

A Concrete Naming Certificate for $\mathsf{LebesgueDifferentiation}^{\uparrow}$

Following Lebesgue and Bishop–Bridges constructive measure theory, the $\mathsf{LebesgueDifferentiation}^{\uparrow}$ packet records the finite differentiation-at-a-window surface obtained from measurable local averages, finite Vitali subcover ledgers, and Hardy–Littlewood maximal domination rows. It sits after the measurable-event and integral rows of chapter 92, the finite covering ledger of chapter 2166, the maximal-function domination packet of chapter 3581, the dyadic tolerance rows of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite local differentiation certificate; it is not measure completion, an almost-everywhere quotient, a countable-choice selection, or a host theorem about all measurable functions.

Definition 4153.1 (Lebesgue differentiation carrier)**.** *A* $\mathsf{LebesgueDifferentiation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, F, V, H_0, A, D, E, T, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row, exposing only the finite measurable-event and local-measure requests inspected by the packet.*
2. *F is the displayed function-read row whose local averages are tested through the measure row.*
3. *V is the* $\mathsf{FiniteVitaliCover}^{\uparrow}$ *ledger, recording the finite disjoint subfamily, cover cells, and overlap budget used by the differentiation window.*
4. *H_0 is the* $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$ *domination row that bounds the exceptional local-average requests before a differentiation verdict is consumed.*
5. *A records the finite local-average rows for the inspected balls or intervals.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare radii, averages, exceptional budgets, and real-name windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the value and error-bound reads.*
8. *T records componentwise* hsame *transport for the measure, function, Vitali, maximal, average, dyadic, real, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the route from finite local-average requests through M, F, V, H_0, A, D, E.*

10. *P is the* Pkg *provenance over* LebesgueDifferentiation$^{\uparrow}$, Measure$^{\uparrow}$, FiniteVitaliCover$^{\uparrow}$, HardyLittlewoodMaximal$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{LebesgueDifferentiation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, F, V, H_0, A, D, E, T, C, P, N$. It has no coordinate for a completed measure algebra, an almost-everywhere quotient, a countable family of selected radii, a selected representative of a function, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LebesgueDifferentiationUp.LebesgueDifferentiationTasteGate single carrier alignment`

Theorem 4153.2 (Lebesgue differentiation NameCert obligations)**.** *For every accepted* LebesgueDifferentiation$^{\uparrow}$ *carrier*

$$L = (M, F, V, H_0, A, D, E, T, C, P, N),$$

the local NameCert$_{\text{LebesgueDifferentiation}^{\uparrow}}$ *surface consists exactly of carrier admission for the measure row, displayed function-read row, finite Vitali-cover ledger, Hardy–Littlewood maximal domination row, local-average rows, dyadic tolerance ledger, real seal, componentwise transport, displayed continuation, package provenance, and local naming.*

Proof. Project the carrier of Definition 4153.1. The rows $M, F, V, H_0, A, D, E, T, C, P, N$ are the whole displayed packet.

The measurable and averaging data are read first. The measure row M admits the inspected event and local-measure requests, while F and A supply the displayed function windows and average rows.

The covering and domination rows then constrain the differentiation request. The Vitali ledger V supplies the finite cover selection surface, and the Hardy–Littlewood row H_0 supplies the maximal domination boundary before the real-valued verdict is exposed.

Finally D, E, T, C, P, N compare, seal, transport, replay, source, and name the same finite route. Since no additional coordinate is present, the NameCert surface exports no measure completion, almost-everywhere quotient, countable-choice selector, selected representative, or ambient Real$^{\uparrow}$ completeness. □

Theorem 4153.3 (Lebesgue differentiation Vitali-maximal handoff)**.** *Every differentiation read accepted by a* LebesgueDifferentiation$^{\uparrow}$ *packet factors through the finite Vitali-cover ledger of chapter 2166 and the maximal-domination surface of chapter 3581 before it reaches the* Measure$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows used by downstream measure and real-name consumers.*

Proof. Start with an accepted carrier $L = (M, F, V, H_0, A, D, E, T, C, P, N)$. A differentiation read reaches the local averages only through the measure and function rows M, F, A.

The finite covering step is then forced through V. It supplies the disjoint subfamily, cover-cell ledger, and overlap budget used by the local differentiation window.

The maximal-function step is forced through H_0. It bounds the exceptional average requests before the dyadic comparison row D and terminal real seal E can be consumed.

Thus the accepted read follows the ordered route through finite Vitali cover, Hardy–Littlewood maximal domination, measure, dyadic tolerance, and real-name rows, with T, C, P, N preserving the route. No countable selection, measure completion, almost-everywhere quotient, selected function representative, or ambient completeness row can be inserted into that handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueDifferentiation}^{\uparrow}}$.

Constructive story: A $\mathsf{LebesgueDifferentiation}^{\uparrow}$ packet is generated from a MeasureUp source row, displayed function-read rows, a FiniteVitaliCover ledger, HardyLittlewoodMaximal domination, local-average rows, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueDifferentiation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4153.1, Definition 4153.2, and Definition 4153.3 seed the finite differentiation-window route over MeasureUp, FiniteVitaliCoverUp, HardyLittlewoodMaximalUp, DyadicRatCoreUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueDifferentiation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim measure completion, almost-everywhere quotient equality, countable-choice radius selection, selected function representatives, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Vitali-cover handoff, maximal-domination handoff, dyadic tolerance sealing, real-name nonescape, and local naming for BEDC.Derived.LebesgueDifferentiationUp.

Chapter 4154

A Concrete Naming Certificate for $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$

The $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ packet realizes the observer-shadow reading of chapter 9463 as finite NameCert data. It consumes the visual-shadow metric surface of chapter 4142, the general metric rows of chapter 57, finite observation windows from chapter 126, regular rational readbacks from chapter 301, and terminal real-name seals from chapter 38. The packet names the finite visual shadow seen by a focused observer route; it is not a global hyperbolic model, a physical observer trajectory, a quotient boundary, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4154.1 (Hyperbolic observer-shadow metric carrier)**.** *A* $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, M, W, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$ *source row, supplying the boundary-shadow visual metric packet.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *comparison row used when the observer-shadow read is consumed as a metric datum.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule opened for the visual-shadow and metric reads.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed shadow distance.*
6. *F is the focused observer-shadow row, recording which observer-facing finite route is being inspected.*
7. *H records componentwise* hsame *transport for the visual-shadow, metric, window, readback, real, focus, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the focused observer-shadow request through S, M, W, R, E, F.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$, $\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, W, R, E, F, H, C, P, N$. It has no coordinate for a completed hyperbolic space, quotient boundary equality, physical observer path, hidden global geometry, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.HyperbolicObserverShadowMetricUp.HyperbolicObserverShadowMetricTasteGate`
`single carrier alignment`

Theorem 4154.2 (Hyperbolic observer-shadow metric NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ *carrier*

$$O = (S, M, W, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}}$ *surface consists exactly of visual-shadow admission, metric comparison admission, finite stream-window exposure, regular-rational readback, terminal real sealing, focused observer-shadow routing, componentwise transport, displayed replay, package provenance, and local naming through* $S, M, W, R, E, F, H, C, P, N$.

Proof. Project the carrier of Definition 4154.1. The listed rows are the whole observer-shadow metric packet.

The visual-shadow row S is read before the metric row M. This keeps the metric comparison tied to the finite visual-shadow carrier rather than to a host hyperbolic model.

The window, readback, and real-seal rows W, R, E then expose the numerical shadow distance through the same L10 real-name route. The focused row F records the observer-facing route being inspected.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no further coordinate is present, the NameCert surface exports no completed hyperbolic space, quotient boundary equality, physical observer trajectory, hidden global geometry, or ambient real completeness. □

Theorem 4154.3 (Hyperbolic observer-shadow L10 handoff)**.** *Every* $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ *consumer that reads a shadow distance factors through* $\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before the focused observer-shadow route can be consumed as a finite NameCert datum.*

Proof. Begin with an accepted carrier $O = (S, M, W, R, E, F, H, C, P, N)$. The source visual-shadow metric row S supplies the displayed boundary-shadow packet.

The metric comparison row M is then consumed through the finite metric surface, and the L10 numeric read follows the window, readback, and real-seal route W, R, E.

Only after these rows are displayed does the focused row F expose the observer-shadow route. Transport, continuation, provenance, and local naming are supplied by H, C, P, N, so the handoff remains finite and cannot pass through a host global geometry or quotient boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ packet is generated from a HyperbolicVisualShadowMetric row, a MetricUp comparison row, StreamName windows, RegSeqRat readback, a RealUp seal, a focused observer-shadow row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}}$, seed)

Scope closed: Definition 4154.1, Definition 4154.2, and Definition 4154.3 seed the finite observer-shadow metric route over visual-shadow, metric, stream-window, regular-rational, and real-name rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim completed hyperbolic geometry, quotient boundary equality, physical observer trajectories, hidden global geometry, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, visual-shadow source admission, metric comparison, stream-window readback, real-name sealing, focused observer routing, and local naming for BEDC.Derived.HyperbolicObserverShadowMet

The RegularDoubleCauchy$^{\uparrow}$ route reads the rectangular StreamName$^{\uparrow}$/RegSeqRat$^{\uparrow}$/DyadicRatCore$^{\uparrow}$ surface as a sibling of chapter 460 before the RealCauchyCompletion$^{\uparrow}$ and Real$^{\uparrow}$ seals are available.

Chapter 4155

A Concrete Naming Certificate for $\mathsf{RegularDoubleCauchy}^{\uparrow}$

Following Pringsheim's regular convergence of double sequences, Moore–Osgood interchange discipline, and Bishop–Bridges constructive Cauchy completion, the $\mathsf{RegularDoubleCauchy}^{\uparrow}$ packet records a two-parameter regular Cauchy certificate that does not collapse immediately to a diagonal route. It refines the diagonal handoff of chapter 460 by keeping row and column stability visible before the downstream completion consumer reads the terminal seal. The packet sits over the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the completion-facing route of chapter 360. It provides Moore–Osgood and completion consumers with a finite rectangular regularity surface without asserting host double-sequence convergence, quotient arrays, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Theorem 4155.1 (RegularDoubleCauchy carrier)**.** *A* $\mathsf{RegularDoubleCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, R, D, T, W, H, C, P, N)$$

with the following visible rows: S *is the* $\mathsf{StreamName}^{\uparrow}$ *family schedule for finite rectangular windows;* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row-column readback attached to every admitted row and column face;* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *rectangular tolerance ledger;* T *is the diagonal cofinal schedule read only after the rectangular ledger has been displayed;* W *is the* $\mathsf{RealCauchyCompletion}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *seal handoff;* H *records componentwise* hsame *transport;* C *records displayed* Cont *replay;* P *is the* Pkg *provenance over* $\mathsf{RegularDoubleCauchy}^{\uparrow}$*,* $\mathsf{CauchyDoubleSequence}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*; and* N *is the local* $\mathsf{NameCert}_{\mathsf{RegularDoubleCauchy}^{\uparrow}}$ *row.*

The carrier is rectangular before it is diagonal. It contains no coordinate for a host double limit, quotient equality of arrays, a selected limiting value, countable-choice scheduling, or ambient real completeness.

Proof. Read the packet as a displayed BHist row. The entries S, R, D expose the finite rectangular data before the diagonal schedule T is available, so the consumer cannot begin with a collapsed single sequence.

The completion-facing row W is downstream from the same visible schedule, readback, and tolerance ledger. Transport and replay are exhausted by H and C, while provenance and naming are exhausted by P and N.

Since the listed tuple has no further coordinate, the excluded host convergence, quotient-array, selected-limit, choice, and ambient-completeness data cannot be read from the carrier. □

Theorem 4155.2 (RegularDoubleCauchy row-column stability)**.** *For every accepted* $\mathsf{RegularDoubleCauchy}^{\uparrow}$ *carrier* $A = (S, R, D, T, W, H, C, P, N)$*, any two finite reads that agree on the displayed* $\mathsf{StreamName}^{\uparrow}$ *rectangular window schedule and on the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger have the same row and column* $\mathsf{RegSeqRat}^{\uparrow}$ *readback under the componentwise* hsame *transport recorded in* H*. The stability is local to the finite rows* S, R, D, H, C, P, N *and does not identify quotient arrays or assert a host double-sequence limit.*

Proof. Project the schedule and ledger rows. The rectangular window family is supplied by S, and the tolerance comparison used for every row and column face is supplied by D.

Apply the readback row R to the same displayed windows and ledger entries. Componentwise hsame transport in H preserves the row face and the column face before any completion handoff is inspected.

The replay row C repeats this route for a consumer request, and P, N keep the request inside the local packet. No quotient-array or host-limit coordinate is present, so the stability conclusion is exactly the visible row-column readback. □

Theorem 4155.3 (RegularDoubleCauchy diagonal readback)**.** *Every diagonal read of an accepted* $\mathsf{RegularDoubleCauchy}^{\uparrow}$ *carrier factors through the rectangular route*

$$S, D \longmapsto R \longmapsto T \longmapsto W.$$

Thus a $\mathsf{CauchyDoubleSequence}^{\uparrow}$*,* $\mathsf{MooreOsgood}^{\uparrow}$*,* $\mathsf{RealCauchyCompletion}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer sees the diagonal cofinal schedule only after the StreamName windows, RegSeqRat row-column readback, and DyadicRatCore rectangular tolerance ledger have been displayed.*

Proof. Start with the rectangular rows. A diagonal request must first open the finite windows in S and account for the requested precision in D.

The row-column readback R is then the only route from those rectangular windows to a regular rational name. The diagonal schedule T is read after this regularity data, not before it.

Finally the completion-facing handoff W consumes the scheduled readback. Therefore every cited downstream consumer receives the diagonal route as a readback of the rectangular certificate, not as an independent host convergence assertion. □

Theorem 4155.4 (RegularDoubleCauchy rectangular modulus extraction)**.** *For every accepted* $\mathsf{RegularDoubleCauchy}^{\uparrow}$ *carrier* $A = (S, R, D, T, W, H, C, P, N)$*, the rows* S, D, R, H, C, P, N *determine a finite rectangular modulus surface before* T *or* W *may be consumed. Every* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read of* A *factors through that surface, so the diagonal schedule and terminal seal are downstream of the displayed StreamName windows, DyadicRatCore tolerance ledger, row-column RegSeqRat readback, componentwise transport, replay, provenance, and local naming rows.*

Proof. Project the carrier rows S, D, R, H, C, P, N. The StreamName row supplies the rectangular windows, the DyadicRatCore row supplies the tolerance ledger, and the RegSeqRat row reads row and column faces against those displayed budgets.

Apply Definition 4155.2. It binds finite rectangular windows and dyadic tolerances to the row-column readback under the same componentwise hsame transport, with C, P, N replaying and naming the route.

Only after this rectangular surface is displayed may Definition 4155.3 read the diagonal schedule T and the completion-facing handoff W. The extracted surface contains no selected double limit,

quotient array, choice schedule, or ambient Real-completeness row, so every RealCauchyCompletion or Real read factors through the finite modulus surface first. □

Theorem 4155.5 (RegularDoubleCauchy ledger exactness)**.** *In an accepted* $\mathsf{RegularDoubleCauchy}^{\uparrow}$ *carrier, the dyadic tolerance ledger D is the unique finite row from which a completion-facing consumer may justify rectangular Cauchy bounds before reading the diagonal schedule T or the seal handoff W. Every precision request must pass through S, D, R with the same H, C, P, N provenance, and no selected limit, countable-choice schedule, quotient array, or ambient completeness row can replace that ledger.*

Proof. Project the accepted carrier. The only tolerance row is D, and it is attached to the same finite window schedule S that supplies the rectangular observations.

Readback through R uses that ledger before any diagonal schedule or completion-facing row appears. The continuation row C records the same order for each accepted request, while H transports the ledger componentwise.

The remaining rows P, N only source and name the route. Since there is no second tolerance, selected-limit, quotient, choice, or completeness coordinate, ledger exactness is forced by the tuple inventory. □

Theorem 4155.6 (RegularDoubleCauchy NameCert surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularDoubleCauchy}^{\uparrow}}$ *surface consists exactly of carrier admission, rectangular window scheduling, row-column* $\mathsf{RegSeqRat}^{\uparrow}$ *stability,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger exactness, diagonal cofinal readback,* $\mathsf{RealCauchyCompletion}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. It is the non-diagonal regularity certificate consumed by CauchyDoubleSequence and Moore–Osgood routes before their diagonal or iterated-limit handoffs, and it exports no host double-sequence convergence theorem, quotient-array classifier, selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Combine the carrier theorem with row-column stability. These statements expose the rectangular windows, regular readback faces, tolerance ledger, transport, replay, provenance, and local name.

The diagonal readback theorem supplies the only passage from the rectangular surface to a completion-facing diagonal route. Ledger exactness supplies the only precision evidence available on that passage.

Thus the NameCert surface is the finite union of the listed rows and obligations. Downstream CauchyDoubleSequence and Moore–Osgood consumers may use this surface as a regularity certificate, but no excluded host or choice principle has a row from which it could be exported. □

Theorem 4155.7 (RegularDoubleCauchy obligation scope)**.** *For every accepted* $\mathsf{RegularDoubleCauchy}^{\uparrow}$ *carrier, the five obligation rows of carrier admission, row-column stability, diagonal readback, ledger exactness, and local NameCert surface are scoped exactly by the displayed* BHist *packet together with rectangular* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *row-column readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the diagonal schedule, the* $\mathsf{RealCauchyCompletion}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegularDoubleCauchy}^{\uparrow}}$ *row.*

No quotient array, selected limit, countable-choice schedule, host double-limit theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle may be used as an alternate scope for any of these obligations.*

Proof. Begin with Definition 4155.1. It fixes the only visible carrier rows as the BHist packet $S, R, D, T, W, H, C, P, N$, with rectangular StreamName windows, RegSeqRat row-column readback, the dyadic tolerance ledger, the diagonal schedule, the RealCauchyCompletion and Real seal handoff, transport, replay, provenance, and local naming.

Apply Definition 4155.2 and Definition 4155.5. These two results bind row-column comparison and precision evidence to the same displayed rectangular windows, readback faces, tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Next apply Definition 4155.3. It forces every diagonal or completion-facing read to pass through the rectangular route before the $\mathsf{RealCauchyCompletion}^{\uparrow}/\mathsf{Real}^{\uparrow}$ handoff can be consumed.

Finally, Definition 4155.6 identifies the local NameCert surface with exactly these rows. Since the carrier and surface theorems expose no quotient array, selected limit, countable-choice schedule, host double limit, or ambient Real-completeness row, none of those objects can provide an alternate obligation scope. □

Theorem 4155.8 (RegularDoubleCauchy obligation-closure package)**.** *The carrier of Definition 4155.1, together with row-column stability, diagonal readback, rectangular modulus extraction, ledger exactness, the local NameCert surface, and the obligation scope theorem, packages the five* $\mathsf{RegularDoubleCauchy}^{\uparrow}$ *obligation rows into one completion-facing surface. Every accepted consumer must pass through rectangular* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *row-column readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the diagonal schedule, the* $\mathsf{RealCauchyCompletion}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RegularDoubleCauchy}^{\uparrow}}$ *before reading a diagonal or completion endpoint.*

Proof. Begin with Definition 4155.1. It exposes the finite rectangular packet $S, R, D, T, W, H, C, P, N$ and excludes host double limits, quotient arrays, selected limits, countable-choice schedules, and ambient Real completeness.

Use Definition 4155.2, Definition 4155.4, and Definition 4155.5. These theorems bind rectangular StreamName windows, row-column RegSeqRat readback, and the DyadicRatCore tolerance ledger into the same finite modulus surface.

Next apply Definition 4155.3. It places the diagonal schedule and the RealCauchyCompletion or Real seal strictly downstream of the rectangular surface, so a completion-facing read cannot start from the terminal handoff.

Finally combine Definition 4155.6 with Definition 4155.7. The local NameCert rows and scope theorem identify exactly the structural transport, replay, provenance, and naming data that travel with the five obligation rows, leaving no alternate obligation coordinate outside the displayed packet. □

Falsifiable prediction: Every accepted $\mathsf{RegularDoubleCauchy}^{\uparrow}$ read factors through rectangular StreamName windows, RegSeqRat row-column readback, a DyadicRatCore tolerance ledger, a diagonal cofinal schedule, RealCauchyCompletion and Real seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchydoublesequence, mooreosgood, streamname, regseqrat, dyadicratcore, realcauchycompletion, real: $\mathsf{RegularDoubleCauchy}^{\uparrow}$ is not bijective to any listed sibling because it keeps rectangular row-column regularity visible before the diagonal or iterated-limit consumer is allowed to read a completion-facing seal.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularDoubleCauchy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularDoubleCauchy}^{\uparrow}$ packet is generated from finite rectangular StreamName windows, RegSeqRat row-column readback, a DyadicRatCore tolerance ledger, a diagonal cofinal schedule, a RealCauchyCompletion

and Real seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RegularDoubleCauchy}^{\uparrow}}$, seed)

Scope closed: Definition 4155.1, Definition 4155.2, Definition 4155.3, Definition 4155.5, and Definition 4155.6 seed the rectangular two-parameter regularity surface for downstream diagonal and completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularDoubleCauchy}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host double-sequence convergence, quotient arrays, selected limits, countable choice, ambient Real$^{\uparrow}$ completeness, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, row-column stability, diagonal readback, ledger exactness, and local NameCert surface proofs for BEDC.Derived.RegularDoubleCauchyUp.

The RegularDoubleCauchy$^{\uparrow}$ route reads paired Cauchy windows through the finite stream surface of chapter 126 and the regular rational readback of chapter 301 before any Real-facing handoff. This sibling dependency keeps the double-window packet tied to displayed StreamName$^{\uparrow}$ and RegSeqRat$^{\uparrow}$ rows, with the downstream Real$^{\uparrow}$ seal supplied only through chapter 38. The RegularDoubleCauchy$^{\uparrow}$ route consumes the diagonal handoff of chapter 460 only after the rectangular StreamName$^{\uparrow}$ windows of chapter 126, the RegSeqRat$^{\uparrow}$ row-column readback of chapter 301, the DyadicRatCore$^{\uparrow}$ tolerance ledger of chapter 291, and the RealCauchyCompletion$^{\uparrow}$/Real$^{\uparrow}$ seal of chapter 360 and chapter 38 are displayed. The RegularDoubleCauchy$^{\uparrow}$ route reads CauchyAcceleration$^{\uparrow}$ and CauchySequenceSpace$^{\uparrow}$ before a diagonal or rectangular Real-facing handoff is exported. The acceleration row of chapter 4222 supplies the finite speedup ledger, while the sequence-space surface of chapter 406 keeps the downstream Cauchy-name consumer tied to the same RegSeqRat$^{\uparrow}$ readback of chapter 301 and the terminal Real$^{\uparrow}$ seal of chapter 38. DyadicIntervalNewtonBisection$^{\uparrow}$ reads interval Newton narrowing through chapter 1570, dyadic interval endpoints through chapter 306, bisection fallback through chapter 1489, and Real-facing readback through chapter 301.

Chapter 4156

A Concrete Naming Certificate for DyadicIntervalNewtonBisection$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the DyadicIntervalNewtonBisection$^{\uparrow}$ packet records the finite branch where interval Newton narrowing is interleaved with dyadic bisection before a regular Cauchy or Real-facing consumer reads the result. It refines the dyadic endpoint surface of chapter 306, the Newton enclosure certificate of chapter 1570, the bisection step of chapter 1489, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet gives root-isolation and completion routes a finite certificate without importing quotient reals, selected roots, trichotomy, countable choice, or ambient completeness.

Definition 4156.1 (Dyadic interval Newton bisection carrier)**.** *A* DyadicIntervalNewtonBisection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (D, I, H, N, B, R, E, T, C, P, L)$$

with the following displayed rows:

1. *D is the* DyadicInterval$^{\uparrow}$ *endpoint row for the parent cell and the inspected child cells.*
2. *I is the* IntervalNewton$^{\uparrow}$ *correction row, including the displayed enclosure and containment ledger.*
3. *H is the* IntervalHalving$^{\uparrow}$ *bisection row used when the Newton enclosure does not yet supply the retained child cell.*
4. *N records the finite narrowing decision: accept the Newton child, accept the bisection child, or replay both rows before the next finite inspection.*
5. *B is the dyadic diameter and containment ledger attached to the retained child interval.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row produced only after D, I, H, N, B have been displayed.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row exposed to completion consumers.*
8. *T records componentwise* hsame *transport for the dyadic interval, Newton row, halving row, narrowing decision, diameter ledger, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through the same rows.*
10. *P is the* Pkg *provenance over* DyadicIntervalNewtonBisection$^{\uparrow}$, DyadicInterval$^{\uparrow}$, IntervalNewton$^{\uparrow}$, IntervalHalving$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. L is the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalNewtonBisection}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $D, I, H, N, B, R, E, T, C, P, L$. It has no coordinate for a selected zero, quotient real equality, host trichotomy, completed branch choice, or ambient completeness theorem.

Theorem 4156.2 (Dyadic interval Newton bisection NameCert obligations)**.** *For every accepted* $\mathsf{DyadicIntervalNewtonBisection}^{\uparrow}$ *carrier $Z = (D, I, H, N, B, R, E, T, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalNewtonBise}}$ *surface consists exactly of carrier admission, dyadic endpoint exposure, interval Newton correction exposure, interval-halving fallback exposure, retained-child narrowing, diameter containment, regular rational readback, terminal Real sealing, componentwise transport, displayed replay, package provenance, and local naming for the carrier of Definition 4156.1.*

Proof. Carrier admission is projection from Definition 4156.1. The dyadic row D, Newton row I, halving row H, narrowing row N, and diameter ledger B are the only rows that expose interval refinement data.

The readback rows are downstream of that finite refinement. Row R can read a regular rational name only after the retained dyadic child and its containment ledger are displayed, and row E seals only that readback route.

Transport, replay, provenance, and local naming are exactly T, C, P, L. Since the carrier has no selected-root, quotient-real, trichotomy, completed-branch, or completeness coordinate, those objects cannot become local NameCert obligations. □

Theorem 4156.3 (Dyadic interval Newton bisection regular Cauchy handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$*, root-isolation, or completion-facing consumer of an accepted* $\mathsf{DyadicIntervalNewtonBisection}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicInterval}^{\uparrow} \longmapsto \mathsf{IntervalNewton}^{\uparrow} \longmapsto \mathsf{IntervalHalving}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff supplies retained dyadic child data, Newton or bisection narrowing, a diameter ledger, regular rational readback, and a terminal Real seal. It supplies no quotient real, selected root, trichotomy proof, countable-choice branch, or ambient completeness principle.

Proof. Project the accepted carrier $Z = (D, I, H, N, B, R, E, T, C, P, L)$. The rows D, I, H, N, B expose the entire finite narrowing branch before any regular Cauchy consumer can inspect the packet.

Read R through the retained child and diameter ledger. The regular rational handoff is therefore attached to the displayed dyadic interval, Newton enclosure, and bisection fallback rows, not to an external root selector.

Finally read the terminal seal E through T, C, P, L. These structural rows preserve the same finite route under transport, replay, provenance, and local naming. No stronger principle is present among the carrier coordinates, so every completion-facing read remains the displayed handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalNewtonBisection}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalNewtonBisection}^{\uparrow}$ packet is generated from a DyadicInterval endpoint row, an IntervalNewton correction row, an IntervalHalving fallback row, a retained-child narrowing decision, a dyadic diameter ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalNewtonBisection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4156.1, Definition 4156.2, and Definition 4156.3 seed the finite interval Newton and dyadic bisection route over DyadicIntervalUp, IntervalNewtonUp, IntervalHalvingUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{DyadicIntervalNewtonBisection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient reals, selected roots, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic endpoint exposure, Newton correction exposure, halving fallback exposure, retained-child narrowing, diameter containment, regular readback, Real-seal nonescape, transport, replay, provenance, and local NameCert field faithfulness for BEDC.Derived.DyadicIntervalNewtonBisectionUp.

The KadecKleeProperty$^{\uparrow}$ route reads weak convergence through chapter 3597, norm convergence through chapter 89, and its Banach/Hilbert source through chapter 90 and chapter 91 before the Radon–Riesz handoff is exposed.

Chapter 4157

A Concrete Naming Certificate for $\mathsf{KadecKleeProperty}^{\uparrow}$

Following Kadec and Klee on the Radon–Riesz property, the $\mathsf{KadecKleeProperty}^{\uparrow}$ packet records the finite BEDC surface where weak convergence plus convergence of norms is accepted as a strong convergence handoff. It sits between the normed and complete linear analysis packets of chapter 89, chapter 90, and chapter 91, reads the weak-convergence boundary of chapter 3597, and keeps every scalar comparison at the real-name seal of chapter 38. The carrier consumes the $\mathsf{Norm}^{\uparrow}$ norm-readback row from chapter 89 and, when present, the $\mathsf{UniformlyConvexSpace}^{\uparrow}$ or $\mathsf{Hilbert}^{\uparrow}$ source row before exposing weak-plus-norm convergence as a strong-convergence row. The chapter names only the displayed Radon–Riesz handoff route and does not import Hahn–Banach separation, choice-selected weak limits, quotient vector equality, or ambient completeness.

Definition 4157.1 (Kadec–Klee property carrier)**.** *A* $\mathsf{KadecKleeProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, H, N, W, Q, S, T, C, P, L)$$

with the following displayed rows:

1. *B is the ambient* $\mathsf{Banach}^{\uparrow}$ *row, exposing the vector-name surface used by the sequence and limit entries;*
2. *H is the optional* $\mathsf{Hilbert}^{\uparrow}$ *refinement row, used only when the consumer already works over an inner-product source;*
3. *N is the* $\mathsf{Norm}^{\uparrow}$ *row recording the norm readback and its* $\mathsf{Real}^{\uparrow}$ *comparison seal;*
4. *W is the* $\mathsf{WeakTopology}^{\uparrow}$ *row that displays weak convergence of the named sequence to the named candidate limit;*
5. *Q is the norm-convergence row, whose scalar values are read through* $\mathsf{Real}^{\uparrow}$ *names rather than through host real equality;*
6. *S is the strong-convergence handoff row asserting that the same displayed sequence and candidate limit may be consumed as norm convergence after W and Q have both been read;*
7. *T records componentwise* hsame *transport for B, H, N, W, Q, S and for the local certificate rows;*
8. *C records the displayed* Cont *replay from weak observations and norm-value observations to the strong-convergence handoff;*

9. *P is the* Pkg *provenance over* $\mathsf{KadecKleeProperty}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{WeakTopology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

10. *L is the local* $\mathsf{NameCert}_{\mathsf{KadecKleeProperty}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for Hahn–Banach separation, a selected weakly convergent subnet, quotient equality of vectors, a detached norm limit, or a completeness principle beyond the displayed source rows.

Theorem 4157.2 (Kadec–Klee NameCert obligations)**.** *For an accepted* $\mathsf{KadecKleeProperty}^{\uparrow}$ *carrier*

$$K = (B, H, N, W, Q, S, T, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{KadecKleeProperty}^{\uparrow}}$ *surface consists exactly of carrier admission for the Banach row, optional Hilbert refinement, norm row, weak-topology row, norm-convergence row, strong-convergence handoff, componentwise transport, continuation replay, provenance, and local naming; classifier stability under the same displayed rows; exactness of the* $\mathsf{Real}^{\uparrow}$ *norm-value comparisons; visibility of the weak convergence row before any strong handoff is read; and refusal of Hahn–Banach separation, choice-selected weak limits, quotient vector equality, detached scalar limits, and ambient completeness.*

Proof. Project the carrier of Definition 4157.1. The projection exposes exactly the analysis rows B, H, N, W, Q, S and the structural rows T, C, P, L.

The weak and norm routes are separate until both have been displayed. The weak route reads W over the same named vector sequence and candidate limit, while the norm route reads Q through the $\mathsf{Norm}^{\uparrow}$ row N and the $\mathsf{Real}^{\uparrow}$ scalar seal.

Now replay the handoff through C and transport it through T. The strong-convergence row S is available only downstream from W and Q, and the provenance and naming rows attach no additional selection, separation, quotient equality, detached limit, or completeness data. □

Theorem 4157.3 (Kadec–Klee weak-strong handoff)**.** *Let $K = (B, H, N, W, Q, S, T, C, P, L)$ be an accepted* $\mathsf{KadecKleeProperty}^{\uparrow}$ *carrier. Any consumer that reads the strong-convergence handoff S must first read the weak-convergence row W, the norm row N, the norm-convergence row Q, the shared* $\mathsf{Real}^{\uparrow}$ *scalar seal, componentwise* hsame *transport T, displayed* Cont *replay C,* Pkg *provenance P, and the local* NameCert *row L. Thus the Radon–Riesz handoff is a finite BEDC route over* $\mathsf{Banach}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{WeakTopology}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *not a consequence of Hahn–Banach separation, choice-selected weak limits, quotient vector equality, or ambient completeness.*

Proof. Start with a request for S. Carrier admission gives the only available predecessors: weak convergence through W, norm readback through N, scalar convergence through Q, and the structural rows T, C, P, L.

Use the NameCert obligation surface of Definition 4157.2. It forces the weak observation and the norm-value comparison to share the same displayed sequence, candidate limit, transport row, and real-name scalar boundary before strong convergence can be consumed.

Because no other coordinate exists in the carrier, the consumer cannot replace the handoff by a separation theorem, a selected weak limit, quotient vector equality, a hidden scalar limit, or an ambient completeness argument. The handoff is exactly the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{KadecKleeProperty}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KadecKleeProperty}^{\uparrow}$ packet is generated from Banach, optional Hilbert, Norm, WeakTopology, Real scalar, weak-convergence, norm-convergence, strong-handoff, transport, replay, provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KadecKleeProperty}^{\uparrow}}$, seed)

Scope closed: Definition 4157.1, Definition 4157.2, and Definition 4157.3 seed the Radon–Riesz route from weak convergence and norm convergence to strong convergence over displayed Banach, Hilbert, Norm, WeakTopology, and Real rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{KadecKleeProperty}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Hahn–Banach separation, choice-selected weak limits, quotient vector equality, detached scalar limits, ambient completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, weak-row visibility, norm-scalar exactness, strong-handoff routing, transport replay, provenance, and consumer refusal for BEDC.Derived.KadecKleePropertyUp.

The $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ hub routes its uniform tail-budget packet through chapter 126, chapter 301, chapter 291, chapter 38, and chapter 292 before the child files expose the local carrier and dependency routes.

Chapter 4158

A Concrete Naming Certificate for $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$

Following Bishop and Bridges, a regular Cauchy real name is useful to Real and Completion consumers only when its uniform tail budget is displayed before any terminal real seal is consumed. The $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ packet records that budget as finite BEDC data over the stream-window surface of chapter 126, the dyadic observation ledger of chapter 291, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. It names the explicit uniform-modulus surface needed by regular Cauchy tails; it is not a quotient of sequences, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4158.1 (Regular Cauchy uniform modulus carrier)**.** *A* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, M, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row, carrying the finite windows opened on the source name before any regular readback is inspected.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, containing the dyadic tolerance requests and arithmetic comparisons used by the tail budget.*
3. *M is the displayed regular modulus row; for each requested dyadic tolerance it records the finite index bound after which the regular Cauchy readbacks are stable inside that tolerance.*
4. *T is the finite tail ledger joining stream windows, dyadic tolerances, regular readbacks, and the modulus row.*
5. *H records componentwise* hsame *transport for S, D, M, T and the structural certificate rows.*
6. *C records displayed* Cont *replay from a tail-stability request through the same stream, dyadic, modulus, and tail-ledger rows.*
7. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through S, D, M, T, H, C, P, N. It has no coordinate for quotient stream equality, selected limit witnesses, host real equality, countable choice, or ambient completeness.

Theorem 4158.2 (Regular Cauchy uniform modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *carrier* $U = (S, D, M, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, stream-window exposure, dyadic tolerance accounting, displayed regular modulus admission, finite tail-ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer that uses a regular tail budget must read these rows before it can consume the terminal real-name seal.*

Proof. Project the carrier of Definition 4158.1. The projection displays the stream row S, dyadic observation row D, regular modulus row M, finite tail ledger T, transport row H, continuation row C, provenance row P, and local name N.

The numerical obligations are exhausted by S, D, M, T. Stream windows are opened in S, tolerance comparisons are read in D, the index bound is displayed in M, and the ledger T records the finite route joining those rows to regular rational readbacks.

The structural obligations are exhausted by H, C, P, N. They transport, replay, source, and name the same displayed route, while the carrier lists no quotient stream, selected limit, host equality, choice schedule, or ambient completeness coordinate. Hence the listed rows are exactly the local $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformModulus}^{\uparrow}}$ obligations. □

Theorem 4158.3 (Regular Cauchy uniform tail stability)**.** *Let* $U = (S, D, M, T, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *carrier. Every tail-stability request for the associated regular Cauchy readback factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{RegularCauchyUniformModulus}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Na}$$

After the modulus row M has supplied the displayed index bound, the tail ledger T is the only admissible source of stability data for the requested dyadic tolerance. No consumer may replace that route by a host convergence theorem, a selected Cauchy limit, quotient equality of streams, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 4158.2. A tail-stability request first opens the stream row S and the dyadic observation row D for the requested tolerance.

The modulus row M then supplies the finite index bound. The ledger T binds that bound to the same stream windows and dyadic comparisons, so the regular rational readback can only be consumed through the displayed route.

Finally H, C, P, N transport, replay, source, and name the packet. Since no carrier coordinate stores a selected limit, quotient stream class, host real equality, choice schedule, or ambient completeness principle, the displayed tail ledger is the complete stability surface. □

Theorem 4158.4 (Regular Cauchy uniform modulus tail-budget exactness)**.** *Let* $U = (S, D, M, T, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *carrier. Before any tail-stability or completion-facing consumer reads the modulus row, the packet exposes the same finite dyadic budget in D, the same* $\mathsf{StreamName}^{\uparrow}$ *window in S, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback boundary carried by T, and the same* $\mathsf{Real}^{\uparrow}$ *seal route recorded by H, C, P, N. Thus the tail budget is exact as a displayed BEDC row: no later consumer may widen it into a quotient stream, selected limit, host real equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project the carrier of Definition 4158.1. The rows S, D, M, T expose the stream window, dyadic tolerance ledger, displayed modulus, and finite tail ledger before the structural rows are consulted.

Use Definition 4158.2. Its obligation list requires every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer to read the stream-window exposure, dyadic tolerance accounting, modulus-row admission, and tail-ledger exactness before the terminal real-name seal is consumed.

Apply Definition 4158.3. The tail-stability route factors through the same S, D, M, T rows, so a completion-facing read cannot replace the displayed budget by a different modulus surface.

Finally inspect the carrier inventory. There is no quotient stream row, selected limit row, host real equality row, countable-choice row, or ambient completeness row, and H, C, P, N only transport, replay, source, and name the already displayed packet. Hence the exposed tail budget is exact for every downstream read. □

Theorem 4158.5 (Regular Cauchy uniform modulus tail composition)**.** *Let $U = (S, D, M, T, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *carrier. Suppose its* $\mathsf{StreamName}^{\uparrow}$ *windows replay through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows in D and through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback boundary carried by T. Then every admitted unary precision row composes to the terminal* $\mathsf{Real}^{\uparrow}$ *seal without selecting a limit: the modulus tail bound in M supplies the* $\mathsf{RegSeqRat}^{\uparrow}$ *closeness witness consumed by the seal route recorded in H, C, P, N.*

Proof. Use Definition 4158.2. It requires every regular rational or real consumer to expose stream-window, dyadic tolerance, modulus-row, and tail-ledger data before the terminal seal is read.

Apply Definition 4158.3. The admitted precision row first opens the $\mathsf{StreamName}^{\uparrow}$ window and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and the modulus row M supplies the finite tail bound used by the regular readback.

Now apply Definition 4158.4. The same displayed budget is preserved through S, D, M, T, so the $\mathsf{RegSeqRat}^{\uparrow}$ closeness witness consumed by the terminal $\mathsf{Real}^{\uparrow}$ route is the witness supplied by the accepted packet.

The sibling chapters chapter 126, chapter 291, chapter 301, chapter 38, and chapter 292 provide the named row surfaces. Since the carrier has no selected-limit coordinate, the composition remains a finite handoff rather than a limit-selection principle. □

Theorem 4158.6 (Regular Cauchy uniform modulus dyadic locator handoff)**.** *Let $U = (S, D, M, T, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *carrier. Every Real- or Completion-facing consumer receives the dyadic tolerance row D before it may consume the regular modulus row M, the finite tail ledger T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. Thus the handoff from dyadic locator data to regular tail data is a displayed BEDC boundary; it exports no quotient stream, selected limit, countable-choice schedule, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with Definition 4158.2. Its obligation surface places dyadic tolerance accounting in D before displayed regular modulus admission in M and finite tail-ledger exactness in T.

Apply Definition 4158.3. A tail-stability request opens the $\mathsf{StreamName}^{\uparrow}$ row S and the $\mathsf{DyadicRatCore}^{\uparrow}$ row D before the modulus bound and regular rational readback are available.

Now use Definition 4158.4. The exposed budget remains the same displayed dyadic row throughout the completion-facing route, so the terminal $\mathsf{Real}^{\uparrow}$ seal can only be read after D, M, T have been consumed in that order.

Finally inspect the carrier inventory. The rows H, C, P, N transport, replay, source, and name the same handoff, while the carrier has no coordinate for quotient streams, selected limits, countable choice, host equality, or ambient completeness. □

Definition 4158.7 (Located real comparison aperture carrier)**.** *A located real comparison aperture over an accepted* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *packet is a finite* BHist *packet*

$$A_{\mathrm{loc}} = (S, D, M, T, R, A, H, C, P, N)$$

whose rows refine the carrier of Definition 4158.1. The rows S, D, M, T, H, C, P, N *are the stream-window, dyadic-tolerance, uniform-modulus, finite tail-ledger, transport, replay, provenance, and local naming rows already displayed by the uniform-modulus packet. The row* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback boundary exposed by the tail ledger, and* A *is a* $\mathsf{LocatedRealComparison}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*-facing comparison boundary. Any route to* A *must expose the* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and uniform modulus before any comparison read is consumed.*

Theorem 4158.8 (Located real comparison aperture NameCert obligations)**.** *For every accepted located real comparison aperture* $A_{\mathrm{loc}} = (S, D, M, T, R, A, H, C, P, N)$*, the local comparison-facing obligation surface consists of carrier admission for the displayed aperture, stream-window exposure through* S*, dyadic tolerance accounting through* D*, uniform-modulus admission through* M*, tail-ledger exactness through* T*, readback boundary exposure through* R*, comparison-boundary exposure through* A*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the aperture carrier of Definition 4158.7. Its coordinates display exactly the rows named in the statement, with R and A added as the readback and comparison-facing boundary rows over the existing uniform-modulus packet.

Apply Definition 4158.3. Every tail-stability request first opens the stream window and dyadic tolerance rows, then reads the displayed modulus and the finite tail ledger.

Apply Definition 4158.4. The budget exposed to the comparison boundary is the same displayed S, D, M, T route, so R and A cannot introduce quotient stream equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 4158.9 (Located real comparison aperture gap route)**.** *Every positive-gap, overlap, or comparison-read consumer of an accepted aperture* $A_{\mathrm{loc}} = (S, D, M, T, R, A, H, C, P, N)$ *factors through*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{RegularCauchyUniformModulus}^{\uparrow},\ \mathsf{LocatedRealComparison}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In particular, the comparison boundary A *is visible only after the stream windows* S*, dyadic tolerances* D*, uniform modulus* M*, tail ledger* T*, and readback boundary* R *have been displayed.*

Proof. Use Definition 4158.6. It places the dyadic locator row before the uniform modulus, finite tail ledger, regular readback route, and terminal real seal.

Now apply Definition 4158.8. The comparison boundary row A is a coordinate of the aperture, but its obligation surface requires the preceding S, D, M, T, R rows to be exposed before A is read.

Finally use the sibling comparison surface of chapter 1730. The gap or overlap consumer receives a finite located-comparison route over the already displayed regular-Cauchy readback, not a host comparison or an ambient completeness principle. □

Theorem 4158.10 (Regular Cauchy uniform modulus lattice crosslink)**.** *Every accepted* RegularCauchyUniformMod *carrier presents the same*

$$S, D, M, T, H, C, P, N$$

route needed by downstream $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *completion-facing reads. The crosslink keeps stream windows, dyadic budgets, regular readback, uniform tail ledgers, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming visible as one L10 lattice route; it exports no quotient stream equality, selected limit, host real equality, countable-choice schedule, or ambient completeness row.*

Proof. Project the carrier of Definition 4158.1. The rows S, D, M, T expose the stream window, dyadic tolerance ledger, displayed modulus, and finite tail ledger, while H, C, P, N transport, replay, source, and name that same packet.

Apply Definition 4158.2. Its obligation surface requires every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer to pass through the displayed stream-window, dyadic tolerance, modulus, and tail-ledger rows before the terminal seal is consumed.

Apply Definition 4158.4. The tail budget exposed to a completion-facing read is the same displayed BEDC row throughout the route, so it cannot be replaced by a quotient stream, selected Cauchy limit, host real equality, choice schedule, or ambient completeness theorem.

The sibling completion-facing window route is the one named in chapter 406. Therefore the accepted carrier supplies exactly the S, D, M, T, H, C, P, N lattice crosslink used by $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchySequenceSpace}^{\uparrow}$ consumers.

The displayed modulus row is read through the sibling certificate of chapter 292 before tail-budget replay reaches the $\mathsf{RegSeqRat}^{\uparrow}$ readback boundary and the terminal $\mathsf{Real}^{\uparrow}$ seal. □

Theorem 4158.11 (Regular Cauchy uniform modulus window refinement)**.** *Let*

$$U_0 = (S, D, M_0, T_0, H_0, C_0, P_0, N_0) \quad \textit{and} \quad U_1 = (S, D, M_1, T_1, H_1, C_1, P_1, N_1)$$

be accepted $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *carriers sharing the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and displayed* Cont *replay route. If the unary precision displayed by* U_1 *refines the unary precision displayed by* U_0*, then the later tail-budget route factors through the earlier uniform-modulus ledger and cannot widen the exported* $\mathsf{Real}^{\uparrow}$ *handoff.*

Proof. Project both carriers using Definition 4158.1. The shared rows S, D and shared replay route in C_0, C_1 place both packets on the same stream-window and dyadic-tolerance surface before either tail ledger is read.

Apply the NameCert obligations, Definition 4158.2, and tail stability, Definition 4158.3. The finer unary window may only ask for a later displayed tail budget along the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ route.

Use tail-budget exactness, Definition 4158.4, and tail composition, Definition 4158.5. Exactness keeps each budget as a displayed BEDC row, while composition routes the later tail request through the earlier uniform-modulus ledger instead of replacing it.

Finally apply the dyadic-locator handoff, Definition 4158.6, and the lattice crosslink, Definition 4158.10. Since the carrier inventory has no selected limit, quotient equality, trichotomy, or ambient completeness row, the refined window cannot widen the terminal $\mathsf{Real}^{\uparrow}$ handoff. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ consumer displays a $\mathsf{StreamName}^{\uparrow}$ row, a $\mathsf{DyadicRatCore}^{\uparrow}$ observation row, a regular modulus row, a finite tail ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before any $\mathsf{RegSeqRat}^{\uparrow}$ readback or terminal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Independence witness: streamname, dyadicratcore, regseqrat, real: RegularCauchyUniformModulus$^{\uparrow}$ is not bijective to any listed sibling because it packages the displayed uniform tail budget and finite tail ledger as one NameCert surface between stream observations, dyadic tolerances, regular rational readback, and the terminal real-name seal.

Closure status for NameCert$_{\text{RegularCauchyUniformModulus}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyUniformModulus}^{\uparrow}}$, seed)

Scope closed: Definition 4158.1, Definition 4158.2, and Definition 4158.3 seed the finite uniform-modulus surface over StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyUniformModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, quotient stream equality, selected limits, host real equality, countable choice, bridge checking, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exposure, dyadic tolerance accounting, modulus-row admission, finite tail-ledger exactness, transport replay, and non-escape over the same displayed packet.

Constructive story: A RegularCauchyUniformModulus$^{\uparrow}$ packet is generated from finite stream windows, dyadic tolerance observations, a displayed regular modulus row, a tail ledger, componentwise transport, displayed continuation replay, package provenance, and local naming evidence.

Theorem 4158.12 (RegularCauchyUniformModulus Cauchy criterion route)**.** *Every accepted* RegularCauchyUniformModulus$^{\uparrow}$ *read depends on the* CauchyModulus$^{\uparrow}$ *schedule of chapter 292 and the* UniformCauchyCriterion$^{\uparrow}$ *shared-threshold row of chapter 435 before any* RegSeqRat$^{\uparrow}$ *or* Real$^{\uparrow}$ *consumer inspects the displayed modulus. The schedule supplies the finite tolerance-to-index request, the uniform criterion row synchronizes that request across the relevant tail windows, and only then may the regular rational readback and terminal Real seal be consumed. The route exports no selected limit, quotient stream equality, host real equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Read the CauchyModulus$^{\uparrow}$ dependency first. It provides the finite schedule that turns a dyadic tolerance request into the index boundary used by the modulus row.

Then read the UniformCauchyCriterion$^{\uparrow}$ dependency. Its shared-threshold row records that the same index boundary controls all tail-window comparisons needed by the regular readback.

Only after those two dependency rows are visible can the existing RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ consumers inspect the displayed RegularCauchyUniformModulus$^{\uparrow}$ packet. Since the route contains no selected limit, quotient stream, host equality, choice schedule, or ambient completeness row, the dependency remains a finite sibling route. □

Theorem 4158.13 (Regular Cauchy uniform modulus RegSeqRat–Real forward lattice)**.** *Every* RegularCauchyUniformModulus$^{\uparrow}$ *consumer that exports a uniform tail budget must first read the sibling rows* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$ *through the same finite packet. The uniform bound is available only after the stream windows, regular rational readback, dyadic tolerance ledger, and terminal Real seal route have been displayed with componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. The forward lattice exports no quotient stream, selected limit, countable-choice schedule, host real equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the RegularCauchyUniformModulus$^{\uparrow}$ carrier. The stream row supplies the finite windows, the dyadic row supplies the tolerance ledger, and the modulus row supplies the uniform tail budget.

The regular rational and Real-facing reads are downstream of those rows. A consumer must keep the $\mathsf{RegSeqRat}^{\uparrow}$ readback and terminal $\mathsf{Real}^{\uparrow}$ seal on the same displayed route before exporting the tail budget to a completion-facing use.

Finally read the structural rows. The hsame, Cont, Pkg, and NameCert data preserve and name the same packet, and no row supplies quotient streams, selected limits, countable choice, host real equality, or ambient completeness. □

Theorem 4158.14 (RegularCauchyUniformModulus dependency route)**.** *Every accepted* RegularCauchyUniformMo *read consumes the substantive dependency route from the* $\mathsf{Cauchy}^{\uparrow}$ *tail-window and modulus rows of chapter 3413, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of chapter 301, the terminal* $\mathsf{Real}^{\uparrow}$ *seal data of chapter 38, and the tolerance-only ledger rows of chapter 369. The packet therefore belongs to the L10 Cauchy and uniform-modulus lattice, not to an isolated orphan carrier surface.*

Proof. Read the Cauchy side first. The tail-window and modulus rows fix the finite observation and tolerance route before any regular rational or Real-facing consumer can inspect the packet.

The regular-rational and Real rows then provide readback and sealing. The uniform-modulus side contributes only the tolerance ledger needed by the same route, so no independent host modulus, selected limit, quotient real equality, or ambient completeness object enters the dependency. □

Theorem 4158.15 (Regular Cauchy uniform modulus StreamName and RegSeqRat route)**.** *Every* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *consumer that exports a uniform-modulus claim must first read the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. The route therefore presents the uniform-modulus claim as a finite sibling dependency over stream observations and regular rational readback, not as a quotient stream, selected limit, host real equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Read the carrier and obligation rows from the hub spine. They expose the stream windows, dyadic tolerances, regular readback, modulus schedule, transport, replay, provenance, and local naming before any uniform-modulus claim is available.

The existing sibling routes keep the $\mathsf{CauchyModulus}^{\uparrow}$ schedule and $\mathsf{RegSeqRat}^{\uparrow}$ handoff visible. Combining those routes with the $\mathsf{StreamName}^{\uparrow}$ row leaves no coordinate for quotient stream equality, selected limits, host equality, countable choice, or ambient real completeness. □

Theorem 4158.16 (Regular Cauchy uniform modulus L10 sibling route)**.** *Every* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *consumer that reads a uniform modulus factors first through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-schedule rows of chapter 301, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows of chapter 291, and the* $\mathsf{Real}^{\uparrow}$ *seal rows of chapter 38. Only after those L10 sibling rows are displayed may the consumer inspect the uniform modulus row. The route exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project the carrier of Definition 4158.1. Its rows expose the stream window S, dyadic tolerance row D, displayed modulus row M, finite tail ledger T, componentwise transport H, replay C, provenance P, and local name N.

Use the NameCert obligations of Definition 4158.2. They require the stream-window exposure, dyadic tolerance accounting, modulus-row admission, and finite tail-ledger exactness before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer receives the terminal seal.

Now read the sibling routes already present in the chapter. The forward lattice of Definition 4158.13 keeps $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ on the same finite path, while Definition 4158.15 records the stream and regular-schedule handoff.

Since the carrier has no coordinate for quotient streams, selected limits, choice schedules, host equality, or ambient completeness, the displayed L10 sibling rows are the only admissible route to the uniform modulus. □

The $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ tail-budget route consumes the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback of chapter 301, the $\mathsf{DyadicTailBall}^{\uparrow}$ late-tail containment boundary of chapter 1633, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38 in that order. A consumer may inspect the displayed modulus only after the stream windows and regular readback have exposed the dyadic late-tail ledger, and it may pass to $\mathsf{Real}^{\uparrow}$ only through the same seal-facing route. The route exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Chapter 4159

A Concrete Naming Certificate for $\mathsf{SpectralRadiusFormula}^{\uparrow}$

Following Gelfand's spectral-radius formula for Banach algebras, the $\mathsf{SpectralRadiusFormula}^{\uparrow}$ packet records the finite norm-power route by which displayed operator-algebra data can be read as a spectral-radius comparison without importing a host spectrum or an ambient limit theorem. It sits after the spectral-radius boundary of chapter 2352, the bounded-operator carrier of chapter 1644, the norm carrier of chapter 89, the Banach source of chapter 90, and the real-name seal of chapter 38.

Definition 4159.1 (Spectral-radius formula carrier)**.** *A* $\mathsf{SpectralRadiusFormula}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, T, N, P, W, D, R, E, H, C, Q, L)$$

with the following displayed rows:

1. *A is the* $\mathsf{Banach}^{\uparrow}$ *or Banach-algebra row carrying the complete normed algebra surface from which powers are read.*
2. *T is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row for the operator or algebra element whose powers are inspected.*
3. *N is the* $\mathsf{Norm}^{\uparrow}$ *norm-power row, recording each displayed norm endpoint for T^n in the requested window.*
4. *P is the power-iteration ledger, exposing only the finite multiplication and composition rows needed to form the displayed powers.*
5. *W is the finite window of requested exponents.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used when the comparison is requested at finite rational precision.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the displayed norm-power window and dyadic tolerance.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *spectral-radius seal reached only after W, D, R have been replayed.*
9. *H records componentwise* hsame *transport for A, T, N, P, W, D, R, E and the structural rows.*
10. *C records displayed* Cont *replay of the route*

$$\mathsf{Banach}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{Norm}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow} \longmapsto E \longmapsto \mathsf{SpectralRadiusFormula}^{\uparrow}.$$

11. *Q is the* Pkg *provenance over* $\mathsf{SpectralRadiusFormula}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *L is the local* $\mathsf{NameCert}_{\mathsf{SpectralRadiusFormula}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through $A, T, N, P, W, D, R, E, H, C, Q, L$ and has no coordinate for a host spectrum equality, quotient completion, selected limits, Classical choice, an ambient spectral theorem, or a completed all-powers limit.

Lean4 ✓ `BEDC.Derived.SpectralRadiusFormulaUp.SpectralRadiusFormulaTasteGate single carrier alignment`

Theorem 4159.2 (Spectral-radius formula NameCert obligations)**.** *For every accepted* $\mathsf{SpectralRadiusFormula}^{\uparrow}$ *carrier*

$$F = (A, T, N, P, W, D, R, E, H, C, Q, L),$$

the local $\mathsf{NameCert}_{\mathsf{SpectralRadiusFormula}^{\uparrow}}$ *surface consists exactly of carrier admission, norm-power window stability, spectral-radius comparison against the displayed* $\mathsf{SpectralRadius}^{\uparrow}$ *row,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise transport, continuation replay, provenance, and local naming. Any downstream operator-algebra consumer reading the formula must pass through the finite window W, the norm-power row N, the power ledger P, the dyadic tolerance D, and the readback rows R, E before a spectral-radius comparison is public.*

The certificate exports no host spectrum equality, no quotient completion, no selected limit over all powers, no Classical-choice selector, and no ambient spectral theorem.

Proof. Project the carrier of Definition 4159.1. The rows $A, T, N, P, W, D, R, E, H, C, Q, L$ are the whole accepted surface, so every formula read begins with the displayed Banach source, bounded-operator row, norm row, and finite power ledger.

Norm-power window stability is finite. The exponent window W names the inspected powers, P records how those powers are assembled, and N records only their displayed norm endpoints. Componentwise transport through H preserves those rows before replay through C exposes any real-facing readback.

The spectral-radius comparison is then routed through the sibling $\mathsf{SpectralRadius}^{\uparrow}$ boundary. The comparison consumes the same finite norm-power data and the same dyadic tolerance D; it does not replace the packet by a completed spectrum or an all-powers limit.

Finally R and E perform the regular-rational and real-name handoff. Since no carrier coordinate stores host spectrum equality, quotient completion, selected limits, Classical choice, or an ambient spectral theorem, the local $\mathsf{NameCert}_{\mathsf{SpectralRadiusFormula}^{\uparrow}}$ names exactly the finite Gelfand formula route stated above. □

Falsifiable prediction: Every accepted $\mathsf{SpectralRadiusFormula}^{\uparrow}$ consumer exposes the Banach source row, bounded-operator row, norm-power row, power-iteration ledger, finite exponent window, dyadic tolerance, regular-rational readback, RealUp seal, componentwise transport, replay, provenance, and local naming before reading a spectral-radius formula comparison.

Independence witness: spectralradius, boundedlinearoperator, norm, banach, real: SpectralRadiusUp supplies the radius boundary without the finite norm-power formula ledger; BoundedLinearOperatorUp supplies action and norm-bound data without the Gelfand formula readback; NormUp supplies norm endpoints without power-window replay; BanachUp supplies the complete

normed source without the formula carrier; RealUp seals readbacks without naming the operator-power route.

Closure status for $\mathsf{NameCert}_{\mathsf{SpectralRadiusFormula}^{\uparrow}}$.

Constructive story: A $\mathsf{SpectralRadiusFormula}^{\uparrow}$ packet is generated from a Banach source row, a bounded-operator row, a norm-power row, a power-iteration ledger, a finite exponent window, a DyadicRatCore tolerance row, a RegSeqRat readback row, a RealUp spectral-radius seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpectralRadiusFormula}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4159.1, Definition 4159.2, the falsifiable prediction, and the independence witness seed the finite Gelfand spectral-radius formula route over SpectralRadiusUp, BoundedLinearOperatorUp, NormUp, BanachUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpectralRadiusFormula}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host spectrum equality, quotient completion, selected limits, Classical choice, an ambient spectral theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, norm-power window stability, spectral-radius comparison, regular-rational and Real seal handoff, classifier transport, and consumer non-escape for BEDC.Derived.SpectralRadiusFormulaUp.

Chapter 4160

A Concrete Naming Certificate for $\mathsf{NestedIntervalsTheorem}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{NestedIntervalsTheorem}^{\uparrow}$ packet records the theorem-shaped finite route by which a nested sequence of closed bounded intervals supplies a real-name witness when each displayed stage carries an explicit shrinking and containment ledger. It reads the base closed-interval source of chapter 1591, the nested-prefix surface of chapter 320, the dyadic endpoint ledger of chapter 306, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the Bishop-style nested-interval theorem as a finite NameCert obligation surface; it does not assert open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient equality of real names, countable choice, trichotomy, or selected host endpoints.

Definition 4160.1 (NestedIntervalsTheorem carrier)**.** *A* $\mathsf{NestedIntervalsTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, J, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row carrying lower and upper endpoint data, endpoint order, containment ledgers, finite windows, regular readback, and a real-name seal boundary.*
2. *J is the* $\mathsf{NestedInterval}^{\uparrow}$ *prefix row recording the displayed containment chain over the same interval source.*
3. *D is the* $\mathsf{DyadicInterval}^{\uparrow}$ *shrinking ledger attached to the displayed endpoints and nested-containment rows.*
4. *W is the finite observation-window row that records which source stages and precisions are opened.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from B, J, D, W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the closed-bounded source, nested prefix, dyadic ledger, and regular readback have been displayed.*
7. *H records componentwise* hsame *transport for the source interval, nested prefix, dyadic ledger, windows, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the theorem request through $B, J, D, W, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* NestedIntervalsTheorem$^{\uparrow}$, ClosedBoundedInterval$^{\uparrow}$, NestedInterval$^{\uparrow}$, DyadicInterval$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{NestedIntervalsTheorem}^{\uparrow}}$ *row.*

The carrier is theorem-shaped because it names the obligation route from a displayed nested closed-interval prefix to a real-name witness seal. It has no coordinate for an arbitrary open cover, selected host endpoint, quotient real equality, trichotomy decision, countable-choice selector, ambient Real$^{\uparrow}$ *completeness theorem, Lean verification row, or bridge row.*

Theorem 4160.2 (NestedIntervalsTheorem NameCert obligations)**.** *For every accepted* NestedIntervalsTheorem$^{\uparrow}$ *carrier $T = (B, J, D, W, R, E, H, C, P, N)$, the local* NameCert$_{\text{NestedIntervalsTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the closed-bounded interval source B, the nested-prefix row J, the dyadic shrinking ledger D, the finite observation windows W, regular rational readback R, terminal* Real$^{\uparrow}$ *seal E, componentwise transport H, displayed replay C, provenance P, and local naming N. Every Real-facing witness read must pass through B, J, D, W, R before E is visible, and no obligation may be discharged by open-cover compactness, ambient real completeness, quotient equality, countable choice, trichotomy, or selected host endpoints.*

Lean4 ✓ `BEDC.Derived.NestedIntervalsTheoremUp.NestedIntervalsTheoremTasteGate single carrier alignment`

Proof. Project the carrier of Definition 4160.1. The displayed analytic rows are the closed-bounded source B, nested-prefix row J, dyadic shrinking ledger D, finite window row W, regular readback R, and terminal seal E.

The witness route is ordered by those rows. The closed-bounded source supplies endpoint order and containment, the nested-prefix row supplies inclusion, the dyadic ledger supplies shrinking data, and the finite observation windows determine the regular rational readback before the Real seal can be consumed.

The structural rows add no hidden theorem. Transport through H, replay through C, provenance through P, and local naming through N preserve the same finite route. Since the carrier has no coordinate for open-cover compactness, ambient completeness, quotient equality, countable choice, trichotomy, or selected endpoints, the listed rows exhaust the NameCert obligations. □

Closure status for NameCert$_{\text{NestedIntervalsTheorem}^{\uparrow}}$.

Constructive story: A NestedIntervalsTheorem$^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, a NestedIntervalUp prefix, a DyadicIntervalUp shrinking ledger, finite observation windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{NestedIntervalsTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 4160.1 and Definition 4160.2 seed the Bishop-style nested-interval theorem route as finite NameCert data over closed bounded intervals, nested prefixes, dyadic ledgers, regular rational readback, and real-name seals.

Formal verification: FormalStatus(NameCert$_{\text{NestedIntervalsTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, ambient Real$^{\uparrow}$ completeness, quotient real equality, trichotomy, countable choice, selected host endpoints, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-prefix containment, dyadic shrinking, finite-window readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.NestedIntervalsTheoremUp.

CauchyRealSpread$^{\uparrow}$ reads its spread packet through chapter 126, chapter 301, chapter 38, chapter 333, and chapter 95.

Chapter 4161

A Concrete Naming Certificate for $\mathsf{CauchyRealSpread}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names and Brouwer-style spread presentations, the $\mathsf{CauchyRealSpread}^{\uparrow}$ packet records the finite spread interface through which a countable family of regular Cauchy real-name windows is read without importing choice sequences or quotient reals. It sits after the prefix discipline of chapter 1677, the finite window schedule of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet is a spread-indexed real-name boundary, not a completed branch, not a selected Cauchy representative, not countable choice, not quotient real equality, and not a completeness principle for $\mathsf{Real}^{\uparrow}$.

The spread-indexed real-name boundary consumes chapter 1677 for prefix-tree admission, chapter 126 for finite window scheduling, chapter 301 for regular rational readback, and chapter 38 only as the terminal seal.

Before a Real-completion consumer reads the spread as a terminal $\mathsf{Real}^{\uparrow}$ handoff, the packet consumes the finite diagonal-window route of chapter 4080 as a displayed $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{DyadicRatCore}^{\uparrow}$ route rather than as a selected subsequence or host completeness argument.

Definition 4161.1 (CauchyRealSpread carrier)**.** *A* $\mathsf{CauchyRealSpread}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, W, E, T, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the spread root row inherited from* $\mathsf{BrouwerSpread}^{\uparrow}$*, recording the displayed root prefix and its admitted prefix-tree boundary.*
2. *W is the finite window row, listing the spread prefixes and request windows whose regular Cauchy real-name data may be inspected.*
3. *E is the extension law row, requiring every displayed extension of an admitted prefix to remain inside the same spread discipline before any real-name read is public.*
4. *T is the* $\mathsf{StreamName}^{\uparrow}$ *row that schedules finite observations over the admitted prefixes.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row obtained from the scheduled windows and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the spread root, finite window, extension law, stream schedule, dyadic ledger, and regular rational readback have been displayed.*

7. *H records componentwise* hsame *transport for the spread root, finite window, extension law, StreamName, RegSeqRat, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from spread-prefix admission through finite window inspection, extension-law checking, stream scheduling, regular rational readback, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyRealSpread}^{\uparrow}$, $\mathsf{BrouwerSpread}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealSpread}^{\uparrow}}$ *row.*

The carrier has no coordinate for completed infinite branches, choice-sequence selection, quotient real equality, selected Cauchy representatives, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 4161.2 (CauchyRealSpread NameCert obligations)**.** *For an accepted* $\mathsf{CauchyRealSpread}^{\uparrow}$ *carrier $S = (R, W, E, T, Q, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyRealSpread}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the spread root, finite window, extension law, StreamName row, RegSeqRat row, Real seal, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *root compatibility, requiring every public real-name request to start from the displayed* $\mathsf{BrouwerSpread}^{\uparrow}$ *root row R;*
3. *window discipline, requiring the finite request window W to be read before any stream, rational, or real-seal row is consumed;*
4. *extension stability, requiring each admitted prefix extension to pass through the law row E before the scheduled stream row T is public;*
5. *regular readback exactness, requiring every finite real-name observation to pass through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q before the* $\mathsf{Real}^{\uparrow}$ *seal A is read;*
6. *transport and replay, requiring H and C to preserve the same ordered route under* hsame *transport and displayed* Cont *replay;*
7. *ledger non-escape, excluding completed branches, choice-sequence selection, quotient real equality, selected Cauchy representatives, host real equality, countable choice, and ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier. The tuple exposes exactly the spread root R, finite window W, extension law E, stream schedule T, regular rational readback Q, Real seal A, and structural rows H, C, P, N.

Root compatibility and window discipline follow from the tuple order. A public real-name request begins with the displayed $\mathsf{BrouwerSpread}^{\uparrow}$ root and then reads only the finite windows stored in W.

Extension stability is recorded by E. The row checks each displayed prefix extension before the scheduled $\mathsf{StreamName}^{\uparrow}$ observations in T can be consumed, so no completed branch or choice-sequence selection is introduced.

Regular readback exactness then routes every tolerance request through the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger and the $\mathsf{RegSeqRat}^{\uparrow}$ row Q before the terminal $\mathsf{Real}^{\uparrow}$ seal A is available. The rows H and C transport and replay this same ordered route, while P and N record provenance and local naming.

Since the carrier has no further coordinate, quotient real equality, selected representatives, host real equality, countable choice, and ambient completeness of $\mathsf{Real}^{\uparrow}$ cannot be read from the packet. □

Theorem 4161.3 (CauchyRealSpread root and window discipline)**.** *For every accepted* $\mathsf{CauchyRealSpread}^{\uparrow}$ *carrier*

$$S = (R, W, E, T, Q, A, H, C, P, N),$$

each public spread-indexed real-name request must preserve the $\mathsf{BrouwerSpread}^{\uparrow}$ *root row* R *and the finite window row* W *before it reads the* $\mathsf{StreamName}^{\uparrow}$ *schedule* T*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal* A*. The route records only root admission and finite window discipline; it does not select completed branches, choice sequences, quotient real equality, or ambient Real completeness.*

Proof. Project the carrier of Definition 4161.1 and the obligation list of Definition 4161.2. The rows R and W are displayed before the stream schedule, regular readback, Real seal, and structural rows.

The root row R supplies the admitted $\mathsf{BrouwerSpread}^{\uparrow}$ prefix surface. A public request that omits R has no displayed spread root from which a finite real-name window can be read.

The window row W then lists the finite spread prefixes and request windows available to the consumer. Only after this row is visible may the route pass to the $\mathsf{StreamName}^{\uparrow}$ schedule T, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row Q, and the terminal $\mathsf{Real}^{\uparrow}$ seal A.

The rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since no row stores a completed branch, choice sequence, quotient equality, or completeness theorem, the discipline is exactly the finite root-window route. □

Theorem 4161.4 (CauchyRealSpread sibling route)**.** *For every accepted* $\mathsf{CauchyRealSpread}^{\uparrow}$ *carrier*

$$S = (R, W, E, T, Q, A, H, C, P, N),$$

any read exposing a spread of regular Cauchy names must factor through the sibling route consisting of the $\mathsf{StreamName}^{\uparrow}$ *window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the diagonal-selection boundary of chapter 4080. The route is a finite dependency surface: it adds no selected host subsequence, no quotient stream equality, and no ambient completeness coordinate.*

Proof. Project the carrier rows from Definition 4161.1. The rows W, T display the finite windows and StreamName schedule, while Q is the regular rational readback row and A is the terminal Real seal.

Use the route discipline of Definition 4161.3. A spread-indexed request begins from the root and window rows before it can expose StreamName observations.

The regular readback then passes through Q and reaches A only after the finite schedule is visible. The diagonal-selection sibling of chapter 4080 may consume this surface as a boundary for comparing displayed Cauchy windows, but it does not supply an external subsequence selector.

Transport through H, replay through C, and naming through P, N preserve the same sibling route. Since the carrier has no coordinate for a selected host subsequence, quotient stream equality, or ambient completeness, the exposed spread of regular Cauchy names remains inside the finite L10 route. □

The downstream countable-dense handoff of chapter 1809 reads $\mathsf{CauchyRealSpread}^{\uparrow}$ only through the finite window route of chapter 4080. In precise dependency terms, the spread root row R and finite window row W feed the diagonal finite-window selection before any separability or completion-facing consumer may inspect a terminal $\mathsf{Real}^{\uparrow}$ seal, so the Real-facing read remains downstream of the displayed root/window rows rather than a direct completeness or quotient route.

Theorem 4161.5 (CauchyRealSpread extension readback stability)**.** *For an accepted* $\mathsf{CauchyRealSpread}^{\uparrow}$ *carrier* $S = (R, W, E, T, Q, A, H, C, P, N)$*, every readback along an admitted prefix extension is stable only when the extension law row* E *remains visible between the root-window route* R, W *and the* $\mathsf{StreamName}^{\uparrow}$ *schedule* T*. The resulting readback passes through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *as finite rows and never becomes a completed branch, a selected Cauchy representative, quotient real equality, or a Real-completeness assertion.*

Proof. Begin with Definition 4161.2. Its extension-stability clause places E before the scheduled stream observations and after the displayed root-window route.

For an admitted prefix extension, read R and W first. The row E checks that the displayed extension remains inside the same spread discipline before any observation in T is public.

After E has been read, the route may consume the $\mathsf{StreamName}^{\uparrow}$ schedule T, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ row Q, and finally the $\mathsf{Real}^{\uparrow}$ seal A. Transport through H and replay through C preserve this order for the same finite packet.

There is no carrier coordinate for an infinite branch, choice-sequence selector, selected representative, quotient equality, or completeness principle. Thus extension readback stability is a finite routing condition, not an external real-analysis closure claim. □

Theorem 4161.6 (CauchyRealSpread regular-seal route)**.** *Every accepted* $\mathsf{CauchyRealSpread}^{\uparrow}$ *route to the terminal* $\mathsf{Real}^{\uparrow}$ *seal* A *must pass through the ordered rows*

$$R, W, E, T, Q, A, H, C, P, N.$$

The route starts at the $\mathsf{BrouwerSpread}^{\uparrow}$ *root, keeps the finite window and extension-law rows visible, reads the* $\mathsf{StreamName}^{\uparrow}$ *schedule, consumes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and only then exposes the Real seal. It exports no completed branch, no choice sequence, no quotient real equality, no selected representative, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the carrier definition and Definition 4161.3. They force every public real-name request to begin with the $\mathsf{BrouwerSpread}^{\uparrow}$ root row R and finite window row W.

Next apply extension readback stability, Definition 4161.5. The extension law row E remains visible before the schedule T can expose finite observations along admitted prefixes.

The regular readback exactness clause of Definition 4161.2 then routes tolerance and rational data through $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ in Q before the terminal $\mathsf{Real}^{\uparrow}$ seal A is public.

Finally the structural rows H, C, P, N carry the same route under componentwise transport, displayed replay, provenance, and local naming. Because the accepted carrier has no coordinate for the excluded objects, the regular-seal route cannot be retyped as a completed branch, choice sequence, quotient equality, selected representative, or Real-completeness theorem. □

Theorem 4161.7 (CauchyRealSpread diagonal product route)**.** *For an accepted* $\mathsf{CauchyRealSpread}^{\uparrow}$ *carrier*

$$S = (R, W, E, T, Q, A, H, C, P, N),$$

any product read over spread-indexed regular Cauchy names must factor through the $\mathsf{BrouwerSpread}^{\uparrow}$ *root row R, the finite window row W, the extension row E, the* $\mathsf{StreamName}^{\uparrow}$ *schedules in T, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in Q, the diagonal-selection boundary of chapter 4080, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *seals. The route composes finite regular-Cauchy windows; it does not select subsequences, identify quotient reals, choose completed branches, or import ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 4161.3. It forces every spread-indexed real-name request to preserve the $\mathsf{BrouwerSpread}^{\uparrow}$ root row R and finite window row W before StreamName, RegSeqRat, DyadicRatCore, or Real-facing rows are read.

Use the sibling route of Definition 4161.4. A product read of regular Cauchy names is therefore not an ambient product of host sequences; it is a read through the displayed StreamName windows, RegSeqRat rows, Real seal rows, and the diagonal-selection boundary.

Apply Definition 4161.5. The extension row E remains visible between the root-window route and the $\mathsf{StreamName}^{\uparrow}$ schedule, so each product component is still an admitted finite spread window before its rational readback is consumed.

Finally use Definition 4161.6. It orders the dyadic tolerance data, regular rational readback, and terminal Real seal after the root, window, extension, and schedule rows. The diagonal-selection boundary can compare these finite regular-Cauchy windows, but no row in the carrier supplies a selected subsequence, quotient real equality, completed branch, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealSpread}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealSpread}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4161.1 and Definition 4161.2 seed the spread-indexed regular Cauchy real-name surface through $\mathsf{BrouwerSpread}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealSpread}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed infinite branches, choice-sequence selection, quotient real equality, selected Cauchy representatives, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, spread-root compatibility, finite-window discipline, extension stability, regular readback exactness, transport replay, provenance, and non-escape for BEDC.Derived.CauchyRealSpreadUp.

Constructive story: A $\mathsf{CauchyRealSpread}^{\uparrow}$ packet is generated from a BrouwerSpread root, finite request windows, an extension law, a StreamName schedule, DyadicRatCore tolerance data, RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

The L10 dependency route for $\mathsf{CauchyRealSpread}^{\uparrow}$ consumes the $\mathsf{BrouwerSpread}^{\uparrow}$ prefix discipline of chapter 1677, the $\mathsf{StreamName}^{\uparrow}$ finite-window surface of chapter 126, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row of chapter 301, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38 before any spread-indexed real-name read is public. Every downstream $\mathsf{CauchyRealSpread}^{\uparrow}$ consumer that reaches a Real-completion read factors through the displayed spread root of chapter 1677, the finite-window schedule of chapter 126, the tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal seal of chapter 38. This is a forward dependency route for spread-indexed Cauchy reads; it does not assert completion, select an infinite branch, identify quotient real names, or add an ambient $\mathsf{Real}^{\uparrow}$ completeness principle. The $\mathsf{CauchyRealSpread}^{\uparrow}$ child route through chapter 126, chapter 301, and chapter 38 is the displayed L10 completion stack for spread-indexed Cauchy reads. The $\mathsf{StreamName}^{\uparrow}$ row supplies finite prefix windows, the $\mathsf{RegSeqRat}^{\uparrow}$ row reads those windows as regular rational observations, and the $\mathsf{Real}^{\uparrow}$ row is only the terminal seal after the displayed readback has been consumed; the route is not an ambient $\mathsf{Real}^{\uparrow}$ completeness principle, a quotient real equality, or a selected completed branch.

Theorem 4161.8 (CauchyRealSpread StreamName and RegSeqRat dependency anchor)**.** *Every* $\mathsf{CauchyRealSpread}^{\uparrow}$ *consumer that reads a public spread-indexed real-name row must pass through the sibling* $\mathsf{StreamName}^{\uparrow}$ *scheduling route, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback route, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger before any Cauchy-real spread datum is exposed. Thus the dependency route factors through chapter 126, chapter 301, and chapter 38, with the dyadic tolerance row retained as finite NameCert data rather than as a host completeness or quotient-real principle.*

Theorem 4161.9 (CauchyRealSpread sibling dependency)**.** *Every accepted* $\mathsf{CauchyRealSpread}^{\uparrow}$ *read that exports a Real-and-Completion spread packet consumes the sibling route through chapter 126, chapter 301, chapter 38, chapter 333, and chapter 95. The consumer must first read the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback, then the terminal* $\mathsf{Real}^{\uparrow}$ *seal, then the* $\mathsf{CauchyFilter}^{\uparrow}$ *filter-facing route, and only then the* $\mathsf{Completion}^{\uparrow}$ *handoff before any spread packet is public. This route exports no selected branch, quotient stream equality, selected Cauchy representative, countable choice, or ambient Real-completeness coordinate.*

Proof. Project the accepted $\mathsf{CauchyRealSpread}^{\uparrow}$ carrier of Definition 4161.1. Its public read rows expose finite windows through $\mathsf{StreamName}^{\uparrow}$, regular rational readback through $\mathsf{RegSeqRat}^{\uparrow}$, and a terminal $\mathsf{Real}^{\uparrow}$ seal before any downstream completion-facing consumer is available.

The filter and completion siblings are reached only after those displayed rows have been consumed. The $\mathsf{CauchyFilter}^{\uparrow}$ route reads the same finite StreamName and RegSeqRat data as a filter-facing boundary, and the $\mathsf{Completion}^{\uparrow}$ handoff receives only that displayed filter boundary together with the structural rows H, C, P, N.

Thus the Real-and-Completion spread packet is a horizontal dependency route through the named sibling chapters. Since no row stores an infinite selected branch, quotient stream equality, a selected Cauchy representative, countable choice, or ambient Real completeness, the exported packet has exactly the displayed sibling dependencies. □

The $\mathsf{CauchyRealSpread}^{\uparrow}$ packet is read through chapter 1677, chapter 126, chapter 291, chapter 301, and chapter 38 before any spread-indexed $\mathsf{Real}^{\uparrow}$ seal is public.

Chapter 4162

A Concrete Naming Certificate for $\mathsf{CompactImageClosed}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompactImageClosed}^{\uparrow}$ packet records the closed-target reading of the image of a compact metric source under a displayed continuous map into a separated metric target. It consumes the compact source surface of chapter 129, the finite image-net source of chapter 3604, and the separated target boundary of chapter 1411. The packet names the finite route by which image-net data and target separatedness force closed-boundary reads; it does not introduce open-cover compactness, a host image set, a selected preimage, or ambient completeness.

Definition 4162.1 (Compact image closed carrier)**.** *A* $\mathsf{CompactImageClosed}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (K, F, I, S, C, M, R, H, T, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the compact metric inspection data and finite source-net provenance consumed by the image route.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row from the source surface displayed by K into the target metric surface.*
3. *I is the* $\mathsf{ContinuousImageCompact}^{\uparrow}$ *finite image-net row, recording the target centers and tolerances produced from K and F.*
4. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *target row, used only for zero-distance target identity and boundary comparison.*
5. *C is the* $\mathsf{ClosedSet}^{\uparrow}$ *boundary row for the named target-image read.*
6. *M is the target* $\mathsf{Met}^{\uparrow}$ *distance row, exposing only displayed distances between target names.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *distance readback row for zero and positive tolerance comparisons.*
8. *H records componentwise* hsame *transport for $K, F, I, S, C, M, R, T, P, N$.*
9. *T records displayed* Cont *replay from a closed-target-boundary request through the compact source, continuous-map row, image-net row, separated target row, metric and real readbacks, provenance, and local naming rows.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactImageClosed}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{ContinuousImageCompac}$ $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{ClosedSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactImageClosed}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $K, F, I, S, C, M, R, H, T, P, N$. It has no coordinate for open-cover compactness, host image subsets, selected preimages, quotient equality of target names, ambient completeness, or a hidden closure operator.

Lean4 ✓ `BEDC.Derived.CompactImageClosedUp.CompactImageClosedTasteGate single carrier alignment`

Theorem 4162.2 (Compact image closed NameCert obligations)**.** *For every accepted* $\mathsf{CompactImageClosed}^{\uparrow}$ *carrier $Q = (K, F, I, S, C, M, R, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactImageClosed}^{\uparrow}}$ *surface consists exactly of six finite obligation rows:*

1. *carrier admission for the compact source, continuous-map graph, finite image-net, separated target, closed-boundary, metric, real readback, transport, replay, provenance, and local naming rows;*
2. *image-net accountability, requiring every target center and tolerance in I to be read through the* $\mathsf{ContinuousImageCompact}^{\uparrow}$ *route over the same K and F;*
3. *separated-boundary accountability, requiring target identity at zero distance to pass through S, M, R before the closed-boundary row C is exposed;*
4. *closed-target exactness, requiring every boundary read of the displayed image to be witnessed by finite image-net approximation together with separated target comparison;*
5. *componentwise transport and replay stability under H and T for the same displayed rows;*
6. *ledger refusal, stating that open-cover compactness, host image subsets, selected preimages, quotient equality of target names, ambient completeness, and hidden closure operators are not carrier coordinates.*

No local obligation is stored outside these rows.

Proof. Project the accepted carrier. The mathematical rows are K, F, I, S, C, M, R, and the structural rows are H, T, P, N.

The image-net obligation is read first. Row I may expose only target centers and tolerances obtained from the compact source row K and the continuous-map row F, as in chapter 3604.

The target boundary obligation is then read through the separated metric. A zero-distance comparison between a displayed target read and the finite image-net route must pass through M and R, and the target identity conclusion is allowed only through S.

The closed-boundary row C is forced by this finite route. A boundary read of the target image can cite the finite image-net approximation and the separated zero-distance classifier, but it cannot cite a host image subset, an open cover, or a selected inverse image.

Transport, replay, provenance, and local naming preserve the same row inventory. Since the refused objects do not occur among $K, F, I, S, C, M, R, H, T, P, N$, no local NameCert obligation can export them. □

Theorem 4162.3 (Compact image closed target route)**.** *Every accepted* $\mathsf{CompactImageClosed}^{\uparrow}$ *carrier $Q = (K, F, I, S, C, M, R, H, T, P, N)$ exports closedness of the displayed compact image only through the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}, \quad \mathsf{ContinuousImageCompact}^{\uparrow}, \quad \mathsf{SeparatedMetric}^{\uparrow}, \quad \mathsf{ClosedSet}^{\uparrow}.$$

A downstream closed-set consumer receives the finite image-net row I, the target distance readbacks M, R, the separated identity row S, and the closed-boundary row C. It receives no open-cover compactness datum, host image subset, selected preimage, quotient equality of target names, ambient completeness coordinate, or hidden closure operator.

Proof. Start with a target-boundary request for the displayed image. The carrier first exposes the compact source row K and the continuous-map row F.

Read the finite image-net source through I. This gives target centers and tolerances produced by the $\mathsf{ContinuousImageCompact}^{\uparrow}$ packet from the same K and F; no open-cover row or host image subset is introduced.

Now compare the requested boundary target with the finite image-net route. The metric and real readbacks M, R provide the zero-distance surface, and the separated target row S converts that displayed zero-distance comparison into target identity.

Finally expose C as the closed-boundary row for the named image read. Rows H, T, P, N transport, replay, package, and name the same finite route. Thus closedness is exported only as the finite image-net plus separated-boundary route and not as any host image-set or open-cover principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactImageClosed}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactImageClosed}^{\uparrow}$ packet is generated from a CompactMetricUp source row, ContinuousMapUp graph row, ContinuousImageCompactUp finite image-net row, SeparatedMetricUp target row, ClosedSetUp boundary row, MetricUp and RealUp distance readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactImageClosed}^{\uparrow}}$, seed)

Scope closed: Definition 4162.1, Definition 4162.2, and Definition 4162.3 seed the finite closed-target route for compact images in separated metric targets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactImageClosed}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, host image-set construction, selected preimages, quotient equality of target names, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite image-net accountability, separated-boundary accountability, closed-target exactness, transport and replay stability, and local NameCert registration for BEDC.Derived.CompactImageClosedUp.

Chapter 4163

A Concrete Naming Certificate for $\mathsf{FarEndDiagram}^{\uparrow}$

The $\mathsf{FarEndDiagram}^{\uparrow}$ packet realizes the human-origin diagrammatic surface of chapter 9403 as finite NameCert data. It sits beside the apophatic fixed-point packet of chapter 1068, the apophatic far-end socket packet of chapter 1061, and the hash-like apophatic seal of chapter 1079. The packet keeps records, generators, classifiers, continuations, GAP ledgers, sockets, provenance fibers, apophatic far-end rows, and local naming in one displayed carrier without turning the far end into a kernel object.

Definition 4163.1 (Far-end diagram packet)**.** *A* $\mathsf{FarEndDiagram}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (R, G, K, C, L, S, F, A, H, T, P, N)$$

with the following displayed rows:

1. *R is the records row, exposing the finite observation or digest readouts available to the closed substrate.*
2. *G is the generator row, recording which displayed generator creates each records-side readout.*
3. *K is the classifier row, comparing diagram nodes only by displayed classifier data.*
4. *C is the* Cont *row, replaying the route from records through generators and classifiers.*
5. *L is the* GAP *ledger row, marking the provenance boundary behind each accepted readout.*
6. *S is the forward-socket row, listing the finite sockets opened by the closed substrate.*
7. *F is the provenance-fiber row attached to the visible records-side digest.*
8. *A is the apophatic far-end row, naming the far side of the provenance fiber without internalizing it.*
9. *H records componentwise* hsame *transport for $R, G, K, C, L, S, F, A, T, P, N$.*
10. *T records displayed continuation replay for the full diagram route from records to local NameCert.*
11. *P is the* Pkg *provenance over records, generators, classifiers,* Cont*,* GAP*, forward sockets, provenance fibers, apophatic far-end rows,* BHist*,* hsame*, and* NameCert*.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FarEndDiagram}^{\uparrow}}$ *row.*

The carrier contains no coordinate for an internal object named T*, no global observer, no global digest, no unledgered far-end arrow, no hidden source selector, and no object-level equality between a local readout and the apophatic boundary.*

Lean4 ✓ `BEDC.Derived.FarEndDiagramUp.FarEndDiagramTasteGate single carrier alignment`

Theorem 4163.2 (Far-end diagram packet NameCert obligations)**.** *For every accepted* $\mathsf{FarEndDiagram}^{\uparrow}$ *carrier* $D = (R, G, K, C, L, S, F, A, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FarEndDiagram}^{\uparrow}}$ *surface consists exactly of six finite obligation rows:*

1. *carrier admission for the records, generators, classifiers, continuation,* GAP*, forward-socket, provenance-fiber, apophatic far-end, transport, replay, provenance, and local naming rows;*
2. *records-to-classifier routing, requiring each visible readout to pass through* R, G, K, C *before a diagram edge is exported;*
3. *socket accountability, requiring each forward socket in* S *to be ledgered by* L *before its far end is named;*
4. *provenance-fiber accountability, requiring each visible digest or records-side readout to carry a displayed fiber row* F *before the far-end row* A *is exposed;*
5. *componentwise transport and replay stability under* H *and* T *for the same displayed rows;*
6. *ledger refusal, stating that internal* T *objects, global observers, global digests, unledgered far-end arrows, hidden source selectors, and object-level self-center equalities are not carrier coordinates.*

No local obligation is stored outside these rows.

Proof. Project the accepted carrier. The diagrammatic rows are R, G, K, C, L, S, F, A, and the structural rows are H, T, P, N.

The records side is read first. A visible readout must pass through the generator and classifier rows before the continuation row C can replay it as a diagram edge.

The socket side is then checked. Each forward socket in S must be present in the GAP ledger L, so no unledgered far-end arrow can be exported.

Next read the provenance fiber. Row F records the source-side residue behind the visible readout, and row A names only the apophatic far end of that fiber. This is the finite socket, fiber, provenance, and boundary-name route described by the vision source.

Transport, replay, provenance, and local naming preserve the same rows. Since the refused objects are absent from $R, G, K, C, L, S, F, A, H, T, P, N$, the local NameCert obligations are exhausted by the displayed carrier. □

Theorem 4163.3 (Far-end diagram ledger unity)**.** *Every accepted* $\mathsf{FarEndDiagram}^{\uparrow}$ *carrier exports the unity of its far-end diagram only as the finite ledger route*

$$R, G, K, C \longmapsto L, S, F, A \longmapsto H, T, P, N.$$

Each visible records-side readout is generated, classified, replayed, ledgered, attached to a provenance fiber, and then named at the apophatic far end. The packet exports no internal T *object, global observer, global digest, unledgered far-end arrow, hidden source selector, or object-level equality between a local readout and the far-end boundary.*

Proof. Start with a records-side readout. The carrier requires the readout to be displayed in R, generated by G, compared through K, and replayed by C before it can participate in the diagram.

Now follow the forward edge. The socket row S lists the boundary positions opened by the closed substrate, and the GAP ledger L records the non-internalized provenance route for those positions.

Attach the provenance fiber. The row F records the fiber behind the visible readout, while A names the far end apophatically. The target is a boundary name, not an internal object.

Rows H, T, P, N preserve, replay, package, and name this same finite route. Therefore the diagram's unity is a ledger unity over displayed rows, not an equality of objects or an unledgered collapse of fibers. □

Closure status for $\mathsf{NameCert}_{\mathsf{FarEndDiagram}^{\uparrow}}$.

Constructive story: A $\mathsf{FarEndDiagram}^{\uparrow}$ packet is generated from records, generators, classifiers, Cont replay, GAP ledger rows, forward sockets, provenance fibers, apophatic far-end rows, componentwise hsame transport, displayed route replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FarEndDiagram}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4163.1, Definition 4163.2, and Definition 4163.3 seed the finite records-to-socket-to-fiber route for the far-end diagram surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FarEndDiagram}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.FarEndDiagramUp.FarEndDiagramTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: human

Not claimed: This chapter does not internalize T, add a global observer, add a global digest, identify local readouts with the far-end boundary, provide Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, records-to-classifier routing, socket accountability, provenance-fiber accountability, transport and replay stability, and local NameCert registration for BEDC.Derived.FarEndDiagramUp.

Chapter 4164

A Concrete Naming Certificate for $\mathsf{ScottDomain}^{\uparrow}$

Following Scott and Abramsky–Jung on domain theory, the $\mathsf{ScottDomain}^{\uparrow}$ packet records a finite naming certificate for the order-theoretic surface used by domain semantics before any completion-facing consumer reads a dcpo-style object. It sits after the preorder surface of chapter 52, the observable open-test discipline of chapter 1860, the represented-space handoff of chapter 1494, and the finite stream window route of chapter 126. The packet names a displayed directed-supremum carrier; it does not assert a host dcpo, quotient domain, selected basis enumeration, classical lub principle, or ambient semantic completeness.

Definition 4164.1 (ScottDomain carrier)**.** *A* $\mathsf{ScottDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (O, S, U, B, A, V, R, H, C, P, N)$$

with the following rows:

1. *O is the preorder and partial-order carrier row, exposing the displayed comparison relation and the antisymmetry witness used by the local packet;*
2. *S is the directed-family schedule row, listing the finite inspection schedule for the directed pieces that a consumer may request;*
3. *U is the supremum row, recording the displayed least-upper-bound read served by the finite directed-family schedule;*
4. *B is the compact-basis approximation row, listing the compact basis tokens and finite approximation evidence visible to the packet;*
5. *A is the approximation-order row, routing basis-token comparisons back through O and the directed schedule S;*
6. *V is the Scott-open observable row, read through* $\mathsf{SierpinskiSpace}^{\uparrow}$ *tests rather than host subsets;*
7. *R is the represented-space handoff row, packaging the same observations through* $\mathsf{RepresentedSpace}^{\uparrow}$ *and finite* $\mathsf{StreamName}^{\uparrow}$ *windows;*
8. *H records componentwise* hsame *transport for O, S, U, B, A, V, R;*
9. *C records displayed* Cont *replay of directed-supremum and Scott-open reads;*

10. *P is the* Pkg *provenance over* $\mathsf{ScottDomain}^{\uparrow}$, $\mathsf{Preorder}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{RepresentedSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ScottDomain}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host dcpo, quotient order, selected infinite basis enumeration, classical pointwise lub, ambient topology, or semantic completeness theorem.

Lean4 ✓ `BEDC.Derived.ScottDomainUp.ScottDomainTasteGate single carrier alignment`

Theorem 4164.2 (ScottDomain NameCert obligations)**.** *For the carrier of Definition 4164.1, the local* $\mathsf{NameCert}_{\mathsf{ScottDomain}^{\uparrow}}$ *surface consists exactly of preorder and partial-order admission, directed-family schedule admission, supremum-row admission, compact-basis approximation admission, Scott-open observability, represented-space handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer of the packet must read the rows $O, S, U, B, A, V, R, H, C, P, N$ before treating a directed supremum or Scott-open test as public.*

Proof. Project the carrier. The order-theoretic rows are O, S, U, B, A, V, R, and the structural rows are H, C, P, N.

The preorder and partial-order read begins at O. A directed-supremum read then uses S to expose the inspected directed schedule before U names the supremum row.

The basis read is separate but attached. The compact-basis row B and approximation row A route finite basis tokens back through O and S, so a consumer cannot replace the displayed approximation surface by a host basis enumeration.

Finally, the Scott-open observable row V and represented-space row R package those finite reads through chapter 1860, chapter 1494, and chapter 126. Rows H, C, P, N preserve, replay, source, and name the same carrier, exhausting the local obligations. □

Theorem 4164.3 (ScottDomain directed-supremum stability)**.** *Every accepted* $\mathsf{ScottDomain}^{\uparrow}$ *packet preserves directed-supremum visibility under componentwise transport and continuation replay. If a consumer reads the supremum row U through the directed-family schedule S, any transported or replayed read of the same packet factors again through*

$$O, S, U, B, A, V, R, H, C, P, N.$$

Thus Scott-open observations and represented-space handoffs remain downstream of the displayed directed schedule and never expose a host dcpo, quotient domain, selected infinite basis enumeration, or ambient completeness witness.

Proof. Start with a directed-supremum read. By Definition 4164.1, the read reaches U only after the order row O and the directed-family schedule S are displayed.

Apply the NameCert obligations of Definition 4164.2. Componentwise transport through H preserves the same rows, and Cont replay through C reuses the displayed schedule rather than generating a second supremum source.

The observable and representation rows are downstream. A Scott-open test reads V through the Sierpinski surface, and the represented-space handoff reads R through finite stream windows. Since the excluded host objects are absent from $O, S, U, B, A, V, R, H, C, P, N$, no transported or replayed directed-supremum read can expose them. □

Closure status for $\mathsf{NameCert}_{\mathsf{ScottDomain}^{\uparrow}}$.

Constructive story: A $\mathsf{ScottDomain}^{\uparrow}$ packet is generated from preorder and partial-order rows, directed-family schedules, supremum rows, compact-basis approximation rows, Scott-open observable rows, represented-space handoff rows, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ScottDomain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4164.1, Definition 4164.2, and Definition 4164.3 seed the finite directed-supremum and Scott-open observation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ScottDomain}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ScottDomainUp.ScottDomainTasteGate\_single\_carrier\_alignment`

Bridge status: none

Origin: human

Not claimed: This chapter does not close host dcpos, quotient domains, selected basis enumerations, classical lub principles, ambient topology, semantic completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean-backed carrier admission, directed-schedule stability, Scott-open observability, represented-space handoff, and local NameCert registration for BEDC.Derived.ScottDomainUp.

Chapter 4165

A Concrete Naming Certificate for $\mathsf{FarEndDiagrammatics}^{\uparrow}$

The $\mathsf{FarEndDiagrammatics}^{\uparrow}$ packet realizes the apophatic diagrammatics route of chapter 9403 as finite NameCert data. It sits beside the far-end diagram carrier of chapter 4163, the apophatic far-end socket of chapter 1061, and the forward socket ledger of chapter 3387. The packet binds socket exposure, provenance fibers, far-end boundary rows, apophatic-unity rows, transport, continuation, provenance, and local naming before any T-boundary read is public.

Falsifiable prediction: Every accepted $\mathsf{FarEndDiagrammatics}^{\uparrow}$ packet exposes socket, provenance-fiber, far-end boundary, apophatic-unity, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows before a T-boundary read is public.

Definition 4165.1 (Far-end diagrammatics carrier)**.** *A* $\mathsf{FarEndDiagrammatics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, L, G, B, U, H, C, P, N)$$

with the following rows:

1. *S is the socket row, listing the forward sockets that may expose a far-end boundary read;*
2. *L is the provenance-fiber ledger, recording which finite fiber supports each visible socket read;*
3. *G is the gap row, marking the non-internalized boundary between source-side ledger data and the far-end read;*
4. *B is the far-end boundary row, naming the boundary without turning it into a kernel object;*
5. *U is the apophatic-unity row, binding socket, fiber, gap, and boundary reads into one diagrammatic route;*
6. *H records componentwise* hsame *transport for S, L, G, B, U;*
7. *C records displayed* Cont *replay of the same socket-ledger route;*
8. *P is the* Pkg *provenance over* $\mathsf{FarEndDiagrammatics}^{\uparrow}$, $\mathsf{FarEndDiagram}^{\uparrow}$, $\mathsf{ApophaticFarEndSocket}^{\uparrow}$, $\mathsf{ForwardSocketLedger}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FarEndDiagrammatics}^{\uparrow}}$ *row.*

The carrier has no coordinate for an internal T object, a hidden source selector, an unledgered far-end arrow, a global observer, or an equality between the provenance fiber and the far-end boundary.

Lean4 ✓ BEDC.Derived.FarEndDiagrammaticsUp.FarEndDiagrammaticsTasteGate single carrier alignment

Theorem 4165.2 (Far-end diagrammatics NameCert obligations)**.** *For the carrier of Definition 4165.1, the local* $\mathsf{NameCert}_{\mathsf{FarEndDiagrammatics}^{\uparrow}}$ *surface consists exactly of socket admission, provenance-fiber admission, gap-boundary admission, far-end boundary naming, apophatic-unity routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public* T*-boundary read factors through* $S, L, G, B, U, H, C, P, N$*.*

Proof. Project the carrier. The diagrammatic rows are S, L, G, B, U, and the structural rows are H, C, P, N.

The socket row S is read first. A boundary read is not public until L supplies the provenance fiber and G marks the gap between the visible source-side ledger and the non-internalized far end.

The far-end boundary row B is then named only through the apophatic-unity row U. This row records unity of the diagrammatic route, not identity between a source object and the boundary.

Rows H, C, P, N transport, replay, source, and name exactly the displayed route. Since no other coordinate occurs in the carrier, the local NameCert obligations are exhausted by those rows. □

Theorem 4165.3 (Far-end diagrammatics unity route)**.** *Every accepted* $\mathsf{FarEndDiagrammatics}^{\uparrow}$ *packet exposes diagrammatic unity only as the finite route*

$$S, L, G, B, U \longmapsto H, C, P, N.$$

The route is consumed after the socket ledger, provenance fiber, far-end boundary, and apophatic-unity rows are displayed. It exports no internal T *object, hidden source selector, unledgered far-end arrow, global observer, or equality between the provenance fiber and the far-end boundary.*

Proof. Start with the socket ledger. The row S lists the requested forward sockets, while L records the provenance fiber supporting each visible socket read.

Read the gap and boundary rows next. The row G marks the non-internalized far-end boundary, and B names that boundary without adding it as a kernel object.

The apophatic-unity row U binds the visible socket, fiber, gap, and boundary rows into one route. It is therefore a route unity, not a collapse of the source-side fiber into the far-end boundary.

Finally, H, C, P, N preserve, replay, package, and name the same finite route. The excluded objects are absent from Definition 4165.1, so they cannot be exported by the unity route. □

Independence witness: apophaticname, forward-socket-ledger, gap, package, namecert: $\mathsf{FarEndDiagrammatics}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries socket, provenance-fiber, far-end boundary, apophatic-unity, transport, continuation, provenance, and local NameCert rows before a T-boundary read is public.

Closure status for $\mathsf{NameCert}_{\mathsf{FarEndDiagrammatics}^{\uparrow}}$.

Constructive story: A $\mathsf{FarEndDiagrammatics}^{\uparrow}$ packet is generated from socket rows, provenance-fiber ledgers, gap rows, far-end boundary names, apophatic-unity rows, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FarEndDiagrammatics}^{\uparrow}}$, seed)

Scope closed: Definition 4165.1, Definition 4165.2, and Definition 4165.3 seed the finite socket-to-fiber-to-boundary route for far-end diagrammatics.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FarEndDiagrammatics}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not internalize T, add a global observer, identify provenance fibers with the far-end boundary, provide Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean-backed carrier admission, socket ledger accountability, provenance-fiber routing, apophatic-unity nonescape, TasteGate instances, and local NameCert registration for BEDC.Derived.FarEndDiagrammaticsUp.

Chapter 4166

A Concrete Naming Certificate for $\mathsf{PolishBasis}^{\uparrow}$

Following Bourbaki and Kelley, a countable basis for a Polish presentation is treated here as a finite naming certificate over an already displayed complete separable metric route. The $\mathsf{PolishBasis}^{\uparrow}$ packet sits beside the Polish-space synthesis of chapter 1490, the metric carrier of chapter 57, the dense schedule of chapter 1458, the completion handoff of chapter 128, the stream-window interface of chapter 126, and the regular rational readback surface of chapter 301. It names basic-open data as countable finite rows, not as an ambient topology, an open-cover principle, or a choice-selected basis.

Definition 4166.1 (Polish-basis carrier)**.** *A* $\mathsf{PolishBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, D, K, S, R, I, F, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row supplying the point-history carrier, distance classifier, and metric* $\mathsf{NameCert}$ *used by basis balls.*
2. *D is the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense-schedule row whose named centers are inspected by finite stream positions.*
3. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row over the same metric carrier; it is recorded so Polish-space consumers can pass from basis windows to complete-separable metric reads.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row enumerating the basis-center names and the finite Cauchy-window requests visible to consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row that reads rational radii, tolerance windows, and comparison bounds from the same finite stream positions.*
6. *I is the basis-index window row. It stores the finite index interval, center-name handle, radius handle, and requested observation window for each basic-open read.*
7. *F is the finite-intersection refinement row. It records the displayed refinement witness that sends two accepted basis windows to a third window contained in their metric intersection.*
8. *H records componentwise* hsame *transport for M, D, K, S, R, I, F and the local certificate rows.*

9. *C records displayed* Cont *replay from a basis request through metric comparison, dense-center inspection, rational-radius readback, finite-intersection refinement, and complete-separable handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{PolishBasis}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PolishBasis}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting $M, D, K, S, R, I, F, H, C, P, N$ to the same metric and stream-readback surface. It has no coordinate for a host topology, arbitrary open covers, selected dense points, quotient completion equality, or ambient set membership.

Lean4 ✓ `BEDC.Derived.PolishBasisUp.PolishBasisTasteGate single carrier alignment`

Theorem 4166.2 (Polish-basis NameCert obligations)**.** *For every accepted* $\mathsf{PolishBasis}^{\uparrow}$ *carrier*

$$B = (M, D, K, S, R, I, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PolishBasis}^{\uparrow}}$ *surface consists exactly of metric-source admission, separable dense-schedule admission, complete-metric handoff admission, stream-window exposure, regular-rational readback, basis-index windowing, finite-intersection refinement, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through $M, D, K, S, R, I, F, H, C, P, N$.*

Proof. Project the carrier of Definition 4166.1. The rows $M, D, K, S, R, I, F, H, C, P, N$ are the whole countable-basis packet.

The metric row M fixes the surface on which basis balls are read. The dense schedule D, stream row S, and regular rational row R then expose center names and radius windows as finite observations.

The basis-index row I records the inspected finite window, and the refinement row F supplies the finite witness for binary intersections of displayed basic opens. The completion handoff K remains attached to the same metric carrier for Polish-space consumers.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no further coordinate is present, the NameCert surface exports no host topology, open-cover compactness, selected dense points, quotient completion equality, or ambient set membership. □

Theorem 4166.3 (Polish-basis complete-separable handoff)**.** *Every accepted* $\mathsf{PolishBasis}^{\uparrow}$ *read handed to a* $\mathsf{PolishSpace}^{\uparrow}$ *or* $\mathsf{CompleteSeparableMetric}^{\uparrow}$ *consumer factors through the* $\mathsf{Met}^{\uparrow}$ *row M,* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule D,* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff K,* $\mathsf{StreamName}^{\uparrow}$ *finite windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, basis-index windows I, finite-intersection refinement F, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N.*

Proof. Begin with an accepted carrier $B = (M, D, K, S, R, I, F, H, C, P, N)$. A Polish-space consumer first reads the metric source M, then the dense schedule D through stream windows S and regular rational observations R.

The basis-index row I identifies the finite window being consumed. When a consumer asks for closure under finite intersections, F supplies the displayed refinement witness over the same metric surface.

The complete-metric handoff K is then available over that metric source, while H, C, P, N transport, replay, source, and name the route. Thus the handoff is finite and cannot pass through a host topology, an arbitrary open cover, quotient completion equality, or a selected dense subset. □

Closure status for $\mathsf{NameCert}_{\mathsf{PolishBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{PolishBasis}^{\uparrow}$ packet is generated from MetricSpace rows, SeparableMetric dense schedules, CompleteMetric handoffs, StreamName windows, RegSeqRat readbacks, basis-index windows, finite-intersection refinement rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PolishBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4166.1, Definition 4166.2, and Definition 4166.3 seed the countable-basis certificate route supporting $\mathsf{PolishSpace}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PolishBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host topologies, arbitrary open covers, selected dense points, quotient completion equality, ambient set membership, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-schedule readback, finite basis-index windowing, finite-intersection refinement, complete-separable handoff, and local naming for BEDC.Derived.PolishBasisUp.

Chapter 4167

A Concrete Naming Certificate for $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$

The $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ packet realizes the observer-expansion reading of chapter 9463 as finite observer-shadow certificate data. It consumes the visual-shadow metric of chapter 4142, the boundary-shadow route of chapter 3813, the metric surface of chapter 57, the stream-window interface of chapter 126, and the terminal real-name surface of chapter 38. The packet names an expansion-facing shadow route, not a global hyperbolic space, physical observer history, quotient boundary, or ambient field semantics.

Definition 4167.1 (Hyperbolic observer-expansion carrier)**.** *A* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (V, B, M, S, R, Q, F, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$ *source row, supplying the visual-shadow metric packet read by the observer-facing expansion route.*
2. *B is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row that records the boundary-shadow datum inspected by the expansion packet.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *comparison row used when the shadow expansion is consumed as metric evidence.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the visual-shadow, boundary-shadow, metric, and real-seal reads.*
5. *R is the regular readback row for rational windows opened by S.*
6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed expansion magnitude or shadow-distance comparison.*
7. *F is the observer-expansion row, recording the focused expansion-shadow route being inspected.*
8. *H records componentwise* hsame *transport for V, B, M, S, R, Q, F and the local certificate rows.*
9. *C records displayed* Cont *replay from an observer-expansion request through visual-shadow metric, boundary shadow, metric comparison, stream windows, regular readback, real sealing, and focused routing.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, $\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverExpansion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $V, B, M, S, R, Q, F, H, C, P, N$. It has no coordinate for completed hyperbolic geometry, physical observers, quotient boundary equality, global field interpretation, or unlogged expansion flow.

Lean4 ✓ `BEDC.Derived.HyperbolicObserverExpansionUp.HyperbolicObserverExpansionTasteGate single carrier alignment`

Theorem 4167.2 (Hyperbolic observer-expansion NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *carrier*

$$E = (V, B, M, S, R, Q, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicObserverExpansion}^{\uparrow}}$ *surface consists exactly of visual-shadow metric admission, boundary-shadow admission, metric comparison, stream-window exposure, regular readback, terminal real sealing, focused observer-expansion routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through $V, B, M, S, R, Q, F, H, C, P, N$.*

Proof. Project the carrier of Definition 4167.1. The rows $V, B, M, S, R, Q, F, H, C, P, N$ are the whole observer-expansion packet.

The source read begins with the visual-shadow metric row V and the boundary-shadow row B. The metric row M then gives the comparison surface on which the expansion-facing shadow is inspected.

The finite observation route is supplied by S, R, Q: stream windows, regular readbacks, and the terminal real seal. The focused row F records which observer-expansion shadow route is being named.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no further coordinate is present, the NameCert surface exports no completed hyperbolic geometry, physical observer, quotient boundary equality, global field interpretation, or unlogged expansion flow. □

Theorem 4167.3 (Hyperbolic observer-expansion finite shadow handoff)**.** *Every accepted* HyperbolicObserverExpar *read factors through* $\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before the observer-expansion route can be consumed as a local* NameCert *datum.*

Proof. Begin with an accepted carrier $E = (V, B, M, S, R, Q, F, H, C, P, N)$. The visual-shadow metric row V and boundary-shadow row B present the finite shadow data.

The metric comparison M is then read through finite windows S, regular readback R, and the real seal Q. Only after these rows are displayed does the focused route F expose the observer-expansion datum.

Transport, continuation, provenance, and local naming are supplied by H, C, P, N. Therefore the handoff remains finite and cannot pass through completed hyperbolic geometry, physical observer history, quotient boundary equality, or ambient field semantics. □

Falsifiable prediction: Every accepted hyperbolic_observer_expansion read factors through hyperbolic_visual_shadow_metric, hyperbolic_boundary_shadow, metric, streamname, regular readback, real sealing, displayed replay, provenance, and local NameCert rows.

Independence witness: hyperbolic_visual_shadow_metric, hyperbolic_boundary_shadow, metric, streamname, real: no listed sibling is bijective to $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ because this packet jointly carries visual-shadow metric data, boundary-shadow data, metric comparison, finite stream windows, real sealing, focused observer-expansion routing, replay, provenance, and local naming.

The Lean TasteGate route must provide `Nontrivial HyperbolicObserverExpansionUp` and `FieldFaithful HyperbolicObserverExpansionUp` instances in `lean4/BEDC/Derived/HyperbolicObserverExpa` Those instances must preserve $V, B, M, S, R, Q, F, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicObserverExpansion}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ packet is generated from HyperbolicVisualShadowMetric rows, HyperbolicBoundaryShadow rows, Metric rows, StreamName windows, regular readback, Real sealing, focused observer-expansion routing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverExpansion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4167.1, Definition 4167.2, and Definition 4167.3 seed the finite observer-shadow expansion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverExpansion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed hyperbolic geometry, physical observer histories, quotient boundary equality, global field interpretation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, visual-shadow metric admission, boundary-shadow admission, metric comparison, stream readback, real sealing, TasteGate nontriviality, field faithfulness, and local naming for BEDC.Derived.HyperbolicObserverExpansionUp.

Chapter 4168

A Concrete Naming Certificate for $\mathsf{Met}^{\uparrow}$

Following Bishop and Bridges and Bourbaki, the $\mathsf{Met}^{\uparrow}$ packet records the traditional metric-space interface as finite BEDC NameCert data. It sits over the generic distance-witness surface of chapter 57, the real-valued distance route of chapter 1638, the dyadic tolerance core of chapter 291, the finite stream-name interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter gives completion, topology, total-boundedness, compactness, and Polish-space consumers a single cited carrier surface without importing quotient equality, selected limits, countable choice, or ambient completeness.

Definition 4168.1 (MetricSpace carrier)**.** *A* $\mathsf{Met}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, \sigma, D, Z, S, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the point-carrier row. It names the displayed point observations and the finite windows through which downstream consumers may inspect them.*
2. *σ is the point-classifier row. It records the accepted point equivalence used by* hsame *transport and by the zero-distance classifier handoff.*
3. *D is the* $\mathsf{Real}^{\uparrow}$*-valued distance row. It is read through the* $\mathsf{Met}^{\uparrow}$ *witness surface of chapter 57 and the* $\mathsf{RealMetric}^{\uparrow}$ *distance route of chapter 1638.*
4. *Z is the zero-distance classifier row, requiring any request that turns distance zero into point equivalence to pass through σ rather than through host equality.*
5. *S is the symmetry row, carrying the componentwise reversal of endpoint observations and the corresponding distance readback.*
6. *T is the triangle row, carrying the three endpoint-pair distance reads and the dyadic tolerance budget used to compose them.*
7. *H records componentwise* hsame *transport for the point carrier, classifier, distance, zero-distance, symmetry, triangle, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a metric request through the finite route*

$$X, \sigma \longmapsto \mathsf{Met}^{\uparrow}, \mathsf{RealMetric}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto Z, S, T, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{Met}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, \sigma, D, Z, S, T, H, C, P, N$. It has no coordinate for host equality of points, quotient completion equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached topology.*

Lean4 ✓ `BEDC.Derived.MetricSpaceUp.MetricSpaceTasteGate single carrier alignment`

Theorem 4168.2 (MetricSpace NameCert obligations)**.** *For every accepted* $\mathsf{Met}^{\uparrow}$ *carrier*

$$M = (X, \sigma, D, Z, S, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Met}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the point carrier, point classifier, real-valued distance, zero-distance classifier, symmetry, triangle, transport, replay, provenance, and local naming rows;*
2. *distance visibility, requiring every distance read to expose the* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{RealMetric}^{\uparrow}$ *rows before any downstream consumer reads a real-valued metric comparison;*
3. *zero-distance exactness, requiring zero distance to return to the displayed classifier σ through Z and never through host point equality;*
4. *symmetry replay, requiring endpoint reversal to be witnessed by S together with the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback route;*
5. *triangle-budget replay, requiring the three distance reads and their dyadic comparison budget to be displayed by T before a triangle consumer may use the row;*
6. *structural preservation through H, C, P, N.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4230.1. An accepted packet displays the point-carrier row X, the classifier σ, the distance row D, the zero-distance row Z, the symmetry row S, the triangle row T, and the structural rows H, C, P, N.

Distance visibility is forced by the placement of D in the carrier. A distance consumer first opens the generic $\mathsf{Met}^{\uparrow}$ witness surface and the $\mathsf{RealMetric}^{\uparrow}$ readback route, and only then reads the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows needed for a finite comparison.

The zero-distance, symmetry, and triangle clauses are rowwise. The row Z is the only route from distance zero back to the point classifier, S is the only endpoint-reversal row, and T is the only triangle-budget row.

Finally, H, C, P, N transport, replay, source, and name exactly the displayed rows. Since the carrier has no other coordinate, the listed rows exhaust the local NameCert surface and cannot export host equality, quotient completion equality, selected representatives, countable choice, ambient completeness, or a detached topology. □

Theorem 4168.3 (MetricSpace distance route)**.** *Every completion, topology, total-boundedness, compactness, or Polish-space consumer of an accepted* $\mathsf{Met}^{\uparrow}$ *carrier reads distance information through the finite route*

$$X, \sigma, D \longmapsto \mathsf{Met}^{\uparrow}, \mathsf{RealMetric}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto Z, S, T, H, C, P, N.$$

Thus the public distance surface is the displayed BEDC route from point observations and classifier data to real-valued metric reads, zero-distance classification, symmetry, and triangle replay. It exports no quotient equality, selected limit, countable-choice schedule, ambient completeness theorem, or open-set lattice.

Proof. Let a downstream consumer inspect an accepted carrier $M = (X, \sigma, D, Z, S, T, H, C, P, N)$. The point surface is opened first through X and σ, so every later distance read remains attached to the displayed point classifier.

The distance row D then routes the request through $\mathsf{Met}^{\uparrow}$ and $\mathsf{RealMetric}^{\uparrow}$. The numerical readback is finite because the dyadic tolerance, stream-window, regular-rational, and real-name rows are displayed before any metric comparison is consumed.

Metric laws are read only after this route is visible. Zero distance returns through Z to σ, symmetry reverses endpoints through S, and triangle use exposes the three pairwise reads and dyadic budget through T.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since none of the excluded objects appears in the carrier, no listed downstream consumer can read quotient equality, a selected limit, a choice schedule, ambient completeness, or an open-set lattice from the $\mathsf{Met}^{\uparrow}$ packet. □

Chapter 4169

A Concrete Naming Certificate for $\mathsf{MetricCompletionKleisli}^{\uparrow}$

Following Mac Lane's Kleisli categories, and Bishop–Bridges and Kelley on metric completion, the $\mathsf{MetricCompletionKleisli}^{\uparrow}$ packet records the metric-specific bind consumer for completion-valued maps as finite BEDC data. It reads the metric completion carrier of chapter 1506, the metric adjunction route of chapter 3836, the Cauchy Kleisli consumer of chapter 1845, and the completion universal property of chapter 397. The chapter names a consumer route for bind-style completion reads; it is not a quotient completion, selected representative, countable-choice schedule, host equality of completed points, or ambient completeness theorem.

Definition 4169.1 (MetricCompletionKleisli carrier)**.** *A* $\mathsf{MetricCompletionKleisli}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, A, L, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row, displaying the source metric, completion carrier, separated comparison, dense-source access, and readback branch before any bind consumer is opened.*
2. *A is the* $\mathsf{MetricCompletionAdjunction}^{\uparrow}$ *row, displaying the unit, counit, triangle ledger, and metric universal mapping boundary read by the consumer.*
3. *L is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *row, recording the unit, bind, and reassociated-bind consumer route inherited from the L10 completion algebra.*
4. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row, exposing the extension surface through which a displayed metric source map is consumed as a completion-valued map.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used by the metric completion and Cauchy Kleisli routes.*
6. *E is the public* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, A, L, U, R have been displayed.*
7. *H records componentwise* hsame *transport for the metric completion row, metric adjunction row, Cauchy Kleisli row, universal-property row, regular readback, Real seal, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from a bind consumer request through $M, A, L, U, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionKleisli}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{MetricCompletionAdjunction}^{\uparrow}$, $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{MetricCompletionKleisli}^{\uparrow}}$ *row.*
The classifier accepts only packets whose bind consumer first displays the metric completion, metric adjunction, Cauchy Kleisli, universal-property, regular readback, Real seal, hsame, Cont, Pkg, *and local* NameCert *rows listed above.*

Lean4 ✓ `BEDC.Derived.MetricCompletionKleisliUp.MetricCompletionKleisliTasteGate single carrier alignment`

Theorem 4169.2 (MetricCompletionKleisli NameCert obligations)**.** *For every accepted* $\mathsf{MetricCompletionKleisli}^{\uparrow}$ *carrier*

$$K = (M, A, L, U, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricCompletionKleisli}^{\uparrow}}$ *surface consists exactly of metric-completion admission, metric-adjunction admission, Cauchy-Kleisli bind exposure, completion-universal-property exposure, RegSeqRat readback, Real seal readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the rows of K. No obligation may be discharged by a quotient completion, selected Cauchy representative, countable-choice selector, host equality of completed points, or ambient complete metric space.*

Proof. Project the carrier of Definition 4218.1. Its analytic rows are precisely the metric completion row M, the metric adjunction row A, the Cauchy Kleisli row L, the universal-property row U, the regular readback row R, and the Real seal row E.

The metric rows determine the order of access. A bind consumer opens M before it can read the adjunction data in A, and it opens A before the Cauchy Kleisli consumer L can hand off unit, bind, or reassociated-bind requests to the universal-property row U.

Transport and replay add no analytic coordinate. The rows H and C compare and replay only the displayed completion, adjunction, Kleisli, universal-property, readback, and seal data.

Finally P and N source and name the same finite packet. Since no listed row stores a quotient completion, selected representative, countable-choice selector, host equality, or ambient complete metric space, the displayed rows exhaust the NameCert surface. □

Theorem 4169.3 (MetricCompletionKleisli bind handoff)**.** *Every bind-style consumer read of an accepted* $\mathsf{MetricCompletionKleisli}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{MetricCompletionAdjunction}^{\uparrow} \longmapsto \mathsf{CauchyCompletionKleisli}^{\uparrow} \longmapsto \mathsf{CompletionUniversalProperty}$$

The handoff reaches the displayed $\mathsf{Real}^{\uparrow}$ *seal only through componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionKleisli}^{\uparrow}}$ *row carried by the same packet.*

Proof. Begin with the metric completion row M. It displays the source metric, completion carrier, separated comparison, dense-source access, and readback branch before a consumer can request completion-valued bind data.

Next read the adjunction row A. The unit, counit, triangle ledger, and metric universal mapping boundary are the only route by which the metric completion packet exposes extension data to a downstream consumer.

Attach the Cauchy Kleisli row L and the universal-property row U. The row L supplies the unit, bind, and reassociated-bind consumer surface, while U records the extension route that consumes a displayed source map as a completion-valued map.

The readback and seal rows close the route. The row R supplies the regular rational readback used by both completion and Kleisli sides, and E is the only public Real seal. The structural

rows H, C, P, N transport, replay, source, and name this same route, so no quotient completion, selected representative, choice schedule, host equality, or ambient completeness theorem can enter the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionKleisli}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionKleisli}^{\uparrow}$ packet is generated from metric completion, metric adjunction, Cauchy Kleisli, completion universal property, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionKleisli}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4218.1, Definition 4218.2, and Definition 4218.3 seed the metric-specific Kleisli consumer route for bind-style completion reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionKleisli}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, host equality of completed points, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-adjunction exposure, Cauchy-Kleisli exposure, universal-property exposure, RegSeqRat/Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionKleisliUp.

Chapter 4170

A Concrete Naming Certificate for $\mathsf{LocatedRegularRealCut}^{\uparrow}$

Following Bishop and Bridges' constructive real analysis, the $\mathsf{LocatedRegularRealCut}^{\uparrow}$ packet records the finite boundary where regular-Cauchy real names expose located lower and upper rational cut rows before the terminal real seal is read. It sits beside the dyadic tolerance core of chapter 291, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, the real-name seal of chapter 38, the Dedekind cut carrier of chapter 436, and the located regular sequence route of chapter 2376. The packet is a finite NameCert bridge from regular-Cauchy observations to located cut boundaries; it does not claim Dedekind completeness, quotient equality of real names, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4170.1 (Located regular real cut carrier)**.** *A* $\mathsf{LocatedRegularRealCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, U, M, D, R, A, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower rational cut row, recording inhabited rounded lower observations read through the finite cut-facing side of* $\mathsf{DedekindCut}^{\uparrow}$*.*
2. *U is the upper rational cut row, recording rounded upper observations attached to the same inspected real-name request.*
3. *M is the locatedness modulus row, binding every rational comparison request to a finite window on which either the lower row or the upper row is displayed with the required separation.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row supplying dyadic radii, bracket widths, midpoint requests, and comparison tolerances for the cut boundary.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular rational observations from which the cut rows and locatedness modulus are read.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, U, M, D, R have been displayed.*
7. *H records componentwise* hsame *transport for lower cut rows, upper cut rows, locatedness modulus rows, dyadic tolerance rows, regular readback rows, Real seal rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a cut-boundary request through L, U, M, D, R, A, H.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedRegularRealCut}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{LocatedRegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRegularRealCut}^{\uparrow}}$ *row.*

The carrier accepts only the displayed lower row, upper row, locatedness modulus, dyadic tolerance, regular readback, Real seal, transport, replay, provenance, and naming rows. It has no coordinate for Dedekind completeness, quotient real equality, selected representatives, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.LocatedRegularRealCutUp.LocatedRegularRealCutUp`

Theorem 4170.2 (Located regular real cut obligations)**.** *For every accepted* $\mathsf{LocatedRegularRealCut}^{\uparrow}$ *carrier* $K = (L, U, M, D, R, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRegularRealCut}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed lower cut row, upper cut row, locatedness modulus, dyadic tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local naming row;*
2. *located lower and upper stability, requiring L and U to remain rounded, separated, and transported componentwise under the same* hsame *row;*
3. *regular Cauchy handoff, requiring every cut-boundary read to pass through R and the located regular sequence discipline of chapter 2376;*
4. *Real seal non-escape, requiring A to be downstream of L, U, M, D, R and not an independent completeness row;*
5. *ledger exactness, requiring P and N to name only L, U, M, D, R, A, H, C and to exclude quotient equality, selected limits, trichotomy, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 4219.1. The displayed analytic rows are the lower cut row L, upper cut row U, locatedness modulus M, dyadic tolerance row D, regular readback row R, and Real seal row A.

The lower and upper stability clauses are componentwise. Transport through H preserves the two cut rows together with the same modulus and dyadic tolerance row, so the classifier cannot move a lower observation without moving the matching upper boundary data.

The regular Cauchy handoff is the route through R. The located regular sequence sibling supplies the finite windows and readback discipline before the cut boundary can be consumed, while D supplies the tolerance ledger on which the locatedness modulus is read.

Finally A, C, P, N seal, replay, source, and name only the displayed route. Since none of the carrier coordinates is a quotient, selected limit, trichotomy branch, choice schedule, or ambient completeness theorem, the listed obligations exhaust the local certificate. □

Theorem 4170.3 (Located regular real cut Cauchy boundary route)**.** *Every accepted* $\mathsf{LocatedRegularRealCut}^{\uparrow}$ *consumer factors through*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{LocatedRegSeqRat}^{\uparrow},\ \mathsf{DedekindCut}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

as displayed finite rows before it can read the local $\mathsf{NameCert}_{\mathsf{LocatedRegularRealCut}^{\uparrow}}$ *row. The route exports a located lower–upper cut boundary for a regular-Cauchy real name; it does not export Dedekind completeness, quotient real equality, selected limits, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with Definition 4219.2. A consumer first sees the dyadic tolerance row D, regular readback row R, and locatedness modulus M before the lower and upper cut rows can be treated as a located boundary.

The Dedekind cut sibling supplies the cut-facing row shape, while the located regular sequence sibling supplies the Cauchy-facing source and tail-window discipline. These rows meet only through the displayed finite packet K.

The Real seal row A is terminal for this route. Componentwise transport, continuation replay, package provenance, and local naming preserve the same displayed rows, so no consumer can bypass them by invoking quotient equality, a selected representative, trichotomy, choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{LocatedRegularRealCut}^{\uparrow}$ read factors through displayed lower rational cut, upper rational cut, locatedness modulus, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedRegSeqRat}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and local NameCert rows.

Independence witness: dyadicratcore, regseqrat, real, dedekindcut, located-regseqrat: no listed sibling is bijective to $\mathsf{LocatedRegularRealCut}^{\uparrow}$ because this packet alone binds lower and upper cut rows, a locatedness modulus, dyadic tolerance, regular readback, terminal real seal, transport, replay, provenance, and local naming into one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRegularRealCut}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRegularRealCut}^{\uparrow}$ packet is generated from lower rational cut rows, upper rational cut rows, a locatedness modulus, DyadicRatCore tolerance rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedRegularRealCut}^{\uparrow}}$, seed)

Scope closed: Definition 4219.1, Definition 4219.2, and Definition 4219.3 seed the finite bridge from regular-Cauchy real names to located lower–upper cut boundaries.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedRegularRealCut}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Dedekind completeness, quotient real equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located lower and upper stability, regular Cauchy handoff, Real seal non-escape, and ledger exactness for BEDC.Derived.LocatedRegularRealCutUp.

Chapter 4171

A Concrete Naming Certificate for $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$

The $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$ packet realizes the orbit and codon inventory polynomials of Definition 9462.1713 as finite BEDC NameCert data. It consumes the boundary-tile source of chapter 3393, the coverage packet of chapter 3470, the codon window source of chapter 2234, and the finite polynomial carrier of chapter 50. The packet records orbit rows, codon-count rows, coefficient ledgers, and marginal projections; it is not a biological stochastic model, an empirical code table, a hidden enumeration oracle, or quotient codon semantics.

Definition 4171.1 (Boundary orbit inventory polynomial carrier)**.** *A* $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (O, K, E, M, H, C, P, N)$$

with the following displayed rows:

1. *O is the orbit table row, recording the finite orbit types classified by support size m, overlap defect δ, lift imbalance b, and orbit size.*
2. *K is the codon count table row, recording the weighted counts of lifted triggers over the same triples (m, δ, b).*
3. *E is the coefficient ledger row, storing the displayed coefficients of the orbit inventory polynomial $\mathcal{O}(u, v, w)$ and the codon inventory polynomial $\mathcal{C}(u, v, w)$.*
4. *M is the marginal projection row, recording the one-variable and bivariate specializations read from the coefficient ledger.*
5. *H records componentwise* hsame *transport for the orbit table, codon count table, coefficient ledger, marginal projections, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from an inventory query through O, K, E, M, H.*
7. *P is the* Pkg *provenance over* $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, *the source vision of Definition 9462.1713,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}}$ *row.*

The carrier accepts coefficient and marginal reads only through O, K, E, M, H, C, P, N. It has no coordinate for a hidden biological code table, probabilistic fitness model, unbounded orbit enumeration, quotient codon equality, or unstated polynomial coefficient source.

Lean4 ✓ `BEDC.Derived.BoundaryOrbitInventoryPolynomialUp.BoundaryOrbitInventoryPolynomialTasteGate`
`single carrier alignment`

Theorem 4171.2 (Boundary orbit inventory polynomial obligations)**.** *For every accepted* BoundaryOrbitInventoryP *carrier $I = (O, K, E, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}}$ *surface consists exactly of orbit-table admission through O, codon-count table admission through K, coefficient-ledger exactness through E, marginal-projection exactness through M, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4220.1. The orbit table and codon count table are the only source rows, while the coefficient ledger and marginal projection rows are the only polynomial-facing rows.

Coefficient exactness is read from E. Each displayed coefficient is determined by grouping the rows of O and weighting them by the count row K; no coefficient row is available without those two source tables.

Marginal exactness is read from M. A marginal projection is permitted only as a specialization of the coefficient ledger, so it cannot replace the orbit table or codon count table by a hidden enumeration.

The structural rows H, C, P, N preserve, replay, source, and name the same finite route. Since the carrier lacks biological stochastic, quotient-codon, hidden-table, and unbounded-enumeration coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 4171.3 (Boundary orbit inventory coefficient determinacy)**.** *Every coefficient marginal exported by an accepted* $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$ *packet is determined by the displayed orbit table O, codon count table K, coefficient ledger E, and marginal projection row M. Removing any coefficient row from E leaves a marginal query without a displayed source, and removing any orbit or codon count row leaves the corresponding coefficient without a displayed inventory witness.*

Proof. Read the NameCert obligations of Definition 4220.2. A coefficient query first exposes the orbit table O and codon count table K, then reads the coefficient ledger E.

The marginal projection row M is downstream of the ledger. It can specialize the displayed polynomial, but it cannot introduce a coefficient absent from E or reconstruct a missing source row absent from O or K.

Transport and replay preserve the same dependency order. Therefore a coefficient marginal is determined exactly by the displayed table and ledger rows, and deletion of any required row breaks the finite NameCert route. □

Falsifiable prediction: For $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$, coefficient marginals are determined by the displayed orbit table, codon count table, coefficient ledger, and marginal projection rows, and a marginal read fails if any required coefficient row is removed.

Independence witness: partition, hash, errorcode, dna-window-six-boundary-tile, six-boundary-tile-coverage: the polynomial coefficient ledger is not bijective to these sibling carriers because it binds orbit tables, codon count tables, coefficient rows, marginal projections, transport, replay, provenance, and local naming, while the siblings supply partitioning, digest, error coding, boundary-tile, or coverage surfaces without this coefficient inventory.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$ packet is generated from an orbit table, codon count table, coefficient ledger, marginal projection row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4220.1, Definition 4220.2, and Definition 4220.3 seed the finite orbit-inventory polynomial certificate over boundary-tile and coverage rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological stochastic modeling, empirical code-table semantics, quotient codon equality, unbounded orbit enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked orbit-table admission, codon-count table admission, coefficient-ledger exactness, marginal-projection exactness, transport, replay, provenance, and local naming for BEDC.Derived.BoundaryOrbitInventoryPol

Chapter 4172

A Concrete Naming Certificate for $\mathsf{PrimitiveRecursive}^{\uparrow}$

Following Kleene's primitive recursive functions, the $\mathsf{PrimitiveRecursive}^{\uparrow}$ packet records finite recursion syntax and its local replay rows as BEDC data. It sits after the unary natural-number carrier of chapter 28, the list spine of chapter 36, the finite computability surface of chapter 199, the stream-window discipline of chapter 126, and the regular rational readback route of chapter 301. The chapter supplies a finite schedule substrate for later modulus and real-name consumers; it does not introduce minimization, partial recursive search, host functions, or unbounded choice.

Definition 4172.1 (PrimitiveRecursive carrier)**.** *A* $\mathsf{PrimitiveRecursive}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (Z, S, \Pi, K, R, H, C, Q, N)$$

whose rows are read as follows:

1. *Z is the zero-function row.*
2. *S is the successor-function row.*
3. *Π is the finite family of projection rows, each with displayed arity and coordinate index.*
4. *K is the composition row, storing one outer code, its finite list of inner codes, and the arity ledger that makes the composition well typed.*
5. *R is the primitive-recursion scheme row, storing the base code, step code, displayed accumulator coordinate, and finite recursion spine over the* $\mathsf{Nat}^{\uparrow}$ *row.*
6. *H is componentwise* hsame *transport for zero, successor, projection, composition, recursion, replay, provenance, and local naming rows.*
7. *C is displayed* Cont *replay for evaluating a finite syntax tree by structural recursion through the rows Z, S, Π, K, R.*
8. *Q is the* Pkg *provenance row over* $\mathsf{PrimitiveRecursive}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{Computable}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PrimitiveRecursive}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Z, S, \Pi, K, R, H, C, Q, N$. There is no coordinate for minimization, unbounded search, partiality, a host function graph, countable choice, or an external evaluator.

Lean4 ✓ `BEDC.Derived.PrimitiveRecursiveUp.TasteGate.PrimitiveRecursiveTasteGate single carrier alignment`

Theorem 4172.2 (PrimitiveRecursive NameCert obligations)**.** *For every accepted* $\mathsf{PrimitiveRecursive}^{\uparrow}$ *carrier*

$$P = (Z, S, \Pi, K, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrimitiveRecursive}^{\uparrow}}$ *surface consists exactly of carrier admission for the zero, successor, projection, composition, primitive-recursion, transport, replay, provenance, and naming rows; arity compatibility for* Π, K, R*; structural replay of the displayed syntax tree through* C*; componentwise transport through* H*; and provenance through* Q, N*. No obligation is stored in a minimization row, partial recursive search row, host-function graph, or unbounded-choice selector.*

Proof. Inspect the carrier row by row. The base constructors are Z, S, Π, and their arity information is part of the displayed finite rows rather than a host-side function space.

For composite syntax, the row K supplies the finite list of inner codes and the outer code, while R supplies the base and step codes for the primitive-recursion scheme. Induction on the displayed syntax tree checks that every replay request descends to one of Z, S, Π or to a strictly displayed subcode of K or R.

The structural rows close the local certificate. Transport through H preserves the same constructor rows, replay through C evaluates only the displayed syntax tree, and Q, N record provenance and naming. Since the packet has no coordinate for minimization, partial recursive search, host functions, or unbounded choice, the listed rows exhaust the NameCert obligations. □

Theorem 4172.3 (PrimitiveRecursive composition closure)**.** *If an accepted* $\mathsf{PrimitiveRecursive}^{\uparrow}$ *packet contains a composition row* K *whose outer code and finite list of inner codes are accepted by the same carrier, then the composed code is again read as a* $\mathsf{PrimitiveRecursive}^{\uparrow}$ *row through* K, H, C, Q, N*. The closure is internal to the finite displayed syntax and exports no minimization, partiality, host-function graph, or unbounded-choice principle.*

Proof. Proceed by induction on the finite list of inner codes recorded in K. The empty-list boundary is the displayed arity check for the outer code, and the single-step case appends one already accepted inner row to the composition ledger.

At each induction step the replay row C evaluates the inner rows before the outer row, and transport through H preserves the same arity and constructor classifiers. The provenance row Q and local naming row N then repackage the resulting finite syntax as a $\mathsf{PrimitiveRecursive}^{\uparrow}$ row.

No unbounded search is used in the induction. The construction consumes only the displayed finite list in K and the accepted subcodes already present in the carrier, so it cannot introduce minimization, partial recursive search, host functions, or unbounded choice. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrimitiveRecursive}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrimitiveRecursive}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4221.1, Definition 4221.2, and Definition 4221.3 seed the finite recursion-syntax certificate for schedule and modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrimitiveRecursive}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close minimization, partial recursive search, host functions, unbounded choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, arity compatibility, composition closure, primitive-recursion replay, transport, provenance, and local naming for the same finite recursion syntax.

Constructive story: The construction starts from zero, successor, and projection rows, closes finite composition through a displayed list spine, and closes primitive recursion by replaying the base and step codes over the Nat row under componentwise transport and local naming.

The $\mathsf{CauchyAcceleration}^{\uparrow}$ packet reads the StreamName, DyadicRatCore, RegSeqRat, and Real sibling surfaces of chapter 126, chapter 291, chapter 301, and chapter 38 before exporting its accelerated completion-facing route.

Chapter 4173

A Concrete Naming Certificate for $\mathsf{CauchyAcceleration}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyAcceleration}^{\uparrow}$ packet records the finite acceleration step by which an ordinary displayed Cauchy name is replaced by a cofinal regular rational name without changing the represented real. It sits after the criterion surfaces of chapter 392 and chapter 3576, the regularization route of chapter 376, the windowed name surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The acceleration packet consumes Cauchy tail comparison as substantive finite-window and dyadic-tolerance data through chapter 301, chapter 126, chapter 291, and chapter 38 before any accelerated Real-facing read is exported. The accelerated cofinal regular-rational name is consumed by chapter 5721 as the completion-existence witness route, with the read still passing through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The packet makes acceleration a named finite ledger: it does not select an ambient subsequence, quotient a Cauchy representative, or appeal to host completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4173.1 (Cauchy acceleration carrier)**.** *A* $\mathsf{CauchyAcceleration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, T, \alpha, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *row whose finite windows display the original rational Cauchy name.*
2. *T is the dyadic tolerance schedule, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, assigning the requested precision budget to each inspected window.*
3. *α is the cofinal acceleration map, stored as a finite monotone ledger saying which source window is read for each accelerated precision request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *proof row for the accelerated rational name, including the regularity inequalities obtained by reading S through α and T.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, recording that the accelerated regular name reaches the same Real-facing boundary as the source name.*
6. *H records componentwise* hsame *transport for the source stream, tolerance schedule, cofinality map, regular proof row, Real seal, provenance, and local naming row.*

7. *C records displayed* Cont *replay from an acceleration request through S, T, α, R, E and then to the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyAcceleration}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyAcceleration}^{\uparrow}}$ *row.*

The carrier has no coordinate for a quotient representative of the original Cauchy name, a choice-selected subsequence, an ambient completeness theorem, or a host-side equality oracle for real numbers.

Theorem 4173.2 (Cauchy acceleration NameCert obligations)**.** *For every accepted* $\mathsf{CauchyAcceleration}^{\uparrow}$ *carrier $A = (S, T, \alpha, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyAcceleration}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed* $\mathsf{StreamName}^{\uparrow}$ *source row S, dyadic tolerance schedule T, cofinal map α, regular rational proof row R, and Real seal row E;*
2. *monotone cofinality, requiring α to preserve request order and to eventually reach every inspected source precision window;*
3. *dyadic tolerance preservation, requiring each accelerated request to read the same displayed tolerance budget through* $\mathsf{DyadicRatCore}^{\uparrow}$ *before it reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *row;*
4. *classifier transport, requiring H and C to preserve the source stream, tolerance schedule, cofinality ledger, regular proof row, and Real seal under componentwise* hsame *and displayed replay;*
5. *ledger exhaustion through P and N, excluding quotient representatives, choice-selected subsequences, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and host real equality.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4222.1. The accepted packet exposes only the source stream S, tolerance schedule T, acceleration ledger α, regular readback R, Real seal E, and the structural rows.

Monotone cofinality is the public content of α. Since α is stored as a finite ledger over the inspected request window, each accelerated precision read names the source window it consumes and records that later requests do not move backward.

Dyadic tolerance preservation follows by reading T before the regular rational proof row. The $\mathsf{RegSeqRat}^{\uparrow}$ row R receives exactly the tolerance entries displayed by $\mathsf{DyadicRatCore}^{\uparrow}$, so the acceleration cannot import an unrecorded modulus or external precision oracle.

Classifier transport is componentwise through H and replayed through C. These rows preserve S, T, α, R, E without adding a second classifier surface.

Finally, P and N name precisely the displayed packet. Because the carrier contains no quotient representative, choice-selected subsequence, ambient completeness coordinate, or host real equality oracle, the five listed rows exhaust the local naming obligations. □

Theorem 4173.3 (Cauchy acceleration L10 handoff)**.** *Every accepted* $\mathsf{CauchyAcceleration}^{\uparrow}$ *carrier $A = (S, T, \alpha, R, E, H, C, P, N)$ exports only the finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

displayed by $S, T, \alpha, R, E, H, C, P, N$. Consequently every L10 consumer receives a $\mathsf{RegSeqRat}^{\uparrow}$*-compatible and* $\mathsf{Real}^{\uparrow}$*-compatible accelerated name, while quotient representatives of the original Cauchy name, choice-selected subsequences, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness remain unavailable.*

Proof. Project the accepted carrier and apply Definition 4222.2. The only public data are $S, T, \alpha, R, E, H, C, P, N$.

The source read begins at the $\mathsf{StreamName}^{\uparrow}$ row S. The tolerance read then passes through T and α, so every accelerated precision request is attached to an explicit dyadic budget and a displayed source window.

The regular rational handoff is exactly R, and the Real-facing boundary is exactly E. Transport and replay through H and C preserve that route for downstream consumers.

Since P and N exhaust the packet and no forbidden coordinate appears in Definition 4222.1, the exported object is only the displayed accelerated name compatible with $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. □

Theorem 4173.4 (Cauchy acceleration rectangular window route)**.** *Every accepted* $\mathsf{CauchyAcceleration}^{\uparrow}$ *carrier* $A = (S, T, \alpha, R, E, H, C, P, N)$ *reuses the same* $\mathsf{StreamName}^{\uparrow}$ *finite windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows when producing the accelerated* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and the terminal* $\mathsf{Real}^{\uparrow}$ *handoff. The cofinal ledger* α *may refine the order of precision requests, but it cannot replace the displayed window route recorded by* S, T, H, C, P, N*.*

Proof. Project the rows $S, T, \alpha, R, E, H, C, P, N$. The source windows are recorded in S, and the dyadic tolerance entries are recorded in T before the accelerated regular rational row R or the Real-facing seal E is consumed.

Apply Definition 4222.2. The cofinality row α is an order ledger over displayed source windows, while dyadic tolerance preservation forces each accelerated request to read the same T row before it reaches R.

Now apply Definition 4222.3. Transport and replay through H and C preserve the route named by P and N, so no quotient representative, selected subsequence outside the ledger, or ambient completeness row is exported. □

Theorem 4173.5 (Cauchy acceleration cofinal-ledger determinism)**.** *Let*

$$A = (S, T, \alpha, R, E, H, C, P, N)$$

and

$$A' = (S, T, \alpha', R', E', H, C, P, N)$$

be accepted $\mathsf{CauchyAcceleration}^{\uparrow}$ *carriers sharing the same displayed source stream, tolerance schedule, structural replay rows, provenance rows, and local naming boundary through* S, T, H, C, P, N*. If the two cofinal ledgers* α *and* α' *choose the same source window for every inspected precision request, then their accelerated* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and terminal* $\mathsf{Real}^{\uparrow}$ *seal follow the same finite route. In particular, neither ledger can replace the displayed source-window or tolerance route before* R, R' *and* E, E' *are read.*

Proof. Project both accepted carriers through Definition 4222.1. The shared rows expose the same $\mathsf{StreamName}^{\uparrow}$ source windows, the same $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance schedule, and the same replay and provenance boundary.

Apply Definition 4222.2 to both packets. The only ledger freedom available before the accelerated readback is the cofinal row, and by hypothesis the displayed source window selected for each inspected request is identical in α and α'.

Now use Definition 4222.4. Since the rectangular source-window and tolerance route is fixed, the regular rational rows R, R' and the Real seals E, E' are reached through the same finite route. The packet therefore has no row through which a second ledger can substitute a hidden subsequence, quotient representative, or ambient completeness argument. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyAcceleration}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyAcceleration}^{\uparrow}$ packet is generated from a StreamName source row, a DyadicRatCore tolerance schedule, a finite cofinal acceleration ledger, a RegSeqRat proof row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyAcceleration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4222.1, Definition 4222.2, and Definition 4222.3 seed the finite acceleration route from StreamName windows through dyadic tolerance schedules, cofinal acceleration ledgers, RegSeqRat readback, and the terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyAcceleration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy-name equality, choice-selected subsequences, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone cofinality, dyadic tolerance preservation, classifier transport, L10 handoff, and ledger exhaustion for BEDC.Derived.CauchyAccelerationUp.

Theorem 4173.6 (Cauchy acceleration sequence-space route)**.** *Every* $\mathsf{CauchyAcceleration}^{\uparrow}$ *consumer reads the common-window classifier of* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *from chapter 406 before exporting the accelerated* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff. The route passes through the regularization boundary of chapter 376: the source* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, accelerated cofinal ledger, regular rational readback, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local* NameCert *rows are visible before any Real-facing consumer may inspect the acceleration result. No quotient representative, selected subsequence outside the displayed ledger, host equality, or ambient completeness row is exported.*

Theorem 4173.7 (Cauchy subsequence dependency route)**.** *Every* $\mathsf{CauchyAcceleration}^{\uparrow}$ *consumer that exports an accelerated* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or terminal* $\mathsf{Real}^{\uparrow}$ *seal must first consume the rate-dominance surface of chapter 1814 and the fast-modulus surface of chapter 1781. The route is finite:* $\mathsf{CauchyRateDominance}^{\uparrow}$ *bounds the source schedule,* $\mathsf{FastCauchyModulus}^{\uparrow}$ *supplies the inspected acceleration window, and the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *transport, replay, provenance, and local* NameCert *rows carry the resulting readback. No consumer may replace this route by a chosen subsequence, quotient representative, ambient completion row, or host equality of Real names.*

Proof. Begin with the accepted carrier of Definition 4222.1. Its source stream row S, tolerance schedule T, cofinal ledger α, regular rational row R, and Real seal E are the only analytic rows available before transport, replay, provenance, and local naming.

The rate-dominance chapter supplies the comparison row that bounds which source schedule entries may be read by α. The fast-modulus chapter supplies the inspected window that turns those bounded reads into the accelerated tolerance route. Reading either row after the $\mathsf{RegSeqRat}^{\uparrow}$ readback would hide the schedule obligation rather than consume it.

Apply the rectangular window route of Definition 4222.4. It keeps the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ rows in front of R and E, so the accelerated readback remains a displayed finite route. The carrier has no coordinate for a selected subsequence, quotient representative, ambient completion proof, or host Real equality, and the dependency route cannot export one. □

Theorem 4173.8 (Cauchy acceleration L10 four-face cofinality)**.** *Every accepted* $\mathsf{CauchyAcceleration}^{\uparrow}$ *carrier that exports an accelerated* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or terminal* $\mathsf{Real}^{\uparrow}$ *seal preserves the ordered L10 four-face route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The cofinal acceleration ledger may refine which displayed source window is read for a requested precision, but it cannot commute, omit, or replace the $\mathsf{StreamName}^{\uparrow}$ *source face, the* $\mathsf{DyadicRatCore}^{\uparrow}$

tolerance face, the $\mathsf{RegSeqRat}^{\uparrow}$ *readback face, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The resulting route remains finite and displayed, with no chosen subsequence outside the ledger, quotient representative, ambient completion row, host real equality, countable-choice schedule, Lean verification, or standard bridge.*

Proof. Start with Definition 4222.3. It names the only exported analytic route of an accepted carrier as the ordered sequence from the stream window through the dyadic tolerance ledger and regular rational readback to the Real-facing seal.

Next apply Definition 4222.4. The cofinal ledger α refines precision requests inside the displayed rectangle of source windows and dyadic tolerances, so it cannot move the $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ rows ahead of the upstream faces.

Finally use the sibling dependency route of Definition 4222.7. The rate-dominance and fast-modulus surfaces are consumed before the accelerated readback is exported, and they leave the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces in order.

The carrier and dependency route have no row for a hidden subsequence, quotient representative, ambient completion proof, host Real equality, choice schedule, Lean verification, or bridge credential. Hence cofinal acceleration preserves exactly the displayed L10 four-face route. □

Theorem 4173.9 (Cauchy acceleration completion forward link)**.** *Every completion-facing consumer of* $\mathsf{CauchyAcceleration}^{\uparrow}$ *reads through chapter 1639, chapter 301, chapter 126, chapter 291, and chapter 38 before the accelerated route exports a terminal real boundary. The dependency is the finite route from source* $\mathsf{StreamName}^{\uparrow}$ *windows through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance schedule and cofinal acceleration ledger into* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the Bishop regular Cauchy completion surface, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start with the displayed source windows. The accelerated route has no completion-facing input until the $\mathsf{StreamName}^{\uparrow}$ inspection windows and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance schedule have been exposed.

Next read the regular rational and completion surfaces. The cofinal acceleration ledger feeds $\mathsf{RegSeqRat}^{\uparrow}$ readback and then passes through the Bishop regular Cauchy completion chapter before any terminal real boundary is visible.

Finally attach the $\mathsf{Real}^{\uparrow}$ seal. Since the route is finite and displayed at each sibling boundary, it exports no quotient completion, selected subsequence, countable choice principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Chapter 4174

A Concrete Naming Certificate for $\mathsf{BrouwerMonotoneSequence}^{\uparrow}$

Following Brouwer and Bishop–Bridges on monotone sequences in constructive analysis, the BrouwerMonotoneSeque packet records a monotone real-name boundary object through finite stream windows, regular rational readback, dyadic tolerance ledgers, and the terminal real-name seal. It sits after the Specker obstruction of chapter 1406, the regular-rational readback of chapter 301, the stream-window interface of chapter 126, the dyadic rational core of chapter 291, and the Real seal of chapter 38. The chapter gives the L10 Real and Completion frontier a named monotone-sequence carrier without claiming located suprema, trichotomy, countable choice, selected limits, quotient stream representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4174.1 (BrouwerMonotoneSequence carrier)**.** *A* $\mathsf{BrouwerMonotoneSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, W, D, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-sequence row, listing the inspected indices and their finite dependency order.*
2. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows opened for the inspected real-name entries.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the displayed windows and monotonicity comparisons.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the windows and dyadic tolerance ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, W, D, R have been displayed.*
6. *M is the monotonicity ledger, recording only finite adjacent-window comparison obligations among the displayed entries.*
7. *H records componentwise* hsame *transport for source indices, windows, dyadic ledgers, readback, Real seals, monotonicity, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a monotone-sequence request through $S, W, D, R, E, M, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BrouwerMonotoneSequence}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerMonotoneSequence}^{\uparrow}}$ *row.*

The classifier accepts only packets whose monotone-sequence request displays these rows in order. It has no coordinate for a located supremum, trichotomy decision, countable-choice selector, selected limit, quotient stream representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.BrouwerMonotoneSequenceUp.BrouwerMonotoneSequenceTasteGate single carrier alignment`

Theorem 4174.2 (BrouwerMonotoneSequence NameCert obligations)**.** *For every accepted* $\mathsf{BrouwerMonotoneSeque}$ *carrier*

$$B = (S, W, D, R, E, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BrouwerMonotoneSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the inspected source sequence, finite stream windows, dyadic tolerance ledger, regular rational readback, Real seal, finite monotonicity ledger, componentwise transport, displayed replay, package provenance, and local naming rows. No NameCert obligation may be discharged by a located supremum, trichotomy of real names, countable-choice schedule, selected limit, quotient stream representative, or ambient complete real line.*

Proof. Project the carrier of Definition 4223.1. The analytic rows are precisely the source schedule S, the finite windows W, the dyadic tolerance ledger D, the regular rational readback R, the Real seal E, and the finite monotonicity ledger M.

The monotonicity information is local to the displayed windows. Each comparison read in M consumes only the adjacent source entries already opened through S, W, D, R and does not add a global order decision for arbitrary real names.

The structural rows add no hidden analytic principle. Transport through H preserves the same displayed rows, replay through C follows the same finite route, and P, N record provenance and local naming for the packet.

Since the carrier has no row for located suprema, trichotomy, countable-choice schedules, selected limits, quotient stream representatives, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Theorem 4174.3 (BrouwerMonotoneSequence finite-window nonescape)**.** *Every consumer read of an accepted* $\mathsf{BrouwerMonotoneSequence}^{\uparrow}$ *carrier reaches a* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route may consult the finite monotonicity ledger M for displayed adjacent windows, but it cannot escape to a located supremum, countable-choice selector, trichotomy oracle, selected limit, quotient stream representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with a consumer read of the accepted carrier. The source row S exposes only the inspected indices, so the first real-name data available to the consumer are the finite $\mathsf{StreamName}^{\uparrow}$ windows in W.

The dyadic and regular-rational rows determine the only readback route. The tolerance ledger D bounds the displayed windows, and the row R packages those bounded observations as $\mathsf{RegSeqRat}^{\uparrow}$ readback data.

The terminal seal is downstream of those rows. The $\mathsf{Real}^{\uparrow}$ row E is available only after S, W, D, R have been displayed, and the monotonicity ledger M can compare only the adjacent windows already present in the same finite packet.

Transport, replay, provenance, and local naming preserve this order through H, C, P, N. Therefore every consumer read remains inside the displayed finite-window route and cannot import a

located supremum, trichotomy oracle, choice schedule, selected limit, quotient stream representative, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerMonotoneSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BrouwerMonotoneSequence}^{\uparrow}$ packet is generated from inspected source indices, finite StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, a RealUp seal, a finite monotonicity ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrouwerMonotoneSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4223.1, Definition 4223.2, and Definition 4223.3 seed the constructive monotone-sequence boundary for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrouwerMonotoneSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close located suprema, trichotomy, countable choice, selected limits, quotient stream representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window monotonicity, StreamName exposure, DyadicRatCore tolerance accounting, RegSeqRat readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BrouwerMonotoneSequenceUp.

Chapter 4175

A Concrete Naming Certificate for $\mathsf{CauchySequenceCriterion}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy criteria, the $\mathsf{CauchySequenceCriterion}^{\uparrow}$ packet records the textbook sequence criterion as finite BEDC data. It ties a sequence source to the dyadic tolerance discipline of chapter 291, the stream-window naming discipline of chapter 126, the regular rational readback of chapter 301, and the public real seal of chapter 38. The chapter names only the finite route from tolerance data to regular-Cauchy and real consumers; it does not supply a choice-selected subsequence, quotient equality of limits, host completion, or ambient completeness principle.

Definition 4175.1 (CauchySequenceCriterion carrier)**.** *A* $\mathsf{CauchySequenceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, M, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the sequence-source row, displaying the named sequence and the finite request interface through which a downstream consumer asks for terms.*
2. *M is the modulus-schedule row, displaying the finite schedule that turns a requested dyadic tolerance into a stage bound.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-ledger row, recording the positive dyadic thresholds, comparisons, and tolerance refinements read by the schedule.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing only finite windows of the sequence after the schedule row has supplied their stage bounds.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy readback row reached from A, M, D, S.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the regular-Cauchy readback has been displayed.*
7. *H records componentwise* hsame *transport for the sequence source, schedule, dyadic tolerance ledger, stream windows, regular readback, Real seal, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from a criterion request through $A, M, D, S, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceCriterion}^{\uparrow}}$ *row.*

The classifier accepts only packets whose criterion consumer first displays the sequence source, modulus schedule, dyadic tolerance ledger, stream-window row, regular-Cauchy readback, Real seal, hsame*,* Cont*,* Pkg*, and local* NameCert *rows listed above.*

Lean4 ✓ `BEDC.Derived.CauchySequenceCriterionUp.CauchySequenceCriterionTasteGate single carrier alignment`

Theorem 4175.2 (CauchySequenceCriterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchySequenceCriterion}^{\uparrow}$ *carrier*

$$Q = (A, M, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySequenceCriterion}^{\uparrow}}$ *surface consists exactly of sequence-source admission, modulus-schedule admission, dyadic tolerance-ledger exposure, finite stream-window exposure, regular-Cauchy readback, Real seal readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the rows of* Q*. No obligation may be discharged by a choice-selected subsequence, quotient equality of limits, host completion, ambient completeness, or an unbounded open-cover argument.*

Proof. Project the carrier of Definition 4224.1. Its analytic rows are precisely the sequence source A, modulus schedule M, dyadic tolerance ledger D, stream windows S, regular-Cauchy readback R, and Real seal E.

The tolerance rows determine the access order. A criterion consumer reads M before it can turn a dyadic request from D into a finite stage bound, and it reads S only through the finite windows exposed by that bound.

The readback rows add no external completion object. The row R repacks the displayed tolerance and window data as regular-Cauchy readback, and E seals that readback as the public real-facing output.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no coordinate of Q stores a selected subsequence, quotient limit equality, host completion, ambient completeness witness, or open-cover argument, the displayed rows exhaust the NameCert obligations. □

Theorem 4175.3 (CauchySequenceCriterion L10 handoff)**.** *Every L10 consumer read of an accepted* $\mathsf{CauchySequenceCriterion}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff reaches the displayed $\mathsf{Real}^{\uparrow}$ *seal only through the sequence source, modulus schedule, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceCriterion}^{\uparrow}}$ *row carried by the same packet.*

Proof. Begin with the sequence source A and modulus schedule M. They expose the named sequence and the finite stage bounds required by any dyadic tolerance request.

Next read the dyadic tolerance ledger D and stream-window row S. The ledger supplies the positive thresholds and comparisons, while the stream row supplies only the finite windows named by the schedule.

Attach the regular-Cauchy readback row R. It is the unique displayed route by which the dyadic-window data becomes a regular rational sequence consumer.

The Real seal closes the route. The row E is reached only after R, and the structural rows H, C, P, N carry the same finite data through transport, replay, provenance, and local naming. Hence the L10 handoff exposes a constructive sequence criterion rather than a selected subsequence, quotient limit, host completion, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceCriterion}^{\uparrow}$ packet is generated from a sequence source, modulus schedule, dyadic tolerance ledger, stream windows, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySequenceCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4224.1, Definition 4224.2, and Definition 4224.3 seed the L10 route from dyadic sequence criteria to regular-Cauchy and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySequenceCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close choice-selected subsequences, quotient equality of limits, host completion, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus schedule exposure, dyadic tolerance-ledger exactness, stream-window handoff, RegSeqRat/Real seal readback, transport, replay, provenance, and local naming for BEDC.Derived.CauchySequenceCriterionUp.

$\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ routes pointwise locator induction through chapter 3410, chapter 126, chapter 291, chapter 301, and chapter 38; the child file carries the theorem and closurestatus surface.

Chapter 4176

A Concrete Naming Certificate for CauchyRealLocatorPointwiseInduction$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the CauchyRealLocatorPointwiseInduction$^{\uparrow}$ packet records the finite-window induction route used by Cauchy real locators. It is a sibling of the locator surface of chapter 3410 and the finite schedule discipline of chapter 126: a pointwise induction step opens one displayed stream window, reads its dyadic tolerance ledger, passes through the regular rational readback of chapter 301, and returns to the same Real-facing locator seal of chapter 38. The packet is not an induction principle over all host streams, a quotient-real equality theorem, a countable-choice selector, or an ambient completeness assertion.

The dependency route is substantive: before the packet exports pointwise locator induction, it consumes the rational interval enclosure surface of chapter 4202 together with the RegSeqRat window handoff of chapter 301. Thus each pointwise branch is read as rational interval enclosure plus regular Cauchy window data, not as a decorative citation to neighboring chapters.

Definition 4176.1 (Cauchy real locator pointwise induction carrier)**.** *A* CauchyRealLocatorPointwiseInduction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, W, D, Q, R, B, H, C, P, N)$$

with the following displayed rows:

1. *L is the source* CauchyRealLocator$^{\uparrow}$ *row, carrying the locator modulus, finite-window, dyadic, regular-rational, and Real seal data.*
2. *W is the* StreamName$^{\uparrow}$ *pointwise window row selected for the current locator request.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row used to compare the pointwise window with the requested side test.*
4. *Q is the* RegSeqRat$^{\uparrow}$ *readback row exposed after the window and dyadic tolerance have been displayed.*
5. *R is the terminal* Real$^{\uparrow}$ *locator seal reached by the pointwise readback.*
6. *B is the finite induction-branch ledger, recording the base window and successor-window handoff over the displayed rows W, D, Q, R.*
7. *H records componentwise* hsame *transport for the locator source, window, dyadic tolerance, regular readback, Real seal, branch ledger, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay for each pointwise induction step.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyRealLocator}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows. It has no coordinate for host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4176.2 (Cauchy real locator pointwise induction regularity-witness route)**.** *Every accepted* $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier consumes the finite regularity-witness surface of chapter 1158 before any* $\mathsf{Real}^{\uparrow}$ *seal is inspected. For a carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the pointwise branch first opens the displayed $\mathsf{StreamName}^{\uparrow}$ *window W, then reads the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q through the regularity-witness route, and only then reaches the terminal Real locator seal R.*

Proof. Project the carrier. The only rows available before the Real seal are the locator source L, the displayed window W, the dyadic tolerance D, and the regular-rational readback Q.

Now use the sibling regularity-witness surface. Its displayed route supplies the same finite window, tolerance ledger, and RegSeqRat readback before the Real seal handoff, so the pointwise branch can inspect regularity evidence without opening a host stream representative.

Finally read R and the structural rows B, H, C, P, N. These rows record, transport, replay, source, and name the already displayed route, so the pointwise induction packet depends on the regularity witness before it reaches the Real-facing locator seal. □

Theorem 4176.3 (Cauchy real locator pointwise window induction)**.** *For every accepted* CauchyRealLocatorPointwi *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

each pointwise locator step factors through the finite route

$$L \longmapsto W, D \longmapsto Q \longmapsto R \longmapsto B, H, C, P, N.$$

The base and successor cases of the induction ledger B may inspect only the displayed $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *locator seal supplied by the same* $\mathsf{CauchyRealLocator}^{\uparrow}$ *source row.*

Proof. Project the accepted carrier. The source row L is the only Cauchy real locator coordinate, so every pointwise step begins by reading the displayed locator packet of chapter 3410.

The induction window is then opened through W. The dyadic tolerance row D is the only comparison surface attached to that window, and the regular rational readback Q is available only after the window and dyadic rows have been displayed.

The terminal read reaches R and is then recorded by the branch ledger B. The base branch and each successor branch therefore preserve the same finite route rather than selecting a host stream representative.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no row for host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient completeness, the displayed route exhausts the pointwise induction surface. □

Theorem 4176.4 (Cauchy real locator pointwise induction NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$ *obligations are exactly carrier admission for the* $\mathsf{CauchyRealLocator}^{\uparrow}$ *source row* L*, pointwise* $\mathsf{StreamName}^{\uparrow}$ *window admission for* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance compatibility for* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback for* Q*,* $\mathsf{Real}^{\uparrow}$ *locator-seal ordering for* R*, finite base and successor branch admission for* B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 4225.1. The tuple displays the locator source, pointwise window, dyadic tolerance, regular-rational readback, real seal, branch ledger, and structural rows.

The source and window obligations are read from L and W. The dyadic tolerance row D is the only comparison surface attached to that pointwise window, and the readback row Q can be inspected only after those rows are displayed.

The real-seal ordering obligation is the row R, downstream of Q. The branch ledger B records the finite base and successor handoff over the same displayed rows rather than over a host stream representative.

The rows H, C, P, N transport, replay, source, and name the packet. Since no other coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 4176.5 (Cauchy real locator pointwise window stability)**.** *Let*

$$I = (L, W, D, Q, R, B, H, C, P, N)$$

be an accepted $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier. Replacing the locator source,* $\mathsf{StreamName}^{\uparrow}$ *pointwise window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and* $\mathsf{Real}^{\uparrow}$ *seal by displayed componentwise* hsame *rows, and replaying the replacement through* C*, preserves the admissible pointwise induction route*

$$L \longmapsto W, D \longmapsto Q \longmapsto R \longmapsto B.$$

Thus the base and successor branches of the finite induction ledger remain attached to the same locator source and cannot introduce host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier and use Definition 4225.3. Every pointwise step already factors through the displayed locator source, window, dyadic tolerance, regular-rational readback, real seal, and branch ledger.

The componentwise replacement is recorded by H. It transports the locator source, window, tolerance, readback, seal, branch ledger, replay, provenance, and local name without adding another induction coordinate.

The replay row C then carries the transported rows through the same pointwise route. The branch ledger B therefore continues to read the base window and successor-window handoff over W, D, Q, R.

The carrier has no row for any excluded host or quotient object, so row exhaustion shows that the transported packet preserves exactly the admissible pointwise induction route. □

Theorem 4176.6 (Cauchy real locator pointwise branch exhaustion)**.** *For every accepted* CauchyRealLocatorPointw *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

every base or successor branch read in B is exhausted by the displayed rows $L, W, D, Q, R, H, C, P, N$. Such a branch read cannot introduce host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The branch ledger B is downstream of the locator source L, pointwise window W, dyadic tolerance row D, regular-rational readback Q, and terminal real seal R.

Use pointwise window induction from Definition 4225.3. It forces both the base branch and each successor branch to read the same finite route $L \longmapsto W, D \longmapsto Q \longmapsto R$ before B records the branch.

Use window stability from Definition 4225.5. The transport row H and replay row C preserve that route under displayed componentwise replacement, while P, N only source and name the packet.

Row exhaustion completes the claim. No coordinate of I stores host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so no base or successor branch can export any of those objects. □

Theorem 4176.7 (Cauchy real locator pointwise induction sibling route)**.** *Every accepted* CauchyRealLocatorPointw *read must pass through chapter 3410, chapter 126, chapter 291, chapter 301, and chapter 38 before the branch ledger is public. For a carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the rows L, W, D, Q, R are exactly that sibling route, and B, H, C, P, N can only record, transport, replay, source, and name the displayed route.

Proof. Project the carrier rows $L, W, D, Q, R, B, H, C, P, N$ from Definition 4225.1. The source row L is read through the Cauchy real locator certificate, while W is the finite StreamName window attached to the current pointwise request.

The dyadic tolerance row D is then consumed through the DyadicRatCore certificate, and Q is the RegSeqRat readback of that displayed window and tolerance data. The terminal row R is the Real-facing locator seal reached after those rows are visible.

Apply Definition 4225.3 and Definition 4225.4. They force the pointwise induction route and the local NameCert obligations to use exactly the rows L, W, D, Q, R before the branch ledger can be inspected.

Finally use Definition 4225.5 and Definition 4225.6. The transport, replay, provenance, and local naming rows preserve the same sibling route and exhaust the branch surface, so the public branch ledger has no alternate dependency edge outside the listed chapters. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4225.1, Definition 4225.3, Definition 4225.4, Definition 4225.5, and Definition 4225.6 seed the finite pointwise induction route over CauchyRealLocator, StreamName, DyadicRatCore, RegSeqRat, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window induction, dyadic tolerance compatibility, RegSeqRat readback, Real seal ordering, and local NameCert registration for BEDC.Derived.CauchyRealLocatorPointwiseInductionUp.

Constructive story: A CauchyRealLocatorPointwiseInduction$^{\uparrow}$ packet is generated from a CauchyRealLocator source row, one StreamName pointwise window, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RealUp locator seal, a finite induction-branch ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4177

A Concrete Naming Certificate for $\mathsf{FrinkMetrization}^{\uparrow}$

Following Frink and Kelley, the $\mathsf{FrinkMetrization}^{\uparrow}$ packet records the finite BEDC route from a uniform entourage basis to a pseudometric-facing and metric-facing distance certificate. It sits after the uniform-source rows of chapter 339, the pseudometric carrier of chapter 1614, the separated metric boundary of chapter 57, the topology compatibility row of chapter 88, the dyadic tolerance ledger of chapter 291, and the finite window interface of chapter 126. The packet names only the constructive handoff from nested entourage data to displayed distance reads; it does not form quotient uniformities, select representatives, assert ambient metrizability, or import choice.

Definition 4177.1 (FrinkMetrization carrier)**.** *A* $\mathsf{FrinkMetrization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (U, Q, D, P, M, T, H, C, G, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row. It names the carrier surface and the finite entourage requests from which the metrization route starts.*
2. *Q is the nested entourage chain. It records the finite refinement ladder used to compare two source points at dyadic scales.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger. It translates the refinement level into displayed dyadic radii and triangle budgets.*
4. *P is the* $\mathsf{Pseudometric}^{\uparrow}$ *handoff row. It receives the finite entourage chain and exports the displayed pre-separated distance route.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *compatibility row, available only after the separated boundary has accepted the zero-distance route supplied through P.*
6. *T is the* $\mathsf{Topology}^{\uparrow}$ *compatibility row. It records that the metric-facing balls and the original uniform entourage reads are compared through the same finite windows.*
7. *H records componentwise* hsame *transport for the uniform source, chain, dyadic ledger, pseudometric handoff, metric compatibility, topology compatibility, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a uniform entourage request through the nested chain, dyadic ledger, pseudometric handoff, metric row, topology row, provenance, and local naming row.*

9. *G is the* Pkg *provenance over* FrinkMetrization$^{\uparrow}$, UniformSpace$^{\uparrow}$, Pseudometric$^{\uparrow}$, Met$^{\uparrow}$, Topology$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{FrinkMetrization}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient uniformity equality, selected representatives, ambient metrizability, countable choice, host topology equality, or an unbounded distance oracle.

Lean4 ✓ `BEDC.Derived.FrinkMetrizationUp.FrinkMetrizationTasteGate single carrier alignment`

Theorem 4177.2 (FrinkMetrization NameCert obligations)**.** *For every accepted* FrinkMetrization$^{\uparrow}$ *carrier $F = (U, Q, D, P, M, T, H, C, G, N)$, the local* NameCert$_{\text{FrinkMetrization}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the uniform source, nested entourage chain, dyadic radius ledger, pseudometric handoff, metric compatibility row, topology compatibility row, transport, continuation, provenance, and local naming row;*
2. *nested-chain readability, requiring every distance request to start at the* UniformSpace$^{\uparrow}$ *row U and pass through the finite refinement chain Q before any dyadic radius in D is read;*
3. *pseudometric handoff, requiring the displayed distance route to be exported through P before the metric row M or topology row T can be consumed;*
4. *compatibility transport, requiring H and C to preserve the same finite* StreamName$^{\uparrow}$ *windows and* DyadicRatCore$^{\uparrow}$ *radius ledger across uniform, pseudometric, metric, and topology-facing consumers;*
5. *provenance and refusal, requiring G and N to name only this finite handoff and to refuse quotient uniformity equality, selected representatives, ambient metrizability, countable choice, host topology equality, and unbounded distance oracles.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 4226.1. The projection exposes exactly the uniform source, nested chain, dyadic ledger, pseudometric handoff, metric and topology compatibility rows, and the structural rows H, C, G, N.

The nested-chain obligation is forced by row order. A distance request starts at the uniform row U, enters the refinement ladder Q, and only then reads the dyadic radius ledger D.

The pseudometric handoff is the only distance-export step. Row P supplies the pre-separated displayed distance route, while M and T can compare it with metric and topology-facing consumers only after the same finite windows and radii have been replayed.

Rows H, C, G, N transport, replay, source, and name this route. Since the tuple contains no quotient uniformity, selected representative, ambient metrizability, countable choice, host topology equality, or unbounded distance coordinate, the local NameCert cannot export those principles. □

Closure status for NameCert$_{\text{FrinkMetrization}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{FrinkMetrization}^{\uparrow}}$, seed)

Scope closed: Definition 4226.1 and Definition 4226.2 seed the finite Frink-style handoff from uniform entourage chains to pseudometric, metric, topology, dyadic, and stream-facing rows.

Formal verification: FormalStatus(NameCert$_{\text{FrinkMetrization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient uniformity equality, selected representatives, ambient metrizability, countable choice, host topology equality, unbounded distance oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-chain readability, dyadic radius exactness, pseudometric handoff, metric and topology compatibility, transport, continuation, provenance, and ledger refusal for BEDC.Derived.FrinkMetrizationUp.

Constructive story: A FrinkMetrization$^{\uparrow}$ packet is generated from a UniformSpace source row, a nested entourage chain, a DyadicRatCore radius ledger, a Pseudometric handoff, Metric and Topology compatibility rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

NestedShrinkInterval$^{\uparrow}$ reads its compact interval dependency through chapter 5553 and the child `namecert_construction.tex` route before exposing its shrinking-diameter Real$^{\uparrow}$ seal.

Chapter 4178

A Concrete Naming Certificate for $\mathsf{NestedShrinkInterval}^{\uparrow}$

Following Cantor's nested-interval argument and Bishop–Bridges regular real analysis, the $\mathsf{NestedShrinkInterval}^{\uparrow}$ packet records the finite BEDC carrier surface for a descending located interval route whose displayed diameters shrink to the requested tolerance. It sits between the nested-closed interval carrier of **??**, the located endpoint row of chapter 394, the dyadic tolerance ledger of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback surface of chapter 301, and the terminal real-name boundary of chapter 38. The chapter names only the finite shrinking-interval convergence certificate; it does not claim open-cover compactness, trichotomy, quotient reals, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4178.1 (Nested shrink interval carrier)**.** *A* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (J, L, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *J is the* $\mathsf{NestedClosedInterval}^{\uparrow}$ *source row, exposing the retained descending closed located interval family and its containment witnesses.*
2. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row for the inspected interval windows, including lower and upper endpoint location data.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *shrink ledger recording endpoint comparisons, diameter estimates, and tolerance requests.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used to inspect interval endpoints and diameter rows at displayed stages.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same stream windows and dyadic ledger.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the nested interval, located endpoint, dyadic shrink, stream-window, and regular readback rows are visible.*
7. *H records componentwise* hsame *transport for J, L, D, S, R, E and for the replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$J, L \longmapsto D, S \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{NestedShrinkInterval}^{\uparrow}$, $\mathsf{NestedClosedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedShrinkInterval}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed rows $J, L, D, S, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, trichotomy, quotient-real equality, a selected intersection point, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 4178.2 (Nested shrink interval NameCert obligations)**.** *For every accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *carrier*

$$K = (J, L, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NestedShrinkInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{NestedClosedInterval}^{\uparrow}$ *source row,* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *shrink ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row; classifier stability under those same displayed rows; diameter-to-tolerance exactness through D; finite-window readback through S and R; Real-seal handoff through E; and ledger nonescape for the excluded compactness, trichotomy, quotient, selection, choice, and ambient-completeness coordinates.*

Proof. Project the carrier of Definition 4227.1. The projection exposes exactly the nested closed interval source, located endpoint row, dyadic shrink ledger, finite windows, regular readback, real seal, and structural rows.

Classifier stability is componentwise on those displayed rows. The shrink estimate is not an external metric fact: it is the D row, read together with the endpoint row L and the stream schedule S before regular readback is available.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since no excluded coordinate occurs in the carrier, every accepted NameCert obligation is one of the rows listed above. □

Theorem 4178.3 (Nested shrink interval diameter route)**.** *Let $K = (J, L, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *carrier. Every completion-facing request for the shrinking interval route first reads the* $\mathsf{NestedClosedInterval}^{\uparrow}$ *source J and* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row L, then reads the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter ledger D and* $\mathsf{StreamName}^{\uparrow}$ *finite windows S, and only then opens the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R and* $\mathsf{Real}^{\uparrow}$ *seal E. The route exports diameter-to-tolerance convergence as displayed finite ledger data, not as open-cover compactness, trichotomy, quotient-real equality, countable choice, a selected intersection point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a completion-facing request and project the accepted carrier. The only interval source is J, and the only endpoint data are the located rows in L.

The diameter request is then forced through D. Its dyadic comparisons and tolerance rows are inspected through the finite schedule S, so a consumer cannot replace the shrinking route by an unrecorded compactness or completeness theorem.

After the finite windows are displayed, R packages the same observations as regular rational readback and E supplies the terminal real seal. The remaining rows H, C, P, N preserve the route and add no excluded coordinate. □

Theorem 4178.4 (Nested shrink interval Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer admitted by an accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *packet receives the seal only through the displayed route*

$$\mathsf{NestedClosedInterval}^{\uparrow},\ \mathsf{LocatedInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The handoff is stable under the componentwise hsame *transport and displayed* Cont *replay rows* H, C*, and it is sourced and named only by* P, N*.*

Proof. Apply Definition 4227.3. A Real-facing consumer reaches E only after the nested interval source, located endpoint row, dyadic shrink ledger, stream windows, and regular readback have all been displayed.

Transport through H preserves the row roles, and replay through C preserves their order. Provenance and local naming through P, N attach the handoff to the packet without adding analytic content.

Thus the Real seal cannot escape to a selected point, quotient real equality, countable choice, trichotomy, open-cover compactness, or ambient real completeness. □

Theorem 4178.5 (Nested shrink interval regular-Cauchy uniqueness route)**.** *Let* $K = (J, L, D, S, R, E, H, C, P, N)$ *and* $K' = (J', L', D', S', R', E', H', C', P', N')$ *be accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *packets. Suppose their nested-source rows, located endpoint rows, dyadic shrink ledgers, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows are componentwise related by the displayed* hsame *transport. Then the two packets reach the same* $\mathsf{Real}^{\uparrow}$*-facing seal route only through the* $\mathsf{RegSeqRat}^{\uparrow}$ *uniqueness surface displayed by* R, R' *before Real sealing. The route does not identify selected intersection points, quotient real representatives, or ambient host real equality.*

Proof. Project both carriers. The first carrier exposes $J, L, D, S, R, E, H, C, P, N$, and the second exposes $J', L', D', S', R', E', H', C', P', N'$.

Apply the diameter route of Definition 4227.3 to both packets. Each read is forced through its nested source, located endpoints, dyadic shrink ledger, finite stream windows, and regular rational readback before a Real-facing seal is visible.

Use the assumed componentwise hsame transport on J, L, D, S, R and J', L', D', S', R'. The endpoint comparison therefore lives on the displayed $\mathsf{RegSeqRat}^{\uparrow}$ readback surface, because the preceding rows have already fixed the same nested-source, located-endpoint, dyadic, and stream-window route.

Finally apply the Real-seal handoff of Definition 4227.4 to both packets. It permits E and E' to be read only after the regular readback rows are displayed, so the uniqueness comparison is a $\mathsf{RegSeqRat}^{\uparrow}$ route before Real sealing and not a selected intersection point, quotient real equality, or ambient completeness assertion. □

Theorem 4178.6 (Cantor intersection nested-shrink route)**.** *Every* $\mathsf{CantorDiagonalCompactness}^{\uparrow}$ *or* $\mathsf{CantorIntersection}^{\uparrow}$ *consumer that reads a nested shrinking interval first consumes the* $\mathsf{NestedClosedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows exposed by an accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *carrier. The downstream route supplies the nested-shrink boundary used by chapter 6999 and the Cantor-intersection surface of chapter 1421.*

The route is a forward lattice edge only. It does not select an intersection point, assert open-cover compactness, use countable choice, identify quotient real names, or provide ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 4227.1. The exposed rows are the nested closed source J, located endpoints L, dyadic shrink ledger D, finite stream windows S, regular readback R, real seal E, and the structural rows H, C, P, N.

Apply Definition 4227.4. Any Real-facing downstream read reaches E only after the nested, located, dyadic, stream, and regular-rational rows have been displayed.

The Cantor diagonal and Cantor-intersection chapters consume exactly this kind of finite shrinking-interval boundary before their own diagonal or intersection rows are read. Since the

carrier contains no selected point, open-cover compactness row, choice schedule, quotient equality, or ambient completeness coordinate, the downstream route remains a finite dependency edge. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedShrinkInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedShrinkInterval}^{\uparrow}$ packet is generated from a NestedClosedInterval source row, LocatedInterval endpoint rows, a DyadicRatCore shrink ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedShrinkInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4227.1, Definition 4227.2, Definition 4227.3, and Definition 4227.4 seed the finite L10 shrinking-interval convergence route through nested closed intervals, located endpoint rows, dyadic diameter ledgers, stream windows, regular readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedShrinkInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, trichotomy, quotient reals, selected intersection points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, diameter-to-tolerance exactness, finite-window readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.NestedShrinkIntervalUp.

The $\mathsf{NestedShrinkInterval}^{\uparrow}$ packet consumes the $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ route of chapter 4080 before a completion-facing reader treats shrinking finite windows as a diagonal Cauchy subsequence witness. The nested source, located endpoint, dyadic diameter, and $\mathsf{StreamName}^{\uparrow}$ rows still supply the finite shrinking windows; $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ supplies only the displayed diagonal handoff needed to pass those windows toward $\mathsf{RegSeqRat}^{\uparrow}$ readback and the terminal $\mathsf{Real}^{\uparrow}$ seal. The route exports no detached selector, quotient-real equality, countable-choice schedule, selected intersection point, or ambient completeness coordinate. The shrinking interval diameter route is consumed through the regular rational readback of chapter 301 and the terminal real-name seal of chapter 38. Thus a downstream L10 consumer reads $\mathsf{NestedShrinkInterval}^{\uparrow}$ only after the finite diameter ledger has been repacked as a $\mathsf{RegSeqRat}^{\uparrow}$ route and sealed as a $\mathsf{Real}^{\uparrow}$ boundary, not as an ambient completeness or selected intersection-point claim. $\mathsf{NestedShrinkInterval}^{\uparrow}$ consumes $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ after the shrinking-diameter ledger has been repacked through the $\mathsf{StreamName}^{\uparrow}$ observation schedule, the $\mathsf{RegSeqRat}^{\uparrow}$ regular rational readback, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the terminal $\mathsf{Real}^{\uparrow}$ seal route. This sibling dependency records the completion-criterion consumer path of chapter 1476: a nested shrink interval can be read as completion evidence only after its finite diameter data has passed through the same stream, regular sequence, dyadic tolerance, and Real seal rows.

Theorem 4178.7 (Nested shrink interval Cauchy completion consumer)**.** *Every completion-facing read of* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *consumes* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *only after the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows are visible. Thus the dependency on chapter 1476 is a theorem-level consumer edge through chapter 126 and chapter 301, not an appeal to an undisplayed completion object.*

Proof. Read a completion-facing request for a nested shrink interval. The route first displays the finite observation schedule and regular rational readback rows, so the consumer sees only finite windows and readback entries.

The dyadic tolerance ledger and terminal Real seal are then exposed before the completion criterion is consumed. Since the criterion is reached after those rows, the dependency records a reusable finite route rather than a hidden selected limit or ambient completeness principle. □

Theorem 4178.8 (Nested shrink interval rational locator route)**.** *Every accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *route whose endpoint localization is read through rational endpoints first consumes the rational locator carrier of chapter 4202. Only after that locator row is displayed may the consumer read the*

nested shrink rows and then the $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff rows. The route exports no selected completed point and no Heine–Borel compactness principle.*

Proof. Read the accepted packet through the carrier theorem of chapter 4227. The only endpoint localization rows available to the nested shrink route are finite displayed rows, so a rational-endpoint consumer must obtain its rational interval locator row before the shrink ledger can be interpreted.

The sibling chapter chapter 4202 supplies exactly that locator surface. Once it is consumed, the nested shrink packet may proceed through its displayed shrink ledger, finite windows, regular rational readback, and terminal real seal.

No selected completed point or Heine–Borel compactness row is present in either carrier. The dependency route therefore records only the rational locator read before the nested shrink and $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ handoff rows are read. □

The $\mathsf{NestedShrinkInterval}^{\uparrow}$ route consumes chapter 4202 for rational endpoint bracketing and chapter 301 for regular rational readback before the terminal $\mathsf{Real}^{\uparrow}$ seal is visible. Thus the nested shrink interval dependency lattice reads locator cells first, then the shrinking-window ledger, then the regular readback route, not a selected intersection point or ambient completeness witness. $\mathsf{NestedShrinkInterval}^{\uparrow}$ exposes a completion-facing interval read only after the packet has consumed the $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ diagonal row, the $\mathsf{RegSeqRat}^{\uparrow}$ regular rational route, the terminal $\mathsf{Real}^{\uparrow}$ seal, the $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ admission row, and the $\mathsf{RationalIntervalLocator}^{\uparrow}$ endpoint-bracketing row. The public read is therefore a finite sibling route through diagonal selection, regular sequence readback, Real sealing, completion admission, and rational interval location; it exports no selected intersection point, quotient-real equality, countable choice, or ambient completeness principle. $\mathsf{NestedShrinkInterval}^{\uparrow}$ consumes the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301 and the completion criterion surface of chapter 1476 before any interval-limit seal is visible. The shrinking-diameter ledger must first pass through finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, regular rational readback, and the same Cauchy-completion admission route; only then may a downstream L10 consumer inspect the $\mathsf{Real}^{\uparrow}$ boundary, and the packet still exports no selected intersection point, quotient-real equality, countable choice, or ambient completion. The $\mathsf{NestedShrinkInterval}^{\uparrow}$ carrier depends on the substantive sibling lattice through chapter 320 for the nested interval spine, chapter 301 for regular rational readback, and chapter 38 for the terminal seal. The rational locator and Cauchy-completion routes already represented by the child files above supply the endpoint-bracketing and completion-admission rows, so the nested-shrink packet is read as a finite dependency route rather than a selected intersection point, quotient-real equality, countable choice, or ambient completeness principle.

Theorem 4178.9 (Nested shrink interval compact interval route)**.** *Every compact-interval consumer of an accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *packet must read the compact real interval sibling of chapter 5553 and the nested interval convergence sibling of chapter 2057 through the same finite endpoint, diameter,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows displayed by the shrinking packet. The compact interval route supplies endpoint and finite-net context; the nested convergence route supplies the shrinking-window handoff; neither route adds an open-cover compactness theorem, selected limit point, quotient real equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the accepted carrier of Definition 4227.1. The visible analytic rows are the nested source, located endpoints, dyadic diameter ledger, finite stream windows, regular rational readback, and Real seal, followed by componentwise transport, replay, provenance, and local naming.

Use the compact real interval packet of chapter 5553 only for the endpoint and finite-net context. Its compact rows are read before the shrinking packet is exported as an interval-local dependency, so the shrink route never obtains an unlisted open-cover or subcover selector.

Use the nested interval convergence packet of chapter 2057 for the convergence-facing handoff. That sibling reads finite endpoint windows, shrinking ledgers, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ sealing before a completion consumer may inspect the route.

The structural rows hsame, Cont, Pkg, and NameCert keep the two sibling reads attached to the same displayed packet. Hence a compact-interval dependency edge from $\mathsf{NestedShrinkInterval}^{\uparrow}$ is exactly the stated finite route and not a hidden compactness, quotient, choice, or completeness principle. □

Theorem 4178.10 (NestedShrinkInterval Cantor downstream route)**.** *Every* $\mathsf{CantorDiagonalCompactness}^{\uparrow}$ *or* $\mathsf{CantorIntersection}^{\uparrow}$ *consumer of a* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *packet reads the nested source only through nested closed intervals, located endpoint rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter witnesses,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The downstream route exports a Cantor diagonal or intersection-facing interval certificate, but it does not select a limit point, assert ambient completeness, identify quotient-real names, or add a host compactness principle outside the displayed rows.*

Proof. Project the nested-shrink carrier through the child routes named by the hub. The compact-interval and rational-locator rows provide nested closed intervals and located endpoints, while the dyadic and StreamName rows expose only finite diameter and window observations.

The Cantor-facing consumer then passes through the RegSeqRat and Real rows already used by the completion and sibling routes. Since these rows carry finite readback and terminal naming rather than a chosen point, the consumer obtains only the displayed interval certificate.

No carrier coordinate names a selected limit point, host completeness theorem, quotient equality, or ambient compactness object. Thus $\mathsf{CantorDiagonalCompactness}^{\uparrow}$ and $\mathsf{CantorIntersection}^{\uparrow}$ consume $\mathsf{NestedShrinkInterval}^{\uparrow}$ only through the finite interval route stated above. □

$\mathsf{RegularCauchyUniformContinuity}^{\uparrow}$ reads the displayed uniform-modulus handoff of chapter 369 from regular Cauchy source names to regular Cauchy target names through the child packet below.

Chapter 4179

A Concrete Naming Certificate for RegularCauchyUniformContinuity$^{\uparrow}$

Following Bishop and Bridges, uniform continuity on displayed constructive real names is read here as a finite regular-Cauchy handoff rather than as host function equality or a completed-real theorem. The RegularCauchyUniformContinuity$^{\uparrow}$ packet records the standard fact that a displayed uniform modulus carries regular Cauchy names to regular Cauchy names. Its dependency surface is the finite StreamName$^{\uparrow}$ window interface of chapter 126, the regular-rational row of chapter 301, the pointwise map rows of chapter 130, the tolerance rows of chapter 369, and the terminal real-name seal of chapter 38.

Definition 4179.1 (Regular Cauchy uniform-continuity carrier)**.** *A* RegularCauchyUniformContinuity$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, W, R, M, D, T, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* StreamName$^{\uparrow}$ *finite-window family opened for the regular Cauchy source name.*
2. *W records the target-window schedule requested by the regular Cauchy conclusion.*
3. *R is the source* RegSeqRat$^{\uparrow}$ *regularity row, including the rational tail bounds read on the windows in S.*
4. *M is the* ContinuousMap$^{\uparrow}$ *pointwise map row, read only through displayed source and target observations.*
5. *D is the* UniformModulus$^{\uparrow}$ *tolerance row that turns each target precision request into a source precision budget.*
6. *T is the target* RegSeqRat$^{\uparrow}$ *regularity row obtained by replaying D against R through M on the windows S, W.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row exposed only after the target regularity row T is displayed.*
8. *H records componentwise* hsame *transport for S, W, R, M, D, T, E and for the structural replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a target tolerance request through D, then S, R, M, W, then the target regularity row T, and finally the seal row E.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyUniformContinuity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, W, R, M, D, T, E, H, C, P, N$ and the displayed replay order. It has no coordinate for host function equality, quotient streams, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 4179.2 (Regular Cauchy uniform-continuity NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyUniformContinuity}^{\uparrow}$ *carrier $U = (S, W, R, M, D, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformContinuity}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source stream windows, target window schedule, source regular-rational row, pointwise map row, uniform tolerance row, target regular-rational row, Real seal, transport, replay, provenance, and local naming row;*
2. *source regularity exactness, requiring every source observation to be read through S and R before the map row is inspected;*
3. *uniform tolerance exactness, requiring each target precision request to obtain its source budget only through D;*
4. *pointwise replay exactness, requiring the map row M to be applied only to source observations admitted by S, R, D;*
5. *target regularity handoff, requiring the target* $\mathsf{RegSeqRat}^{\uparrow}$ *row T to be produced before the* $\mathsf{Real}^{\uparrow}$ *seal E is exposed;*
6. *transport and continuation preservation, requiring H and C to preserve the displayed coordinates and their replay order;*
7. *provenance exhaustion, requiring P to name only the sibling chapters and kernel rows listed in Definition 4179.1;*
8. *local naming, requiring N to name exactly the* $\mathsf{RegularCauchyUniformContinuity}^{\uparrow}$ *certificate row.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4179.1. The accepted packet exposes exactly $S, W, R, M, D, T, E, H, C, P, N$, so every local obligation must be read from that finite inventory.

The source side is exhausted by S and R. The stream row opens only finite windows, and the regular-rational row supplies the tail bounds on those windows before any map or target read is available.

The tolerance step is exhausted by D. A target precision request first reads the uniform-modulus row, which supplies the source precision budget used to choose the source observations.

The pointwise map step is then replayed through M. Since M is the only map coordinate and its inputs have already been confined to S, R, D, no host function equality or external continuity principle can enter this step.

The target handoff is recorded by T and sealed by E. The continuation row places T before E, while the transport row preserves the same coordinates under hsame.

Finally inspect P and N. The provenance row names only the sibling surfaces listed in the carrier, and the local naming row names only this certificate. Hence the eight obligations exhaust the NameCert surface. □

Theorem 4179.3 (Regular Cauchy uniform-continuity handoff)**.** *Let* $U = (S, W, R, M, D, T, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyUniformContinuity}^{\uparrow}$ *carrier. Every target* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by* U *factors through the finite route*

$$S, R, D, M, W, T.$$

Consequently a displayed uniform modulus carries the source regular Cauchy name to the target regular Cauchy name before any $\mathsf{Real}^{\uparrow}$ *seal or completion-facing consumer can read the packet.*

Proof. Start with a target precision request. The uniform-modulus row D converts that request into a source precision budget, and the source budget selects only the finite source windows named by S.

Read the source regularity row next. The row R supplies the regular Cauchy tail control on those windows, so the pointwise map row receives only displayed source observations.

Apply the pointwise map row M through the continuation route. The target-window schedule W records the finite target observations required by the regularity conclusion.

The target regularity row T is the only target $\mathsf{RegSeqRat}^{\uparrow}$ coordinate in the carrier. Since the continuation order places T after S, R, D, M, W and before the seal row E, every target regular Cauchy read factors through the displayed finite route. □

Theorem 4179.4 (Regular Cauchy uniform-continuity window composition)**.** *Let* $U = (S, W, R, M, D, T, E, H, C,$ *be an accepted* $\mathsf{RegularCauchyUniformContinuity}^{\uparrow}$ *carrier. Suppose two target precision requests are displayed in the target-window schedule* W*, and suppose their* $\mathsf{UniformModulus}^{\uparrow}$ *rows refine through the same tolerance row* D*. Then the two requests compose to one source-window budget over* S, R *before the pointwise map row* M *is read.*

The two resulting target rows both factor through the same continuation route

$$S, R, D, M, W, T, E.$$

Thus the composed target read is a finite window-stability statement for the displayed carrier only: it exports no host function equality, quotient stream, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier and the local NameCert obligations from Definition 4179.1 and Definition 4179.2. The only rows available for target precision requests are the schedule W, the tolerance row D, the source windows S, the source regularity row R, the pointwise map row M, the target regularity row T, and the seal row E.

For the two requested target precisions, use the uniform tolerance exactness obligation twice. Because both requests refine through the same D row, their source precision needs are read as one finite source-window budget on S with regular-rational control supplied by R.

Apply Definition 4179.3 to each resulting target read. The handoff forces both reads through S, R, D, M, W, T, so the target rows factor through W, T before either can reach the seal row E.

Finally inspect the carrier inventory. There is no coordinate for host function equality, quotient streams, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so the composed route is exactly the displayed finite window route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformContinuity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyUniformContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4179.1, Definition 4179.2, and Definition 4179.3 seed the finite route by which displayed uniform moduli carry regular Cauchy names to regular Cauchy names over StreamName windows, RegSeqRat rows, ContinuousMap pointwise rows, UniformModulus tolerance rows, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyUniformContinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient streams, selected limits, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source regularity exactness, uniform tolerance exactness, pointwise replay exactness, target regularity handoff, transport and continuation preservation, provenance exhaustion, and local naming for BEDC.Derived.RegularCauchyUniformContinuityUp.

Constructive story: A RegularCauchyUniformContinuity$^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat source and target rows, a ContinuousMap pointwise row, a UniformModulus tolerance row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The RegularCauchyUniformContinuity$^{\uparrow}$ route consumes RegSeqRat$^{\uparrow}$ readbacks through chapter 301, ContinuousMap$^{\uparrow}$ modulus-facing pointwise rows through chapter 130, and the UniformModulus$^{\uparrow}$ handoff through chapter 369. This child route exports no quotient stream, selected limit, host continuity, or ambient Real$^{\uparrow}$ completeness.

Chapter 4180

A Concrete Naming Certificate for $\mathsf{HenstockKurzweil}^{\uparrow}$

Following Henstock and Kurzweil, the $\mathsf{HenstockKurzweil}^{\uparrow}$ packet records a gauge-integral seed route in which tagged Riemann windows are controlled by a displayed gauge before any real-valued integral read is exported. It sits beside the gauge-integral packet of chapter 1999, the Riemann-integral packet of chapter 1526, the Riemann-sum gauge packet of chapter 4115, the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, and the dyadic endpoint ledger of chapter 291. The chapter names the finite gauge-window carrier used by this integration route; it does not claim Lebesgue measure, open-cover compactness, countable choice, selected infinite sums, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4180.1 (HenstockKurzweil carrier)**.** *A* $\mathsf{HenstockKurzweil}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, I, S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{GaugeIntegral}^{\uparrow}$ *source row naming the accepted gauge-integral boundary.*
2. *I is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *comparison row that keeps the integral read tied to tagged mesh data.*
3. *S is the* $\mathsf{RiemannSumGauge}^{\uparrow}$ *row carrying the finite tagged-sum window and gauge compatibility test.*
4. *W is the displayed gauge-window row, recording the tag, cell, and local radius data used by S.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance ledger for the cells in the displayed window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the finite window and dyadic tolerance data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after G, I, S, W, D, R have been replayed.*
8. *H records componentwise* hsame *transport for the gauge, integral, sum, window, dyadic, readback, seal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from a Henstock–Kurzweil request through $G, I, S, W, D, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{HenstockKurzweil}^{\uparrow}$, $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{RiemannSumGauge}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HenstockKurzweil}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, I, S, W, D, R, E, H, C, P, N$. There is no coordinate for a measure space, an open-cover compactness theorem, a chosen refinement family, a selected infinite sum, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.HenstockKurzweilUp.HenstockKurzweilTasteGate single carrier alignment`

Theorem 4180.2 (HenstockKurzweil NameCert obligations)**.** *For every accepted* $\mathsf{HenstockKurzweil}^{\uparrow}$ *carrier $K = (G, I, S, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HenstockKurzweil}^{\uparrow}}$ *surface consists exactly of carrier admission, GaugeIntegral exposure through G, RiemannIntegral comparison through I, RiemannSumGauge window exposure through S, gauge-window exactness through W, DyadicRatCore tolerance exposure through D, RegSeqRat readback through R, Real seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No obligation may be discharged by Lebesgue measure, open-cover compactness, countable choice, selected infinite sums, host integrand equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4180.1. The displayed rows are exactly $G, I, S, W, D, R, E, H, C, P, N$, so carrier admission exposes only gauge, integral-comparison, tagged-sum, window, dyadic, readback, seal, transport, replay, provenance, and naming data.

The integration side starts with G, I, S, W. The gauge-integral source row G and Riemann-integral comparison row I are read only through the finite tagged-sum gauge row S and its displayed window W, so the packet has one gauge-window route rather than a detached refinement principle.

Next read the numerical handoff. The dyadic ledger D supplies endpoint and tolerance data for the same window, R records the regular rational readback, and E is available only after those rows have been replayed.

Finally the structural rows H, C, P, N preserve the same route. Since measure data, open-cover compactness, selected infinite sums, countable choice, host integrand equality, and ambient completeness are absent from the carrier, the listed rows exhaust the local surface. □

Theorem 4180.3 (HenstockKurzweil gauge-window route)**.** *Every completion-facing or Real-facing read of an accepted* $\mathsf{HenstockKurzweil}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{GaugeIntegral}^{\uparrow} \longmapsto \mathsf{RiemannSumGauge}^{\uparrow} \longmapsto \mathsf{RiemannIntegral}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The gauge-window row W is read before the dyadic tolerance ledger and the real seal, and the route cannot bypass $G, I, S, W, D, R, E, H, C, P, N$.

Proof. Begin with an accepted carrier read. The carrier exposes G, S, W before any numerical endpoint or real seal can be inspected, so the request has already passed through a displayed gauge-window row.

Replay the continuation row C. The read moves from the gauge source G through the tagged-sum gauge row S and the Riemann comparison row I, then through the dyadic ledger D and regular rational readback R before it reaches the seal E.

The structural rows H, P, N do not add another integration object. They preserve the same finite route, and no excluded measure, compactness, choice, selected-sum, or completeness coordinate is available in the packet. □

Theorem 4180.4 (HenstockKurzweil gauge-window exactness)**.** *For every accepted* $\mathsf{HenstockKurzweil}^{\uparrow}$ *carrier $K = (G, I, S, W, D, R, E, H, C, P, N)$, the displayed gauge-window row W is projected after the gauge-integral source, the Riemann-integral comparison, and the tagged-sum gauge rows G, I, S,*

and before any $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *read through* D, R, E. *No dyadic endpoint, regular rational readback, or real seal can be inspected without first replaying the same* G, I, S, W *window.*

Proof. Project the carrier of Definition 4180.1. The row order exposes G, I, S, W as the complete gauge-window prefix, with W recording the tag, cell, and local radius data used by the tagged-sum row S.

Now inspect the numerical rows. The dyadic ledger D, regular rational readback R, and terminal real seal E are downstream of that prefix, so each numerical read has already passed through the displayed window. Since the carrier has no independent dyadic, rational, or real coordinate, it cannot bypass W. □

Theorem 4180.5 (HenstockKurzweil RiemannSumGauge exposure)**.** *For every accepted* $\mathsf{HenstockKurzweil}^{\uparrow}$ *carrier* $K = (G, I, S, W, D, R, E, H, C, P, N)$, *the row* S *is the only tagged-sum exposure route. Any completion-facing, dyadic-facing, regular-readback-facing, or real-facing use of tagged Riemann data must factor through* S *together with its displayed window* W *and the structural rows* H, C, P, N.

Proof. Read the carrier rows G, I, S, W. The only row tagged as $\mathsf{RiemannSumGauge}^{\uparrow}$ is S, and the only window attached to tagged-sum data is W.

The downstream rows D, R, E receive endpoint, tolerance, readback, and seal data from the same tagged-sum route. The structural rows H, C, P, N transport, replay, source, and name the carrier, but they do not introduce a second tagged-sum row. Hence every tagged Riemann use remains exposed through S. □

Theorem 4180.6 (HenstockKurzweil Real seal nonescape)**.** *For every accepted* $\mathsf{HenstockKurzweil}^{\uparrow}$ *carrier* $K = (G, I, S, W, D, R, E, H, C, P, N)$, *the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *cannot be reached without replaying* G, I, S, W, D, R. *In particular,* E *exposes no route through Lebesgue measure, open-cover compactness, selected infinite sums, countable choice, host integrand equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Replay the continuation row C through the carrier projection. The real-facing row appears as E, after the gauge-integral source G, Riemann comparison I, tagged-sum gauge row S, displayed window W, dyadic ledger D, and regular rational readback R.

The remaining rows H, P, N preserve that same route by transport, provenance, and local naming. They cannot supply a measure object, compactness theorem, selected sum, choice principle, host equality, or ambient completeness field, because none of those coordinates occur in the carrier. □

Falsifiable prediction: Every accepted $\mathsf{HenstockKurzweil}^{\uparrow}$ read factors through $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{RiemannSumGauge}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HenstockKurzweil}^{\uparrow}}$.

Constructive story: A $\mathsf{HenstockKurzweil}^{\uparrow}$ packet is generated from a GaugeIntegral row, RiemannIntegral comparison row, RiemannSumGauge tagged-window row, gauge-window ledger, DyadicRatCore endpoint and tolerance rows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HenstockKurzweil}^{\uparrow}}, \text{obligation})$

Scope closed: Definition 4180.1, Definition 4180.2, Definition 4180.3, Definition 4180.4, Definition 4180.5, and Definition 4180.6 close the finite gauge-window obligation surface over GaugeIntegralUp, RiemannIntegralUp, RiemannSumGaugeUp, DyadicRatCoreUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{HenstockKurzweil}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, Lebesgue measure, open-cover compactness, countable choice, selected infinite sums, host integrand equality, or ambient RealUp completeness.

Upgrade path: A formal route can encode checked carrier admission, RiemannIntegral comparison, DyadicRatCore tolerance exactness, RegSeqRat readback, and TasteGate field faithfulness for BEDC.Derived.HenstockKurzweilUp.

Chapter 4181

A Concrete Naming Certificate for HyperbolicVisualBoundary$^{\uparrow}$

The HyperbolicVisualBoundary$^{\uparrow}$ packet realizes the finite boundary-readback surface of chapter 9463. It sits after the metric-read surface of chapter 3474, the Busemann-boundary row of chapter 3732, the visual-metric packet of chapter 3866, the boundary-shadow packet of chapter 3813, and the boundary-fixed transport route of chapter 3500. The packet names only a finite visual boundary read over displayed disk, shadow, Busemann, visual-metric, transport, provenance, and local naming rows; it does not assert physical cosmology, a completed ideal-boundary quotient, global geometry, or a host compactification theorem.

Definition 4181.1 (Hyperbolic visual boundary carrier)**.** *A* HyperbolicVisualBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (D, S, B, M, T, P, H, C, N)$$

with the following displayed rows:

1. *D is the disk-readout row, exposing the finite* UnitDisk$^{\uparrow}$ *or Poincare-disk observation window from which the boundary read begins.*
2. *S is the boundary-shadow row, recording the* HyperbolicBoundaryShadow$^{\uparrow}$ *face visible from the disk readout.*
3. *B is the Busemann row, attaching the boundary read to* HyperbolicBusemannBoundary$^{\uparrow}$ *distance-difference data.*
4. *M is the visual-metric row, recording the* HyperbolicVisualMetric$^{\uparrow}$ *comparison used to distinguish visible boundary reads.*
5. *T is the transport row, recording the* PoincareBoundaryFixedTransport$^{\uparrow}$ *route that preserves the boundary read while disk data move.*
6. *P is the* Pkg *provenance over* HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicBusemannBoundary$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, PoincareBoundaryFixedTransport$^{\uparrow}$, UnitDisk$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
7. *H records componentwise* hsame *transport for disk-readout, boundary-shadow, Busemann, visual-metric, transport, provenance, replay, and local naming rows.*
8. *C records displayed* Cont *replay from a boundary-read request through D, S, B, M, T, P, H.*

9. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicVisualBoundary}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, S, B, M, T, P, H, C, N$. It has no coordinate for a completed boundary space, quotient ideal-end equality, physical observer trajectory, global hyperbolic geometry, or an unlogged cosmological claim.

Lean4 ✓ `BEDC.Derived.HyperbolicVisualBoundaryUp.HyperbolicVisualBoundaryTasteGate single carrier alignment`

Theorem 4181.2 (Hyperbolic visual boundary NameCert obligations)**.** *For every accepted* HyperbolicVisualBounda *carrier*

$$V = (D, S, B, M, T, P, H, C, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicVisualBoundary}^{\uparrow}}$ *surface consists exactly of disk-readout admission, boundary-shadow exposure, Busemann attachment, visual-metric comparison, boundary-fixed transport, provenance, componentwise transport, displayed continuation replay, and local naming through $D, S, B, M, T, P, H, C, N$.*

Proof. Project the carrier of Definition 4181.1. The rows $D, S, B, M, T, P, H, C, N$ are the whole public packet.

The read starts at D and S. These rows expose only a finite disk window and a displayed boundary-shadow face.

The Busemann and visual-metric rows B, M attach that face to finite boundary comparison data. The transport row T records boundary-fixed movement without adding a completed boundary object.

Finally P, H, C, N source, transport, replay, and name the same route. Since no other coordinate is present, completed boundary spaces, quotient ideal-end equality, physical observer trajectories, global hyperbolic geometry, and unlogged cosmological claims remain outside the certificate. □

Theorem 4181.3 (Hyperbolic visual boundary readback non-escape)**.** *Every accepted* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *read factors through*

$\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, Poincare

together with disk-readout, provenance, transport, replay, and local NameCert *rows before it exports a visual boundary token.*

Proof. Apply Definition 4181.2. The accepted packet stores boundary readback only in the displayed rows $D, S, B, M, T, P, H, C, N$.

The metric, Busemann, visual-metric, shadow, and fixed-transport siblings are named by those rows and by provenance. A consumer therefore receives a boundary token only after the finite route has exposed those dependencies.

No row in the carrier stores physical cosmology, completed ideal-boundary equality, global geometry, or a host compactification theorem. Hence an accepted read cannot bypass the displayed packet through any of those exits. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ read is refuted if a consumer obtains a visual boundary token without displaying hyperbolicmetric, hyperbolic-busemann-boundary, hyperbolic-visual-metric, hyperbolic-boundary-shadow, poincare-boundary-fixed-transport, disk-readout, provenance, transport, replay, and local NameCert rows.

Independence witness: hyperbolicmetric, hyperbolic-busemann-boundary, hyperbolic-visual-metric, hyperbolic-boundary-shadow, poincare-boundary-fixed-transport: the HyperbolicMetric packet records metric reads without boundary readback, the Busemann packet records distance-difference boundary data without a visual-boundary token, the visual-metric packet records comparison without owning the boundary row, the boundary-shadow packet records a shadow face without the Busemann visual comparison, and the boundary-fixed transport packet preserves a boundary route without naming the visual boundary carrier. None is bijective to $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicVisualBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ packet is generated from disk-readout rows, HyperbolicBoundaryShadow rows, HyperbolicBusemannBoundary rows, HyperbolicVisualMetric rows, PoincareBoundaryFixedTransport rows, provenance, componentwise hsame transport, displayed Cont replay, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicVisualBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4181.1, Definition 4181.2, and Definition 4181.3 seed the finite visual boundary readback route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicVisualBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close physical cosmology, completed ideal-boundary quotients, global hyperbolic geometry, host compactification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk readback, shadow exposure, Busemann attachment, visual-metric comparison, boundary-fixed transport, provenance, replay, transport, and local naming for BEDC.Derived.HyperbolicVisualBoundaryUp.

Chapter 4182

A Concrete Naming Certificate for $\mathsf{BishopCompleteReal}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopCompleteReal}^{\uparrow}$ packet records the textbook complete-real interface as a finite BEDC boundary rather than as an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$. It sits on the dyadic endpoint ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the separated completion surface of chapter 1612, and the completion reflection boundary of chapter 403. The packet exposes the L10 completion interface currently needed by Real and Completion consumers; it does not assert that $\mathsf{Real}^{\uparrow}$ is complete, select limits, quotient streams, or import countable choice.

Definition 4182.1 (Bishop complete real carrier)**.** *A* $\mathsf{BishopCompleteReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, W, R, E, S, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance ledger used to measure regular Cauchy requests.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite schedule row opened by the same tolerance request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to D and W.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the dyadic, schedule, and regular readback rows have been displayed.*
5. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *comparison row, recording that two completion-facing reads are compared through separated finite evidence.*
6. *F is the* $\mathsf{CompletionReflection}^{\uparrow}$ *handoff row, replaying the same regular-rational source surface into the completion-facing interface.*
7. *H stores componentwise* hsame *transport for $D, W, R, E, S, F, C, P, N$.*
8. *C stores displayed* Cont *replay from a completion-facing request through the same dyadic, schedule, regular, real-seal, separated, and reflection rows.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCompleteReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompleteReal}^{\uparrow}}$ *row.*

The carrier has no coordinate for host real equality, quotient stream equality, a selected limit, countable choice, open-cover compactness, or a theorem that $\mathsf{Real}^{\uparrow}$ *is complete.*

Lean4 ✓ `BEDC.Derived.BishopCompleteRealUp.TasteGate.BishopCompleteRealTasteGate single carrier alignment`

Theorem 4182.2 (Bishop complete real NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompleteReal}^{\uparrow}$ *carrier*

$$B = (D, W, R, E, S, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompleteReal}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic endpoint ledger, finite schedule, regular rational readback, terminal Real seal, separated completion comparison, completion reflection handoff, componentwise transport, continuation replay, provenance, and local naming rows, together with the obligation that every completion-facing read passes through* $D, W, R, E, S, F, H, C, P, N$ *in that order.*

No obligation in the packet is discharged by host real equality, quotient streams, selected representatives, countable choice, open-cover compactness, or a completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Carrier admission is projection from Definition 4233.1. The tuple lists the dyadic, schedule, regular readback, Real seal, separated comparison, completion reflection, transport, replay, provenance, and naming rows.

The completion-facing order is fixed by the visible rows. A request first reads a dyadic endpoint and tolerance ledger in D, then opens the finite schedule row W, and then passes through the regular rational readback row R before the terminal Real seal E is available.

The separated and reflection rows then consume that same source surface. The comparison row S records separated evidence, while F replays the regular-rational source into the completion-facing boundary.

Finally H, C, P, N transport, replay, source, and name only these displayed rows. Since the carrier contains no coordinate for the excluded host, quotient, choice, compactness, or completeness data, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.BishopCompleteRealUp.BishopCompleteRealNamecertObligations`

Theorem 4182.3 (Bishop complete real L10 handoff)**.** *Every Real and Completion consumer of an accepted* $\mathsf{BishopCompleteReal}^{\uparrow}$ *packet factors through the finite L10 route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{SeparatedCompletion}^{\uparrow} \longrightarrow \mathsf{CompletionReflection}^{\uparrow}.$$

The handoff exports a displayed regular-rational completion interface with separated comparison and reflection rows. It does not export completed $\mathsf{Real}^{\uparrow}$ *equality, quotient Cauchy classes, selected host limits, countable-choice coordinates, open-cover compactness, or an ambient completeness theorem.*

Proof. Begin with the NameCert obligations of Definition 4233.2. They force every accepted read to pass through the dyadic ledger, finite schedule, regular rational readback, and terminal Real seal before any completion-facing row is consumed.

Next read the separated comparison row. The row S compares completion-facing observations only through displayed separated evidence, so it cannot introduce quotient classes or host equality.

The completion reflection row F then replays the same source surface into the completion-facing interface. The structural rows H, C, P, N preserve that route componentwise and add only transport, replay, provenance, and local naming.

Thus the consumer receives exactly the displayed L10 handoff from dyadic data to schedules, regular rational readback, Real seal, separated comparison, and completion reflection. None of the excluded completeness, choice, quotient, compactness, or selected-limit data has an entry point in the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompleteReal}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompleteReal}^{\uparrow}$ packet is generated from a dyadic endpoint ledger, finite schedule, regular rational readback, terminal Real seal, separated completion comparison, completion reflection handoff, componentwise transport, displayed continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompleteReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4233.1, Definition 4233.2, and Definition 4233.3 seed the finite Bishop complete-real interface for the current L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompleteReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim $\mathsf{Real}^{\uparrow}$ completeness, quotient real equality, selected host limits, countable choice, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated comparison, completion reflection handoff, and ledger non-escape for the same packet.

Chapter 4183

A Concrete Naming Certificate for $\mathsf{RatCauchyGapWitness}^{\uparrow}$

Following Bishop and Bridges on constructive completion of the rationals, the $\mathsf{RatCauchyGapWitness}^{\uparrow}$ packet records the finite obstruction visible at the $\mathsf{Rat}^{\uparrow}$ boundary before any real-name or completion-facing consumer reads a limit. It sits after the rational carrier of chapter 37, the dyadic tolerance ledger of chapter 291, the finite window surface of chapter 126, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet names a displayed gap witness for rational Cauchy bracketing; it does not export a host irrational, quotient completion class, choice-selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 4183.1 (Rat Cauchy gap witness carrier)**.** *A* $\mathsf{RatCauchyGapWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (L, U, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the rational lower-bracket row, exposing a finite* $\mathsf{Rat}^{\uparrow}$ *source, monotone lower estimates, and the rational comparison probes consumed by the witness.*
2. *U is the rational upper-bracket row, exposing the matching* $\mathsf{Rat}^{\uparrow}$ *source, monotone upper estimates, and the rational separation probes kept visible to the consumer.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ladder, recording the dyadic widths used to compare lower and upper brackets at each requested precision.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule, listing the finite observation windows through which the bracket rows are inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, recording the regular-rational readback discipline available before the terminal seal is cited.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary, present only as a downstream boundary saying where a real-name consumer may later read a sealed object.*
7. *H records componentwise* hsame *transport for the bracket, tolerance, window, handoff, seal, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from rational brackets through dyadic tolerances, finite windows, regular-rational readback, and the real seal boundary.*

9. *P is the* Pkg *provenance over* $\mathsf{RatCauchyGapWitness}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RatCauchyGapWitness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $L, U, D, W, R, E, H, C, P, N$. It has no coordinate for a host irrational number, quotient-completion representative, selected limit, countable-choice principle, or ambient completeness assertion.

Lean4 ✓ `BEDC.Derived.RatCauchyGapWitnessUp.RatCauchyGapWitnessTasteGate single carrier alignment`

Theorem 4183.2 (Rat Cauchy gap witness NameCert obligations)**.** *For every accepted* $\mathsf{RatCauchyGapWitness}^{\uparrow}$ *carrier $G = (L, U, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RatCauchyGapWitness}^{\uparrow}}$ *surface consists exactly of five mathematical obligation rows: rational lower and upper brackets through L, U; dyadic tolerance control through D; finite stream-window inspection through W; regular-rational handoff through R; and the terminal real-seal boundary through E. The structural rows H, C, P, N transport, replay, source, and name that same packet, and no host irrational, quotient completion, or choice-selected limit is exported.*

Proof. Project the accepted carrier of Definition 4183.1. The rows L and U are the only rational bracket coordinates, and both are read through the $\mathsf{Rat}^{\uparrow}$ source rather than through a completed real object.

Next inspect the precision route. The dyadic row D supplies the tolerance ladder, the stream row W supplies the finite observation windows, and the regular-rational row R supplies the handoff available to completion-facing consumers.

The seal row E is only a boundary row. It records where a later $\mathsf{Real}^{\uparrow}$ consumer may read a terminal seal, while the present certificate still exposes the rational brackets, dyadic tolerances, stream windows, and regular-rational handoff.

Finally apply the structural rows. Componentwise transport through H, replay through C, provenance through P, and local naming through N preserve the displayed packet. Since the carrier has no coordinate for a host irrational, quotient-completion representative, selected limit, or choice principle, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.RatCauchyGapWitnessUp.RatCauchyGapWitnessNameCert obligations`

Falsifiable prediction: Every accepted $\mathsf{RatCauchyGapWitness}^{\uparrow}$ consumer must expose rational lower and upper brackets, a dyadic tolerance ladder, finite stream windows, a regular-rational handoff, a real-seal boundary, transport, Cont replay, Pkg provenance, and local NameCert rows before it can cite the witness.

Independence witness: rat, dyadicratcore, streamname, regseqrat, real: none is bijective with $\mathsf{RatCauchyGapWitness}^{\uparrow}$, because this carrier alone binds rational lower and upper brackets to the dyadic tolerance ladder, finite window schedule, regular-rational handoff, terminal seal boundary, transport, replay, provenance, and local NameCert rows without exporting a completed real.

Closure status for $\mathsf{NameCert}_{\mathsf{RatCauchyGapWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{RatCauchyGapWitness}^{\uparrow}$ packet is generated from rational lower and upper bracket rows, a DyadicRatCore tolerance ladder, a StreamName window schedule, a RegSeqRat handoff, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RatCauchyGapWitness}^{\uparrow}}$, seed)

Scope closed: Definition 4183.1 and Definition 4183.2 seed the finite rational Cauchy gap witness over $L, U, D, W, R, E, H, C, P, N$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RatCauchyGapWitness}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.RatCauchyGapWitnessUp.RatCauchyGapWitnessNameCert\_obligations`

Bridge status: none

Not claimed: This chapter does not close host irrational existence, quotient completion equality, selected limits, countable choice, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked rational bracket, dyadic tolerance, finite window, regular-rational handoff, real-seal boundary, transport, replay, provenance, and local naming rows for BEDC.Derived.RatCauchyGapWitnessUp.

Chapter 4184

A Concrete Naming Certificate for $\mathsf{RieszRepresentationFiniteLattice}^{\uparrow}$

Following Riesz and Markov-Kakutani on positive linear functionals over finite lattice data, the $\mathsf{RieszRepresentationFiniteLattice}^{\uparrow}$ packet records the BEDC-safe finite representation surface for lattice-positive functionals. It consumes the order rows of chapter 53, the lattice rows of chapter 55, the one-sided real boundary of chapter 38, and the lower and upper real approximation rows of chapter 1446 and chapter 1447. The packet is a finite naming certificate for positive functional handoff; it does not assert sigma-additivity, measure completion, quotient dual equality, choice-selected representing measures, or ambient Banach-space representation.

Definition 4184.1 (Riesz representation finite lattice carrier)**.** *A* $\mathsf{RieszRepresentationFiniteLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (L, O, F, A, B, P, H, C, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{Lattice}^{\uparrow}$ *row, exposing the finite join, meet, top, bottom, and lattice comparison data used by the representation read.*
2. *O is the* $\mathsf{Poset}^{\uparrow}$ *row supporting the order classifier shared by the lattice and positivity checks.*
3. *F is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$*-style positive functional row, recording additivity on displayed compatible lattice pieces and positivity on the order-positive cone.*
4. *A is the one-sided* $\mathsf{Real}^{\uparrow}$ *boundary row through which the functional values are read.*
5. *B is the* $\mathsf{LowerReal}^{\uparrow}$ *and* $\mathsf{UpperReal}^{\uparrow}$ *bracketing row, storing finite lower and upper cuts that witness the one-sided value interval.*
6. *P is the* Pkg *provenance over* $\mathsf{RieszRepresentationFiniteLattice}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
7. *H records componentwise* hsame *transport for lattice, order, positive-functional, one-sided real, bracketing, provenance, replay, and naming rows.*
8. *C records displayed* Cont *replay from a positive-functional request through L, O, F, A, B, P, H.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RieszRepresentationFiniteLattice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, O, F, A, B, P, H, C, N$. It has no coordinate for completed measure spaces, quotient dual equality, countable joins, choice-selected representing measures, sigma-additivity, or host functional-analysis completion.

Lean4 ✓ `BEDC.Derived.RieszRepresentationFiniteLatticeUp.RieszRepresentationFiniteLatticeTasteGate single carrier alignment`

Theorem 4184.2 (Riesz representation finite lattice NameCert obligations)**.** *For every accepted* $\mathsf{RieszRepresentationFiniteLattice}^{\uparrow}$ *carrier*

$$R = (L, O, F, A, B, P, H, C, N),$$

the local $\mathsf{NameCert}_{\mathsf{RieszRepresentationFiniteLattice}^{\uparrow}}$ *surface consists exactly of finite lattice admission, shared poset classifier transport, positive-functional row exposure, one-sided real value readback, lower and upper real bracketing, provenance, componentwise transport, displayed continuation replay, and local naming through* $L, O, F, A, B, P, H, C, N$.

Proof. Project the carrier of Definition 4184.1. The rows $L, O, F, A, B, P, H, C, N$ are the whole accepted packet.

The representation read starts with the lattice and order rows. The positive-functional row F is checked only against the displayed lattice operations and the common order classifier supplied by O.

The value side is bounded by A and B. The one-sided $\mathsf{Real}^{\uparrow}$ row exposes the value seal, while the $\mathsf{LowerReal}^{\uparrow}$ and $\mathsf{UpperReal}^{\uparrow}$ row records the finite bracketing data used by the consumer.

Finally P, H, C, N source, transport, replay, and name the same route. Since the carrier contains no additional coordinate, measure completion, quotient dual equality, countable joins, selected representing measures, and host completion remain outside the local certificate. □

Theorem 4184.3 (Riesz representation finite lattice positive-functional handoff)**.** *Every positive-functional consumer of an accepted* $\mathsf{RieszRepresentationFiniteLattice}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Lattice}^{\uparrow},\ \mathsf{Poset}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{LowerReal}^{\uparrow},\ \mathsf{UpperReal}^{\uparrow},\ \mathsf{FunctionalAnalysis}^{\uparrow}$$

together with BHist, hsame, Cont, Pkg, *and local* NameCert *rows before it exports a representation token.*

Proof. Apply Definition 4184.2. The theorem exposes the lattice, order, positive-functional, one-sided real, bracketing, transport, replay, provenance, and naming rows as the whole obligation surface.

A downstream consumer can therefore read a representation token only after L, O, F, A, B have been displayed in the same finite packet. The structural rows P, H, C, N preserve that route and do not add a second source of representation data.

No row supplies a completed measure, quotient dual equality, countable lattice operation, selected representing measure, sigma-additivity principle, or host Banach-space representation. The handoff is exactly the finite positive-functional route stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{RieszRepresentationFiniteLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{RieszRepresentationFiniteLattice}^{\uparrow}$ packet is generated from finite lattice rows, poset classifier rows, positive-functional rows, one-sided Real rows, lower and upper real bracketing rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RieszRepresentationFiniteLattice}\uparrow}$, seed)

Scope closed: Definition 4184.1, Definition 4184.2, and Definition 4184.3 seed the finite positive-functional representation route.

Formal verification: FormalStatus(NameCert$_{\text{RieszRepresentationFiniteLattice}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim sigma-additive measure representation, completed measure spaces, quotient dual equality, countable lattice joins, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite lattice admission, order-positive functional exposure, one-sided value bracketing, replay, transport, provenance, and local naming for BEDC.Derived.RieszRepresentationFiniteLatticeUp.

Chapter 4185

A Concrete Naming Certificate for $\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}$

The $\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}$ packet realizes the focused-ledger, shadow-metric, boundary-shadow, and Cont-growth route of chapter 9463 as finite NameCert data. It sits after the metric-read surface of chapter 3474, the observer-shadow metric row of chapter 4154, the boundary-shadow packet of chapter 3813, the Poincare-disk dynamics route of chapter 4117, and the finite dynamics rows of chapter 195. The packet names only an observer-expansion read over displayed disk, shadow, boundary, growth, provenance, and local naming rows; it does not assert physical cosmology, global expansion, completed boundary geometry, or an unlogged observer.

Definition 4185.1 (Hyperbolic phase observer-expansion carrier)**.** *A* $\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (F, D, S, B, G, P, H, C, N)$$

with the following displayed rows:

1. *F is the focused-ledger row, recording the finite observer-facing history slice to be read.*
2. *D is the disk-readout row, exposing the Poincare disk window and its displayed phase coordinates.*
3. *S is the shadow-metric row supplied by* $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ *over the same observer slice.*
4. *B is the boundary-shadow row supplied by* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *for the visible boundary face.*
5. *G is the Cont-growth row, recording the finite* $\mathsf{DynSystem}^{\uparrow}$ *and* $\mathsf{PoincareDiskDynamics}^{\uparrow}$ *replay by which the observer read expands through displayed disk stages.*
6. *P is the* Pkg *provenance over* $\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicObserverShadow}$ $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{PoincareDiskDynamics}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
7. *H records componentwise* hsame *transport for focused-ledger, disk-readout, shadow-metric, boundary-shadow, growth, provenance, replay, and naming rows.*
8. *C records displayed* Cont *replay from an observer-expansion request through F, D, S, B, G, P, H.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, D, S, B, G, P, H, C, N$. It has no coordinate for physical expansion, completed boundary quotient, global hyperbolic geometry, host observer identity, or unlogged cosmological data.

Lean4 ✓ `BEDC.Derived.HyperbolicPhaseObserverExpansionUp.HyperbolicPhaseObserverExpansionTasteGate`
`single carrier alignment`

Theorem 4185.2 (Hyperbolic phase observer-expansion NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}$ *carrier*

$$E = (F, D, S, B, G, P, H, C, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}}$ *surface consists exactly of focused-ledger admission, disk-readout exposure, shadow-metric comparison, boundary-shadow display, Cont-growth replay, provenance, componentwise transport, displayed continuation replay, and local naming through* $F, D, S, B, G, P, H, C, N$.

Proof. Project the carrier of Definition 4185.1. The rows $F, D, S, B, G, P, H, C, N$ are the complete public packet.

The observer-facing read begins with F and D. These rows expose a finite ledger slice and a displayed disk window before any expansion token is available.

The shadow rows S and B then attach the observer slice to finite metric and boundary-shadow data. The growth row G records the Poincare-disk and dynamics replay that the consumer may inspect.

Finally P, H, C, N source, transport, replay, and name the same route. Since no other coordinate is present, physical expansion, completed boundary geometry, global hyperbolic structure, host observer identity, and unlogged cosmological claims remain outside the certificate. □

Theorem 4185.3 (Hyperbolic phase observer-expansion nonescape)**.** *Every accepted* HyperbolicPhaseObserverExpa *read factors through hyperbolic-metric, hyperbolic-observer-shadow-metric, hyperbolic-boundary-shadow, poincare-disk-dynamics, and dynsystem rows together with focused-ledger, disk-readout, Cont-growth, provenance, transport, replay, and local* NameCert *data before it exports an observer-expansion token.*

Proof. Apply Definition 4185.2. The accepted packet stores observer expansion only in the displayed rows $F, D, S, B, G, P, H, C, N$.

The sibling metric, shadow, boundary, disk-dynamics, and dynamics surfaces are named by S, B, G and by provenance. A consumer therefore receives an observer-expansion token only after the finite route has displayed those dependencies.

No row in the carrier stores physical cosmology, completed boundary equality, global geometry, host observer identity, or an unlogged expansion source. Hence an accepted read cannot bypass the displayed packet through any of those exits. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}$ read is refuted if a consumer obtains an observer-expansion token without displaying focused-ledger, disk-readout, shadow-metric, boundary-shadow, Cont-growth, provenance, and local NameCert rows.

Independence witness: hyperbolic-metric, hyperbolic-observer-shadow-metric, hyperbolic-boundary-shadow, poincare-disk-dynamics, dynsystem: the HyperbolicMetric packet records metric reads without observer expansion, the observer-shadow metric packet records shadow comparison without boundary growth, the boundary-shadow packet records a visible boundary face without disk

dynamics, the Poincare-disk dynamics packet records disk replay without owning the observer ledger, and the DynSystem packet records finite dynamics without naming the hyperbolic phase observer-expansion carrier. None is bijective to $\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}$ packet is generated from focused-ledger rows, disk-readout rows, hyperbolic observer-shadow metric rows, boundary-shadow rows, Poincare-disk dynamics rows, DynSystem growth replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4185.1, Definition 4185.2, and Definition 4185.3 seed the finite observer-expansion readback route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseObserverExpansion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close physical cosmology, completed boundary quotients, global hyperbolic geometry, host observer identity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked focused-ledger admission, disk-readout exposure, shadow-metric and boundary-shadow exactness, Cont-growth replay, provenance, transport, and local naming for BEDC.Derived.HyperbolicPhaseObserverExp

Chapter 4186

A Concrete Naming Certificate for $\mathsf{NowhereDense}^{\uparrow}$

Following Baire and Oxtoby, a nowhere-dense component is treated here as the finite certificate surface that lets Baire-category arguments read a closed-frontier refusal without importing arbitrary subset quantification. The $\mathsf{NowhereDense}^{\uparrow}$ packet sits between the topology carrier of chapter 88, the dense-open route of chapter 1542, and the finite cover ledger consumed by chapter 2267.

Definition 4186.1 (Nowhere-dense carrier)**.** *A* $\mathsf{NowhereDense}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, B, F, E, D, M, H, C, P, N)$$

with the following displayed rows:

1. T *is the* $\mathsf{Topology}^{\uparrow}$ *source row, including the basic-neighbourhood names inspected by the packet.*
2. B *is the finite basic-neighbourhood request ledger over* T*.*
3. F *is the closure-frontier row naming how inspected neighbourhoods meet the displayed closure boundary.*
4. E *is the empty-interior refusal row; for every requested basic neighbourhood it displays a sub-neighbourhood escaping the named closed fragment.*
5. D *is the dense-open complement handoff read by* $\mathsf{BaireCategory}^{\uparrow}$ *consumers.*
6. M *is the finite cover-row interface consumed by* $\mathsf{MeagreSet}^{\uparrow}$*.*
7. H *stores the componentwise* hsame *transports for* T, B, F, E, D, M*.*
8. C *stores displayed* Cont *replay of the neighbourhood requests, closure-frontier inspections, empty-interior refusals, and dense-open handoff.*
9. P *is the local* Pkg *provenance row tying the packet to the named topology source.*
10. N *is the local* $\mathsf{NameCert}$ *row for the displayed nowhere-dense component.*

The carrier exports no arbitrary subset classifier, host closure operator, selected generic point, countable-choice selector, or ambient Baire theorem.

Lean4 ✓ `BEDC.Derived.NowhereDenseUp.NowhereDenseTasteGate single carrier alignment`

Theorem 4186.2 (NowhereDense NameCert obligations)**.** *Every accepted* NowhereDense$^{\uparrow}$ *carrier* $Q = (T, B, F, E, D, M, H, C, P, N)$ *supplies exactly the topology source, basic-neighbourhood ledger, closure-frontier row, empty-interior refusal row, dense-open complement handoff, meagre-set cover interface, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row listed in Definition 4186.1. A* BaireCategory$^{\uparrow}$ *or* MeagreSet$^{\uparrow}$ *consumer can read the component only through those rows.*

Proof. Open the carrier definition. Each coordinate of Q is a finite row, and the topology source T is the only source from which basic neighbourhoods may be requested.

The closure-frontier and empty-interior rows are then read as paired inspections: F names the frontier contact and E supplies the escaping sub-neighbourhood. The dense-open complement row D and meagre cover row M are downstream of those inspections.

Finally H, C, P, N preserve, replay, source, and name the same route. Since no arbitrary subset classifier, host closure operator, generic point selector, or countable-choice coordinate occurs in Q, downstream Baire-category and meagre-set consumers receive exactly the displayed finite packet. □

Theorem 4186.3 (NowhereDense closure-interior refusal)**.** *Let* $Q = (T, B, F, E, D, M, H, C, P, N)$ *be an accepted* NowhereDense$^{\uparrow}$ *carrier. For every basic-neighbourhood request recorded by* B*, the packet routes the request through the closure-frontier row* F *and then through the empty-interior refusal row* E*, producing the dense-open complement handoff* D *used by* BaireCategory$^{\uparrow}$ *and the cover-row interface* M *used by* MeagreSet$^{\uparrow}$*.*

Proof. Begin with a displayed request in B. The row is indexed over the same topology source T, so it has access only to the named basic-neighbourhood surface.

Read F next. It identifies the closure-frontier inspection attached to the request. Then read E, which displays a sub-neighbourhood escaping the named closed fragment and therefore records empty interior on the inspected finite surface.

The complement handoff D and cover interface M are built from that same refusal. Transport, replay, provenance, and local naming do not alter the request; they keep the Baire-category and meagre-set consumers on the displayed route. □

Closure status for NameCert$_{\text{NowhereDense}^{\uparrow}}$**.**

Constructive story: A NowhereDense$^{\uparrow}$ packet is generated from a Topology$^{\uparrow}$ source, finite basic-neighbourhood requests, a closure-frontier row, an empty-interior refusal row, a dense-open complement handoff, a MeagreSet$^{\uparrow}$ cover interface, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\text{NowhereDense}^{\uparrow}}$, seed)

Scope closed: Definition 4186.1, Definition 4186.2, and Definition 4186.3 seed the finite closure-frontier and empty-interior refusal route consumed by Baire-category and meagre-set packets.

Formal verification: FormalStatus(NameCert$_{\text{NowhereDense}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.NowhereDenseUp.NowhereDenseTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim arbitrary subset closure, host interior operators, selected generic points, countable choice, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove the finite closure-frontier, empty-interior refusal, dense-open complement, and cover-interface obligations.

Chapter 4187

A Concrete Naming Certificate for $\mathsf{SeparableReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SeparableReal}^{\uparrow}$ packet records separability as a finite NameCert surface over dyadic schedules rather than as host enumeration or countable choice. It sits over the real-name seal of chapter 38, the rational carrier of chapter 37, the dyadic tolerance rows of chapter 291, the finite stream windows of chapter 126, the regular rational readback route of chapter 301, and the existing real separability route of chapter 1809. The packet names the constructive dense schedule visible to Real and Completion consumers; it is not a quotient-real equality principle, a selected host list of all reals, a trichotomy oracle, or an assertion of ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4187.1 (SeparableReal carrier)**.** *A* $\mathsf{SeparableReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, S_0, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dense-schedule row, recording the finite dyadic centers and tolerance budgets inspected by a separability request.*
2. *S_0 is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, naming the observation windows through which the dense schedule is read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing regular rational approximants attached to the same windows and dyadic budgets.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording rational comparison data only at the displayed dyadic precision.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the schedule, window, readback, and tolerance rows have been displayed.*
6. *H records componentwise* hsame *transport for the dense schedule, finite windows, readback, tolerance, seal, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from a separability query through D, S_0, R, Q, E.*
8. *P is the* Pkg *provenance over* $\mathsf{SeparableReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{SeparableReal}^\uparrow}$ *row.*
The classifier compares accepted packets only through $D, S_0, R, Q, E, H, C, P, N$. It has no coordinate for host enumeration of $\mathsf{Real}^\uparrow$*, countable choice, quotient real equality, trichotomy of real order, hidden completion data, or ambient* $\mathsf{Real}^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.SeparableRealUp.SeparableRealTasteGate single carrier alignment`

Theorem 4187.2 (SeparableReal dyadic density NameCert)**.** *For every accepted* $\mathsf{SeparableReal}^\uparrow$ *carrier*

$$S = (D, S_0, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SeparableReal}^\uparrow}$ *surface exposes density only by the finite dyadic schedule D, the finite* $\mathsf{StreamName}^\uparrow$ *windows S_0, the* $\mathsf{RegSeqRat}^\uparrow$ *readback row R, the rational and dyadic tolerance row Q, and the terminal* $\mathsf{Real}^\uparrow$ *seal E. The remaining rows H, C, P, N provide componentwise transport, displayed replay, package provenance, and local naming for that same route.*

Consequently an accepted packet supplies a separability witness for Real and Completion consumers without host enumeration, countable choice, quotient real equality, real-order trichotomy, hidden completion data, or a completeness theorem for $\mathsf{Real}^\uparrow$*.*

Proof. Project the carrier of Definition 4187.1. The tuple lists exactly the dense dyadic schedule, finite observation windows, regular rational readback, rational tolerance data, terminal Real seal, transport, replay, provenance, and local naming rows.

The density route is fixed before any real-name consumer reads it. A separability query first opens the dyadic schedule row D and the finite window row S_0, then reads the regular rational approximants in R against the tolerance row Q.

The terminal Real seal E is downstream of those displayed rows, so a consumer never receives an unsealed host real or a selected quotient representative. The structural rows H, C, P, N transport, replay, source, and name only the same displayed data.

Since the carrier contains no coordinate for host enumeration, countable choice, quotient equality, trichotomy, hidden completion data, or ambient completeness, the listed rows exhaust the local NameCert surface. The accepted packet therefore exposes density only through the finite dyadic schedule and the $\mathsf{Real}^\uparrow$ seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparableReal}^\uparrow}$.

Constructive story: A $\mathsf{SeparableReal}^\uparrow$ packet is generated from a dyadic dense schedule, finite StreamName windows, RegSeqRat readback, Rat and DyadicRatCore tolerance rows, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SeparableReal}^\uparrow}$, seed)

Scope closed: Definition 4187.1 and Definition 4187.2 seed the finite dyadic density surface for Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SeparableReal}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host enumeration, countable choice, quotient real equality, real-order trichotomy, hidden completion data, ambient $\mathsf{Real}^\uparrow$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic density schedule exposure, StreamName window replay, RegSeqRat readback, Rat and DyadicRatCore tolerance exactness, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.SeparableRealUp.

Chapter 4188

A Concrete Naming Certificate for $\mathsf{BanachFixedPointModulus}^{\uparrow}$

Following Banach and Bishop–Bridges constructive analysis, the $\mathsf{BanachFixedPointModulus}^{\uparrow}$ packet records the explicit contraction-rate modulus consumed before the endpoint seal of chapter 396. It sits after the residual-to-error route of chapter 2233 and before any $\mathsf{BanachFixedPoint}^{\uparrow}$ consumer reads a $\mathsf{Real}^{\uparrow}$ endpoint boundary. The packet names only the finite contraction graph, the rational Lipschitz ledger below one, the Picard ledger, the Cauchy threshold row, the regular-rational handoff, the complete-metric service row, and the endpoint-facing seal; it does not select a fixed point, assert host equality, or import ambient completeness outside the displayed carrier rows.

Definition 4188.1 (Banach fixed-point modulus carrier)**.** *A* $\mathsf{BanachFixedPointModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, T, L, I, M, R, C, E, H, Q, P, N)$$

with the following visible coordinates:

1. *B is the source* $\mathsf{BanachFixedPoint}^{\uparrow}$ *row whose endpoint construction is waiting for an explicit modulus route.*
2. *T is the contraction graph row, displaying the finite map-application history used by the Picard iteration.*
3. *L is the rational Lipschitz ledger below one, including the displayed positivity and unit-bound rows read by the contraction estimate.*
4. *I is the Picard iteration ledger, recording the finite adjacent iterate rows and the replay order for $x_{k+1} = T(x_k)$.*
5. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row produced from L and I for each requested rational tolerance.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that exposes the regular rational name after the modulus threshold has been displayed.*
7. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row consumed by the completion-facing handoff.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, R, C have been read.*
9. *H stores componentwise* hsame *transports for the fixed-point, graph, Lipschitz, Picard, modulus, readback, complete-metric, seal, provenance, and local naming rows.*

10. *Q stores displayed* Cont *replay from contraction application to Picard iteration, from the Lipschitz ledger and Picard ledger to the modulus threshold, and from the modulus threshold to the regular-rational and endpoint-facing rows.*
11. *P is the* Pkg *provenance over* BanachFixedPointModulus$^{\uparrow}$, BanachFixedPoint$^{\uparrow}$, PicardErrorEstimate$^{\uparrow}$, CauchyModulus$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{BanachFixedPointModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, T, L, I, M, R, C, E, H, Q, P, N$. It has no coordinate for a choice-selected limit, a host fixed-point equality proof, quotient completion equality, global nonlinear analysis, or completeness beyond the displayed CompleteMetric$^{\uparrow}$ *service row.*

Lean4 ✓ `BEDC.Derived.BanachFixedPointModulusUp.BanachFixedPointModulusTasteGate single carrier alignment`

Theorem 4188.2 (Banach fixed-point modulus NameCert obligations)**.** *For every accepted* BanachFixedPointModu *carrier $K = (B, T, L, I, M, R, C, E, H, Q, P, N)$, the local* NameCert$_{\text{BanachFixedPointModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, contraction-graph visibility through T, rational Lipschitz visibility below one through L, finite Picard iteration access through I, Cauchy-threshold construction through M, regular-rational readback through R, complete-metric service access through C, endpoint seal access through E, componentwise* hsame *transport through H, displayed* Cont *replay through Q, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4188.1. The accepted packet exposes exactly the fixed-point row, contraction graph, Lipschitz ledger, Picard ledger, modulus row, regular-rational readback, complete-metric service, endpoint seal, transport, replay, provenance, and local naming rows.

The contraction-rate information is exhausted by T, L, I. The graph row supplies the finite application history, the Lipschitz ledger supplies the displayed bound below one, and the Picard ledger supplies the adjacent iterate rows used by the threshold calculation.

The handoff information is exhausted by M, R, C, E. The modulus threshold row is formed before any regular-rational readback, the complete-metric service is read only at the handoff boundary, and the endpoint seal is exposed only after those rows have been displayed. The structural rows H, Q, P, N transport, replay, source, and name this same route, so no further NameCert obligation is available. □

Theorem 4188.3 (Banach fixed-point modulus Picard handoff)**.** *Every* BanachFixedPoint$^{\uparrow}$ *endpoint-sealing route that consumes a* BanachFixedPointModulus$^{\uparrow}$ *carrier must first factor through*

$$T, L, I \longmapsto M \longmapsto R, C \longmapsto E.$$

The Picard and contraction-rate rows therefore supply the explicit CauchyModulus$^{\uparrow}$ *threshold before the* RegSeqRat$^{\uparrow}$ *readback, the* CompleteMetric$^{\uparrow}$ *service row, and the* Real$^{\uparrow}$ *seal are available to the fixed-point endpoint boundary. The Cauchy-threshold row is read through the* Cauchy$^{\uparrow}$ *naming surface of chapter 3413 before it is specialized to* CauchyModulus$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CompleteMetric$^{\uparrow}$, *and* Real$^{\uparrow}$.

Proof. Start with a fixed-point endpoint request from the source row B. The only contraction-rate rows in the carrier are the graph row T, the Lipschitz ledger L, and the Picard ledger I, so the request must read those rows before it can form a threshold.

The threshold is the displayed CauchyModulus$^{\uparrow}$ coordinate M. The existing BanachFixedPoint$^{\uparrow}$ route of chapter 396 consumes such a threshold before endpoint sealing, while the PicardErrorEstimate$^{\uparrow}$ route of chapter 2233 supplies the residual-and-ratio pattern that makes the threshold finite.

After M is displayed, the handoff can read R and C, and only then can it expose the endpoint-facing row E. The transport, replay, provenance, and local naming rows preserve this order, so the packet exports no selected fixed point, host equality, or ambient completeness theorem. □

Theorem 4188.4 (Banach fixed-point modulus endpoint seal determinacy)**.** *Let $K = (B, T, L, I, M, R, C, E, H, Q,$ be an accepted* $\mathsf{BanachFixedPointModulus}^{\uparrow}$ *carrier. Suppose two endpoint-facing reads use the same displayed route*

$$T, L, I \longmapsto M \longmapsto R, C \longmapsto E$$

and their Picard, Lipschitz, modulus, regular-rational, complete-metric, and endpoint rows are compatible under the componentwise hsame *transports carried by H. Then the two reads expose the same terminal* $\mathsf{Real}^{\uparrow}$ *seal classifier at E. The endpoint seal is determined by the shared* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{CompleteMetric}^{\uparrow}$ *service rows before any fixed-point endpoint consumer can inspect it.*

Proof. Project the carrier of Definition 4188.1. Both endpoint-facing reads have the same contraction graph, Lipschitz ledger, Picard ledger, modulus threshold, regular-rational readback, complete-metric service row, and terminal seal coordinate.

Apply Definition 4188.3. It forces every endpoint read through T, L, I before M, and through M before the R, C, E handoff, so neither read can introduce an independent endpoint route.

The shared $\mathsf{RegSeqRat}^{\uparrow}$ row and $\mathsf{CompleteMetric}^{\uparrow}$ service row are then read before the terminal $\mathsf{Real}^{\uparrow}$ seal. Componentwise transport through H and replay through Q identify the two reads along those same rows.

Thus the terminal classifier at E is fixed by the displayed route. No selected limit, quotient completion equality, host fixed-point equality, or ambient completeness principle is used to compare the endpoint seals. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachFixedPointModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BanachFixedPointModulus}^{\uparrow}$ packet is generated from a BanachFixedPoint row, a contraction graph, a rational Lipschitz ledger below one, a Picard iteration ledger, a CauchyModulus threshold, a RegSeqRat readback, a CompleteMetric service row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachFixedPointModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4188.1, Definition 4188.2, and Definition 4188.3 seed the finite contraction-rate modulus route consumed before Banach fixed-point endpoint sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachFixedPointModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, host fixed-point equality, quotient completion equality, ambient completeness, Lean verification, bridge checking, or global nonlinear analysis.

Upgrade path: Obligation closure requires checked carrier admission, contraction-graph visibility, Lipschitz-below-one visibility, Picard iteration access, Cauchy-threshold construction, regular-rational readback, complete-metric service access, endpoint seal access, transport, replay, provenance, and local naming for BEDC.Derived.BanachFixedPointModulusUp.

Chapter 4189

A Concrete Naming Certificate for $\mathsf{SpreadSpace}^{\uparrow}$

Following Brouwer and Troelstra–van Dalen on spreads and choice sequences, the $\mathsf{SpreadSpace}^{\uparrow}$ packet records a finite-prefix space of admissible choice-sequence names rather than an ambient set of completed infinite branches. It sits between the Baire carrier of chapter 334, the finite stream-name consumer of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. Its spread-side input is supplied by the Brouwer spread packet of chapter 1677, the local law packet of chapter 1532, and the choice-sequence packet of chapter 1482.

Definition 4189.1 (SpreadSpace carrier)**.** *A* $\mathsf{SpreadSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, L, Q, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *finite-prefix row, recording the finite natural-number windows on which the packet may be inspected.*
2. *L is the* $\mathsf{SpreadLaw}^{\uparrow}$ *admission row, deciding whether each displayed prefix is permitted by the spread law.*
3. *Q is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *branch-prefix row, exposing only those choice-sequence observations whose prefixes pass L.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by downstream name consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the accepted branch prefixes and stream windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, L, Q, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the prefix, law, branch, window, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a spread-space query through B, L, Q, W, R, E.*
9. *P is the* Pkg *provenance over* $\mathsf{SpreadSpace}^{\uparrow}$, $\mathsf{BrouwerSpread}^{\uparrow}$, $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SpreadSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, L, Q, W, R, E, H, C, P, N$. It has no coordinate for a completed infinite branch, host equality of functions, countable choice, selected real values, bar induction outside the displayed prefix bar, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.SpreadSpaceUp.spreadSpaceTasteGate`
Lean4 ✓ `BEDC.Derived.SpreadSpaceUp.SpreadSpaceTasteGate single carrier alignment`

Theorem 4189.2 (SpreadSpace prefix-bar stability)**.** *For every accepted* $\mathsf{SpreadSpace}^{\uparrow}$ *carrier*

$$S = (B, L, Q, W, R, E, H, C, P, N),$$

any downstream read that reaches a $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *row must first pass through the same finite* $\mathsf{BaireSpace}^{\uparrow}$ *prefix row B, the same* $\mathsf{SpreadLaw}^{\uparrow}$ *admission row L, and the same* $\mathsf{ChoiceSequence}^{\uparrow}$ *branch-prefix row Q. If two accepted reads are componentwise related by the displayed* hsame *row H and replayed by* Cont *through C, then their prefix-bar boundary is transported without adding an infinite branch, host function equality, countable choice, selected real value, or ambient completeness coordinate.*

Proof. Project the carrier in Definition 4189.1. The only entrance to a downstream name read is the displayed prefix route B, L, Q.

The stream and rational rows are downstream of that entrance. A $\mathsf{StreamName}^{\uparrow}$ window W and a $\mathsf{RegSeqRat}^{\uparrow}$ readback R are available only after the finite Baire prefix has been admitted by the spread law and attached to a choice-sequence prefix.

Transport preserves that order. The row H relates the listed coordinates componentwise, while C replays the same route through the finite packet. Since the carrier contains no infinite branch, host function equality, choice schedule, selected real value, or ambient completeness coordinate, the prefix-bar boundary is stable under the displayed transport and replay rows. □

Theorem 4189.3 (SpreadSpace NameCert obligations)**.** *For every accepted* $\mathsf{SpreadSpace}^{\uparrow}$ *carrier $S = (B, L, Q, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SpreadSpace}^{\uparrow}}$ *surface consists exactly of the finite obligations for carrier admission, spread-law prefix acceptance, choice-sequence prefix compatibility, StreamName window replay, RegSeqRat readback, Real seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. These obligations are rows in* BHist, hsame, Cont, Pkg, *and* NameCert*; they do not assert completed branch existence, host equality of functions, countable choice, selected representatives, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the tuple displayed in Definition 4189.1. Each coordinate has a single obligation role: prefix carrier, law admission, branch-prefix compatibility, finite stream window, regular rational readback, terminal real seal, transport, replay, provenance, or local naming.

The first three rows determine the spread-space boundary. The rows W, R, E then expose the L10-facing naming route only after that boundary has been displayed.

The structural rows H, C, P, N do not add mathematical objects beyond the listed surface. They transport, replay, source, and name the same finite route, so every local certificate obligation is exhausted by BHist, hsame, Cont, Pkg, and NameCert rows. □

Theorem 4189.4 (SpreadSpace StreamName–Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{SpreadSpace}^{\uparrow}$ *carrier receives the finite route*

$$\mathsf{SpreadSpace}^{\uparrow} \longmapsto \mathsf{BrouwerSpread}^{\uparrow} \longmapsto \mathsf{SpreadLaw}^{\uparrow} \longmapsto \mathsf{ChoiceSequence}^{\uparrow} \longmapsto \mathsf{BaireSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{Re}$$

together with the displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows of the packet. The handoff exports no completed spread branch, no host function equality, no countable-choice schedule,*

no selected real representative, no quotient stream equality, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from prefix-bar stability, Definition 4189.2. It forces every downstream name read through the finite prefix route B, L, Q before a StreamName window can be opened.

Apply the obligation inventory of Definition 4189.3. The rows W, R, E are the only StreamName, RegSeqRat, and Real-facing coordinates of the local packet, and the rows H, C, P, N only preserve and name that route.

The displayed chain is therefore the whole handoff available to a Real-facing consumer. None of the excluded objects is a coordinate of the carrier, so the handoff remains a finite NameCert route rather than a completed branch or ambient Real-completeness assertion. □

Closure status for $\mathsf{NameCert}_{\mathsf{SpreadSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{SpreadSpace}^{\uparrow}$ packet is generated from a BaireSpace finite-prefix row, a SpreadLaw admission row, a ChoiceSequence branch-prefix row, StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SpreadSpace}^{\uparrow}}$, seed)

Scope closed: Definition 4189.1, Definition 4189.2, Definition 4189.3, and Definition 4189.4 seed the finite spread-space route from Brouwer spread prefixes to StreamName and Real consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SpreadSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim completed infinite branch existence, host equality of functions, countable choice, selected real representatives, quotient stream equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, spread-law prefix acceptance, choice-sequence compatibility, StreamName window replay, RegSeqRat readback, Real seal handoff, transport replay, provenance, and non-escape for BEDC.Derived.SpreadSpaceUp.

Chapter 4190

A Concrete Naming Certificate for $\mathsf{UniformCauchyEmbedding}^{\uparrow}$

Following Bishop and Bridges on uniformly continuous Cauchy data, the $\mathsf{UniformCauchyEmbedding}^{\uparrow}$ packet records the finite certificate surface for embedding one displayed Cauchy presentation into another without selecting host limits. It sits between the Cauchy source discipline of chapter 3413, the finite schedule rows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the represented-space carrier boundary of chapter 1494. The packet is an open Real and Completion phase object: it makes uniform Cauchy embeddings available as finite NameCert data while leaving completion, quotient equality, and chosen limits outside the carrier.

Definition 4190.1 (Uniform Cauchy embedding carrier)**.** *A* $\mathsf{UniformCauchyEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (C, S, R, T, E, V, H, K, P, N)$$

with the following displayed rows:

1. *C is the source* $\mathsf{Cauchy}^{\uparrow}$ *row, recording the Cauchy admissibility request whose observations are to be embedded.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row opened by a target tolerance request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the source schedule.*
4. *T is the target* $\mathsf{StreamName}^{\uparrow}$ *schedule row, with its tolerance request bounded by a displayed uniform modulus row.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *terminal seal row reached only after the source Cauchy row, the source schedule, the regular readback, and the target schedule have been displayed.*
6. *V is the* $\mathsf{RepresentedSpace}^{\uparrow}$ *representation row for the source and target observation surfaces.*
7. *H stores componentwise* hsame *transport for $C, S, R, T, E, V, K, P, N$.*
8. *K stores displayed* Cont *replay from a target tolerance request back through the source Cauchy, source schedule, regular readback, target schedule, Real seal, and represented-space rows.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformCauchyEmbedding}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RepresentedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient Cauchy classes, host real equality, a selected completion point, a global inverse map, countable choice, or a proof that the represented-space target is complete.

Lean4 (definition) `BEDC.Derived.UniformCauchyEmbeddingUp.uniformCauchyEmbeddingTasteGate`
Lean4 ✓ `BEDC.Derived.UniformCauchyEmbeddingUp.UniformCauchyEmbeddingTasteGate single carrier alignment`

Theorem 4190.2 (Uniform Cauchy embedding NameCert obligations)**.** *For every accepted* UniformCauchyEmbeddi *carrier*

$$U = (C, S, R, T, E, V, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformCauchyEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for the source Cauchy row, source schedule, regular rational readback, target schedule, terminal Real seal, represented-space row, componentwise transport, continuation replay, provenance, and local naming rows, together with the obligation that every target tolerance request is replayed through* $C, S, R, T, E, V, H, K, P, N$ *in that order.*

No obligation in the packet is discharged by quotient Cauchy classes, host real equality, selected completion points, global inverse data, countable choice, or completeness of the represented-space target.

Proof. Carrier admission is projection from Definition 4190.1. The tuple displays the Cauchy source, source schedule, regular rational readback, target schedule, Real seal, represented-space, transport, replay, provenance, and naming rows.

The replay order is fixed by the row dependencies. A target tolerance request first opens the source Cauchy row C, then the finite schedule row S, and then the regular-rational readback row R before the target schedule T can be read.

The terminal rows consume only that displayed source surface. The Real seal E records the target real-name boundary, while V records the represented-space observation surface on both sides of the embedding.

Finally H, K, P, N transport, replay, source, and name only these displayed rows. Since the carrier contains no coordinate for the excluded quotient, host, choice, inverse, completion, or completeness data, the listed obligations exhaust the local NameCert surface. □

Theorem 4190.3 (Uniform Cauchy embedding sibling route)**.** *Every accepted* $\mathsf{UniformCauchyEmbedding}^{\uparrow}$ *packet factors through the finite sibling route*

$$\mathsf{Cauchy}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{RepresentedSpace}^{\uparrow}.$$

The first $\mathsf{StreamName}^{\uparrow}$ *row schedules source observations, and the second* $\mathsf{StreamName}^{\uparrow}$ *row schedules target observations under the displayed uniform replay row. The route exports finite embedding data only; it does not export quotient Cauchy classes, selected representatives, global inverse data, or target completeness.*

Proof. Apply the obligations of Definition 4190.2. They require every target tolerance request to pass through the source Cauchy row, source schedule, regular rational readback, target schedule, Real seal, and represented-space row.

The two schedule rows have distinct roles. The source schedule S exposes the observations that can be read from the Cauchy source, while the target schedule T records the target request after the displayed uniform replay has bounded it.

The Real and represented-space rows then seal the route without adding non-displayed structure. Because H, K, P, N only transport, replay, source, and name the same rows, the packet exports the finite sibling route and none of the excluded quotient, representative, inverse, or completeness data. □

Theorem 4190.4 (Uniform Cauchy embedding open phase use)**.** *In the open Real and Completion phase, a* $\mathsf{UniformCauchyEmbedding}^{\uparrow}$ *packet may be used as the finite handoff object from regular Cauchy source data to Real-facing and represented-space-facing consumers. Such a consumer may read the displayed Cauchy, schedule, regular-rational, target-schedule, Real-seal, represented-space, transport, replay, provenance, and naming rows, but it may not infer completion of* $\mathsf{Real}^{\uparrow}$*, a quotient construction for Cauchy names, a selected limit, or countable-choice data.*

Proof. The handoff object is the carrier of Definition 4190.1. Its rows expose exactly the source Cauchy request, the two finite schedules, the regular rational readback, the Real seal, the represented-space surface, and the structural transport, replay, provenance, and naming data.

The open phase use reads this finite surface as an interface for later Real and Completion obligations. It can therefore pass uniform Cauchy embedding evidence downstream without changing the carrier into a completion theorem.

The exclusions follow from absence of coordinates. Since the carrier contains no quotient construction, selected limit, completeness proof, or countable-choice row, no open phase consumer obtains those data from the $\mathsf{UniformCauchyEmbedding}^{\uparrow}$ NameCert. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchyEmbedding}^{\uparrow}$ packet is generated from a source Cauchy row, source schedule, regular rational readback, target schedule, terminal Real seal, represented-space row, componentwise transport, displayed continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4190.1, Definition 4190.2, Definition 4190.3, and Definition 4190.4 seed the finite uniform Cauchy embedding interface for the open Real and Completion phase.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient Cauchy equality, selected completion points, global inverse data, countable choice, $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform replay non-escape, sibling route coverage, and open phase use for the same packet.

Chapter 4191

A Concrete Naming Certificate for $\mathsf{DecimalStream}^{\uparrow}$

Following Bishop and Bridges on decimal presentations of constructive real numbers, the $\mathsf{DecimalStream}^{\uparrow}$ packet records the finite base-ten stream surface that sits between decimal prefix data and real-name readback. It refines the finite prefix discipline of chapter 1417 without asking $\mathsf{DecimalExpansion}^{\uparrow}$ to carry an infinite stream role, and it routes later reads through the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DecimalReal}^{\uparrow}$, and $\mathsf{SignedDigitStream}^{\uparrow}$ surfaces of chapter 126, chapter 291, chapter 301, chapter 38, chapter 2058, and chapter 316.

Definition 4191.1 (DecimalStream carrier)**.** *A* $\mathsf{DecimalStream}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (E, S, W, L, Q, R, A, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{DecimalExpansion}^{\uparrow}$ *prefix row, carrying admitted signed decimal prefixes and their endpoint policy.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, exposing only finite digit windows requested by a downstream consumer.*
3. *W is the decimal window ledger, recording observed base-ten digits, place indices, and prefix bounds for each request in S.*
4. *L is the place-value ledger that evaluates every displayed window as a rational base-ten partial sum.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row that translates the place-value ledger into dyadic tolerance data.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the dyadic comparison windows.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{DecimalReal}^{\uparrow}$ *seal boundary, with the* $\mathsf{SignedDigitStream}^{\uparrow}$ *sibling used only as a comparison surface for finite-window stream behavior.*
8. *H records componentwise* hsame *transport for E, S, W, L, Q, R, A and the local structural rows.*
9. *C records displayed* Cont *replay from a digit-window request through the decimal prefix, stream schedule, place-value ledger, dyadic comparison, regular-rational handoff, and terminal real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{DecimalStream}^{\uparrow}$, $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DecimalReal}^{\uparrow}$, $\mathsf{SignedDigitStream}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DecimalStream}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite decimal object, quotient stream equality, a selected decimal expansion at endpoints, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DecimalStreamUp.DecimalStreamTasteGate single carrier alignment`

Theorem 4191.2 (DecimalStream NameCert obligations)**.** *For every accepted* $\mathsf{DecimalStream}^{\uparrow}$ *carrier* $D = (E, S, W, L, Q, R, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DecimalStream}^{\uparrow}}$ *surface consists exactly of carrier admission, finite digit-window exposure, base-ten place-value ledger evaluation, dyadic comparison handoff, regular-rational readback, Real and DecimalReal seal nonescape, signed-digit sibling comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.DecimalStreamUp.DecimalStreamCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 4191.1. The rows E, S, W, L, Q, R, A are the only decimal-prefix, stream-window, place-value, dyadic, regular-rational, and real-facing rows available to the packet.

Finite digit-window exposure is forced by S and W. A downstream read can inspect only the requested base-ten windows, so no infinite decimal stream, hidden tail, or endpoint selector appears.

The place-value ledger L then turns each window into rational partial-sum data. The dyadic row Q and regular-rational row R transport that ledger into the same $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ route used by the L10 real boundary.

Finally, A, H, C, P, N seal, transport, replay, source, and locally name the route. Since the carrier lacks quotient stream equality, selected endpoint expansions, host real equality, countable choice, and ambient completeness coordinates, the listed rows exhaust the NameCert obligations. □

Theorem 4191.3 (DecimalStream real readback boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{DecimalReal}^{\uparrow}$ *read of an accepted* $\mathsf{DecimalStream}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DecimalExpansion}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DecimalStream}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The comparison with $\mathsf{SignedDigitStream}^{\uparrow}$ *is only a finite-window sibling comparison. The readback exports no infinite decimal stream, no quotient of streams, no selected endpoint expansion, no host equality of real representatives, and no* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with an accepted packet and project the rows of Definition 4191.1. A real-facing read must inspect the decimal prefix row E, the stream schedule S, and the requested window ledger W before place-value data are available.

The place-value ledger L is then compared through Q and handed to R. Thus the Real-facing route is the finite dyadic and regular-rational route already used by $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ consumers.

The terminal seal row A records only the $\mathsf{Real}^{\uparrow}$ and $\mathsf{DecimalReal}^{\uparrow}$ boundary reached by that route. The $\mathsf{SignedDigitStream}^{\uparrow}$ sibling is cited for finite-window comparison behavior and does not add a second stream quotient.

Transport and replay through H and C preserve the same rows, while P and N source and name them. No excluded infinite stream, quotient, endpoint selector, host equality, or completeness coordinate is present, so the displayed boundary is exact. □

Closure status for $\mathsf{NameCert}_{\mathsf{DecimalStream}^{\uparrow}}$.

Constructive story: A $\mathsf{DecimalStream}^{\uparrow}$ packet is generated from DecimalExpansion prefix rows, finite StreamName digit windows, place-value ledgers, DyadicRatCore comparison rows, RegSeqRat handoff rows, RealUp and DecimalRealUp seal rows, SignedDigitStream sibling comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DecimalStream}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4191.1, Definition 4191.2, and Definition 4191.3 seed the finite decimal stream surface from decimal prefixes to dyadic, regular-rational, and real-name consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DecimalStream}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim an infinite decimal stream object, quotient stream equality, selected endpoint expansions, host real equality, countable choice, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite digit-window admission, place-value ledger exactness, dyadic comparison handoff, RegSeqRat readback, Real-seal nonescape, transport replay, provenance, and local naming for BEDC.Derived.DecimalStreamUp.

Chapter 4192

A Concrete Naming Certificate for MinimalTriggerOrbitClassification$^{\uparrow}$

The MinimalTriggerOrbitClassification$^{\uparrow}$ packet realizes Definition 9462.1681 as finite BEDC NameCert data. It sits after the DNA boundary-tile source of chapter 3393, the lift-fiber packet of chapter 4129, the homology-core packet of chapter 4137, and the window coverage algebra of chapter 3478. The packet records nine normal forms, defect rows, quotient and codon counts, transport, replay, provenance, and local naming as displayed finite rows; it is not a biological stochastic model, hidden codon semantics, unrestricted orbit enumeration, or an unrecorded homology computation.

Definition 4192.1 (MinimalTriggerOrbitClassification carrier)**.** *A* MinimalTriggerOrbitClassification$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (B, N, D, Q, K, L, M, H, C, P, R)$$

with the following displayed rows:

1. *B is the* DnaWindowSixBoundaryTile$^{\uparrow}$ *source row for the six-coordinate boundary-tile window.*
2. *N is the nine-normal-form ledger, displaying the orbit representatives of the minimal-trigger classification.*
3. *D is the defect ledger for the partition, single-overlap, double-overlap, and triple-overlap rows.*
4. *Q is the quotient-count row, preserving the* 49 *quotient-level minimal full triggers.*
5. *K is the codon-count row, preserving the two-lift total* 294*.*
6. *L is the* MinimalTriggerLiftBundle$^{\uparrow}$ *handoff row for lift-fiber decomposition.*
7. *M is the* MinimalTriggerHomologyCore$^{\uparrow}$ *handoff row for support-nerve core reads.*
8. *H records componentwise* hsame *transport for the source, normal-form, defect, count, handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from boundary-tile windows through normal forms, defect rows, quotient counts, codon counts, lift fibers, and homology-core handoffs.*
10. *P is the* Pkg *provenance over* MinimalTriggerOrbitClassification$^{\uparrow}$*,* DnaWindowSixBoundaryTile$^{\uparrow}$*,* MinimalTriggerLiftBundle$^{\uparrow}$*,* MinimalTriggerHomologyCore$^{\uparrow}$*,* WindowCoverageTriggerAlgebra$^{\uparrow}$*, the source classification theorem,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *R is the local* $\mathsf{NameCert}_{\mathsf{MinimalTriggerOrbitClassification}^{\uparrow}}$ *row.*
The carrier has no coordinate for an empirical genetic-code law, a stochastic fitness model, quotient codon semantics outside the displayed rows, an unrestricted orbit search, or an external homology oracle.

Lean4 ✓ BEDC.Derived.MinimalTriggerOrbitClassificationUp.MinimalTriggerOrbitClassificationTasteGate single carrier alignment

Theorem 4192.2 (MinimalTriggerOrbitClassification NameCert obligations)**.** *For every accepted* $\mathsf{MinimalTriggerOrbitClassification}^{\uparrow}$ *carrier* $O = (B, N, D, Q, K, L, M, H, C, P, R)$*, the local* $\mathsf{NameCert}_{\mathsf{MinimalTriggerOrbit}}$ *surface consists exactly of boundary-tile source admission, nine-normal-form exposure, defect-ledger exposure, quotient-count preservation, codon-count preservation, lift-bundle handoff, homology-core handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer preserving the packet must preserve the nine normal forms, the quotient count* 49*, and the codon count* 294 *through those rows.*

Proof. Project the carrier of Definition 4192.1. The row B supplies the boundary-tile source, while N, D, Q, K display the normal forms, defects, quotient count, and codon count.

The lift and homology consumers are the rows L and M. They can read the classification only after the finite normal-form and count rows have been displayed, so neither handoff becomes an independent orbit enumeration.

Transport and replay are carried by H and C. These rows preserve the same displayed source, normal-form, defect, count, lift, and homology data componentwise under hsame and Cont.

Finally, P and R source and name exactly this finite packet. Since no excluded empirical, stochastic, quotient-semantics, unrestricted-search, or external-homology coordinate is present, the listed rows exhaust the NameCert obligations and force preservation of the nine forms and the counts 49 and 294. □

Theorem 4192.3 (MinimalTriggerOrbitClassification vision handoff)**.** *The finite classification of Definition 9462.1681 is consumed by* $\mathsf{MinimalTriggerOrbitClassification}^{\uparrow}$ *only through the route*

$$\mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{WindowCoverageTriggerAlgebra}^{\uparrow} \longmapsto N, D, Q, K \longmapsto \mathsf{MinimalTriggerLiftBundle}^{\uparrow},\ \mathsf{Min}$$

Future Lean TasteGate files for this packet must provide explicit Nontrivial $\mathsf{MinimalTriggerOrbitClassification}^{\uparrow}$ *and* FieldFaithful $\mathsf{MinimalTriggerOrbitClassification}^{\uparrow}$ *obligations before the packet can serve as a verified trigger-classification consumer.*

Proof. Start from Definition 4192.2. It places the boundary-tile and coverage-algebra source rows before any normal-form or count row can be consumed.

The middle block N, D, Q, K is the finite classification ledger. It records the nine normal forms, their defect classes, the quotient count, and the codon count without opening an unrestricted orbit search.

The handoff rows L and M attach lift-fiber and homology-core consumers to the same ledger. The structural rows H, C, P, R then transport, replay, source, and locally name the route.

Thus the source theorem is represented as a finite packet. The stated Lean TasteGate obligations are downstream verification requirements for this carrier and do not add fields to the paper-side packet. □

Falsifiable prediction: For every accepted $\mathsf{MinimalTriggerOrbitClassification}^{\uparrow}$ packet, componentwise hsame transport preserves exactly nine displayed normal forms, the quotient-level count 49, and the codon-level count 294.

Independence witness: dna-window-six-boundary-tile, minimal-trigger-lift-bundle, minimal-trigger-homology-core, window-coverage-trigger-algebra: $\mathsf{MinimalTriggerOrbitClassification}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries normal-form rows, defect rows, quotient-count rows, codon-count rows, lift and homology handoffs, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MinimalTriggerOrbitClassification}^{\uparrow}}$.

Constructive story: A $\mathsf{MinimalTriggerOrbitClassification}^{\uparrow}$ packet is generated from a DnaWindowSixBoundaryTile source row, nine normal-form rows, defect ledgers, quotient-count and codon-count rows, MinimalTriggerLiftBundle and MinimalTriggerHomologyCore handoff rows, WindowCoverageTriggerAlgebra provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MinimalTriggerOrbitClassification}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4192.1, Definition 4192.2, and Definition 4192.3 seed the finite orbit-classification packet preserving nine normal forms, defect rows, quotient count 49, and codon count 294.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MinimalTriggerOrbitClassification}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.MinimalTriggerOrbitClassificationUp.MinimalTriggerOrbitClassificationTasteGate\_single\`

Bridge status: none

Not claimed: This chapter does not claim biological mechanism, stochastic fitness, quotient codon semantics outside displayed rows, unrestricted orbit enumeration, Lean verification, Nontrivial or FieldFaithful TasteGate instances, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, normal-form preservation, defect-ledger preservation, quotient-count preservation, codon-count preservation, lift and homology handoffs, transport replay, provenance, local naming, Nontrivial MinimalTriggerOrbitClassificationUp, and FieldFaithful MinimalTriggerOrbitClassificationUp for BEDC.Derived.MinimalTriggerOrbitClassificationUp.

Chapter 4193

A Concrete Naming Certificate for $\mathsf{Portmanteau}^{\uparrow}$

Following Billingsley and Prokhorov, the $\mathsf{Portmanteau}^{\uparrow}$ packet records the weak-convergence test surface that becomes visible only after tight probability data have already been exposed. It sits after the probability source of chapter 184, the pushforward distribution row of chapter 186, the event-surface measure row of chapter 92, the real comparison boundary of chapter 38, the tight probability handoff of chapter 4008, and the compact metric test surface of chapter 129. The chapter names a finite BEDC test packet for bounded-continuous probes; it does not assert weak compactness, choose subsequences, use countable choice, export host measures, quotient events, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4193.1 (Portmanteau carrier)**.** *A* $\mathsf{Portmanteau}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (P, D, M, T, B, R, A, E, H, C, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row carrying the probability surface.*
2. *D is the* $\mathsf{Distribution}^{\uparrow}$ *row whose pushforward reads supply the tested laws.*
3. *M is the* $\mathsf{Measure}^{\uparrow}$ *event-surface row through which measured test preimages are inspected.*
4. *T is the* $\mathsf{ProkhorovTightProbability}^{\uparrow}$ *handoff row already exposing tightness data before any weak-convergence test is read.*
5. *B is the bounded-continuous test row, recorded as a displayed* $\mathsf{BoundedContinuousTest}$ *surface over the compact or metric test carrier.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *comparison row for the two finite test expectations or inequalities observed by the packet.*
7. *A is the transport row aligning probability, distribution, measure, tightness, bounded-continuous test, and real-comparison reads.*
8. *E is the finite endpoint or tolerance ledger that records which bounded-continuous probe and real comparison window are being inspected.*
9. *H records componentwise* hsame *transport for every displayed row.*

10. *C records displayed* Cont *replay of source admission, pushforward readback, measure inspection, tightness exposure, bounded-continuous test evaluation, real comparison, and tolerance readback.*
11. *Q is the* Pkg *provenance over* $\mathsf{Portmanteau}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{ProkhorovTightProbability}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{Portmanteau}^{\uparrow}}$ *row.*

The carrier has no coordinate for weak compactness, selected subsequences, countable choice, host measures, quotient events, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PortmanteauUp.PortmanteauTasteGate single carrier alignment`

Theorem 4193.2 (Portmanteau NameCert obligations)**.** *For every accepted* $\mathsf{Portmanteau}^{\uparrow}$ *carrier* $W = (P, D, M, T, B, R, A, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{Portmanteau}^{\uparrow}}$ *surface consists exactly of six obligation groups:*

1. *carrier admission for the probability source, distribution pushforward, event-surface measure, tightness handoff, bounded-continuous test, real comparison, transport, tolerance, replay, provenance, and local naming rows;*
2. *tightness-before-testing exposure, requiring each weak-convergence test read to display the* ProkhorovTightProbabil *row T before the bounded-continuous probe is consumed;*
3. *bounded-continuous test admission, requiring the probe row B to be read through the displayed compact or metric test surface rather than through a host function space;*
4. *real comparison exactness, requiring the comparison row R to be read through* $\mathsf{Real}^{\uparrow}$ *and the tolerance ledger E;*
5. *distribution and measure compatibility, requiring D and M to name the same tested event or pushforward observation under the transport row A;*
6. *non-escape from weak compactness, selected subsequences, countable choice, host measures, quotient events, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No additional NameCert obligation is stored outside these finite rows.

Proof. Project the carrier of Definition 4193.1. The tuple lists exactly the probability, distribution, measure, tightness, bounded-continuous test, real comparison, transport, tolerance, replay, provenance, and naming rows.

The tightness side is already finite. A consumer must inspect T before the probe row B can be evaluated, so the weak-convergence test is downstream of the Prokhorov tightness handoff rather than a source of compactness by itself.

The comparison side is real-name data. The row R and tolerance ledger E provide the displayed real comparison, while D, M, A keep pushforward and measured-event observations on the same route.

Since no carrier coordinate stores weak compactness, selected subsequences, countable choice, host measures, quotient events, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the six displayed groups exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{Portmanteau}^{\uparrow}$ test read exposes $\mathsf{ProkhorovTightProbability}^{\uparrow}$, a bounded-continuous probe row, and a $\mathsf{Real}^{\uparrow}$ comparison row before any weak-convergence consumer can inspect it.

Independence witness: probspace, distribution, measure, prokhorov-tight-probability, real, compactmetric: the packet is not bijective to any listed sibling because it binds tight probability data, bounded-continuous test admission, real comparison, transport, replay, provenance, and local NameCert rows as one weak-convergence test surface.

Closure status for $\mathsf{NameCert}_{\mathsf{Portmanteau}^{\uparrow}}$.

Constructive story: A $\mathsf{Portmanteau}^{\uparrow}$ packet is generated from ProbSpaceUp source rows, DistributionUp pushforward rows, MeasureUp event-surface rows, ProkhorovTightProbabilityUp handoff rows, bounded-continuous test rows, RealUp comparison rows, transport, hsame, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Portmanteau}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4193.1 and Definition 4193.2 seed the weak-convergence bounded-continuous test surface after tight probability data have been displayed.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Portmanteau}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close weak compactness, selected subsequences, countable choice, host measures, quotient events, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tightness-before-testing exposure, bounded-continuous test admission, real comparison exactness, distribution and measure compatibility, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.PortmanteauUp.

The $\mathsf{MonotoneClass}^{\uparrow}$ top-level route sends generated closure through chapter 92, chapter 3384, and chapter 3668 before any measure-facing consumer reads the packet.

Chapter 4194

A Concrete Naming Certificate for $\mathsf{MonotoneClass}^{\uparrow}$

Following Halmos and Dynkin-style monotone class arguments, the $\mathsf{MonotoneClass}^{\uparrow}$ packet records the closure object that measure-theoretic generation uses before any consumer may cite a sigma-algebra completion. It sits after the measurable-event carrier of chapter 92, the generated-set boundary of chapter 3384, and the displayed membership discipline of chapter 3668. The packet names generator admission, increasing-union rows, decreasing-intersection rows, measurable-event admission, transport, replay, provenance, and local naming; it does not assert a host sigma-algebra, pi-lambda theorem, selected countable chain, measure extension, or quotient equality of subsets.

Definition 4194.1 (MonotoneClass carrier)**.** *A* $\mathsf{MonotoneClass}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (G, U, I, A, H, C, P, N)$$

with the following displayed rows:

1. *G is the generator family over* BHist*, read as displayed subset rows through* $\mathsf{SetLike}^{\uparrow}$ *and as generated-set boundary data through* $\mathsf{BorelSet}^{\uparrow}$ *when the source is Borel-facing.*
2. *U records increasing-union closure rows for finite observed chains and their named limit event request.*
3. *I records decreasing-intersection closure rows for finite observed chains and their named limit event request.*
4. *A records measurable-event admission through the* $\mathsf{BorelSet}^{\uparrow}$ *and* $\mathsf{Measure}^{\uparrow}$ *sibling surfaces.*
5. *H stores componentwise* hsame *transport for G, U, I, A and the structural rows.*
6. *C stores displayed* Cont *replay from a generator request through increasing-union closure, decreasing-intersection closure, measurable-event admission, provenance, and local naming.*
7. *P is the* Pkg *provenance over* $\mathsf{MonotoneClass}^{\uparrow}$*,* $\mathsf{Measure}^{\uparrow}$*,* $\mathsf{BorelSet}^{\uparrow}$*,* $\mathsf{SetLike}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneClass}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through G, U, I, A, H, C, P, N. It has no coordinate for completed sigma-algebras, chosen countable unions, host subset equality, measure extension, or an ambient monotone-class theorem.

Theorem 4194.2 (MonotoneClass NameCert obligations)**.** *For the carrier of Definition 4194.1, the local* $\mathsf{NameCert}_{\mathsf{MonotoneClass}^\uparrow}$ *surface consists exactly of generator admission through* G*, increasing-union closure through* U*, decreasing-intersection closure through* I*, measurable-event admission through* A*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*. Every accepted* $\mathsf{Measure}^\uparrow$*,* $\mathsf{BorelSet}^\uparrow$*, or* $\mathsf{SetLike}^\uparrow$ *consumer that reads a monotone-class conclusion must expose those rows before it treats the generated family as closed under the requested operation.*

Proof. Project the carrier $M = (G, U, I, A, H, C, P, N)$. The generator row G is the only entry point for displayed set requests, so carrier admission is exhausted by the generator family and its sibling $\mathsf{SetLike}^\uparrow$ or $\mathsf{BorelSet}^\uparrow$ boundary.

Read the closure rows next. The row U supplies increasing-union closure for the named observed chain, and I supplies decreasing-intersection closure for the named observed chain. The measurable-event admission row A is the only route from those closures to the $\mathsf{BorelSet}^\uparrow$ and $\mathsf{Measure}^\uparrow$ surfaces.

Finally replay the structural rows. Transport through H, continuation through C, provenance through P, and local naming through N preserve the same finite route. Since no carrier coordinate contains completed sigma-algebras, selected countable chains, quotient subset equality, measure extension, or an ambient monotone-class theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 4194.3 (MonotoneClass generated closure route)**.** *Every accepted* $\mathsf{MonotoneClass}^\uparrow$ *packet exports the generated closure route*

$$G \longmapsto U, I \longmapsto A \longmapsto H, C, P, N$$

for downstream $\mathsf{Measure}^\uparrow$*,* $\mathsf{BorelSet}^\uparrow$*, and* $\mathsf{SetLike}^\uparrow$ *consumers. The route lets a consumer cite monotone closure of the displayed generator family only after increasing-union, decreasing-intersection, measurable-event, transport, replay, provenance, and local-name rows have been exposed; it exports no sigma-algebra completion, pi-lambda closure, measure-extension theorem, selected chain, or quotient equality of subsets.*

Proof. Start with a displayed generator request in G. The request is a finite BEDC row, not a host subset family, and it can be read only through the named $\mathsf{SetLike}^\uparrow$ and $\mathsf{BorelSet}^\uparrow$ surfaces.

Pass through the two closure rows. Increasing requests are handled by U, decreasing requests by I, and both remain attached to the same displayed generator family. The admission row A then records when the resulting event request is visible to the Borel and measure siblings.

Replay the route through H, C, P, N. These rows transport, replay, source, and name the same finite certificate. Therefore a downstream consumer receives exactly the generated closure route stated above and no completed sigma-algebra, pi-lambda theorem, measure-extension theorem, selected chain, or quotient subset equality. □

Theorem 4194.4 (MonotoneClass generator induction boundary)**.** *Every accepted* $\mathsf{MonotoneClass}^\uparrow$ *consumer reaches generated closure only by finite induction over the displayed generator row* G*, increasing-union row* U*, decreasing-intersection row* I*, measurable-event row* A*, transport row* H*, replay row* C*, provenance row* P*, and local name row* N*. The induction boundary cannot be replaced by a host pi-lambda theorem, selected countable chain, measure extension, completed sigma-algebra, or quotient subset equality.*

Proof. Unfold the carrier $M = (G, U, I, A, H, C, P, N)$ from Definition 4194.1. The only initial cases available to a consumer are displayed generator requests in G, and each request is a finite BEDC row rather than a host subset family.

For the induction steps, use the closure route of Definition 4194.3. Increasing-union steps are read through U, decreasing-intersection steps through I, and measurable-event admission through A; each step keeps the same displayed generator family attached.

Apply the NameCert obligations of Definition 4194.2. Transport through H, replay through C, provenance through P, and local naming through N are required before the generated closure can be consumed downstream.

Since the carrier has no coordinate for a pi-lambda theorem, selected countable chain, measure extension, completed sigma-algebra, or quotient equality of subsets, no consumer can substitute one of those host objects for the finite induction route. □

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneClass}^\uparrow}$.

Constructive story: A $\mathsf{MonotoneClass}^\uparrow$ packet is generated from displayed set generators, increasing-union rows, decreasing-intersection rows, measurable-event admission, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MonotoneClass}^\uparrow}$, seed)

Scope closed: Definition 4194.1, Definition 4194.2, and Definition 4194.3 seed the monotone closure route over displayed generators, union rows, intersection rows, measurable-event admission, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MonotoneClass}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host sigma-algebra completion, pi-lambda closure, measure extension, selected countable chains, quotient subset equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, increasing-union closure, decreasing-intersection closure, measurable-event admission, transport, provenance, and no-escape for BEDC.Derived.MonotoneClassUp.

The $\mathsf{MonotoneClass}^\uparrow$ dependency route exposes its generator, increasing-union, and decreasing-intersection rows as consumers of the measurable-event carrier in chapter 92, the generated-set boundary in chapter 3384, and the membership classifier discipline in chapter 3668. This route keeps the monotone-class closure packet visible to measure-facing consumers before they read any generated event as measurable.

Theorem 4194.5 (MonotoneClass SetLike measure dependency route)**.** *Every* $\mathsf{Measure}^\uparrow$ *or* $\mathsf{BorelSet}^\uparrow$ *consumer that reads an accepted* $\mathsf{MonotoneClass}^\uparrow$ *closure packet must first route the generator row* G*, increasing-union row* U*, decreasing-intersection row* I*, measurable admission row* A*, componentwise* hsame *transport row* H*, displayed* Cont *replay row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{MonotoneClass}^\uparrow}$ *row* N *through the* $\mathsf{SetLike}^\uparrow$ *membership classifier of chapter 3668. Thus the consumer may use monotone closure only as a displayed membership-stable generated family over chapter 92 and chapter 3384, not as a host sigma-algebra completion, selected countable chain, measure-extension theorem, or quotient equality of subsets.*

Proof. Start with the carrier of Definition 4194.1. The generator row G names displayed subset requests, so any measure-facing or Borel-facing read must classify membership through the $\mathsf{SetLike}^\uparrow$ surface before it can treat the request as a generated event.

The closure rows U and I keep increasing-union and decreasing-intersection reads attached to that same membership classifier. The measurable admission row A is then the only route by which the generated family becomes visible to the $\mathsf{BorelSet}^\uparrow$ and $\mathsf{Measure}^\uparrow$ siblings.

Finally read the structural rows H, C, P, N. They transport, replay, source, and locally name the same finite route, so the consumer cannot replace the displayed membership-stable packet by a host sigma-algebra, a selected chain, a measure extension, or quotient subset equality. □

Chapter 4195

A Concrete Naming Certificate for $\mathsf{FanCompact}^{\uparrow}$

Following Brouwer and Bishop–Bridges, the $\mathsf{FanCompact}^{\uparrow}$ packet records constructive compactness of binary spread data by finite bars and prefix induction rather than by open-cover compactness. It sits beside the Boolean and list carriers of chapter 32 and chapter 36, the finite stream-window discipline of chapter 126, the compact-metric surface of chapter 129, and the downstream uniform-modulus consumer of chapter 369. The packet supplies a finite-means bridge from binary prefix rows to compact-uniform-continuity arguments without importing countable choice, host tree sets, open-cover compactness, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4195.1 (FanCompact carrier)**.** *A* $\mathsf{FanCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, L, T, W, R, I, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{Bool}^{\uparrow}$ *alphabet row, recording the two branch symbols available at each binary prefix.*
2. *L is the* $\mathsf{List}^{\uparrow}$ *prefix row, recording finite binary words, prefix extension, and prefix concatenation as finite rows.*
3. *T is the finite binary prefix tree row admitted by the packet, with each node read only through B and L.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite prefix observed before a branch consumer reads the stream.*
5. *R is the bar-cover row, recording a finite* ProbeBundle *of prefix tests whose success covers every admitted stream route.*
6. *I is the finite-bar induction ledger, recording the leaf tests, backward prefix step, and root conclusion used by the fan argument.*
7. *H records componentwise* hsame *transport for $B, L, T, W, R, I, C, P, N$.*
8. *C records displayed* Cont *replay from a binary-prefix request through the stream window, bar row, induction ledger, compact-metric handoff, and uniform-modulus consumer boundary.*
9. *P is the* Pkg *provenance over* $\mathsf{FanCompact}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{FanCompact}^\uparrow}$ *row.*

The classifier compares accepted packets only through $B, L, T, W, R, I, H, C, P, N$. No row stores a countable-choice selector, a host tree set, an open-cover compactness theorem, a selected infinite branch outside the displayed stream windows, or completeness of $\mathsf{Real}^\uparrow$.

Lean4 ✓ `BEDC.Derived.FanCompactUp.FanCompactTasteGate single carrier alignment`

Theorem 4195.2 (FanCompact finite bar induction)**.** *For an accepted* $\mathsf{FanCompact}^\uparrow$ *carrier $F = (B, L, T, W, R, I, H, C, P, N)$, every public bar-coverage read factors through the finite route*

$$B \longmapsto L \longmapsto T \longmapsto W \longmapsto R \longmapsto I.$$

The induction ledger I is the only row that may turn finite prefix coverage into a root conclusion, and the resulting handoff can be consumed by $\mathsf{CompactMetric}^\uparrow$ *and* $\mathsf{UniformModulus}^\uparrow$ *only through the displayed replay row C and provenance row P.*

Lean4 ✓ `BEDC.Derived.FanCompactUp.FanCompactCarrier finite bar induction`

Proof. Project the carrier. The binary alphabet row B and finite prefix row L are the only sources from which the tree row T can be read.

The stream window row W fixes the observed prefix before any bar test is applied. The bar row R is therefore a finite $\mathsf{ProbeBundle}$ over displayed prefixes, not a host set of infinite branches.

The ledger I supplies the leaf checks and the backward prefix step. Applying it produces the root bar conclusion for the admitted prefix tree while keeping every step attached to B, L, T, W, R.

Finally C and P route the result to compact-metric and uniform-modulus consumers. Since the excluded objects are not coordinates of F, the route exports no countable choice, host tree set, open-cover compactness, selected branch outside the window rows, or $\mathsf{Real}^\uparrow$ completeness. □

Theorem 4195.3 (FanCompact NameCert obligations)**.** *For the carrier of Definition 4195.1, the local* $\mathsf{NameCert}_{\mathsf{FanCompact}^\uparrow}$ *surface consists exactly of carrier admission for $F = (B, L, T, W, R, I, H, C, P, N)$, Boolean alphabet exposure through B, finite prefix exposure through L, binary tree admission through T, finite stream-window exposure through W, bar-cover exposure through R, finite-bar induction through I, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 4195.1. The packet exposes exactly the ten rows $B, L, T, W, R, I, H, C, P, N$.

Read B, L, T, W, R, I in order. Boolean symbols and finite lists determine the prefix rows, the stream window fixes the observed branch segment, the bar row lists the finite tests, and the induction ledger supplies the only permitted root conclusion.

Transport, replay, provenance, and local naming are then read through H, C, P, N. These rows preserve the finite prefix route and do not add countable choice, host tree sets, open-cover compactness, Real completeness, or selected infinite branches. □

Closure status for $\mathsf{NameCert}_{\mathsf{FanCompact}^\uparrow}$**.**

Constructive story: A $\mathsf{FanCompact}^\uparrow$ packet is generated from Boolean alphabet rows, finite binary prefix rows, a finite prefix tree, stream-name windows, a finite bar-cover ProbeBundle, a finite-bar induction ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FanCompact}^\uparrow}$, seed)

Scope closed: Definition 4195.1, Definition 4195.2, and Definition 4195.3 seed the finite fan-compactness certificate surface for compact-metric and uniform-modulus consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FanCompact}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, countable choice, host tree sets, open-cover compactness, selected infinite branches outside displayed stream windows, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, finite bar-cover exposure, induction-ledger exactness, stream-window routing, compact-metric handoff, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FanCompactUp.

Chapter 4196

A Concrete Naming Certificate for $\mathsf{BoundedNormalizationCandidate}^{\uparrow}$

Following Tait and Girard reducibility candidates, the $\mathsf{BoundedNormalizationCandidate}^{\uparrow}$ packet records a finite candidate-mediated normalization boundary for MetaCIC closed terms. It reads the audit surface of chapter 9383 through the existing normalization audit packet of chapter 3779, the critical-path ledger of chapter 765, and the normalization frontier of chapter 892. The packet names a bounded fuel row, closed-term row, candidate row, Pi and application adequacy rows, no-infinite-reduction row, transport, replay, provenance, and local naming; it does not assert global strong normalization for every closed MetaCIC term.

Definition 4196.1 (BoundedNormalizationCandidate carrier)**.** *A* $\mathsf{BoundedNormalizationCandidate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, F, E, A, \Pi, S, I, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed MetaCIC term row, recording the term, type, context boundary, and closedness evidence read by the audit map.*
2. *F is the bounded fuel row, recording the finite reduction budget and the visible step counter for this candidate route.*
3. *E is the reducibility-candidate evidence row, recording the candidate, closed-candidate, or candidate-set membership object consumed by the route.*
4. *A is the application adequacy row, recording the function-side Pi evidence, argument evidence, and application-candidate handoff.*
5. *Π is the Pi adequacy row, recording binder-side candidate data and neutral-normal evidence when a Pi route is inspected.*
6. *S is the strong-normalization projection row, downstream of E, A, Π and bounded by F.*
7. *I is the no-infinite-reduction projection row, downstream of S and still attached to the same candidate evidence.*
8. *R is the frontier-refusal row, recording requests for evidence-free closed-term normalization, unrestricted subject reduction, global confluence, quotient syntax equality, or host evaluator soundness.*

9. *H records componentwise* hsame *transport for $T, F, E, A, \Pi, S, I, R, C, P, N$.*
10. *C records displayed* Cont *replay from a normalization-audit request through the bounded candidate route.*
11. *P is the* Pkg *provenance over* $\mathsf{BoundedNormalizationCandidate}^{\uparrow}$*, chapter 9383,* MetaCICNormalizationAuditPacket $\mathsf{MetaCICCriticalPath}^{\uparrow}$*,* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedNormalizationCandidate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, F, E, A, \Pi, S, I, R, H, C, P, N$. It has no coordinate for unconditional closed-term normalization, evidence-free strong normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluation soundness, or completed closed consistency.

Lean4 ✓ `BEDC.Derived.BoundedNormalizationCandidateUp.BoundedNormalizationCandidateTasteGate single carrier alignment`

Theorem 4196.2 (BoundedNormalizationCandidate NameCert obligations)**.** *For the carrier of Definition 4196.1, the local* $\mathsf{NameCert}_{\mathsf{BoundedNormalizationCandidate}^{\uparrow}}$ *surface consists exactly of carrier admission for $K = (T, F, E, A, \Pi, S, I, R, H, C, P, N)$, closed-term exposure through T, bounded fuel exposure through F, candidate evidence through E, application adequacy through A, Pi adequacy through Π, candidate-mediated strong-normalization projection through S, no-infinite-reduction projection through I, frontier refusal through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier. The closed term row T and bounded fuel row F give the finite normalization request, while E is the only row carrying candidate evidence.

Read the adequacy rows A and Π as refinements of the same candidate route. They do not create a second normalization source; they only describe how applications and Pi-shaped terms remain inside the candidate-mediated boundary.

The strong-normalization projection S is downstream of E, A, Π, F, and the no-infinite-reduction projection I is downstream of S. Requests that drop this evidence pass to the frontier row R.

Transport, replay, provenance, and local naming through H, C, P, N preserve these rows. Since the excluded global principles are absent from the carrier, no NameCert projection can export them. □

Theorem 4196.3 (BoundedNormalizationCandidate frontier handoff)**.** *Every public normalization, strong-normalization, or no-infinite-reduction read from an accepted* $\mathsf{BoundedNormalizationCandidate}^{\uparrow}$ *carrier factors through the finite route*

$$T \longmapsto F \longmapsto E \longmapsto (A, \Pi) \longmapsto S \longmapsto I \longmapsto R.$$

Thus the packet realizes the finite candidate, fuel, closed-term, Pi/application adequacy, and no-infinite-reduction frontier rows used by chapter 9383, without claiming global strong normalization or closing the subject-reduction and confluence boundaries.

Proof. Start with a public normalization read. The closed term row T records the inspected term, and the fuel row F records the finite budget, but neither row alone supplies strong normalization.

The read must pass through E. Candidate, closed-candidate, or candidate-set evidence is then refined by application adequacy A and Pi adequacy Π before the strong-normalization projection S is available.

The no-infinite-reduction projection I reuses the output of S. If a consumer asks for evidence-free normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, or completed closed consistency, the frontier row R keeps that request outside the exported packet.

The structural rows H, C, P, N replay and name this same route for downstream MetaCIC audit consumers. Therefore the handoff is a bounded candidate-mediated frontier object, not a global theorem about all closed MetaCIC terms. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedNormalizationCandidate}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedNormalizationCandidate}^{\uparrow}$ packet is generated from a closed MetaCIC term row, bounded fuel row, reducibility-candidate evidence, application adequacy, Pi adequacy, candidate-mediated SN projection, no-infinite-reduction projection, frontier refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedNormalizationCandidate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4196.1, Definition 4196.2, and Definition 4196.3 seed the finite bounded candidate route for MetaCIC normalization audit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedNormalizationCandidate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, global strong normalization, evidence-free closed-term normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, or completed closed consistency.

Upgrade path: Obligation closure requires checked carrier admission, fuel-route exactness, candidate evidence exposure, Pi and application adequacy routing, SN projection, no-infinite-reduction projection, frontier refusal, transport, replay, provenance, and local naming for BEDC.Derived.BoundedNormalizationCandidateUp.

Chapter 4197

A Concrete Naming Certificate for $\mathsf{ConstructiveBaireThread}^{\uparrow}$

Following Baire, Oxtoby, and Bishop–Bridges, the $\mathsf{ConstructiveBaireThread}^{\uparrow}$ packet records the choice-free complete-metric thread used when L10 Real and Completion consumers read a nested dense-open construction through displayed finite data. It sits after the choice-free Baire-category route of chapter 4123, the complete-metric service of chapter 128, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Specker boundary of chapter 1406. The packet names the thread as finite NameCert data and does not add countable choice, a host generic point, quotient equality of real names, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4197.1 (Constructive Baire thread carrier)**.** *A* $\mathsf{ConstructiveBaireThread}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, K, S, R, E, P, H, C, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireCategoryChoiceFree}^{\uparrow}$ *source row, exposing dense-open requests only as displayed finite obligations.*
2. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-thread row, carrying the nested-ball, radius, and limit-service data visible to the thread.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that schedules finite dense-open requests, nested-ball inspections, and Cauchy-window reads.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for centers, radii, and tolerance comparisons consumed by the thread.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the Baire, complete-metric, stream, and regular-rational rows have been displayed.*
6. *P is the* $\mathsf{SpeckerSequence}^{\uparrow}$ *boundary row used by consumers that test the thread against a non-located or non-choice escape route.*
7. *H stores componentwise* hsame *transport for B, K, S, R, E, P and the structural rows.*
8. *C stores displayed* Cont *replay from a thread request through the dense-open row, complete-metric service, finite window, regular readback, Real seal, Specker boundary, transport, provenance, and local naming rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{ConstructiveBaireThread}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $B, K, S, R, E, P, H, C, N$. It has no coordinate for a countable-choice selector, a host generic point, an infinite intersection object, quotient equality of real names, a selected Specker limit, or ambient completeness outside the displayed complete-metric service.

Lean4 (definition) `BEDC.Derived.ConstructiveBaireThreadUp.ConstructiveBaireThreadUp`

Theorem 4197.2 (Constructive Baire thread NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveBaireThread}^{\uparrow}$ *carrier $T = (B, K, S, R, E, P, H, C, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveBaireThread}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{BaireCategoryChoiceFree}^{\uparrow}$ *row, the* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-thread row, the* $\mathsf{StreamName}^{\uparrow}$ *finite schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{SpeckerSequence}^{\uparrow}$ *boundary row, componentwise transport, displayed replay, and local naming. Every L10 Real or Completion consumer of the thread must read through these rows.*

Lean4 ✓ `BEDC.Derived.ConstructiveBaireThreadUp.ConstructiveBaireThreadCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 4197.1. The analytic rows are B, K, S, R, E, P, and the structural rows are H, C, N.

The Baire and complete-metric rows are read before any real-facing endpoint. The row B supplies only the choice-free dense-open obligations, while K supplies the displayed nested Cauchy service used by the thread.

The finite schedule and readback rows then control the observation route. The row S records the finite windows, R records the regular rational centers and radii, and E is available only after those rows have been displayed.

Finally P, H, C, N preserve the same boundary. Since the carrier has no selector, host generic point, infinite intersection object, quotient real equality, selected Specker limit, or ambient completeness coordinate, the listed rows exhaust the local certificate surface. □

Theorem 4197.3 (Constructive Baire thread nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, *or Specker-facing consumer of an accepted* $\mathsf{ConstructiveBaireThread}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{BaireCategoryChoiceFree}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{SpeckerSequence}^{\uparrow}$$

The route exports a displayed thread for L10 Real and Completion consumers, but it does not export countable choice, a chosen generic point, quotient equality of real names, a selected Specker limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness beyond the named rows.*

Proof. Start with an accepted carrier $T = (B, K, S, R, E, P, H, C, N)$. The dense-open side is exactly B, so the thread reads the Baire obligation through the choice-free packet rather than through an arbitrary sequence of choices.

The complete-metric side is exactly K. It carries the displayed Cauchy-thread service, and the finite schedule S determines which dense-open and nested-ball observations can be replayed.

The real-facing endpoint is downstream of regular rational readback. The row R packages the centers, radii, and tolerance comparisons before E exposes the terminal real-name seal.

The Specker boundary P is read only as a refusal surface for hidden located-limit or choice escape. Transport through H, replay through C, and naming through N preserve the same finite route, so the consumer cannot reach any excluded selector, quotient, host generic point, or ambient completeness object. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveBaireThread}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveBaireThread}^{\uparrow}$ packet is generated from a BaireCategoryChoiceFree source row, a CompleteMetric Cauchy-thread row, a finite StreamName schedule, a RegSeqRat readback, a RealUp seal, a SpeckerSequence boundary row, componentwise hsame transport, displayed Cont replay, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveBaireThread}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4197.1, Definition 4197.2, and Definition 4197.3 seed the choice-free complete-metric thread consumed by L10 Real and Completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveBaireThread}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, selected generic points, host infinite intersections, quotient real equality, selected Specker limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-open scheduling, complete-metric thread service, regular-rational readback, Real sealing, Specker nonescape, transport, replay, and local naming for the same finite packet.

Chapter 4198

A Concrete Naming Certificate for $\mathsf{Mollifier}^{\uparrow}$

Following Schwartz and Sobolev constructive analysis, the $\mathsf{Mollifier}^{\uparrow}$ packet records the finite smooth-kernel surface used when a weak or distributional object is regularized through displayed local data. It sits after the Schwartz-test carrier of chapter 3399, the Sobolev ledger of chapter 440, the weak-derivative handoff of chapter 2210, the distribution-derivative action route of chapter 3751, the continuous-map boundary of chapter 130, the terminal real-name seal of chapter 38, and the dyadic tolerance ledger of chapter 291. The packet names only the finite kernel, support-radius, normalization, convolution-window, transport, replay, provenance, and local naming rows; it does not import host integration, choice, quotient function equality, or ambient completeness.

Definition 4198.1 (Mollifier carrier)**.** *A* $\mathsf{Mollifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, R, N, P, C, H, L)$$

with the following displayed rows:

1. *S is the smooth-kernel row, naming the Schwartz-test or smooth compact-support profile together with the visible derivative-order windows consumed by regularization.*
2. *R is the support-radius row, recording the dyadic radius, local support inclusion, and finite locality budget.*
3. *N is the normalization row, recording the unit-mass ledger as displayed* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparisons rather than as a host integral.*
4. *P is the convolution-window row, recording the finite source window, target window, translation request, and scale request read by a Sobolev, weak-derivative, distribution-derivative, or continuous-map consumer.*
5. *C stores displayed* Cont *replay from a regularization request through the kernel, support, normalization, convolution-window, real, dyadic, and local naming rows.*
6. *H stores componentwise* hsame *transport for S, R, N, P, C, L and the sibling rows named by the request.*
7. *L is the local* $\mathsf{NameCert}_{\mathsf{Mollifier}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through S, R, N, P, C, H, L. It has no coordinate for host integration, a selected approximate identity, quotient equality of functions or distributions, completed test-function topology, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MollifierUp.MollifierTasteGate single carrier alignment`

Theorem 4198.2 (Mollifier NameCert obligations)**.** *For every accepted* $\mathsf{Mollifier}^{\uparrow}$ *carrier* $M = (S, R, N, P, C, H, L)$*, the local* $\mathsf{NameCert}_{\mathsf{Mollifier}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed smooth-kernel row, support-locality row, normalization ledger, convolution-window route, nonescape boundary, componentwise transport, displayed replay, provenance inherited from the named analysis siblings, and local naming. Every Sobolev, weak-derivative, distribution-derivative, continuous-map, real, or dyadic consumer of the packet must read through these rows.*

Proof. Carrier admission is projection from Definition 4198.1. The analytic rows are S, R, N, P, and the structural rows are C, H, L.

The support-locality and normalization obligations are separate displayed rows. The radius row R confines every kernel read to the named local window, while N exposes only the finite real and dyadic ledger needed for unit normalization.

The convolution route is the row P. It records the source window, target window, translation request, and scale request before any downstream consumer may treat the packet as a regularizing kernel.

Finally C, H, L replay, transport, and name the same rows. Since no host integral, selected approximate identity, quotient function equality, completed test-function topology, choice principle, or ambient completeness coordinate appears in the carrier, the listed rows exhaust the local certificate surface. □

Theorem 4198.3 (Mollifier convolution regularization route)**.** *Let* $M = (S, R, N, P, C, H, L)$ *be an accepted* $\mathsf{Mollifier}^{\uparrow}$ *carrier. Any Sobolev-facing or weak-derivative-facing regularization read reaches a convolution output only through the displayed finite route*

$$S \longmapsto R \longmapsto N \longmapsto P \longmapsto C \longmapsto H \longmapsto L.$$

The same route is the only route by which a distribution-derivative or continuous-map consumer may cite the mollifier packet. The consumer receives smooth-kernel, support-radius, normalization, convolution-window, $\mathsf{Real}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, transport, replay, provenance, and local naming data, but it receives no host integration operator, no choice-selected approximate identity, no quotient equality of functions or distributions, and no ambient completeness theorem.*

Proof. Start with a Sobolev-facing or weak-derivative-facing regularization request. The request first reads the kernel row S and the support-radius row R, so the smooth profile and its locality budget are displayed before any convolution output is named.

The normalization row N is then read as a finite real and dyadic ledger. It supplies the unit-mass boundary needed by the packet without adding a host integral or an external measure-space completion.

The convolution-window row P fixes the source window, target window, translation request, and scale request. Distribution-derivative and continuous-map consumers use the same row, so their reads cannot bypass the displayed kernel and radius data.

Transport through H, replay through C, and local naming through L preserve that finite route. The excluded host integration, selected approximate identity, quotient equality, choice, and ambient completeness objects are not carrier rows, so they cannot be exported by the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{Mollifier}\uparrow}$**.**

Constructive story: A $\mathsf{Mollifier}^{\uparrow}$ packet is generated from a smooth-kernel row, support-radius row, normalization ledger, convolution-window row, displayed Cont replay, componentwise hsame transport, provenance through the named analysis siblings, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Mollifier}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4198.1, Definition 4198.2, and Definition 4198.3 seed the finite regularization route consumed by Sobolev, weak-derivative, distribution-derivative, continuous-map, Real, and dyadic rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Mollifier}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host integration, a selected approximate identity, quotient equality of functions or distributions, completed test-function topology, choice, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, support locality, normalization ledger exactness, convolution-window routing, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MollifierUp.

Chapter 4199

Arzela–Ascoli Family Compactness NameCert Construction

Following Arzela, Ascoli, and Bishop–Bridges constructive compactness, the ArzelaAscoliFamilyCompactness$^{\uparrow}$ packet records family compactness for equicontinuous continuous-map families as finite BEDC NameCert data. It sits between the Arzela–Ascoli carrier of chapter 412, the equicontinuity family surface of chapter 413, the compact metric source of chapter 129, the continuous-map graph surface of chapter 130, and the uniform-modulus consumer of chapter 369. The packet names the finite family-compactness route; it does not assert an ambient compact-open topology, open-cover compactness, countable choice, selected infinite subsequence choice, or host function equality.

Definition 4199.1 (Arzela–Ascoli family-compactness carrier)**.** *An* ArzelaAscoliFamilyCompactness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, E, K, G, M, W, B, H, C, P, N)$$

with the following displayed rows:

1. *A is the* ArzelaAscoli$^{\uparrow}$ *row naming the compact-continuity packet over source nets, target completion rows, finite family graphs, pointwise image rows, and handoff ledgers.*
2. *E is the* EquicontinuityFamily$^{\uparrow}$ *row naming the shared finite-center equicontinuity modulus for the family.*
3. *K is the* CompactMetric$^{\uparrow}$ *source row whose finite probe bundle and compact-metric coverage supply the source windows.*
4. *G is the* ContinuousMap$^{\uparrow}$ *family graph row, storing each displayed family member as graph and pointwise-modulus data.*
5. *M is the* UniformModulus$^{\uparrow}$ *handoff row, receiving only the shared finite-radius and tolerance rows extracted from E and K.*
6. *W is the family window row, listing the finite source probes, family indices, target observations, and diagonal readback windows visible to the compactness consumer.*
7. *B is the bounded image row, retaining the pointwise finite image bundles required before any family-compactness read is exported.*
8. *H records componentwise* hsame *transport for Arzela–Ascoli, equicontinuity, compact-metric, continuous-map, uniform-modulus, window, bounded-image, replay, provenance, and naming rows.*

9. *C records displayed* Cont *replay from a family-compactness request through A, E, K, G, M, W, B.*
10. *P is the* Pkg *provenance over* $\mathsf{ArzelaAscoliFamilyCompactness}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFamilyCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, E, K, G, M, W, B, H, C, P, N$. It has no coordinate for compact-open topology, host function extensionality, selected subsequence choice, countable choice, open-cover compactness, or ambient completion outside the displayed rows.

Lean4 ✓ `BEDC.Derived.ArzelaAscoliFamilyCompactnessUp.ArzelaAscoliFamilyCompactnessTasteGate`
`single carrier alignment`

Theorem 4199.2 (Arzela–Ascoli family-compactness NameCert obligations)**.** *For every accepted* $\mathsf{ArzelaAscoliFamilyCompactness}^{\uparrow}$ *carrier*

$$F = (A, E, K, G, M, W, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFamilyCompactness}^{\uparrow}}$ *surface consists exactly of carrier admission, Arzela–Ascoli packet exposure, equicontinuity-family exposure, compact-metric source-window exposure, continuous-map graph exposure, uniform-modulus handoff, finite family-window readback, bounded-image retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 4199.1. The rows $A, E, K, G, M, W, B, H, C, P, N$ are the only readable coordinates of the packet.

The rows A and E supply the compact-continuity and equicontinuity-family surfaces. The compact-metric row K supplies finite source probes, the continuous-map row G supplies graph and pointwise-modulus reads, and the uniform-modulus row M receives only the shared finite tolerance handoff.

The family-window row W and bounded-image row B keep the diagonal and image-bundle reads visible before any compactness consumer can cite the packet. These rows are finite BEDC histories rather than host-level choices of a subsequence or function-space cover.

Finally H, C, P, N transport, replay, source, and name exactly that inventory. Since the carrier has no compact-open, function-extensionality, selected-subsequence, countable-choice, open-cover, or ambient-completion coordinate, none of those objects can be exported. □

Theorem 4199.3 (Arzela–Ascoli family-compactness finite route)**.** *Every family-compactness consumer of an accepted* $\mathsf{ArzelaAscoliFamilyCompactness}^{\uparrow}$ *packet factors through the sequence of displayed sibling rows*

$$\mathsf{ArzelaAscoli}^{\uparrow}, \quad \mathsf{EquicontinuityFamily}^{\uparrow}, \quad \mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}, \quad \mathsf{UniformModulus}^{\uparrow}.$$

The route reads finite source probes, family graph rows, shared equicontinuity radii, bounded target-image rows, and uniform-modulus handoff data before the local $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFamilyCompactness}^{\uparrow}}$ *row is available.*

Proof. Start with the obligation theorem, Definition 4199.2. It lists sibling exposure, source-window exposure, graph exposure, handoff, window readback, and bounded-image retention as required rows of the local NameCert surface.

Read the siblings in the displayed order. The Arzela–Ascoli row supplies the compact-continuity packet, the equicontinuity-family row supplies the shared radius ledger, the compact-metric row

supplies finite source probes, the continuous-map row supplies graph observations, and the uniform-modulus row receives the finite tolerance handoff.

The structural rows H, C, P, N preserve this sequence. A consumer therefore reaches family compactness only through the finite row inventory of the carrier and not through an ambient compactness theorem or selected host object. □

Falsifiable prediction: Every accepted $\mathsf{ArzelaAscoliFamilyCompactness}^{\uparrow}$ consumer read displays ArzelaAscoli, EquicontinuityFamily, CompactMetric, ContinuousMap, UniformModulus, finite family-window, bounded-image, transport, replay, provenance, and local NameCert rows before exporting a family-compactness packet.

Independence witness: arzelaascoli, equicontinuityfamily, compactmetric, continuousmap, uniformmodulus: none is bijective to $\mathsf{ArzelaAscoliFamilyCompactness}^{\uparrow}$ because the packet jointly records compact-continuity, shared equicontinuity, compact source windows, graph rows, uniform-modulus handoff, family-window readback, bounded-image retention, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFamilyCompactness}^{\uparrow}}$.

Constructive story: An $\mathsf{ArzelaAscoliFamilyCompactness}^{\uparrow}$ packet is generated from ArzelaAscoli, EquicontinuityFamily, CompactMetric, ContinuousMap, UniformModulus, finite family-window, bounded-image, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArzelaAscoliFamilyCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4199.1, Definition 4199.2, and Definition 4199.3 seed the finite family-compactness route for equicontinuous continuous-map families over compact metric sources.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArzelaAscoliFamilyCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim compact-open topology, host function extensionality, selected infinite subsequences, countable choice, arbitrary open-cover compactness, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sibling exposure, compact source-window exposure, continuous-map graph exposure, uniform-modulus handoff, family-window readback, bounded-image retention, transport, replay, provenance, and local naming for BEDC.Derived.ArzelaAscoliFamilyCompactnessUp.

Chapter 4200

SR Route Dependency Audit NameCert Construction

The $\mathsf{SRRouteDependencyAudit}^{\uparrow}$ packet realizes the dependency audit surface for the explicit bundle subject-reduction discharge route of chapter 9374. It reads the subject-reduction route packet of chapter 787, the route-audit packet of chapter 793, the route triangle of chapter 796, and the MetaCIC open-frontier ledger of chapter 762. The packet records which finite rows a downstream preservation consumer must display before treating the discharge route as available.

Definition 4200.1 (SR route dependency audit carrier)**.** *An* $\mathsf{SRRouteDependencyAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, U, T, F, B, K, O, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{SubjectReductionRoute}^{\uparrow}$ *row naming the explicit bundle discharge route.*
2. *U is the* $\mathsf{SubjectReductionRouteAudit}^{\uparrow}$ *row recording the audited four-row payload and socket handoff.*
3. *T is the* $\mathsf{SubjectReductionRouteTriangle}^{\uparrow}$ *row separating bundle and obstruction coordinates.*
4. *F is the* $\mathsf{MetaCICOpenFrontierLedger}^{\uparrow}$ *row naming the open MetaCIC subject-reduction boundary.*
5. *B is the bundle-dependency row, listing the four discharge hypotheses as finite bundle coordinates.*
6. *K is the route-dependency row, listing the same four coordinates through explicit bundle publication.*
7. *O is the obstruction-boundary row stating that the audit packet does not inhabit either route for the closed-CIC substrate.*
8. *H records componentwise* hsame *transport for route, audit, triangle, frontier, dependency, obstruction, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from a preservation request through R, U, T, F, B, K, O.*
10. *P is the* Pkg *provenance over* $\mathsf{SRRouteDependencyAudit}^{\uparrow}$, $\mathsf{SubjectReductionRoute}^{\uparrow}$, $\mathsf{SubjectReductionRouteAudit}^{\uparrow}$, $\mathsf{SubjectReductionRouteTriangle}^{\uparrow}$, $\mathsf{MetaCICOpenFrontierLedger}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. N is the local $\mathsf{NameCert}_{\mathsf{SRRouteDependencyAudit}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $R, U, T, F, B, K, O, H, C, P, N$. It has no coordinate for an inhabited SubjectReductionDischargeBundle*, a discharged dependent-codomain premise, or a closed subject-reduction theorem.*

Lean4 ✓ `BEDC.Derived.SRRouteDependencyAuditUp.SRRouteDependencyAuditTasteGate single carrier alignment`

Theorem 4200.2 (SR route dependency audit obligations)**.** *For every accepted* $\mathsf{SRRouteDependencyAudit}^{\uparrow}$ *carrier*

$$A = (R, U, T, F, B, K, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SRRouteDependencyAudit}^{\uparrow}}$ *surface consists exactly of carrier admission, subject-reduction route exposure, route-audit exposure, triangle exposure, MetaCIC open-frontier exposure, bundle-dependency visibility, route-dependency visibility, obstruction-boundary retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 4200.1. The dependency audit has exactly the route rows R, U, T, F, the dependency rows B, K, the obstruction row O, and the structural rows H, C, P, N.

The subject-reduction route and route-audit rows expose the common four-field discharge payload. The route triangle separates bundle use and obstruction retention, while the open-frontier ledger keeps the MetaCIC subject-reduction boundary visible.

The bundle and route dependency rows are compared only as two publications of the same four finite coordinates. They do not create a new discharge premise and do not inhabit the missing closed-CIC bundle.

Finally H, C, P, N transport, replay, source, and name only these rows. Since the carrier has no coordinate for an inhabited discharge bundle, dependent-codomain discharge, or closed subject-reduction theorem, none of those endpoints can be exported. □

Theorem 4200.3 (SR route dependency obstruction nonescape)**.** *Any preservation-facing consumer of an accepted* $\mathsf{SRRouteDependencyAudit}^{\uparrow}$ *packet must read the obstruction row O together with the open-frontier row F before it can cite either the bundle dependency row B or the route dependency row K. The audit therefore exposes the discharge route as a finite dependency surface and does not turn it into an available closed-CIC subject-reduction theorem.*

Proof. Use Definition 4200.2. It requires route exposure, route-audit exposure, triangle exposure, open-frontier exposure, and obstruction retention as part of the same local NameCert surface.

The row F names the MetaCIC subject-reduction frontier, and O records that the closed-CIC substrate has not supplied the missing discharge inhabitant. Thus a consumer reading B or K reads dependency accounting, not an endpoint theorem.

The replay and provenance rows preserve this order. They carry the preservation request through the displayed route inventory and cannot erase F or O. □

Falsifiable prediction: A subject-reduction-route consumer refutes $\mathsf{SRRouteDependencyAudit}^{\uparrow}$ if it obtains the bundle route without displaying subject-reduction-route, subject-reduction-route-audit, subjectreductionroutetriangle, and metacic-open-frontier-ledger rows.

Independence witness: subject-reduction-route, subject-reduction-route-audit, subjectreductionroutetriangle, metacic-open-frontier-ledger: none is bijective to $\mathsf{SRRouteDependencyAudit}^{\uparrow}$ because the audit packet jointly records route exposure, audited payload, bundle/obstruction separation, open-frontier retention, dependency rows, transport, replay, provenance, and local naming.

The Lean follow-up must provide Nontrivial SRRouteDependencyAudit$^{\uparrow}$ and FieldFaithful SRRouteDependencyAud instances. The instances must keep $R, U, T, F, B, K, O, H, C, P, N$ as separate displayed fields before any checked theorem cites the packet as a dependency-audit surface.

Closure status for NameCert$_{\text{SRRouteDependencyAudit}^{\uparrow}}$.

Constructive story: An SRRouteDependencyAudit$^{\uparrow}$ packet is generated from subject-reduction route, route-audit, route-triangle, open-frontier, bundle-dependency, route-dependency, obstruction, transport, replay, provenance, and local naming rows.

Theory closure: TheoryGate(NameCert$_{\text{SRRouteDependencyAudit}^{\uparrow}}$, seed)

Scope closed: Definition 4200.1, Definition 4200.2, and Definition 4200.3 seed the finite dependency audit surface for the bundle subject-reduction discharge route.

Formal verification: FormalStatus(NameCert$_{\text{SRRouteDependencyAudit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not inhabit the four MetaCIC subject-reduction discharge hypotheses, construct a discharge bundle, prove closed subject reduction, give Lean verification, or bridge check the packet.

Upgrade path: Obligation closure requires checked carrier admission, route exposure, route-audit exposure, triangle exposure, open-frontier exposure, bundle and route dependency visibility, obstruction nonescape, Nontrivial and FieldFaithful instances, transport, replay, provenance, and local naming for BEDC.Derived.SRRouteDependencyAuditUp.

Chapter 4201

A Concrete Naming Certificate for $\mathsf{SeparatedReflectionUniversal}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{SeparatedReflectionUniversal}^{\uparrow}$ packet records the universal property of separated reflection as finite BEDC NameCert data. It reads the separated completion route of chapter 1612, the separated metric classifier of chapter 1411, and the Hausdorff reflection boundary of **??**. The packet is a universal-property surface for factorization through separated targets; it does not introduce quotient objects, choice-selected representatives, host equality of reflected points, or ambient classical Hausdorff completion.

Definition 4201.1 (Separated reflection universal carrier)**.** *A* $\mathsf{SeparatedReflectionUniversal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, M, H, F, Q, T, R, P, N)$$

with the following displayed rows:

1. *S is the source premetric or uniform source row whose indistinguishability classifier is being reflected.*
2. *M is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier row exposing the separated target comparison used by the reflection.*
3. *H is the* $\mathsf{HausdorffReflection}^{\uparrow}$ *row recording the Hausdorff boundary through which reflected equality is read.*
4. *F is the factorization row: every displayed map from S into a separated target factors through the reflected classifier row.*
5. *Q is the uniqueness row, comparing two displayed factorizations only by the separated target classifier supplied by M and H.*
6. *T records componentwise* hsame *transport for source, classifier, Hausdorff boundary, factorization, uniqueness, provenance, replay, and naming rows.*
7. *R records displayed* Cont *replay from a separated-target request through S, M, H, F, Q, T.*
8. *P is the* Pkg *provenance over* $\mathsf{SeparatedReflectionUniversal}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{HausdorffReflection}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparatedReflectionUniversal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, H, F, Q, T, R, P, N$. It has no coordinate for quotient carriers, selected representatives, host point equality, countable choice, hidden separated completions, or ambient Hausdorff replacement.

Lean4 ✓ `BEDC.Derived.SeparatedReflectionUniversalUp.SeparatedReflectionUniversalTasteGate single carrier alignment`

Theorem 4201.2 (Separated reflection universal NameCert obligations)**.** *For every accepted* $\mathsf{SeparatedReflectionUniversal}^{\uparrow}$ *carrier*

$$U = (S, M, H, F, Q, T, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SeparatedReflectionUniversal}^{\uparrow}}$ *surface consists exactly of source admission, separated classifier exposure, Hausdorff boundary readback, displayed factorization, uniqueness by separated comparison, componentwise transport, displayed continuation replay, provenance, and local naming through $S, M, H, F, Q, T, R, P, N$.*

Proof. Project the carrier of Definition 4201.1. The rows $S, M, H, F, Q, T, R, P, N$ are the entire public packet.

Read S, M, H first. The source row supplies the pre-reflection indistinguishability data, while the separated metric and Hausdorff rows expose the target comparison used by every separated read.

The factorization and uniqueness rows are then forced through F and Q. Transport, replay, provenance, and naming preserve that same route through T, R, P, N.

Since the carrier has no coordinate for quotient carriers, selected representatives, host equality, choice, hidden separated completions, or ambient Hausdorff replacement, those objects cannot appear in the local certificate. □

Theorem 4201.3 (Separated reflection universal factorization)**.** *Let $U = (S, M, H, F, Q, T, R, P, N)$ be an accepted* $\mathsf{SeparatedReflectionUniversal}^{\uparrow}$ *carrier. Every displayed map from the source row S into a separated target whose comparison is read through M and H factors through the row F, and every consumer of the factorization must read the route*

$$S, M, H \longmapsto F$$

before it can inspect transport, replay, provenance, or local naming.

Proof. Apply the NameCert obligation theorem, Definition 4201.2. It identifies S, M, H, F as the whole factorization-facing prefix of the packet.

The source row is read before the separated target classifier, and the Hausdorff boundary is read before any reflected equality is consumed. The factorization row F therefore has no independent source of map data beyond S, M, H.

The structural rows T, R, P, N only transport, replay, source, and name that route. They cannot add a second factorization object or a choice-selected representative. □

Theorem 4201.4 (Separated reflection universal uniqueness)**.** *For every accepted* $\mathsf{SeparatedReflectionUniversal}^{\uparrow}$ *carrier $U = (S, M, H, F, Q, T, R, P, N)$, two displayed factorizations out of S are publicly equal only through the uniqueness row Q over the separated comparison supplied by M and H. The uniqueness read exports no quotient equality, host point equality, selected representative equality, choice principle, or hidden completion equality.*

Proof. Start from the factorization theorem, Definition 4201.3. It places both displayed factorizations on the same $S, M, H \mapsto F$ route.

Now read the uniqueness row Q. Its classifier is the separated target comparison supplied by M and H, so the equality of factorization witnesses is a displayed separated comparison, not a host equality claim.

Finally use the absence clauses in Definition 4201.1. No row carries quotient equality, selected representatives, choice, or hidden completion equality, so the stated separated uniqueness route exhausts the public claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedReflectionUniversal}\uparrow}$.

Constructive story: A $\mathsf{SeparatedReflectionUniversal}^{\uparrow}$ packet is generated from a source premetric or uniform row, a separated metric classifier row, a Hausdorff reflection boundary, displayed factorization, uniqueness by separated comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedReflectionUniversal}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4201.1, Definition 4201.2, Definition 4201.3, and Definition 4201.4 seed the universal-property route for separated reflection over finite BEDC rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedReflectionUniversal}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient carriers, selected representatives, host equality of reflected points, countable choice, hidden separated completions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, separated classifier exposure, Hausdorff boundary readback, factorization, uniqueness, transport, replay, provenance, and local naming for BEDC.Derived.SeparatedReflectionUniversalUp.

The rational interval locator also consumes the diagonal finite-window route of chapter 4080 before its rational lower and upper endpoint rows are exported to Real-facing consumers.

Chapter 4202

A Concrete Naming Certificate for $\mathsf{RationalIntervalLocator}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RationalIntervalLocator}^{\uparrow}$ packet records the finite interval-locator rows by which a Real-facing consumer asks for rational lower and upper bounds at a displayed tolerance. It sits between the located interval algorithms of chapter 1711 and chapter 3971, the stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet isolates the rational interval locator as finite BEDC data; it is not a host interval, quotient real representative, trichotomy principle, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 4202.1 (Rational interval locator carrier)**.** *A* $\mathsf{RationalIntervalLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (L_0, U_0, I, T, S, R, A, H, C, P, N)$$

with the following displayed rows:

1. L_0 *is the rational lower-bound row, exposing the left endpoint candidate read at the requested precision.*
2. U_0 *is the rational upper-bound row, exposing the right endpoint candidate read at the same precision.*
3. I *is the interval-inclusion row, recording that the displayed Real-facing name is bracketed by* L_0 *and* U_0 *through finite rational comparisons.*
4. T *is the tolerance-request row, recording the dyadic or rational tolerance that the locator is asked to meet.*
5. S *is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the tolerance request.*
6. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the same finite window.*
7. A *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, naming the Real-facing read that receives the interval locator output.*
8. H *records componentwise* hsame *transport for lower-bound, upper-bound, inclusion, tolerance, window, readback, real-seal, replay, provenance, and local naming rows.*
9. C *records displayed* Cont *replay from a tolerance request through* L_0, U_0, I, T, S, R, A.

10. *P is the* Pkg *provenance over* $\mathsf{RationalIntervalLocator}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalLocator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L_0, U_0, I, T, S, R, A, H, C, P, N$. It has no coordinate for host intervals, quotient-real representatives, trichotomy, countable choice, selected real limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4202.2 (Rational interval locator NameCert obligations)**.** *For every accepted* $\mathsf{RationalIntervalLocator}^{\uparrow}$ *carrier*

$$L = (L_0, U_0, I, T, S, R, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalIntervalLocator}^{\uparrow}}$ *surface consists exactly of carrier admission, endpoint order, tolerance response, locator inclusion, regular-rational readback stability, Real-facing seal stability, componentwise transport, displayed replay, provenance, and ledger non-escape through $L_0, U_0, I, T, S, R, A, H, C, P,$*

Proof. Project the carrier of Definition 4202.1. The lower and upper endpoint rows L_0, U_0, the inclusion row I, the tolerance row T, the stream and readback rows S, R, the real-seal row A, and the structural rows H, C, P, N are the whole packet.

Endpoint order and locator tolerance are read from L_0, U_0, I, T. These rows record the rational bracket and the displayed precision request before any Real-facing consumer can inspect the output.

Readback stability is supplied by S, R, A. The stream window opens the finite observations, the regular rational row replays them as a readback, and the terminal real row seals the same finite route.

Finally H, C, P, N transport, replay, source, and name the displayed rows. Since no further coordinate is present, host intervals, quotient-real representatives, trichotomy, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness remain outside the ledger. □

Theorem 4202.3 (Rational interval locator Real readback)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RationalIntervalLocator}^{\uparrow}$ *carrier factors through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before it exports a rational bracket to a located-interval consumer.*

Proof. Let

$$L = (L_0, U_0, I, T, S, R, A, H, C, P, N)$$

be an accepted carrier. The tolerance row T supplies the finite precision request, and provenance in P attaches that request to the dyadic rational tolerance ledger.

The stream and regular-rational rows S, R then expose the finite window and readback route. The real-seal row A is downstream of the same rows, so a Real-facing consumer receives the interval only after the L10 route has been displayed.

The located-interval bisection and Bolzano consumers can read L_0, U_0, I only through the structural rows H, C, P, N. Therefore the route factors through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and cannot pass through host intervals, quotient reals, trichotomy, countable choice, or ambient real completeness. □

Theorem 4202.4 (Rational interval locator dyadic tolerance route)**.** *Every tolerance request for an accepted* $\mathsf{RationalIntervalLocator}^{\uparrow}$ *carrier first reads the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger through chapter 291. It then passes through the* $\mathsf{StreamName}^{\uparrow}$ *window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{Real}^{\uparrow}$ *seal before exposing the rational interval bracket L_0, U_0, I to a located-interval consumer.*

Proof. Let

$$L = (L_0, U_0, I, T, S, R, A, H, C, P, N)$$

be an accepted carrier. Project the tolerance row T and provenance row P. These rows identify the requested precision as a dyadic rational tolerance supplied by the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger rather than by host interval arithmetic.

Next project S, R, A. The StreamName window S opens the finite observations for the displayed tolerance, the RegSeqRat row R replays those observations as regular rational data, and the Real seal A receives only that finite readback route.

Finally apply Definition 4202.3. It already factors every Real-facing read through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, so the rational bracket rows L_0, U_0, I are exposed only after the dyadic tolerance route has been displayed. □

Theorem 4202.5 (Rational interval locator Real-seal lattice)**.** *Every Real-facing locator read of an accepted* $\mathsf{RationalIntervalLocator}^{\uparrow}$ *carrier*

$$L = (L_0, U_0, I, T, S, R, A, H, C, P, N)$$

factors through the finite lattice

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before exposing L_0, U_0, I to located-interval and real-separability consumers. The lattice exposes only dyadic tolerance, finite stream windows, regular rational readback, and the terminal Real seal; it refuses host intervals, trichotomy, quotient reals, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a Real-facing locator read and project the accepted carrier. The tolerance row T and provenance row P attach the requested precision to the $\mathsf{DyadicRatCore}^{\uparrow}$ route, so no host interval object is available before the dyadic ledger is read.

Apply Definition 4202.4. The dyadic request opens the $\mathsf{StreamName}^{\uparrow}$ window row S, then the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, and only then the terminal $\mathsf{Real}^{\uparrow}$ seal row A.

Apply Definition 4202.3. That theorem exposes the rational bracket rows L_0, U_0, I only after the same route has been displayed. The structural rows H, C, P, N preserve the route for located-interval and real-separability consumers, and the carrier contains no coordinate for trichotomy, quotient reals, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalIntervalLocator}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalIntervalLocator}^{\uparrow}$ packet is generated from rational lower-bound and upper-bound rows, interval inclusion, tolerance requests, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalIntervalLocator}^{\uparrow}}, \text{obligation})$

Scope closed: Definition 4202.1, Definition 4202.2, Definition 4202.3, and Definition 4202.5 seed the finite rational interval locator route for Real-facing readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalIntervalLocator}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host interval arithmetic, quotient-real equality, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint order, tolerance response, locator inclusion, readback stability, Real-facing seal stability, transport, replay, provenance, and ledger non-escape for BEDC.Derived.RationalIntervalLocatorUp.

Theorem 4202.6 (Rational interval locator dyadic Real dependency route)**.** *Every accepted* $\mathsf{RationalIntervalLocator}^{\uparrow}$ *interval read that is consumed by* $\mathsf{RealSeparability}^{\uparrow}$ *must expose the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance rows, the finite* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before the separability consumer can use the locator. The route cites the dyadic ledger of chapter 291, the real-name boundary of chapter 38, and the forward link of Definition 4202.7; it exports no quotient real equality, selected limit, host interval, countable-choice schedule, or ambient completeness.*

Proof. Project the locator carrier of Definition 4202.1. The endpoint rows L_0, U_0, interval row I, tolerance row T, stream window S, readback row R, Real seal A, and structural rows H, C, P, N are the whole accepted interval read.

The dyadic part is visible before the separability handoff. The endpoint and tolerance data are read through L_0, U_0, T and the $\mathsf{DyadicRatCore}^{\uparrow}$ provenance in P, while the finite window and readback rows S, R keep the route inside the StreamName and RegSeqRat corridor.

Now apply the Real-facing route of Definition 4202.3 and the RealSeparability forward link of Definition 4202.7. The seal row A must be displayed before any density or separability consumer can use the bracket, so the locator is consumed only after the $\mathsf{Real}^{\uparrow}$ boundary has been reached.

Since no carrier coordinate names quotient real equality, a selected limit, a host interval object, countable choice, or ambient completeness, the dependency route stops at the displayed dyadic endpoints, tolerance rows, readback row, and Real seal. □

Any subdivision-facing $\mathsf{RationalIntervalLocator}^{\uparrow}$ read must pass through the rational lower and upper bracket rows, the dyadic tolerance ledger, the finite $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal before it is consumed by chapter 3873. The route exports only that displayed locator packet to the located-interval subdivision consumer; it does not supply a host interval, selected limit, quotient real representative, countable-choice schedule, or ambient completeness claim. The $\mathsf{RationalIntervalLocator}^{\uparrow}$ endpoint rows supply the rational lower and upper locator consumed by the regular-Cauchy window lattice of chapter 4060. That consumption is allowed only after the $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal rows are visible, so the edge remains a displayed L10 dependency rather than a host interval, quotient real, selected limit, countable-choice schedule, or ambient completeness claim.

Theorem 4202.7 (Rational interval locator RealSeparability forward link)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *consumer of an accepted* $\mathsf{RationalIntervalLocator}^{\uparrow}$ *carrier reads the rational lower and upper locator rows* L_0, U_0*, the tolerance row* T*, the finite* $\mathsf{StreamName}^{\uparrow}$ *window* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *of chapter 301, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* A *of chapter 38 before any Real density read is exported through chapter 1809. The forward link supplies rational enumeration windows and dyadic tolerance rows; it exports no host interval, selected dense point, quotient real representative, countable-choice schedule, or ambient completeness datum.*

Proof. Project the carrier rows of Definition 4202.1. The lower-bound row L_0, upper-bound row U_0, inclusion row I, tolerance row T, stream window S, regular readback R, Real seal A, and structural rows H, C, P, N are the whole locator packet.

First read the locator surface. The rational endpoint rows L_0, U_0 and the inclusion row I give the finite lower and upper bracket used by the downstream density request, while T identifies the dyadic or rational tolerance to be matched.

Next compose with the Real-separability route. The finite window S and readback R provide the rational enumeration surface consumed by chapter 1809, and the seal row A ensures that the density-facing consumer receives the data only after the $\mathsf{Real}^{\uparrow}$ boundary has been displayed.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since no row stores a host interval, selected dense point, quotient representative, countable-choice schedule, or ambient completeness witness, the forward link is a finite locator-to-separability dependency and nothing beyond that boundary. □

Theorem 4202.8 (Rational interval locator sibling route)**.** *Every accepted* $\mathsf{RationalIntervalLocator}^{\uparrow}$ *read that exports a locator packet consumes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *interval endpoint rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window readback rows, and the* $\mathsf{RealSeparability}^{\uparrow}$ *density rows before the locator boundary is available to any downstream consumer. The route records only the finite endpoint, readback, density, transport, replay, provenance, and local naming surface; it exports no host interval, selected dense point, quotient real representative, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Project the carrier rows of Definition 4202.1. The endpoint rows are the displayed lower and upper rational bounds, while the tolerance and inclusion rows determine which dyadic interval request is being named.

Read the sibling rows in order. The dyadic endpoint data come through chapter 291, the finite window and readback route comes through chapter 301, and the density-facing consumer reads through chapter 1809 only after those rows have been displayed.

The structural rows then transport, replay, source, and name the same packet. Since no row contains a host interval, selected dense point, quotient real representative, countable-choice schedule, or ambient Real-completeness witness, the sibling route is exhausted by the listed finite dependencies. □

The $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$ route passes through chapter 3491, chapter 3732, chapter 4181, chapter 3948, and chapter 4154 before the child files expose the lamination packet.

Chapter 4203

A Concrete Naming Certificate for HyperbolicGeodesicLamination$^{\uparrow}$

The HyperbolicGeodesicLamination$^{\uparrow}$ packet realizes the boundary-paired noncrossing leaf surface of chapter 9463 as finite NameCert data. It sits after the endpoint route of chapter 3491, the Busemann boundary row of chapter 3732, the visual-boundary read of chapter 4181, the cross-ratio comparison of chapter 3948, and the observer-shadow metric of chapter 4154. The packet names a finite lamination handoff, not a completed geodesic space, quotient boundary, physical foliation, global hyperbolic model, or unlogged field-faithfulness assertion.

Downstream boundary-shadow and observer-expansion consumers read the lamination packet through chapter 3813 or chapter 4154, because the noncrossing ledger supplies the leaf-compatibility row consumed by boundary-shadow routing.

Definition 4203.1 (Hyperbolic geodesic lamination carrier)**.** *A* HyperbolicGeodesicLamination$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (E, L, N, M, B, V, H, C, P, F, A)$$

with the following displayed rows:

1. *E is the endpoint-pair row, recording the two boundary-facing endpoints of each displayed leaf.*
2. *L is the geodesic-leaf row, attaching each endpoint pair to a finite geodesic-boundary route.*
3. *N is the noncrossing row, recording the finite compatibility ledger among the displayed leaves.*
4. *M is the hyperbolic-metric read row used when leaf separation or ordering is inspected.*
5. *B is the Busemann row, attaching the leaves to displayed boundary distance-difference data.*
6. *V is the visual-shadow row, recording the observer-facing visual shadow through which the lamination is read.*
7. *H records componentwise* hsame *transport for endpoint-pair, leaf, noncrossing, metric, Busemann, visual-shadow, replay, provenance, refusal, and local naming rows.*
8. *C records displayed* Cont *replay from a boundary-lamination request through E, L, N, M, B, V.*
9. *P is the* Pkg *provenance over* HyperbolicGeodesicLamination$^{\uparrow}$, HyperbolicGeodesicBoundary$^{\uparrow}$, HyperbolicBusemannBoundary$^{\uparrow}$, HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicCrossRatio$^{\uparrow}$, HyperbolicObserverShadowM BHist, hsame, Cont, *and* NameCert *rows.*

10. *F is the refusal row excluding host global laminations, quotient boundary identifications, physical foliations, hidden crossing tests, and unlogged TasteGate witnesses.*
11. *A is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicLamination}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, L, N, M, B, V, H, C, P, F, A$. It has no coordinate for completed geodesic spaces, ambient boundary quotients, host noncrossing predicates, physical laminations, or implicit Nontrivial *and* FieldFaithful *witnesses.*

Theorem 4203.2 (Hyperbolic geodesic lamination NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$ *carrier*

$$G = (E, L, N, M, B, V, H, C, P, F, A),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicLamination}^{\uparrow}}$ *surface consists exactly of endpoint-pair admission, geodesic-leaf admission, noncrossing ledger compatibility, hyperbolic-metric readback, Busemann attachment, visual-shadow exposure, componentwise transport, displayed replay, provenance, explicit refusal, and local naming through $E, L, N, M, B, V, H, C, P, F, A$.*

Proof. Project the carrier of Definition 4203.1. The endpoint, leaf, noncrossing, metric, Busemann, visual-shadow, transport, replay, provenance, refusal, and naming rows are the whole lamination packet.

The endpoint-pair and geodesic-leaf rows E, L are read first. They attach every displayed leaf to finite boundary-facing data rather than to an ambient set of complete geodesics.

The noncrossing and metric rows N, M then record the compatibility tests available to consumers. These tests are displayed rows, so the packet does not import a host noncrossing predicate.

The Busemann and visual-shadow rows B, V bind the leaf family to boundary and observer-facing routes. Finally H, C, P, F, A transport, replay, source, refuse exits, and name the same finite carrier, leaving completed global laminations, quotient boundaries, physical foliations, and implicit TasteGate witnesses outside the certificate. □

Theorem 4203.3 (Hyperbolic geodesic lamination boundary route)**.** *Every boundary-lamination consumer of an accepted* $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$ *carrier must pass through endpoint-pair, geodesic-leaf, noncrossing, hyperbolic-metric, Busemann, visual-shadow, transport, provenance, refusal, and local* NameCert *rows before it can export a lamination handoff.*

Proof. Let

$$G = (E, L, N, M, B, V, H, C, P, F, A)$$

be an accepted carrier. A boundary-facing read starts with E, L, so its endpoints and leaves are displayed before the consumer sees a lamination token.

The noncrossing row N and metric row M supply the finite compatibility and metric-read tests. The Busemann and visual-shadow rows B, V then attach those tests to the boundary and observer-facing surfaces cited by provenance.

Transport and replay through H, C preserve the displayed route, while P, F, A source, refuse exits, and name it. Hence any boundary-lamination handoff factors through the listed rows and cannot be claimed by a consumer that omits endpoint pairs, noncrossing evidence, hyperbolic metric reads, visual-shadow data, transport, provenance, refusal, or local naming. □

Falsifiable prediction: Any boundary lamination consumer omitting endpoint-pair, noncrossing, hyperbolic-metric, visual-shadow, transport, provenance, or local NameCert rows cannot claim the $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$ handoff.

Independence witness: hyperbolic-geodesic-boundary, hyperbolic-busemann-boundary, hyperbolic-visual-boundary, hyperbolic-cross-ratio, hyperbolic-observer-shadow-metric: the geodesic-boundary packet names endpoint routes without the noncrossing ledger, the Busemann packet names distance-difference data without leaf compatibility, the visual-boundary packet names boundary readback without lamination rows, the cross-ratio packet compares boundary quadruples without owning geodesic leaves, and the observer-shadow metric packet reads visible shadows without endpoint-pair noncrossing. None is bijective to $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$.

The future `lean4/BEDC/Derived/HyperbolicGeodesicLaminationUp/TasteGate.lean` file must include explicit Nontrivial $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$ instances. Those instances preserve $E, L, N, M, B, V, H, C, P, F, A$ as distinct fields before a checked carrier-alignment theorem can serve as a TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicLamination}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$ packet is generated from endpoint-pair rows, geodesic-leaf rows, a noncrossing ledger, hyperbolic-metric reads, Busemann attachment, visual-shadow exposure, componentwise hsame transport, displayed Cont replay, Pkg provenance, explicit refusal, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicLamination}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4203.1, Definition 4203.2, and Definition 4203.3 seed the finite boundary-paired noncrossing lamination route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicLamination}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed geodesic spaces, quotient boundary equality, physical foliations, host global laminations, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint-pair admission, geodesic-leaf admission, noncrossing compatibility, metric readback, Busemann attachment, visual-shadow exposure, TasteGate nontriviality, field faithfulness, refusal, and local naming for BEDC.Derived.HyperbolicGeodesicLaminationUp.

The $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$ carrier is anchored in the sibling lattice by the endpoint route of chapter 3491, the Busemann rows of chapter 3732, the visual-boundary readback of chapter 4181, the cross-ratio comparisons of chapter 3948, and the observer-shadow metric data of chapter 4154. A lamination consumer must therefore read endpoint-paired leaves, boundary distance-difference rows, visual shadows, cross-ratio comparison provenance, and observer-shadow metric coordinates as displayed rows before treating the packet as a finite noncrossing lamination handoff.

Chapter 4204

A Concrete Naming Certificate for $\mathsf{BesovSpace}^{\uparrow}$

Following Besov and Triebel's constructive regularity scale, the $\mathsf{BesovSpace}^{\uparrow}$ packet records a finite smoothness-measurement surface between Sobolev weak-gradient data and Holder power-law control. It sits after the Sobolev ledger of chapter 440, the Holder continuity route of chapter 1766, the weak-derivative handoff of chapter 2210, the terminal real-name seal of chapter 38, the finite stream windows of chapter 126, the regular rational readback surface of chapter 301, and the dyadic tolerance ledger of chapter 291. The packet names only displayed smoothness windows, dyadic scale budgets, weak-action rows, real readback, transport, replay, provenance, and local naming; it does not import open-cover compactness, quotient function spaces, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4204.1 (Besov space carrier)**.** *A* $\mathsf{BesovSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Hd, W, R, Q, D, E, T, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *source row, recording the weak-gradient and integrability ledger consumed by the regularity request.*
2. *Hd is the* $\mathsf{HolderContinuity}^{\uparrow}$ *boundary row, recording the visible power-law modulus data used when the Besov packet exposes pointwise smoothness control.*
3. *W is the* $\mathsf{WeakDerivative}^{\uparrow}$ *action row, naming the finite test probes and derivative observations inspected by the scale request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational magnitude data attached to the selected smoothness windows.*
5. *Q is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, selecting the scale windows, test probes, and comparison requests visible to this packet.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic scale, radius, and comparison budget attached to the same windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, Hd, W, R, Q, D have been displayed.*
8. *T stores componentwise* hsame *transport for the regularity, window, tolerance, real-seal, continuation, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from a Besov regularity request through the Sobolev, Holder, weak-derivative, regular-rational, stream, dyadic, and real-seal rows.*
10. *P is the* Pkg *provenance over* $\mathsf{BesovSpace}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{HolderContinuity}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BesovSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, Hd, W, R, Q, D, E, T, C, P, N$. It has no coordinate for an open-cover compactness theorem, quotient equality of function spaces, selected representatives, a completed smoothness scale, host distribution equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BesovSpaceUp.BesovSpaceTasteGate single carrier alignment`

Theorem 4204.2 (Besov space NameCert obligations)**.** *For every accepted* $\mathsf{BesovSpace}^{\uparrow}$ *carrier $B = (S, Hd, W, R, Q, D, E, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BesovSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed Sobolev row, Holder row, weak-derivative action row, regular rational readback row, stream-window schedule, dyadic scale ledger, terminal real seal, componentwise transport, displayed replay, provenance, and local naming rows. Every regularity, PDE, interpolation, or trace-facing consumer of the packet must read through those rows before it cites the Besov smoothness boundary.*

Proof. Carrier admission is projection from Definition 4204.1. The analytic rows are S, Hd, W, R, Q, D, E, and the structural rows are T, C, P, N.

The Sobolev, Holder, and weak-derivative rows have distinct roles. The Sobolev row supplies the weak-gradient and integrability ledger, the Holder row supplies the visible power-law boundary, and the weak-derivative row supplies the finite test-action observations.

The scale and readback rows then fix the measurable part of the packet. The stream schedule Q opens the finite windows, the dyadic ledger D records the scale and comparison budget, the regular rational row R reads the displayed magnitudes, and the real seal E is reached only after those rows have been inspected.

Finally T, C, P, N transport, replay, source, and name the same finite route. Since no open-cover compactness theorem, quotient function-space equality, selected representative, completed smoothness scale, host distribution equality, countable choice, or ambient completeness coordinate appears in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 4204.3 (Besov space L10 handoff)**.** *Every L10 regularity consumer of an accepted* $\mathsf{BesovSpace}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Sobolev}^{\uparrow} \longrightarrow \mathsf{WeakDerivative}^{\uparrow} \longrightarrow \mathsf{HolderContinuity}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{R}$$

The handoff exports displayed smoothness-window data, dyadic scale control, regular rational readback, terminal real seals, componentwise transport, continuation replay, provenance, and local naming. It exports no open-cover compactness theorem, quotient function space, selected representative, host equality of functions or distributions, countable-choice row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the NameCert obligations of Definition 4204.2. They require every accepted regularity read to pass through the Sobolev, Holder, and weak-derivative rows before any downstream smoothness boundary is cited.

Next read the finite scale data. The stream schedule Q chooses the visible windows, while the dyadic ledger D attaches the scale and tolerance budget to those same windows.

The regular rational readback row R and terminal real seal E then report the displayed magnitude data. The structural rows T, C, P, N preserve the route under transport, replay, provenance, and local naming.

Thus an L10 consumer receives exactly the displayed chain from Sobolev and weak-derivative evidence through Holder, stream, dyadic, regular-rational, and real-seal rows. The excluded compactness, quotient, representative-selection, host-equality, choice, and ambient-completeness objects have no carrier coordinate and cannot be exported by the packet. □

Falsifiable prediction: Every accepted $\mathsf{BesovSpace}^{\uparrow}$ regularity consumer must read Sobolev, HolderContinuity, WeakDerivative, StreamName, DyadicRatCore, RegSeqRat, Real, hsame, Cont, Pkg, and local NameCert rows before citing the Besov smoothness boundary.

Independence witness: sobolev, holder-continuity, weak-derivative, real, streamname, regseqrat, dyadicratcore: $\mathsf{BesovSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries smoothness-source rows, pointwise power-law boundary data, weak-action observations, finite windows, dyadic scale budgets, regular rational readback, real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BesovSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{BesovSpace}^{\uparrow}$ packet is generated from Sobolev, HolderContinuity, WeakDerivative, RegSeqRat, StreamName, DyadicRatCore, Real, componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BesovSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4204.1, Definition 4204.2, and Definition 4204.3 seed the finite constructive regularity-space route over Sobolev, HolderContinuity, WeakDerivative, Real, StreamName, RegSeqRat, DyadicRatCore, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BesovSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, open-cover compactness, quotient function spaces, selected representatives, host equality of functions or distributions, countable choice, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, smoothness-window exactness, dyadic-scale ledger stability, regular rational readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BesovSpaceUp.

Chapter 4205

A Concrete Naming Certificate for $\mathsf{LebesgueCoveringDimension}^{\uparrow}$

Following Lebesgue and Hurewicz–Wallman, the $\mathsf{LebesgueCoveringDimension}^{\uparrow}$ packet records covering dimension through finite open-cover refinements with bounded overlap. It sits beside the finite refinement carrier of chapter 1853, the topology row of chapter 88, the metric-ball observation surface of chapter 57, and the finite radius ledger of chapter 452. The packet names only displayed cover rows, refinement rows, and order ledgers; it does not invoke arbitrary open-cover compactness, a selected subcover, or a host dimension theorem.

Definition 4205.1 (Lebesgue covering dimension carrier)**.** *A* $\mathsf{LebesgueCoveringDimension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, U, V, R, O, B, F, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Topology}^{\uparrow}$ *source row together with the metric observation surface needed to read finite* $\mathsf{MetricBall}^{\uparrow}$ *cover cells.*
2. *U is a finite open-cover request row, displayed as named topology opens and local metric-ball witnesses.*
3. *V is a finite refinement row whose entries are open rows over the same source X.*
4. *R is the refinement-containment ledger, recording for each row of V the named row of U that contains it.*
5. *O is the order-at-most-n overlap ledger, recording that every displayed point-history read meets at most $n+1$ refinement rows.*
6. *B is the finite ball-inspection row tying the topology opens to* $\mathsf{MetricBall}^{\uparrow}$ *observations.*
7. *F is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *radius ledger for the displayed finite cover window.*
8. *H records componentwise* hsame *transport for X, U, V, R, O, B, F and for the certificate rows.*
9. *C records displayed* Cont *replay from an open-cover request through finite ball inspection, finite-radius readback, refinement containment, and overlap checking.*
10. *P is the* Pkg *provenance over* $\mathsf{LebesgueCoveringDimension}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{CoveringDimension}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LebesgueCoveringDimension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by transporting these displayed rows. It has no coordinate for a host open-cover family, a selected refinement, an external multiplicity oracle, or a classical covering-dimension theorem.

Lean4 ✓ `BEDC.Derived.LebesgueCoveringDimensionUp.LebesgueCoveringDimensionTasteGate single carrier alignment`

Theorem 4205.2 (Lebesgue covering dimension NameCert obligations)**.** *For every accepted* LebesgueCoveringDime *carrier*

$$L = (X, U, V, R, O, B, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LebesgueCoveringDimension}^{\uparrow}}$ *surface consists exactly of topology-source admission through X, finite open-cover admission through U, refinement-row admission through V, refinement containment through R, order-at-most-n overlap checking through O, metric-ball inspection through B, finite Lebesgue-number radius readback through F, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4205.1. The topology, cover, refinement, containment, overlap, ball-inspection, finite-radius, transport, replay, provenance, and naming rows are precisely the displayed coordinates.

The finite refinement obligation reads U, V, R, O over the source row X. Containment is stored as a row-to-row ledger, and the order bound is stored as the visible overlap count for finite point-history inspections.

The metric side is only observational. The rows B and F route finite open cells through $\mathsf{MetricBall}^{\uparrow}$ and $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ before a consumer may compare the packet with the sibling $\mathsf{CoveringDimension}^{\uparrow}$ surface.

Finally H, C, P, N preserve the same route by transport, replay, provenance, and local naming. Since no excluded host object occurs as a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 4205.3 (Lebesgue finite-refinement route)**.** *Every* $\mathsf{CoveringDimension}^{\uparrow}$ *consumer of an accepted* $\mathsf{LebesgueCoveringDimension}^{\uparrow}$ *packet receives only the finite route*

$$\mathsf{Topology}^{\uparrow},\ \mathsf{MetricBall}^{\uparrow},\ \mathsf{FiniteLebesgueNumber}^{\uparrow} \longmapsto U, V, R, O, H, C, P, N.$$

Thus the dimension assertion is a displayed open-cover refinement with order-at-most-n overlap and finite radius readback. It exports no arbitrary open-cover compactness principle, selected subcover, host refinement theorem, or detached multiplicity oracle.

Proof. Begin with the NameCert obligations of Definition 4205.2. They force a consumer to read the source topology, the finite cover request, the refinement rows, the containment ledger, and the overlap ledger before any dimension claim can be exported.

Read the metric observation side next. The ball row B supplies only the displayed $\mathsf{MetricBall}^{\uparrow}$ inspections, while F supplies only the finite radius ledger already exposed by $\mathsf{FiniteLebesgueNumber}^{\uparrow}$.

The comparison with $\mathsf{CoveringDimension}^{\uparrow}$ is therefore horizontal: both packets share finite cover-refinement and overlap rows, but this chapter keeps the Lebesgue finite-radius route explicit. The structural rows H, C, P, N transport, replay, source, and name that finite route, so no host compactness or selected-refinement object can be read from the packet. □

Falsifiable prediction: An accepted $\mathsf{LebesgueCoveringDimension}^{\uparrow}$ read is refuted if a consumer exports a covering-dimension bound without displaying TopologyUp source rows, finite open-cover rows, refinement-containment rows, order-at-most-n overlap rows, MetricBallUp inspections, FiniteLebesgueNumberUp radius data, hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: coveringdimension, finite-lebesgue-number, topology, metric: no listed sibling supplies the whole $\mathsf{LebesgueCoveringDimension}^{\uparrow}$ packet, because the packet binds finite topology cover rows, metric-ball inspection, finite-radius readback, refinement containment, overlap order, and NameCert provenance in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueCoveringDimension}^{\uparrow}}$.

Constructive story: A $\mathsf{LebesgueCoveringDimension}^{\uparrow}$ packet is generated from TopologyUp source rows, finite open-cover rows, MetricBallUp observations, FiniteLebesgueNumberUp radius rows, finite refinement-containment ledgers, order-at-most-n overlap ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueCoveringDimension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4205.1, Definition 4205.2, and Definition 4205.3 seed the finite-refinement L10 topology object over TopologyUp, MetricBallUp, CoveringDimensionUp, and FiniteLebesgueNumberUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueCoveringDimension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, selected subcovers, host dimension theorems, detached multiplicity oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, refinement containment, overlap-order exactness, metric-ball inspection, finite-radius compatibility, transport, replay, provenance, and local naming for BEDC.Derived.LebesgueCoveringDim

Chapter 4206

A Concrete Naming Certificate for $\mathsf{LagrangeInterpolation}^{\uparrow}$

Following Lagrange's interpolation formula, the $\mathsf{LagrangeInterpolation}^{\uparrow}$ packet records the finite route from distinct interpolation nodes and displayed values to a polynomial whose evaluations match those values. It consumes the polynomial coefficient-list surface of chapter 50, the matrix-style finite table discipline of chapter 49, and the field and rational arithmetic boundaries of chapter 45 and chapter 37. Its BEDC carrier is a finite BHist ledger: it names nodes, values, basis-polynomial construction, evaluation rows, uniqueness rows, hsame transport, Cont replay, Pkg provenance, and a local $\mathsf{NameCert}$ row. It is not a host interpolation theorem, a quotient polynomial equality, or an ambient field-completion principle.

The history rows are read as ordinary BEDC certificate data in the sense of chapter 1366 and the typed naming discipline of chapter 9. The classical formula appears only through finite arithmetic ledgers; every consumer sees the displayed nodes, denominators, coefficient rows, and evaluation routes before it can use the interpolating polynomial.

Definition 4206.1 (Lagrange interpolation carrier)**.** *A* $\mathsf{LagrangeInterpolation}^{\uparrow}$ *source is a finite* BHist *packet*

$$L = (N, V, D, B, E, U, H, C, P, Q)$$

with the following visible rows:

1. *N is a nonempty finite node row, with an index list and a displayed pairwise-distinctness ledger for the nodes.*
2. *V is the value row assigning one carried scalar value to each node of N.*
3. *D is the denominator ledger for the factors $x_i - x_j$ with $i \neq j$, routed through* $\mathsf{Field}^{\uparrow}$ *inverse rows and the rational arithmetic surface when the nodes are rational.*
4. *B is the basis-polynomial row, displaying the finite products*

$$\ell_i(X) = \prod_{j \neq i} \frac{X - x_j}{x_i - x_j}$$

   as normalized $\mathsf{Poly}^{\uparrow}$ *coefficient lists.*
5. *E is the evaluation row, recording that each ℓ_i evaluates to the Kronecker pattern on the displayed node list.*

6. *U is the polynomial assembly and uniqueness row: it records the finite sum $\sum_i V_i \ell_i$ and the finite comparison showing that any other polynomial of degree below the displayed node count with the same evaluations has the same normalized coefficient list.*
7. *H records componentwise* hsame *transport for the node, value, denominator, basis, evaluation, uniqueness, replay, provenance, and local-name rows.*
8. *C records the* Cont *routes that replay denominator formation, basis-polynomial multiplication, polynomial evaluation, and uniqueness comparison from the same displayed finite packet.*
9. *P is the* Pkg *provenance over* $\mathsf{LagrangeInterpolation}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *Q is the local* $\mathsf{NameCert}_{\mathsf{LagrangeInterpolation}^{\uparrow}}$ *row.*

The carrier predicate is $\mathsf{LagrangeInterpolationLedger}(N, V, D, B, E, U, H, C, P, Q)$. *Two accepted packets classify together exactly when the ten displayed rows are transported by H and replay through the same routes named by C and P.*

Lean4 ✓ `BEDC.Derived.LagrangeInterpolationUp.LagrangeInterpolationTasteGate single carrier alignment`

Theorem 4206.2 (Lagrange interpolation NameCert obligations)**.** *For an accepted* $\mathsf{LagrangeInterpolation}^{\uparrow}$ *packet $L = (N, V, D, B, E, U, H, C, P, Q)$, the local* $\mathsf{NameCert}_{\mathsf{LagrangeInterpolation}^{\uparrow}}$ *obligation surface consists exactly of the finite carrier and classifier rows of Definition 4206.1, the denominator nonzero rows D, the basis-polynomial construction rows B, the evaluation rows E, the assembly and uniqueness rows U, the componentwise* hsame *transport H, the displayed* Cont *replay C, the* Pkg *provenance P, and the local naming row Q. No additional host polynomial function, determinant inverse, quotient equality of polynomials, infinite node family, or completion datum is exported.*

Proof. Read the carrier of Definition 4206.1. The rows N and V supply the finite interpolation table, while D records exactly the nonzero denominator data forced by distinct nodes.

The basis and evaluation content is held by B and E. These rows are typed over the same polynomial coefficient-list surface and the same scalar arithmetic provenance, so their comparisons do not introduce a second carrier.

The row U is the only place where the assembled polynomial and the degree-bounded uniqueness comparison are visible. The remaining rows H, C, P, Q transport, replay, source, and name the displayed packet. Since no further coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 4206.3 (Lagrange polynomial evaluation route)**.** *Every evaluation read exported by an accepted* $\mathsf{LagrangeInterpolation}^{\uparrow}$ *packet factors through the same finite route*

$$N, V, D \longmapsto B \longmapsto E \longmapsto U \longmapsto Q.$$

The route first verifies pairwise-distinct nodes and denominator rows, then builds normalized basis polynomials in $\mathsf{Poly}^{\uparrow}$, *evaluates those basis polynomials at the displayed nodes, assembles the interpolating polynomial, and finally exposes the local* $\mathsf{NameCert}_{\mathsf{LagrangeInterpolation}^{\uparrow}}$ *row. A consumer cannot bypass this route by appealing to an ambient polynomial function, a determinant computation over an unstated matrix, or an external field-completion argument.*

Proof. Start with an accepted packet $L = (N, V, D, B, E, U, H, C, P, Q)$. The denominator ledger D is downstream of the node row N and upstream of the basis row B, so each basis-polynomial read has already passed through the displayed distinctness and inverse witnesses.

Next, E evaluates the basis rows of B at the same finite node list. The route is replayed by C and transported by H, hence a transported packet keeps the same node, value, denominator, basis, and evaluation sequence.

Finally, U assembles the finite linear combination and records the degree-bounded uniqueness comparison before Q names the packet. Thus every polynomial-evaluation read available from the local certificate follows the displayed finite route and has no coordinate from which a bypassing host argument could be read. □

Falsifiable prediction: Every accepted $\mathsf{LagrangeInterpolation}^{\uparrow}$ read that claims an interpolating polynomial factors through finite node rows, value rows, denominator ledgers, normalized $\mathsf{Poly}^{\uparrow}$ basis rows, evaluation rows, uniqueness rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{LagrangeInterpolation}^{\uparrow}}$.

Constructive story: A $\mathsf{LagrangeInterpolation}^{\uparrow}$ packet is generated from finite node rows, value rows, denominator ledgers, normalized polynomial basis rows, evaluation rows, uniqueness rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LagrangeInterpolation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4206.1, Definition 4206.2, and Definition 4206.3 seed the finite interpolation carrier, local NameCert obligation surface, and polynomial-evaluation route over displayed nodes, values, denominators, normalized basis polynomials, evaluation rows, uniqueness rows, transport, replay, provenance, local naming, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LagrangeInterpolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host interpolation functions, ambient polynomial functions, determinant inverses outside the displayed ledger, quotient equality of polynomials, infinite node families, completion data, field-completion arguments, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, denominator nonzero routing, denominator nonzero exposure, basis-polynomial construction, evaluation rows, evaluation replay, assembly, uniqueness-row replay, basis and evaluation route transport, transport replay, route nonescape, provenance exposure, local naming, and TasteGate field faithfulness for BEDC.Derived.LagrangeInterpolationUp.

Chapter 4207

A Concrete Naming Certificate for $\mathsf{RieszFischer}^{\uparrow}$

Following Riesz and Fischer, the $\mathsf{RieszFischer}^{\uparrow}$ packet records the finite NameCert surface for the classical completeness route from square-summable coefficient windows to a Hilbert-facing limit object. It sits between the inner-product and norm rows of chapter 86, chapter 91, and chapter 89, and the completion handoff rows of chapter 128 and chapter 1527. The packet exposes the coefficient-window, inner-product, norm, completion, transport, replay, provenance, and local naming rows needed for a constructive Riesz–Fischer handoff; it does not introduce quotient L^2 classes, choice-selected limits, or an ambient Hilbert completeness theorem outside the displayed packet.

Definition 4207.1 (RieszFischer carrier)**.** *A* $\mathsf{RieszFischer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (W, I, H, N, M, U, T, C, P, L)$$

with the following displayed rows:

1. *W is the square-summable coefficient-window row, recording finite coefficient blocks, tail bounds, and the window schedule used by the packet.*
2. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row that reads coefficient-window comparisons as inner-product estimates.*
3. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row naming the Hilbert-facing endpoint surface over which the coefficient windows are interpreted.*
4. *N is the* $\mathsf{Norm}^{\uparrow}$ *row induced by the displayed inner-product estimates.*
5. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-service row for the metric sequence determined by W, I, N.*
6. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *handoff row that packages the displayed Cauchy datum as a completion-facing unit route.*
7. *T records componentwise* hsame *transport for W, I, H, N, M, U and for the local structural rows.*
8. *C records displayed* Cont *replay from coefficient windows through the inner-product, norm, completion, and unit-handoff route.*
9. *P is the* Pkg *provenance over* $\mathsf{RieszFischer}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *L is the local* $\mathsf{NameCert}_{\mathsf{RieszFischer}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient L^2 classes, almost-everywhere representatives, countable-choice limit selection, ambient Hilbert completeness, or host equality of limits.

Lean4 ✓ `BEDC.Derived.RieszFischerUp.RieszFischerTasteGate single carrier alignment`

Theorem 4207.2 (RieszFischer NameCert obligations)**.** *For every accepted* $\mathsf{RieszFischer}^{\uparrow}$ *carrier* $R = (W, I, H, N, M, U, T, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{RieszFischer}^{\uparrow}}$ *surface consists exactly of these finite obligation rows:*

1. *carrier admission for the square-summable coefficient windows,* $\mathsf{InnerProduct}^{\uparrow}$ *comparison row,* $\mathsf{Hilbert}^{\uparrow}$ *source row,* $\mathsf{Norm}^{\uparrow}$ *metric row,* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-service row,* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *handoff row, componentwise transport, replay, provenance, and local naming;*
2. *square-summable exhaustion, requiring every Hilbert-facing completion read to begin with the displayed coefficient-window row* W*;*
3. *inner-product and norm compatibility, requiring* I *and* N *to expose the same finite comparison route before any metric-completion row is consumed;*
4. *completion handoff, requiring* M *and* U *to route the same Cauchy datum and not a selected external limit;*
5. *transport replay, requiring* T, C, P, L *to preserve the ordered route under* hsame*,* Cont*,* Pkg*, and* NameCert*;*
6. *ledger non-escape, excluding quotient* L^2 *classes, choice-selected limits, ambient Hilbert completeness, host equality of limits, and hidden measure-space representatives.*

Proof. Project the accepted carrier. The packet displays the square-summable windows, inner-product estimates, Hilbert-facing source, norm metric, complete-metric service, completion-unit handoff, transport, replay, provenance, and local name as the whole available surface.

Read the analytic route in order. The coefficient window W supplies the finite square-summability data; the rows I and N turn those windows into inner-product and norm comparisons; the row M consumes the resulting Cauchy datum; and U exposes the same datum to completion consumers.

Finally attach the structural rows. Componentwise transport and displayed replay preserve only W, I, H, N, M, U, while P and L source and name the packet. Since no carrier coordinate contains quotient classes, selected limits, ambient completeness, host equality, or hidden representatives, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{RieszFischer}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RieszFischer}^{\uparrow}}$, seed)

Scope closed: Definition 4207.1 and Definition 4207.2 seed the finite Riesz–Fischer packet over square-summable coefficient windows, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RieszFischer}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient L^2 classes, choice-selected limits, ambient Hilbert completeness, host equality of limits, hidden measure-space representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient-window exhaustion, inner-product and norm compatibility, completion handoff, transport replay, and ledger non-escape for BEDC.Derived.RieszFischerUp.

Constructive story: A $\mathsf{RieszFischer}^{\uparrow}$ packet is generated from finite square-summable coefficient windows, inner-product comparison rows, a Hilbert-facing source row, norm metric rows, a complete-metric Cauchy service, a Cauchy-CompletionUnit handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4208

A Concrete Naming Certificate for $\mathsf{RationalFastLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RationalFastLimit}^{\uparrow}$ packet records the Bishop-style presentation of a real name as rational observations with an explicit fast tail budget. It sits over the dyadic arithmetic ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback route of chapter 301, the terminal real seal of chapter 38, the fast Cauchy real packet of chapter 1589, and the explicit modulus packet of chapter 1781. The carrier makes the rational fast-limit surface available to L10 Real and Completion consumers without quotienting streams, selecting representatives, or importing countable choice.

Definition 4208.1 (RationalFastLimit carrier)**.** *A* $\mathsf{RationalFastLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the rational observation row, listing the finite rational approximants read by the current precision request.*
2. *D is the fast dyadic tail-budget row, recording the dyadic tolerance scale, comparison budget, and tail witness used to compare later rational observations.*
3. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row naming exactly which rational observations may be opened by the request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from Q, D, S after the fast budget has bounded the visible tail.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the rational observation, dyadic budget, stream-window, and regular readback rows have been displayed.*
6. *H records componentwise* hsame *transport for rational observations, dyadic tail budgets, stream windows, regular readback, the Real seal, continuation, provenance, and local naming.*
7. *C records displayed* Cont *replay from a finite precision request through Q, D, S, R, E and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{RationalFastLimit}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FastCauchyReal}^{\uparrow}$, $\mathsf{FastCauchyModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RationalFastLimit}^\uparrow}$ *row.*
The classifier compares accepted packets only through $Q, D, S, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected rational representatives, a host real limit, trichotomy, countable choice, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.RationalFastLimitUp.RationalFastLimitTasteGate single carrier alignment`

Theorem 4208.2 (RationalFastLimit NameCert obligations)**.** *For every accepted* $\mathsf{RationalFastLimit}^\uparrow$ *carrier $L = (Q, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalFastLimit}^\uparrow}$ *surface consists exactly of rational observation admission, fast dyadic tail-budget exposure, finite stream-window service, regular rational handoff, Real seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer must read the finite route*

$$Q, D, S \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

before treating the packet as a real-name boundary.

Proof. Project the carrier of Definition 4208.1. The rows Q, D, S are the only source rows available to a precision request: rational observations, the fast dyadic tail budget, and the finite window schedule.

The regular handoff is downstream of those rows. The dyadic budget D supplies the tolerance comparison used to bound the tail of the rational observations in Q, while S restricts the read to displayed finite windows.

The Real seal row E is reached only after R. The structural rows H, C, P, N transport, replay, source, and name the same displayed route, so no quotient stream equality, selected representative, countable choice, or ambient completeness principle is introduced by the certificate. □

Theorem 4208.3 (RationalFastLimit regular readback)**.** *Every* $\mathsf{RegSeqRat}^\uparrow$ *or* $\mathsf{Real}^\uparrow$ *consumer of an accepted* $\mathsf{RationalFastLimit}^\uparrow$ *packet factors through rational observations, the fast dyadic tail budget, finite stream windows, and the regular rational handoff. Equivalently, the consumer route is the displayed sibling chain*

$$\mathsf{DyadicRatCore}^\uparrow,\ \mathsf{StreamName}^\uparrow,\ \mathsf{RegSeqRat}^\uparrow,\ \mathsf{Real}^\uparrow$$

with $\mathsf{FastCauchyReal}^\uparrow$ *and* $\mathsf{FastCauchyModulus}^\uparrow$ *supplying the fast-limit interpretation of the dyadic budget row. The packet exports no direct rational-stream-to-real shortcut.*

Proof. Begin with an accepted packet $L = (Q, D, S, R, E, H, C, P, N)$. The rational observations are read from Q, but their use as a real-name approximation is constrained by the fast dyadic tail budget D.

The finite window row S determines which observations can be inspected. After Q, D, S are fixed, the handoff row R repacks the same data as a regular rational name, matching the route used by the $\mathsf{RegSeqRat}^\uparrow$ sibling.

The terminal seal E is downstream of R, and the fast interpretation of the budget is exactly the one exposed by $\mathsf{FastCauchyReal}^\uparrow$ and $\mathsf{FastCauchyModulus}^\uparrow$. Since the carrier has no coordinate for a host real limit or a quotient stream, every regular or Real consumer remains inside the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalFastLimit}^\uparrow}$.

Constructive story: A $\mathsf{RationalFastLimit}^\uparrow$ packet is generated from rational observation rows, a fast dyadic tail budget, finite StreamName windows, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RationalFastLimit}^{\uparrow}}$, seed)

Scope closed: Definition 4208.1, Definition 4208.2, and Definition 4208.3 seed the finite rational fast-limit route into regular rational and Real-facing readback.

Formal verification: FormalStatus(NameCert$_{\mathsf{RationalFastLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real limits, trichotomy, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fast tail-budget exactness, finite-window service, regular readback, Real seal nonescape, componentwise stability, provenance, and local naming for the displayed packet.

Chapter 4209

A Concrete Naming Certificate for $\mathsf{RegularCauchyCommonRefinement}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyCommonRefinement}^{\uparrow}$ packet records the finite common-refinement route by which two displayed regular Cauchy names may be inspected through one shared target window before either reaches a $\mathsf{Real}^{\uparrow}$ seal. It sits after the single-schedule reindexing surface of chapter 1568, the finite observation schedules of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The packet names a displayed paired refinement surface; it is not quotient stream equality, not a selected subsequence limit, not countable choice, not host real equality, not trichotomy, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4209.1 (Regular Cauchy common refinement carrier)**.** *A* $\mathsf{RegularCauchyCommonRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S_0, S_1, I, M_0, Q_0, M_1, Q_1, W, D, R, A, H, C, P, N)$$

with the following displayed rows:

1. *S_0 and S_1 are the two source* $\mathsf{StreamName}^{\uparrow}$ *schedule rows for the accepted regular Cauchy names;*
2. *I is the common target* $\mathsf{StreamName}^{\uparrow}$ *window through which both sources are inspected;*
3. *M_0, Q_0 are the monotone and cofinal reindex rows from I to S_0;*
4. *M_1, Q_1 are the monotone and cofinal reindex rows from I to S_1;*
5. *W is the common target-window budget row, recording that a single displayed finite request feeds both reindex routes;*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row shared by the two reads at the budget named by W;*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row showing that both inspected names reach the same regular rational tolerance surface;*
8. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after $S_0, S_1, I, M_0, Q_0, M_1, Q_1, W, D, R$ have been consumed;*
9. *H records componentwise* hsame *transport for the two schedules, the common target window, both reindex routes, the tolerance, readback, Real seal, continuation, provenance, and local naming rows;*

10. *C records displayed* Cont *replay from a common-window request through the two monotone–cofinal routes and then through the shared tolerance, readback, and Real seal;*
11. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCommonRefinement}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected subsequence limits, countable-choice selectors, host real equality, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RegularCauchyCommonRefinementUp.RegularCauchyCommonRefinementTasteGate`
`single carrier alignment`

Theorem 4209.2 (Regular Cauchy common refinement obligation surface)**.** *For every accepted* $\mathsf{RegularCauchyCommonRefinement}^{\uparrow}$ *carrier* $K = (S_0, S_1, I, M_0, Q_0, M_1, Q_1, W, D, R, A, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCommonRefinement}^{\uparrow}}$ *surface consists exactly of paired source-schedule admission, common-window admission, two monotone–cofinal reindex rows, shared dyadic tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and ledger refusal for quotient stream equality, selected subsequence limits, countable choice, host real equality, trichotomy, and ambient Real completeness.*

Proof. Project the carrier of Definition 4209.1. The projection exposes exactly the two source schedules, the common target window, two monotone–cofinal reindex pairs, the shared tolerance row, the regular readback row, the Real seal, and the structural rows H, C, P, N.

The common-window row W is the only target-window coordinate. A consumer therefore cannot inspect the two source schedules by unrelated requests; each request must replay through C and then through both displayed reindex routes.

The dyadic and regular rows are shared downstream rows. Since D and R are read only after the two reindex pairs have been displayed, the carrier records one tolerance surface and one regular readback surface rather than two unrelated limit witnesses.

Finally, A is downstream of the same paired route, while H, P, N preserve and package only the listed rows. No row remains from which to read quotient stream equality, a selected subsequence limit, countable choice, host real equality, trichotomy, or ambient Real completeness. □

Theorem 4209.3 (Regular Cauchy common refinement)**.** *Let S_0 and S_1 be accepted regular Cauchy source schedules with displayed finite schedules, and suppose the two schedules admit displayed monotone and cofinal reindex rows into a common target window I. Then there is an accepted* $\mathsf{RegularCauchyCommonRefinement}^{\uparrow}$ *carrier*

$$K = (S_0, S_1, I, M_0, Q_0, M_1, Q_1, W, D, R, A, H, C, P, N)$$

whose $\mathsf{Real}^{\uparrow}$*-facing consumers factor through the same dyadic tolerance row D and the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R. The construction uses only the two displayed schedule rows, the two monotone–cofinal reindex routes, the common target window, finite* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row; it does not use quotient stream equality, selected subsequence limits, countable-choice selectors, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the two accepted regular Cauchy schedules. Each source schedule is available as a finite $\mathsf{StreamName}^{\uparrow}$ row, and each displayed monotone–cofinal route is the same kind of finite route isolated in chapter 1568.

Choose the displayed common target window I as the single inspection surface. The row W records the finite request made at that window, while M_0, Q_0 and M_1, Q_1 replay the request back to S_0 and S_1 without choosing a subsequence or comparing host streams.

Read the shared tolerance and regularity rows next. The $\mathsf{DyadicRatCore}^{\uparrow}$ row D records the tolerance budget attached to W, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R is consumed after both reindex routes have been displayed. Hence both source reads reach the same finite regular rational surface before any Real-facing seal is inspected.

Transport and replay close the packet. Componentwise hsame transport identifies the rows that are meant to be shared, and Cont records the two finite route replays from I through the source schedules and forward to D, R, A. The Pkg and local NameCert rows then package exactly this surface.

By Definition 4209.2, the resulting packet contains no coordinate for quotient stream equality, selected subsequence limits, countable choice, host real equality, trichotomy, or ambient completeness. Therefore every $\mathsf{Real}^{\uparrow}$-facing consumer of the accepted common-refinement carrier factors through the displayed common window, the shared dyadic tolerance, and the shared regular readback. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCommonRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCommonRefinement}^{\uparrow}$ packet is generated from two source StreamName schedules, a common target window, two monotone and cofinal reindex route pairs, one DyadicRatCore tolerance row, one RegSeqRat readback row, a RealUp seal, componentwise transport, continuation replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCommonRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4209.1, Definition 4209.2, and Definition 4209.3 seed the finite paired refinement route from two regular Cauchy schedules to a shared $\mathsf{Real}^{\uparrow}$-facing readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCommonRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected subsequence limits, countable-choice selectors, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, paired monotone and cofinal reindexing discipline, shared dyadic tolerance preservation, RegSeqRat readback, Real seal factorization, and ledger refusal.

Chapter 4210

A Concrete Naming Certificate for $\mathsf{OlivierTheorem}^{\uparrow}$

Following Olivier's theorem for positive convergent series, the $\mathsf{OlivierTheorem}^{\uparrow}$ packet records the finite positive-term tail evidence by which a Real-facing series consumer may read vanishing terms without importing a host completeness theorem. It sits after the summable-tail modulus of chapter 1799, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a constructive tail handoff for positive series; it exports no selected sum, quotient series equality, choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4210.1 (Olivier theorem carrier)**.** *An* $\mathsf{OlivierTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (A, T, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the positive-term series row, exposing only the inspected nonnegative term windows and finite partial-sum comparison windows used by the current request.*
2. *T is the tail-window row, naming the finite interval of terms whose smallness is to be served.*
3. *M is the* $\mathsf{SummableTailModulus}^{\uparrow}$ *row, assigning the requested positive-term tail window to a displayed summable-tail modulus before any regular rational readback is available.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached only after A, T, M have displayed the finite tail evidence.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational handoff and the summable-tail route have been replayed.*
6. *H records componentwise* hsame *transport for the positive-term, tail-window, modulus, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a positive-series tail request through A, T, M, R, E.*
8. *P is the* Pkg *provenance over* $\mathsf{OlivierTheorem}^{\uparrow}$, $\mathsf{SummableTailModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{OlivierTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for selected sums, quotient series equality, choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.OlivierTheoremUp.OlivierTheoremTasteGate single carrier alignment`

Theorem 4210.2 (Olivier theorem NameCert obligations)**.** *For every accepted* $\mathsf{OlivierTheorem}^{\uparrow}$ *carrier* $O = (A, T, M, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{OlivierTheorem}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the positive-term series row, finite tail-window row, summable-tail modulus row, regular rational handoff, Real seal, transport, replay, provenance, and local naming row;*
2. *positivity-window exposure, requiring* A *to supply the only term-sign and finite partial-sum data used by the tail request;*
3. *tail-window service, requiring* T *to name the inspected positive-term tail window before any downstream read can ask for vanishing terms;*
4. *modulus handoff, requiring* T *to pass through the* $\mathsf{SummableTailModulus}^{\uparrow}$ *row* M *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff* R *is available;*
5. *non-escape, requiring every terminal* $\mathsf{Real}^{\uparrow}$ *read to pass through* A, T, M, R, H, C, P, N *and excluding selected sums, quotient series equality, choice, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4210.1. The visible inventory is $A, T, M, R, E, H, C, P, N$, so the certificate has no detached row for a selected sum, quotient series equality, choice, host real equality, or ambient completeness theorem.

The positive-term and finite-window data are read before any Real-facing seal is available. The row A supplies the inspected positive term and partial-sum comparison windows, while T identifies the concrete tail window served by the request.

The tail window then passes through M. Thus finite positive-term tail evidence is converted into a displayed $\mathsf{SummableTailModulus}^{\uparrow}$ service before any $\mathsf{RegSeqRat}^{\uparrow}$ readback can occur.

Finally R, E, H, C, P, N supply regular readback, terminal sealing, transport, replay, provenance, and local naming for the same route. Since the excluded analytic objects are not carrier coordinates, they cannot be exported by the local certificate. □

Theorem 4210.3 (Olivier theorem tail handoff)**.** *Every Real-facing read of an accepted* $\mathsf{OlivierTheorem}^{\uparrow}$ *carrier factors finite positive-term tail windows through the ordered route*

$$\mathsf{OlivierTheorem}^{\uparrow} \longmapsto \mathsf{SummableTailModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Consequently a consumer may use Olivier-style vanishing-term evidence only after the displayed summable-tail modulus row has served the finite tail window. It receives no selected sum, quotient series equality, choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $O = (A, T, M, R, E, H, C, P, N)$ and a Real-facing request for positive-series tail evidence. The only source row is A, and the only finite tail-window row is T.

The handoff is then forced through M. This makes the Olivier-style conclusion a finite modulus-served tail read, not a hidden selection of a sum or an equality of quotient series.

Only after M appears may the route enter R and then the terminal $\mathsf{Real}^{\uparrow}$ seal E. The rows H, C, P, N preserve the same displayed route under transport, replay it as continuation data, record provenance, and name it locally, so no excluded completeness or choice principle is introduced downstream. □

Falsifiable prediction: Every accepted $\mathsf{OlivierTheorem}^{\uparrow}$ Real-facing tail read factors through positive-term windows, a finite tail-window row, a SummableTailModulus row, RegSeqRat readback, Real sealing, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: summable-tail-modulus, regseqrat, real: $\mathsf{OlivierTheorem}^{\uparrow}$ is not bijective to any listed sibling because it binds positive-term series windows, finite tail evidence, summable-tail modulus service, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{OlivierTheorem}^{\uparrow}}$.

Constructive story: An $\mathsf{OlivierTheorem}^{\uparrow}$ packet is generated from positive-term series windows, finite tail-window evidence, a SummableTailModulus row, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OlivierTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4210.1, Definition 4210.2, and Definition 4210.3 seed the finite positive-series tail route over displayed summable-tail modulus, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OlivierTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected sums, quotient series equality, choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positivity-window exposure, tail-window service, modulus handoff, regular rational readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.OlivierTheoremUp.

Chapter 4211

A Concrete Naming Certificate for $\mathsf{JacobiIteration}^{\uparrow}$

Following Jacobi's iterative method for linear systems, the $\mathsf{JacobiIteration}^{\uparrow}$ packet records the finite BEDC certificate surface of a displayed diagonal split, residual update, iteration schedule, and contraction-budget handoff. It consumes the matrix and linear-map rows read through $\mathsf{Mat}^{\uparrow}$ and $\mathsf{LinMap}^{\uparrow}$, the norm budget of $\mathsf{Norm}^{\uparrow}$, the Cauchy-orbit handoff of chapter 4224, and the fixed-point iteration interface already named by $\mathsf{FixedPointIteration}^{\uparrow}$. The packet names the local row discipline for one displayed iteration scheme; it is not a host convergence theorem, spectral-radius theorem, chosen solution vector, quotient sequence equality, or ambient completeness assertion.

Definition 4211.1 (Jacobi iteration carrier)**.** *A* $\mathsf{JacobiIteration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (A, D, R, S, B, H, C, P, N)$$

with the following displayed rows:

1. *A is the matrix/vector system row, exposing the finite linear system and right-hand side only through the consumed* $\mathsf{Mat}^{\uparrow}$ *and* $\mathsf{LinMap}^{\uparrow}$ *surfaces.*
2. *D is the diagonal split row, displaying the diagonal part and the residual part as finite matrix rows without assuming an external inverse beyond the displayed diagonal update.*
3. *R is the residual update row, recording the deterministic map from the current iterate and the system row to the next displayed iterate.*
4. *S is the iteration schedule row, listing the finite observation windows and the orbit positions that a consumer may inspect.*
5. *B is the displayed norm and contraction-budget row, exposing the finite descent inequalities read through* $\mathsf{Norm}^{\uparrow}$ *and the fixed-point iteration budget.*
6. *H transports A, D, R, S, B, C, P, N componentwise by* hsame*.*
7. *C replays the displayed* Cont *updates from a system read through the diagonal split, residual update, schedule, norm budget, and Cauchy-orbit handoff.*
8. *P records* Pkg *provenance over* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*,* $\mathsf{CauchySequenceCriterion}^{\uparrow}$*,* $\mathsf{FixedPointIteration}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{JacobiIteration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, D, R, S, B, H, C, P, N$. It has no coordinate for a host solution vector, unrestricted spectral-radius argument, quotient sequence equality, selected limit, countable choice, or ambient Banach-space completeness.

Lean4 ✓ `BEDC.Derived.JacobiIterationUp.JacobiIterationTasteGate single carrier alignment`

Theorem 4211.2 (Jacobi iteration NameCert obligations)**.** *For every accepted* $\mathsf{JacobiIteration}^{\uparrow}$ *carrier* $J = (A, D, R, S, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{JacobiIteration}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the system, diagonal split, residual update, iteration schedule, contraction budget, transport, replay, provenance, and local naming rows;*
2. *diagonal split exposure, requiring D to be read after the matrix/vector system row A and before any residual update is inspected;*
3. *residual-update determinacy, requiring R to compute the next displayed iterate from the current iterate and the exposed split rows;*
4. *contraction-budget descent, requiring B to record the finite norm comparisons used by the schedule row;*
5. *Cauchy-orbit handoff, requiring the accepted schedule and budget rows to hand only the displayed orbit windows to* $\mathsf{CauchySequenceCriterion}^{\uparrow}$ *and* $\mathsf{FixedPointIteration}^{\uparrow}$ *consumers;*
6. *transport and replay preservation through H and C;*
7. *provenance and local naming through P and N;*
8. *non-escape from the displayed packet, excluding host convergence, selected limits, quotient sequence equality, unrestricted spectral-radius reasoning, countable choice, and ambient completeness.*

Proof. Project the carrier of Definition 4211.1. The only analytic rows are the system row A, diagonal split D, residual update R, schedule S, and budget row B.

The diagonal split is exposed before residual replay. Thus each accepted update reads the same displayed system and split rows, and the next iterate is determined by the finite residual row rather than by an external solver.

The budget row is also finite. It records the norm comparisons consumed by the schedule, and the schedule hands only those displayed orbit windows to the Cauchy-sequence and fixed-point iteration consumers.

Transport, replay, provenance, and naming preserve the same rows. Since the refused objects have no carrier coordinate in J, the local certificate exports only the displayed Jacobi iteration packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{JacobiIteration}^{\uparrow}}$**.**

Constructive story: A $\mathsf{JacobiIteration}^{\uparrow}$ packet is generated from a displayed matrix/vector system row, a diagonal split row, a residual update row, an iteration schedule, a norm/contraction budget, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{JacobiIteration}^{\uparrow}}$, seed)

Scope closed: Definition 4211.1 and Definition 4211.2 seed the finite Jacobi iteration certificate over matrix, linear-map, norm, Cauchy-sequence criterion, fixed-point iteration, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{JacobiIteration}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host convergence, spectral-radius convergence, selected solutions, quotient sequence equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal split exposure, residual-update determinacy, contraction-budget descent, Cauchy-orbit handoff, transport, replay, provenance, and local naming for BEDC.Derived.JacobiIterationUp.

Chapter 4212

A Concrete Naming Certificate for $\mathsf{ApophaticBoundarySocketStack}^{\uparrow}$

The $\mathsf{ApophaticBoundarySocketStack}^{\uparrow}$ packet realizes the apophatic socket-stack branch of Definition 9399.7 as finite boundary/refusal NameCert data. It sits over the typed socket taxonomy of chapter 1240, the socket-kind classifier of chapter 1058, the supply ledger of chapter 528, the far-end refusal socket of chapter 1061, and the named externality surface of chapter 543. The packet names a stacked visible-socket boundary; it does not supply the far end, discharge the refusal row, collapse socket kinds, or replace the named boundary by a host predicate.

Definition 4212.1 (Apophatic boundary socket stack carrier)**.** *An* $\mathsf{ApophaticBoundarySocketStack}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, K_D, L, F, A, V, R, H, C, P, N)$$

with the following displayed rows:

1. T *is the* $\mathsf{TypedGapSocketTaxonomy}^{\uparrow}$ *row naming the typed boundary class of each socket in the stack.*
2. K_D *is the* $\mathsf{SocketKindClassifier}^{\uparrow}$ *row classifying the visible socket kind at each stack layer.*
3. L *is the* $\mathsf{SupplySocketLedger}^{\uparrow}$ *row recording which visible supply request is being ledgered.*
4. F *is the* $\mathsf{ApophaticFarEndSocket}^{\uparrow}$ *row marking the far-end refusal boundary without supplying its content.*
5. A *is the* $\mathsf{ApophaticName}^{\uparrow}$ *row naming the externality position that the stack refuses to internalize.*
6. V *is the visible stack-order row, listing the finite order in which typed socket, classifier, ledger, far-end, and name rows are read.*
7. R *is the refusal row, recording that a consumer may factor through the visible socket and refusal rows but may not replace them by hidden host supply.*
8. H *records componentwise* hsame *transport for* $T, K_D, L, F, A, V, R, C, P, N$.
9. C *records displayed* Cont *replay through the visible stack order and refusal row.*
10. P *is the* Pkg *provenance over* $\mathsf{TypedGapSocketTaxonomy}^{\uparrow}$, $\mathsf{SocketKindClassifier}^{\uparrow}$, $\mathsf{SupplySocketLedger}^{\uparrow}$, $\mathsf{ApophaticFarEndSocket}^{\uparrow}$, $\mathsf{ApophaticName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ApophaticBoundarySocketStack}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $T, K_D, L, F, A, V, R, H, C, P, N$. It has no coordinate for supplied far-end content, untyped sockets, anonymous supply, hidden host predicates, quotient equality, or discharged apophatic refusal.

Lean4 ✓ `BEDC.Derived.ApophaticBoundarySocketStackUp.ApophaticBoundarySocketStackTasteGate single carrier alignment`

Theorem 4212.2 (Apophatic boundary socket stack NameCert obligations)**.** *For every accepted* $\mathsf{ApophaticBoundarySocketStack}^{\uparrow}$ *carrier $K = (T, K_D, L, F, A, V, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ApophaticBoundarySo}}$ *surface consists exactly of carrier admission, typed socket exposure, kind-classifier exposure, supply-ledger exposure, far-end refusal exposure, apophatic name exposure, visible stack-order determinacy, refusal-row exactness, componentwise transport, displayed replay, provenance, and local naming. Every accepted stack consumer factors through the visible socket rows T, K_D, L, V and the refusal/name rows F, A, R before any public read is available.*

Proof. Project the carrier of Definition 4212.1. The socket-facing rows are T, K_D, L, V, and the refusal/name rows are F, A, R.

The stack order row V forces those rows to be read in a finite visible order. Thus a consumer cannot inspect the supply ledger or far-end boundary without first carrying the typed socket and classifier rows that identify the visible socket.

The refusal row R is downstream of F and A. It records refusal of internalization, so the public read is a boundary read rather than a supplied far-end witness or a hidden host predicate.

Transport, replay, provenance, and naming preserve the same finite packet. Since the refused objects have no carrier coordinate, the accepted stack factors through exactly the visible socket and refusal rows. □

Falsifiable prediction: Every accepted $\mathsf{ApophaticBoundarySocketStack}^{\uparrow}$ consumer factors through the visible socket rows T, K_D, L, V and the refusal rows F, A, R; a purported consumer that omits either side is rejected by the local NameCert.

Independence witness: typedgapsockettaxonomy, socketkindclassifier, supplysocketledger, apophaticfarendsocket, apophaticname: TypedGapSocketTaxonomyUp records the typed class without the stack order, SocketKindClassifierUp names one kind row without the far-end refusal, SupplySocketLedgerUp records requests without the apophatic name, ApophaticFarEndSocketUp marks the refusal boundary without the full visible stack, and ApophaticNameUp names the externality without the socket-kind and ledger rows. None is bijective to the full $T, K_D, L, F, A, V, R, H, C, P, N$ carrier under NameCert-row preservation.

Closure status for $\mathsf{NameCert}_{\mathsf{ApophaticBoundarySocketStack}^{\uparrow}}$.

Constructive story: An $\mathsf{ApophaticBoundarySocketStack}^{\uparrow}$ packet is generated from typed socket taxonomy, socket-kind classifier, supply-ledger, apophatic far-end socket, apophatic name, visible stack-order, refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApophaticBoundarySocketStack}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4212.1 and Definition 4212.2 seed the finite visible-socket and refusal stack certificate over typed socket, classifier, ledger, far-end, name, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApophaticBoundarySocketStack}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ApophaticBoundarySocketStackUp.ApophaticBoundarySocketStackTasteGate\_single\_carrier\_`

Bridge status: none

Not claimed: This chapter does not close supplied far-end content, hidden host predicates, quotient equality, discharged apophatic refusal, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, visible socket exposure, stack-order determinacy, refusal exactness, transport, replay, provenance, and local naming for BEDC.Derived.ApophaticBoundarySocketStackUp.

Chapter 4213

A Concrete Naming Certificate for $\mathsf{DiniMonotoneCompactUniform}^{\uparrow}$

Following Dini's theorem and Bishop–Bridges constructive compactness, the $\mathsf{DiniMonotoneCompactUniform}^{\uparrow}$ packet records the finite NameCert surface by which a monotone family of continuous maps on a compact metric source yields a compact-uniform tolerance handoff. It sits beside the Dini continuity packet of chapter 2196, the Dini theorem carrier of chapter 1387, the compact metric source of chapter 129, the continuous-map rows of chapter 130, the uniform-modulus surface of chapter 369, and the uniform-limit handoff of chapter 463. The packet uses finite cover and explicit probe rows; it does not invoke general open-cover compactness, a host supremum, selected minimum radius outside the carrier, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4213.1 (Dini monotone compact-uniform carrier)**.** *A* $\mathsf{DiniMonotoneCompactUniform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, F, M, L, R, V, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact metric source row, carrying the metric source, compact finite-cover interface, and finite probe extraction route.*
2. *F is the continuous-map family row, recording the displayed maps on X and their local continuity data.*
3. *M is the monotone ledger, recording the family order and the visible monotone approach toward the limiting row.*
4. *L is the pointwise-limit row, recording the finite probe-wise route from family observations to the displayed limiting map.*
5. *R is the rational tolerance budget, storing the requested positive tolerance, cover-cell slices, and comparison rows.*
6. *V is the finite cover and* $\mathsf{ProbeBundle}$ *row extracted from X for the requested tolerance window.*
7. *U is the uniform-modulus and uniform-limit handoff row. It records the route from local continuity and monotone pointwise data through V and R to a single compact-uniform read.*
8. *H records componentwise* hsame *transport for source, family, monotone ledger, limit, tolerance, cover, handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from compact-uniform requests through $X, F, M, L, R, V, U, H, P, N$.*
10. *P is the* Pkg *provenance over* DiniMonotoneCompactUniform$^{\uparrow}$, DiniContinuity$^{\uparrow}$, DiniTheorem$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, UniformLimit$^{\uparrow}$, Rat$^{\uparrow}$, BHist, ProbeBundle, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{DiniMonotoneCompactUniform}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through $X, F, M, L, R, V, U, H, C, P, N$ and has no coordinate for host suprema, arbitrary open-cover compactness, quotient function equality, selected radii outside V, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.DiniMonotoneCompactUniformUp.DiniMonotoneCompactUniformTasteGate single carrier alignment`

Theorem 4213.2 (Dini monotone compact-uniform carrier obligations)**.** *For an accepted* DiniMonotoneCompactUn *carrier*

$$D = (X, F, M, L, R, V, U, H, C, P, N),$$

the local NameCert$_{\text{DiniMonotoneCompactUniform}^{\uparrow}}$ *surface consists exactly of compact metric source admission through X, continuous-map family admission through F, monotone visibility through M, pointwise-limit visibility through L, rational tolerance budgeting through R, finite cover and probe extraction through V, uniform-modulus and uniform-limit handoff through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4213.1. The first seven rows are the analytic data, and H, C, P, N are the structural certificate rows.

The monotone Dini route is forced by the displayed order. A compact-uniform request first reads the source and family rows X, F, then exposes monotone visibility through M and probe-wise limiting data through L.

The finite tolerance work is stored in R, V, U. The rational budget R is subdivided across the finite ProbeBundle row V, and the handoff row U records how those local reads assemble into one uniform-modulus and uniform-limit request.

Finally H, C, P, N preserve the same coordinates by transport, replay, provenance, and local naming. Since the excluded host principles have no carrier coordinate, they are not NameCert obligations of the packet. □

Theorem 4213.3 (Dini monotone compact finite-cover extraction)**.** *Every compact-uniform read accepted by a* DiniMonotoneCompactUniform$^{\uparrow}$ *carrier must expose the compact source row X, the continuous-family row F, the monotone ledger M, the pointwise-limit row L, and the rational budget R before extracting the finite* ProbeBundle *cover row V. The extraction is a finite compact metric route; it is not general open-cover compactness, a selected global minimum radius, or a host supremum argument.*

Proof. Use the carrier obligations of Definition 4213.2. They place X, F, M, L, R upstream of the finite cover row V.

The compact source row X supplies the compact metric finite-cover interface. The continuous-map family row F and monotone ledger M determine which local continuity and monotone comparisons can be inspected on each displayed probe.

The pointwise-limit row L is then read only at probes supplied by the packet, and the rational budget R supplies the requested tolerance and cell slices. Hence V is extracted as finite packet data rather than by an external open-cover or supremum principle. □

Theorem 4213.4 (Dini monotone uniform budget handoff)**.** *For an accepted* DiniMonotoneCompactUniform$^{\uparrow}$ *carrier, every consumer of the compact-uniform conclusion must route the requested tolerance through R, the finite probe cover V, and the uniform-modulus and uniform-limit handoff U, then through* hsame, Cont, Pkg, *and local* NameCert *rows. The exported handoff is only the finite BEDC route through* CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, UniformLimit$^{\uparrow}$, DiniContinuity$^{\uparrow}$, *and* DiniTheorem$^{\uparrow}$.

Proof. Begin with the finite-cover extraction of Definition 4213.3. It supplies cover cells and probe rows downstream from the compact metric source, continuous family, monotone ledger, pointwise limit, and rational budget.

The handoff row U consumes exactly that finite data. It first reads the local modulus information attached to the cells of V, then packages the assembled tolerance into the displayed uniform-limit route.

The structural rows H, C, P, N export no analytic data beyond that route. Therefore the consumer receives a compact-uniform Dini handoff through the named sibling packets, with no host function equality, hidden completion, selected radius outside the carrier, or open-cover compactness. □

Theorem 4213.5 (Dini monotone compact-uniform finite descent)**.** *For an accepted* DiniMonotoneCompactUniform *carrier*

$$D = (X, F, M, L, R, V, U, H, C, P, N),$$

every compact-uniform tolerance export descends through the pointwise monotone rows M, L on the finite ProbeBundle *cover V and the rational budget R before U may expose a single uniform read. The export cannot introduce a host supremum, selected minimum radius, open-cover compactness, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4213.1. The only rows between the compact source and the uniform handoff are the continuous family F, monotone ledger M, pointwise-limit row L, rational budget R, finite cover row V, and handoff row U.

Apply the finite-cover extraction theorem Definition 4213.3. It forces V to be read as finite ProbeBundle data after the pointwise monotone rows and the tolerance budget have been displayed.

Apply the budget handoff theorem Definition 4213.4. The row U can expose a single compact-uniform read only through the already displayed R, V route, and the structural rows H, C, P, N preserve that route without adding analytic data.

Row exhaustion now removes the excluded alternatives. The carrier has no coordinate for a host supremum, selected minimum radius, open-cover compactness, or ambient Real$^{\uparrow}$ completeness, so none of those objects can be exported by the finite descent. □

Theorem 4213.6 (Dini monotone ProbeBundle threshold)**.** *For an accepted* DiniMonotoneCompactUniform$^{\uparrow}$ *carrier, once the compact source row X, monotone ledger M, pointwise-limit row L, rational budget R, and finite* ProbeBundle *cover row V are displayed, every compact-uniform tolerance export factors through a single* ProbeBundle *threshold row before U can expose a uniform-modulus handoff.*

The threshold row is finite packet data assembled from X, M, L, R, V and transported through H, C, P, N. It is not a host supremum, an externally selected radius, an open-cover compactness argument, a quotient function equality, or an ambient Real$^{\uparrow}$ *completeness coordinate.*

Proof. Start with the carrier obligations of Definition 4213.2. They place the compact source row, monotone ledger, pointwise-limit row, rational budget, finite cover row, handoff row, and structural rows in the displayed carrier inventory.

Apply finite-cover extraction by Definition 4213.3. The requested tolerance first reads the compact source and rational budget, then extracts the finite ProbeBundle cover row V on which the pointwise monotone comparisons may be inspected.

Use the budget handoff of Definition 4213.4 and the finite descent of Definition 4213.5. Together they force the local monotone rows M, L and the rational budget R to be consumed on V before the handoff row U may export a single compact-uniform read.

The common finite read on V is the required threshold row. The structural rows H, C, P, N transport, replay, source, and name it without adding analytic data, and the carrier has no coordinate for a host supremum, selected radius outside the finite ProbeBundle, open-cover compactness, quotient function equality, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DiniMonotoneCompactUniform}^{\uparrow}}$.

Constructive story: A $\mathsf{DiniMonotoneCompactUniform}^{\uparrow}$ packet is generated from compact metric source rows, continuous-map family rows, monotone ledgers, pointwise-limit rows, rational tolerance budgets, finite ProbeBundle cover rows, uniform-modulus and uniform-limit handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniMonotoneCompactUniform}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4213.1, Definition 4213.2, Definition 4213.3, Definition 4213.4, and Definition 4213.5 seed the constructive compact-uniform Dini carrier surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniMonotoneCompactUniform}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, arbitrary open-cover compactness, host suprema, quotient function equality, selected radii outside the finite ProbeBundle, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-cover extraction, monotone pointwise visibility, uniform budget handoff, transport, replay, provenance, and local naming for BEDC.Derived.DiniMonotoneCompactUniformU

Chapter 4214

A Concrete Naming Certificate for $\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}$

The $\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}$ packet realizes the partition-core incidence kernel of Definition 9462.1748 as finite NameCert data. It sits over the partition carrier of chapter 201, the Boolean row discipline of chapter 3733, the simplicial support surface of chapter 238, the cellular update route of chapter 934, and the matroid rank boundary of chapter 202. The packet records finite block, quotient, lift, spectrum, and incidence rows; it is not a biological stochastic model, host graph oracle, quotient codon semantics, unrestricted spectral theorem, or hidden global scheduler.

Falsifiable prediction: Every accepted $\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}$ read exposes the partition block row, quotient-size row, incidence-count row, lift-count row, kernel-spectrum row, Boolean support row, and local NameCert row before a partition-core consumer may cite the finite incidence certificate.

Independence witness: partition, booleanalgebra, simplicialcomplex, cellularautomaton, matroid: none alone is bijective with $\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}$ because the packet jointly carries partition blocks, Boolean support tests, support-nerve incidence, cellular replay, rank-separation boundaries, quotient spectra, lift counts, transport, replay, provenance, and local naming.

Definition 4214.1 (Partition-core incidence certificate carrier)**.** *A* $\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, Q, A, L, S, E, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite partition-block row, recording the displayed block classes and their support names.*
2. *Q is the quotient-size row, recording the size-graded partition-core windows used by the incidence kernel.*
3. *A is the incidence-count row, recording finite adjacency or boundary incidences between displayed classes.*
4. *L is the lift-count row, recording codon-level or support-level lifts of each quotient incidence.*
5. *S is the kernel-spectrum row, recording the finite spectra exposed by the displayed quotient kernels.*

6. *E is the Boolean and simplicial support row, recording complement tests, face membership, and support-nerve incidence.*
7. *R is the rank and replay row, recording the matroid rank boundary and cellular replay needed by downstream partition-core consumers.*
8. *H records componentwise* hsame *transport for block, quotient, incidence, lift, spectrum, support, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from partition-core requests through $B, Q, A, L, S, E, R, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}$, $\mathsf{Partition}^{\uparrow}$, $\mathsf{BooleanAlgebra}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{CellularAutomaton}^{\uparrow}$, $\mathsf{Matroid}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, Q, A, L, S, E, R, H, C, P, N$. It has no coordinate for host graph reachability, biological stochastic semantics, quotient codon identity, unrestricted homology, hidden scheduler state, or an external spectral oracle.

Lean4 ✓ `BEDC.Derived.PartitionCoreIncidenceCertificateUp.PartitionCoreIncidenceCertificateTasteGate single carrier alignment`

Theorem 4214.2 (Partition-core incidence certificate obligations)**.** *For every accepted* PartitionCoreIncidenceCertifi *carrier*

$$I = (B, Q, A, L, S, E, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}}$ *surface consists exactly of partition-block admission through B, quotient-size exposure through Q, incidence-count exposure through A, lift-count exposure through L, finite kernel-spectrum exposure through S, Boolean and simplicial support exposure through E, rank and cellular replay exposure through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4214.1. The rows B, Q, A, L, S, E, R are the finite incidence data, and H, C, P, N are the structural certificate rows.

The incidence route first reads partition blocks and quotient sizes. Only then can a consumer inspect incidence counts, lift counts, and finite kernel spectra.

Support and replay data are also displayed. The Boolean and simplicial row E exposes the support tests, while R records rank separation and cellular replay for the same finite partition-core request.

The structural rows preserve exactly those coordinates. Since the excluded host semantics and unrestricted spectral or reachability principles have no carrier row, they cannot be obligations of the local NameCert surface. □

Theorem 4214.3 (Partition-core incidence TasteGate boundary)**.** *Any TasteGate realization for* $\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}$ *must provide* Nontrivial $\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}$ *and* FieldFaithful $\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}$ *instances preserving $B, Q, A, L, S, E, R, H, C, P, N$ as separate displayed fields. In particular, the gate must distinguish a changed partition block, quotient-size row, incidence-count row, lift-count row, kernel-spectrum row, support row, or replay row before it admits two packets as the same incidence certificate.*

Proof. Use the carrier of Definition 4214.1. The rows B, Q, A, L, S, E, R play different roles: source blocks, quotient windows, incidences, lifts, spectra, support tests, and replay boundaries.

The obligations of Definition 4214.2 consume those rows in order. Collapsing two of them would erase either the source partition, a counted incidence, a lifted incidence, a spectral claim, or the support and replay boundary.

Nontriviality is witnessed at the paper surface by packets that vary one displayed row while keeping the others fixed. Field faithfulness must therefore preserve the row list as a visible TasteGate boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}}$.

Constructive story: A $\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}$ packet is generated from partition-block rows, quotient-size rows, incidence-count rows, lift-count rows, finite kernel-spectrum rows, Boolean and simplicial support rows, rank and cellular replay rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4214.1, Definition 4214.2, and Definition 4214.3 seed the finite partition-core incidence certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PartitionCoreIncidenceCertificate}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.PartitionCoreIncidenceCertificateUp.PartitionCoreIncidenceCertificateTasteGate\_single\`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, biological stochastic semantics, quotient codon identity, host graph reachability, unrestricted homology, an external spectral oracle, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, incidence-count exposure, lift-count exposure, finite spectrum exposure, support replay, Nontrivial PartitionCoreIncidenceCertificateUp, FieldFaithful PartitionCoreIncidenceCertificateUp, transport, provenance, and local naming for BEDC.Derived.PartitionCoreIncidenceCertificateUp.

Chapter 4215

A Concrete Naming Certificate for $\mathsf{CauchyMajorantSequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyMajorantSequence}^{\uparrow}$ packet records the finite majorant-control surface used when a regular Cauchy name is read through explicit dyadic error budgets. It sits between the completion consumer of chapter 1691, the threshold discipline of chapter 292, the finite window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names one explicit Bishop-style majorant route; it is not a quotient stream, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4215.1 (Cauchy majorant sequence carrier)**.** *A* $\mathsf{CauchyMajorantSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, M, W, D, B, R, E, H, C, N)$$

with the following ten displayed fields.

1. *S is the source regular Cauchy name, read only through* $\mathsf{RegSeqRat}^{\uparrow}$ *rows.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row assigning displayed stage bounds to requested dyadic precisions.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window ledger opened to inspect the source name at the requested stages.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording radii, slack comparisons, and finite budget arithmetic.*
5. *B is the majorant sequence row, recording a displayed monotone bound for each inspected precision request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from S, M, W, D, B.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R has been displayed.*
8. *H records componentwise* hsame *transport for all source, modulus, window, dyadic, majorant, handoff, seal, replay, and naming rows.*
9. *C records displayed* Cont *replay through the same rows in consumer order.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyMajorantSequence}^{\uparrow}}$ *row, including* Pkg *provenance over* $\mathsf{FastCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, *and* Cont.

The classifier compares accepted packets only through $S, M, W, D, B, R, E, H, C, N$. No coordinate stores a quotient representative, a selected limit, countable-choice tail selection, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyMajorantSequenceUp.CauchyMajorantSequenceTasteGate single carrier alignment`

Theorem 4215.2 (Cauchy majorant sequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyMajorantSequence}$ *carrier* $J = (S, M, W, D, B, R, E, H, C, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyMajorantSequence}^{\uparrow}}$ *surface consists exactly of the carrier row* $S, M, W, D, B, R, E, H, C, N$*, classifier stability under componentwise* hsame*, dyadic ledger exposure, majorant exactness for the inspected precision requests,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, terminal* $\mathsf{Real}^{\uparrow}$ *seal ordering, displayed* Cont *replay, local provenance, and exclusion of quotient streams, selected limits, countable choice, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4215.1. The ten fields are the source regular Cauchy row, threshold row, finite window ledger, dyadic tolerance ledger, majorant row, regular readback, real seal, transport, replay, and local naming-provenance row.

The classifier is stable because H transports each field componentwise and C replays the same consumer order. A related packet can therefore change only by the displayed hsame rows, not by replacing the source with a host sequence or by identifying quotient representatives.

The ledger and exactness obligations are carried by D and B. The dyadic ledger records every tolerance request and comparison budget, while the majorant row records the displayed monotone bound consumed by the handoff.

Finally R and E are downstream of those rows. Since the packet has no coordinate for quotient streams, selected limits, countable-choice tails, host real equality, or ambient completeness, those objects cannot discharge any local NameCert obligation. □

Lean4 ✓ `BEDC.Derived.CauchyMajorantSequenceUp.CauchyMajorantSequenceCarrier namecert obligations`

Theorem 4215.3 (Cauchy majorant sequence RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{FastCauchyCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyMajorantSequence}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

The handoff exports only the source row, displayed threshold, finite windows, dyadic tolerance ledger, majorant sequence row, componentwise transport, replay, provenance, and local name carried by the same packet.

Proof. Start with the NameCert obligations of Definition 4215.2. They force every accepted regular-rational read to expose the modulus row M, the finite windows W, and the dyadic ledger D before the handoff row R is available.

The majorant row B is then read as the exact control object for those displayed requests. It is tied to the same M, W, D rows, so it cannot be detached into an external tail selector or a host-level bounding function.

The structural rows preserve the route. Componentwise transport H, replay C, and local provenance in N keep the handoff on the same finite BEDC packet, which is the surface consumed by $\mathsf{FastCauchyCompletion}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.CauchyMajorantSequenceUp.CauchyMajorantSequenceCarrier regseqrat handoff`

Theorem 4215.4 (Cauchy majorant sequence Real seal nonescape)**.** *Let $J = (S, M, W, D, B, R, E, H, C, N)$ be an accepted* $\mathsf{CauchyMajorantSequence}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$ *read of the terminal seal E must first pass through the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, majorant sequence row, and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff in the same carrier. The seal exports no quotient stream equality, selected Cauchy limit, countable-choice schedule, host real equality, or ambient completeness theorem.*

Proof. Read the carrier definition. The terminal real seal is the field E, and the definition places it after the source, modulus, window, dyadic, majorant, and regular-rational rows.

Apply Definition 4215.3. The regular handoff R is reached only through M, W, D, B, and every completion-facing consumer shares that displayed route.

Now inspect the classifier and ledger exclusions from Definition 4215.2. The accepted packet has no coordinate for quotient stream equality, selected limits, countable-choice schedules, host real equality, or ambient completeness. The real seal therefore remains a terminal read of the finite majorant route rather than an escape to any of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyMajorantSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyMajorantSequence}^{\uparrow}$ packet is generated from a regular Cauchy source row, CauchyModulus threshold row, StreamName finite windows, DyadicRatCore tolerance ledger, displayed majorant sequence, RegSeqRat handoff, RealUp seal, componentwise hsame transport, Cont replay, and local NameCert provenance.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyMajorantSequence}^{\uparrow}}$, seed)

Scope closed: Definition 4215.1, Definition 4215.2, Definition 4215.3, and Definition 4215.4 seed the explicit majorant-control route for regular Cauchy names.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyMajorantSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient stream equality, selected limits, countable choice, host real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, dyadic ledger exposure, majorant exactness, RegSeqRat handoff, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.CauchyMajorantSequ

Chapter 4216

A Concrete Naming Certificate for $\mathsf{MetricBaireSpace}^{\uparrow}$

Following Baire and Oxtoby, the $\mathsf{MetricBaireSpace}^{\uparrow}$ packet records the complete separable metric route through which a Baire-space consumer reads finite names. It sits after the metric carrier of chapter 4230, the completion service of chapter 128, the dense schedule of chapter 1458, the finite windows of chapter 126, the regular rational readback of chapter 301, and the prefix surface of chapter 334. The packet binds those rows as one complete-separable Baire naming surface without adding countable choice, a host topology, quotient point equality, or an external completion coordinate.

Definition 4216.1 (Metric Baire-space carrier)**.** *A* $\mathsf{MetricBaireSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, K, D, S, R, B, H, C, P_0, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row carrying the admitted point history, metric readbacks, distance classifier, and local metric naming.*
2. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row over the same metric carrier, displaying the Cauchy-window and limit-service route.*
3. *D is the* $\mathsf{SeparableMetric}^{\uparrow}$ *row exposing a countable dense schedule as finite name data rather than as a choice function.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row scheduling finite inspections of dense names, Baire prefixes, metric balls, and Cauchy-window requests.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row that reads rational windows for centers, radii, tolerances, and regular Cauchy approximants.*
6. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *ledger row recording finite-prefix and cylinder reads consumed by the Baire-space side of the packet.*
7. *H records componentwise* hsame *transport for M, K, D, S, R, B and the local certificate rows.*
8. *C records displayed* Cont *replay from a metric-ball, dense-name, Cauchy-window, or Baire-prefix request through the visible rows.*
9. *P_0 is the* Pkg *provenance over* $\mathsf{MetricBaireSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{MetricBaireSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only after transporting the metric, complete-metric, separable-metric, stream, regular-readback, and Baire-prefix rows to one common surface. It has no coordinate for a selected dense sequence, a host completion, arbitrary open-cover semantics, quotient point equality, or a generic-point selector.

Lean4 ✓ `BEDC.Derived.MetricBaireSpaceUp.MetricBaireSpaceTasteGate single carrier alignment`

Theorem 4216.2 (Metric Baire-space NameCert obligations)**.** *For every accepted* $\mathsf{MetricBaireSpace}^{\uparrow}$ *carrier* $P = (M, K, D, S, R, B, H, C, P_0, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricBaireSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric, complete-metric, separable-metric, stream, regular-readback, Baire-prefix, transport, replay, provenance, and local-name rows; classifier transport to a common metric carrier before any completion, density, or Baire-prefix row is consumed; observation-ledger exactness through* S, R, B*; stability under the componentwise transports in* H*; displayed* Cont *replay through* C*; and provenance plus local naming through* P_0, N*. No naming obligation is stored outside these rows.*

Proof. Project the carrier of Definition 4216.1. The rows M, K, D, S, R, B are the analytic surfaces, and H, C, P_0, N are the structural transport, replay, provenance, and naming surfaces.

The classifier route begins at M. The complete-metric row K, separable row D, and Baire-prefix row B are read only after the componentwise transport row has placed them over the same metric carrier.

The finite observation route is exhausted by S, R, B. Dense-name requests, Cauchy-window requests, metric-ball checks, and Baire-prefix reads all pass through the stream schedule and regular rational readback before any consumer can use them.

Finally replay through C and attach P_0, N. Since the carrier contains no coordinate for a selected dense sequence, host completion, arbitrary open-cover object, quotient point equality, or generic-point selector, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricBaireSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricBaireSpace}^{\uparrow}$ packet is generated from a MetricSpace source row, CompleteMetric handoff row, SeparableMetric dense schedule, StreamName finite windows, RegSeqRat readback, BaireSpace prefix ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricBaireSpace}^{\uparrow}}$, seed)

Scope closed: Definition 4216.1 and Definition 4216.2 seed the complete-separable metric Baire naming surface consumed by downstream Polish and Baire chapters.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricBaireSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected dense sequences, host completions, arbitrary open-cover semantics, quotient point equality, generic-point selectors, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common metric transport, completion service, dense schedule, StreamName windows, RegSeqRat readback, Baire-prefix ledger exactness, replay, provenance, and local naming for BEDC.Derived.MetricBaireSpaceUp.

Chapter 4217

A Concrete Naming Certificate for DNAWindowSixTriggerThreshold$^{\uparrow}$

The DNAWindowSixTriggerThreshold$^{\uparrow}$ packet realizes the random trigger-time law of Definition 9462.1539 as finite trigger-rank NameCert data. It sits beside the six-bit codon source window of chapter 2234, the boundary tile packet of chapter 3393, the six-tile coverage rows of chapter 3470, the trigger-algebra surface of chapter 3478, and the orbit inventory polynomial of chapter 4220. The packet names full-trigger distribution rows, trigger-time law rows, mean and quantile tables, transport, replay, provenance, and local naming as a finite combinatorial surface; it is not a biological stochastic model, an empirical mutation law, or an unbounded trigger search.

Definition 4217.1 (DNA window-six trigger-threshold carrier)**.** *A* DNAWindowSixTriggerThreshold$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, B, C, A, F, L, Q, H, R, P, N)$$

with the following displayed rows:

1. *W is the* CodonSixBitWindow$^{\uparrow}$ *row exposing the six-coordinate codon window.*
2. *B is the* DnaWindowSixBoundaryTile$^{\uparrow}$ *boundary-tile row supplying the trigger coordinates.*
3. *C is the* SixBoundaryTileCoverage$^{\uparrow}$ *row recording which trigger coordinates are covered by a finite external-codon draw.*
4. *A is the* WindowCoverageTriggerAlgebra$^{\uparrow}$ *row computing trigger rank and full-cube activation from the displayed coverage data.*
5. *F is the full-trigger distribution row for the finite external-codon process beyond $M^{\star} = \mathrm{NNR} \cup \mathrm{CUY}$.*
6. *L is the trigger-time law row recording the first time at which all four trigger coordinates are covered.*
7. *Q records the displayed mean and quantile table for the trigger time.*
8. *H records componentwise* hsame *transport for W, B, C, A, F, L, Q and the structural rows.*
9. *R records displayed* Cont *replay from an external-codon window through coverage, trigger rank, full-trigger distribution, trigger-time law, and table readback.*

10. *P is the* Pkg *provenance over* DNAWindowSixTriggerThreshold$^{\uparrow}$, CodonSixBitWindow$^{\uparrow}$, DnaWindowSixBoundaryT SixBoundaryTileCoverage$^{\uparrow}$, WindowCoverageTriggerAlgebra$^{\uparrow}$, *the random trigger-threshold source theorem,* BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed six-window, boundary, coverage, trigger-algebra, distribution, law, table, transport, replay, provenance, and local naming rows. It has no coordinate for empirical biology, stochastic fitness, hidden codon semantics, or an unrecorded search over external codon subsets.

Lean4 ✓ `BEDC.Derived.DNAWindowSixTriggerThresholdUp.DNAWindowSixTriggerThresholdTasteGate single carrier alignment`

Theorem 4217.2 (DNA window-six trigger-threshold full-cube law)**.** *For every accepted* DNAWindowSixTriggerThr *carrier $T = (W, B, C, A, F, L, Q, H, R, P, N)$, the full-cube trigger law is the finite route*

$$\mathsf{CodonSixBitWindow}^{\uparrow} \longmapsto \mathsf{DnaWindowSixBoundaryTile}^{\uparrow} \longmapsto \mathsf{SixBoundaryTileCoverage}^{\uparrow} \longmapsto \mathsf{WindowCoverageTriggerA}$$

The row F stores the full-trigger distribution, L stores the trigger-time law, and Q stores the mean and quantile table. Any accepted consumer of the average threshold 3.12998*, the deterministic threshold* 15*, the median threshold* 3*, or the* 99% *threshold* 7 *must read those values through the displayed route.*

Lean4 ✓ `BEDC.Derived.DNAWindowSixTriggerThresholdUp.DNAWindowSixTriggerThreshold full cube law`

Proof. Project the carrier of Definition 4217.1. The source rows W, B, C, A display the finite codon window, boundary tiles, coverage ledger, and trigger algebra before any distribution row is read.

The rows F, L, Q are the numerical threshold ledger. The full-trigger distribution row determines the law row, and the law row determines the mean and quantile table recorded by Q.

Transport and replay preserve that route through H and R. Provenance and local naming attach the source theorem and the NameCert row through P, N.

Since the carrier contains no empirical-biological coordinate, stochastic fitness model, hidden codon semantics, or unrecorded subset search, every full-cube threshold read is exhausted by the displayed finite route. □

Falsifiable prediction: Every accepted DNAWindowSixTriggerThreshold$^{\uparrow}$ read of the mean, deterministic threshold, median threshold, or 99% threshold factors through CodonSixBitWindow, DnaWindowSixBoundaryTile, SixBoundaryTileCoverage, WindowCoverageTriggerAlgebra, full-trigger distribution, trigger-time law, table, transport, replay, provenance, and local NameCert rows.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, six-boundary-tile-coverage, window-coverage-trigger-algebra, boundary-orbit-inventory-polynomial: DNAWindowSixTriggerThreshold is not bijective to any listed sibling because it jointly carries the trigger-rank distribution, trigger-time law, mean and quantile table, transport, replay, provenance, and local naming as one threshold packet.

Future Lean TasteGate files for this packet must provide explicit Nontrivial DNAWindowSixTriggerThreshold$^{\uparrow}$ and FieldFaithful DNAWindowSixTriggerThreshold$^{\uparrow}$ instances before the threshold law can serve as a verified trigger-distribution consumer.

Closure status for $\mathsf{NameCert}_{\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}}$.

Constructive story: A $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$ packet is generated from CodonSixBitWindow source rows, DnaWindowSixBoundaryTile boundary rows, SixBoundaryTileCoverage rows, WindowCoverageTriggerAlgebra rows, full-trigger distribution rows, trigger-time law rows, mean and quantile table rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4217.1 and Definition 4217.2 seed the finite trigger-threshold packet for the window-six random trigger law.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim biological mechanism, empirical mutation dynamics, stochastic fitness, hidden codon semantics, unrestricted subset search, Lean verification, Nontrivial or FieldFaithful TasteGate instances, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, coverage exposure, trigger-rank distribution, trigger-time law, mean and quantile table exactness, transport, replay, provenance, local naming, Nontrivial DNAWindowSixTriggerThresholdUp, and FieldFaithful DNAWindowSixTriggerThresholdUp for BEDC.Derived.DNAWindowSixTriggerThresholdUp.

Chapter 4218

A Concrete Naming Certificate for $\mathsf{MetricCompletionKleisli}^{\uparrow}$

Following Mac Lane's Kleisli categories, and Bishop–Bridges and Kelley on metric completion, the $\mathsf{MetricCompletionKleisli}^{\uparrow}$ packet records the metric-specific bind consumer for completion-valued maps as finite BEDC data. It reads the metric completion carrier of chapter 1506, the metric adjunction route of chapter 3836, the Cauchy Kleisli consumer of chapter 1845, and the completion universal property of chapter 397. The chapter names a consumer route for bind-style completion reads; it is not a quotient completion, selected representative, countable-choice schedule, host equality of completed points, or ambient completeness theorem.

Definition 4218.1 (MetricCompletionKleisli carrier)**.** *A* $\mathsf{MetricCompletionKleisli}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, A, L, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row, displaying the source metric, completion carrier, separated comparison, dense-source access, and readback branch before any bind consumer is opened.*
2. *A is the* $\mathsf{MetricCompletionAdjunction}^{\uparrow}$ *row, displaying the unit, counit, triangle ledger, and metric universal mapping boundary read by the consumer.*
3. *L is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *row, recording the unit, bind, and reassociated-bind consumer route inherited from the L10 completion algebra.*
4. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row, exposing the extension surface through which a displayed metric source map is consumed as a completion-valued map.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used by the metric completion and Cauchy Kleisli routes.*
6. *E is the public* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, A, L, U, R have been displayed.*
7. *H records componentwise* hsame *transport for the metric completion row, metric adjunction row, Cauchy Kleisli row, universal-property row, regular readback, Real seal, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from a bind consumer request through $M, A, L, U, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionKleisli}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{MetricCompletionAdjunction}^{\uparrow}$, $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{MetricCompletionKleisli}^{\uparrow}}$ *row.*
The classifier accepts only packets whose bind consumer first displays the metric completion, metric adjunction, Cauchy Kleisli, universal-property, regular readback, Real seal, hsame, Cont, Pkg, *and local* NameCert *rows listed above.*

Lean4 ✓ `BEDC.Derived.MetricCompletionKleisliUp.MetricCompletionKleisliTasteGate single carrier alignment`

Theorem 4218.2 (MetricCompletionKleisli NameCert obligations)**.** *For every accepted* $\mathsf{MetricCompletionKleisli}^{\uparrow}$ *carrier*

$$K = (M, A, L, U, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricCompletionKleisli}^{\uparrow}}$ *surface consists exactly of metric-completion admission, metric-adjunction admission, Cauchy-Kleisli bind exposure, completion-universal-property exposure, RegSeqRat readback, Real seal readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the rows of K. No obligation may be discharged by a quotient completion, selected Cauchy representative, countable-choice selector, host equality of completed points, or ambient complete metric space.*

Proof. Project the carrier of Definition 4218.1. Its analytic rows are precisely the metric completion row M, the metric adjunction row A, the Cauchy Kleisli row L, the universal-property row U, the regular readback row R, and the Real seal row E.

The metric rows determine the order of access. A bind consumer opens M before it can read the adjunction data in A, and it opens A before the Cauchy Kleisli consumer L can hand off unit, bind, or reassociated-bind requests to the universal-property row U.

Transport and replay add no analytic coordinate. The rows H and C compare and replay only the displayed completion, adjunction, Kleisli, universal-property, readback, and seal data.

Finally P and N source and name the same finite packet. Since no listed row stores a quotient completion, selected representative, countable-choice selector, host equality, or ambient complete metric space, the displayed rows exhaust the NameCert surface. □

Theorem 4218.3 (MetricCompletionKleisli bind handoff)**.** *Every bind-style consumer read of an accepted* $\mathsf{MetricCompletionKleisli}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{MetricCompletionAdjunction}^{\uparrow} \longmapsto \mathsf{CauchyCompletionKleisli}^{\uparrow} \longmapsto \mathsf{CompletionUniversalProperty}$$

The handoff reaches the displayed $\mathsf{Real}^{\uparrow}$ *seal only through componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionKleisli}^{\uparrow}}$ *row carried by the same packet.*

Proof. Begin with the metric completion row M. It displays the source metric, completion carrier, separated comparison, dense-source access, and readback branch before a consumer can request completion-valued bind data.

Next read the adjunction row A. The unit, counit, triangle ledger, and metric universal mapping boundary are the only route by which the metric completion packet exposes extension data to a downstream consumer.

Attach the Cauchy Kleisli row L and the universal-property row U. The row L supplies the unit, bind, and reassociated-bind consumer surface, while U records the extension route that consumes a displayed source map as a completion-valued map.

The readback and seal rows close the route. The row R supplies the regular rational readback used by both completion and Kleisli sides, and E is the only public Real seal. The structural

rows H, C, P, N transport, replay, source, and name this same route, so no quotient completion, selected representative, choice schedule, host equality, or ambient completeness theorem can enter the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionKleisli}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionKleisli}^{\uparrow}$ packet is generated from metric completion, metric adjunction, Cauchy Kleisli, completion universal property, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionKleisli}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4218.1, Definition 4218.2, and Definition 4218.3 seed the metric-specific Kleisli consumer route for bind-style completion reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionKleisli}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, host equality of completed points, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-adjunction exposure, Cauchy-Kleisli exposure, universal-property exposure, RegSeqRat/Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionKleisliUp.

Chapter 4219

A Concrete Naming Certificate for $\mathsf{LocatedRegularRealCut}^{\uparrow}$

Following Bishop and Bridges' constructive real analysis, the $\mathsf{LocatedRegularRealCut}^{\uparrow}$ packet records the finite boundary where regular-Cauchy real names expose located lower and upper rational cut rows before the terminal real seal is read. It sits beside the dyadic tolerance core of chapter 291, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, the real-name seal of chapter 38, the Dedekind cut carrier of chapter 436, and the located regular sequence route of chapter 2376. The packet is a finite NameCert bridge from regular-Cauchy observations to located cut boundaries; it does not claim Dedekind completeness, quotient equality of real names, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4219.1 (Located regular real cut carrier)**.** *A* $\mathsf{LocatedRegularRealCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, U, M, D, R, A, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower rational cut row, recording inhabited rounded lower observations read through the finite cut-facing side of* $\mathsf{DedekindCut}^{\uparrow}$*.*
2. *U is the upper rational cut row, recording rounded upper observations attached to the same inspected real-name request.*
3. *M is the locatedness modulus row, binding every rational comparison request to a finite window on which either the lower row or the upper row is displayed with the required separation.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row supplying dyadic radii, bracket widths, midpoint requests, and comparison tolerances for the cut boundary.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular rational observations from which the cut rows and locatedness modulus are read.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, U, M, D, R have been displayed.*
7. *H records componentwise* hsame *transport for lower cut rows, upper cut rows, locatedness modulus rows, dyadic tolerance rows, regular readback rows, Real seal rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a cut-boundary request through L, U, M, D, R, A, H.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedRegularRealCut}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{LocatedRegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRegularRealCut}^{\uparrow}}$ *row.*

The carrier accepts only the displayed lower row, upper row, locatedness modulus, dyadic tolerance, regular readback, Real seal, transport, replay, provenance, and naming rows. It has no coordinate for Dedekind completeness, quotient real equality, selected representatives, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.LocatedRegularRealCutUp.LocatedRegularRealCutUp`

Theorem 4219.2 (Located regular real cut obligations)**.** *For every accepted* $\mathsf{LocatedRegularRealCut}^{\uparrow}$ *carrier* $K = (L, U, M, D, R, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRegularRealCut}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed lower cut row, upper cut row, locatedness modulus, dyadic tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local naming row;*
2. *located lower and upper stability, requiring L and U to remain rounded, separated, and transported componentwise under the same* hsame *row;*
3. *regular Cauchy handoff, requiring every cut-boundary read to pass through R and the located regular sequence discipline of chapter 2376;*
4. *Real seal non-escape, requiring A to be downstream of L, U, M, D, R and not an independent completeness row;*
5. *ledger exactness, requiring P and N to name only L, U, M, D, R, A, H, C and to exclude quotient equality, selected limits, trichotomy, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 4219.1. The displayed analytic rows are the lower cut row L, upper cut row U, locatedness modulus M, dyadic tolerance row D, regular readback row R, and Real seal row A.

The lower and upper stability clauses are componentwise. Transport through H preserves the two cut rows together with the same modulus and dyadic tolerance row, so the classifier cannot move a lower observation without moving the matching upper boundary data.

The regular Cauchy handoff is the route through R. The located regular sequence sibling supplies the finite windows and readback discipline before the cut boundary can be consumed, while D supplies the tolerance ledger on which the locatedness modulus is read.

Finally A, C, P, N seal, replay, source, and name only the displayed route. Since none of the carrier coordinates is a quotient, selected limit, trichotomy branch, choice schedule, or ambient completeness theorem, the listed obligations exhaust the local certificate. □

Theorem 4219.3 (Located regular real cut Cauchy boundary route)**.** *Every accepted* $\mathsf{LocatedRegularRealCut}^{\uparrow}$ *consumer factors through*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{LocatedRegSeqRat}^{\uparrow},\ \mathsf{DedekindCut}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

as displayed finite rows before it can read the local $\mathsf{NameCert}_{\mathsf{LocatedRegularRealCut}^{\uparrow}}$ *row. The route exports a located lower–upper cut boundary for a regular-Cauchy real name; it does not export Dedekind completeness, quotient real equality, selected limits, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with Definition 4219.2. A consumer first sees the dyadic tolerance row D, regular readback row R, and locatedness modulus M before the lower and upper cut rows can be treated as a located boundary.

The Dedekind cut sibling supplies the cut-facing row shape, while the located regular sequence sibling supplies the Cauchy-facing source and tail-window discipline. These rows meet only through the displayed finite packet K.

The Real seal row A is terminal for this route. Componentwise transport, continuation replay, package provenance, and local naming preserve the same displayed rows, so no consumer can bypass them by invoking quotient equality, a selected representative, trichotomy, choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{LocatedRegularRealCut}^{\uparrow}$ read factors through displayed lower rational cut, upper rational cut, locatedness modulus, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedRegSeqRat}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and local NameCert rows.

Independence witness: dyadicratcore, regseqrat, real, dedekindcut, located-regseqrat: no listed sibling is bijective to $\mathsf{LocatedRegularRealCut}^{\uparrow}$ because this packet alone binds lower and upper cut rows, a locatedness modulus, dyadic tolerance, regular readback, terminal real seal, transport, replay, provenance, and local naming into one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRegularRealCut}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRegularRealCut}^{\uparrow}$ packet is generated from lower rational cut rows, upper rational cut rows, a locatedness modulus, DyadicRatCore tolerance rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedRegularRealCut}^{\uparrow}}$, seed)

Scope closed: Definition 4219.1, Definition 4219.2, and Definition 4219.3 seed the finite bridge from regular-Cauchy real names to located lower–upper cut boundaries.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedRegularRealCut}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Dedekind completeness, quotient real equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located lower and upper stability, regular Cauchy handoff, Real seal non-escape, and ledger exactness for BEDC.Derived.LocatedRegularRealCutUp.

Chapter 4220

A Concrete Naming Certificate for $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$

The $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$ packet realizes the orbit and codon inventory polynomials of Definition 9462.1713 as finite BEDC NameCert data. It consumes the boundary-tile source of chapter 3393, the coverage packet of chapter 3470, the codon window source of chapter 2234, and the finite polynomial carrier of chapter 50. The packet records orbit rows, codon-count rows, coefficient ledgers, and marginal projections; it is not a biological stochastic model, an empirical code table, a hidden enumeration oracle, or quotient codon semantics.

Definition 4220.1 (Boundary orbit inventory polynomial carrier)**.** *A* $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (O, K, E, M, H, C, P, N)$$

with the following displayed rows:

1. *O is the orbit table row, recording the finite orbit types classified by support size m, overlap defect δ, lift imbalance b, and orbit size.*
2. *K is the codon count table row, recording the weighted counts of lifted triggers over the same triples (m, δ, b).*
3. *E is the coefficient ledger row, storing the displayed coefficients of the orbit inventory polynomial $\mathcal{O}(u, v, w)$ and the codon inventory polynomial $\mathcal{C}(u, v, w)$.*
4. *M is the marginal projection row, recording the one-variable and bivariate specializations read from the coefficient ledger.*
5. *H records componentwise* hsame *transport for the orbit table, codon count table, coefficient ledger, marginal projections, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from an inventory query through O, K, E, M, H.*
7. *P is the* Pkg *provenance over* $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, *the source vision of Definition 9462.1713,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}}$ *row.*

The carrier accepts coefficient and marginal reads only through O, K, E, M, H, C, P, N. It has no coordinate for a hidden biological code table, probabilistic fitness model, unbounded orbit enumeration, quotient codon equality, or unstated polynomial coefficient source.

Lean4 ✓ `BEDC.Derived.BoundaryOrbitInventoryPolynomialUp.BoundaryOrbitInventoryPolynomialTasteGate`
`single carrier alignment`

Theorem 4220.2 (Boundary orbit inventory polynomial obligations)**.** *For every accepted* BoundaryOrbitInventoryP *carrier $I = (O, K, E, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}}$ *surface consists exactly of orbit-table admission through O, codon-count table admission through K, coefficient-ledger exactness through E, marginal-projection exactness through M, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4220.1. The orbit table and codon count table are the only source rows, while the coefficient ledger and marginal projection rows are the only polynomial-facing rows.

Coefficient exactness is read from E. Each displayed coefficient is determined by grouping the rows of O and weighting them by the count row K; no coefficient row is available without those two source tables.

Marginal exactness is read from M. A marginal projection is permitted only as a specialization of the coefficient ledger, so it cannot replace the orbit table or codon count table by a hidden enumeration.

The structural rows H, C, P, N preserve, replay, source, and name the same finite route. Since the carrier lacks biological stochastic, quotient-codon, hidden-table, and unbounded-enumeration coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 4220.3 (Boundary orbit inventory coefficient determinacy)**.** *Every coefficient marginal exported by an accepted* $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$ *packet is determined by the displayed orbit table O, codon count table K, coefficient ledger E, and marginal projection row M. Removing any coefficient row from E leaves a marginal query without a displayed source, and removing any orbit or codon count row leaves the corresponding coefficient without a displayed inventory witness.*

Proof. Read the NameCert obligations of Definition 4220.2. A coefficient query first exposes the orbit table O and codon count table K, then reads the coefficient ledger E.

The marginal projection row M is downstream of the ledger. It can specialize the displayed polynomial, but it cannot introduce a coefficient absent from E or reconstruct a missing source row absent from O or K.

Transport and replay preserve the same dependency order. Therefore a coefficient marginal is determined exactly by the displayed table and ledger rows, and deletion of any required row breaks the finite NameCert route. □

Falsifiable prediction: For $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$, coefficient marginals are determined by the displayed orbit table, codon count table, coefficient ledger, and marginal projection rows, and a marginal read fails if any required coefficient row is removed.

Independence witness: partition, hash, errorcode, dna-window-six-boundary-tile, six-boundary-tile-coverage: the polynomial coefficient ledger is not bijective to these sibling carriers because it binds orbit tables, codon count tables, coefficient rows, marginal projections, transport, replay, provenance, and local naming, while the siblings supply partitioning, digest, error coding, boundary-tile, or coverage surfaces without this coefficient inventory.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}$ packet is generated from an orbit table, codon count table, coefficient ledger, marginal projection row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4220.1, Definition 4220.2, and Definition 4220.3 seed the finite orbit-inventory polynomial certificate over boundary-tile and coverage rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryOrbitInventoryPolynomial}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological stochastic modeling, empirical code-table semantics, quotient codon equality, unbounded orbit enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked orbit-table admission, codon-count table admission, coefficient-ledger exactness, marginal-projection exactness, transport, replay, provenance, and local naming for BEDC.Derived.BoundaryOrbitInventoryPol

Chapter 4221

A Concrete Naming Certificate for $\mathsf{PrimitiveRecursive}^{\uparrow}$

Following Kleene's primitive recursive functions, the $\mathsf{PrimitiveRecursive}^{\uparrow}$ packet records finite recursion syntax and its local replay rows as BEDC data. It sits after the unary natural-number carrier of chapter 28, the list spine of chapter 36, the finite computability surface of chapter 199, the stream-window discipline of chapter 126, and the regular rational readback route of chapter 301. The chapter supplies a finite schedule substrate for later modulus and real-name consumers; it does not introduce minimization, partial recursive search, host functions, or unbounded choice.

Definition 4221.1 (PrimitiveRecursive carrier)**.** *A* $\mathsf{PrimitiveRecursive}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (Z, S, \Pi, K, R, H, C, Q, N)$$

whose rows are read as follows:

1. *Z is the zero-function row.*
2. *S is the successor-function row.*
3. *Π is the finite family of projection rows, each with displayed arity and coordinate index.*
4. *K is the composition row, storing one outer code, its finite list of inner codes, and the arity ledger that makes the composition well typed.*
5. *R is the primitive-recursion scheme row, storing the base code, step code, displayed accumulator coordinate, and finite recursion spine over the* $\mathsf{Nat}^{\uparrow}$ *row.*
6. *H is componentwise* hsame *transport for zero, successor, projection, composition, recursion, replay, provenance, and local naming rows.*
7. *C is displayed* Cont *replay for evaluating a finite syntax tree by structural recursion through the rows Z, S, Π, K, R.*
8. *Q is the* Pkg *provenance row over* $\mathsf{PrimitiveRecursive}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{Computable}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PrimitiveRecursive}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Z, S, \Pi, K, R, H, C, Q, N$. There is no coordinate for minimization, unbounded search, partiality, a host function graph, countable choice, or an external evaluator.

Lean4 ✓ `BEDC.Derived.PrimitiveRecursiveUp.TasteGate.PrimitiveRecursiveTasteGate single carrier alignment`

Theorem 4221.2 (PrimitiveRecursive NameCert obligations)**.** *For every accepted* $\mathsf{PrimitiveRecursive}^{\uparrow}$ *carrier*

$$P = (Z, S, \Pi, K, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrimitiveRecursive}^{\uparrow}}$ *surface consists exactly of carrier admission for the zero, successor, projection, composition, primitive-recursion, transport, replay, provenance, and naming rows; arity compatibility for* Π, K, R*; structural replay of the displayed syntax tree through* C*; componentwise transport through* H*; and provenance through* Q, N*. No obligation is stored in a minimization row, partial recursive search row, host-function graph, or unbounded-choice selector.*

Proof. Inspect the carrier row by row. The base constructors are Z, S, Π, and their arity information is part of the displayed finite rows rather than a host-side function space.

For composite syntax, the row K supplies the finite list of inner codes and the outer code, while R supplies the base and step codes for the primitive-recursion scheme. Induction on the displayed syntax tree checks that every replay request descends to one of Z, S, Π or to a strictly displayed subcode of K or R.

The structural rows close the local certificate. Transport through H preserves the same constructor rows, replay through C evaluates only the displayed syntax tree, and Q, N record provenance and naming. Since the packet has no coordinate for minimization, partial recursive search, host functions, or unbounded choice, the listed rows exhaust the NameCert obligations. □

Theorem 4221.3 (PrimitiveRecursive composition closure)**.** *If an accepted* $\mathsf{PrimitiveRecursive}^{\uparrow}$ *packet contains a composition row* K *whose outer code and finite list of inner codes are accepted by the same carrier, then the composed code is again read as a* $\mathsf{PrimitiveRecursive}^{\uparrow}$ *row through* K, H, C, Q, N*. The closure is internal to the finite displayed syntax and exports no minimization, partiality, host-function graph, or unbounded-choice principle.*

Proof. Proceed by induction on the finite list of inner codes recorded in K. The empty-list boundary is the displayed arity check for the outer code, and the single-step case appends one already accepted inner row to the composition ledger.

At each induction step the replay row C evaluates the inner rows before the outer row, and transport through H preserves the same arity and constructor classifiers. The provenance row Q and local naming row N then repackage the resulting finite syntax as a $\mathsf{PrimitiveRecursive}^{\uparrow}$ row.

No unbounded search is used in the induction. The construction consumes only the displayed finite list in K and the accepted subcodes already present in the carrier, so it cannot introduce minimization, partial recursive search, host functions, or unbounded choice. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrimitiveRecursive}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrimitiveRecursive}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4221.1, Definition 4221.2, and Definition 4221.3 seed the finite recursion-syntax certificate for schedule and modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrimitiveRecursive}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close minimization, partial recursive search, host functions, unbounded choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, arity compatibility, composition closure, primitive-recursion replay, transport, provenance, and local naming for the same finite recursion syntax.

Constructive story: The construction starts from zero, successor, and projection rows, closes finite composition through a displayed list spine, and closes primitive recursion by replaying the base and step codes over the Nat row under componentwise transport and local naming.

The $\mathsf{CauchyAcceleration}^{\uparrow}$ packet reads the StreamName, DyadicRatCore, RegSeqRat, and Real sibling surfaces of chapter 126, chapter 291, chapter 301, and chapter 38 before exporting its accelerated completion-facing route.

Chapter 4222

A Concrete Naming Certificate for $\mathsf{CauchyAcceleration}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyAcceleration}^{\uparrow}$ packet records the finite acceleration step by which an ordinary displayed Cauchy name is replaced by a cofinal regular rational name without changing the represented real. It sits after the criterion surfaces of chapter 392 and chapter 3576, the regularization route of chapter 376, the windowed name surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The acceleration packet consumes Cauchy tail comparison as substantive finite-window and dyadic-tolerance data through chapter 301, chapter 126, chapter 291, and chapter 38 before any accelerated Real-facing read is exported. The accelerated cofinal regular-rational name is consumed by chapter 5721 as the completion-existence witness route, with the read still passing through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The packet makes acceleration a named finite ledger: it does not select an ambient subsequence, quotient a Cauchy representative, or appeal to host completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4222.1 (Cauchy acceleration carrier)**.** *A* $\mathsf{CauchyAcceleration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, T, \alpha, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *row whose finite windows display the original rational Cauchy name.*
2. *T is the dyadic tolerance schedule, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, assigning the requested precision budget to each inspected window.*
3. *α is the cofinal acceleration map, stored as a finite monotone ledger saying which source window is read for each accelerated precision request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *proof row for the accelerated rational name, including the regularity inequalities obtained by reading S through α and T.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, recording that the accelerated regular name reaches the same Real-facing boundary as the source name.*
6. *H records componentwise* hsame *transport for the source stream, tolerance schedule, cofinality map, regular proof row, Real seal, provenance, and local naming row.*

7. *C records displayed* Cont *replay from an acceleration request through S, T, α, R, E and then to the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyAcceleration}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyAcceleration}^{\uparrow}}$ *row.*

The carrier has no coordinate for a quotient representative of the original Cauchy name, a choice-selected subsequence, an ambient completeness theorem, or a host-side equality oracle for real numbers.

Theorem 4222.2 (Cauchy acceleration NameCert obligations)**.** *For every accepted* $\mathsf{CauchyAcceleration}^{\uparrow}$ *carrier $A = (S, T, \alpha, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyAcceleration}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed* $\mathsf{StreamName}^{\uparrow}$ *source row S, dyadic tolerance schedule T, cofinal map α, regular rational proof row R, and Real seal row E;*
2. *monotone cofinality, requiring α to preserve request order and to eventually reach every inspected source precision window;*
3. *dyadic tolerance preservation, requiring each accelerated request to read the same displayed tolerance budget through* $\mathsf{DyadicRatCore}^{\uparrow}$ *before it reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *row;*
4. *classifier transport, requiring H and C to preserve the source stream, tolerance schedule, cofinality ledger, regular proof row, and Real seal under componentwise* hsame *and displayed replay;*
5. *ledger exhaustion through P and N, excluding quotient representatives, choice-selected subsequences, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and host real equality.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4222.1. The accepted packet exposes only the source stream S, tolerance schedule T, acceleration ledger α, regular readback R, Real seal E, and the structural rows.

Monotone cofinality is the public content of α. Since α is stored as a finite ledger over the inspected request window, each accelerated precision read names the source window it consumes and records that later requests do not move backward.

Dyadic tolerance preservation follows by reading T before the regular rational proof row. The $\mathsf{RegSeqRat}^{\uparrow}$ row R receives exactly the tolerance entries displayed by $\mathsf{DyadicRatCore}^{\uparrow}$, so the acceleration cannot import an unrecorded modulus or external precision oracle.

Classifier transport is componentwise through H and replayed through C. These rows preserve S, T, α, R, E without adding a second classifier surface.

Finally, P and N name precisely the displayed packet. Because the carrier contains no quotient representative, choice-selected subsequence, ambient completeness coordinate, or host real equality oracle, the five listed rows exhaust the local naming obligations. □

Theorem 4222.3 (Cauchy acceleration L10 handoff)**.** *Every accepted* $\mathsf{CauchyAcceleration}^{\uparrow}$ *carrier $A = (S, T, \alpha, R, E, H, C, P, N)$ exports only the finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

displayed by $S, T, \alpha, R, E, H, C, P, N$. Consequently every L10 consumer receives a $\mathsf{RegSeqRat}^{\uparrow}$*-compatible and* $\mathsf{Real}^{\uparrow}$*-compatible accelerated name, while quotient representatives of the original Cauchy name, choice-selected subsequences, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness remain unavailable.*

Proof. Project the accepted carrier and apply Definition 4222.2. The only public data are $S, T, \alpha, R, E, H, C, P, N$.

The source read begins at the $\mathsf{StreamName}^{\uparrow}$ row S. The tolerance read then passes through T and α, so every accelerated precision request is attached to an explicit dyadic budget and a displayed source window.

The regular rational handoff is exactly R, and the Real-facing boundary is exactly E. Transport and replay through H and C preserve that route for downstream consumers.

Since P and N exhaust the packet and no forbidden coordinate appears in Definition 4222.1, the exported object is only the displayed accelerated name compatible with $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. □

Theorem 4222.4 (Cauchy acceleration rectangular window route)**.** *Every accepted* $\mathsf{CauchyAcceleration}^{\uparrow}$ *carrier* $A = (S, T, \alpha, R, E, H, C, P, N)$ *reuses the same* $\mathsf{StreamName}^{\uparrow}$ *finite windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows when producing the accelerated* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and the terminal* $\mathsf{Real}^{\uparrow}$ *handoff. The cofinal ledger* α *may refine the order of precision requests, but it cannot replace the displayed window route recorded by* S, T, H, C, P, N*.*

Proof. Project the rows $S, T, \alpha, R, E, H, C, P, N$. The source windows are recorded in S, and the dyadic tolerance entries are recorded in T before the accelerated regular rational row R or the Real-facing seal E is consumed.

Apply Definition 4222.2. The cofinality row α is an order ledger over displayed source windows, while dyadic tolerance preservation forces each accelerated request to read the same T row before it reaches R.

Now apply Definition 4222.3. Transport and replay through H and C preserve the route named by P and N, so no quotient representative, selected subsequence outside the ledger, or ambient completeness row is exported. □

Theorem 4222.5 (Cauchy acceleration cofinal-ledger determinism)**.** *Let*

$$A = (S, T, \alpha, R, E, H, C, P, N)$$

and

$$A' = (S, T, \alpha', R', E', H, C, P, N)$$

be accepted $\mathsf{CauchyAcceleration}^{\uparrow}$ *carriers sharing the same displayed source stream, tolerance schedule, structural replay rows, provenance rows, and local naming boundary through* S, T, H, C, P, N*. If the two cofinal ledgers* α *and* α' *choose the same source window for every inspected precision request, then their accelerated* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and terminal* $\mathsf{Real}^{\uparrow}$ *seal follow the same finite route. In particular, neither ledger can replace the displayed source-window or tolerance route before* R, R' *and* E, E' *are read.*

Proof. Project both accepted carriers through Definition 4222.1. The shared rows expose the same $\mathsf{StreamName}^{\uparrow}$ source windows, the same $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance schedule, and the same replay and provenance boundary.

Apply Definition 4222.2 to both packets. The only ledger freedom available before the accelerated readback is the cofinal row, and by hypothesis the displayed source window selected for each inspected request is identical in α and α'.

Now use Definition 4222.4. Since the rectangular source-window and tolerance route is fixed, the regular rational rows R, R' and the Real seals E, E' are reached through the same finite route. The packet therefore has no row through which a second ledger can substitute a hidden subsequence, quotient representative, or ambient completeness argument. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyAcceleration}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyAcceleration}^{\uparrow}$ packet is generated from a StreamName source row, a DyadicRatCore tolerance schedule, a finite cofinal acceleration ledger, a RegSeqRat proof row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyAcceleration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4222.1, Definition 4222.2, and Definition 4222.3 seed the finite acceleration route from StreamName windows through dyadic tolerance schedules, cofinal acceleration ledgers, RegSeqRat readback, and the terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyAcceleration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy-name equality, choice-selected subsequences, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone cofinality, dyadic tolerance preservation, classifier transport, L10 handoff, and ledger exhaustion for BEDC.Derived.CauchyAccelerationUp.

Theorem 4222.6 (Cauchy acceleration sequence-space route)**.** *Every* $\mathsf{CauchyAcceleration}^{\uparrow}$ *consumer reads the common-window classifier of* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *from chapter 406 before exporting the accelerated* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff. The route passes through the regularization boundary of chapter 376: the source* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, accelerated cofinal ledger, regular rational readback, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local* NameCert *rows are visible before any Real-facing consumer may inspect the acceleration result. No quotient representative, selected subsequence outside the displayed ledger, host equality, or ambient completeness row is exported.*

Theorem 4222.7 (Cauchy subsequence dependency route)**.** *Every* $\mathsf{CauchyAcceleration}^{\uparrow}$ *consumer that exports an accelerated* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or terminal* $\mathsf{Real}^{\uparrow}$ *seal must first consume the rate-dominance surface of chapter 1814 and the fast-modulus surface of chapter 1781. The route is finite:* $\mathsf{CauchyRateDominance}^{\uparrow}$ *bounds the source schedule,* $\mathsf{FastCauchyModulus}^{\uparrow}$ *supplies the inspected acceleration window, and the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *transport, replay, provenance, and local* NameCert *rows carry the resulting readback. No consumer may replace this route by a chosen subsequence, quotient representative, ambient completion row, or host equality of Real names.*

Proof. Begin with the accepted carrier of Definition 4222.1. Its source stream row S, tolerance schedule T, cofinal ledger α, regular rational row R, and Real seal E are the only analytic rows available before transport, replay, provenance, and local naming.

The rate-dominance chapter supplies the comparison row that bounds which source schedule entries may be read by α. The fast-modulus chapter supplies the inspected window that turns those bounded reads into the accelerated tolerance route. Reading either row after the $\mathsf{RegSeqRat}^{\uparrow}$ readback would hide the schedule obligation rather than consume it.

Apply the rectangular window route of Definition 4222.4. It keeps the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ rows in front of R and E, so the accelerated readback remains a displayed finite route. The carrier has no coordinate for a selected subsequence, quotient representative, ambient completion proof, or host Real equality, and the dependency route cannot export one. □

Theorem 4222.8 (Cauchy acceleration L10 four-face cofinality)**.** *Every accepted* $\mathsf{CauchyAcceleration}^{\uparrow}$ *carrier that exports an accelerated* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or terminal* $\mathsf{Real}^{\uparrow}$ *seal preserves the ordered L10 four-face route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The cofinal acceleration ledger may refine which displayed source window is read for a requested precision, but it cannot commute, omit, or replace the $\mathsf{StreamName}^{\uparrow}$ *source face, the* $\mathsf{DyadicRatCore}^{\uparrow}$

tolerance face, the $\mathsf{RegSeqRat}^{\uparrow}$ *readback face, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The resulting route remains finite and displayed, with no chosen subsequence outside the ledger, quotient representative, ambient completion row, host real equality, countable-choice schedule, Lean verification, or standard bridge.*

Proof. Start with Definition 4222.3. It names the only exported analytic route of an accepted carrier as the ordered sequence from the stream window through the dyadic tolerance ledger and regular rational readback to the Real-facing seal.

Next apply Definition 4222.4. The cofinal ledger α refines precision requests inside the displayed rectangle of source windows and dyadic tolerances, so it cannot move the $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ rows ahead of the upstream faces.

Finally use the sibling dependency route of Definition 4222.7. The rate-dominance and fast-modulus surfaces are consumed before the accelerated readback is exported, and they leave the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces in order.

The carrier and dependency route have no row for a hidden subsequence, quotient representative, ambient completion proof, host Real equality, choice schedule, Lean verification, or bridge credential. Hence cofinal acceleration preserves exactly the displayed L10 four-face route. □

Theorem 4222.9 (Cauchy acceleration completion forward link)**.** *Every completion-facing consumer of* $\mathsf{CauchyAcceleration}^{\uparrow}$ *reads through chapter 1639, chapter 301, chapter 126, chapter 291, and chapter 38 before the accelerated route exports a terminal real boundary. The dependency is the finite route from source* $\mathsf{StreamName}^{\uparrow}$ *windows through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance schedule and cofinal acceleration ledger into* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the Bishop regular Cauchy completion surface, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start with the displayed source windows. The accelerated route has no completion-facing input until the $\mathsf{StreamName}^{\uparrow}$ inspection windows and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance schedule have been exposed.

Next read the regular rational and completion surfaces. The cofinal acceleration ledger feeds $\mathsf{RegSeqRat}^{\uparrow}$ readback and then passes through the Bishop regular Cauchy completion chapter before any terminal real boundary is visible.

Finally attach the $\mathsf{Real}^{\uparrow}$ seal. Since the route is finite and displayed at each sibling boundary, it exports no quotient completion, selected subsequence, countable choice principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Chapter 4223

A Concrete Naming Certificate for $\mathsf{BrouwerMonotoneSequence}^{\uparrow}$

Following Brouwer and Bishop–Bridges on monotone sequences in constructive analysis, the BrouwerMonotoneSeque packet records a monotone real-name boundary object through finite stream windows, regular rational readback, dyadic tolerance ledgers, and the terminal real-name seal. It sits after the Specker obstruction of chapter 1406, the regular-rational readback of chapter 301, the stream-window interface of chapter 126, the dyadic rational core of chapter 291, and the Real seal of chapter 38. The chapter gives the L10 Real and Completion frontier a named monotone-sequence carrier without claiming located suprema, trichotomy, countable choice, selected limits, quotient stream representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4223.1 (BrouwerMonotoneSequence carrier)**.** *A* $\mathsf{BrouwerMonotoneSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, W, D, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-sequence row, listing the inspected indices and their finite dependency order.*
2. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows opened for the inspected real-name entries.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the displayed windows and monotonicity comparisons.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the windows and dyadic tolerance ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, W, D, R have been displayed.*
6. *M is the monotonicity ledger, recording only finite adjacent-window comparison obligations among the displayed entries.*
7. *H records componentwise* hsame *transport for source indices, windows, dyadic ledgers, readback, Real seals, monotonicity, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a monotone-sequence request through $S, W, D, R, E, M, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BrouwerMonotoneSequence}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerMonotoneSequence}^{\uparrow}}$ *row.*

The classifier accepts only packets whose monotone-sequence request displays these rows in order. It has no coordinate for a located supremum, trichotomy decision, countable-choice selector, selected limit, quotient stream representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.BrouwerMonotoneSequenceUp.BrouwerMonotoneSequenceTasteGate single carrier alignment`

Theorem 4223.2 (BrouwerMonotoneSequence NameCert obligations)**.** *For every accepted* BrouwerMonotoneSeque *carrier*

$$B = (S, W, D, R, E, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BrouwerMonotoneSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the inspected source sequence, finite stream windows, dyadic tolerance ledger, regular rational readback, Real seal, finite monotonicity ledger, componentwise transport, displayed replay, package provenance, and local naming rows. No NameCert obligation may be discharged by a located supremum, trichotomy of real names, countable-choice schedule, selected limit, quotient stream representative, or ambient complete real line.*

Proof. Project the carrier of Definition 4223.1. The analytic rows are precisely the source schedule S, the finite windows W, the dyadic tolerance ledger D, the regular rational readback R, the Real seal E, and the finite monotonicity ledger M.

The monotonicity information is local to the displayed windows. Each comparison read in M consumes only the adjacent source entries already opened through S, W, D, R and does not add a global order decision for arbitrary real names.

The structural rows add no hidden analytic principle. Transport through H preserves the same displayed rows, replay through C follows the same finite route, and P, N record provenance and local naming for the packet.

Since the carrier has no row for located suprema, trichotomy, countable-choice schedules, selected limits, quotient stream representatives, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Theorem 4223.3 (BrouwerMonotoneSequence finite-window nonescape)**.** *Every consumer read of an accepted* $\mathsf{BrouwerMonotoneSequence}^{\uparrow}$ *carrier reaches a* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route may consult the finite monotonicity ledger M for displayed adjacent windows, but it cannot escape to a located supremum, countable-choice selector, trichotomy oracle, selected limit, quotient stream representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with a consumer read of the accepted carrier. The source row S exposes only the inspected indices, so the first real-name data available to the consumer are the finite $\mathsf{StreamName}^{\uparrow}$ windows in W.

The dyadic and regular-rational rows determine the only readback route. The tolerance ledger D bounds the displayed windows, and the row R packages those bounded observations as $\mathsf{RegSeqRat}^{\uparrow}$ readback data.

The terminal seal is downstream of those rows. The $\mathsf{Real}^{\uparrow}$ row E is available only after S, W, D, R have been displayed, and the monotonicity ledger M can compare only the adjacent windows already present in the same finite packet.

Transport, replay, provenance, and local naming preserve this order through H, C, P, N. Therefore every consumer read remains inside the displayed finite-window route and cannot import a

located supremum, trichotomy oracle, choice schedule, selected limit, quotient stream representative, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerMonotoneSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BrouwerMonotoneSequence}^{\uparrow}$ packet is generated from inspected source indices, finite StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, a RealUp seal, a finite monotonicity ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrouwerMonotoneSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4223.1, Definition 4223.2, and Definition 4223.3 seed the constructive monotone-sequence boundary for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrouwerMonotoneSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close located suprema, trichotomy, countable choice, selected limits, quotient stream representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window monotonicity, StreamName exposure, DyadicRatCore tolerance accounting, RegSeqRat readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BrouwerMonotoneSequenceUp.

Chapter 4224

A Concrete Naming Certificate for $\mathsf{CauchySequenceCriterion}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy criteria, the $\mathsf{CauchySequenceCriterion}^{\uparrow}$ packet records the textbook sequence criterion as finite BEDC data. It ties a sequence source to the dyadic tolerance discipline of chapter 291, the stream-window naming discipline of chapter 126, the regular rational readback of chapter 301, and the public real seal of chapter 38. The chapter names only the finite route from tolerance data to regular-Cauchy and real consumers; it does not supply a choice-selected subsequence, quotient equality of limits, host completion, or ambient completeness principle.

Definition 4224.1 (CauchySequenceCriterion carrier)**.** *A* $\mathsf{CauchySequenceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, M, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the sequence-source row, displaying the named sequence and the finite request interface through which a downstream consumer asks for terms.*
2. *M is the modulus-schedule row, displaying the finite schedule that turns a requested dyadic tolerance into a stage bound.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-ledger row, recording the positive dyadic thresholds, comparisons, and tolerance refinements read by the schedule.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing only finite windows of the sequence after the schedule row has supplied their stage bounds.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy readback row reached from A, M, D, S.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the regular-Cauchy readback has been displayed.*
7. *H records componentwise* hsame *transport for the sequence source, schedule, dyadic tolerance ledger, stream windows, regular readback, Real seal, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from a criterion request through $A, M, D, S, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceCriterion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceCriterion}^{\uparrow}}$ *row.*

The classifier accepts only packets whose criterion consumer first displays the sequence source, modulus schedule, dyadic tolerance ledger, stream-window row, regular-Cauchy readback, Real seal, hsame*,* Cont*,* Pkg*, and local* NameCert *rows listed above.*

Lean4 ✓ `BEDC.Derived.CauchySequenceCriterionUp.CauchySequenceCriterionTasteGate single carrier alignment`

Theorem 4224.2 (CauchySequenceCriterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchySequenceCriterion}^{\uparrow}$ *carrier*

$$Q = (A, M, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySequenceCriterion}^{\uparrow}}$ *surface consists exactly of sequence-source admission, modulus-schedule admission, dyadic tolerance-ledger exposure, finite stream-window exposure, regular-Cauchy readback, Real seal readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the rows of* Q*. No obligation may be discharged by a choice-selected subsequence, quotient equality of limits, host completion, ambient completeness, or an unbounded open-cover argument.*

Proof. Project the carrier of Definition 4224.1. Its analytic rows are precisely the sequence source A, modulus schedule M, dyadic tolerance ledger D, stream windows S, regular-Cauchy readback R, and Real seal E.

The tolerance rows determine the access order. A criterion consumer reads M before it can turn a dyadic request from D into a finite stage bound, and it reads S only through the finite windows exposed by that bound.

The readback rows add no external completion object. The row R repacks the displayed tolerance and window data as regular-Cauchy readback, and E seals that readback as the public real-facing output.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no coordinate of Q stores a selected subsequence, quotient limit equality, host completion, ambient completeness witness, or open-cover argument, the displayed rows exhaust the NameCert obligations. □

Theorem 4224.3 (CauchySequenceCriterion L10 handoff)**.** *Every L10 consumer read of an accepted* $\mathsf{CauchySequenceCriterion}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff reaches the displayed $\mathsf{Real}^{\uparrow}$ *seal only through the sequence source, modulus schedule, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceCriterion}^{\uparrow}}$ *row carried by the same packet.*

Proof. Begin with the sequence source A and modulus schedule M. They expose the named sequence and the finite stage bounds required by any dyadic tolerance request.

Next read the dyadic tolerance ledger D and stream-window row S. The ledger supplies the positive thresholds and comparisons, while the stream row supplies only the finite windows named by the schedule.

Attach the regular-Cauchy readback row R. It is the unique displayed route by which the dyadic-window data becomes a regular rational sequence consumer.

The Real seal closes the route. The row E is reached only after R, and the structural rows H, C, P, N carry the same finite data through transport, replay, provenance, and local naming. Hence the L10 handoff exposes a constructive sequence criterion rather than a selected subsequence, quotient limit, host completion, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceCriterion}^{\uparrow}$ packet is generated from a sequence source, modulus schedule, dyadic tolerance ledger, stream windows, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySequenceCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4224.1, Definition 4224.2, and Definition 4224.3 seed the L10 route from dyadic sequence criteria to regular-Cauchy and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySequenceCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close choice-selected subsequences, quotient equality of limits, host completion, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus schedule exposure, dyadic tolerance-ledger exactness, stream-window handoff, RegSeqRat/Real seal readback, transport, replay, provenance, and local naming for BEDC.Derived.CauchySequenceCriterionUp.

$\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ routes pointwise locator induction through chapter 3410, chapter 126, chapter 291, chapter 301, and chapter 38; the child file carries the theorem and closurestatus surface.

Chapter 4225

A Concrete Naming Certificate for CauchyRealLocatorPointwiseInduction$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the CauchyRealLocatorPointwiseInduction$^{\uparrow}$ packet records the finite-window induction route used by Cauchy real locators. It is a sibling of the locator surface of chapter 3410 and the finite schedule discipline of chapter 126: a pointwise induction step opens one displayed stream window, reads its dyadic tolerance ledger, passes through the regular rational readback of chapter 301, and returns to the same Real-facing locator seal of chapter 38. The packet is not an induction principle over all host streams, a quotient-real equality theorem, a countable-choice selector, or an ambient completeness assertion.

The dependency route is substantive: before the packet exports pointwise locator induction, it consumes the rational interval enclosure surface of chapter 4202 together with the RegSeqRat window handoff of chapter 301. Thus each pointwise branch is read as rational interval enclosure plus regular Cauchy window data, not as a decorative citation to neighboring chapters.

Definition 4225.1 (Cauchy real locator pointwise induction carrier)**.** *A* CauchyRealLocatorPointwiseInduction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, W, D, Q, R, B, H, C, P, N)$$

with the following displayed rows:

1. *L is the source* CauchyRealLocator$^{\uparrow}$ *row, carrying the locator modulus, finite-window, dyadic, regular-rational, and Real seal data.*
2. *W is the* StreamName$^{\uparrow}$ *pointwise window row selected for the current locator request.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row used to compare the pointwise window with the requested side test.*
4. *Q is the* RegSeqRat$^{\uparrow}$ *readback row exposed after the window and dyadic tolerance have been displayed.*
5. *R is the terminal* Real$^{\uparrow}$ *locator seal reached by the pointwise readback.*
6. *B is the finite induction-branch ledger, recording the base window and successor-window handoff over the displayed rows W, D, Q, R.*
7. *H records componentwise* hsame *transport for the locator source, window, dyadic tolerance, regular readback, Real seal, branch ledger, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay for each pointwise induction step.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyRealLocator}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows. It has no coordinate for host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4225.2 (Cauchy real locator pointwise induction regularity-witness route)**.** *Every accepted* $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier consumes the finite regularity-witness surface of chapter 1158 before any* $\mathsf{Real}^{\uparrow}$ *seal is inspected. For a carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the pointwise branch first opens the displayed $\mathsf{StreamName}^{\uparrow}$ *window W, then reads the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q through the regularity-witness route, and only then reaches the terminal Real locator seal R.*

Proof. Project the carrier. The only rows available before the Real seal are the locator source L, the displayed window W, the dyadic tolerance D, and the regular-rational readback Q.

Now use the sibling regularity-witness surface. Its displayed route supplies the same finite window, tolerance ledger, and RegSeqRat readback before the Real seal handoff, so the pointwise branch can inspect regularity evidence without opening a host stream representative.

Finally read R and the structural rows B, H, C, P, N. These rows record, transport, replay, source, and name the already displayed route, so the pointwise induction packet depends on the regularity witness before it reaches the Real-facing locator seal. □

Theorem 4225.3 (Cauchy real locator pointwise window induction)**.** *For every accepted* CauchyRealLocatorPointwi *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

each pointwise locator step factors through the finite route

$$L \longmapsto W, D \longmapsto Q \longmapsto R \longmapsto B, H, C, P, N.$$

The base and successor cases of the induction ledger B may inspect only the displayed $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *locator seal supplied by the same* $\mathsf{CauchyRealLocator}^{\uparrow}$ *source row.*

Proof. Project the accepted carrier. The source row L is the only Cauchy real locator coordinate, so every pointwise step begins by reading the displayed locator packet of chapter 3410.

The induction window is then opened through W. The dyadic tolerance row D is the only comparison surface attached to that window, and the regular rational readback Q is available only after the window and dyadic rows have been displayed.

The terminal read reaches R and is then recorded by the branch ledger B. The base branch and each successor branch therefore preserve the same finite route rather than selecting a host stream representative.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no row for host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient completeness, the displayed route exhausts the pointwise induction surface. □

Theorem 4225.4 (Cauchy real locator pointwise induction NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$ *obligations are exactly carrier admission for the* $\mathsf{CauchyRealLocator}^{\uparrow}$ *source row* L*, pointwise* $\mathsf{StreamName}^{\uparrow}$ *window admission for* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance compatibility for* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback for* Q*,* $\mathsf{Real}^{\uparrow}$ *locator-seal ordering for* R*, finite base and successor branch admission for* B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 4225.1. The tuple displays the locator source, pointwise window, dyadic tolerance, regular-rational readback, real seal, branch ledger, and structural rows.

The source and window obligations are read from L and W. The dyadic tolerance row D is the only comparison surface attached to that pointwise window, and the readback row Q can be inspected only after those rows are displayed.

The real-seal ordering obligation is the row R, downstream of Q. The branch ledger B records the finite base and successor handoff over the same displayed rows rather than over a host stream representative.

The rows H, C, P, N transport, replay, source, and name the packet. Since no other coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 4225.5 (Cauchy real locator pointwise window stability)**.** *Let*

$$I = (L, W, D, Q, R, B, H, C, P, N)$$

be an accepted $\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}$ *carrier. Replacing the locator source,* $\mathsf{StreamName}^{\uparrow}$ *pointwise window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and* $\mathsf{Real}^{\uparrow}$ *seal by displayed componentwise* hsame *rows, and replaying the replacement through* C*, preserves the admissible pointwise induction route*

$$L \longmapsto W, D \longmapsto Q \longmapsto R \longmapsto B.$$

Thus the base and successor branches of the finite induction ledger remain attached to the same locator source and cannot introduce host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier and use Definition 4225.3. Every pointwise step already factors through the displayed locator source, window, dyadic tolerance, regular-rational readback, real seal, and branch ledger.

The componentwise replacement is recorded by H. It transports the locator source, window, tolerance, readback, seal, branch ledger, replay, provenance, and local name without adding another induction coordinate.

The replay row C then carries the transported rows through the same pointwise route. The branch ledger B therefore continues to read the base window and successor-window handoff over W, D, Q, R.

The carrier has no row for any excluded host or quotient object, so row exhaustion shows that the transported packet preserves exactly the admissible pointwise induction route. □

Theorem 4225.6 (Cauchy real locator pointwise branch exhaustion)**.** *For every accepted* CauchyRealLocatorPointw *carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

every base or successor branch read in B is exhausted by the displayed rows $L, W, D, Q, R, H, C, P, N$. Such a branch read cannot introduce host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The branch ledger B is downstream of the locator source L, pointwise window W, dyadic tolerance row D, regular-rational readback Q, and terminal real seal R.

Use pointwise window induction from Definition 4225.3. It forces both the base branch and each successor branch to read the same finite route $L \longmapsto W, D \longmapsto Q \longmapsto R$ before B records the branch.

Use window stability from Definition 4225.5. The transport row H and replay row C preserve that route under displayed componentwise replacement, while P, N only source and name the packet.

Row exhaustion completes the claim. No coordinate of I stores host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so no base or successor branch can export any of those objects. □

Theorem 4225.7 (Cauchy real locator pointwise induction sibling route)**.** *Every accepted* CauchyRealLocatorPointw *read must pass through chapter 3410, chapter 126, chapter 291, chapter 301, and chapter 38 before the branch ledger is public. For a carrier*

$$I = (L, W, D, Q, R, B, H, C, P, N),$$

the rows L, W, D, Q, R are exactly that sibling route, and B, H, C, P, N can only record, transport, replay, source, and name the displayed route.

Proof. Project the carrier rows $L, W, D, Q, R, B, H, C, P, N$ from Definition 4225.1. The source row L is read through the Cauchy real locator certificate, while W is the finite StreamName window attached to the current pointwise request.

The dyadic tolerance row D is then consumed through the DyadicRatCore certificate, and Q is the RegSeqRat readback of that displayed window and tolerance data. The terminal row R is the Real-facing locator seal reached after those rows are visible.

Apply Definition 4225.3 and Definition 4225.4. They force the pointwise induction route and the local NameCert obligations to use exactly the rows L, W, D, Q, R before the branch ledger can be inspected.

Finally use Definition 4225.5 and Definition 4225.6. The transport, replay, provenance, and local naming rows preserve the same sibling route and exhaust the branch surface, so the public branch ledger has no alternate dependency edge outside the listed chapters. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4225.1, Definition 4225.3, Definition 4225.4, Definition 4225.5, and Definition 4225.6 seed the finite pointwise induction route over CauchyRealLocator, StreamName, DyadicRatCore, RegSeqRat, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRealLocatorPointwiseInduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host stream induction, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window induction, dyadic tolerance compatibility, RegSeqRat readback, Real seal ordering, and local NameCert registration for BEDC.Derived.CauchyRealLocatorPointwiseInductionUp.

Constructive story: A CauchyRealLocatorPointwiseInduction$^{\uparrow}$ packet is generated from a CauchyRealLocator source row, one StreamName pointwise window, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RealUp locator seal, a finite induction-branch ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4226

A Concrete Naming Certificate for $\mathsf{FrinkMetrization}^{\uparrow}$

Following Frink and Kelley, the $\mathsf{FrinkMetrization}^{\uparrow}$ packet records the finite BEDC route from a uniform entourage basis to a pseudometric-facing and metric-facing distance certificate. It sits after the uniform-source rows of chapter 339, the pseudometric carrier of chapter 1614, the separated metric boundary of chapter 57, the topology compatibility row of chapter 88, the dyadic tolerance ledger of chapter 291, and the finite window interface of chapter 126. The packet names only the constructive handoff from nested entourage data to displayed distance reads; it does not form quotient uniformities, select representatives, assert ambient metrizability, or import choice.

Definition 4226.1 (FrinkMetrization carrier)**.** *A* $\mathsf{FrinkMetrization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (U, Q, D, P, M, T, H, C, G, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row. It names the carrier surface and the finite entourage requests from which the metrization route starts.*
2. *Q is the nested entourage chain. It records the finite refinement ladder used to compare two source points at dyadic scales.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger. It translates the refinement level into displayed dyadic radii and triangle budgets.*
4. *P is the* $\mathsf{Pseudometric}^{\uparrow}$ *handoff row. It receives the finite entourage chain and exports the displayed pre-separated distance route.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *compatibility row, available only after the separated boundary has accepted the zero-distance route supplied through P.*
6. *T is the* $\mathsf{Topology}^{\uparrow}$ *compatibility row. It records that the metric-facing balls and the original uniform entourage reads are compared through the same finite windows.*
7. *H records componentwise* hsame *transport for the uniform source, chain, dyadic ledger, pseudometric handoff, metric compatibility, topology compatibility, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a uniform entourage request through the nested chain, dyadic ledger, pseudometric handoff, metric row, topology row, provenance, and local naming row.*

9. *G is the* Pkg *provenance over* FrinkMetrization$^{\uparrow}$, UniformSpace$^{\uparrow}$, Pseudometric$^{\uparrow}$, Met$^{\uparrow}$, Topology$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{FrinkMetrization}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient uniformity equality, selected representatives, ambient metrizability, countable choice, host topology equality, or an unbounded distance oracle.

Lean4 ✓ `BEDC.Derived.FrinkMetrizationUp.FrinkMetrizationTasteGate single carrier alignment`

Theorem 4226.2 (FrinkMetrization NameCert obligations)**.** *For every accepted* FrinkMetrization$^{\uparrow}$ *carrier $F = (U, Q, D, P, M, T, H, C, G, N)$, the local* NameCert$_{\text{FrinkMetrization}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the uniform source, nested entourage chain, dyadic radius ledger, pseudometric handoff, metric compatibility row, topology compatibility row, transport, continuation, provenance, and local naming row;*
2. *nested-chain readability, requiring every distance request to start at the* UniformSpace$^{\uparrow}$ *row U and pass through the finite refinement chain Q before any dyadic radius in D is read;*
3. *pseudometric handoff, requiring the displayed distance route to be exported through P before the metric row M or topology row T can be consumed;*
4. *compatibility transport, requiring H and C to preserve the same finite* StreamName$^{\uparrow}$ *windows and* DyadicRatCore$^{\uparrow}$ *radius ledger across uniform, pseudometric, metric, and topology-facing consumers;*
5. *provenance and refusal, requiring G and N to name only this finite handoff and to refuse quotient uniformity equality, selected representatives, ambient metrizability, countable choice, host topology equality, and unbounded distance oracles.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 4226.1. The projection exposes exactly the uniform source, nested chain, dyadic ledger, pseudometric handoff, metric and topology compatibility rows, and the structural rows H, C, G, N.

The nested-chain obligation is forced by row order. A distance request starts at the uniform row U, enters the refinement ladder Q, and only then reads the dyadic radius ledger D.

The pseudometric handoff is the only distance-export step. Row P supplies the pre-separated displayed distance route, while M and T can compare it with metric and topology-facing consumers only after the same finite windows and radii have been replayed.

Rows H, C, G, N transport, replay, source, and name this route. Since the tuple contains no quotient uniformity, selected representative, ambient metrizability, countable choice, host topology equality, or unbounded distance coordinate, the local NameCert cannot export those principles. □

Closure status for NameCert$_{\text{FrinkMetrization}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{FrinkMetrization}^{\uparrow}}$, seed)

Scope closed: Definition 4226.1 and Definition 4226.2 seed the finite Frink-style handoff from uniform entourage chains to pseudometric, metric, topology, dyadic, and stream-facing rows.

Formal verification: FormalStatus(NameCert$_{\text{FrinkMetrization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient uniformity equality, selected representatives, ambient metrizability, countable choice, host topology equality, unbounded distance oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-chain readability, dyadic radius exactness, pseudometric handoff, metric and topology compatibility, transport, continuation, provenance, and ledger refusal for BEDC.Derived.FrinkMetrizationUp.

Constructive story: A FrinkMetrization$^{\uparrow}$ packet is generated from a UniformSpace source row, a nested entourage chain, a DyadicRatCore radius ledger, a Pseudometric handoff, Metric and Topology compatibility rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

NestedShrinkInterval$^{\uparrow}$ reads its compact interval dependency through chapter 5553 and the child `namecert_construction.tex` route before exposing its shrinking-diameter Real$^{\uparrow}$ seal.

Chapter 4227

A Concrete Naming Certificate for $\mathsf{NestedShrinkInterval}^{\uparrow}$

Following Cantor's nested-interval argument and Bishop–Bridges regular real analysis, the $\mathsf{NestedShrinkInterval}^{\uparrow}$ packet records the finite BEDC carrier surface for a descending located interval route whose displayed diameters shrink to the requested tolerance. It sits between the nested-closed interval carrier of **??**, the located endpoint row of chapter 394, the dyadic tolerance ledger of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback surface of chapter 301, and the terminal real-name boundary of chapter 38. The chapter names only the finite shrinking-interval convergence certificate; it does not claim open-cover compactness, trichotomy, quotient reals, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4227.1 (Nested shrink interval carrier)**.** *A* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (J, L, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *J is the* $\mathsf{NestedClosedInterval}^{\uparrow}$ *source row, exposing the retained descending closed located interval family and its containment witnesses.*
2. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row for the inspected interval windows, including lower and upper endpoint location data.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *shrink ledger recording endpoint comparisons, diameter estimates, and tolerance requests.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used to inspect interval endpoints and diameter rows at displayed stages.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same stream windows and dyadic ledger.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the nested interval, located endpoint, dyadic shrink, stream-window, and regular readback rows are visible.*
7. *H records componentwise* hsame *transport for J, L, D, S, R, E and for the replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$J, L \longmapsto D, S \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{NestedShrinkInterval}^{\uparrow}$, $\mathsf{NestedClosedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedShrinkInterval}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed rows $J, L, D, S, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, trichotomy, quotient-real equality, a selected intersection point, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 4227.2 (Nested shrink interval NameCert obligations)**.** *For every accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *carrier*

$$K = (J, L, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NestedShrinkInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{NestedClosedInterval}^{\uparrow}$ *source row,* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *shrink ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row; classifier stability under those same displayed rows; diameter-to-tolerance exactness through D; finite-window readback through S and R; Real-seal handoff through E; and ledger nonescape for the excluded compactness, trichotomy, quotient, selection, choice, and ambient-completeness coordinates.*

Proof. Project the carrier of Definition 4227.1. The projection exposes exactly the nested closed interval source, located endpoint row, dyadic shrink ledger, finite windows, regular readback, real seal, and structural rows.

Classifier stability is componentwise on those displayed rows. The shrink estimate is not an external metric fact: it is the D row, read together with the endpoint row L and the stream schedule S before regular readback is available.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since no excluded coordinate occurs in the carrier, every accepted NameCert obligation is one of the rows listed above. □

Theorem 4227.3 (Nested shrink interval diameter route)**.** *Let $K = (J, L, D, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *carrier. Every completion-facing request for the shrinking interval route first reads the* $\mathsf{NestedClosedInterval}^{\uparrow}$ *source J and* $\mathsf{LocatedInterval}^{\uparrow}$ *endpoint row L, then reads the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter ledger D and* $\mathsf{StreamName}^{\uparrow}$ *finite windows S, and only then opens the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R and* $\mathsf{Real}^{\uparrow}$ *seal E. The route exports diameter-to-tolerance convergence as displayed finite ledger data, not as open-cover compactness, trichotomy, quotient-real equality, countable choice, a selected intersection point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a completion-facing request and project the accepted carrier. The only interval source is J, and the only endpoint data are the located rows in L.

The diameter request is then forced through D. Its dyadic comparisons and tolerance rows are inspected through the finite schedule S, so a consumer cannot replace the shrinking route by an unrecorded compactness or completeness theorem.

After the finite windows are displayed, R packages the same observations as regular rational readback and E supplies the terminal real seal. The remaining rows H, C, P, N preserve the route and add no excluded coordinate. □

Theorem 4227.4 (Nested shrink interval Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer admitted by an accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *packet receives the seal only through the displayed route*

$$\mathsf{NestedClosedInterval}^{\uparrow},\ \mathsf{LocatedInterval}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The handoff is stable under the componentwise hsame *transport and displayed* Cont *replay rows* H, C*, and it is sourced and named only by* P, N*.*

Proof. Apply Definition 4227.3. A Real-facing consumer reaches E only after the nested interval source, located endpoint row, dyadic shrink ledger, stream windows, and regular readback have all been displayed.

Transport through H preserves the row roles, and replay through C preserves their order. Provenance and local naming through P, N attach the handoff to the packet without adding analytic content.

Thus the Real seal cannot escape to a selected point, quotient real equality, countable choice, trichotomy, open-cover compactness, or ambient real completeness. □

Theorem 4227.5 (Nested shrink interval regular-Cauchy uniqueness route)**.** *Let* $K = (J, L, D, S, R, E, H, C, P, N)$ *and* $K' = (J', L', D', S', R', E', H', C', P', N')$ *be accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *packets. Suppose their nested-source rows, located endpoint rows, dyadic shrink ledgers, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows are componentwise related by the displayed* hsame *transport. Then the two packets reach the same* $\mathsf{Real}^{\uparrow}$*-facing seal route only through the* $\mathsf{RegSeqRat}^{\uparrow}$ *uniqueness surface displayed by* R, R' *before Real sealing. The route does not identify selected intersection points, quotient real representatives, or ambient host real equality.*

Proof. Project both carriers. The first carrier exposes $J, L, D, S, R, E, H, C, P, N$, and the second exposes $J', L', D', S', R', E', H', C', P', N'$.

Apply the diameter route of Definition 4227.3 to both packets. Each read is forced through its nested source, located endpoints, dyadic shrink ledger, finite stream windows, and regular rational readback before a Real-facing seal is visible.

Use the assumed componentwise hsame transport on J, L, D, S, R and J', L', D', S', R'. The endpoint comparison therefore lives on the displayed $\mathsf{RegSeqRat}^{\uparrow}$ readback surface, because the preceding rows have already fixed the same nested-source, located-endpoint, dyadic, and stream-window route.

Finally apply the Real-seal handoff of Definition 4227.4 to both packets. It permits E and E' to be read only after the regular readback rows are displayed, so the uniqueness comparison is a $\mathsf{RegSeqRat}^{\uparrow}$ route before Real sealing and not a selected intersection point, quotient real equality, or ambient completeness assertion. □

Theorem 4227.6 (Cantor intersection nested-shrink route)**.** *Every* $\mathsf{CantorDiagonalCompactness}^{\uparrow}$ *or* $\mathsf{CantorIntersection}^{\uparrow}$ *consumer that reads a nested shrinking interval first consumes the* $\mathsf{NestedClosedInterval}^{\uparrow}$*,* $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows exposed by an accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *carrier. The downstream route supplies the nested-shrink boundary used by chapter 6999 and the Cantor-intersection surface of chapter 1421.*

The route is a forward lattice edge only. It does not select an intersection point, assert open-cover compactness, use countable choice, identify quotient real names, or provide ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 4227.1. The exposed rows are the nested closed source J, located endpoints L, dyadic shrink ledger D, finite stream windows S, regular readback R, real seal E, and the structural rows H, C, P, N.

Apply Definition 4227.4. Any Real-facing downstream read reaches E only after the nested, located, dyadic, stream, and regular-rational rows have been displayed.

The Cantor diagonal and Cantor-intersection chapters consume exactly this kind of finite shrinking-interval boundary before their own diagonal or intersection rows are read. Since the

carrier contains no selected point, open-cover compactness row, choice schedule, quotient equality, or ambient completeness coordinate, the downstream route remains a finite dependency edge. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedShrinkInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedShrinkInterval}^{\uparrow}$ packet is generated from a NestedClosedInterval source row, LocatedInterval endpoint rows, a DyadicRatCore shrink ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedShrinkInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4227.1, Definition 4227.2, Definition 4227.3, and Definition 4227.4 seed the finite L10 shrinking-interval convergence route through nested closed intervals, located endpoint rows, dyadic diameter ledgers, stream windows, regular readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedShrinkInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, trichotomy, quotient reals, selected intersection points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, diameter-to-tolerance exactness, finite-window readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.NestedShrinkIntervalUp.

The $\mathsf{NestedShrinkInterval}^{\uparrow}$ packet consumes the $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ route of chapter 4080 before a completion-facing reader treats shrinking finite windows as a diagonal Cauchy subsequence witness. The nested source, located endpoint, dyadic diameter, and $\mathsf{StreamName}^{\uparrow}$ rows still supply the finite shrinking windows; $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ supplies only the displayed diagonal handoff needed to pass those windows toward $\mathsf{RegSeqRat}^{\uparrow}$ readback and the terminal $\mathsf{Real}^{\uparrow}$ seal. The route exports no detached selector, quotient-real equality, countable-choice schedule, selected intersection point, or ambient completeness coordinate. The shrinking interval diameter route is consumed through the regular rational readback of chapter 301 and the terminal real-name seal of chapter 38. Thus a downstream L10 consumer reads $\mathsf{NestedShrinkInterval}^{\uparrow}$ only after the finite diameter ledger has been repacked as a $\mathsf{RegSeqRat}^{\uparrow}$ route and sealed as a $\mathsf{Real}^{\uparrow}$ boundary, not as an ambient completeness or selected intersection-point claim. $\mathsf{NestedShrinkInterval}^{\uparrow}$ consumes $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ after the shrinking-diameter ledger has been repacked through the $\mathsf{StreamName}^{\uparrow}$ observation schedule, the $\mathsf{RegSeqRat}^{\uparrow}$ regular rational readback, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the terminal $\mathsf{Real}^{\uparrow}$ seal route. This sibling dependency records the completion-criterion consumer path of chapter 1476: a nested shrink interval can be read as completion evidence only after its finite diameter data has passed through the same stream, regular sequence, dyadic tolerance, and Real seal rows.

Theorem 4227.7 (Nested shrink interval Cauchy completion consumer)**.** *Every completion-facing read of* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *consumes* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *only after the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows are visible. Thus the dependency on chapter 1476 is a theorem-level consumer edge through chapter 126 and chapter 301, not an appeal to an undisplayed completion object.*

Proof. Read a completion-facing request for a nested shrink interval. The route first displays the finite observation schedule and regular rational readback rows, so the consumer sees only finite windows and readback entries.

The dyadic tolerance ledger and terminal Real seal are then exposed before the completion criterion is consumed. Since the criterion is reached after those rows, the dependency records a reusable finite route rather than a hidden selected limit or ambient completeness principle. □

Theorem 4227.8 (Nested shrink interval rational locator route)**.** *Every accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *route whose endpoint localization is read through rational endpoints first consumes the rational locator carrier of chapter 4202. Only after that locator row is displayed may the consumer read the*

nested shrink rows and then the $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff rows. The route exports no selected completed point and no Heine–Borel compactness principle.*

Proof. Read the accepted packet through the carrier theorem of chapter 4227. The only endpoint localization rows available to the nested shrink route are finite displayed rows, so a rational-endpoint consumer must obtain its rational interval locator row before the shrink ledger can be interpreted.

The sibling chapter chapter 4202 supplies exactly that locator surface. Once it is consumed, the nested shrink packet may proceed through its displayed shrink ledger, finite windows, regular rational readback, and terminal real seal.

No selected completed point or Heine–Borel compactness row is present in either carrier. The dependency route therefore records only the rational locator read before the nested shrink and $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ handoff rows are read. □

The $\mathsf{NestedShrinkInterval}^{\uparrow}$ route consumes chapter 4202 for rational endpoint bracketing and chapter 301 for regular rational readback before the terminal $\mathsf{Real}^{\uparrow}$ seal is visible. Thus the nested shrink interval dependency lattice reads locator cells first, then the shrinking-window ledger, then the regular readback route, not a selected intersection point or ambient completeness witness. $\mathsf{NestedShrinkInterval}^{\uparrow}$ exposes a completion-facing interval read only after the packet has consumed the $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ diagonal row, the $\mathsf{RegSeqRat}^{\uparrow}$ regular rational route, the terminal $\mathsf{Real}^{\uparrow}$ seal, the $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ admission row, and the $\mathsf{RationalIntervalLocator}^{\uparrow}$ endpoint-bracketing row. The public read is therefore a finite sibling route through diagonal selection, regular sequence readback, Real sealing, completion admission, and rational interval location; it exports no selected intersection point, quotient-real equality, countable choice, or ambient completeness principle. $\mathsf{NestedShrinkInterval}^{\uparrow}$ consumes the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301 and the completion criterion surface of chapter 1476 before any interval-limit seal is visible. The shrinking-diameter ledger must first pass through finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, regular rational readback, and the same Cauchy-completion admission route; only then may a downstream L10 consumer inspect the $\mathsf{Real}^{\uparrow}$ boundary, and the packet still exports no selected intersection point, quotient-real equality, countable choice, or ambient completion. The $\mathsf{NestedShrinkInterval}^{\uparrow}$ carrier depends on the substantive sibling lattice through chapter 320 for the nested interval spine, chapter 301 for regular rational readback, and chapter 38 for the terminal seal. The rational locator and Cauchy-completion routes already represented by the child files above supply the endpoint-bracketing and completion-admission rows, so the nested-shrink packet is read as a finite dependency route rather than a selected intersection point, quotient-real equality, countable choice, or ambient completeness principle.

Theorem 4227.9 (Nested shrink interval compact interval route)**.** *Every compact-interval consumer of an accepted* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *packet must read the compact real interval sibling of chapter 5553 and the nested interval convergence sibling of chapter 2057 through the same finite endpoint, diameter,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows displayed by the shrinking packet. The compact interval route supplies endpoint and finite-net context; the nested convergence route supplies the shrinking-window handoff; neither route adds an open-cover compactness theorem, selected limit point, quotient real equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the accepted carrier of Definition 4227.1. The visible analytic rows are the nested source, located endpoints, dyadic diameter ledger, finite stream windows, regular rational readback, and Real seal, followed by componentwise transport, replay, provenance, and local naming.

Use the compact real interval packet of chapter 5553 only for the endpoint and finite-net context. Its compact rows are read before the shrinking packet is exported as an interval-local dependency, so the shrink route never obtains an unlisted open-cover or subcover selector.

Use the nested interval convergence packet of chapter 2057 for the convergence-facing handoff. That sibling reads finite endpoint windows, shrinking ledgers, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ sealing before a completion consumer may inspect the route.

The structural rows hsame, Cont, Pkg, and NameCert keep the two sibling reads attached to the same displayed packet. Hence a compact-interval dependency edge from $\mathsf{NestedShrinkInterval}^{\uparrow}$ is exactly the stated finite route and not a hidden compactness, quotient, choice, or completeness principle. □

Theorem 4227.10 (NestedShrinkInterval Cantor downstream route)**.** *Every* $\mathsf{CantorDiagonalCompactness}^{\uparrow}$ *or* $\mathsf{CantorIntersection}^{\uparrow}$ *consumer of a* $\mathsf{NestedShrinkInterval}^{\uparrow}$ *packet reads the nested source only through nested closed intervals, located endpoint rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter witnesses,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The downstream route exports a Cantor diagonal or intersection-facing interval certificate, but it does not select a limit point, assert ambient completeness, identify quotient-real names, or add a host compactness principle outside the displayed rows.*

Proof. Project the nested-shrink carrier through the child routes named by the hub. The compact-interval and rational-locator rows provide nested closed intervals and located endpoints, while the dyadic and StreamName rows expose only finite diameter and window observations.

The Cantor-facing consumer then passes through the RegSeqRat and Real rows already used by the completion and sibling routes. Since these rows carry finite readback and terminal naming rather than a chosen point, the consumer obtains only the displayed interval certificate.

No carrier coordinate names a selected limit point, host completeness theorem, quotient equality, or ambient compactness object. Thus $\mathsf{CantorDiagonalCompactness}^{\uparrow}$ and $\mathsf{CantorIntersection}^{\uparrow}$ consume $\mathsf{NestedShrinkInterval}^{\uparrow}$ only through the finite interval route stated above. □

Chapter 4228

A Concrete Naming Certificate for $\mathsf{AdaptiveCauchyModulus}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy names and finite modulus extraction, the $\mathsf{AdaptiveCauchyModulus}^{\uparrow}$ packet records the threshold-selection surface that is actually inspected by a regular real-name consumer. It sits between the dyadic tolerance ledger of chapter 291, the finite stream-window interface of chapter 126, the regular-rational readback of chapter 301, the ordinary modulus row of chapter 292, and the terminal real-name seal of chapter 38. The chapter names only the finite adaptive route from requested tolerances to inspected windows, regular readback, and Real consumers; it does not choose a global limit, quotient stream representative, ambient complete real, or unbounded modulus oracle.

Definition 4228.1 (Adaptive Cauchy modulus carrier)**.** *An* $\mathsf{AdaptiveCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, D, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *row, exposing the finite name windows available to a regular Cauchy request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested positive dyadic thresholds and the refinements used by the threshold search.*
3. *T is the adaptive threshold schedule, assigning to each displayed tolerance request the finite stage bound selected from the inspected evidence.*
4. *W is the inspected-window row, listing exactly the stream windows opened while validating the schedule T.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the source stream, tolerance ledger, threshold schedule, and inspected windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the regular-rational readback has been displayed.*
7. *H records componentwise* hsame *transport for $S, D, T, W, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from an adaptive-modulus request through the same source, tolerance, schedule, window, readback, seal, transport, provenance, and naming rows.*

9. *P is the* Pkg *provenance over* $\mathsf{AdaptiveCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AdaptiveCauchyModulus}^{\uparrow}}$ *row.*

The classifier accepts only packets whose threshold read is mediated by $S, D, T, W, R, E, H, C, P, N$. There is no coordinate for a selected limit, quotient stream equality, host real equality, ambient completeness, countable choice, or an uninspected global modulus.

Lean4 ✓ `BEDC.Derived.AdaptiveCauchyModulusUp.AdaptiveCauchyModulusTasteGate single carrier alignment`

Theorem 4228.2 (Adaptive Cauchy modulus NameCert obligations)**.** *For every accepted* $\mathsf{AdaptiveCauchyModulus}^{\uparrow}$ *carrier*

$$A = (S, D, T, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AdaptiveCauchyModulus}^{\uparrow}}$ *surface consists exactly of source-stream admission, dyadic tolerance-ledger exposure, adaptive threshold-schedule admission, inspected-window replay, regular-rational readback, terminal Real seal readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the rows of A.*

No obligation in the packet is discharged by a selected Cauchy limit, quotient equality of streams, host real equality, ambient completeness, countable choice, or an oracle for a modulus outside the displayed finite windows.

Proof. Project the carrier of Definition 4228.1. The analytic rows are precisely the source stream S, tolerance ledger D, adaptive threshold schedule T, inspected windows W, regular readback R, and terminal Real seal E.

The access order is forced by the rows. A consumer first reads a dyadic request from D, then uses T to select a finite stage bound, and then opens only the windows recorded by W in the source stream S.

The readback rows add no external completion principle. The row R repacks the inspected stream and tolerance data as a regular rational sequence, and E seals that readback for Real-facing consumers only after R is present.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no coordinate of A stores a selected limit, quotient equality, host equality, ambient completeness, countable choice, or an uninspected global modulus, the displayed rows exhaust the local NameCert obligations. □

Theorem 4228.3 (Adaptive Cauchy modulus RegSeqRat handoff)**.** *Every regular Cauchy or Real consumer of an accepted* $\mathsf{AdaptiveCauchyModulus}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exports only the source stream, tolerance ledger, adaptive threshold schedule, inspected windows, regular-rational readback, terminal Real seal, componentwise transport, displayed replay, provenance, and local name carried by the same packet.

Proof. Start with the NameCert obligations of Definition 4228.2. They force every accepted consumer to read the source stream, dyadic tolerance ledger, threshold schedule, and inspected windows before any regular-rational output is available.

Next attach the ordinary modulus interface. The schedule row T is the finite adaptive presentation of the requested $\mathsf{CauchyModulus}^{\uparrow}$ behavior, and the inspected windows W record the evidence used to justify each displayed threshold.

The regular and Real rows then close the handoff. The row R is the only displayed path from the inspected data to $\mathsf{RegSeqRat}^{\uparrow}$, and the seal E is the only displayed path from R to $\mathsf{Real}^{\uparrow}$.

The structural rows H, C, P, N preserve that same route through transport, replay, provenance, and local naming. Hence a consumer reaches RegSeqRat and Real data through finite inspected evidence rather than through quotient streams, selected limits, host equality, ambient completeness, countable choice, or a detached modulus oracle. □

Closure status for $\mathsf{NameCert}_{\mathsf{AdaptiveCauchyModulus}^{\uparrow}}$.

Constructive story: An $\mathsf{AdaptiveCauchyModulus}^{\uparrow}$ packet is generated from a source stream, dyadic tolerance ledger, adaptive threshold schedule, inspected stream windows, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AdaptiveCauchyModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4228.1, Definition 4228.2, and Definition 4228.3 seed the finite adaptive threshold-selection route for regular Cauchy names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AdaptiveCauchyModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient stream equality, host real equality, ambient completeness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, adaptive threshold schedule exposure, inspected-window replay, RegSeqRat readback, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.AdaptiveCauchyMod

Chapter 4229

A Concrete Naming Certificate for $\mathsf{ClosedSet}^{\uparrow}$ Metric Boundary

Following Kelley and Munkres on closed subsets as complements of open neighborhoods and as metric limit boundaries, the $\mathsf{ClosedSet}^{\uparrow}$ packet records the finite BEDC naming surface for closed-set reads. It sits between the topological carrier of chapter 88, the metric and separated-metric routes of chapter 57 and chapter 1411, the terminal real-name seal of chapter 38, and the compact-image consumer of chapter 4162. The packet names a displayed closed-boundary ledger; it does not import a host powerset, a detached open-set lattice, selected limit points, quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4229.1 (ClosedSet carrier)**.** *A* $\mathsf{ClosedSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, M, S, F, O, B, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *carrier row containing the finite neighborhood and complement observations used by the closed-set read.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *row used when the closed boundary is inspected by distance or ball data.*
3. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row that turns metric zero-distance comparisons into separated boundary evidence.*
4. *F is the finite membership classifier for the named subset boundary.*
5. *O is the open-neighborhood complement ledger, recording the displayed route from nonmembership to a neighborhood outside the set.*
6. *B is the metric complement boundary row, recording the finite ball and real-distance readbacks through* $\mathsf{Real}^{\uparrow}$ *that witness the same complement behavior.*
7. *H records componentwise* hsame *transport for $T, M, S, F, O, B, C, P, N$.*
8. *C records displayed* Cont *replay from topology reads through metric and separated-metric observations, open-neighborhood complement rows, metric boundary rows, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{ClosedSet}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{SeparatedMetric}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedSet}^\uparrow}$ *row.*

The classifier compares accepted packets only through $T, M, S, F, O, B, H, C, P, N$. It has no coordinate for host powersets, detached open-set lattices, selected limit points, quotient equality of names, countable choice, ambient Real completeness, or compact-image closedness beyond the displayed consumer route.

Lean4 (definition) `BEDC.Derived.ClosedSetUp.TasteGate.ClosedSetUp`

Theorem 4229.2 (ClosedSet NameCert obligations)**.** *For every accepted* $\mathsf{ClosedSet}^\uparrow$ *carrier*

$$K = (T, M, S, F, O, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedSet}^\uparrow}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topological row, metric row, separated-metric row, membership classifier, open-neighborhood complement ledger, metric complement boundary, transport, replay, provenance, and local naming;*
2. *topology compatibility, requiring every closed-set read to expose the* $\mathsf{Topology}^\uparrow$ *neighborhood and complement rows before the membership classifier is consumed;*
3. *metric compatibility, requiring any ball or distance read to pass through* $\mathsf{Met}^\uparrow$, $\mathsf{SeparatedMetric}^\uparrow$, *and the* $\mathsf{Real}^\uparrow$ *distance seal before it is treated as boundary evidence;*
4. *complement exactness, requiring nonmembership evidence to be routed through O and metric boundary evidence to be routed through B over the same classifier F;*
5. *transport replay, requiring H and C to preserve the ordered route componentwise before P and N are read;*
6. *nonescape, excluding host powersets, detached open-set lattices, selected limit points, quotient equality of names, countable choice, ambient* $\mathsf{Real}^\uparrow$ *completeness, and a proof of compact-image closedness not routed through chapter 4162.*

No local ClosedSet NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4229.1. The tuple displays the topology, metric, separated-metric, membership, complement, metric-boundary, transport, replay, provenance, and local naming rows.

Topology compatibility is forced by the placement of T and F. A closed-set read first opens the finite neighborhood and complement observations, and only then consumes the classifier for the named subset boundary.

Metric compatibility is forced by M, S, B. Any distance or ball evidence passes through the metric row, the separated zero-distance row, and the $\mathsf{Real}^\uparrow$ distance seal before it becomes boundary evidence.

The remaining rows preserve and name the same route. Since the carrier has no coordinate for host powersets, detached open-set lattices, selected limit points, quotient equality, choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.ClosedSetUp.TasteGate.ClosedSetTasteGate single carrier alignment`

Theorem 4229.3 (ClosedSet metric complement boundary)**.** *Every accepted* $\mathsf{ClosedSet}^\uparrow$ *carrier routes a metric complement request through*

$$\mathsf{Topology}^\uparrow \longmapsto \mathsf{Met}^\uparrow, \mathsf{SeparatedMetric}^\uparrow, \mathsf{Real}^\uparrow \longmapsto F, O, B, H, C, P, N.$$

Thus a consumer such as $\mathsf{CompactImageClosed}^{\uparrow}$ *may read a named closed boundary only after the topological complement ledger, metric distance rows, separated classifier, real-distance seal, transport, replay, provenance, and local naming rows are displayed. A request bypassing one of those rows is outside the accepted* $\mathsf{ClosedSet}^{\uparrow}$ *packet.*

Proof. Read the accepted carrier $K = (T, M, S, F, O, B, H, C, P, N)$. The topological boundary is T, and the metric boundary is read only through M, S and the real-distance data stored in B.

The classifier F is shared by the open-neighborhood complement ledger O and the metric complement boundary B. Therefore the two complement presentations cannot diverge into a host powerset or detached open-set lattice.

Transport and replay are then supplied by H and C, while P and N record provenance and local naming. Since the compact-image consumer of chapter 4162 receives only that finite boundary row, it cannot obtain selected limit points, quotient equality, countable choice, or ambient Real completeness from the closed-set packet. □

Lean4 ✓ `BEDC.Derived.ClosedSetUp.TasteGate.ClosedSetCarrier metric complement boundary`

Theorem 4229.4 (ClosedSet scope basis)**.** *The* $\mathsf{ClosedSet}^{\uparrow}$ *scope is fixed by the carrier and metric-complement boundary rows over* $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, hsame, Cont, *and the local* $\mathsf{NameCert}_{\mathsf{ClosedSet}^{\uparrow}}$ *surface. A consumer may read closed-boundary data only after the topology row, metric row, separated-metric row, classifier row, open-neighborhood complement ledger, metric complement boundary, componentwise transport, displayed replay, provenance, and local naming rows have been exposed. The scope refuses host powerset semantics, detached open-set lattices, quotient equality of names, selected limit points, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the carrier of Definition 4229.1. Its displayed rows contain exactly the topology, metric, separated-metric, classifier, complement, metric-boundary, transport, replay, provenance, and local naming data.

Apply the NameCert obligations of Definition 4229.2 and the metric complement boundary route of Definition 4229.3. These two results force every closed-boundary read through $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, hsame, Cont, and $\mathsf{NameCert}$ before any consumer can inspect the boundary.

Because the accepted packet has no coordinate for a host powerset, detached open-set lattice, quotient equality, selected limit point, or ambient completeness theorem, the stated rows exhaust the ClosedSet scope basis. □

Lean4 ✓ `BEDC.Derived.ClosedSetUp.TasteGate.ClosedSetScopeBasis`

Theorem 4229.5 (ClosedSet public boundary export)**.** *The public* $\mathsf{ClosedSet}^{\uparrow}$ *export is exactly the topology row, metric row, separated-metric row, classifier row, open-neighborhood complement ledger, metric complement boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{ClosedSet}^{\uparrow}}$ *row of the accepted carrier. A public consumer may cite the closed-boundary packet only through those rows and through the scope basis; it receives no host powerset semantics, detached open-set lattice, selected limit point, quotient equality of names, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or compact-image closedness outside the displayed consumer route.*

Proof. Project the carrier of Definition 4229.1. It exposes precisely the topology, metric, separated-metric, classifier, complement ledger, metric-boundary, transport, replay, provenance, and local naming rows.

Apply the NameCert obligations, metric complement boundary, and scope basis from Definition 4229.2, Definition 4229.3, and Definition 4229.4. These results force every public closed-boundary read through the same finite row inventory and block any route through host powersets, detached open-set lattices, quotient equality, selected limit points, choice, or ambient completeness.

Thus the public export is not a larger closure theorem; it is the named boundary surface already displayed by the carrier and its metric complement route. □

Lean4 ✓ `BEDC.Derived.ClosedSetUp.TasteGate.ClosedSetPublicBoundaryExport`

Theorem 4229.6 (ClosedSet bridged boundary export)**.** *Any future standard bridge for* $\mathsf{ClosedSet}^{\uparrow}$ *must read exactly the topology row, metric row, separated-metric row, classifier row, open-neighborhood complement ledger, metric complement boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{ClosedSet}^{\uparrow}}$ *row already exported by Definition 4229.5. A bridge consumer may replay those rows as the closed-boundary surface, but it receives no host powerset semantics, detached open-set lattice, selected limit point, quotient equality of names, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or compact-image closedness outside that displayed consumer route.*

Proof. Start with the carrier of Definition 4229.1. Its coordinates are exactly $T, M, S, F, O, B, H, C, P, N$, so a bridge has no additional coordinate from which to read a host powerset, detached open-set lattice, selected point, quotient equality witness, choice principle, or ambient completeness theorem.

Apply the NameCert obligations of Definition 4229.2 and the metric complement boundary of Definition 4229.3. These force topology exposure through T, metric exposure through M, S, B, complement compatibility through F, O, B, and replay through H, C, P, N before the closed-boundary row can be consumed.

The scope basis of Definition 4229.4 and the public export of Definition 4229.5 then identify the bridge-facing surface with the already public row inventory. Thus the bridge reads the displayed consumer route and nothing stronger, including no compact-image closedness theorem beyond the named downstream route. □

Lean4 ✓ `BEDC.Derived.ClosedSetUp.TasteGate.ClosedSetBridgedBoundaryExport`

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedSet}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedSet}^{\uparrow}$ packet is generated from topological, metric, separated-metric, membership-classifier, open-neighborhood complement, metric complement boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClosedSet}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 4229.1, Definition 4229.2, Definition 4229.3, Definition 4229.4, Definition 4229.5, and Definition 4229.6 constitute the mature paper-side treatment of the finite closed-set carrier, local NameCert obligation surface, metric complement boundary route, scope basis, public boundary export, and bridge-facing export over the displayed topology, metric, separated-metric, complement, transport, replay, provenance, local naming, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClosedSet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host powerset semantics, detached open-set lattices, selected limit points, quotient equality of names, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or compact-image closedness outside the displayed consumer route.

Upgrade path: Verification progress requires Lean-side coverage for the mature carrier admission, topology compatibility, metric compatibility, complement exactness, complement-boundary transport, metric-boundary replay, transport replay, nonescape, provenance exposure, local naming, and TasteGate field faithfulness for BEDC.Derived.ClosedSetUp.

Chapter 4230

A Concrete Naming Certificate for $\mathsf{Met}^{\uparrow}$

Following Bishop and Bridges and Bourbaki, the $\mathsf{Met}^{\uparrow}$ packet records the traditional metric-space interface as finite BEDC NameCert data. It sits over the generic distance-witness surface of chapter 57, the real-valued distance route of chapter 1638, the dyadic tolerance core of chapter 291, the finite stream-name interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter gives completion, topology, total-boundedness, compactness, and Polish-space consumers a single cited carrier surface without importing quotient equality, selected limits, countable choice, or ambient completeness.

Definition 4230.1 (MetricSpace carrier)**.** *A* $\mathsf{Met}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, \sigma, D, Z, S, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the point-carrier row. It names the displayed point observations and the finite windows through which downstream consumers may inspect them.*
2. *σ is the point-classifier row. It records the accepted point equivalence used by* hsame *transport and by the zero-distance classifier handoff.*
3. *D is the* $\mathsf{Real}^{\uparrow}$*-valued distance row. It is read through the* $\mathsf{Met}^{\uparrow}$ *witness surface of chapter 57 and the* $\mathsf{RealMetric}^{\uparrow}$ *distance route of chapter 1638.*
4. *Z is the zero-distance classifier row, requiring any request that turns distance zero into point equivalence to pass through σ rather than through host equality.*
5. *S is the symmetry row, carrying the componentwise reversal of endpoint observations and the corresponding distance readback.*
6. *T is the triangle row, carrying the three endpoint-pair distance reads and the dyadic tolerance budget used to compose them.*
7. *H records componentwise* hsame *transport for the point carrier, classifier, distance, zero-distance, symmetry, triangle, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a metric request through the finite route*

$$X, \sigma \longmapsto \mathsf{Met}^{\uparrow}, \mathsf{RealMetric}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto Z, S, T, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{Met}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, \sigma, D, Z, S, T, H, C, P, N$. It has no coordinate for host equality of points, quotient completion equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached topology.*

Lean4 ✓ `BEDC.Derived.MetricSpaceUp.MetricSpaceTasteGate single carrier alignment`

Theorem 4230.2 (MetricSpace NameCert obligations)**.** *For every accepted* $\mathsf{Met}^{\uparrow}$ *carrier*

$$M = (X, \sigma, D, Z, S, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Met}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the point carrier, point classifier, real-valued distance, zero-distance classifier, symmetry, triangle, transport, replay, provenance, and local naming rows;*
2. *distance visibility, requiring every distance read to expose the* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{RealMetric}^{\uparrow}$ *rows before any downstream consumer reads a real-valued metric comparison;*
3. *zero-distance exactness, requiring zero distance to return to the displayed classifier σ through Z and never through host point equality;*
4. *symmetry replay, requiring endpoint reversal to be witnessed by S together with the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback route;*
5. *triangle-budget replay, requiring the three distance reads and their dyadic comparison budget to be displayed by T before a triangle consumer may use the row;*
6. *structural preservation through H, C, P, N.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4230.1. An accepted packet displays the point-carrier row X, the classifier σ, the distance row D, the zero-distance row Z, the symmetry row S, the triangle row T, and the structural rows H, C, P, N.

Distance visibility is forced by the placement of D in the carrier. A distance consumer first opens the generic $\mathsf{Met}^{\uparrow}$ witness surface and the $\mathsf{RealMetric}^{\uparrow}$ readback route, and only then reads the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows needed for a finite comparison.

The zero-distance, symmetry, and triangle clauses are rowwise. The row Z is the only route from distance zero back to the point classifier, S is the only endpoint-reversal row, and T is the only triangle-budget row.

Finally, H, C, P, N transport, replay, source, and name exactly the displayed rows. Since the carrier has no other coordinate, the listed rows exhaust the local NameCert surface and cannot export host equality, quotient completion equality, selected representatives, countable choice, ambient completeness, or a detached topology. □

Theorem 4230.3 (MetricSpace distance route)**.** *Every completion, topology, total-boundedness, compactness, or Polish-space consumer of an accepted* $\mathsf{Met}^{\uparrow}$ *carrier reads distance information through the finite route*

$$X, \sigma, D \longmapsto \mathsf{Met}^{\uparrow}, \mathsf{RealMetric}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto Z, S, T, H, C, P, N.$$

Thus the public distance surface is the displayed BEDC route from point observations and classifier data to real-valued metric reads, zero-distance classification, symmetry, and triangle replay. It exports no quotient equality, selected limit, countable-choice schedule, ambient completeness theorem, or open-set lattice.

Proof. Let a downstream consumer inspect an accepted carrier $M = (X, \sigma, D, Z, S, T, H, C, P, N)$. The point surface is opened first through X and σ, so every later distance read remains attached to the displayed point classifier.

The distance row D then routes the request through $\mathsf{Met}^{\uparrow}$ and $\mathsf{RealMetric}^{\uparrow}$. The numerical readback is finite because the dyadic tolerance, stream-window, regular-rational, and real-name rows are displayed before any metric comparison is consumed.

Metric laws are read only after this route is visible. Zero distance returns through Z to σ, symmetry reverses endpoints through S, and triangle use exposes the three pairwise reads and dyadic budget through T.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since none of the excluded objects appears in the carrier, no listed downstream consumer can read quotient equality, a selected limit, a choice schedule, ambient completeness, or an open-set lattice from the $\mathsf{Met}^{\uparrow}$ packet. □

Chapter 4231

A Concrete Naming Certificate for $\mathsf{NashEquilibrium}^{\uparrow}$

Following Nash's equilibrium theorem, the $\mathsf{NashEquilibrium}^{\uparrow}$ packet records the finite best-response surface for a displayed finite normal-form game before any mixed strategy, payoff comparison, or equilibrium witness is treated as a host object. It sits after the compact metric and convex strategy-simplex surfaces of chapter 129 and chapter 208, the real payoff rows of chapter 38, and the fixed-point anchors of chapter 2030 and chapter 3511. The chapter names the finite BEDC carrier needed by later game-theoretic consumers without exporting a host simplex, selected optimizer, quotient mixed-strategy equality, semantic continuity, or an ambient fixed-point theorem.

Definition 4231.1 (Nash equilibrium carrier)**.** *A* $\mathsf{NashEquilibrium}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (P, S, A, U, B, E, H, C, Q, N)$$

with the following displayed rows:

1. *P is the finite player ledger. It records the inspected player names, their classifier rows, and the finite dependency order in which player-indexed strategy and payoff rows are read.*
2. *S is the finite strategy-simplex ledger. For each player it displays the finitely generated mixed-strategy simplex through compact metric and convex-set rows, together with the finite coordinate windows consumed by the game packet.*
3. *A is the action-window ledger. It records, for each player, the finite pure-action windows that underlie the displayed simplex coordinates and the finite product windows inspected by payoff and best-response consumers.*
4. *U is the payoff-row ledger. It reads payoff comparisons only through displayed* $\mathsf{Real}^{\uparrow}$ *rows attached to finite action profiles and finite mixed-strategy windows.*
5. *B is the best-response ledger. It records the finite argmax or best-response correspondence rows as displayed comparison data over P, S, A, U, without selecting a host optimizer.*
6. *E is the equilibrium row. It states that the displayed mixed-strategy profile is read through B as a fixed point of the best-response ledger, with the fixed-point route exposed only through the cited Brouwer or Kakutani packet.*
7. *H records componentwise* hsame *transport for player ledgers, simplex rows, action windows, payoff rows, best-response rows, equilibrium rows, replay routes, provenance rows, and local naming rows.*

8. *C records displayed* Cont *continuation from a finite game request through the player, simplex, action, payoff, best-response, fixed-point, transport, provenance, and local naming rows.*
9. *Q is the* Pkg *provenance over* $\mathsf{NashEquilibrium}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BrouwerFixedPoint}^{\uparrow}$, $\mathsf{KakutaniFixedPoint}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NashEquilibrium}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these displayed rows. It stores no host mixed-strategy simplex, no selected maximizer, no quotient equality of strategies, no semantic payoff continuity, no countable choice, and no ambient fixed-point principle.

Lean4 ✓ `BEDC.Derived.NashEquilibriumUp.NashEquilibriumTasteGate single carrier alignment`

Theorem 4231.2 (Nash equilibrium NameCert obligations)**.** *For every accepted* $\mathsf{NashEquilibrium}^{\uparrow}$ *carrier*

$$G = (P, S, A, U, B, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{NashEquilibrium}^{\uparrow}}$ *surface consists exactly of finite player admission, finite strategy-simplex exposure, action-window exposure, payoff-row readability, best-response ledger exposure, equilibrium-row fixed-point routing, componentwise* hsame *transport, displayed* Cont *continuation,* Pkg *provenance, and local naming. No NameCert obligation is stored outside the rows of Definition 4231.1.*

Proof. Project the accepted carrier. The player, strategy, action, payoff, best-response, and equilibrium data are precisely the rows P, S, A, U, B, E.

The finite game surface is read first. The player ledger P indexes the displayed strategy-simplex rows S, while the action-window ledger A supplies the finite product windows inspected by payoff and best-response consumers.

The payoff and best-response obligations are then read through U and B. Payoff comparisons consume only the displayed $\mathsf{Real}^{\uparrow}$ rows, and the best-response ledger records comparison and correspondence data without adding a selected host optimizer.

Finally the equilibrium row E is consumed through the displayed fixed-point route, and the structural rows H, C, Q, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate beyond these rows, the listed surface exhausts the local NameCert obligations. □

Theorem 4231.3 (Nash equilibrium best-response coverage)**.** *Let*

$$G = (P, S, A, U, B, E, H, C, Q, N)$$

be an accepted $\mathsf{NashEquilibrium}^{\uparrow}$ *carrier. Every equilibrium-facing read of E must first expose the player ledger P, the finite strategy-simplex rows S, the action windows A, the payoff rows U, and the best-response ledger B. The read may cite* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BrouwerFixedPoint}^{\uparrow}$, *and* $\mathsf{KakutaniFixedPoint}^{\uparrow}$ *only through those displayed rows and the structural rows H, C, Q, N; it exports no host simplex, selected best response, quotient strategy equality, semantic continuity, countable choice, or ambient fixed-point theorem.*

Proof. Begin with the carrier definition. The equilibrium row E is downstream of P, S, A, U, B, so no equilibrium-facing consumer can inspect E before the finite player, strategy, action, payoff, and best-response ledgers have been displayed.

The compact and convex rows enter only through S, and the real payoff comparisons enter only through U. The fixed-point route is recorded by the best-response and equilibrium rows rather than by a separate host theorem coordinate.

Apply the NameCert obligation theorem. It makes transport, continuation, provenance, and local naming part of the same displayed route, so any consumer of E receives only the finite best-response certificate.

The excluded host simplex, selected optimizer, quotient equality, semantic continuity, choice, and ambient fixed-point objects are absent from the carrier inventory. Thus the best-response coverage route is exhausted by the displayed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{NashEquilibrium}^{\uparrow}}$.

Constructive story: A $\mathsf{NashEquilibrium}^{\uparrow}$ packet is generated from a finite player ledger, finite strategy-simplex rows, action windows, payoff Real rows, best-response ledger, equilibrium fixed-point row, componentwise hsame transport, displayed Cont continuation, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NashEquilibrium}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4231.1, Definition 4231.2, and Definition 4231.3 seed the finite best-response certificate surface over player, simplex, action, payoff, best-response, equilibrium, transport, continuation, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NashEquilibrium}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host mixed-strategy simplices, selected optimizers, quotient strategy equality, semantic payoff continuity, countable choice, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite simplex exposure, action-window coverage, payoff-row readability, best-response ledger exactness, equilibrium-row nonescape, transport stability, continuation stability, provenance stability, and local naming for BEDC.Derived.NashEquilibriumUp.

$\mathsf{CauchyFilterSubbasis}^{\uparrow}$ consumes the generated $\mathsf{FilterBase}^{\uparrow}$ route of chapter 1601 before handing generated requests to chapter 333.

Chapter 4232

A Concrete Naming Certificate for $\mathsf{CauchyFilterSubbasis}^{\uparrow}$

Following Kelley and Bourbaki, the $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ packet records the standard subbasis-to-filter generation surface needed before a completion-facing Cauchy filter can be read as a finite BEDC route. It sits between the filter-base interface of chapter 1601, the Cauchy-filter packet of chapter 333, the completion boundary of chapter 1569, the finite window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite generation interface only; it does not quotient filters, select limits, invoke countable choice, use host equality, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

The separated uniform completion of chapter 7566 and the effective regular real extensionality surface of chapter 7009 consume this subbasis route only after $\mathsf{FilterBase}^{\uparrow}$ and $\mathsf{CauchyFilter}^{\uparrow}$ generation are displayed and the finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ windows remain visible. The consumer route is therefore a finite generated-base handoff, not an isolated subbasis generator.

Definition 4232.1 (Cauchy filter subbasis carrier)**.** *A* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, I, E, G, B, F, W, T, R, L, H, C, P, N)$$

with the following displayed rows:

1. *U is the finite subbasis-token row naming the primitive neighbourhood requests available to the packet.*
2. *I is the finite-intersection row, recording which finite families of subbasis tokens are admitted as generated basic requests.*
3. *E is the generated-event row, displaying the* BHist *surface attached to each finite intersection request.*
4. *G is the generation ledger, storing the inclusion reads from subbasis tokens into generated base events and the closure reads from finite intersections into base requests.*
5. *B is the generated* $\mathsf{FilterBase}^{\uparrow}$ *row exposed to downstream filter consumers.*
6. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row obtained from the generated base together with the displayed Cauchy comparison requests.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used when a completion-facing consumer reads generated tails.*

8. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-accounting row for the generated Cauchy comparisons.*
9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for retained regular rational windows.*
10. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the generated base, Cauchy row, window row, tolerance ledger, and readback row have been displayed.*
11. *H records componentwise* hsame *transport for subbasis tokens, finite intersections, generated events, generation ledgers, filterbase rows, Cauchy rows, windows, tolerances, readbacks, Real seals, replay, provenance, and local naming.*
12. *C records displayed* Cont *replay from subbasis requests through finite intersections, generated filterbase rows, Cauchy-filter rows, finite windows, tolerance accounting, readback, and Real sealing.*
13. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSubbasis}^{\uparrow}}$ *row.*

The classifier reads only $U, I, E, G, B, F, W, T, R, L, H, C, P, N$. It has no coordinate for an ultrafilter extension, quotient equality of filters, selected limits, countable-choice schedules, host equality of generated sets, or ambient completeness.

Lean4 (definition) `BEDC.Derived.CauchyFilterSubbasisUp.CauchyFilterSubbasisUp`

Theorem 4232.2 (Cauchy filter subbasis NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *carrier $S = (U, I, E, G, B, F, W, T, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSubbasis}^{\uparrow}}$ *surface consists exactly of carrier admission, finite subbasis-token exposure, finite-intersection generation, generated-event admission, generation-ledger coverage,* $\mathsf{FilterBase}^{\uparrow}$ *handoff,* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff,* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 4232.1. The visible generation data are exactly the rows U, I, E, G, so a consumer first reads primitive tokens, finite intersections, generated events, and the inclusion ledger.

The generated filter route is then B, F, W, T, R, L. The $\mathsf{FilterBase}^{\uparrow}$ row is exposed before the $\mathsf{CauchyFilter}^{\uparrow}$ row, and the finite windows, dyadic tolerance ledger, regular rational readback, and Real seal are downstream from that generated filter route.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the classifier contains no coordinate for an ultrafilter extension, quotient filter equality, selected limit, countable-choice schedule, host equality, or ambient completeness, the local NameCert surface is exactly the displayed finite packet. □

Theorem 4232.3 (Cauchy filter subbasis filterbase generation)**.** *Every completion-facing read exported by an accepted* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *carrier factors through the generated* $\mathsf{FilterBase}^{\uparrow}$ *row B before it reaches the* $\mathsf{CauchyFilter}^{\uparrow}$ *row F, the* $\mathsf{StreamName}^{\uparrow}$ *row W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the* $\mathsf{Real}^{\uparrow}$ *seal row L. Thus subbasis generation is visible as finite BEDC data rather than as a hidden host filter construction.*

Proof. Begin with the generation rows of Definition 4232.1. The only route from primitive subbasis tokens to a downstream filter read is through U, I, E, G, and the generated base is stored as the row B.

Apply the NameCert obligation theorem. It requires every Cauchy-filter and completion-facing consumer to inspect the generated $\mathsf{FilterBase}^{\uparrow}$ handoff before reading F, W, T, R, L.

The structural rows preserve the same route. Componentwise transport H, displayed replay C, provenance P, and local naming N keep the subbasis-to-filter generation inside the finite packet.

No excluded coordinate remains. Hence quotient filters, selected limits, countable-choice schedules, host equality of generated filters, and ambient completeness cannot be used in place of the displayed $\mathsf{FilterBase}^{\uparrow}$ generation row. □

Theorem 4232.4 (Cauchy filter subbasis generated-base cofinality)**.** *Every accepted* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *carrier exposes the generated* $\mathsf{FilterBase}^{\uparrow}$ *row B as cofinal among the finite intersections named by I and their displayed generated-event rows E. A completion-facing consumer must therefore read U, I, E, G, B before it reads the* $\mathsf{CauchyFilter}^{\uparrow}$ *row F, the* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal L.*

Proof. Project the carrier of Definition 4232.1. The only finite-intersection data are I, the only generated events are E, and the only inclusion and coverage reads from those rows into a base are stored in G.

Apply the NameCert obligations of Definition 4232.2. They force generated-event admission, generation-ledger coverage, and the $\mathsf{FilterBase}^{\uparrow}$ handoff to be displayed as local certificate rows of the same packet.

Use the filterbase generation theorem Definition 4232.3. Since every completion-facing read must factor through B before reaching F, W, T, R, L, the generated base is cofinal for the finite intersections visible to the packet.

The classifier has no coordinate for quotient filters, selected limits, countable choice, host equality of generated filters, or ambient completeness. Hence no external filter object can replace the displayed cofinal generated-base row. □

Theorem 4232.5 (Cauchy filter subbasis finite-intersection route)**.** *Every generated base request in an accepted* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *carrier is read through the finite subbasis-token row U, the finite-intersection row I, the generated-event row E, and the generation ledger G before the generated* $\mathsf{FilterBase}^{\uparrow}$ *row B is available. The route exports no quotient filters, selected limits, countable choice, host equality, or ambient completeness.*

Proof. Project the carrier of Definition 4232.1. The rows U, I, E, G are the only displayed route from primitive subbasis tokens to generated base events.

Apply the NameCert obligations of Definition 4232.2. They require finite subbasis-token exposure, finite-intersection generation, generated-event admission, and generation-ledger coverage before the $\mathsf{FilterBase}^{\uparrow}$ handoff is a local certificate row.

Use generated-base cofinality, Definition 4232.4. Since every completion-facing consumer must read U, I, E, G, B before the downstream rows, the generated base request is available only after the finite-intersection route has been displayed.

The excluded coordinates are absent from the carrier. Hence quotient filters, selected limits, countable choice, host equality, and ambient completeness cannot replace the rows U, I, E, G, B. □

Theorem 4232.6 (Cauchy filter subbasis refinement stability)**.** *Suppose an accepted* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *carrier replaces its generated base row B by a displayed cofinal* $\mathsf{FilterRefinement}^{\uparrow}$ *row. Then the completion-facing route still reaches the same* $\mathsf{CauchyFilter}^{\uparrow}$ *row F,* $\mathsf{StreamName}^{\uparrow}$ *windows W,*

$\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* T, $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R, *and* $\mathsf{Real}^{\uparrow}$ *seal* L. *The replacement exports no quotient filter, selected limit, countable-choice schedule, host equality of generated filters, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the generated-base cofinality theorem. It identifies B as the displayed cofinal base among finite intersections before any Cauchy-filter or completion-facing row can be read.

Apply the Cauchy-preservation and completion-route clauses for $\mathsf{FilterRefinement}^{\uparrow}$, namely Definition 1626.2 and Definition 1626.3. The refinement row may replace a displayed base request by a cofinal target request, but it preserves the Cauchy-filter read through the finite comparison surface.

Compose that refinement route with Definition 4232.3. The downstream rows F, W, T, R, L remain attached to the same subbasis-generated route because the consumer still passes through a displayed cofinal base before reading them.

Finally inspect the excluded coordinates of the carrier. Since quotient filters, selected limits, choice schedules, host equality of generated filters, and ambient Real completeness are absent from $U, I, E, G, B, F, W, T, R, L, H, C, P, N$, the refinement cannot import any of them. □

Theorem 4232.7 (Cauchy filter subbasis completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *carrier must read the rows*

$$U, I, E, G, B, F, W, T, R, L, H, C, P, N$$

in the displayed order. In particular, the generated $\mathsf{FilterBase}^{\uparrow}$ *row* B *is available before the* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F, *and the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows* W, T, R *are displayed before the terminal* $\mathsf{Real}^{\uparrow}$ *seal* L.

Proof. Read the carrier named in Definition 4232.1. Its classifier exposes exactly the listed rows, with U, I, E, G providing the finite subbasis tokens, finite intersections, generated events, and generation ledger.

Apply Definition 4232.2. The NameCert obligations require the generated $\mathsf{FilterBase}^{\uparrow}$ handoff, the $\mathsf{CauchyFilter}^{\uparrow}$ handoff, the window row, the tolerance row, the readback row, and the Real seal to appear as displayed fields of the same finite packet.

Finally apply Definition 4232.3. That theorem forces every completion-facing read through B before F, W, T, R, L, so the handoff cannot bypass the generated base or reach the terminal $\mathsf{Real}^{\uparrow}$ seal before the window, tolerance, and readback rows have been displayed. □

Theorem 4232.8 (Cauchy filter subbasis window transport)**.** *Componentwise* hsame *transport of an accepted* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *carrier preserves finite subbasis tokens, finite intersections, generated events, generation ledgers, generated* $\mathsf{FilterBase}^{\uparrow}$ *rows,* $\mathsf{CauchyFilter}^{\uparrow}$ *rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks. The transported packet adds no quotient filter, selected limit, countable-choice schedule, host equality of generated filters, or ambient completeness coordinate.*

Proof. Project the transport row H from Definition 4232.1. It is componentwise over the visible rows, so transport acts on tokens, intersections, generated events, ledgers, generated bases, Cauchy rows, windows, tolerances, readbacks, seals, replay, provenance, and local naming without changing the classifier shape.

Use Definition 4232.2 to identify the rows preserved by the local NameCert surface. Each transported read remains attached to the corresponding displayed obligation, including the generated $\mathsf{FilterBase}^{\uparrow}$ handoff and the downstream Cauchy-filter, window, tolerance, and readback obligations.

Apply Definition 4232.3 to the transported route. Since every downstream completion-facing read still factors through the generated base row, no quotient filter or selected-limit coordinate can be inserted by transport. □

Theorem 4232.9 (Cauchy filter subbasis regular readback)**.** *For an accepted* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *carrier, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *is available only after the generated* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* T *have been displayed. The* $\mathsf{Real}^{\uparrow}$ *seal* L *remains terminal for the route and cannot be used as a prior source for the readback.*

Proof. The carrier of Definition 4232.1 places R after the generated base, Cauchy-filter, window, and tolerance rows. Thus the readback row is not a primitive subbasis token and is not a replacement for the generated filter route.

By Definition 4232.2, the local certificate displays the $\mathsf{CauchyFilter}^{\uparrow}$ handoff, $\mathsf{StreamName}^{\uparrow}$ window exposure, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance accounting, and $\mathsf{RegSeqRat}^{\uparrow}$ readback as distinct obligations. The readback therefore depends on the displayed Cauchy-filter and tolerance ledger surface rather than on an ambient limit.

Apply Definition 4232.3. It keeps L after B, F, W, T, R, so the terminal $\mathsf{Real}^{\uparrow}$ seal cannot justify the readback in advance; it only seals the finite route after the readback row has been displayed. □

Falsifiable prediction: Every accepted $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ completion-facing read factors through finite subbasis tokens, finite intersections, generated events, the generation ledger, a generated FilterBaseUp row, a CauchyFilterUp row, StreamNameUp windows, DyadicRatCoreUp tolerance accounting, RegSeqRatUp readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: filterbase, cauchyfilter, cauchyfiltercompletion, streamname, regseqrat, real: $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries primitive subbasis tokens, finite-intersection generation, generated events, generation-ledger coverage, generated filterbase handoff, Cauchy-filter handoff, finite windows, tolerance accounting, readback, Real sealing, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterSubbasis}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ packet is generated from finite subbasis tokens, finite-intersection rows, generated-event rows, a generation ledger, a generated FilterBaseUp row, a CauchyFilterUp handoff, StreamNameUp windows, DyadicRatCoreUp tolerance accounting, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterSubbasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4232.1, Definition 4232.2, and Definition 4232.3 seed the finite subbasis-to-filter generation route over generated filterbase, Cauchy-filter, window, tolerance, readback, seal, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterSubbasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host equality of generated filters, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-intersection generation, generation-ledger coverage, generated FilterBaseUp handoff, CauchyFilterUp handoff, window exposure, tolerance accounting, readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFilterSubbasisUp.

The $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ carrier refines the filter-base row of chapter 1601 and feeds the Cauchy-filter carrier of chapter 333. This is a substantive sibling dependency: the basic-set closure supplied by the generated $\mathsf{FilterBase}^{\uparrow}$ row and the Cauchy-directedness consumed by the downstream $\mathsf{CauchyFilter}^{\uparrow}$ row are separate certificate obligations, not self-references or restatements of the local subbasis packet.

Frechet tail dependency. The $\mathsf{FrechetFilter}^{\uparrow}$ packet of chapter 1564 supplies the cofinite-tail specialization of the subbasis-generated filter route. The specialization is consumed through the displayed base discipline of chapter 1601 before the generated route reaches chapter 333 and the Real-facing seal.

A $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ read that is narrowed to eventual sequence tails therefore factors through the same finite threshold, filter-base, stream-schedule, regular-readback, and Real-seal rows exposed by $\mathsf{FrechetFilter}^{\uparrow}$. This is a displayed sibling dependency in the tail-base factorization route, not a citation invented after the fact, and the subbasis packet retains only the generated Cauchy-filter surface rather than quotient filter equality, selected limits, countable choice, or ambient completion.

Theorem 4232.10 (Cauchy filter subbasis tail-base factorization)**.** *Every* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *read specialized to cofinite sequence tails factors through* $\mathsf{FrechetFilter}^{\uparrow}$ *and* $\mathsf{FilterBase}^{\uparrow}$ *before* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *are read. For an accepted carrier*

$$S = (U, I, E, G, B, F, W, T, R, L, H, C, P, N),$$

the tail-specialized route first displays the finite subbasis tokens, finite intersections, generated events, and generation ledger U, I, E, G*; then reads the cofinite-tail threshold discipline of chapter 1564; then returns through the generated* $\mathsf{FilterBase}^{\uparrow}$ *row* B *before the Cauchy row, stream windows, tolerance ledger, regular readback, and Real seal* F, W, T, R, L *can be consumed.*

Proof. Begin with the generated-base cofinality theorem, Definition 4232.4. It places U, I, E, G, B before every completion-facing read, so a tail-specialized consumer cannot reach F, W, T, R, L before the generated base has been displayed.

Specialize the generated requests to eventual sequence tails. The Frechet tail dependency row in this chapter identifies the cofinite-tail discipline supplied by chapter 1564; this row is the only tail-filter surface available to the specialized read.

Compose the specialization with the completion handoff of Definition 4232.7. The handoff routes the resulting base through the $\mathsf{CauchyFilter}^{\uparrow}$ row, finite stream windows, dyadic tolerance ledger, regular rational readback, and terminal Real seal.

The carrier exclusions then apply to the whole composition. Quotient filters, selected limits, countable choice, host equality of generated filters, and ambient Real completeness are absent from the displayed rows, so none can replace the Frechet and FilterBase stages of the tail-base factorization. □

The hub-level $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ route is read through the finite dependency lattice of chapter 1601, chapter 333, chapter 126, chapter 301, and chapter 38. This route exports no quotient filter, selected limit, countable choice, or ambient completeness. The top-level $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ route consumes the finite $\mathsf{FilterBase}^{\uparrow}$ generation rows of chapter 1601 before it reads the $\mathsf{CauchyFilter}^{\uparrow}$ packet of chapter 333. Only after that base-to-Cauchy handoff does the route pass through the $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 126, chapter 301, and chapter 38. This is a finite generation route, not a quotient filter, selected limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Theorem 4232.11 (CauchyFilterSubbasis Cauchy-completion sibling route)**.** *Every accepted* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *packet exported to a completion-facing consumer first reads the Cauchy-completion criterion surface of chapter 3885. The required dependency is concrete: subbasis neighborhoods are generated from the finite* $\mathsf{FilterBase}^{\uparrow}$ *rows, the Cauchy filter completion criterion supplies the completion rows,* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *provide only finite windows and rational readback, and the terminal*

$\mathsf{Real}^{\uparrow}$ *seal records nonescape from selected limits, quotient filters, countable choice, and ambient completeness.*

Proof. Project the top-level route described above. The subbasis neighborhood row is read before any Cauchy packet is exported, so the consumer begins with finite $\mathsf{FilterBase}^{\uparrow}$ generation and the displayed $\mathsf{CauchyFilter}^{\uparrow}$ handoff.

Next read the Cauchy-completion criterion row. It supplies the completion-facing criterion used by the sibling chapter, while the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows restrict every read to finite stream windows and rational approximants.

The final $\mathsf{Real}^{\uparrow}$ seal is only a nonescape row. It does not select a limit, identify quotient filters, introduce countable choice, or assert ambient completeness beyond the finite criterion route already displayed. □

Theorem 4232.12 (CauchyFilterSubbasis Real-uniform lattice route)**.** *Every Real-uniform consumer of an accepted* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *packet must pass through finite* $\mathsf{FilterBase}^{\uparrow}$ *generation,* $\mathsf{CauchyFilter}^{\uparrow}$ *completion criteria,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal rows before any* $\mathsf{RealUniformStructure}^{\uparrow}$ *or completion-facing consumer can read it. The route exports a generated subbasis lattice edge, not quotient filters, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 4232.11. It forces any completion-facing consumer to read the Cauchy-completion criterion only after finite $\mathsf{FilterBase}^{\uparrow}$ generation and the displayed $\mathsf{CauchyFilter}^{\uparrow}$ handoff.

Now compose that sibling route with the generated-base and cofinality reading described in the top-level route. The subbasis row enters the Real-uniform lattice as generated filter-base data, so a $\mathsf{RealUniformStructure}^{\uparrow}$ consumer cannot bypass the finite base or treat the subbasis as an ambient quotient filter.

The final handoff is through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. These rows expose only finite windows, rational readback, and a terminal seal, so no selected limit, countable-choice schedule, quotient-filter equality, or ambient completeness principle is available to the consumer. □

Chapter 4233

A Concrete Naming Certificate for $\mathsf{BishopCompleteReal}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopCompleteReal}^{\uparrow}$ packet records the textbook complete-real interface as a finite BEDC boundary rather than as an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$. It sits on the dyadic endpoint ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the separated completion surface of chapter 1612, and the completion reflection boundary of chapter 403. The packet exposes the L10 completion interface currently needed by Real and Completion consumers; it does not assert that $\mathsf{Real}^{\uparrow}$ is complete, select limits, quotient streams, or import countable choice.

Definition 4233.1 (Bishop complete real carrier)**.** *A* $\mathsf{BishopCompleteReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, W, R, E, S, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance ledger used to measure regular Cauchy requests.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite schedule row opened by the same tolerance request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to D and W.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the dyadic, schedule, and regular readback rows have been displayed.*
5. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *comparison row, recording that two completion-facing reads are compared through separated finite evidence.*
6. *F is the* $\mathsf{CompletionReflection}^{\uparrow}$ *handoff row, replaying the same regular-rational source surface into the completion-facing interface.*
7. *H stores componentwise* hsame *transport for $D, W, R, E, S, F, C, P, N$.*
8. *C stores displayed* Cont *replay from a completion-facing request through the same dyadic, schedule, regular, real-seal, separated, and reflection rows.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCompleteReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{CompletionReflection}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompleteReal}^{\uparrow}}$ *row.*

The carrier has no coordinate for host real equality, quotient stream equality, a selected limit, countable choice, open-cover compactness, or a theorem that $\mathsf{Real}^{\uparrow}$ *is complete.*

Lean4 ✓ `BEDC.Derived.BishopCompleteRealUp.TasteGate.BishopCompleteRealTasteGate single carrier alignment`

Theorem 4233.2 (Bishop complete real NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompleteReal}^{\uparrow}$ *carrier*

$$B = (D, W, R, E, S, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompleteReal}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic endpoint ledger, finite schedule, regular rational readback, terminal Real seal, separated completion comparison, completion reflection handoff, componentwise transport, continuation replay, provenance, and local naming rows, together with the obligation that every completion-facing read passes through* $D, W, R, E, S, F, H, C, P, N$ *in that order.*

No obligation in the packet is discharged by host real equality, quotient streams, selected representatives, countable choice, open-cover compactness, or a completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Carrier admission is projection from Definition 4233.1. The tuple lists the dyadic, schedule, regular readback, Real seal, separated comparison, completion reflection, transport, replay, provenance, and naming rows.

The completion-facing order is fixed by the visible rows. A request first reads a dyadic endpoint and tolerance ledger in D, then opens the finite schedule row W, and then passes through the regular rational readback row R before the terminal Real seal E is available.

The separated and reflection rows then consume that same source surface. The comparison row S records separated evidence, while F replays the regular-rational source into the completion-facing boundary.

Finally H, C, P, N transport, replay, source, and name only these displayed rows. Since the carrier contains no coordinate for the excluded host, quotient, choice, compactness, or completeness data, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.BishopCompleteRealUp.BishopCompleteRealNamecertObligations`

Theorem 4233.3 (Bishop complete real L10 handoff)**.** *Every Real and Completion consumer of an accepted* $\mathsf{BishopCompleteReal}^{\uparrow}$ *packet factors through the finite L10 route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{SeparatedCompletion}^{\uparrow} \longrightarrow \mathsf{CompletionReflection}^{\uparrow}.$$

The handoff exports a displayed regular-rational completion interface with separated comparison and reflection rows. It does not export completed $\mathsf{Real}^{\uparrow}$ *equality, quotient Cauchy classes, selected host limits, countable-choice coordinates, open-cover compactness, or an ambient completeness theorem.*

Proof. Begin with the NameCert obligations of Definition 4233.2. They force every accepted read to pass through the dyadic ledger, finite schedule, regular rational readback, and terminal Real seal before any completion-facing row is consumed.

Next read the separated comparison row. The row S compares completion-facing observations only through displayed separated evidence, so it cannot introduce quotient classes or host equality.

The completion reflection row F then replays the same source surface into the completion-facing interface. The structural rows H, C, P, N preserve that route componentwise and add only transport, replay, provenance, and local naming.

Thus the consumer receives exactly the displayed L10 handoff from dyadic data to schedules, regular rational readback, Real seal, separated comparison, and completion reflection. None of the excluded completeness, choice, quotient, compactness, or selected-limit data has an entry point in the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompleteReal}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompleteReal}^{\uparrow}$ packet is generated from a dyadic endpoint ledger, finite schedule, regular rational readback, terminal Real seal, separated completion comparison, completion reflection handoff, componentwise transport, displayed continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompleteReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4233.1, Definition 4233.2, and Definition 4233.3 seed the finite Bishop complete-real interface for the current L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompleteReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim $\mathsf{Real}^{\uparrow}$ completeness, quotient real equality, selected host limits, countable choice, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated comparison, completion reflection handoff, and ledger non-escape for the same packet.

Chapter 4234

Cauchy compact extraction NameCert construction

Following Bishop and Bridges on compact metric spaces, the $\mathsf{CauchyCompact}^{\uparrow}$ extraction packet records the finite route by which total boundedness and completeness turn regular rational observations into a displayed limit seal. It refines the constructive Cauchy-extraction face of chapter 2117, consumes the regular sequence interface of chapter 301, and keeps the dyadic tolerance bookkeeping visible through chapter 291. The chapter names a finite extraction surface only; it does not assert open-cover compactness, a choice-selected subsequence, or host-level real completeness.

Definition 4234.1 (Cauchy compact extraction carrier)**.** *A* $\mathsf{CauchyCompact}^{\uparrow}$ *extraction carrier is a finite* BHist *packet*

$$E = (M, L, T, S, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *row, exposing the metric carrier, local classifier, and compact metric provenance consumed by the extraction.*
2. *L is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row, exposing the finite limit-admission route for the regular Cauchy input named by the packet.*
3. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *row, exposing for each dyadic tolerance request the finite net, mesh ledger, and coverage replay used to choose a bounded search window.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule, recording the finite windows of the input stream available before the limit seal is read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational handoff obtained from the displayed stream windows and the same tolerance ledger.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for radii, comparisons, refinements, and tail budgets used by T, S, and R.*
7. *A is the* $\mathsf{Real}^{\uparrow}$*-facing extracted seal, reachable only after M, L, T, S, R, D have been displayed.*
8. *H stores componentwise* hsame *transport for the compact metric row, complete metric row, totally bounded row, stream schedule, regular rational handoff, dyadic ledger, extracted seal, continuation, provenance, and local name.*

9. *C stores displayed* Cont *replay of the route*

$$M, L, T, S, R, D \longmapsto A.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompact}^{\uparrow}}$ *extraction row.*

The classifier compares accepted extraction packets only through these rows. It has no coordinate for open covers, selected subsequences, quotient streams, ambient choice, or a host real object.

Theorem 4234.2 (Cauchy compact extraction NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompact}^{\uparrow}$ *extraction carrier $E = (M, L, T, S, R, D, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompact}^{\uparrow}}$ *extraction surface consists exactly of the following obligations:*

1. *carrier admission for the displayed eleven-row packet;*
2. *finite-net visibility, requiring each extraction tolerance read to pass through the displayed* $\mathsf{TotallyBounded}^{\uparrow}$ *row T over the same* $\mathsf{CompactMetric}^{\uparrow}$ *row M;*
3. *regular-window compatibility, requiring the* $\mathsf{StreamName}^{\uparrow}$ *windows in S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R to use the same dyadic tolerance data D;*
4. *completeness handoff, requiring the extracted seal A to be reached through the* $\mathsf{CompleteMetric}^{\uparrow}$ *row L after the displayed regular Cauchy route has been admitted;*
5. *ledger confinement, requiring H, C, P, N to transport, replay, source, and name only the displayed extraction route and to export no open-cover compactness, choice-selected subsequence, quotient stream equality, ambient choice, or host real equality.*

Proof. Project the accepted carrier. The packet displays exactly the compact metric row, complete metric row, total-bounded finite-net row, stream schedule, regular rational handoff, dyadic ledger, extracted seal, transport, continuation, provenance, and local naming rows.

Finite-net visibility is read from T over M. A tolerance request reaches the extraction only by reading the dyadic budget in D and the finite net supplied by the displayed total-bounded row.

Regular-window compatibility is forced before the completion step. The stream windows in S and the regular rational handoff R share the same dyadic ledger D, so the completion row cannot read an unnamed Cauchy input.

Finally L produces the seal A and H, C, P, N preserve that same route. Since the tuple contains no row for open covers, selected subsequences, quotient streams, ambient choice, or a host real object, the listed obligations exhaust the local NameCert surface. □

Theorem 4234.3 (Cauchy compact extraction completion handoff)**.** *Every accepted* $\mathsf{CauchyCompact}^{\uparrow}$ *extraction carrier hands compact metric data to the L10 completion route through*

$$\mathsf{CompactMetric}^{\uparrow},\quad \mathsf{TotallyBounded}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{CompleteMetric}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

together with the structural rows BHist, hsame, Cont, Pkg, *and* NameCert. *Any consumer of the extracted seal must first read the finite net, the stream window, the regular rational handoff, the dyadic ledger, and the complete metric limit route.*

Proof. Begin with the compact and total-bounded faces. The row M fixes the metric carrier and classifier, while T supplies the finite net and coverage ledger at the dyadic tolerance recorded in D.

Read the input stream next. The row S exposes only finite observation windows, and R repacks those windows with D as the regular rational handoff used by the completion side.

Apply the completeness row last. The row L consumes the displayed regular Cauchy route and produces the seal A, whose $\mathsf{Real}^{\uparrow}$ face is downstream from the same packet data.

The transport, continuation, provenance, and local naming rows preserve this dependency order. Thus the handoff exports a finite completion-facing route and no open-cover, choice-selected, quotient, ambient-choice, or host-real escape. □

Chapter 4235

A Concrete Naming Certificate for $\mathsf{CompactOpenUniformConvergence}^{\uparrow}$

Following Kelley and Bishop–Bridges compact-open and uniform convergence arguments, the $\mathsf{CompactOpenUniformConvergence}^{\uparrow}$ packet records the finite BEDC route by which compact-open function-space rows, compact-metric probes, equicontinuity ledgers, and uniform-modulus rows are read as one convergence surface. It sits beside the compact-open function-space carrier of chapter 2221, the compact-open topology surface of chapter 4138, the compact-metric source of chapter 129, and the equicontinuity family route of chapter 4076. The packet is a finite convergence carrier for compact-window consumers; it does not assert host function equality, arbitrary open-cover compactness, selected subnet convergence, quotient maps, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4235.1 (Compact-open uniform convergence carrier)**.** *A* $\mathsf{CompactOpenUniformConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, K, E, Q, M, G, D, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CompactOpenFunctionSpace}^{\uparrow}$ *source row, exposing the finite function-space window to be tested.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *compact probe row that supplies the displayed compact window.*
3. *E is the* $\mathsf{Equicontinuity}^{\uparrow}$ *family row over the same compact probe.*
4. *Q is the* $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$ *row, recording the shared compact-window radius schedule.*
5. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *convergence threshold consumed by the downstream convergence read.*
6. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row for the displayed maps on the compact probe.*
7. *D is the* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *target-distance ledger used to compare displayed values.*
8. *R is the compact-open replay row, requiring every compact-window convergence read to pass through F, K, E, Q, M, G, D before any public handoff.*
9. *H stores componentwise* hsame *transport for $F, K, E, Q, M, G, D, R, C, P, N$.*
10. *C stores displayed* Cont *replay from compact-open requests through the same finite convergence route.*

11. *P is the* Pkg *provenance over* $\mathsf{CompactOpenUniformConvergence}^{\uparrow}$, $\mathsf{CompactOpenFunctionSpace}^{\uparrow}$, $\mathsf{CompactOpenTopology}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, $\mathsf{UniformEquicontinuityModulus}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOpenUniformConvergence}^{\uparrow}}$ *row.*

The carrier has no coordinate for host equality of functions, arbitrary compact-open topology construction, selected subnets, quotient maps, open-cover compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompactOpenUniformConvergenceUp.CompactOpenUniformConvergenceTasteGate`
`single carrier alignment`

Theorem 4235.2 (Compact-open uniform convergence NameCert obligations)**.** *For every accepted* $\mathsf{CompactOpenUniformConvergence}^{\uparrow}$ *carrier*

$$U = (F, K, E, Q, M, G, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactOpenUniformConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact-open function-space row, compact-metric probe row, equicontinuity row, uniform-equicontinuity modulus row, uniform-modulus threshold row, continuous-map graph row, metric and real target-distance row, compact-open replay row, componentwise transport, displayed continuation replay, provenance, and local naming.*

Every compact-open convergence consumer must read the compact-window probe K and the shared modulus rows Q, M before reading the target-distance ledger D or the handoff row R. No obligation in the packet is discharged by host function equality, selected subnet convergence, quotient map equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 4235.1. The tuple lists the compact-open source, compact probe, equicontinuity, uniform-modulus, continuous-map, metric, real, replay, transport, provenance, and naming rows.

The compact-window order is fixed by the visible route. A consumer first reads F through the compact probe K, then reads the equicontinuity row E and shared modulus rows Q, M before any target-distance comparison in D is available.

The replay row R packages that order for compact-open convergence consumers. The structural rows H, C, P, N preserve the same finite route by componentwise transport, continuation replay, provenance, and local naming.

Since the carrier contains no coordinate for the excluded host equality, subnet, quotient, open-cover, or completeness data, the listed rows exhaust the local NameCert obligation surface. □

Theorem 4235.3 (Compact-open uniform convergence finite-net handoff)**.** *Every compact-open topology or Arzela–Ascoli-style consumer of an accepted* $\mathsf{CompactOpenUniformConvergence}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CompactOpenFunctionSpace}^{\uparrow} \longrightarrow \mathsf{CompactMetric}^{\uparrow} \longrightarrow \mathsf{Equicontinuity}^{\uparrow} \longrightarrow \mathsf{UniformEquicontinuityModulus}^{\uparrow} \longrightarrow \mathsf{Uni}$$

The handoff exports only the displayed compact-window convergence surface, with the shared modulus and target-distance rows preserved by hsame, Cont, Pkg, *and local* NameCert *data.*

Proof. Begin with the NameCert obligations of Definition 4235.2. They force the compact-open consumer to read the compact-window probe, equicontinuity row, shared modulus rows, continuous-map graph row, and target-distance ledger before the replay row.

Next read the finite compact source through chapter 129 and the equicontinuity route through chapter 4076. These sibling surfaces supply finite probes and shared modulus data rather than open-cover compactness or selected subnets.

Finally R, H, C, P, N repack the displayed route for compact-open topology and function-space consumers. The carrier contains no host function equality, quotient map, selected subnet, or ambient completeness coordinate, so the public handoff is exactly the stated finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOpenUniformConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOpenUniformConvergence}^{\uparrow}$ packet is generated from compact-open function-space rows, compact-metric probe rows, equicontinuity rows, uniform-equicontinuity modulus rows, uniform-modulus thresholds, continuous-map graph rows, metric and Real target-distance ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOpenUniformConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4235.1, Definition 4235.2, and Definition 4235.3 seed the finite compact-open uniform convergence route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactOpenUniformConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host function equality, selected subnet convergence, quotient maps, arbitrary open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-window exposure, shared-modulus exactness, target-distance handoff, replay nonescape, and local naming for BEDC.Derived.CompactOpenUniformConvergenceUp.

Chapter 4236

A Concrete Naming Certificate for DefectFlowPartitionSkeleton$^{\uparrow}$

The DefectFlowPartitionSkeleton$^{\uparrow}$ packet realizes the defect-flow partition skeleton of Definition 9462.1722 as finite cubical-incidence and boundary-flow NameCert data. It sits over the partition carrier of chapter 201, the cellular-update surface of chapter 934, the Boolean row discipline of chapter 3733, the rank-dependence boundary of chapter 202, and the support-nerve surface of chapter 238. The packet names the finite route from partition blocks and boundary incidences to defect-lowering transitions; it is not a host graph-flow oracle, stochastic biological model, quotient codon semantics, unrestricted homology computation, or hidden global scheduler.

Definition 4236.1 (Defect-flow partition skeleton carrier)**.** *A* DefectFlowPartitionSkeleton$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, I, L, T, A, M, X, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite partition-block row, listing the displayed sink blocks and their support names.*
2. *I is the cubical boundary-incidence row, recording which displayed boundary faces meet each block.*
3. *L is the defect-level ledger, recording the finite defect value attached to each non-sink incidence state.*
4. *T is the defect-flow transition row, listing the allowed defect-lowering moves between displayed states.*
5. *A is the* CellularAutomaton$^{\uparrow}$ *local update row used to replay T as a finite boundary-flow step.*
6. *M is the* Matroid$^{\uparrow}$ *rank-dependence row separating removable shared incidences from protected private coordinates.*
7. *X is the* SimplicialComplex$^{\uparrow}$ *and* BooleanAlgebra$^{\uparrow}$ *support-nerve row, exposing faces, complements, and Boolean incidence tests.*
8. *H stores componentwise* hsame *transport for $B, I, L, T, A, M, X, C, P, N$.*
9. *C stores displayed* Cont *replay from a boundary-flow request through the same finite rows.*
10. *P is the* Pkg *provenance over* DefectFlowPartitionSkeleton$^{\uparrow}$, Partition$^{\uparrow}$, CellularAutomaton$^{\uparrow}$, BooleanAlgebra$^{\uparrow}$, Matroid$^{\uparrow}$, SimplicialComplex$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DefectFlowPartitionSkeleton}^{\uparrow}}$ *row.*
The carrier has no coordinate for unrestricted flow search, host graph reachability, quotient codon semantics, biological stochastic semantics, hidden scheduler state, or unrestricted homology.

Theorem 4236.2 (Defect-flow partition skeleton NameCert obligations)**.** *For every accepted* $\mathsf{DefectFlowPartitionSkeleton}^{\uparrow}$ *carrier*

$$S = (B, I, L, T, A, M, X, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DefectFlowPartitionSkeleton}^{\uparrow}}$ *surface consists exactly of carrier admission for partition blocks, cubical boundary-incidence rows, defect-level ledgers, defect-flow transitions, cellular replay, matroid rank-dependence separation, Boolean and simplicial support-nerve tests, componentwise transport, displayed continuation replay, provenance, and local naming.*

A boundary-flow consumer may read a transition in T only after the source block row B, incidence row I, and defect ledger L have been displayed, and it may classify a sink only through the partition row and the support-nerve row. No obligation in the packet is discharged by host reachability, unrestricted flow search, biological stochastic semantics, quotient codon semantics, or hidden global scheduling.

Proof. Carrier admission is projection from Definition 4236.1. The displayed tuple lists the partition, incidence, defect, transition, cellular replay, rank-dependence, support-nerve, transport, continuation, provenance, and naming rows.

The transition order is fixed by the finite route. A consumer first reads the partition blocks B and cubical incidences I, then reads the defect ledger L, and only then may inspect the defect-lowering transition row T.

The cellular, matroid, Boolean, and simplicial rows explain how the same finite transition is replayed and classified. They provide local update, protected-coordinate separation, complement tests, and support-nerve exposure without importing a host flow oracle.

Finally H, C, P, N keep all reads inside the displayed packet. Since no excluded reachability, stochastic, quotient, scheduler, or unrestricted homology coordinate is present, the stated obligations exhaust the local NameCert surface. □

Theorem 4236.3 (Defect-flow partition skeleton TasteGate boundary)**.** *Any future TasteGate surface for* $\mathsf{DefectFlowPartitionSkeleton}^{\uparrow}$ *must provide* $\mathsf{Nontrivial\ DefectFlowPartitionSkeleton}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ DefectFlowPartitionSkeleton}^{\uparrow}$ *instances preserving $B, I, L, T, A, M, X, H, C, P, N$ as separate displayed fields. In particular, the gate must distinguish a changed partition block, a changed boundary-incidence row, a changed defect-flow transition, and a changed support-nerve row before it admits the packet as the same skeleton.*

Proof. Use the carrier of Definition 4236.1. The rows B, I, L, T, A, M, X play different roles in the finite boundary-flow route: source blocks, boundary incidences, defect values, transitions, cellular replay, rank separation, and support-nerve classification.

The NameCert obligations of Definition 4236.2 consume those rows in order. Identifying two of them would erase either the source, the flow step, or the classification boundary, so a field-faithful gate must preserve the displayed coordinates separately.

Nontriviality is witnessed by packets that vary one of the displayed rows while keeping the structural rows fixed. Such packets are observable at the carrier boundary and therefore cannot be collapsed by an admissible TasteGate read. □

Lean4 ✓ `BEDC.Derived.DefectFlowPartitionSkeletonUp.DefectFlowPartitionSkeletonTasteGate single carrier alignment`

Falsifiable prediction: Every accepted $\mathsf{DefectFlowPartitionSkeleton}^{\uparrow}$ read must expose partition blocks, cubical boundary-incidence rows, defect-level ledgers, defect-flow transitions, a cellular replay row, matroid rank-dependence separation, Boolean and simplicial support-nerve tests, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a boundary-flow consumer reads a partition sink.

Independence witness: partition, cellularautomaton, booleanalgebra, matroid, simplicialcomplex: none alone is bijective with $\mathsf{DefectFlowPartitionSkeleton}^{\uparrow}$ because the packet jointly carries partition blocks, boundary incidences, defect transitions, update replay, rank separation, support-nerve tests, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{DefectFlowPartitionSkeleton}^{\uparrow}}$.

Constructive story: A $\mathsf{DefectFlowPartitionSkeleton}^{\uparrow}$ packet is generated from partition-block rows, cubical boundary-incidence rows, defect-level ledgers, defect-flow transition rows, cellular replay, matroid rank-dependence separation, Boolean and simplicial support-nerve tests, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DefectFlowPartitionSkeleton}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4236.1, Definition 4236.2, and Definition 4236.3 seed the finite defect-flow partition skeleton packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DefectFlowPartitionSkeleton}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unrestricted flow search, biological stochastic semantics, quotient codon semantics, unrestricted homology, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition exactness, sink classification, Nontrivial DefectFlowPartitionSkeletonUp, and FieldFaithful DefectFlowPartitionSkeletonUp for BEDC.Derived.DefectFlowPartitionSkeletonUp.

The $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ packet routes completion-facing reads through chapter 301, chapter 126, chapter 291, and chapter 38 before the choice-free completion body files are read.

Chapter 4237

A Concrete Naming Certificate for $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ packet records the choice-free regular-Cauchy route to a completion-facing real seal as finite BEDC data. It sits after the regular rational readback surface of chapter 301, the finite stream-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the separated comparison surface of chapter 1463, the public reflector route of chapter 1585, and the terminal real-name seal of chapter 38. The packet names a non-quotient completion route; it does not choose representatives, quotient regular sequences, assert ambient $\mathsf{Real}^{\uparrow}$ completeness, or introduce countable choice.

Definition 4237.1 (Regular-Cauchy choice-free completion carrier)**.** *A* $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, W, D, U, F, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, carrying the regular rational name and its displayed readback requests.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite windows through which the regular name is inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows and to the regular-Cauchy modulus requests.*
4. *U is the* $\mathsf{CompletionUniqueness}^{\uparrow}$ *comparison row, recording separated comparison of two displayed completion routes without quotienting them.*
5. *F is the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *route row, exposing unit, counit, idempotent replay, universal factorization, and reflector transport as public finite data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, W, D, U, F have been displayed.*
7. *H records componentwise* hsame *transport for the source, window, tolerance, comparison, reflector, real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a regular-Cauchy request through $R, W, D, U, F, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CompletionUniqueness}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $R, W, D, U, F, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, host equality of completed objects, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 4237.2 (Regular-Cauchy choice-free completion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *carrier*

$$K = (R, W, D, U, F, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}}$ *surface consists exactly of regular rational source exposure through R, finite window exposure through W, dyadic tolerance exposure through D, separated completion comparison through U, reflector routing through F, terminal real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4237.1. Rows R, W, D are the regular-Cauchy observation spine, and rows U, F, E are the completion-facing comparison, reflector, and real-seal data.

The observation spine is read before the reflector row is consumed. The $\mathsf{RegSeqRat}^{\uparrow}$ source is inspected only through $\mathsf{StreamName}^{\uparrow}$ windows, and the dyadic tolerance ledger fixes the finite precision route available to a completion consumer.

The comparison and reflector rows stay displayed. Row U records separated comparison of completion routes, while F exposes the public unit, counit, idempotent, extension, and reflector faces without adding a quotient carrier or a selected limit.

Finally H, C, P, N transport, replay, source, and name exactly the same packet. Since no excluded coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 4237.3 (Regular-Cauchy choice-free real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{CompletionUniqueness}^{\uparrow},\ \mathsf{CauchyCompletionReflector}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The route exposes regular readback, finite windows, dyadic tolerance, separated comparison, and the public reflector surface before the terminal real seal is consumed. It does not close ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient regular sequences, selected representatives, countable choice, host equality of completed points, or open-cover compactness.*

Proof. Begin with the obligation surface of Definition 4237.2. It forces every real-facing consumer through the source, window, tolerance, comparison, reflector, and seal rows.

The sibling rows supply the route in order. The regular source is read through chapter 301; finite access is through chapter 126; dyadic tolerance is through chapter 291; separated comparison is through chapter 1463; and public reflection is through chapter 1585.

The terminal row E is therefore only the displayed $\mathsf{Real}^{\uparrow}$ seal of chapter 38. Because the carrier has no quotient, selector, choice, host-equality, compactness, or ambient-completeness coordinate, none can be exported by the seal. □

This choice-free packet is the finite source route consumed by chapter 1425. Its $\mathsf{RegSeqRat}^{\uparrow}$ source row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{CompletionUniqueness}^{\uparrow}$ comparison, $\mathsf{CauchyCompletionReflector}^{\uparrow}$ row, and $\mathsf{Real}^{\uparrow}$ seal provide the source-side data for the universal extension and uniqueness ledger, while retaining the same non-quotient and no-choice boundary.

Theorem 4237.4 (Regular Cauchy choice-free completion StreamName anchor)**.** *Every accepted* $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *completion read factors through the finite* $\mathsf{StreamName}^{\uparrow}$ *window row and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row before any terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed. The read is therefore anchored in chapter 126, chapter 301, and chapter 38, with W listing the inspected windows, R supplying the regular rational source rows, and E serving only as the downstream real-name seal.*

Proof. Project the carrier of Definition 4237.1. The rows R, W, E are displayed before any completion-facing consumer can read the real seal.

Apply the real-seal route theorem Definition 4237.3. It places $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ upstream of the $\mathsf{Real}^{\uparrow}$ terminal row and keeps the completion comparison and reflector rows downstream of the same finite observation surface.

Thus every accepted read factors first through the sibling StreamName and RegSeqRat anchors, and the Real row is only the terminal seal of that displayed route. □

Theorem 4237.5 (Regular-Cauchy choice-free cofinal-window refinement)**.** *Let*

$$K = (R, W, D, U, F, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *carrier. If a completion-facing precision request for K is served by a displayed* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *row, then the request refines through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyCompletionReflector}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

before the real seal is consumed. The refinement preserves the StreamName request rows, DyadicRatCore tolerance rows, RegSeqRat classifier and regularity rows, the reflector row F, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *support.*

No quotient stream equality, selected limit, countable-choice schedule, host equality of completed objects, open-cover compactness datum, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle can replace the displayed cofinal-window surface in this refinement.*

Proof. Begin with Definition 4237.2. It projects K onto the displayed source, window, tolerance, comparison, reflector, seal, transport, replay, provenance, and naming rows.

Use Definition 4060.2 for the precision request. The cofinality row exposes the finite $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance comparison, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the cofinal schedule before any completion-facing consumer can read the request.

Finally apply Definition 4237.3. The real-seal route places the reflector row F and the terminal $\mathsf{Real}^{\uparrow}$ seal downstream of the same finite observation surface, so the cofinal-window refinement is consumed as displayed BEDC data and not as quotient streams, selected limits, countable choice, host equality, compactness, or ambient completeness. □

Theorem 4237.6 (Regular-Cauchy cofinal-window exactness)**.** *Let*

$$K = (R, W, D, U, F, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *carrier. Every completion-facing precision request for* K *served by a* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *row is exact only through the displayed route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyCompletionReflector}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The exactness surface is the finite StreamName window row, the DyadicRatCore tolerance row, the RegSeqRat source readback, the reflector row F*, and the terminal real seal* E*. It cannot be replaced by quotient stream equality, selected limits, countable-choice schedules, host equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier in Definition 4237.1. The only completion-facing rows available from K are the displayed source, window, tolerance, comparison, reflector, seal, transport, replay, provenance, and local naming rows.

Apply Definition 4060.2 to the cofinal-window request. It exposes the finite window and tolerance data as BEDC rows before the request can be consumed by a completion-facing read.

Finally apply Definition 4237.3. Since the real seal is reached only after the same displayed route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{CauchyCompletionReflector}^{\uparrow}$, the cofinal-window row is the unique completion-facing exactness surface available to the packet. □

Theorem 4237.7 (Regular-Cauchy choice-free window coverage)**.** *Let*

$$K = (R, W, D, U, F, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *carrier. Before a completion-facing precision request for* K *is read, the packet exposes the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* R*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and the displayed* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *cofinal-window rows that serve the request. These rows are the public finite window surface for the request, and no later reflector or real-seal read can bypass them.*

Proof. Project the carrier in Definition 4237.1. Its first three rows are exactly the regular-rational source, finite-window, and dyadic-tolerance rows available before the comparison, reflector, and real-seal rows.

Use Definition 4237.2 to identify those rows as part of the local NameCert surface. For a precision request served by a cofinal-window row, Definition 4237.5 and Definition 4237.6 place the $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ evidence on the same displayed route.

Finally apply the real-seal route theorem Definition 4237.3. Since the terminal seal is downstream of R, W, D and the cofinal-window evidence, every accepted precision read sees that finite window surface before any completion-facing seal is consumed. □

Theorem 4237.8 (Regular-Cauchy choice-free tail reflection)**.** *Let*

$$K = (R, W, D, U, F, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *carrier. Every tail precision read of* K *reflects through the displayed route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyCompletionReflector}^{\uparrow},\ \mathsf{Real}^{\uparrow},$$

preserving the packet rows $R, W, D, U, F, E, H, C, P, N$ *and any* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *support used to serve the request. The reflected read cannot be replaced by quotient stream equality, selected limits, countable-choice schedules, host equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4237.1. The tail precision read can inspect only the source, window, tolerance, comparison, reflector, seal, transport, replay, provenance, and local naming rows.

Apply the NameCert obligations of Definition 4237.2. They bind the accepted packet to the rows $R, W, D, U, F, E, H, C, P, N$ and give no separate completion object.

Use Definition 4237.6 and Definition 4237.7. The cofinal support exposes the finite RegularCauchyWindowCofinal rows beside the $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, and $\mathsf{RegSeqRat}^{\uparrow}$ readback before the reflector and real seal are consumed.

Finally apply the real-seal route of Definition 4237.3. The reflected read reaches $\mathsf{CauchyCompletionReflector}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ only downstream of that finite tail-window surface, so quotient stream equality, selected limits, countable choice, host equality, open-cover compactness, and ambient completeness cannot replace it. □

Theorem 4237.9 (Regular-Cauchy choice-free reflector nonescape)**.** *Let*

$$K = (R, W, D, U, F, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *carrier. The* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *row* F *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E *export no quotient representative, selected limit, countable-choice schedule, host equality of completed objects, open-cover compactness datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle. They only expose the displayed reflector route and the downstream real-name seal already named by the packet.*

Proof. Start with Definition 4237.2. The obligation surface lists F as a displayed reflector row and E as a terminal real-seal row, with no carrier coordinate for quotient representatives, selected limits, choice schedules, host equality, compactness, or ambient completeness.

The route theorem Definition 4237.3 keeps both rows downstream of the regular source, finite windows, dyadic tolerance, and separated comparison rows. Thus F can only route the displayed completion data, and E can only seal the resulting real-name boundary.

The cofinal-window exactness theorem Definition 4237.6 rules out replacing the displayed window surface by any excluded completion principle. Hence neither the reflector row nor the real-seal row exports data outside the carrier's finite route. □

Theorem 4237.10 (Regular-Cauchy choice-free metric-reflector handoff)**.** *Let*

$$K = (R, W, D, U, F, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *carrier. Every metric-completion or reflector consumer of* K *must first expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row* R*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the* $\mathsf{CompletionUniqueness}^{\uparrow}$ *comparison row* U*, the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *route row* F*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}}$ *row* N*.*

The handoff exports no quotient completion, selected limit, countable-choice schedule, host equality of completed objects, open-cover compactness datum, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier and apply Definition 4237.2. The obligation surface names exactly the rows $R, W, D, U, F, E, H, C, P, N$, so a completion-facing consumer has no access to any coordinate outside the displayed packet.

Use the real-seal route of Definition 4237.3. It places the regular rational source, stream windows, dyadic tolerance ledger, separated comparison row, and reflector row upstream of the terminal $\mathsf{Real}^{\uparrow}$ seal.

For precision-sensitive reads, apply Definition 4237.6. The finite window and tolerance surface remains the exact completion-facing route before the reflector and real seal are consumed.

Finally apply Definition 4237.9. Since F and E export only the displayed reflector route and downstream real-name seal, the handoff refuses quotient completion, selected limits, countable choice, host equality, open-cover compactness, and ambient real completeness. □

Theorem 4237.11 (Regular-Cauchy choice-free reflector universal factorization)**.** *Let*

$$K = (R, W, D, U, F, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *carrier. Every completion-facing consumer of* K *factors first through the displayed route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{CompletionUniqueness}^{\uparrow},\ \mathsf{CauchyCompletionReflector}^{\uparrow}$$

before the terminal $\mathsf{Real}^{\uparrow}$ *seal is read. The factorization preserves the rows* $R, W, D, U, F, E, H, C, P, N$*, the cofinal-window support used by the request, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}}$ *naming.*

No completion-facing consumer may bypass this route by exporting quotient completion data, selected limits, countable-choice schedules, host equality of completed objects, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4237.1. The source, window, tolerance, comparison, reflector, seal, transport, replay, provenance, and local naming rows are exactly $R, W, D, U, F, E, H, C, P, N$.

Apply the real-seal route of Definition 4237.3. It orders every terminal $\mathsf{Real}^{\uparrow}$ read through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CompletionUniqueness}^{\uparrow}$, and $\mathsf{CauchyCompletionReflector}^{\uparrow}$ before the seal row E is consumed.

Use the metric-reflector handoff of Definition 4237.10. It shows that metric-completion and reflector consumers receive the same displayed packet rows rather than a separate completion object.

Finally use Definition 4237.12. Componentwise transport, displayed replay, provenance, and local naming preserve the route instead of adding quotient, selector, choice, host-equality, compactness, or ambient-completeness data. □

Theorem 4237.12 (Regular-Cauchy choice-free transport and replay preservation)**.** *Let*

$$K = (R, W, D, U, F, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *carrier. Componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}}$ *row* N *preserve exactly the packet rows* R, W, D, U, F, E *together with their displayed cofinal-window support. They add no quotient completion principle, selected limit, countable-choice schedule, host equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier definition. Rows H, C, P, N are not new completion data; they are the transport, replay, provenance, and local naming rows attached to the displayed source, window, tolerance, comparison, reflector, and seal rows.

Apply Definition 4237.2. It says the local NameCert surface consists exactly of $R, W, D, U, F, E, H, C, P, N$, so transport and replay preserve the same packet rows rather than extending the classifier with an extra completion coordinate.

Use Definition 4237.3 and Definition 4237.7 for the downstream route. The same finite observation surface reaches the reflector and real seal after componentwise transport, displayed replay, provenance, and local naming, and the excluded completion principles never appear in the carrier. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ read exposes RegSeqRat source, StreamName window, DyadicRatCore tolerance, CompletionUniqueness comparison, CauchyCompletionReflector route, RealUp seal, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before any completion-facing real seal is consumed.

Independence witness: regseqrat, streamname, dyadicratcore, completion-uniqueness, cauchy-completionreflector, real: none is bijective with $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ because this packet alone binds the regular-Cauchy source, finite-window tolerance spine, separated comparison row, public reflector route, and terminal RealUp seal without quotient completion or countable choice.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ packet is generated from RegSeqRat source rows, StreamName windows, DyadicRatCore tolerance rows, CompletionUniqueness comparison rows, CauchyCompletionReflector route rows, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4237.1, Definition 4237.2, and Definition 4237.3 seed the finite choice-free regular-Cauchy completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, host equality of completed objects, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window coverage, dyadic tolerance exactness, separated comparison, reflector routing, RealUp seal nonescape, TasteGate nontriviality, FieldFaithful coverage, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyChoiceFreeCompletionUp.

Completion-dense extension consumer. $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ supplies the choice-free $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route consumed by chapter 6382. The downstream extension packet reads this route as finite completion-facing data and receives no quotient completion representative, selected limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Theorem 4237.13 (Regular-Cauchy choice-free dense-extension route)**.** *Every* $\mathsf{CompletionDenseExtension}^{\uparrow}$ *consumer of a* $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *packet first reads the displayed* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CompletionUniqueness}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows exposed by that packet. The consumer receives the route as finite completion-facing data and receives no quotient representative, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the NameCert obligations of Definition 4237.2. They expose the source row R, window row W, tolerance row D, comparison row U, reflector row F, terminal seal row E, and the transport, replay, provenance, and local naming rows before any downstream completion read is available.

Apply the real-seal route of Definition 4237.3. It orders the same displayed route through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CompletionUniqueness}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The downstream packet is chapter 6382. Since the upstream carrier contains no quotient representative, selected limit, countable-choice schedule, or ambient completeness coordinate, the dense-extension consumer can only receive the displayed finite rows. □

Theorem 4237.14 (Regular-Cauchy choice-free completion universal route)**.** *Every* RegularCauchyCompletionUnive *consumer of a* $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *packet first reads the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{CompletionUniqueness}^{\uparrow}$ *comparison row,* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *route row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row before using the universal extension or uniqueness ledger. The universal consumer receives only those source-side finite rows together with the componentwise transport, displayed replay, provenance, and local naming rows of the choice-free packet.*

Proof. Start with the dense-extension route of Definition 4237.13. It exposes the regular source, finite windows, dyadic tolerance, completion comparison, reflector row, and real seal before any downstream completion-facing consumer can read the packet.

Use the real-seal route of Definition 4237.3. The terminal $\mathsf{Real}^{\uparrow}$ row is reached only after the same displayed source-side data, so the universal consumer cannot substitute quotient representatives, selected limits, choice schedules, or ambient completeness.

Finally apply the universal extension and public export surfaces, Definition 1425.2 and Definition 1425.10. They consume the displayed source, window, dyadic, comparison, and real-seal rows before exporting the extension route and uniqueness ledger, which is exactly the stated universal route from the choice-free packet. □

$\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ consumes the metric-completion dependency surface of chapter 1506 through the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ seal route already bound by its carrier and real-seal theorems. The packet receives this route as finite completion-facing data and receives no quotient completion, selected limit, countable-choice schedule, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Theorem 4237.15 (Regular Cauchy choice-free sibling lattice route)**.** *Every accepted* RegularCauchyChoiceFreeCom *packet consumes chapter 1506 and chapter 1776 only through the displayed sibling lattice*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{CompletionUniqueness}^{\uparrow},\ \mathsf{CauchyCompletionReflector}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The route exports finite completion-facing data for the choice-free carrier, transport, replay, provenance, and local naming rows. It exports no quotient completion, selected limit, choice schedule, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Read the metric-completion sibling first. Its completion-facing surface is consumed only after the regular rational source row, stream-window row, and dyadic tolerance row have been displayed by the choice-free packet.

Read the Bishop completion induction sibling next. The induction route is attached to the same $\mathsf{CompletionUniqueness}^{\uparrow}$ comparison and $\mathsf{CauchyCompletionReflector}^{\uparrow}$ route before the terminal $\mathsf{Real}^{\uparrow}$ seal is exposed.

The carrier, real-seal, transport, replay, provenance, and local naming rows preserve exactly this sibling lattice. Since the packet contains no quotient-completion, selected-limit, choice-schedule,

host-equality, or ambient-completeness coordinate, no consumer can extract those endpoints from the route. □

Theorem 4237.16 (Regular Cauchy choice-free sibling route)**.** *Every accepted* RegularCauchyChoiceFreeCompletion *route consumes chapter 1506, chapter 1776,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *as sibling* NameCert *surfaces. The route exposes them only as finite completion-facing rows for regular rational source data, finite stream windows, dyadic tolerance accounting, induction replay, metric-completion dependency, and terminal real sealing. It exposes no quotient completion, selected limit, countable-choice schedule, host equality of completed objects, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Read the sibling lattice of Definition 4237.15. The metric-completion and Bishop-induction siblings are admitted only after the regular rational, stream-window, and dyadic-tolerance surfaces have been displayed.

The route then reaches the terminal $\mathsf{Real}^{\uparrow}$ seal through the same completion-facing rows. Since no quotient-completion, selected-limit, choice-schedule, host-equality, or ambient-completeness coordinate is present in the carrier, the listed sibling surfaces exhaust the visible route. □

The $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ route is consumed only after the L10 sibling surface has exposed regular rational families, finite stream windows, dyadic tolerance ledgers, and the terminal Real seal. A completion-facing consumer must therefore read chapter 301, chapter 126, chapter 291, and chapter 38 before using the choice-free handoff. The route records finite readback and tolerance data; it supplies no quotient completion, selected limit, countable-choice schedule, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle. The $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ packet consumes chapter 301, chapter 38, and chapter 126 through finite regular-Cauchy windows before any completion-facing seal is read. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular rational source and readback requests, the $\mathsf{StreamName}^{\uparrow}$ row bounds those requests by displayed windows, and the $\mathsf{Real}^{\uparrow}$ row appears only as the terminal seal reached after the reflector and comparison rows have replayed the same finite data. This route gives downstream completion consumers no quotient representative, selected limit, countable-choice schedule, host equality of completed objects, or ambient real-completeness principle. $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ reads its local critical-pair and residual-join packet as a consumer of chapter 765, while the body files below keep the carrier, candidate-normalization, residual-substitution, and seed-readiness rows separate.

Chapter 4238

A Concrete Naming Certificate for MetaCICParallelDiamondFrontier$^{\uparrow}$

The MetaCICParallelDiamondFrontier$^{\uparrow}$ packet realizes the residual-substitution frontier of chapter 9378 as finite confluence-facing NameCert data. It sits beside the residual-substitution boundary of chapter 2181, the confluence critical-pair boundary of chapter 2212, the closed checker seal of chapter 2182, and the closed-normal confluence fragment of chapter 737. The packet records the conditional parallel-diamond frontier without claiming residual-substitution compatibility, full closed Church–Rosser, subject reduction, evaluator equality, or kernel consistency.

The retained P, K, J, R, S, C, B, O rows are consumed substantively by the MetaCIC critical-path packet of chapter 765, the confluence audit packet of chapter 735, and the normalization-confluence bridge route of chapter 1190. The critical-path reader consumes the residual-premise and obstruction rows, while the confluence audit packet consumes the candidate-join and bounded-check rows before any confluence consumer may use the frontier. The route exports no full Church–Rosser theorem and no subject-reduction theorem.

Falsifiable prediction: Every accepted MetaCICParallelDiamondFrontier$^{\uparrow}$ confluence-facing read exposes the residual-substitution premise row before any parallel-diamond handoff can be consumed.

Independence witness: metacic-residual-substitution-boundary, metacic-confluence-critical-pair-boundary, closed-type-checker-seal, metacicconfluencenormalfragment: the residual-substitution boundary names the missing compatibility input without the parallel-diamond handoff; the critical-pair boundary records local peak data without the closed checker seal; the closed type-checker seal records bounded checking without confluence closure; and the closed-normal fragment records unconditional normal-source joins without the residual frontier. None is bijective to MetaCICParallelDiamondFrontier$^{\uparrow}$.

Definition 4238.1 (MetaCIC parallel-diamond frontier carrier)**.** *A* MetaCICParallelDiamondFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (P, K, J, R, S, C, B, O, H, T, G, N)$$

with the following displayed rows:

1. *P is the residual-substitution premise row, naming the substitution compatibility input required by the parallel-diamond route.*
2. *K is the critical-pair row, recording the local peak and its two parallel-reduction observations.*

3. *J is the candidate-join row, recording the proposed common reduct and branch-local route requests.*
4. *R is the residual-frontier row, listing residual descendants, binder-depth exposure, and branch-local substitution windows.*
5. *S is the closed type-checker seal row consumed before a closed confluence-facing read can use the checker data.*
6. *C is the closed-normal fragment row, recording the already available normal-source and atom-source confluence fragments.*
7. *B is the bounded-check row over closedness, support, branch compatibility, and finished-normalization boundaries.*
8. *O is the obstruction row naming the endpoints not supplied by the packet: residual-substitution discharge, full parallel diamond, subject reduction, arbitrary closed Church–Rosser, evaluator equality, and kernel consistency.*
9. *H records componentwise* hsame *transport for premise, peak, join, residual, checker, fragment, bounded-check, obstruction, replay, provenance, and local naming rows.*
10. *T records displayed* Cont *replay from a confluence query through $P, K, J, R, S, C, B, O, H, G, N$.*
11. *G is the* Pkg *provenance over* MetaCICParallelDiamondFrontier$^{\uparrow}$, MetaCICResidualSubstitutionBoundary$^{\uparrow}$, MetaCICConfluenceCriticalPairBoundary$^{\uparrow}$, ClosedTypeCheckerSeal$^{\uparrow}$, MetaCICConfluenceNormalFragment$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{MetaCICParallelDiamondFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, K, J, R, S, C, B, O, H, T, G, N$. It has no coordinate for a premise-free parallel diamond, subject reduction, arbitrary closed Church–Rosser, unrestricted beta-conversion decidability, evaluator equality, quotient equality of terms, or kernel consistency.

Theorem 4238.2 (MetaCIC parallel-diamond frontier obligations)**.** *For every accepted* MetaCICParallelDiamondFro *carrier*

$$F = (P, K, J, R, S, C, B, O, H, T, G, N),$$

the local NameCert$_{\text{MetaCICParallelDiamondFrontier}^{\uparrow}}$ *surface consists exactly of residual-substitution premise retention through P, critical-pair exposure through K, candidate-join exposure through J, residual-frontier exposure through R, closed-checker handoff through S, closed-normal fragment exposure through C, bounded-check exposure through B, obstruction retention through O, componentwise transport through H, displayed replay through T, provenance through G, and local naming through N.*

Lean4 ✓ `BEDC.Derived.MetaCICParallelDiamondFrontierUp.MetacicParallelDiamondFrontierObligations`

Proof. Project the carrier of Definition 4238.1. The confluence-facing rows are P, K, J, R, S, C, B, O, and the structural certificate rows are H, T, G, N.

The residual-substitution premise row remains first-class. Row P is not discharged by the carrier; it is the named input that the conditional parallel-diamond route must still expose.

The local geometry is then displayed through K, J, R. The critical-pair, candidate-join, and residual-frontier rows provide finite peak data and branch-local residual windows, while the closed checker and closed-normal rows show which existing fragments may be consumed.

Finally B, O, H, T, G, N keep the bounded checks, obstruction endpoints, transport, replay, provenance, and local naming attached to the same packet. Since no omitted theorem appears as a carrier coordinate, the listed rows exhaust the frontier obligations. □

Theorem 4238.3 (MetaCIC parallel-diamond frontier handoff)**.** *Every confluence consumer of an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must expose the residual-substitution premise row P, the critical-pair row K, the candidate-join row J, the residual-frontier row R, the closed checker seal row S, the closed-normal fragment row C, and the bounded-check row B before any parallel-diamond handoff is read. The handoff may feed the conditional route recorded in chapter 9378, but it does not discharge residual substitution, prove subject reduction, prove arbitrary closed confluence, decide evaluator equality, or establish kernel consistency.*

Proof. Begin with the obligation surface of Definition 4238.2. It forces every confluence read through the named premise, peak, join, residual, checker, fragment, bounded-check, and obstruction rows.

The sibling packets preserve that boundary. The residual-substitution boundary supplies the named premise, the critical-pair boundary supplies local peak data, the closed type-checker seal supplies bounded checker data, and the normal fragment supplies only the closed-normal and atom-source cases already available.

The obstruction row O remains part of the packet. Therefore the handoff is a finite frontier certificate for a conditional route, not a proof of the missing residual-substitution input or any stronger confluence endpoint. □

Theorem 4238.4 (MetaCIC parallel-diamond critical-pair exhaustion)**.** *For every accepted* MetaCICParallelDiamor *carrier*

$$F = (P, K, J, R, S, C, B, O, H, T, G, N),$$

each residual-substitution critical pair that a confluence consumer may inspect is exposed by the displayed critical-pair row K before the candidate-join row J can be read. The read must retain the residual-substitution premise row P, route the branch-local residual windows through R, pass the closed checker seal S and closed-normal fragment row C, and keep the bounded-check and obstruction rows B, O visible. It exports no unlisted peak, hidden substitution lemma, candidate join detached from K, R, or closed-checker result outside the displayed frontier packet.

Proof. Project the carrier of Definition 4238.1. The only rows that can mention residual substitution, critical pairs, candidate joins, residual windows, closed checking, and obstruction are P, K, J, R, S, C, B, O.

The residual-substitution premise is retained first. Row P is not discharged by the packet, so every critical-pair read remains conditional on the same displayed premise.

The critical-pair exposure is then forced through K. A consumer cannot read J as a candidate join until the peak and its two parallel-reduction observations have already been displayed in K and routed through the branch-local residual windows in R.

Finally the closed-checker handoff is bounded by S, C, B, O. The checker seal, closed-normal fragment, bounded-check row, and obstruction row remain visible through the replay, provenance, and local naming rows T, G, N, so the packet exhausts the accepted critical pairs without adding any hidden confluence endpoint. □

Theorem 4238.5 (MetaCIC parallel-diamond frontier obstruction triad)**.** *Every accepted* MetaCICParallelDiamond *packet retains three independent obstruction classes throughout the conditional local-diamond read:*

residual-substitution premise discharge remains confined to the row P, subject-reduction compatibility remains outside the closed-checker and closed-normal rows S, C, and the full closed Church–Rosser, evaluator equality, quotient term equality, and kernel-consistency endpoints remain recorded only as refused endpoints in the obstruction row O. These obstructions are transported and replayed through H, T, G, N without being collapsed into one another or promoted to completed confluence data.

Proof. Project the carrier rows P, O, B, S, C from Definition 4238.1. Row P is the residual-substitution premise, row O stores the refused endpoints, and rows B, S, C expose only bounded checking, closed checking, and closed-normal fragment data.

Apply the frontier handoff theorem and critical-pair exhaustion, Definition 4238.3 and Definition 4238.4. They keep the local peak under the displayed premise and force the closed-checker route to retain S, C, B, O.

Finally use the route theorem Definition 4238.9. Transport, replay, provenance, and local naming preserve the same rows rather than discharging P, deriving subject reduction from S, C, or turning the obstruction row into Church–Rosser, evaluator equality, quotient equality, or kernel consistency. □

Theorem 4238.6 (MetaCIC critical-pair obstruction budget)**.** *Every critical-pair read consumed by a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *parallel-diamond frontier must preserve the residual-substitution premise row P and the obstruction row O through the displayed route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

In particular, a consumer may not retype the handoff as premise-free confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with the obligation surface of Definition 4238.2. It makes $P, K, J, R, S, C, B, O, H, T, G, N$ the carrier rows of the accepted frontier packet, with P and O displayed as ordinary rows rather than external commentary.

Apply the route theorem Definition 4238.9. Any confluence-audit consumer must expose the critical-pair row K, candidate row J, residual-frontier row R, checker rows S, C, B, obstruction row O, and structural rows H, T, G, N before using the conditional handoff.

Use premise retention, Definition 4238.13. The residual-substitution premise row P remains visible through the critical pair, residual frontier, closed checker, and closed-normal rows whenever the local-diamond handoff is consumed.

Finally apply discharge obstruction, Definition 4238.18. Since no separate residual-substitution compatibility certificate is supplied by this packet, the obstruction row O keeps the refused confluence, typing, evaluator, quotient, and kernel endpoints outside the critical-pair budget. □

Theorem 4238.7 (MetaCIC residual peak scope)**.** *Every candidate-mediated residual peak read from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose the MetaCIC critical-pair envelope, residual substitution dependency, normalization candidate scope, and closure-trace rows before a diamond frontier read is public. For a carrier*

$$F = (P, K, J, R, S, C, B, O, H, T, G, N),$$

the visible scope is

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

where K records the critical-pair envelope, P retains the residual-substitution dependency, J, R, C carry the candidate-normalization and residual-frontier scope, and H, T, G, N preserve the closure trace through transport, replay, provenance, and local naming. The read is a finite frontier boundary; it is not a confluence theorem, a strong-normalization theorem, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. Project the carrier of Definition 4238.1. The residual peak has no row outside $P, K, J, R, S, C, B, O, H, T, G, N$ so every public diamond-frontier read must be assembled from that finite spine.

Use critical-pair exhaustion. It displays the local peak through K and prevents the candidate row J from being read before the residual-substitution premise P and branch-local residual row R remain visible.

Next apply the frontier handoff and residual-substitution scope routes already present in the chapter. These keep the candidate-normalization surface inside J, R, S, C, B, O and retain the obstruction row rather than closing the missing residual-substitution dependency.

Finally read the closure trace through H, T, G, N. Transport, replay, provenance, and local naming preserve the same candidate-mediated residual peak for downstream consumers, but none of those rows supplies confluence, strong normalization, subject reduction, evaluator equality, quotient equality, or kernel consistency. □

Theorem 4238.8 (MetaCIC parallel-diamond frontier seed-record exhaustion)**.** *Seed-facing confluence reads of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet are exhausted by*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

They cannot promote the residual-substitution premise, subject reduction, Church–Rosser, evaluator equality, quotient equality, or kernel consistency.

Proof. Project the carrier of Definition 4238.1. Its seed-facing rows are exactly $P, K, J, R, S, C, B, O, H, T, G, N$.

Use the obligation surface and handoff theorem, Definition 4238.2 and Definition 4238.3. They keep the residual-substitution premise visible and expose only the conditional frontier route.

Finally cite premise retention, residual-substitution scope, and discharge obstruction. These retain P, scope the candidate frontier, and keep the refused confluence, typing, evaluator, quotient, and kernel endpoints outside the seed record. □

Theorem 4238.9 (MetaCIC parallel-diamond frontier route)**.** *Every confluence-audit consumer that reads an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose the residual-substitution premise row P, critical-pair row K, candidate-join row J, residual-frontier row R, closed-checker seal S, closed-normal fragment C, bounded-check row B, obstruction row O, transport row H, replay row T, provenance row G, and local name row N before using a conditional parallel-diamond handoff. The route does not turn the residual-substitution premise into a theorem, does not prove full Church–Rosser, and does not discharge subject reduction, evaluator equality, quotient term equality, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICParallelDiamondFrontierUp.MetacicParallelDiamondFrontierRoute`

Proof. Begin with the carrier of Definition 4238.1. It displays exactly the premise, peak, join, residual, checker, fragment, bounded-check, obstruction, transport, replay, provenance, and local naming rows.

The obligation theorem Definition 4238.2 keeps P, K, J, R, S, C, B, O as first-class rows. A confluence-audit consumer therefore cannot use the handoff before the missing residual-substitution premise and the obstruction boundary are visible.

The handoff theorem Definition 4238.3 supplies only a conditional frontier route. The added transport, replay, provenance, and local name rows preserve that boundary for downstream audit consumers.

Since no row discharges residual substitution or full closed confluence, the route is a sharper obligation boundary rather than a completed Church–Rosser certificate. □

Theorem 4238.10 (MetaCIC local-diamond frontier)**.** *Let*

$$F_0 = (P, K, J_0, R, S, C, B, O, H, T, G, N) \quad \textit{and} \quad F_1 = (P, K, J_1, R, S, C, B, O, H, T, G, N)$$

be accepted $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packets with the same residual-substitution premise row P and the same critical-pair row K. If the candidate-join rows J_0 and J_1 agree through the displayed residual-frontier row R, then every confluence-audit consumer reads the same conditional local-diamond handoff through S, C, B, O, H, T, G, N. The obstruction row O remains visible in the handoff, so the result does not discharge residual-substitution compatibility, subject reduction, full closed Church–Rosser, evaluator equality, quotient equality of terms, or kernel consistency.*

Proof. Project the two carriers through Definition 4238.1. The hypotheses identify the premise and peak rows P, K, and they make the two candidate-join rows agree at the residual-frontier row R.

Apply Definition 4238.2 to each packet. The only confluence-facing rows available to a consumer before replay are P, K, J, R, S, C, B, O, with the structural rows H, T, G, N attached to the same packet.

Now use Definition 4238.3 and Definition 4238.9. Since P, K agree and J_0, J_1 agree through R, both handoff readings reach the same closed-checker row S, closed-normal fragment row C, bounded-check row B, obstruction row O, transport row H, replay row T, provenance row G, and local name row N.

The obstruction row is not removed by this comparison. It is carried in both packets and remains part of the consumer-visible handoff, so the theorem records a local-diamond frontier fact rather than a proof of the missing residual-substitution or closed confluence endpoints. □

Theorem 4238.11 (MetaCIC parallel-diamond residual square)**.** *Every accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *carrier*

$$F = (P, K, J, R, S, C, B, O, H, T, G, N)$$

exposes a residual square only through the retained residual-substitution premise row P, the critical-pair row K, the candidate-join row J, the residual-frontier row R, the closed-checker seal S, the closed-normal fragment C, the bounded-check row B, the obstruction row O, and the transport, replay, provenance, and local naming rows H, T, G, N. Any consumer of the square must therefore factor through those rows before using a conditional local-diamond handoff. The square does not discharge residual substitution, subject reduction, full closed Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.

Proof. Project the carrier through Definition 4238.1. Its confluence-facing rows are exactly P, K, J, R, S, C, B, O, and its structural rows are exactly H, T, G, N.

Use critical-pair exhaustion, Definition 4238.4. It places the local peak data inside the displayed critical-pair row K and keeps the closed-checker and obstruction rows visible.

Apply the local-diamond frontier theorem Definition 4238.10. A conditional local-diamond read can compare candidate joins only through the residual-frontier row R, with S, C, B, O, H, T, G, N still present in the handoff.

Finally route the resulting read through Definition 4238.9. Since that route retains $P, K, J, R, S, C, B, O, H, T, G$ before any consumer sees the handoff, the residual square is a frontier obligation over the displayed rows rather than any of the refused residual-substitution, typing, confluence, equality, quotient, or kernel endpoints. □

Theorem 4238.12 (MetaCIC parallel-diamond residual-substitution scope)**.** *Every use of the* MetaCICParallelDiamondFrontier$^{\uparrow}$ *local-diamond frontier must pass through the residual-substitution boundary, the confluence critical-pair boundary, and the closed-normal fragment before it claims a local join. In carrier terms, a consumer must expose the residual-substitution premise row P, the critical-pair row K, the residual-frontier row R, the closed checker seal row S, and the closed-normal fragment row C before reading the candidate-join handoff. The resulting claim remains a local frontier claim; it does not close full Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.*

Proof. Apply the route theorem Definition 4238.9. It requires the residual-substitution premise row, the critical-pair row, the residual-frontier row, the closed-checker seal, and the closed-normal fragment to remain visible before the conditional handoff is consumed.

Then apply the local-diamond frontier theorem Definition 4238.10. The agreement of candidate-join rows is read only through the displayed residual-frontier row, and the obstruction row remains visible in the handoff.

The sibling boundaries named in the chapter introduction supply exactly the surrounding scope: the residual-substitution boundary names the missing compatibility premise, the confluence critical-pair boundary names the local peak surface, and the closed-normal fragment names the already available normal-source joins. Since none of these rows removes the obstruction row, the theorem records a residual-substitution-scoped local join rather than any stronger confluence endpoint. □

Lean4 ✓ BEDC.Derived.MetaCICParallelDiamondFrontierUp.MetacicParallelDiamondFrontierResidualSubstitutio

Theorem 4238.13 (MetaCIC parallel-diamond frontier premise retention)**.** *Any accepted* MetaCICParallelDiamond *packet whose local-diamond handoff is consumed retains the residual-substitution premise row P through the critical-pair row K, residual-frontier row R, closed-checker row S, and closed-normal row C. No consumer may reinterpret that handoff as residual-substitution compatibility, premise-free parallel diamond, full Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.*

Proof. Apply the obligations theorem Definition 4238.2. It makes P a first-class residual-substitution premise row and keeps K, R, S, C among the confluence-facing rows rather than structural metadata.

Next use the handoff and route theorems, Definition 4238.3 and Definition 4238.9. They require a consumer to expose the premise, critical-pair, residual-frontier, checker, and closed-normal rows before the conditional handoff is read.

Finally apply the residual-substitution scope theorem Definition 4238.12. Since the local-diamond frontier remains scoped by the residual-substitution boundary and the obstruction row is still visible, the retained handoff cannot be retyped as any of the refused confluence endpoints. □

Theorem 4238.14 (MetaCIC parallel-diamond closed-normal join socket)**.** *Any closed-normal join socket consumed by a MetaCIC confluence audit must expose the residual-substitution premise row P, critical-pair row K, candidate-join row J, residual-frontier row R, closed-checker seal S, closed-normal fragment C, bounded-check row B, obstruction row O, componentwise* hsame *support*

row H, displayed Cont *replay row T,* Pkg *provenance row G, and local* NameCert *row N before any local join is read. The socket retains the residual-substitution premise and obstruction boundary; it does not claim residual-substitution compatibility or full closed Church–Rosser.*

Proof. Start with the obligations and handoff theorems, Definition 4238.2 and Definition 4238.3. They list $P, K, J, R, S, C, B, O, H, T, G, N$ as the confluence-facing packet and require the handoff to stay inside those rows.

Use the route and local-diamond theorems, Definition 4238.9 and Definition 4238.10. These force any local join to pass through the critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal, bounded-check, obstruction, and structural rows before a confluence audit reads it.

Finally apply residual-substitution scope and premise retention, Definition 4238.12 and Definition 4238.13. The premise row P remains visible throughout the closed-normal socket, and O keeps the refused endpoints outside the handoff. □

Theorem 4238.15 (MetaCIC parallel-diamond frontier local-join ledger pullback)**.** *Let*

$$F = (P, K, J, R, S, C, B, O, H, T, G, N)$$

be an accepted MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet, and let*

$$L = (K, J, B, R, S, O, G_L, H_L, C_L, P_L, N_L)$$

be an accepted MetaCICLocalJoinLedger$^{\uparrow}$ *packet. Suppose the two packets share the same residual-substitution premise, critical-pair row, candidate-join row, bounded-check row, obstruction row, transport, replay, provenance, and local naming rows, with the frontier rows R, S, C preserving the same residual-substitution scope as the ledger rows R, S. Then every confluence-audit consumer reads the local join through the same residual-substitution-scoped route. The pullback keeps the obstruction row visible, and it does not claim full Church–Rosser, subject reduction, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Project the frontier carrier through Definition 4238.1. The accepted packet exposes $P, K, J, R, S, C, B, O, H$, with P and O retained as confluence-facing rows rather than external annotations.

Read the local-join ledger through chapter 4126. The shared rows identify the local peak, candidate join, bounded checker, residual frontier, substitution boundary, obstruction readback, transport, replay, provenance, and local naming surfaces.

Apply the frontier obligations and route theorems, Definition 4238.2 and Definition 4238.9. They force any confluence-audit consumer to expose the premise, critical-pair, candidate-join, residual-frontier, checker, bounded-check, obstruction, and structural rows before using a handoff.

Finally use premise retention, Definition 4238.13. Since the ledger rows are shared with the frontier rows and the obstruction row is preserved on both sides, the consumer-visible local join is read through the same residual-substitution-scoped route, not through an unconditional confluence endpoint. □

Theorem 4238.16 (MetaCIC parallel-diamond typed boundary)**.** *Any accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet whose conditional local-diamond handoff is read under a typed-window premise must retain the typed window, residual-substitution premise row P, critical-pair row K, candidate-join row J, residual-frontier row R, closed-checker row S, closed-normal row C, bounded-check row B, and obstruction row O before the handoff is consumed. The packet may not be cited as a premise-free parallel diamond, subject reduction, full Church–Rosser theorem, evaluator equality, quotient term equality, or kernel-consistency certificate.*

Proof. Apply the obligations theorem Definition 4238.2. It lists the premise, critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal, bounded-check, and obstruction rows as the confluence-facing surface of the accepted packet.

Use the route theorem Definition 4238.9. A typed-window consumer can read the conditional handoff only after those rows have been exposed together with transport, replay, provenance, and local naming.

Apply the residual-substitution scope theorem Definition 4238.12. The typed window is read through the same residual-substitution boundary, confluence critical-pair boundary, and closed-normal fragment that scope the local join.

Finally use premise retention, Definition 4238.13. The retained premise and obstruction rows prevent the handoff from being retyped as a premise-free diamond or any of the refused confluence, equality, or kernel endpoints. □

Theorem 4238.17 (MetaCIC parallel-diamond frontier typed-window handoff)**.** *Any typed-window consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must read the full route*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

before feeding candidate-normalization or confluence-audit consumers. In this route P remains the residual-substitution premise, O remains the obstruction row, and the handoff cannot be consumed as a premise-free parallel diamond, full Church–Rosser theorem, subject reduction, evaluator equality, quotient equality of terms, or kernel-consistency certificate.

Proof. Project the carrier of Definition 4238.1. The displayed packet contains the premise, critical-pair, candidate-join, residual-frontier, checker, fragment, bounded-check, obstruction, transport, replay, provenance, and local naming rows.

Apply the obligations theorem and the typed boundary theorem, Definition 4238.2 and Definition 4238.16. Together they force a typed-window consumer to expose P, K, J, R, S, C, B, O before any conditional handoff is read.

Use premise retention and discharge obstruction, Definition 4238.13 and Definition 4238.18. The residual-substitution premise row P is still a premise, and the obstruction row O still blocks discharge unless a separate compatibility certificate is supplied.

Finally route the exported handoff through the structural rows H, T, G, N. Candidate-normalization and confluence-audit consumers therefore receive exactly the retained typed-window spine, not a completed parallel-diamond, Church–Rosser, subject-reduction, evaluator-equality, quotient-equality, or kernel-consistency endpoint. □

Theorem 4238.18 (MetaCIC parallel-diamond frontier discharge obstruction)**.** *Any accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet consumed as a local-diamond handoff still exposes the residual-substitution premise row P and obstruction row O. Unless a separate* MetaCICResidualSubstitutionCompatib *certificate is supplied through chapter 4370, no consumer may read that handoff as a premise-free parallel diamond, full closed confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Project the carrier of Definition 4238.1. The rows P and O are displayed coordinates of the accepted packet, not annotations around the handoff.

Apply premise retention, Definition 4238.13. It keeps P visible through the critical-pair, residual-frontier, closed-checker, and closed-normal rows whenever the local-diamond handoff is consumed.

Now use the sibling route theorem Definition 4238.21. The exported contribution is exactly retained premise and obstruction data for confluence-facing siblings, so the handoff cannot be consumed as a premise-free diamond.

The only admissible discharge surface is the residual-substitution compatibility chapter named in the statement. Without that separate certificate, the obstruction row O continues to block full closed confluence, subject reduction, evaluator equality, quotient term equality, and kernel consistency. □

Theorem 4238.19 (MetaCIC parallel-diamond frontier compatibility discharge surface)**.** *For an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet, only a separate* MetaCICResidualSubstitutionCompatibility$^{\uparrow}$ *row may turn the retained P, O premise-obstruction surface into a discharged local diamond. Without that compatibility row, every confluence consumer retains the full conditional spine*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

and may read the packet only as a conditional parallel-diamond frontier, not as premise-free confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with the discharge obstruction theorem, Definition 4238.18. It identifies P as the retained residual-substitution premise and O as the obstruction row that remains visible unless the separate compatibility chapter supplies a certificate.

Next use premise retention, Definition 4238.13. The premise row is not confined to the statement of the theorem; it is transported through the critical-pair, residual-frontier, closed-checker, and closed-normal rows of the accepted carrier.

Finally apply the confluence handoff, Definition 4238.22. That handoff exports the complete route $P, K, J, R, S, C, B, O, H, T, G, N$ to confluence-facing consumers. Since no row in this packet is the separate MetaCICResidualSubstitutionCompatibility$^{\uparrow}$ certificate, the handoff remains conditional and the refused endpoints stay outside the frontier. □

Theorem 4238.20 (MetaCIC parallel-diamond closed-checker retention)**.** *Any accepted* MetaCICParallelDiamondFr *packet whose local-diamond handoff retains the residual-substitution premise row P must also retain the closed-checker seal row S and the closed-normal fragment row C before that handoff can be read. Thus the conditional handoff boundary is the joint row surface P, S, C together with the displayed critical-pair, residual-frontier, bounded-check, obstruction, transport, replay, provenance, and local naming rows. It is not a proof of residual substitution, subject reduction, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Apply the obligations theorem Definition 4238.2. It lists P, S, C as confluence-facing rows of the same accepted carrier, so the checker seal and closed-normal fragment are not optional metadata around the premise row.

Next apply the handoff and route theorems, Definition 4238.3 and Definition 4238.9. Both require the closed-checker seal and closed-normal fragment to be exposed before any conditional parallel-diamond handoff is consumed.

Finally use premise retention, Definition 4238.13. Since the retained premise row is read through K, R, S, C and the obstruction row remains visible, the closed-checker seal and closed-normal fragment remain part of the boundary rather than consequences of the handoff. The refused endpoints therefore stay outside the packet. □

Theorem 4238.21 (MetaCIC parallel-diamond frontier sibling route)**.** *Every accepted* MetaCICParallelDiamondFro *packet that exports its premise-retention handoff feeds two confluence-facing sibling routes: the*

candidate-normalization confluence handoff of chapter 5547 and the audit-packet boundary of chapter 735. The exported contribution is exactly the residual-substitution premise row P, the local critical-pair row K, the residual-frontier row R, and the obstruction row O retained by Definition 4238.13; it does not supply a premise-free diamond, a completed residual-substitution theorem, full closed confluence, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.

Proof. Apply Definition 4238.13. Any consumed local-diamond handoff keeps the residual-substitution premise row visible through the critical-pair, residual-frontier, closed-checker, and closed-normal rows.

The candidate-normalization confluence handoff can therefore read this packet only as retained frontier data: P names the missing residual-substitution input, K and R name the local peak and residual window, and O keeps the obstruction endpoints visible before candidate-normalization routes are consumed.

The confluence audit packet reads the same rows as an audit boundary. It can cite the retained premise and obstruction rows when it records a conditional local-diamond route, but it cannot erase them into a completed confluence theorem.

Thus the sibling lattice is substantive rather than bibliographic: the frontier supplies exactly the residual-substitution premise retention and local-diamond obstruction rows consumed by those confluence-facing packets, while the refused endpoints remain outside the carrier. □

Theorem 4238.22 (MetaCIC parallel-diamond confluence handoff)**.** *An accepted* MetaCICParallelDiamondFrontier *packet whose local-diamond, premise-retention, and residual-substitution rows have been displayed exports exactly the conditional confluence handoff consumed by chapter 5547 and bounded by chapter 5126. In carrier terms, the handoff is the retained route through $P, K, J, R, S, C, B, O, H, T, G, N$: P remains the residual-substitution premise, K, J, R expose the local-diamond and residual windows, S, C, B keep the closed checker and bounded fragment visible, and O records the still-open endpoints. The handoff does not claim global confluence, full strong normalization, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.*

Proof. Project the frontier carrier. The rows P, K, J, R, S, C, B, O are the confluence-facing data, while H, T, G, N transport, replay, source, and name the same packet.

Apply Definition 4238.13. The residual-substitution premise row P is retained through the local critical-pair and residual-frontier rows, so the exported route cannot be read as a premise-free diamond.

Next use Definition 4238.18. It keeps the obstruction row O visible unless a separate residual-substitution compatibility certificate is supplied, and therefore preserves the boundary checked by the parallel-diamond residual packet.

Finally apply the sibling route theorem. The candidate-normalization handoff receives only the closed checker boundary, local-diamond window, residual ledger, retained premise, and obstruction data displayed by this packet. Since no carrier row contains global confluence, full strong normalization, subject reduction, evaluator equality, quotient equality, or kernel consistency, none of those endpoints is exported by the handoff. □

Theorem 4238.23 (MetaCIC parallel-diamond premise preservation)**.** *Any confluence consumer that reads the conditional parallel-diamond handoff of Definition 4238.22 must retain the residual-substitution premise row P through the full packet spine*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

In particular, the handoff cannot erase P into a completed residual-substitution theorem, premise-free parallel diamond, full Church–Rosser theorem, subject-reduction theorem, evaluator equality, quotient equality of terms, or kernel-consistency certificate.

Proof. Start with Definition 4238.2. It makes the residual-substitution premise row P part of the local $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}}$ surface together with $K, J, R, S, C, B, O, H, T, G, N$.

Next apply premise retention, Definition 4238.13. The retained premise is still visible when the local-diamond handoff is consumed, and the discharge-obstruction theorem Definition 4238.18 keeps O displayed unless a separate compatibility certificate is supplied.

Finally use the confluence handoff theorem itself. Its exported route is exactly the conditional path through $P, K, J, R, S, C, B, O, H, T, G, N$, so any consumer that drops P or reads the route as one of the refused endpoints has left the packet described by the carrier. □

Theorem 4238.24 (MetaCIC parallel-diamond residual budget)**.** *Any exported* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *parallel-diamond budget that feeds candidate-normalization or audit-packet consumers must consume the retained residual-substitution premise row P, critical-pair row K, residual-frontier row R, closed-checker row S, closed-normal row C, obstruction row O, and structural rows H, T, G, N before the consumer receives the handoff. The budget cannot omit P or O, and it cannot be read as a premise-free parallel diamond, residual-substitution theorem, full Church–Rosser theorem, subject-reduction theorem, evaluator equality, quotient equality of terms, or kernel-consistency certificate.*

Proof. Start from the carrier obligations Definition 4238.2. They keep the residual-substitution premise, critical-pair, residual-frontier, closed-checker, closed-normal, obstruction, transport, replay, provenance, and naming rows inside the accepted packet.

Use the route and premise-retention theorems, Definition 4238.9 and Definition 4238.13. They require the premise row P to remain visible when a local-diamond handoff is consumed.

Next apply discharge obstruction and the sibling route, Definition 4238.18 and Definition 4238.21. The candidate-normalization and audit-packet consumers receive only the retained premise, critical-pair, residual-frontier, obstruction, and structural rows named by the frontier.

Finally use premise preservation Definition 4238.23. Since its full spine includes $P, K, J, R, S, C, B, O, H, T, G, N$ any exported budget that forgets P or O has left the displayed packet and cannot be consumed as a BEDC parallel-diamond frontier. □

Theorem 4238.25 (MetaCIC parallel-diamond frontier obstruction monotonicity)**.** *Let $F = (P, K, J, R, S, C, B, O, H, T, G, N)$ be an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet. Any refinement of F that preserves the displayed rows $P, K, J, R, S, C, B, O, H, T, G, N$ may strengthen the finite evidence attached to those rows, but it cannot weaken the obstruction row O or discharge the residual-substitution premise row P unless it also supplies a separate residual-substitution compatibility certificate. Consequently the refined packet remains a conditional frontier and cannot be consumed as full Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.*

Proof. Start with the obligation surface of Definition 4238.2. The premise row P and obstruction row O are carrier coordinates of the accepted packet, not side assumptions that a refinement may silently erase.

Apply premise retention and discharge obstruction, Definition 4238.13 and Definition 4238.18. They force the local-diamond handoff to keep P visible and keep O active unless a separate compatibility certificate supplies the missing residual-substitution discharge.

Finally use the residual budget theorem Definition 4238.24. A refinement that preserves $P, K, J, R, S, C, B, O, H, T, G, N$ preserves the same budget boundary, so it cannot convert retained obstruction data into a premise-free endpoint. The stronger claims listed in the statement therefore remain outside the packet. □

Theorem 4238.26 (MetaCIC parallel-diamond residual confluence)**.** *Every confluence consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must factor its exported result through the full residual spine*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The exported result is conditional residual confluence with the residual-substitution premise retained; it is not a premise-free parallel diamond, subject reduction theorem, evaluator equality, quotient term equality, closed Church–Rosser theorem, or kernel-consistency certificate.

Proof. Start with the obligation surface of Definition 4238.2. It makes $P, K, J, R, S, C, B, O, H, T, G, N$ the visible rows of any accepted frontier packet, with P retained as a residual-substitution premise.

Use the route theorem and premise retention, Definition 4238.9 and Definition 4238.13. Together they force confluence consumers to expose the premise, peak, join, residual, checker, fragment, bounded-check, obstruction, transport, replay, provenance, and local name rows before the handoff is consumed.

Apply discharge obstruction and the confluence handoff theorem, Definition 4238.18 and Definition 4238.22. These results keep the obstruction row visible and identify the exported route as the retained conditional handoff consumed by confluence-facing siblings.

Finally use the residual budget theorem Definition 4238.24. Since the budget cannot omit P or O, any exported confluence result remains conditional residual confluence over the displayed spine rather than one of the refused premise-free, typing, equality, quotient, Church–Rosser, or kernel endpoints. □

Theorem 4238.27 (MetaCIC residual-join readback)**.** *For an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *carrier* $F = (P, K, J, R, S, C, B, O, H, T, G, N)$*, every residual-join readback consumed by bounded conversion must display the closed substitution boundary rows, candidate-mediated strong-normalization rows, residual budget rows, typed-example boundary rows, and the four L10 source faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

before reading the handoff. In carrier terms, the readback must expose $P, K, J, R, S, C, B, O, H, T, G, N$ *together with the typed-window and L10 source rows, and it cannot be consumed as full confluence, global beta decidability, closed subject reduction, quotient term equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with residual confluence, Definition 4238.26. It forces a confluence consumer to keep the residual-substitution premise, local critical pair, candidate join, residual frontier, checker seal, closed-normal fragment, bounded-check row, obstruction row, and structural rows visible through the full spine $P, K, J, R, S, C, B, O, H, T, G, N$.

Next use the typed-window handoff of Definition 4238.17. A bounded-conversion consumer may read the frontier only after the typed window has retained the same residual spine for candidate-normalization and confluence-audit consumers.

Premise preservation, Definition 4238.23, keeps the residual-substitution row P from disappearing into a completed diamond. The local-diamond and critical-pair routes of Definition 4238.10

and Definition 4238.9 supply the candidate join and residual budget rows without discharging the obstruction row O.

The typed-example boundary and the four L10 source faces are then read as source rows, not as semantic quotients. They expose $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the bounded-conversion handoff is consumed, so selected limits and ambient real completeness are unavailable.

Combining these routes gives a finite residual-join readback frontier. Since every step retains the premise and obstruction rows, the result is not full confluence, global beta decidability, closed subject reduction, quotient term equality, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 4238.28 (MetaCIC critical-overlap residual budget)**.** *For an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *carrier* $F = (P, K, J, R, S, C, B, O, H, T, G, N)$*, every critical overlap between two local reductions is budgeted by the finite row surface*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The overlap budget must expose the residual-substitution premise row P*, the critical-pair row* K*, the candidate-join row* J*, the residual-frontier row* R*, the closed checker seal* S*, the closed-normal fragment* C*, the bounded-check row* B*, and the obstruction row* O *before any local join is read. It does not supply source-equivalence transport, abstract carrier equivalence, premise-free parallel diamond, subject reduction, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Start with the obligation surface of Definition 4238.2. It makes the premise, critical-pair, candidate-join, residual-frontier, checker, fragment, bounded-check, obstruction, transport, replay, provenance, and local naming rows the finite carrier of an accepted frontier packet.

Use the residual-substitution scope theorem Definition 4238.12. A local join may be read only after the residual-substitution boundary, critical-pair boundary, and closed-normal fragment have remained visible.

Now apply premise preservation and the residual budget theorem, Definition 4238.23 and Definition 4238.24. These keep P and O inside the exported budget and prevent a critical overlap from being consumed as a premise-free diamond.

Finally use residual confluence, Definition 4238.26. Since the confluence consumer factors through the same displayed spine, the critical-overlap budget is finite and row-local rather than a transport across source equivalence or abstract carrier equivalence. □

Theorem 4238.29 (MetaCIC candidate-mediated residual route)**.** *Let two local reductions be recorded by the critical-pair row* K *of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet* $F = (P, K, J, R, S, C, B, O, H, T, G, N)$*. If the candidate-join row* J *is accepted through the displayed residual-frontier row* R*, then both local reductions route to the shared residual packet*

$$J, R, S, C, B, O, H, T, G, N$$

under the retained premise P*. The route is candidate-mediated: it identifies the common residual packet available to the frontier consumer, but it does not discharge residual-substitution compatibility, source-equivalence transport, subject reduction, full closed Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Project the carrier in Definition 4238.1. The critical-pair row K records the two local reduction observations, and the candidate-join row J records the proposed common reduct together with branch-local route requests.

Apply the obligations theorem Definition 4238.2. It keeps J and R as displayed rows of the same packet, so the candidate route is not an external equivalence between carriers.

Use the residual-substitution scope theorem and premise preservation, Definition 4238.12 and Definition 4238.23. The two local reductions may reach the candidate only while P remains visible and while the residual-frontier row controls the branch windows.

Finally apply residual confluence and residual-join readback, Definition 4238.26 and Definition 4238.27. They identify the consumer-facing route as the shared residual packet through $J, R, S, C, B, O, H, T, G, N$, with the premise and obstruction still retained. □

Definition 4238.30 (MetaCIC parallel-diamond frontier finite budget)**.** *The finite budget for a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *read is the row surface*

$$\mathcal{B}_{\text{frontier}} = (W, K, P, J, R, S, C, B, O, H, T, G, N).$$

Here W is the typed-window row, K is the critical-pair row, P is the residual-substitution boundary, J is the local-join row, R is the residual-frontier row, S is the closed-checker seal, C is the closed-normal fragment, B is the bounded-checker row, O is the obstruction row, H is componentwise hsame *transport, T is displayed* Cont *replay, G is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}}$ *row. The budget has no coordinate for premise-free confluence, subject reduction, evaluator equality, quotient term equality, global normalization, or kernel consistency.*

Theorem 4238.31 (MetaCIC typed-window local-join scope)**.** *Under a typed MetaCIC window, an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet permits only local joins whose two branches pass through the retained residual-substitution premise P, critical-pair row K, candidate-join row J, residual-frontier row R, closed checker seal S, closed-normal fragment C, and bounded-check row B. The local join scope is therefore the typed-window row surface*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

with O still visible. It is not a source-equivalence transport theorem, an abstract carrier-equivalence theorem, a premise-free parallel diamond, subject reduction, global beta decidability, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with the typed boundary and typed-window handoff, Definition 4238.16 and Definition 4238.17. They force a typed-window consumer to expose the same residual spine before candidate-normalization or confluence-audit consumers can read a handoff.

Use the critical-overlap budget of Definition 4238.28. It keeps every local overlap inside $P, K, J, R, S, C, B, O, H, T, G, N$ and blocks readings that omit the premise or obstruction rows.

Next apply the candidate-mediated route Definition 4238.29. The two branches can meet only through the displayed candidate row and residual-frontier row, not through an ambient source-equivalence or carrier-equivalence transport.

Finally use residual-join readback, Definition 4238.27. The readback keeps bounded conversion, typed windows, and the L10 source faces visible before the handoff, so the permitted local join remains a scoped MetaCIC window claim rather than any stronger confluence, typing, equality, quotient, or kernel endpoint. □

Theorem 4238.32 (MetaCIC parallel-diamond frontier local join budget)**.** *Any local join read accepted by a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet consumes the finite budget of Definition 4238.30*

before it can reach a normalization-facing consumer. In particular, the typed-window row, critical-pair row, residual-substitution boundary, local-join row, residual-frontier row, closed-checker seal, bounded-checker row, obstruction row, transport, replay, provenance, and local naming remain visible at the handoff.

Proof. Start with the typed-window local-join scope of Definition 4238.31. It forces any accepted local join to expose the residual-substitution premise, critical pair, candidate join, residual-frontier row, checker rows, and obstruction row.

Apply the finite budget definition Definition 4238.30. The typed-window row and structural rows H, T, G, N are part of the same budget surface, so the local join cannot be consumed as a free-standing confluence fact.

Use the residual budget theorem Definition 4238.24. It keeps the obstruction and residual-substitution rows visible before normalization consumers read the packet. Therefore the handoff remains a finite typed-window claim and does not become premise-free normalization or global confluence. □

Theorem 4238.33 (MetaCIC parallel-diamond frontier residual boundary)**.** *Residual-substitution compatibility remains a visible boundary in every accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *local-join read. The row P of Definition 4238.30 is consumed before J, R, S, C, B can be used, and it is not erased into an unconditional confluence theorem, subject-reduction theorem, evaluator equality, quotient term equality, global normalization statement, or kernel-consistency certificate.*

Proof. Project the budget surface of Definition 4238.30. The residual-substitution boundary P is an explicit coordinate, not a proof obligation hidden behind the local-join row.

Apply premise preservation and the residual-substitution scope theorem, Definition 4238.23 and Definition 4238.12. These keep P visible whenever the critical-pair, residual-frontier, checker, and bounded-check rows are read.

Finally use the local join budget theorem Definition 4238.32. Since every normalization-facing read consumes the full finite budget first, no consumer can erase the residual boundary and present the packet as an unconditional confluence or kernel result. □

Theorem 4238.34 (MetaCIC parallel-diamond frontier obligation basis)**.** *Every accepted* MetaCICParallelDiamondF *packet presents a finite obligation basis for the typed-window frontier. The basis is the row surface*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

where P is the residual-substitution boundary, K is the critical-pair envelope, J is the local-join row, R is the residual-frontier row, S is the closed checker seal, C is the closed-normal fragment, B is the bounded-check row, O is the obstruction row, H is hsame *transport, T is* Cont *replay, G is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}}$ *row. Any confluence consumer must read this basis before it may cite the typed-window local join, and the basis does not discharge residual substitution, subject reduction, full closed Church–Rosser, evaluator equality, quotient equality of terms, or kernel consistency.*

Proof. Start with the residual budget theorem Definition 4238.24. It keeps the retained premise, critical-pair row, residual-frontier row, closed-checker row, closed-normal row, obstruction row, and structural rows visible before any exported budget is consumed.

Apply residual confluence and residual-join readback, Definition 4238.26 and Definition 4238.27. These route confluence-facing reads through the same residual spine and require bounded-conversion readback to keep the typed-window and L10 source rows visible.

Use the critical-overlap budget and candidate-mediated residual route, Definition 4238.28 and Definition 4238.29. The local peak may reach a candidate only through the displayed K, J, R rows, with P and O retained.

Finally apply the typed-window local-join scope theorem Definition 4238.31. It identifies the permitted local join as exactly the typed-window row surface, so the listed rows form the finite obligation basis and no stronger confluence endpoint is exported. □

Theorem 4238.35 (MetaCIC parallel-diamond frontier seed status)**.** *Every conditional parallel-diamond handoff consumed through an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must first expose the residual-substitution premise row P, critical-pair row K, candidate-join row J, residual-frontier row R, checker row S, bounded-check row B, obstruction row O, componentwise* hsame *transport row H, displayed* Cont *replay row T,* Pkg *provenance row G, and local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}}$ *row N. The consumed handoff is therefore a seed-status frontier: it records which residual premises and finite checks remain visible before use, and it is not a parameter-transport equivalence, source-equivalence theorem, full Church–Rosser theorem, subject-reduction theorem, evaluator equality, quotient equality of terms, or kernel-consistency certificate.*

Proof. Begin with the obligations theorem Definition 4238.2. It makes the residual-substitution premise, critical-pair, candidate-join, residual-frontier, checker, bounded-check, obstruction, transport, replay, provenance, and naming rows part of the finite carrier surface.

Apply the obligation-basis theorem Definition 4238.34. It packages those rows as the typed-window basis that a confluence consumer must read before citing a local join.

The residual-frontier and obstruction rows stay visible throughout the handoff. Consequently the theorem records seed status for the remaining residual-discharge work rather than converting the packet into a parameter-transport equivalence or any stronger confluence endpoint. □

Theorem 4238.36 (MetaCIC parallel-diamond residual obstruction ledger)**.** *Every candidate-mediated local join read from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must keep the residual-substitution premise row P, residual-frontier row R, and obstruction row O visible alongside*

$$K, J, S, C, B, H, T, G, N$$

before any confluence-facing packet consumes the read. The retained ledger is therefore

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

It is not a premise-free parallel diamond, full Church–Rosser theorem, subject-reduction theorem, evaluator equality, quotient equality of terms, or kernel-consistency certificate.

Proof. Begin with the obligation basis Definition 4238.34. It fixes the consumer-visible packet as $P, K, J, R, S, C, B, O, H, T, G, N$ and makes the obstruction row an explicit coordinate of the finite basis.

Apply the candidate-mediated residual route Definition 4238.29. A local peak may reach the candidate row J only through the displayed critical-pair and residual-frontier route, while P remains the retained residual-substitution premise.

Finally use the local-join scope theorem Definition 4238.31. It allows confluence-facing consumers to read only the typed-window surface with O still visible, so the obstruction ledger cannot be erased before the handoff is consumed.

Thus every candidate-mediated join read carries P, R, O together with $K, J, S, C, B, H, T, G, N$. Since neither the premise nor the obstruction is discharged, the statement exports only a residual

obstruction ledger and not any refused confluence, typing, equality, quotient, or kernel endpoint. □

Theorem 4238.37 (MetaCIC residual pasting frontier)**.** *Suppose an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet has two typed-window residual reads whose critical-pair observations share the same* $P, K, R, S, C, B, O, H, T,$ *rows and whose candidate row is* J*. Then the two reads paste only through the displayed residual packet*

$$J, R, S, C, B, O, H, T, G, N$$

under the retained premise P*. The pasted read is a finite* NameCert *route with* hsame *transport,* Cont *replay, and* Pkg *provenance; it is not a source-equivalence transport theorem, abstract carrier equivalence, premise-free parallel diamond, subject-reduction theorem, evaluator equality, quotient equality of terms, or kernel-consistency certificate.*

Proof. Begin with Definition 4238.34. It fixes the consumer-visible basis as $P, K, J, R, S, C, B, O, H, T, G, N$ and keeps the obstruction row visible.

Use candidate-mediated residual routing, Definition 4238.29. The two local reductions may meet only at the displayed candidate row J and residual-frontier row R, while the residual-substitution premise P remains retained.

Apply residual confluence and residual-join readback. These theorems keep the closed checker, closed-normal fragment, bounded-check row, obstruction, transport, replay, provenance, and local naming attached to the same packet before any bounded-conversion consumer can read the handoff.

The pasted route is therefore the shared residual packet $J, R, S, C, B, O, H, T, G, N$ under P. Since the construction never introduces a source-equivalence carrier or removes O, the conclusion is a finite frontier pasting claim and not any refused confluence, typing, equality, quotient, or kernel endpoint. □

Theorem 4238.38 (MetaCIC substitution nonescape frontier)**.** *In every accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet, substitution data remains confined to the residual-substitution boundary row* P *and the residual-frontier row* R *throughout the typed-window local join. No* hsame *transport row,* Cont *replay row,* Pkg *provenance row, or local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}}$ *row may reinterpret the handoff as a discharged residual-substitution theorem, premise-free parallel diamond, subject reduction, full closed Church–Rosser, evaluator equality, quotient equality of terms, or kernel consistency.*

Proof. Start from the obligation basis Definition 4238.34. It makes P and R explicit coordinates of the finite packet rather than implicit assumptions around the local join.

Apply the residual-substitution scope theorem and premise preservation, Definition 4238.12 and Definition 4238.23. They keep the substitution premise visible through the critical-pair, residual-frontier, closed-checker, and closed-normal rows.

Use residual pasting, Definition 4238.37. Even when two typed-window residual reads are pasted through the candidate row, the pasted route still runs under P and through R.

Finally read the structural rows H, T, G, N. They transport, replay, source, and name the displayed packet, but they do not contain a carrier slot for discharging substitution or erasing the obstruction row. Thus substitution cannot escape the displayed residual boundary into any stronger confluence endpoint. □

Theorem 4238.39 (MetaCIC parallel-diamond residual-substitution route)**.** *Every candidate-mediated local join read from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *carrier* $F = (P, K, J, R, S, C, B, O, H, T,$ *must expose the residual-substitution premise row* P*, critical-pair row* K*, candidate-join row* J*,*

residual-frontier row R, closed-checker seal row S, closed-normal fragment row C, bounded-check row B, obstruction row O, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming before any parallel-diamond frontier handoff is consumed. The route is conditional on the displayed premise and cannot be read as residual-substitution compatibility, full Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.*

Proof. Project the carrier of Definition 4238.1. The rows $P, K, J, R, S, C, B, O, H, T, G, N$ are the full consumer-visible packet, with P retaining the residual-substitution premise and O retaining the refused endpoints.

Apply the candidate-mediated residual route of Definition 4238.29. It allows the two local reductions named by K to meet only through the displayed candidate row J and residual-frontier row R, under the retained premise P.

Next use substitution nonescape, Definition 4238.38. The closed checker row, closed-normal row, bounded-check row, transport, replay, provenance, and local naming cannot discharge substitution or remove the obstruction row.

Thus the route exposes exactly the residual-substitution premise, critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal, bounded-check, obstruction, and structural rows stated above. Since neither P nor O disappears, the handoff remains a conditional frontier and not any refused confluence, typing, equality, quotient, or kernel endpoint. □

Theorem 4238.40 (MetaCIC parallel-diamond normalization-frontier handoff)**.** *Any normalization consumer that reads the* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet may use only the conditional frontier exposed by Definition 4238.39. It may inspect the retained residual-substitution premise, critical-pair row, candidate-join row, residual-frontier row, closed-checker row, closed-normal fragment row, bounded-check row, obstruction row, transport, replay, provenance, and local naming. It may not consume the packet as full Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, kernel consistency, or a completed residual-substitution theorem.*

Proof. Begin with the residual-substitution route theorem. It fixes the normalization-facing read to the displayed finite spine $P, K, J, R, S, C, B, O, H, T, G, N$ and keeps the obstruction row visible.

Use the typed-window local-join scope of Definition 4238.31. A normalization consumer may read local joins only under that typed-window surface, so it cannot erase the residual-frontier or closed-checker conditions.

Apply residual pasting and substitution nonescape, Definition 4238.37 and Definition 4238.38. These theorems keep pasted residual reads under P and prevent structural rows from retyping the handoff as a discharged substitution result.

Consequently the normalization consumer receives only the conditional frontier. The listed stronger endpoints require separate certificates and are not carried by the accepted MetaCICParallelDiamondFrontier$^{\uparrow}$ packet. □

Theorem 4238.41 (MetaCIC parallel-diamond candidate-mediated strong-normalization socket)**.** *For every accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *carrier $F = (P, K, J, R, S, C, B, O, H, T, G, N)$, suppose the closed checker row S accepts both residual branches named by the local critical-pair row K, the candidate-normalization scope row J retains the residual-substitution premise row P, and the local join ledger read through R, C, B, H, T, G, N is available. Then the packet exposes a candidate-mediated strong-normalization socket for that local pair: its readback is the conditional route $P, K, J, R, S, C, B, O, H, T, G, N$ consumed by Definition 4238.40. The socket does not assert*

global strong normalization, full confluence, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.

Proof. Start from the critical-pair envelope of Definition 4238.4. It fixes the two residual branches inside the displayed local pair row K and keeps them tied to the closed checker row S.

Use the residual-substitution dependency route of Definition 4238.12. The premise row P remains an explicit coordinate of the candidate-normalization scope instead of becoming a discharged theorem.

Next apply the closed-normal join socket and local join ledger pullback, Definition 4238.14 and Definition 4238.31. These results route the accepted branches through J, R, C, B while preserving H, T, G, N as transport, replay, provenance, and naming rows.

Finally hand the same finite readback to Definition 4238.40. Since P and O remain visible, the socket is only the candidate-mediated local normalization route promised in the statement, not any global normalization or confluence endpoint. □

Theorem 4238.42 (MetaCIC parallel-diamond frontier typed-window candidate SN route)**.** *Every strong-normalization-facing read of the candidate-mediated socket in an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *carrier* $F = (P, K, J, R, S, C, B, O, H, T, G, N)$ *must pass through the typed-window handoff, residual-substitution scope, premise preservation, local-join scope, and the candidate-mediated strong-normalization socket before it reaches the normalization-frontier handoff. The resulting route is the finite readback*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

with the typed window still visible. It does not assert global strong normalization, full confluence, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.

Proof. Start with the typed-window handoff of Definition 4238.17. It forces every candidate-normalization consumer to expose the same residual spine before any frontier handoff is read.

Next apply residual-substitution scope and premise preservation, Definition 4238.12 and Definition 4238.23. These keep P attached to the critical-pair, residual-frontier, closed-checker, and closed-normal rows rather than turning it into a discharged substitution theorem.

Use the typed-window local-join scope of Definition 4238.31. A candidate join can be consumed only through the displayed K, J, R, S, C, B rows, with the obstruction row O still retained.

Finally apply the candidate-mediated strong-normalization socket and normalization-frontier handoff, Definition 4238.41 and Definition 4238.40. They pass the same finite readback forward as a conditional socket, so the route cannot be retyped as any of the refused normalization, confluence, typing, equality, quotient, or kernel endpoints. □

Theorem 4238.43 (MetaCIC parallel-diamond closed-substitution window scope)**.** *Every candidate-mediated diamond read of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *carrier* $F = (P, K, J, R, S, C, B, O, H, T, G,$ *that exposes the rows* $P, K, J, R, S, C, B, O, H, T, G, N$ *must keep the closed-substitution window visible before the closed checker seal and normalization-confluence handoff are consumed. The read therefore remains a finite frontier route through the displayed residual-substitution premise, typed candidate window, closed checker, local join ledger, obstruction row, transport, replay, provenance, and local naming rows. It cannot be reread as premise-free subject reduction or as closed Church–Rosser.*

Proof. Project the carrier and begin with the premise-retention route of Definition 4238.23. The residual-substitution premise row P remains visible whenever the candidate rows K, J, R, S, C, B, O are exposed.

Apply the typed-window candidate SN route of Definition 4238.42. It sends every strong-normalization-facing read through the typed window and candidate-mediated socket before the normalization-frontier handoff is available.

Finally use the critical-path retained-premise handoff of Definition 4238.85. The structural rows H, T, G, N transport, replay, source, and name the same retained-premise packet, so the closed checker seal and normalization-confluence handoff cannot erase the closed-substitution window. Hence the route is not a premise-free subject-reduction theorem and not closed Church–Rosser. □

Theorem 4238.44 (MetaCIC parallel-diamond finite candidate SN extension)**.** *Let $F = (P, K, J, R, S, C, B, O, H,$ be an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *carrier. If a finite local peak is routed through the displayed candidate row J, residual row R, typed window S, and boundary rows C, B, O, then the only strong-normalization-facing read is the candidate-mediated socket already named by Definition 4238.41. The route cannot be retyped as global strong normalization, full confluence, quotient equality of terms, or a kernel endpoint.*

Proof. Apply the candidate-mediated residual route Definition 4238.29. It sends the finite local peak through the displayed candidate row J and residual row R while retaining the residual-substitution premise row P.

Use the local-join scope Definition 4238.31. The local join is visible only through the typed-window and boundary rows S, C, B, O, so no ambient confluence carrier is introduced.

Next apply the normalization-frontier handoff Definition 4238.40. It restricts normalization consumers to the conditional frontier packet and keeps the refused endpoints outside the carrier.

Finally use the candidate-mediated strong-normalization socket and typed-window candidate SN route, Definition 4238.41 and Definition 4238.42. These results identify the only SN-facing read as the finite candidate-mediated socket through $P, K, J, R, S, C, B, O, H, T, G, N$, so it cannot be reread as global strong normalization, full confluence, quotient equality, or a kernel endpoint. □

Theorem 4238.45 (MetaCIC parallel-diamond frontier seed closure status)**.** *The seed closure surface of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet is exactly the finite conjunction of residual-substitution premise retention, critical-pair envelope exposure, closed-checker retention, closed-normal join socket, candidate-mediated strong-normalization socket, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The seed surface does not discharge residual-substitution compatibility, premise-free parallel diamond, subject reduction, full closed Church–Rosser, evaluator equality, quotient equality of terms, or kernel consistency.*

Proof. Start with residual-substitution scope and premise preservation, Definition 4238.12 and Definition 4238.23. They keep the row P visible through every local-diamond read.

Use the critical-pair envelope and closed-checker retention, Definition 4238.4 and Definition 4238.20. These identify the rows K, S, C, B, O as part of the finite frontier instead of consequences of a discharged confluence theorem.

Apply the local-join and normalization handoff theorems, Definition 4238.31 and Definition 4238.40. Together with the candidate-mediated strong-normalization socket Definition 4238.41, they show that the only normalization-facing read is the conditional route through P, K, J, R, S, C, B, O.

Finally read the structural rows H, T, G, N. They transport, replay, source, and name the same finite packet, so the seed closure surface is exactly the listed conjunction and none of the refused endpoints is exported. □

Theorem 4238.46 (MetaCIC parallel-diamond residual-join induction)**.** *Let $F = (P, K, J, R, S, C, B, O, H, T, G, N$ be an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *carrier. Finite iteration over a displayed list of*

residual pairs preserves the local-diamond route through the critical-pair row K, residual-substitution premise row P, candidate-normalization row J, closed-checker row S, bounded-check row B, obstruction row O, transport row H, replay row T, provenance row G, and local naming row N. The iterated route remains candidate-mediated and exports no premise-free parallel diamond, subject reduction, full closed Church–Rosser theorem, evaluator equality, quotient equality of terms, or kernel consistency endpoint.

Proof. Induct on the finite residual-pair list. The base case is Definition 4238.45: seed readiness already exposes residual-substitution premise retention, critical-pair rows, candidate joins, closed checker rows, bounded checks, obstruction retention, and the structural rows.

For the step, append one displayed residual pair. The residual-substitution dependency route of Definition 4238.12 keeps P visible, while candidate-normalization scope and finite residual witness consumption keep the new pair inside K, J, R, S, C, B, O before any normalization-facing handoff is read.

Finally apply the critical-path consumer route of Definition 4238.85. It passes the extended finite readback through H, T, G, N without changing the refused endpoints, so the induction preserves the local-diamond route claimed above. □

Theorem 4238.47 (MetaCIC parallel-diamond public export)**.** *For an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *carrier $F = (P, K, J, R, S, C, B, O, H, T, G, N)$, the public confluence-facing export is exactly the route through residual-substitution premise P, critical-pair row K, candidate-join row J, residual-frontier row R, closed-checker row S, closed-normal fragment row C, bounded-check row B, obstruction row O, and structural rows H, T, G, N. The export may feed MetaCIC critical-path and confluence-audit consumers, but it does not prove full Church–Rosser, subject reduction, evaluator equality, quotient equality, or kernel consistency.*

Proof. Begin with the obligation surface of Definition 4238.2. It admits the carrier only through the displayed rows $P, K, J, R, S, C, B, O, H, T, G, N$.

Use critical-pair exhaustion, obstruction retention, and local-join scope: Definition 4238.4, Definition 4238.5, and Definition 4238.31. These keep the critical pair, candidate join, residual frontier, bounded check, and obstruction rows visible before any confluence-facing read.

Next apply the normalization handoff and candidate-mediated socket, Definition 4238.40 and Definition 4238.41. They route normalization-facing consumers through the same finite packet without exporting global normalization or confluence.

Finally invoke residual-join induction, Definition 4238.46. The structural rows H, T, G, N transport, replay, source, and name the same packet, so the public export is the listed route and none of the refused endpoints follows. □

The Lean follow-up supplies Nontrivial and FieldFaithful TasteGate instances in `lean4/BEDC/Derived/MetaCICP` by exhibiting distinct accepted and refused frontier packets and by matching on the rows $P, K, J, R, S, C, B, O, H, T,$

Theorem 4238.48 (MetaCIC parallel-diamond scoped closure status)**.** *The seed-readiness surface, retained-premise handoff, obstruction row, residual-substitution premise, critical-path consumer route, and normalization-confluence handoff of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet together scope the chapter to finite candidate-mediated local-diamond evidence. The scoped surface is exactly the displayed route through $P, K, J, R, S, C, B, O, H, T, G, N$ and does not assert subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, residual-substitution discharge, or kernel consistency.*

Proof. Read the seed surface through Definition 4238.83 and Definition 4238.45. These results expose the carrier rows and keep the finite local-diamond evidence inside the displayed packet.

Apply the retained-premise handoff and residual-substitution scope, Definition 4238.85 and Definition 4238.12. They keep the premise row P visible for every critical-path read instead of discharging it as a substitution theorem.

Finally use the obstruction, public export, and normalization-frontier handoff rows of Definition 4238.5, Definition 4238.47, and Definition 4238.40. The resulting scope is finite, candidate-mediated, and local to $P, K, J, R, S, C, B, O, H, T, G, N$, so none of the refused global endpoints is exported. □

Theorem 4238.49 (MetaCIC parallel diamond critical-pair envelope)**.** *Every accepted* MetaCICParallelDiamondFro *packet exposes a critical-pair envelope only after reading a residual substitution row, a local confluence overlap row, a closed-term substitution row, and a binder-budget row. In carrier terms, the envelope is the finite BEDC route through*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

with the residual-substitution and confluence audit-map rows still visible. The conclusion is a concrete frontier envelope for bounded MetaCIC confluence audit; it is not a general strong-normalization theorem, unrestricted confluence theorem, unrestricted beta-reduction theorem, or host equality principle.

Proof. Project the accepted frontier carrier. The residual-substitution premise row P, critical-pair row K, candidate-join row J, residual-frontier row R, closed-checker row S, closed-normal fragment row C, bounded-check row B, obstruction row O, and structural rows H, T, G, N are the only rows exposed by the packet.

Read the residual-substitution route first. The row P supplies the retained premise, while the residual-frontier row R records branch-local substitution windows and binder exposure; neither row discharges compatibility.

Next read the confluence audit-map route. The critical-pair and candidate-join rows K, J supply local overlap data, while S, C, B keep the closed-term substitution and bounded checker information attached to the same finite packet.

The obstruction and structural rows close the envelope. Since O, H, T, G, N preserve the retained premise, bounded replay, provenance, and local name, the packet cannot escape to unrestricted beta reduction, host equality, strong normalization, or a general confluence theorem. □

Theorem 4238.50 (MetaCIC parallel diamond frontier critical-pair envelope)**.** *Every accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet exposes critical-pair requests only through the finite frontier route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The candidate term rows K, J, residual-substitution rows P, R, finite observation confluence rows S, C, B, normalization-frontier row O, componentwise hsame *transport H,* Cont *replay T,* Pkg *provenance G, and local* NameCert *row N remain displayed before any consumer can read a parallel-diamond request. The route does not assert unrestricted confluence, host reduction equality, unbounded critical-pair search, or a global normalization theorem.*

Proof. Project the carrier and the existing critical-pair envelope. The projection exposes $P, K, J, R, S, C, B, O, H, T$ as the only rows available to a frontier request.

Read the candidate and residual rows first. The candidate term rows K, J store the finite overlap and join candidates, while P, R keep substitution and residual windows attached to the same bounded branch data.

Next read the finite observation confluence rows S, C, B and the normalization-frontier row O. These rows certify only the displayed closed-term checks, bounded normal fragments, checker budget, and obstruction boundary.

Finally replay through H, T, G, N. Since transport, replay, provenance, and local naming preserve the same finite packet, the accepted critical-pair request cannot be replaced by unrestricted confluence, host reduction equality, unbounded search, or global normalization. □

Lean4 ✓ BEDC.Derived.MetaCICParallelDiamondFrontierUp.MetacicParallelDiamondFrontierCriticalPairEnvelop

Theorem 4238.51 (MetaCIC parallel diamond frontier visible overlap)**.** *Every accepted* MetaCICParallelDiamondFr *packet exposes local overlap only through*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

Any consumer that reads the candidate join J must first keep the residual-substitution premise row P, the critical-pair row K, the residual-frontier row R, and the bounded checker rows S, C, B visible. The read is therefore a bounded overlap frontier, not subject reduction, full Church–Rosser, unrestricted confluence, host reduction equality, or kernel consistency.

Proof. Start with the critical-pair envelope theorem Definition 4238.49. It exposes the same finite route $P, K, J, R, S, C, B, O, H, T, G, N$ and keeps the residual-substitution and confluence audit-map rows visible.

Apply the frontier envelope theorem Definition 4238.50. It orders critical-pair requests so that K, J are read with P, R, S, C, B, O still attached.

Finally use the route theorem Definition 4238.9. Replay, provenance, transport, and local naming through H, T, G, N preserve the visible premise and bounded checker rows before the candidate join can be consumed. Since the route theorem does not discharge residual substitution or subject reduction, the visible-overlap read remains a frontier certificate rather than a completed confluence result. □

Theorem 4238.52 (MetaCIC parallel-diamond critical-pair join envelope)**.** *Every candidate-mediated strong-normalization or confluence consumer of an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must first display the critical-pair envelope, residual-substitution dependency route, residual-join locality surface, finite residual witness row, and obstruction row for the same finite carrier*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The consumer may read the candidate join only as this bounded envelope. It does not discharge residual substitution, prove subject reduction, identify evaluator equality, identify quotient term equality, prove global confluence, or assert kernel consistency.

Proof. Project the accepted frontier carrier. The displayed rows are the retained residual-substitution premise P, critical-pair row K, candidate join J, residual frontier R, closed-checker row S, closed-normal fragment C, bounded checker B, obstruction row O, and structural rows H, T, G, N.

Read the envelope rows in order. The critical-pair envelope keeps the bounded overlap data visible, while the residual-substitution dependency route places P before any join handoff.

Now attach the local join and witness rows. Residual-join locality keeps J inside the same frontier packet, and the finite residual witness row forces the typed windows, residual data, bounded checker rows, transport, replay, provenance, and local naming to remain visible.

Finally retain the obstruction row. Since O, H, T, G, N preserve only the bounded carrier-local packet, a candidate-mediated consumer receives an envelope rather than residual-substitution discharge, subject reduction, evaluator equality, quotient term equality, global confluence, or kernel consistency. □

Theorem 4238.53 (MetaCIC parallel-diamond frontier critical-pair route)**.** *Every critical-pair read of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *carrier exposes candidate membership, bounded local peak rows, residual envelope rows, retained premise rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *before any join row is consumed. For a carrier*

$$F = (P, K, J, R, S, C, B, O, H, T, G, N),$$

the read must display the retained premise P, local peak row K, residual envelope R, bounded checker rows S, C, B, obstruction row O, and structural rows H, T, G, N before the candidate-join row J can serve a confluence consumer.

Proof. Project the carrier of Definition 4238.1. The only rows available to a critical-pair consumer are $P, K, J, R, S, C, B, O, H, T, G, N$, with P retaining the premise and K, R, S, C, B, O displaying the local peak, residual, checker, and obstruction envelope.

Apply critical-pair exhaustion and residual-substitution scope, Definition 4238.4 and Definition 4238.12. They force the local peak through K under the retained premise P and keep the residual frontier R visible before the candidate join is read.

Finally use the critical-path retained-premise handoff and seed closure status, Definition 4238.85 and Definition 4238.45. These routes pass the same critical-pair read through H, T, G, N without consuming J as a detached join or erasing the obstruction row. □

Theorem 4238.54 (MetaCIC parallel-diamond frontier residual-join nonescape)**.** *Every residual-join read exported by an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *carrier is a candidate-mediated local join through $P, K, J, R, S, C, B, O, H, T, G, N$. The frontier cannot be consumed as full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, closed consistency, or a discharged residual-substitution theorem.*

Proof. Start from the residual-join induction and public export theorems, Definition 4238.46 and Definition 4238.47. They keep finite residual joins inside the displayed route through the retained premise, critical-pair, candidate, residual, checker, obstruction, transport, replay, provenance, and naming rows.

Use local-join scope and the retained-premise handoff, Definition 4238.31 and Definition 4238.85. A join can be read only through the candidate row J under the same premise P and residual envelope R; it is not a premise-free confluence endpoint.

The refused endpoints remain outside the carrier. Since O is still visible and no row supplies subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, closed consistency, or residual-substitution discharge, the exported join remains candidate-mediated and local. □

Theorem 4238.55 (MetaCIC parallel-diamond critical-path consumer route)**.** *Every critical-path consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose the residual-substitution premise row P, critical-pair row K, candidate-join row J, closed-checker row S, closed-normal row C, bounded-check row B, and obstruction row O before any local confluence handoff*

is public. The required consumers are the critical-path packet of chapter 765, the confluence audit packet of chapter 735, and the normalization-confluence bridge of chapter 1190.

Proof. Project the carrier of Definition 4238.1. Its confluence-facing coordinates include P, K, J, S, C, B, O, so none of the three consumer chapters can read the frontier through a smaller public row set.

The $\mathsf{MetaCICCriticalPath}^{\uparrow}$ consumer receives the residual-substitution premise, critical-pair, and obstruction rows as route pressure rather than as a discharged local-confluence theorem. The $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ consumer receives the candidate-join, closed-checker, and bounded-check rows as audit data before it may inspect the local handoff. The MetaCICNormalizationConfluenceBrid consumer receives the closed-normal row and the same obstruction boundary as bridge-facing evidence.

Thus the critical-path, confluence-audit, and normalization-confluence consumers share the full retained frontier. A local confluence handoff is public only after those rows have been displayed, and the route still does not assert residual-substitution compatibility, subject reduction, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.56 (MetaCIC critical-path bridge frontier)**.** *Every accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet that is consumed by a MetaCIC critical-path reader must keep its residual diamond rows as concrete candidate and discharge data for* $\mathsf{MetaCICCriticalPath}^{\uparrow}$*,* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$*, and* $\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}$*. In carrier terms, the rows* $P, K, J, R, S, C, B, O, H, T, G, N$ *may be routed into the critical-path, confluence-audit, and normalization-confluence bridge surfaces only as retained frontier evidence; they do not form a standalone confluence oracle, subject-reduction theorem, evaluator equality row, quotient equality row, or kernel-consistency certificate.*

Proof. Project the frontier carrier through Definition 4238.1. The residual-substitution premise, critical-pair data, candidate join, residual window, closed checker, closed-normal fragment, bounded check, and obstruction rows remain displayed before the transport, replay, provenance, and local name rows are read.

Use the route and handoff theorems of Definition 4238.9 and Definition 4238.22. They make the exported handoff conditional on the retained premise and obstruction rows, so the confluence-audit packet can consume the rows only as bounded local evidence.

Now read the critical-path and normalization-confluence consumers. The $\mathsf{MetaCICCriticalPath}^{\uparrow}$ surface receives the same rows as candidate and discharge pressure, and $\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}$ receives them as bridge-facing boundary data attached to the confluence audit route.

Thus the sibling route is substantive: the frontier contributes concrete residual diamond rows to the critical-path and bridge consumers, while every standalone confluence-oracle, subject-reduction, evaluator-equality, quotient-equality, and kernel-consistency reading remains outside the packet. □

Theorem 4238.57 (MetaCIC parallel-diamond residual-substitution dependency route)**.** *Every accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet that is consumed as a parallel-diamond frontier must first expose the residual-substitution premise row supplied by chapter 2181. The consumer may route that premise into the local critical-pair, candidate-join, residual-frontier, closed-checker, and obstruction rows of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$*, but it cannot replace the premise by residual-substitution compatibility, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICParallelDiamondFrontierUp.MetacicParallelDiamondFrontierResidualSubstitutio`

Proof. Project the frontier carrier of Definition 4238.1. The residual-substitution premise row P is one of the displayed carrier coordinates, not an external theorem attached after the handoff.

Read the residual-substitution boundary chapter named in the statement. It supplies the visible premise boundary that the frontier route consumes before any candidate join or local-diamond handoff is public.

Finally apply the premise-retention and discharge-obstruction surfaces already present in the frontier chapter. They keep P and the obstruction row visible for every consumer, so the dependency route remains a premise boundary rather than any of the refused confluence endpoints. □

Theorem 4238.58 (MetaCIC parallel-diamond residual-premise join determinacy)**.** *Let* $F = (P, K, J, R, S, C, B, O, H, T, G, N)$ *and* $F' = (P, K, J', R, S, C, B, O, H', T', G', N')$ *be accepted* MetaCICParallelDiam *packets whose residual-substitution premise row* P*, critical-pair row* K*, residual-frontier row* R*, closed-checker row* S*, closed-normal row* C*, bounded-check row* B*, and obstruction row* O *agree on the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}}$ *surface. Any common candidate-join handoff exposed by both packets is therefore read only through the same displayed* $P, K, J, R, S, C, B, O, H, T, G, N$ *route, with* J *the candidate row visible on that route. The handoff does not discharge residual substitution, prove subject reduction, give full Church–Rosser, identify evaluator equality, quotient terms, or assert kernel consistency.*

Proof. Project the two frontier carriers through Definition 4238.1. The rows named in the statement are carrier coordinates, so a common candidate-join read cannot be detached from the shared P, K, R, S, C, B, O boundary.

Now apply the dependency route of Definition 4238.57. It places the residual-substitution premise P before the local critical-pair, candidate-join, residual-frontier, closed-checker, and obstruction rows.

Finally use the premise-retention and route surfaces already recorded in the chapter. They keep the displayed rows $P, K, J, R, S, C, B, O, H, T, G, N$ visible for every accepted consumer, so the shared handoff is deterministic only at the finite route boundary and remains separate from the refused confluence and kernel endpoints. □

Theorem 4238.59 (MetaCIC parallel-diamond residual-substitution confluence budget)**.** *Every residual-substitution route that contributes to the* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *parallel-diamond frontier must expose, in order, the retained premise row* P*, residual pair row* R*, local join row* J*, substitution dependency row* S*, and finite budget row* B *before any candidate-mediated strong-normalization handoff may consume it. The budget is a finite row of the frontier carrier, not a global confluence theorem, subject-reduction theorem, evaluator equality, quotient term equality, or kernel-consistency witness.*

Proof. Project the frontier carrier of Definition 4238.1. The retained premise, residual pair, local join, substitution dependency, and budget rows are displayed carrier coordinates, so a consumer cannot read the candidate handoff before these rows are present.

Apply the residual-substitution dependency route of Definition 4238.57. It places the retained premise boundary before the critical-pair and candidate-join rows and keeps residual substitution as a visible dependency of the frontier.

Finally use residual-join locality from the surrounding frontier rows. The local join is certified only inside the finite P, R, J, S, B route, and the candidate-mediated handoff consumes that route as a bounded frontier witness. Since no row stores global confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency, none of those endpoints is exported by the budget. □

Theorem 4238.60 (MetaCIC residual-substitution discharge criterion)**.** *Let an accepted* MetaCICParallelDiamondF *packet supply the retained residual-substitution premise row and let a separate* MetaCICResidualSubstitutionCompatib *certificate be displayed. Then the local-diamond handoff may be read as a discharge-ready boundary for the candidate-normalization confluence handoff.*

This boundary is still only the finite frontier route. It is not full Church–Rosser, subject reduction, evaluator equality, quotient equality, or kernel consistency.

Proof. Start with the discharge obstruction of Definition 4238.18. It identifies the retained residual-substitution premise as the row that remains visible until a separate compatibility certificate is supplied.

Next apply Definition 4238.19. The displayed $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ certificate is exactly the extra row allowed to turn the premise-obstruction surface into a discharged local-diamond boundary.

Finally use the confluence handoff of Definition 4238.22. The handoff remains a candidate-normalization consumer of the finite frontier route, so it exports only discharge-ready local-diamond evidence and none of the refused global endpoints. □

Theorem 4238.61 (MetaCIC observation confluence budget)**.** *Every observation-level confluence consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose the residual-substitution premise row P, critical-pair row K, residual-frontier row R, closed-checker row S, closed-normal fragment row C, bounded-check row B, and obstruction row O before reading any local join through the candidate row J. The observation budget is the finite frontier route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

It may cite the retained-premise route of Definition 4238.12 and the public frontier route of Definition 4238.9, but it does not prove residual-substitution compatibility, subject reduction, arbitrary closed Church–Rosser, evaluator equality, quotient equality of terms, or kernel consistency.

Proof. Start with the carrier and obligation basis of Definition 4238.1 and Definition 4238.34. They make $P, K, J, R, S, C, B, O, H, T, G, N$ the consumer-visible packet, with P and O ordinary rows rather than external assumptions.

Apply residual-substitution scope and the frontier route, Definition 4238.12 and Definition 4238.9. These force the premise row, critical-pair row, residual-frontier row, closed-checker row, and closed-normal fragment row to remain visible before the conditional handoff is consumed.

Finally use local-join scope Definition 4238.31. A local join can be read only after the candidate row has been placed inside the same typed-window surface with B and O still exposed. Thus the theorem records an observation budget for finite confluence consumers, not a closed confluence proof or a discharge of the residual-substitution obstruction. □

Theorem 4238.62 (MetaCIC candidate-normalization scope)**.** *Every candidate-normalization consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose the full frontier spine*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

before it reads the candidate row. The consumer may use J only as the displayed candidate-join row of a candidate-mediated residual route, and only while the residual-substitution premise row P and obstruction row O remain visible. Thus the candidate-normalization read is not a premise-free confluence theorem, not a completed residual-substitution theorem, not full normalization, not subject reduction, not evaluator equality, not quotient equality of terms, and not a kernel-consistency certificate.

Lean4 ✓ BEDC.Derived.MetaCICParallelDiamondFrontierUp.MetacicParallelDiamondFrontierCandidateNormalizat

Proof. Begin with the candidate-mediated residual route of Definition 4238.29. It permits a local peak to reach the candidate row J only through the displayed critical-pair row K and residual-frontier row R, with the retained premise row P still attached.

Next apply substitution nonescape, Definition 4238.38. That theorem keeps substitution data confined to P and R through the typed-window local join, so the candidate-normalization consumer cannot turn J into a discharged substitution result.

Use residual pasting, Definition 4238.37. Even after two typed-window residual reads are pasted through J, the pasted read remains the finite residual packet under P and still carries S, C, B, O, H, T, G, N.

Finally apply the normalization-frontier handoff of Definition 4238.40. The handoff exports only the conditional spine $P, K, J, R, S, C, B, O, H, T, G, N$ to normalization consumers, so P and O cannot be hidden when J is consumed. □

Theorem 4238.63 (MetaCIC parallel-diamond frontier obstruction retention under candidate normalization)**.** *Every candidate-normalization consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *carrier that reads the candidate row J must keep both the residual-substitution premise row P and obstruction row O visible through the full spine*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The read can use J only as a candidate-normalization row inside that conditional spine. It cannot retype candidate normalization as premise-free confluence, residual-substitution compatibility, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.

Proof. Begin with the candidate-normalization scope theorem, Definition 4238.62. It already requires the consumer to expose $P, K, J, R, S, C, B, O, H, T, G, N$ before the candidate row is read, with P and O still visible.

Next use substitution nonescape, Definition 4238.38. The substitution premise remains confined to the displayed residual route, so reading J cannot discharge P or replace it by an unconditional compatibility theorem.

Apply residual pasting, Definition 4238.37. Pasting two typed-window residual reads through J preserves the same finite residual packet and keeps the obstruction row O in the exported spine.

Finally hand the read to Definition 4238.40. That handoff exports only the conditional normalization-facing route, so the consumer cannot obtain premise-free confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency from candidate normalization alone. □

Theorem 4238.64 (MetaCIC candidate-normalization residual budget)**.** *A candidate-normalization consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet may spend only the displayed finite residual rows*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

Every normalization-facing read must keep the residual-substitution premise row P, candidate-join row J, residual-frontier row R, and obstruction row O visible. The budget excludes premise-free confluence, subject reduction, evaluator equality, quotient term equality, and kernel consistency.

Proof. Start with the candidate-normalization scope theorem, Definition 4238.62. It makes the displayed spine $P, K, J, R, S, C, B, O, H, T, G, N$ the only route available to a candidate-normalization consumer.

Use obstruction retention under candidate normalization, Definition 4238.63. This keeps P and O visible when the candidate row J is read, so the residual-substitution premise and obstruction cannot be silently discharged.

Next compose substitution nonescape with residual pasting, Definition 4238.38 and Definition 4238.37. These preserve the residual-frontier row R and candidate-join row J as finite rows of the same packet.

Finally apply the normalization-frontier handoff, Definition 4238.40. The handoff exports only the conditional normalization-facing spine, so the consumer cannot spend the residual budget as premise-free confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.65 (MetaCIC parallel-diamond candidate-normalization frontier scope)**.** *Every candidate-normalization read used by the* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must pass through the visible candidate endpoint row, residual-diamond budget, retained-premise boundary, residual-join locality row, and normal-form obligation row before it can feed a local-confluence consumer. Equivalently, the read remains inside the finite frontier spine*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

where J is read only as the displayed candidate endpoint, R, S, C, B keep the residual-diamond and normal-form budget visible, P and O keep the retained premise and obstruction boundary visible, and H, T, G, N preserve transport, replay, provenance, and local naming. The scope is therefore a bounded candidate-normalization frontier; it is not premise-free local confluence, unrestricted normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with candidate-normalization scope, Definition 4238.62. It requires any consumer of the candidate row to expose the full frontier spine before the candidate endpoint J is read.

Next apply the candidate-mediated strong-normalization handoff of Definition 4238.73. This keeps the candidate endpoint attached to the critical-pair envelope, finite residual witness, bounded checker rows, obstruction row, transport, replay, provenance, and local naming.

Use the residual-join obligation surface, Definition 4238.138. It supplies the residual-diamond budget and local residual-join obligation rows, so a local-confluence consumer cannot read candidate normalization before the residual budget and local join route are visible.

Finally apply the retained-premise closure budget of Definition 4238.150. The retained premise and obstruction rows remain displayed through the normal-form obligation route, so the candidate-normalization read stays inside the bounded frontier and exports none of the refused global endpoints. □

Theorem 4238.66 (MetaCIC candidate-mediated diamond budget route)**.** *Every candidate-mediated parallel-diamond read from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose residual-substitution premise retention, critical-pair envelope rows, candidate normalization handoff, bounded obstruction rows, closed checker rows, and local* $\mathsf{NameCert}$ *rows before any confluence-facing conclusion is exported. The read is the finite route through the displayed frontier packet, not full normalization, global confluence, or host definitional equality.*

Proof. Start with the residual-substitution route Definition 4238.39. It keeps the residual-substitution premise row visible through the same packet that carries critical-pair and candidate rows.

Next read the critical-pair envelope and candidate-normalization scope, Definition 4238.50 and Definition 4238.62. These rows expose the local pair and candidate handoff without discharging substitution or turning the handoff into a global normalization theorem.

Finally apply bounded local-confluence decision and finite residual witness consumption, Definition 4238.70 and Definition 4238.69. They keep the bounded obstruction, closed checker, transport, replay, provenance, and local naming rows attached before a confluence-facing consumer can inspect the result. Hence the exported conclusion is only the finite candidate-budget route stated above. □

Theorem 4238.67 (MetaCIC parallel diamond registered frontier route)**.** *A candidate diamond budget route can expose a bounded checker status and local join candidate only after the retained-premise route, candidate-normalization row, residual envelope, and frontier register have all been displayed. The exposed status is a local registered-frontier read from the same* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet; it is not subject reduction, residual-substitution discharge, quotient equality, global normalization, full confluence, or kernel consistency.*

Proof. Start with the seed route of Definition 4238.66. It already forces residual-substitution premise retention, critical-pair envelope rows, candidate normalization handoff, bounded obstruction rows, closed checker rows, and local NameCert rows to remain visible before any confluence-facing conclusion is exported.

Next read the retained-premise and candidate-normalization rows through the same frontier packet. The existing residual-substitution route keeps the premise attached, while the candidate-normalization scope names the local join candidate without turning it into global normalization or subject reduction.

Finally use the frontier and local-join scope rows already recorded in the chapter. They register the bounded checker status only after the residual envelope and frontier display have been read, so the exported route remains a local finite checker route and refuses the global confluence, quotient, discharge, normalization, and consistency endpoints. □

Theorem 4238.68 (MetaCIC parallel-diamond candidate critical-pair boundary)**.** *Every local diamond budget read from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose the residual-substitution premise row P, the two critical-pair branch rows carried by K and R, the candidate join row J, the normalization-confluence handoff row, the critical-path socket, and the obstruction row O before any confluence-audit consumer can inspect the read. The boundary remains candidate-mediated; it does not assert subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, residual-substitution discharge, or kernel consistency.*

Proof. Begin with seed readiness and public seed readiness, Definition 4238.83 and Definition 4238.84. These rows force the residual branches, candidate join, normalization-confluence handoff, and public frontier route to remain visible before any confluence-facing read is exported.

Next apply the critical-path retained-premise handoff, Definition 4238.85. It keeps the residual-substitution premise and obstruction row attached to the critical-path socket rather than letting the socket discharge the premise.

Finally use the obligation-closure package Definition 4238.87. The package assembles the residual branches, candidate join, normalization-confluence handoff, critical-path socket, and obstruction retention as the finite local surface. Since the surface is still candidate-mediated, none of the refused confluence, equality, normalization, discharge, or kernel endpoints is exported. □

Theorem 4238.69 (MetaCIC parallel-diamond finite residual witness consumption)**.** *Every accepted residual-pair local-diamond witness read in a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must consume the typed window, residual frontier, substitution-boundary row, bounded local-join checker,*

candidate-strong-normalization evidence when present, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before it may be used as input to a closed parallel-diamond route. The consumed packet is the finite route through* $P, K, J, R, S, C, B, O, H, T, G, N$*; it is not a proof of arbitrary closed Church–Rosser.*

Lean4 ✓ BEDC.Derived.MetaCICParallelDiamondFrontierUp.MetacicParallelDiamondFrontierFiniteResidualWitne

Proof. Start with the typed-window local-join scope of Definition 4238.31. It forces a local-diamond consumer to expose the typed window, candidate join, residual frontier, checker rows, and obstruction row before any join read is available.

Next use residual boundary and substitution nonescape, Definition 4238.33 and Definition 4238.38. These keep the residual-substitution premise and substitution-boundary row visible through the finite residual route rather than allowing them to be discharged by structural replay.

Apply the residual-substitution route Definition 4238.39. It identifies the local-diamond input as the conditional frontier packet through $P, K, J, R, S, C, B, O, H, T, G, N$, including transport, replay, provenance, and local naming.

Finally use the candidate-mediated strong-normalization socket Definition 4238.41. When candidate-SN evidence is present, it is consumed as the same finite socket before the closed parallel-diamond route can read the witness. Since the route retains P and O and exports only the displayed packet, it does not prove arbitrary closed Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency. □

Theorem 4238.70 (MetaCIC parallel-diamond bounded local-confluence decision)**.** *A bounded local-join checker for the displayed finite residual witness of a* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet may return a positive local-confluence certificate only after exposing the typed window, residual frontier, substitution-boundary row, candidate join, bounded checker status, componentwise transport, displayed replay, provenance, and local* NameCert *rows. The positive result is a bounded local-confluence certificate for that finite residual witness; it is not residual-substitution compatibility, subject reduction, unrestricted confluence, evaluator equality, quotient equality, or kernel consistency.*

Proof. Start with local-join scope. By Definition 4238.31, a checker read must expose the typed window, candidate join, residual frontier, checker rows, and obstruction row before any local join can be used.

Next apply residual boundary and substitution nonescape, Definition 4238.33 and Definition 4238.38. These rows keep the substitution-boundary premise visible and prevent the bounded decision from being read as residual-substitution compatibility.

Use finite residual witness consumption from Definition 4238.69. It forces the checker status, candidate join, transport, replay, provenance, and local naming rows to be consumed as the finite route through $P, K, J, R, S, C, B, O, H, T, G, N$.

The checker may therefore certify only that this displayed finite residual witness has a bounded local join. Since the route still retains the typed window and substitution-boundary rows and never exports a global reduction relation, the certificate does not imply subject reduction, unrestricted confluence, evaluator equality, quotient equality, or kernel consistency. □

Theorem 4238.71 (MetaCIC parallel-diamond finite candidate frontier)**.** *Any bounded local-confluence certificate consumed from a* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet is limited to the displayed finite candidate rows*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

Candidate-normalization rows and residual-substitution rows must remain visible before a closed parallel-diamond route can read the result. The certificate therefore records only a finite candidate frontier for the displayed packet; it is not full Church–Rosser, subject reduction, evaluator equality, quotient equality, residual-substitution discharge, or kernel consistency.

Proof. Begin with finite residual witness consumption, Definition 4238.69. It forces every local-diamond witness read to pass through the typed window, residual frontier, substitution-boundary row, bounded local-join checker, transport, replay, provenance, and local naming rows.

Next use bounded local-confluence decision, Definition 4238.70. A positive checker result is available only for that displayed finite residual witness and only after the candidate join, checker status, and structural rows have been exposed.

Now attach the candidate-mediated strong-normalization socket and the residual-substitution route, Definition 4238.41 and Definition 4238.39. These keep candidate normalization and residual substitution inside the same $P, K, J, R, S, C, B, O, H, T, G, N$ spine before the closed route may inspect the handoff.

Thus the consumer receives a finite candidate frontier and nothing stronger. Since the residual-substitution and candidate-normalization rows remain visible, the certificate cannot be reread as a premise-free confluence theorem, subject reduction, evaluator equality, quotient equality, residual-substitution discharge, or kernel consistency. □

Theorem 4238.72 (MetaCIC parallel-diamond frontier residual-row visibility)**.** *Any accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *consumer that exports a parallel-diamond handoff must keep the residual-substitution row P, local join row J, typed residual budget row R, componentwise transport row H, displayed replay row T, provenance row G, and local* NameCert *row N visible. The consumer cannot cite bounded normal equality, closed checker data, or confluence audit packets as a replacement for the residual row.*

Proof. Project the frontier carrier of Definition 4238.1. The accepted packet exposes the residual-substitution premise, candidate or local join, residual-frontier budget, transport, replay, provenance, and local naming rows as displayed coordinates rather than as ambient metadata.

Cite the residual-substitution boundary and local-join ledger sibling routes. The boundary keeps the substitution premise explicit, while the local-join ledger reads the join only after the residual rows and bounded-check rows have been exposed.

The remaining claim is nonescape of the carrier rows. Bounded normal equality, closed checker data, and confluence audit packets can be consumed only through the displayed frontier route; none supplies a second coordinate that discharges or hides the residual-substitution row. □

Theorem 4238.73 (MetaCIC parallel-diamond candidate-mediated SN handoff)**.** *Every candidate-mediated strong-normalization budget consumed by an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose, in order, the critical-pair envelope, residual-substitution row, candidate-normalization scope, finite residual witness, and residual-row visibility surface before any confluence or decidability consumer reads the frontier. When the candidate-normalization confluence handoff is consumed, the retained residual-substitution premise row P remains visible in the same read. The consumed route is the finite spine*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

with P retained as the residual-substitution premise, K, J, R retained as the local critical-pair and residual-frontier rows, S, C, B, O retained as the bounded checker and obstruction rows, and H, T, G, N retained as transport, replay, provenance, and local naming. The handoff is therefore a

conditional residual-join frontier and candidate-mediated budget, not a proof of unrestricted confluence, unbounded strong normalization, subject reduction, evaluator equality, quotient term equality, decidability of all reductions, or kernel consistency.

Proof. First read the critical-pair envelope through Definition 4238.50. It exposes K, J, R, S, C, B, O as a bounded local-overlap surface and keeps the frontier carrier rows displayed.

Next read the residual-substitution dependency route of Definition 4238.57. That route places the retained premise row P before the candidate join, residual frontier, closed-checker, and obstruction rows can be consumed.

The candidate-normalization scope of Definition 4238.62 keeps J inside the same conditional spine. It prevents a normalization consumer from hiding P or retyping the candidate row as premise-free confluence.

Together, that candidate-normalization scope and the residual-substitution dependency route require the same retained premise row P to remain visible when the candidate-normalization confluence handoff is consumed; the consumer receives a conditional residual-join frontier, not premise-free confluence or a kernel-consistency certificate.

Now consume the finite residual witness of Definition 4238.69. The witness reads typed windows, residual frontier data, bounded local-join checks, candidate evidence when present, transport, replay, provenance, and local naming before any closed parallel-diamond route can use it.

Finally apply residual-row visibility, Definition 4238.72. The residual row remains visible through H, T, G, N, so confluence and decidability consumers receive only the displayed candidate-mediated budget rather than a discharged substitution theorem, global normalization theorem, evaluator equality, quotient equality, or kernel-consistency certificate. □

Lean4 ✓ `BEDC.Derived.MetaCICParallelDiamondFrontierUp.MetacicParallelDiamondFrontierCandidateSnHandoff`

Theorem 4238.74 (MetaCIC parallel-diamond candidate SN handoff scope)**.** *Every candidate-mediated strong-normalization consumer of an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must expose the residual-substitution premise row, critical-pair row, candidate join row, residual-frontier row, closed-checker row, closed-normal-fragment row, obstruction row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *before using the handoff. In the displayed spine*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

the consumer reads P as the retained substitution premise, K as the critical-pair row, J as the candidate join row, R as the residual-frontier row, S, C, B as closed-checker, closed-normal-fragment, and bounded-check rows, O as the obstruction row, and H, T, G, N as transport, replay, provenance, and local naming. The scope is only a candidate-mediated SN handoff; it is not full substitution discharge, global confluence, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with the candidate-mediated SN handoff of Definition 4238.73. It already forces the accepted packet to display the residual-substitution premise, critical-pair envelope, residual-frontier rows, checker rows, obstruction row, transport, replay, provenance, and local naming before a confluence or decidability consumer reads the frontier.

Next use the retained-premise discharge boundary and residual-substitution dependency route. They keep P visible as a premise row rather than a discharged substitution theorem, so the candidate handoff cannot be read as premise-free confluence or subject reduction.

Finally apply residual-row visibility. The rows K, J, R, S, C, B, O remain attached to H, T, G, N, and every displayed Cont replay preserves the same local NameCert route. Thus the consumer obtains exactly the scoped candidate-mediated handoff and none of the excluded global equality or consistency claims. □

Theorem 4238.75 (MetaCIC parallel diamond typed candidate SN extension)**.** *Every candidate-mediated strong-normalization handoff consumed from an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must retain the residual-substitution premise, critical-pair envelope, candidate row, typed-window row, closed-checker row, bounded-check row, obstruction row, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local* NameCert *row before any normalization-facing consumer reads it. In the frontier spine*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

P remains the residual-substitution premise, K, J, R retain the critical-pair, candidate, and typed-window residual data, S, C, B, O retain closed-checker, bounded-check, and obstruction data, and H, T, G, N retain transport, replay, provenance, and local naming. The extension is a typed candidate socket only; it is not global strong normalization, full confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with the candidate-normalization scope of Definition 4238.62. It forces any candidate-normalization consumer to expose the full spine $P, K, J, R, S, C, B, O, H, T, G, N$ before reading the candidate row.

Next apply the candidate-mediated SN handoff above. The handoff keeps the residual-substitution premise P, critical-pair envelope, candidate row, bounded checker rows, obstruction row, transport, replay, provenance, and local naming visible before any confluence or decidability consumer reads the frontier.

Use finite residual witness consumption, Definition 4238.69. The typed window and residual frontier data remain in the same finite packet with the closed-checker, bounded-check, candidate evidence, transport, replay, provenance, and local NameCert rows.

Finally invoke residual-row visibility, Definition 4238.72. Since the residual-substitution and typed residual rows remain visible through H, T, G, N, a normalization-facing consumer receives only the typed candidate socket and cannot read it as global strong normalization, full confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.76 (MetaCIC parallel-diamond candidate SN frontier extension)**.** *Let $F = (P, K, J, R, S, C, B, O, I$ be an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet. If a consumer displays a candidate-normalization row J, a residual-pair frontier R, a bounded local-join checker B, and the retained substitution-boundary row P through the same transport, replay, provenance, and local naming rows H, T, G, N, then the candidate strong-normalization handoff of F extends to that bounded residual-join frontier. The conclusion is only a bounded candidate-mediated frontier handoff; it does not prove arbitrary closed Church–Rosser, premise-free confluence, global strong normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency.*

Proof. First apply the candidate-mediated SN handoff of Definition 4238.73. It keeps the residual-substitution premise, critical-pair envelope, candidate row, finite residual witness, bounded checker rows, obstruction row, transport, replay, provenance, and local naming visible before any SN-facing consumer reads the frontier.

Next use the typed candidate SN extension of Definition 4238.75. That theorem places J inside the typed residual window and prevents the candidate row from being retyped as a global normalization theorem.

Now read the residual-frontier siblings. The critical-pair envelope and residual-substitution dependency route, Definition 4238.50 and Definition 4238.57, keep K, R downstream of the retained premise P. Finite residual witness consumption and residual-row visibility, Definition 4238.69 and Definition 4238.72, keep the bounded checker and frontier rows attached to H, T, G, N.

Therefore the displayed candidate-normalization row, residual-pair frontier, bounded local-join checker, and substitution-boundary row form a single bounded handoff. Since every step retains P and the structural rows, the exported result remains a candidate-mediated frontier extension rather than an unrestricted Church–Rosser or global normalization theorem. □

Theorem 4238.77 (MetaCIC parallel-diamond candidate SN retained-premise boundary)**.** *Every candidate-mediated strong-normalization handoff exported by an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet retains the residual-substitution premise row and the obstruction rows before it may feed the normalization-confluence handoff. In the displayed route*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

the rows P, J, R, B, O remain visible as premise, candidate-normalization, residual-frontier, bounded-check, and obstruction data, while H, T, G, N preserve the same route under transport, replay, provenance, and local naming. The boundary is not a proof of subject reduction, full Church–Rosser, evaluator equality, quotient term equality, residual-substitution discharge, global strong normalization, or kernel consistency.

Proof. Start with the candidate-mediated SN handoff of Definition 4238.73. It already forces the consumer to expose the critical-pair envelope, residual-substitution row, candidate-normalization scope, finite residual witness, and residual-row visibility surface before any confluence or decidability read.

Now apply the residual-substitution dependency route and candidate-normalization scope, Definition 4238.57 and Definition 4238.62. These rows keep P upstream of J, R, S, C, B, O and prevent the candidate row from being consumed as premise-free normalization or confluence.

Finally use finite residual witness consumption and residual-row visibility, Definition 4238.69 and Definition 4238.72. The bounded witness and obstruction rows remain attached to H, T, G, N, so the normalization-confluence handoff receives only the retained finite packet and none of the excluded global endpoints. □

Theorem 4238.78 (MetaCIC parallel-diamond frontier seed registration)**.** *Every seed read of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet that presents a conditional parallel-diamond handoff must first expose the residual-substitution premise row P, critical-pair row K, candidate join J, residual frontier R, closed checker S, closed-normal fragment C, bounded check B, obstruction O, and structural rows H, T, G, N. The handoff is public only at this finite row surface; it does not claim a premise-free diamond, full Church–Rosser theorem, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.*

Proof. Start from the obligation surface of Definition 4238.2. It makes $P, K, J, R, S, C, B, O, H, T, G, N$ the visible rows of the accepted frontier packet, with P retained as an actual residual-substitution premise.

Next use the route theorem Definition 4238.9. A conditional diamond handoff cannot be consumed until the critical-pair, residual-frontier, closed-checker, closed-normal, bounded-check, and obstruction rows have been read alongside the structural rows.

Finally apply premise retention, Definition 4238.13. The premise row remains visible through the local-diamond route, so the seed registration records the finite frontier interface rather than any of the refused confluence or kernel endpoints. □

Theorem 4238.79 (MetaCIC parallel-diamond frontier seed-status route)**.** *The hub seed registration for* MetaCICParallelDiamondFrontier$^{\uparrow}$ *is valid only through the retained rows*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

and the sibling critical-path consumer route. It does not discharge residual substitution, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, or kernel consistency.

Proof. Read the carrier and obligation surfaces, Definition 4238.1 and Definition 4238.2. They make $P, K, J, R, S, C, B, O, H, T, G, N$ the whole retained packet for the seed registration.

Next use the route theorem and seed-readiness theorem, Definition 4238.9 and Definition 4238.83. These force the seed read to keep the residual-substitution premise, critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal, bounded-check, obstruction, transport, replay, provenance, and local name rows visible.

Finally apply the critical-path consumer route, Definition 4238.55. The downstream consumer receives only that retained row surface, so the seed-status route remains a registered frontier boundary rather than any of the refused residual-substitution, subject-reduction, confluence, evaluator-equality, quotient-equality, or kernel-consistency endpoints. □

Theorem 4238.80 (MetaCIC parallel-diamond frontier seed register)**.** *The seed register for* MetaCICParallelDiamor *is the finite row surface*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

read through the carrier, obligation, seed-registration, and seed-status routes. The register records the chapter as a seed-level frontier packet only; it does not alter the closurestatus theory axis, does not upgrade the verification axis, and does not claim residual-substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, or kernel consistency.

Proof. Project the carrier and obligation surfaces of Definition 4238.1 and Definition 4238.2. They expose exactly the rows $P, K, J, R, S, C, B, O, H, T, G, N$.

Apply Definition 4238.78 and Definition 4238.79. Both routes keep the same retained rows visible before any seed consumer reads the frontier.

The closurestatus block remains in the dedicated route file and reports the independent theory and verification axes. Since this theorem only registers the finite seed surface, it cannot discharge any of the refused MetaCIC endpoints. □

Theorem 4238.81 (MetaCIC parallel-diamond seed registration child route)**.** *The seed registration of an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet is read through the local child rows for critical-pair envelope, residual-join locality, retained-premise budget, seed closure status, closurestatus guard, and local* NameCert *obligations. Concretely, every seed-registration consumer must expose*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

by way of Definition 4238.50, Definition 4238.104, Definition 4238.150, Definition 4238.45, Definition 4238.180, and Definition 4238.2. The child route records seed registration only; it does not discharge residual substitution, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Start with the carrier and local NameCert obligations. They make the retained premise, critical-pair data, candidate join, residual witness, typed window, bounded checker, obstruction, transport, replay, provenance, and local naming rows the whole public packet.

Read the critical-pair envelope and residual-join locality rows next. These keep the local diamond request carrier-local and keep the residual-substitution premise visible before any seed consumer can inspect a join.

The retained-premise closure budget then prevents the premise row from disappearing under seed registration. The seed closure status reader and closurestatus guard identify the seed marker as a pointer into the same displayed packet, rather than as an independent confluence or kernel claim.

Thus the child route is exactly the finite registration spine for the hub: it ties the seed row to existing child files while refusing residual-substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, and kernel consistency. □

Theorem 4238.82 (MetaCIC parallel-diamond frontier seed package)**.** *Every seed consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet receives the seed package only after the existing carrier, obligation surface, handoff route, critical-pair exhaustion rows, obstruction budget, closure seed route, and residual-normalization window have all been displayed. Equivalently, the package is the finite surface*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

read through Definition 4238.1, Definition 4238.2, Definition 4238.9, Definition 4238.66, Definition 4238.100, and Definition 4238.126. It is a registered seed package, not a full confluence theorem, subject-reduction theorem, evaluator equality, quotient term equality, global normalization theorem, residual-substitution discharge, or kernel-consistency certificate.

Proof. Start with the carrier and obligation surfaces. They display the retained residual-substitution premise, critical-pair row, candidate join, residual frontier, closed checker, closed-normal fragment, bounded check, obstruction row, transport, replay, provenance, and local naming rows.

Next read the handoff and critical-pair budget rows. The route theorem and candidate-diamond budget route keep the local diamond inside the displayed candidate window and leave the obstruction budget visible to downstream consumers.

Finally apply the closure seed route and residual-normalization window. These theorems register the same finite package as seed-level data only, so the consumer receives a frontier package rather than any of the refused confluence, subject-reduction, evaluator-equality, quotient-equality, normalization, residual-substitution, or kernel-consistency endpoints. □

Theorem 4238.83 (MetaCIC parallel-diamond frontier seed readiness)**.** *Every candidate-mediated parallel-diamond read from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose both residual branches, the common join candidate, the normalization-confluence handoff row, and the MetaCIC critical-path readback socket before any confluence-frontier claim is available. In carrier notation the readiness route keeps* $P, K, J, R, S, C, B, O, H, T, G, N$ *visible:* K *records the two residual branches,* J *records the common join candidate,* C *and* B *route the normalization-confluence handoff consumed by chapter 1190, and the critical-path socket of chapter 765 reads* P, R, O *as retained boundary data. The theorem is a finite route projection, not a normalization theorem, a strong-normalization theorem, an unrestricted confluence theorem, subject reduction, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Project the frontier carrier from Definition 4238.1. The branch and candidate data are visible only through the critical-pair row K, candidate-join row J, residual-frontier row R, and obstruction row O, with the structural rows attached.

Use the existing confluence handoff route in the chapter. It keeps the local diamond conditional on the residual-substitution premise and routes the closed-normal and bounded-check rows through the normalization-confluence bridge rather than treating them as a global normalization proof.

Finally read the MetaCIC critical-path packet as a socket boundary. The critical-path consumer receives the residual premise, residual windows, and obstruction rows as readback data, so the seed-readiness route exposes the two branches and common join candidate without discharging normalization, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.84 (MetaCIC parallel-diamond public seed readiness)**.** *Every public seed read of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose the full route*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

before any confluence-audit or normalization consumer can inspect the handoff. In particular, the residual-substitution premise row P and obstruction row O remain visible together with the critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal, bounded-check, transport, replay, provenance, and local naming rows. The public seed read is therefore a retained-premise frontier, not full confluence, subject reduction, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Start from Definition 4238.83. It already exposes the two residual branches, the candidate join, and the critical-path readback socket before any frontier claim can be consumed.

Next apply the obligation and route surfaces, Definition 4238.2 and Definition 4238.9. These force the public read through the rows $P, K, J, R, S, C, B, O, H, T, G, N$ rather than through a detached confluence theorem.

Use the premise-retention and obstruction ledgers already present in the chapter, including Definition 4238.23 and Definition 4238.36. They keep P and O visible before confluence-audit or normalization consumers inspect the candidate-mediated handoff.

Finally compose with the critical-path sibling route. The downstream consumer receives only the finite seed-readiness spine, so the packet does not discharge residual substitution, prove subject reduction, establish unrestricted confluence, identify evaluator or quotient equality, prove global normalization, or certify kernel consistency. □

Theorem 4238.85 (MetaCIC parallel-diamond critical-path retained-premise handoff)**.** *Any critical-path consumer reading the candidate-mediated local diamond row of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must keep the residual-substitution premise P and the obstruction row O visible throughout the full route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The packet may be passed to $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$, *and the normalization-confluence bridge of chapter 1190 only as retained frontier evidence. It is not a proof of subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, residual-substitution discharge, or kernel consistency.*

Proof. Start from public seed readiness, Definition 4238.84. It forces any public read of the frontier through the full route $P, K, J, R, S, C, B, O, H, T, G, N$ before a confluence-audit or normalization consumer may inspect the handoff.

Use the seed-readiness route Definition 4238.83. The candidate-mediated local diamond exposes the residual branches, common join candidate, normalization-confluence handoff row, and critical-path readback socket, while leaving the residual-substitution premise as retained boundary data.

Apply the premise preservation and critical-path consumer routes already named in the chapter, including Definition 4238.23 and Definition 4238.55. These keep P and O visible when the handoff is read by $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$, or the normalization-confluence bridge.

The obstruction row then blocks endpoint promotion. Since O remains part of the exported frontier evidence, the consumer cannot reinterpret the handoff as subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, residual-substitution discharge, or kernel consistency. □

Theorem 4238.86 (MetaCIC parallel-diamond residual-substitution local discharge)**.** *When an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet displays a residual-substitution row together with the critical pair, candidate join, residual-frontier, closed-checker, bounded-check, obstruction, transport, replay, provenance, and local* NameCert *rows*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

that packet locally discharges the finite residual window for the current candidate-mediated diamond only. The discharge is the visible closure of that displayed window under the present candidate join and retained obstruction; it is not subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Start with seed readiness and public seed readiness, Definition 4238.83 and Definition 4238.84. They expose the two residual branches, candidate join, residual-frontier row, closed-checker row, bounded-check row, obstruction row, and structural rows as one finite packet.

Apply the critical-path retained-premise handoff, Definition 4238.85. It keeps the residual-substitution premise P and obstruction row O visible while the critical-path consumer reads the candidate-mediated local diamond.

Use premise preservation together with the obligation-closure package, Definition 4238.23 and Definition 4238.87. These rows preserve the displayed premise and obstruction across the finite window and assemble the local obligation surface without promoting it to a global metatheorem.

Thus the only discharged object is the current finite residual window under the displayed candidate join. The packet has no coordinate for subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency, so none of those endpoints is exported. □

Theorem 4238.87 (MetaCIC parallel-diamond frontier obligation-closure package)**.** *The seed-readiness row of Definition 4238.83, the public seed-readiness row of Definition 4238.84, and the critical-path retained-premise handoff of Definition 4238.85 assemble the local obligation surface for residual branches, candidate join, normalization-confluence handoff, critical-path socket, and obstruction retention in an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet. The package refuses subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, premise-free residual-substitution discharge, and kernel consistency.*

Proof. Project the displayed frontier rows. The carrier surface keeps the residual-substitution premise, two residual branches, candidate join, residual frontier, closed-checker row, normalization-confluence handoff rows, obstruction row, transport, replay, provenance, and local naming rows visible.

Apply Definition 4238.83. It places the residual branches, common join candidate, normalization-confluence handoff, and critical-path socket before any confluence-frontier read.

Next apply Definition 4238.84 and Definition 4238.85. These rows preserve the public route and keep the residual premise together with the obstruction row under critical-path consumption, so the package records obligation closure for the finite frontier surface without promoting it to subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, premise-free residual-substitution discharge, or kernel consistency. □

Theorem 4238.88 (MetaCIC parallel-diamond frontier seed closure)**.** *Any seed-closure read of an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must keep*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

visible, retain the residual-substitution premise P, and preserve the obstruction row O before any strong-normalization, confluence-audit, or normalization consumer reads the handoff. The seed closure is a finite retained-premise frontier and not global normalization, unrestricted confluence, subject reduction, evaluator equality, quotient term equality, residual-substitution discharge, or kernel consistency.

Proof. Start with the seed-readiness row of Definition 4238.83. It exposes the residual branches, common join candidate, normalization-confluence handoff row, and critical-path readback socket while keeping the route inside the displayed carrier rows.

Apply the public seed-readiness row of Definition 4238.84. This forces the full spine $P, K, J, R, S, C, B, O, H, T, G$ to remain visible before any confluence-audit or normalization consumer inspects the handoff.

Next use the critical-path retained-premise handoff of Definition 4238.85. It keeps the residual-substitution premise P and obstruction row O visible under MetaCICCriticalPath$^{\uparrow}$, MetaCICConfluenceAuditPacket$^{\uparrow}$, and normalization-confluence consumption.

Finally compose with the obligation-closure package of Definition 4238.87. The resulting seed closure records only retained finite frontier evidence, so it cannot discharge residual substitution or promote the handoff to strong normalization, unrestricted confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.89 (MetaCIC parallel-diamond frontier seed obligations)**.** *Every confluence consumer reading an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must first expose the seed-obligation surface*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The exposed rows include candidate pair rows, one-step residual rows, join-window rows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the carrier-local* NameCert *row. A downstream reader may inspect a diamond conclusion only after these rows have been displayed as local frontier data; the seed surface is not subject reduction, global normalization, unrestricted confluence, evaluator equality, quotient term equality, residual-substitution discharge, or kernel consistency.*

Proof. Project the accepted carrier from Definition 4238.1. The candidate pair and one-step residual data are carried by the critical-pair, candidate-join, and residual-frontier rows K, J, R, with the retained premise row P still visible.

Read the join-window and obstruction rows next. The closed-checker, closed-normal, bounded-check, and obstruction coordinates S, C, B, O keep the local join inside the displayed window instead of promoting it to a global confluence theorem.

Finally apply the structural rows. Componentwise transport H, replay T, provenance G, and local naming N preserve the same row order, so a consumer reaches a diamond conclusion only

through the finite seed-obligation surface and not through subject reduction, evaluator equality, quotient equality, residual-substitution discharge, or kernel consistency. □

Theorem 4238.90 (MetaCIC parallel-diamond retained-obstruction obligation)**.** *Any confluence or normalization consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must keep the residual-substitution premise row P and obstruction row O visible through the displayed route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

If either row is hidden, discharged, or replaced by an endpoint assertion, the read is not a discharge of subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Project the accepted carrier from Definition 4238.1. The rows $P, K, J, R, S, C, B, O, H, T, G, N$ are the local data available to a confluence or normalization consumer, and the residual-substitution premise row P remains part of that display.

Apply Definition 4238.89. Its seed surface already forces the consumer to read the candidate pair, residual rows, join-window rows, closed-checker rows, obstruction row, transport, replay, provenance, and local naming before any diamond conclusion is inspected.

Now use the obstruction row O. It records that the accepted packet has not promoted the local diamond to subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency, so hiding P or O would erase a load-bearing premise rather than discharge it.

The public seed readiness of the chapter therefore remains conditional. A downstream consumer may pass along the finite candidate-mediated diamond surface only while P and O remain visible through the full route, and any endpoint promotion must be supplied by a separate packet. □

Theorem 4238.91 (MetaCIC parallel diamond frontier obligation closure route)**.** *Every residual-join or candidate-normalization consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose the critical-pair envelope, residual substitution dependency, candidate diamond budget, finite residual witness consumption, and residual row visibility before reading any local diamond conclusion. In row form, the consumer must display the route*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

with P retaining the residual-substitution premise, K exposing the critical-pair envelope, J and B carrying the candidate diamond budget, R exposing finite residual witnesses, S and C checking the closed candidate surface, O retaining the obstruction, and H, T, G, N transporting, replaying, sourcing, and naming the same route. The conclusion is obligation closure for the displayed frontier only; it is not subject reduction, global confluence, strong normalization, substitution admissibility, hidden oracle access, or any closed MetaCIC theorem.

Proof. Begin with Definition 4238.89. It forces every confluence consumer to display the seed rows $P, K, J, R, S, C, B, O, H, T, G, N$ before a local diamond conclusion is inspected.

Use the retained-obstruction obligation of Definition 4238.90. The rows P and O remain load-bearing, so the residual-substitution dependency and the obstruction cannot be hidden when the residual join is read.

Now compose with the adjacent residual route files. The residual-witness and candidate-normalization routes expose finite witness consumption through R and the candidate budget through J, S, C, B before the frontier can export a local join.

The structural rows H, T, G, N keep the same displayed packet under transport, replay, provenance, and local naming. Since no row supplies subject reduction, global confluence, strong normalization, substitution admissibility, hidden oracle access, or a closed MetaCIC theorem, the route closes only the finite obligation surface it displays. □

Theorem 4238.92 (MetaCIC parallel-diamond discharge boundary)**.** *A candidate-mediated diamond read from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet can be consumed only while the residual-substitution premise row P and obstruction row O remain visible through the route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The read is therefore a retained frontier surface. It does not discharge subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Project the accepted carrier from Definition 4238.1. The candidate-mediated diamond data are displayed only through the rows $P, K, J, R, S, C, B, O, H, T, G, N$.

Apply the seed-obligations theorem. It requires every confluence consumer to expose the retained premise, candidate pair, residual rows, join window, checker rows, obstruction row, transport, replay, provenance, and local naming before a diamond conclusion is inspected.

Now use the retained-obstruction obligation. That theorem keeps P and O visible as load-bearing rows, so a downstream read may pass along the candidate-mediated diamond surface only as a conditional frontier.

The excluded endpoint claims have no coordinate in the displayed route. Subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, and kernel consistency would require separate discharge data, not the retained candidate packet alone. □

Theorem 4238.93 (MetaCIC parallel-diamond frontier obligation scope)**.** *Every accepted* MetaCICParallelDiamond *packet exposes the residual-substitution premise row P, critical-pair row K, candidate-join row J, residual-frontier row R, closed-checker row S, closed-normal row C, bounded-check row B, obstruction row O, and structural rows H, T, G, N before any confluence consumer reads a parallel-diamond handoff. The visible scope is*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

It is a retained frontier surface, not a discharge of residual substitution, full Church–Rosser, subject reduction, evaluator equality, or kernel consistency.

Proof. Project the accepted carrier from Definition 4238.1. Its finite coordinates are exactly the retained premise, critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal, bounded-check, obstruction, transport, replay, provenance, and naming rows listed above.

Apply Definition 4238.89. That obligation surface forces a confluence consumer to display the candidate pair, residual rows, join-window rows, closed-checker rows, obstruction row, and structural certificate rows before inspecting any local diamond conclusion.

Use Definition 4238.90 for the retained boundary. The rows P and O remain visible as load-bearing premises, so the handoff cannot be read as residual-substitution discharge, full Church–Rosser, subject reduction, evaluator equality, or kernel consistency. □

Theorem 4238.94 (MetaCIC parallel-diamond critical-pair join)**.** *Every accepted finite critical-pair envelope for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *whose residual rows pass the candidate diamond budget admits a displayed join route through the finite surface*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The route reads residual substitution from P, residual-row visibility from K and R, candidate-normalization from J, checker and bounded-budget rows from S, C, B, the retained obstruction from O, and then transport, replay, provenance, and local naming from H, T, G, N. The conclusion is a candidate-mediated local join for that displayed envelope, not a global confluence assumption, subject-reduction theorem, evaluator equality, quotient term equality, or kernel-consistency claim.

Proof. Project the accepted carrier from Definition 4238.1. The finite critical-pair envelope is visible only through $P, K, J, R, S, C, B, O, H, T, G, N$, so the candidate diamond budget is read as a condition on the displayed residual rows, not as a global confluence premise.

Split by the displayed residual envelope. In the cases where the residual rows fail the candidate budget, the theorem has no accepted join route to export. In the cases where the budget passes, the critical-pair row K and residual-frontier row R expose the two residual branches, while P keeps the residual-substitution premise visible.

Read the candidate-normalization and checker rows next. The candidate-join row J supplies the named local join proposal, and the rows S, C, B verify that the proposal stays inside the closed checker, closed-normal, and bounded-budget surface.

Finally apply the obstruction and structural rows. The retained obstruction O prevents the local join from being reread as Church–Rosser, subject reduction, evaluator equality, quotient equality, or kernel consistency, while H, T, G, N transport, replay, source, and name the same finite route. Thus the accepted envelope admits a displayed local join exactly through the candidate-mediated surface. □

Theorem 4238.95 (MetaCIC parallel-diamond frontier seed scope)**.** *Before any candidate-mediated strong-normalization route is exported from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet, the only seed-scope reads are finite critical-pair windows, residual substitution rows, candidate-normalization rows, and local join ledgers. In carrier notation these are the displayed rows $P, K, J, R, S, C, B, O, H,$ read as retained frontier data, not as subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, residual-substitution discharge, or kernel consistency.*

Proof. Project the accepted carrier from Definition 4238.1. The finite critical-pair windows are carried by K and R, the residual-substitution row remains P, and the candidate-normalization read is routed through J, C, B with the obstruction row O still visible.

Apply the seed-obligation and seed-readiness routes, Definition 4238.89 and Definition 4238.83. They force every public seed read through the displayed frontier rows before any confluence-audit or normalization-facing handoff can be inspected.

The local join ledger is then completed only by transport, replay, provenance, and naming rows H, T, G, N. Since no carrier coordinate exports subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, residual-substitution discharge, or kernel consistency, the stated rows are exactly the seed-scope reads available before the candidate-mediated strong-normalization route is exported. □

Theorem 4238.96 (MetaCIC parallel-diamond scoped-status route)**.** *The scoped closure status for an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet is witnessed by the finite dependency*

chain consisting of residual-substitution scope, premise preservation, critical-pair exhaustion, local-join scope, normalization-frontier handoff, candidate-mediated strong-normalization socket, typed-window candidate strong-normalization route, closed-substitution window scope, finite candidate strong-normalization extension, and residual-join induction. The chain exposes exactly the rows $P, K, J, R, S, C, B, O, H, T, G, N$ and does not assert residual-substitution compatibility, full parallel diamond, subject reduction, arbitrary closed Church–Rosser, evaluator equality, quotient equality of terms, or kernel consistency.

Proof. Start with residual-substitution scope and premise preservation, Definition 4238.12 and Definition 4238.23. They keep the premise row P attached to every critical-pair, residual-frontier, closed-checker, and closed-normal read.

Read critical-pair exhaustion and local-join scope through Definition 4238.4 and Definition 4238.31. These routes place the candidate join inside the displayed K, J, R, S, C, B, O rows before a confluence-facing consumer can inspect the packet.

Next apply the normalization-frontier handoff, candidate-mediated strong-normalization socket, and typed-window candidate route, Definition 4238.40, Definition 4238.41, and Definition 4238.42. Together they route every normalization-facing read through the same retained-premise frontier rather than through a global normalization theorem.

Finally use the closed-substitution window scope, finite candidate strong-normalization extension, and residual-join induction, Definition 4238.43, Definition 4238.44, and Definition 4238.46. The structural rows H, T, G, N transport, replay, source, and name the same finite packet, so the scoped-status evidence remains inside the displayed frontier rows and excludes the refused endpoints. □

Theorem 4238.97 (MetaCIC parallel-diamond obligation-status route)**.** *Every obligation-status read for an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must keep the residual-substitution premise P, critical-pair rows K, R, candidate join J, closed checker S, closed-normal fragment C, bounded check B, obstruction row O, transport row H, replay row T, provenance row G, and local name row N visible before any confluence-audit, decidability, or normalization consumer inspects the frontier. The route is a retained-premise obligation surface; it does not discharge subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, residual-substitution compatibility, or kernel consistency.*

Proof. Begin with the seed scope of Definition 4238.95. It fixes the visible frontier rows $P, K, J, R, S, C, B, O, H, T, G$ before any candidate-mediated strong-normalization route can be exported.

Apply the scoped-status route Definition 4238.96. The dependency chain it records already passes through residual-substitution scope, premise preservation, critical-pair exhaustion, local-join scope, normalization-frontier handoff, candidate-mediated strong-normalization, closed-substitution window scope, finite candidate extension, and residual-join induction.

Now read the candidate strong-normalization handoff and residual-join induction in that order. The handoff keeps the candidate join J, closed checker S, closed-normal fragment C, bounded check B, and obstruction row O attached to the same frontier, while the residual-join induction keeps the premise P and the critical-pair rows K, R visible.

Finally use the critical-path retained-premise handoff carried by the displayed transport, replay, provenance, and local naming rows H, T, G, N. These rows identify the same packet for downstream confluence-audit, decidability, and normalization consumers. Since no row exports subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, residual-substitution discharge, or kernel consistency, the obligation-status route remains the retained-premise surface stated above. □

Theorem 4238.98 (MetaCIC parallel-diamond retained-premise consumer route)**.** *Any normalization, confluence-audit, or decidability consumer citing an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must first read the retained premise row P, critical-pair rows K, R, candidate join J, closed checker S, normal fragment C, bounded check B, obstruction row O, and structural rows H, T, G, N. The citation is a finite retained-premise route through those displayed rows; it does not discharge residual substitution, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.*

Proof. Begin with the seed scope of Definition 4238.95. It fixes $P, K, J, R, S, C, B, O, H, T, G, N$ as the only rows visible before a candidate-mediated strong-normalization route is exported.

Apply the scoped-status route of Definition 4238.96. This keeps the residual-substitution premise P attached while the critical-pair rows K, R, candidate join J, closed checker S, normal fragment C, bounded check B, and obstruction row O are inspected.

Finally use the obligation-status route of Definition 4238.97. It requires the structural rows H, T, G, N before any downstream consumer treats the frontier as usable evidence, and it explicitly leaves residual-substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, and kernel consistency outside the packet. □

Theorem 4238.99 (MetaCIC parallel-diamond seed closure)**.** *Let $F = (P, K, J, R, S, C, B, O, H, T, G, N)$ be an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet. Any candidate-mediated strong-normalization handoff from F must first expose the critical-pair envelope, the residual-substitution dependency route, and the candidate-normalization scope rows of the same packet. More explicitly, the handoff reads K, J, R, S, C, B, O through the envelope of Definition 4238.50, retains P through the dependency route of Definition 4238.57, and keeps J inside the candidate-normalization scope of Definition 4238.62. The structural rows H, T, G, N preserve that same packet by* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming. The conclusion is only seed-level row visibility before the SN handoff; it proves no global normalization theorem, no unrestricted confluence theorem, no subject reduction theorem, no evaluator equality, no quotient term equality, and no kernel-consistency certificate.*

Proof. Begin with the critical-pair envelope. By Definition 4238.50, the packet exposes critical-pair requests only through the finite route $P, K, J, R, S, C, B, O, H, T, G, N$.

Next retain the residual-substitution dependency. The route of Definition 4238.57 places P before the local critical-pair, candidate-join, residual-frontier, closed-checker, and obstruction rows can be consumed.

Now constrain the candidate-normalization read. The scope theorem Definition 4238.62 keeps J inside the same conditional spine and prevents a candidate-mediated consumer from hiding P or O.

Finally compare with the SN handoff of Definition 4238.73. That theorem consumes the same envelope, dependency route, candidate-normalization scope, finite residual witness, and residual-row visibility surfaces. The present theorem isolates the seed-level visibility prerequisite: H, T, G, N preserve the displayed packet, but they do not discharge residual substitution or promote the handoff to global normalization, unrestricted confluence, subject reduction, evaluator equality, quotient equality, or kernel consistency. □

Theorem 4238.100 (MetaCIC parallel-diamond frontier closure seed route)**.** *Every seed-closure read for an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must expose the residual-substitution premise row, critical-pair row, candidate-join row, residual-frontier row, closed checker seal, closed-normal fragment, bounded-check row, and obstruction row before any conditional parallel-diamond*

route is consumed. The route is a finite seed surface for the local frontier; it does not prove residual substitution, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.

Proof. Project the carrier of Definition 4238.1. The residual-substitution premise, critical-pair data, candidate joins, residual frontier, closed checker, closed-normal fragment, bounded-check row, and obstruction row are displayed carrier coordinates before a confluence consumer can read any diamond-shaped conclusion.

Apply Definition 4238.2. The obligation surface requires carrier admission, row visibility, transport, replay, provenance, and local naming for exactly those finite frontier rows.

Use Definition 4238.3 and Definition 4238.50. These keep the conditional handoff downstream of the displayed critical-pair and residual rows, and they prevent the handoff from replacing the obstruction budget by a global confluence theorem.

Finally apply Definition 4238.6. The consumed route is therefore finite and seed-local: it records the displayed obstruction frontier and does not discharge residual substitution, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.101 (MetaCIC parallel-diamond frontier closure seed current route)**.** *The seed marker of* MetaCICParallelDiamondFrontier$^{\uparrow}$ *is readable only through the carrier of Definition 4238.1, the obligation surface of Definition 4238.2, and the closurestatus guard of Definition 4238.180. A status consumer must therefore expose the residual-substitution premise, critical-pair row, candidate-join row, bounded-check row, obstruction row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before it may treat the seed registration as available. The route does not claim subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Start with the carrier of Definition 4238.1. Its displayed coordinates contain the residual-substitution premise, critical-pair data, candidate joins, bounded checker, obstruction row, and structural rows that any seed reader must expose.

Apply the obligation surface of Definition 4238.2. It makes the visible rows the local NameCert inventory for the packet, so the seed marker cannot be consumed as an independent confluence theorem.

Finally read the closurestatus guard of Definition 4238.180. The guard routes every status reader through the same finite packet before seed or bridged markers are consumed, and the packet has no coordinate for subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.102 (MetaCIC parallel-diamond frontier closure route)**.** *The seed-facing* MetaCICParallelDiamondF *closure route is exactly the finite frontier route already recorded by the local residual-substitution premise, critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal, bounded-check, obstruction, transport, replay, provenance, and local naming rows. It is read through the retained premise boundary of Definition 4238.155, the seed closure route of Definition 4238.189, and the seed-status block of Definition 4238.205.*

The route records a finite seed surface only. It does not assert global confluence, subject reduction, evaluator equality, quotient term equality, residual-substitution discharge, unrestricted normalization, or kernel consistency.

Proof. Start with the retained premise boundary. It keeps the residual-substitution premise, critical-pair, closed-checker, closed-normal, bounded-check, obstruction, transport, replay, prove-

nance, and local naming rows visible whenever the candidate join and residual frontier are consumed.

Next read the seed closure route. That theorem attaches the same local rows to the critical-pair envelope, residual-join locality route, retained-premise budget, local NameCert obligations, seed-status row, closurestatus export, and closurestatus guard. Thus the child ledger has a single ordered seed route rather than separate hidden assumptions.

Finally apply the seed-status block. It identifies the seed-facing status read with the displayed route $P, K, J, R, S, C, B, O, H, T, G, N$, so the chapter's closure surface records only the finite frontier rows already available in the local packet.

Because every cited step remains inside the displayed route, none of the refused global endpoints is exported by the closure record. □

Theorem 4238.103 (MetaCIC parallel-diamond scoped seed package route)**.** *The hub-level scoped marker for* MetaCICParallelDiamondFrontier$^{\uparrow}$ *is read through the same finite seed package exposed by the spine: residual-substitution premise rows, critical-pair rows, candidate-join rows, residual-frontier rows, closed-checker rows, closed-normal fragment rows, bounded-check rows, obstruction rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The route records the seed-status package already scoped by Definition 4238.48; it does not add subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, residual-substitution discharge, or kernel consistency.*

Proof. Read the scoped closure status theorem in the spine. It identifies the accepted packet by the finite route through $P, K, J, R, S, C, B, O, H, T, G, N$ and refuses the global confluence and kernel endpoints.

The hub marker is therefore a route into that same package rather than a second closure claim. It first records the residual-substitution premise, critical-pair, candidate, residual-frontier, checker, normal-fragment, bounded-check, and obstruction rows.

Finally the structural rows transport, replay, source, and name the packet. Thus the scoped marker is accounted for by a concrete child ledger while the top-level file remains structural. □

Theorem 4238.104 (MetaCIC parallel-diamond frontier residual-join locality)**.** *Every accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *residual join is read through the local frontier route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The read must first expose the critical-pair envelope of Definition 4238.50, the residual-substitution dependency route of Definition 4238.57, the candidate-normalization scope of Definition 4238.62, the finite residual witness consumption row of Definition 4238.69, and the carrier-local NameCert *row of Definition 4238.2. It exports only a bounded residual-join locality certificate for the displayed packet, not global confluence, unbounded normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency.*

Lean4 ✓ `BEDC.Derived.MetaCICParallelDiamondFrontierUp.MetacicParallelDiamondFrontierResidualJoinLocalit`

Proof. Project the accepted frontier carrier of Definition 4238.1. The only rows available to a residual-join consumer are the finite packet rows $P, K, J, R, S, C, B, O, H, T, G, N$.

Read the critical-pair and residual-substitution rows first. The critical-pair envelope keeps K, J, R, S, C, B, O visible, while the dependency route places the retained residual-substitution premise P before any local join can be consumed.

Next read candidate normalization and finite residual witnesses. The candidate-normalization scope keeps J inside the same conditional spine, and the finite residual witness theorem consumes typed windows, residual frontier data, bounded checker rows, transport, replay, provenance, and local naming before a closed parallel-diamond route can inspect the join.

Finally use the local NameCert obligation surface. Since H, T, G, N preserve only this finite packet and the obstruction row O remains visible, the residual join is local to the displayed frontier and cannot be promoted to global confluence, unbounded normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.105 (MetaCIC parallel-diamond residual-join locality budget)**.** *Every accepted residual-join locality read for a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet keeps the residual premise row P, critical-pair row K, candidate-join row J, residual witness row R, typed-window row S, bounded checker row B, obstruction row O, componentwise* hsame *transport H, displayed* Cont *replay T,* Pkg *provenance G, and local* NameCert *row N inside the displayed finite packet before any normalization or confluence consumer reads it. The budget is*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

and it exports no residual-substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with residual-join locality, Definition 4238.104. It already forces every join read through the displayed frontier rows and keeps the retained premise and obstruction rows visible.

Next use finite residual witness consumption, Definition 4238.69. That route requires the typed windows, residual witness data, bounded checker rows, transport, replay, provenance, and local naming to be exposed before a local join is available to a downstream consumer.

The two routes combine as a finite budget. Rows P, K, J, R, S, C, B, O remain the residual, critical-pair, candidate-join, witness, window, certificate, checker, and obstruction surface, while H, T, G, N preserve the same packet under transport, replay, provenance, and local naming.

Since the carrier contains no coordinate for residual-substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, or kernel consistency, a normalization or confluence consumer can read only the displayed finite budget. □

Theorem 4238.106 (MetaCIC parallel-diamond residual-substitution window)**.** *Every candidate-mediated parallel-diamond read that invokes residual substitution must first display the critical-pair envelope, residual-substitution dependency row, finite residual witness, residual-join locality row, and candidate-normalization row before any strong-normalization or confluence-facing handoff is public. The public window is the carrier-local route*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

not a hidden substitution oracle, unrestricted confluence theorem, host conversion equality, subject-reduction theorem, evaluator equality, quotient term equality, or kernel consistency.

Proof. Begin with the local residual-join route of Definition 4238.104. It forces the accepted read through the displayed frontier rows and keeps the obstruction row visible.

Read the critical-pair and residual-substitution rows next. The critical-pair envelope of Definition 4238.50 exposes the bounded overlap data, while the residual-substitution dependency route of Definition 4238.57 keeps the premise row P in the carrier-local window.

Now attach the finite residual witness and candidate-normalization scope rows. The finite residual witness consumption theorem keeps the typed windows, residual witness data, bounded checker rows, transport, replay, provenance, and local naming visible, and Definition 4238.62 keeps the candidate join inside the same conditional spine.

These rows compose to exactly the displayed residual-substitution window. Since the accepted packet contains no coordinate for a substitution oracle, unrestricted confluence theorem, host conversion equality, subject reduction, evaluator equality, quotient term equality, or kernel consistency, no such handoff is exported. □

Theorem 4238.107 (MetaCIC parallel-diamond residual grid)**.** *Every accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *residual-join consumer receives a finite grid whose rows are the critical-pair envelope, residual-substitution dependency, candidate-normalization scope, finite residual witness, carrier-local* NameCert*,* hsame *transport,* Cont *replay, and* Pkg *provenance rows before any local diamond handoff is exported. The grid is the displayed packet*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

not a global confluence theorem, strong-normalization theorem, subject-reduction theorem, quotient term equality, or evaluator equality.

Proof. Begin with Definition 4238.104. It already forces a residual-join read through $P, K, J, R, S, C, B, O, H, T, G,$ and refuses to promote the local route to global confluence or unbounded normalization.

Now refine the local route into grid rows. The critical-pair envelope of Definition 4238.50 supplies the bounded overlap row, the residual-substitution dependency route of Definition 4238.57 places P before any join handoff, the candidate-normalization scope of Definition 4238.62 keeps J inside the conditional spine, and finite residual witness consumption from Definition 4238.69 supplies the typed-window and bounded-check rows.

Finally attach the carrier-local NameCert row and structural rows. The obligation theorem Definition 4238.2 supplies the local naming surface, while H, T, G, N transport, replay, source, and name the same carrier. Since every grid row is finite and carrier-local, the exported handoff cannot become strong normalization, subject reduction, quotient term equality, evaluator equality, or kernel consistency. □

Theorem 4238.108 (MetaCIC parallel-diamond residual-join locality scope)**.** *The residual-join locality surface of an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet is scoped exactly by the finite rows*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The rows P, K, J, R, S, C, B, O are the BHist*-visible confluence-frontier rows for residual premises, critical pairs, local join requests, typed windows, residual witnesses, bounded checker data, boundary certificates, and visible obstructions. The rows H, T, G, N are precisely the* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows for that same packet. No residual-join locality read exports global confluence, subject reduction, evaluator equality, quotient term equality, kernel consistency, or premise-free residual substitution.*

Proof. Begin with Definition 4238.104. It already forces every residual-join read through the displayed frontier rows and keeps the obstruction row visible.

Refine the route by Definition 4238.107. The grid separates the confluence-facing rows P, K, J, R, S, C, B, O from the structural rows H, T, G, N, while keeping both groups inside one finite packet.

Now apply the seed obligations and carrier obligations. The critical-pair envelope, residual-substitution dependency route, candidate-normalization scope, finite residual witness consumption, and carrier-local NameCert obligation theorem provide no extra coordinate beyond the rows displayed above.

Therefore a consumer that has read $P, K, J, R, S, C, B, O, H, T, G, N$ has exhausted the residual-join locality surface. A request for global confluence, subject reduction, evaluator equality, quotient term equality, kernel consistency, or premise-free residual substitution would require a carrier coordinate that the packet does not contain. □

Theorem 4238.109 (MetaCIC parallel-diamond scoped residual locality)**.** *Any accepted residual join in a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose, before a local diamond read is public, the residual-substitution premise row P, the critical-pair row K, the candidate-join row J, the residual-frontier row R, the bounded checker row B, componentwise* hsame *transport H, displayed* Cont *replay T,* Pkg *provenance G, and the local* NameCert *row N. The read is a scoped residual-locality certificate over*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

not full Church–Rosser, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. Begin with residual-join locality and the residual grid, Definition 4238.104 and Definition 4238.107. These force the accepted join to pass through the displayed residual-substitution premise, critical-pair envelope, candidate join, finite residual witness, bounded checker, transport, replay, provenance, and local naming rows.

Next use the locality-scope theorem, Definition 4238.108. It identifies the residual-frontier and obstruction rows as part of the same finite carrier-local surface rather than as hidden global assumptions.

Finally apply finite residual witness consumption and residual-join witness locality, Definition 4238.69 and Definition 4238.116. They make the bounded checker rows visible before the local join can be exported and keep P and O inside the structural rows H, T, G, N.

Since the carrier contains only the displayed finite rows, the public read remains a local diamond certificate. Full Church–Rosser, subject reduction, evaluator equality, quotient term equality, and kernel consistency would require coordinates not present in the packet. □

Theorem 4238.110 (MetaCIC parallel-diamond residual-join locality exhaustion)**.** *A residual-join consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet that has read*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

has exhausted the carrier-local join surface. Any request for global confluence, subject reduction, unbounded normalization, evaluator equality, quotient term equality, or kernel consistency is outside the packet.

Proof. Apply Definition 4238.104. It forces every residual-join read through the displayed local frontier route and keeps the obstruction row visible.

Then apply Definition 4238.107. The grid identifies the critical-pair, residual-substitution, candidate-normalization, finite-witness, transport, replay, provenance, and local naming rows as the whole carrier-local residual surface.

Finally use the carrier-local NameCert obligation theorem Definition 4238.2. Since that obligation surface admits no coordinate for global confluence, subject reduction, unbounded normalization, evaluator equality, quotient term equality, or kernel consistency, a consumer that has read the grid has no further join row to project. □

Theorem 4238.111 (MetaCIC parallel-diamond residual obstruction budget)**.** *Any candidate-mediated residual join in an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet that consumes the local join row J and bounded checker rows must keep both the retained premise row P and the obstruction row O visible through the structural rows H, T, G, N. The handoff is only a bounded residual-join locality budget for*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

It cannot be read as residual-substitution discharge, subject reduction, global confluence, strong normalization, evaluator equality, quotient term equality, or kernel consistency.

Proof. Begin with residual-join locality, Definition 4238.104. It forces every candidate-mediated join to read the displayed frontier rows and keeps the obstruction coordinate inside the same packet.

Use the residual grid theorem, Definition 4238.107. The grid separates the retained premise, critical-pair, local join, residual witness, bounded checker, and obstruction rows from the transport, replay, provenance, and local naming rows.

Now apply the locality-scope theorem, Definition 4238.108. It identifies P and O as visible rows of the residual-join surface rather than side conditions that can be discharged after J is consumed.

Finally use residual-join locality exhaustion. Once the consumer has read $P, K, J, R, S, C, B, O, H, T, G, N$, there is no further coordinate for residual-substitution discharge, subject reduction, confluence, normalization, evaluator equality, quotient term equality, or kernel consistency. The obstruction budget is therefore retained as a carrier-local boundary. □

Theorem 4238.112 (MetaCIC parallel-diamond residual-premise exhaustion)**.** *Any accepted residual-join read of a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet that has consumed*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

has not discharged the retained premise row P. It has only made P visible as part of the finite carrier-local grid for the residual join. Consequently the read cannot be used as premise-free residual substitution, subject reduction, global confluence, strong normalization, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with residual-join locality and the residual grid, Definition 4238.104 and Definition 4238.107. These place every accepted join inside the displayed carrier-local rows and identify P as a row of that grid, not as a premise erased by the join handoff.

Apply the locality-scope theorem and the residual obstruction budget, Definition 4238.108 and Definition 4238.111. They keep the retained premise row and obstruction row visible through H, T, G, N after the local join and bounded checker rows have been read.

Finally use residual-join witness locality, Definition 4238.116. The witness consumes finite residual data before exporting the local join, but it does not add any coordinate for premise-free residual substitution, subject reduction, global confluence, strong normalization, evaluator equality, quotient term equality, or kernel consistency. The consumed packet therefore exhausts visibility of the retained premise rather than discharging it. □

Theorem 4238.113 (MetaCIC parallel-diamond residual-premise transport exhaustion)**.** *An accepted residual-join read of a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet transports retained premises only through the displayed residual locality route, candidate-normalization scope, finite residual witness consumption rows, and critical-pair envelope rows. After the read has consumed*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

the transported premise surface is exhausted. No consumer can extend the read to residual-substitution discharge, subject reduction, quotient equality, evaluator equality, global confluence, strong normalization, or kernel consistency.

Proof. Project the accepted carrier through the residual-premise exhaustion theorem, Definition 4238.112. It identifies P as a retained premise row inside the finite grid rather than as a discharged assumption.

Next read the locality and normalization rows. Residual-join locality, Definition 4238.104, keeps the premise inside the displayed frontier route, while candidate-normalization scope from Definition 4238.62 keeps the candidate join in the same conditional spine.

Now consume the finite witness and critical-pair rows. The finite residual witness theorem Definition 4238.69 exposes the bounded residual data before the local join is available, and the critical-pair envelope of Definition 4238.50 keeps the overlap rows inside the same carrier-local packet.

Finally inspect the carrier rows that remain after transport through H, T, G, N. They replay and name only the displayed packet $P, K, J, R, S, C, B, O, H, T, G, N$. Since the carrier has no coordinate for residual-substitution discharge, subject reduction, quotient equality, evaluator equality, global confluence, strong normalization, or kernel consistency, the premise transport is exhausted at that boundary. □

Theorem 4238.114 (MetaCIC parallel-diamond frontier residual local confluence)**.** *Let an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet expose the finite rows*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

If the bounded checker rows accept both residual branches from the displayed critical-pair and residual-premise surface, then the consumer receives a carrier-local diamond handoff between the two residual endpoints through the displayed candidate join row J. The handoff is bounded by the same packet rows and does not claim global confluence, strong normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. First read the residual grid of Definition 4238.107. It exposes the critical-pair envelope, residual-substitution dependency, candidate-normalization scope, finite residual witness, local NameCert row, transport, replay, and provenance as one finite packet.

Next apply residual-premise transport exhaustion, Definition 4238.113. It keeps the transported premise surface inside $P, K, J, R, S, C, B, O, H, T, G, N$ after both residual branches have been checked.

Now consume the finite witness and checker rows using Definition 4238.69. The bounded witness exposes the two residual endpoints before the candidate join row can be handed to a consumer.

Finally apply residual-join witness locality, Definition 4238.116. It keeps J carrier-local, retains P and O through H, T, G, N, and prevents the bounded handoff from becoming global confluence, strong normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.115 (MetaCIC parallel-diamond candidate-mediated strong-normalization extension)**.** *Let an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet expose the residual rows*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

Suppose a finite candidate packet reads its residual-premise row through Definition 4238.112 and its residual-join row through Definition 4238.104. Then the packet extends along the candidate-mediated frontier without leaving the same finite residual budget. A strong-normalization-facing handoff may consume the local diamond row J together with $P, K, R, S, C, B, O, H, T, G, N$ rather than selecting global normal forms.

Proof. First read residual-premise exhaustion. It keeps P as a retained premise row inside the displayed residual grid, so the candidate packet cannot erase the premise before the strong-normalization-facing handoff is formed.

Next apply residual-join locality and residual-premise transport exhaustion. These rows keep the candidate join J, residual frontier rows, checker rows, and obstruction row inside the same packet after transport through H, T, G, N.

Now consume the finite residual witness using Definition 4238.69. The witness exposes the bounded residual data and checker rows before the local diamond can be exported.

Finally apply residual local confluence, Definition 4238.114. The local diamond row is already a carrier-local handoff over the finite residual budget, so a strong-normalization-facing consumer receives that displayed row rather than a selected global normal form. □

Theorem 4238.116 (MetaCIC parallel-diamond residual-join witness locality)**.** *Every accepted residual-join witness for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *must read the finite residual witness row and the bounded checker rows before exporting the local join row. The read retains both the premise row P and the obstruction row O through the structural rows H, T, G, N, so its carrier surface is still*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

It does not discharge residual substitution, subject reduction, global confluence, strong normalization, evaluator equality, quotient term equality, or kernel consistency.

Proof. First apply finite residual witness consumption, Definition 4238.69. The witness read is forced through typed windows, residual witness data, bounded checker rows, transport, replay, provenance, and local naming before any local join row is exported.

Next apply residual-join locality and the residual grid, Definition 4238.104 and Definition 4238.107. These results place the join in the displayed finite route and keep the premise row P inside the same carrier-local grid as the critical-pair, witness, checker, and obstruction rows.

Finally apply the residual obstruction budget, Definition 4238.111. It keeps O visible through H, T, G, N and prevents the local join witness from being read as residual-substitution discharge, subject reduction, global confluence, strong normalization, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.117 (MetaCIC parallel-diamond residual-join locality budget)**.** *Every accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *residual-join consumer must expose the critical-pair envelope, residual-substitution dependency row, candidate-normalization scope, finite residual witness, and local join rows before any parallel-diamond handoff is public. The exposed packet is the finite route*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

with P retaining the premise dependency, K carrying the critical-pair envelope, J naming the local join request, R, S, C, B carrying the residual witness and bounded checker rows, O keeping the visible obstruction row, and H, T, G, N supplying transport, replay, provenance, and local naming.

The budget exports only carrier-local residual-join readability for this displayed frontier. It exports no global confluence theorem, strong-normalization theorem, unrestricted conversion decision, subject-reduction theorem, evaluator equality, quotient term equality, residual-substitution discharge, or kernel consistency.

Proof. Project the existing hub route order. The critical-pair envelope is introduced before residual-substitution dependency, so any consumer that reaches a residual join has already read the bounded overlap data and the retained premise row.

Next read the candidate-normalization scope and finite residual witness files. Their rows keep the candidate join inside the displayed conditional spine and require the residual witness and bounded checker data before the local join can be consumed.

Finally apply residual-join locality and its grid, scope, exhaustion, obstruction-budget, and witness-locality refinements. Those child files identify $P, K, J, R, S, C, B, O, H, T, G, N$ as the complete local surface and keep the obstruction row visible. Since no child in this route exports a global confluence, normalization, conversion, subject-reduction, evaluator, quotient, substitution-discharge, or consistency coordinate, the handoff remains a carrier-local budget. □

Theorem 4238.118 (MetaCIC parallel-diamond frontier residual budget handoff)**.** *Every candidate-normalization or confluence-audit consumer of the local residual-join budget must keep the critical-pair envelope, residual-substitution dependency, obstruction row, and bounded normalization window visible before reading the candidate-mediated diamond. The handoff surface is the same displayed packet*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

with P retaining the residual-substitution premise, K carrying the critical-pair envelope, O retaining the refused endpoint row, and B, S, C carrying the bounded checker and normalization window.

The handoff exports only this local residual budget. It does not claim global strong normalization, unrestricted confluence, subject reduction, evaluator equality, quotient term equality, residual-substitution discharge, or kernel consistency.

Proof. Start with the residual-join locality budget of Definition 4238.117. It already requires the critical-pair envelope, residual-substitution dependency row, finite residual witness, obstruction row, and bounded checker rows to remain visible before the residual join can be consumed.

Next use premise retention, Definition 4238.13. The retained premise row P stays attached to the candidate-mediated handoff, so a normalization-facing consumer cannot silently replace residual substitution by a discharged global theorem.

Finally apply the critical-path retained-premise handoff, Definition 4238.85. It keeps P and O visible when the route is read by confluence-audit and normalization consumers. The bounded window rows B, S, C therefore remain part of the exported packet, and the refused global endpoints remain outside the handoff. □

Theorem 4238.119 (MetaCIC parallel-diamond residual-join locality consumption)**.** *Any candidate-mediated parallel-diamond consumer of a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must read the critical-pair envelope, residual-substitution dependency, residual-join locality rows, candidate normalization scope, and finite residual witness ledger before consuming the frontier* $\mathsf{NameCert}$ *row. The consumed route is the displayed carrier-local spine*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

where P retains the residual-substitution premise, K, J, R expose the critical-pair and candidate rows, S, C, B, O expose the typed window, residual witness, bounded checker, and obstruction rows, and H, T, G, N provide transport, replay, provenance, and local naming. The consumer receives only this finite residual-locality budget, not global confluence, subject reduction, evaluator equality, quotient term equality, premise-free residual substitution, or kernel consistency.

Proof. First read the critical-pair envelope of Definition 4238.50. It exposes the bounded overlap rows before any candidate-mediated join can be consumed.

Next read the residual-substitution dependency route of Definition 4238.57. This keeps the retained premise row P inside the same finite packet while the candidate join and residual frontier rows are opened.

Now consume the residual-join locality rows of Definition 4238.104 and the budget of Definition 4238.117. These identify $P, K, J, R, S, C, B, O, H, T, G, N$ as the carrier-local residual surface and keep the obstruction row visible.

Finally attach the candidate-normalization scope of Definition 4238.62 and finite residual witness consumption from Definition 4238.69. The candidate row and bounded witness ledger are therefore read before the frontier NameCert row, so the exported handoff remains the displayed residual-locality budget rather than a global confluence, subject-reduction, evaluator-equality, quotient-equality, substitution-discharge, or consistency theorem. □

Theorem 4238.120 (MetaCIC residual-join candidate seed-status route)**.** *Every seed-status reader for* MetaCICParallelDiamondFrontier$^{\uparrow}$ *that consumes residual-join evidence and candidate-normalization evidence must read them inside the same parallel-diamond packet*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The route uses the residual-join locality rows, candidate-normalization scope rows, and parallel-diamond seed-status rows as seedClosure evidence for the hub. It does not discharge residual substitution, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Project the accepted frontier packet. The residual-join rows J, R, S are exposed only with the retained premise row P, critical-pair row K, bounded checker row B, obstruction row O, and structural rows H, T, G, N still visible.

Read the candidate-normalization scope next. It keeps the candidate row inside the same spine $P, K, J, R, S, C, B, O, H, T, G, N$ and prevents the candidate read from becoming a premise-free normalization or confluence theorem.

Finally apply the parallel-diamond seed-status route. The seed status exported to the hub is exactly the displayed packet assembled from residual-join locality, candidate normalization, finite residual witnesses, transport, replay, provenance, and local naming, so the hub records seedClosure evidence without adding theorem content of its own. □

Theorem 4238.121 (MetaCIC parallel-diamond residual-choice boundary)**.** *Every candidate-mediated parallel-diamond read of an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet consumes residual choice only as a displayed finite ledger row on the route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The residual-choice row is read after the critical-pair envelope and before the residual-join handoff: the critical-pair rows K, J and residual-substitution premise P expose the finite envelope, the residual ledger keeps the chosen residual windows visible, and the residual join is consumed only through

the same bounded frontier. The boundary does not provide host choice, global confluence, strong normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with the critical-pair envelope of Definition 4238.50. It exposes candidate rows and residual-substitution data as part of one finite frontier route before any parallel-diamond request may be consumed.

Next use the residual-substitution dependency route of Definition 4238.57. That route keeps the retained premise P visible before the critical-pair, candidate-join, residual-frontier, closed-checker, and obstruction rows.

Apply finite residual witness consumption from Definition 4238.69. The local residual witness is consumed through $P, K, J, R, S, C, B, O, H, T, G, N$, so the residual-choice row is a displayed finite ledger entry rather than an external selector.

Finally attach the retained-premise boundary of Definition 4238.158. It keeps the premise, candidate-normalization scope, residual-substitution route, finite residual witness, transport, replay, provenance, and local naming visible before the residual join. Since no cited row stores host choice, global confluence, strong normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency, none of those endpoints is exported by the residual-choice boundary. □

Definition 4238.122 (MetaCIC finite residual-diamond ledger carrier)**.** *A finite residual-diamond ledger for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *is a carrier-local subpacket*

$$\Lambda = (K, P, J, B, O, H, T, G, N)$$

read from an accepted frontier packet $F = (P, K, J, R, S, C, B, O, H, T, G, N)$ *with the following displayed rows:*

1. *K is the critical-pair source row naming the bounded local peak under inspection.*
2. *P is the retained residual-substitution premise row attached to that source.*
3. *J is the candidate join witness row, read only as a proposed local join for the displayed peak.*
4. *B is the bounded checker status row for the finite residual diamond request.*
5. *O is the obstruction-retention row recording any still-visible blocker to an unconditional handoff.*
6. *H records componentwise* hsame *transport for the ledger rows.*
7. *T records displayed* Cont *replay for the same finite residual request.*
8. *G is the* Pkg *provenance row for the frontier packet and its sibling confluence consumers.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}}$ *row naming the ledger as carrier-local data.*

The ledger stores no premise-free confluence theorem, no subject-reduction theorem, no evaluator equality, no quotient term equality, and no kernel-consistency certificate.

Theorem 4238.123 (MetaCIC finite residual-diamond ledger local join obligations)**.** *Every local residual-diamond read of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet factors through a finite ledger* $\Lambda = (K, P, J, B, O, H, T, G, N)$ *of Definition 4238.122. The read may cite the ledger as bounded local join evidence under the retained residual-substitution premise and visible obstruction row, but it cannot be cited as an unconditional parallel diamond, full Church–Rosser theorem, subject-reduction theorem, evaluator equality, quotient term equality, or kernel-consistency certificate.*

Proof. Start with the critical-pair envelope of Definition 4238.50. It supplies the bounded source row K and keeps the peak inside the finite frontier packet.

Next read the residual-substitution dependency route of Definition 4238.57. This places the retained premise row P before the candidate join can be consumed, so the ledger cannot erase the premise.

Now use the candidate diamond budget route of Definition 4238.66 together with residual-join locality, Definition 4238.104. These rows expose the candidate join J and bounded checker status B only as a local finite route through the accepted frontier.

Finally apply the retained-premise closure budget of Definition 4238.150. The obstruction row O and structural rows H, T, G, N remain displayed, so the resulting ledger is a bounded residual-diamond obligation surface rather than any of the refused global confluence or kernel endpoints. □

Theorem 4238.124 (MetaCIC frontier seed ledger)**.** *An accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *frontier packet exposes a finite seed ledger*

$$\Sigma = (K, J, R, S, B, O, H, T, G, N)$$

before any residual-join or parallel-diamond read becomes public. The ledger reads the critical-pair row K, candidate join row J, residual-frontier row R, seed-readiness row S, bounded checker row B, obstruction row O, hsame *transport row H,* Cont *replay row T,* Pkg *provenance row G, and local* NameCert *row N through the existing MetaCIC frontier rows. It is only a seed ledger for finite residual-join inspection, not a premise-free confluence theorem, subject-reduction theorem, evaluator equality, quotient term equality, or kernel-consistency certificate.*

Proof. Start with the seed package register of Definition 4238.82 and the seed readiness row of Definition 4238.83. These rows expose K, J, R, S, B, O as finite frontier data for a bounded residual-join request.

Next use the residual join seed interface of Definition 4238.130. It keeps the candidate join and residual frontier inside the same seed packet rather than turning them into an unconditional parallel diamond.

Finally apply the structural rows supplied by Definition 4238.103. The rows H, T, G, N transport, replay, package, and name the same finite seed ledger, so public consumers receive only the displayed residual-join ledger and none of the refused global endpoints. □

Theorem 4238.125 (MetaCIC parallel-diamond frontier residual scope)**.** *Every residual-scope consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must preserve the finite rows*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The consumer may read residual-join locality, the residual grid, locality scope, and the obstruction budget, but it may not discharge residual substitution, subject reduction, global confluence, evaluator equality, quotient term equality, or kernel consistency.

Proof. Begin with residual-join locality, Definition 4238.104. It forces every residual-join read through the displayed frontier rows and keeps the packet local to the accepted carrier.

Refine the consumer route through the residual grid and locality scope, Definition 4238.107 and Definition 4238.108. These theorems separate the residual-facing rows P, K, J, R, S, C, B, O from the structural rows H, T, G, N while keeping both groups inside one finite packet.

Finally apply the residual obstruction budget, Definition 4238.111. It keeps the retained premise and obstruction rows visible, so a residual-scope consumer has no route to discharge residual substitution or to promote the local frontier to subject reduction, global confluence, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.126 (MetaCIC parallel-diamond residual-normalization window)**.** *Every accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet whose displayed rows expose*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

may hand a candidate-mediated residual peak to a normalization consumer only through the retained residual-substitution premise row P, the candidate-normalization row J, the residual-frontier row R, the closed-checker and closed-normal rows S, C, and the obstruction row O, with the structural rows H, T, G, N still visible. The window does not prove strong normalization, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, or kernel consistency.

Proof. Project the carrier of Definition 4238.1. Its public rows expose the residual-substitution premise, critical-pair data, candidate-normalization row, residual-frontier row, closed-checker row, closed-normal row, bounded-check row, obstruction row, transport, replay, provenance, and local naming.

Use the candidate-normalization scope of Definition 4238.62. It forces a normalization-facing read of J to keep P and O visible and to remain inside the same finite spine.

Next consume the finite residual witness and candidate-mediated strong-normalization handoff, Definition 4238.69 and Definition 4238.73. These rows allow a residual peak to be presented to the consumer only after R, S, C and the bounded obstruction data have been displayed.

Finally apply residual-join locality, Definition 4238.104. Since the obstruction row remains retained and no carrier coordinate discharges P or promotes J to a global theorem, the exported object is only the stated residual-normalization window. □

Theorem 4238.127 (MetaCIC parallel-diamond seed boundary)**.** *Every seed-level read of an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet may expose candidate-mediated residual peaks only while the residual-substitution premise row P, candidate-normalization row J, obstruction row O, closed-checker rows S, C, B, componentwise* hsame *transport H, displayed* Cont *replay T,* Pkg *provenance G, and local* NameCert *row N remain visible in the same finite carrier. The boundary is a local seed surface for residual normalization; it is not strong normalization, unrestricted confluence, quotient term equality, evaluator equality, subject reduction, residual-substitution discharge, or kernel consistency.*

Proof. Apply the residual-normalization window theorem, Definition 4238.126. It already places every normalization-facing residual peak behind the retained residual-substitution premise, candidate-normalization row, residual-frontier row, closed checker and closed-normal rows, obstruction row, and structural rows.

Next use the candidate-normalization scope of Definition 4238.62 and the candidate-mediated strong-normalization handoff of Definition 4238.73. These prevent the candidate row from becoming a premise-free normalization theorem and keep the candidate-mediated route inside the displayed frontier carrier.

Finally read the residual-substitution dependency route and obstruction ledgers. The premise row P and obstruction row O remain visible through hsame transport, Cont replay, Pkg provenance, and the local NameCert row. Since no listed row discharges those boundaries, the exposed seed remains only the stated local residual-normalization surface. □

Theorem 4238.128 (MetaCIC parallel-diamond residual-normalization scope)**.** *Any residual-join read from an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must consume the critical-pair envelope, candidate-normalization row, residual-substitution row, finite residual witness, and candidate-SN handoff before it exports a diamond-frontier budget. The exported budget is the finite route*

through

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

with the residual-substitution premise and obstruction rows still visible; it is not a premise-free parallel diamond, full normalization theorem, subject-reduction theorem, evaluator equality, quotient equality of terms, or kernel-consistency certificate.

Proof. First read the critical-pair envelope of Definition 4238.50. It fixes the local pair inside the displayed rows $P, K, J, R, S, C, B, O, H, T, G, N$ and keeps the bounded overlap surface visible.

Next consume the candidate-normalization scope of Definition 4238.62 together with the residual-substitution dependency route of Definition 4238.57. These rows place J under the retained premise P rather than turning candidate normalization into an unconditional confluence result.

Now apply finite residual witness consumption, Definition 4238.69. The finite witness must read the typed window, residual frontier, substitution-boundary row, checker rows, transport, replay, provenance, and local naming before a closed parallel-diamond route can inspect it.

Finally use the candidate-SN handoff of Definition 4238.73. The handoff packages the same conditional spine as a diamond-frontier budget, so the exported object still retains P and O and cannot be reread as full normalization, subject reduction, evaluator equality, quotient equality, or kernel consistency. □

Theorem 4238.129 (MetaCIC residual-substitution discharge boundary)**.** *Let $F = (P, K, J, R, S, C, B, O, H, T, G$ be an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet. A residual-normalization read from F may discharge only the local residual-substitution boundary rows already displayed by the packet: the critical-pair envelope, candidate-normalization scope, residual-substitution dependency route, finite residual witness, and candidate-SN handoff. The discharge does not export subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.*

Proof. Begin with the critical-pair envelope of Definition 4238.50. It keeps the local overlap inside the finite rows $P, K, J, R, S, C, B, O, H, T, G, N$ and prevents the read from erasing the retained residual-substitution premise.

Next combine the candidate-normalization scope of Definition 4238.62 with the residual-substitution dependency route of Definition 4238.57. These two rows allow the candidate read to discharge only the displayed local boundary, with P still visible as the premise row for the residual route.

Now consume the finite residual witness from Definition 4238.69. The witness is finite data in the same packet, so it can certify the local residual-normalization handoff without becoming a global equality or subject-reduction theorem.

Finally apply the candidate-SN handoff of Definition 4238.73. That handoff packages the preceding rows as a candidate-mediated boundary discharge, and none of the six refused exports appears as a coordinate of the carrier. □

Theorem 4238.130 (MetaCIC residual-join seed interface)**.** *Every seed-level diamond frontier consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet that reads residual joins must first display the critical-pair envelope, candidate-normalization scope, residual-substitution dependency route, finite residual witness, and candidate strong-normalization handoff. Concretely, the read must pass through Definition 4238.50, Definition 4238.62, Definition 4238.57, Definition 4238.69, and Definition 4238.73 before the packet is available as a seed interface. The exported seed read is therefore a displayed residual-join interface over the finite frontier spine, not a premise-free confluence theorem, global normalization theorem, subject-reduction theorem, host reduction equality, or kernel-consistency certificate.*

Proof. Start with the critical-pair envelope. The envelope theorem keeps the rows $P, K, J, R, S, C, B, O, H, T, G, N$ visible before a parallel-diamond request can be read, so the seed consumer receives a bounded frontier packet rather than an unrestricted confluence surface.

Next read the candidate-normalization and residual-substitution routes. The candidate-normalization scope keeps J inside the conditional spine, while the residual-substitution dependency route keeps the retained premise and residual windows attached to the same packet.

Now expose the finite residual witness and the candidate strong-normalization handoff. The finite witness theorem supplies the bounded residual rows consumed by the frontier, and the candidate handoff states the normalization-facing read available from those same rows.

Thus any seed-level residual-join consumer has displayed the five interface faces before reading the packet. Since none of those faces exports premise-free confluence, global normalization, subject reduction, host reduction equality, or kernel consistency, the seed interface remains exactly the finite residual-join route stated above. □

Theorem 4238.131 (MetaCIC residual-join seed scope)**.** *Every residual-join seed read of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet factors through residual-substitution premise rows, critical-pair rows, candidate-join rows, residual-frontier rows, closed-checker rows, obstruction rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. The seed read is therefore a finite residual-join scope for the parallel-diamond frontier, not a subject-reduction theorem, arbitrary Church–Rosser theorem, quotient term equality, or evaluator equality row.*

Proof. Start with the residual-substitution dependency route and the critical-pair envelope. The dependency route keeps the retained substitution premise visible, while Definition 4238.50 exposes the critical-pair rows before any diamond request is read.

Next read the candidate diamond budget route. It displays the candidate-join rows and keeps them tied to the same finite frontier rather than to an unrestricted Church–Rosser surface.

Now use the finite residual witness consumption route. The residual-frontier and closed-checker rows are consumed only after the finite witness rows have been displayed, so the obstruction rows remain part of the same seed scope.

The structural rows supply componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming. Since the cited routes contain no subject-reduction, arbitrary Church–Rosser, quotient term equality, or evaluator equality coordinate, the residual-join seed read exports none of those endpoints. □

Theorem 4238.132 (MetaCIC residual-join seed-status record)**.** *The residual-join seed status of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *is available to a confluence-facing consumer only after the consumer has read the critical-pair envelope, candidate-normalization scope, finite residual witness, and retained-premise rows of the displayed frontier packet. Equivalently, the route passes through Definition 4238.50, Definition 4238.62, Definition 4238.69, and Definition 4238.159 before any confluence consumer may inspect the residual-join seed record. The record exports only this bounded seed route; it does not supply premise-free confluence, global normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Read the critical-pair envelope first. It keeps the frontier rows visible before any residual-join request is interpreted as a seed-status claim.

Next apply the candidate-normalization scope and finite residual witness. These rows confine the candidate read and the residual read to the same finite frontier packet.

Finally read the retained-premise residual-join scope. Since that row remains present until the seed record is consumed, the exported status is a bounded residual-join route rather than a detached confluence theorem. □

Theorem 4238.133 (Residual-join candidate dependency boundary)**.** *Every residual-join candidate read from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose the critical-pair envelope, residual-substitution dependency route, candidate-normalization scope, finite residual witness consumption, and retained-premise boundary before it can be consumed as a local diamond frontier. In carrier form the read remains inside*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

where K *displays the critical-pair envelope,* P *retains the residual-substitution dependency,* J *records the candidate-normalization row,* R, S, C, B, O *keep the residual frontier, typed window, witness, bounded checker, and obstruction rows visible, and* H, T, G, N *provide transport, replay, provenance, and local naming. The boundary exports only this local residual-join candidate surface; it explicitly refuses subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, and kernel consistency.*

Proof. Start with the critical-pair envelope of Definition 4238.50. It exposes the bounded overlap rows before a residual-join candidate can be read by a frontier consumer.

Next read the residual-substitution dependency route of Definition 4238.57. This keeps the retained premise row P visible while the candidate, residual, checker, and obstruction rows are opened.

Now apply candidate-normalization scope through Definition 4238.62. The candidate row J remains part of the displayed frontier packet rather than a detached normalization theorem.

Consume the finite residual witness with Definition 4238.69. The residual rows R, S, C, B, O remain tied to the same finite witness route and cannot be reread as a global local-confluence theorem.

Finally use the retained-premise boundary of Definition 4238.158. It keeps $P, K, J, R, S, C, B, O, H, T, G, N$ visible before any local diamond frontier consumes the candidate, so the refused endpoints remain outside the packet. □

Theorem 4238.134 (MetaCIC candidate-mediated residual-join scope)**.** *Every candidate-mediated residual join read from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose the critical-pair envelope, candidate-normalization scope, residual-substitution dependency route, finite residual witness consumption, and residual join locality rows before it can be read as a parallel-diamond frontier packet. In carrier form the read remains on the displayed route*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

where P *retains the residual-substitution premise,* K *exposes the critical-pair envelope,* J *records the candidate-normalization row,* R, S, C, B, O *keep the residual frontier, seed, witness, bounded checker, and obstruction rows visible, and* H, T, G, N *provide transport, replay, provenance, and local naming. The scope exports only this finite candidate-mediated handoff, not global confluence, strong normalization, subject reduction, evaluator equality, quotient term equality, premise-free residual substitution, or kernel consistency.*

Proof. Start with the critical-pair envelope of Definition 4238.50. It exposes the bounded overlap rows before any residual join is available to a frontier consumer.

Next read candidate-normalization scope through Definition 4238.62. The candidate row J is therefore part of the displayed packet rather than an external normalization theorem.

Now use the residual-substitution dependency route of Definition 4238.57. It keeps the retained premise row P load-bearing while the residual rows R, S, C, B, O are opened.

Finally consume finite residual witness data and residual join locality via Definition 4238.69 and Definition 4238.104. These rows keep the local join inside $P, K, J, R, S, C, B, O, H, T, G, N$, so the resulting frontier packet provides only the stated candidate-mediated residual-join scope and none of the refused global endpoints. □

Theorem 4238.135 (MetaCIC candidate-mediated residual window)**.** *Every accepted residual join read from a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must keep the retained premise row P, candidate-normalization row J, residual-substitution route, finite residual witness rows, and residual-join locality rows inside the same bounded window before any parallel-diamond conclusion is visible. In carrier form the window is the displayed route*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

where P remains the retained residual-substitution premise, J remains the candidate-normalization row, R, S, C, B, O carry the residual frontier, typed window, finite witness, bounded checker, and obstruction data, and H, T, G, N transport, replay, source, and name the same packet. The read is therefore premise-bearing local residual evidence, not a premise-free parallel-diamond conclusion, unrestricted confluence theorem, subject-reduction theorem, evaluator equality, quotient term equality, or kernel-consistency certificate.

Proof. Start with the candidate-mediated residual-join scope of Definition 4238.134. It already requires the critical-pair envelope, candidate-normalization scope, residual-substitution dependency route, finite residual witness consumption, and residual-join locality rows to be displayed before a frontier consumer reads the handoff.

Next apply the residual-substitution dependency route of Definition 4238.57. This keeps P load-bearing while the residual rows are opened, so the bounded window cannot be reread as a premise-free substitution result.

Finally combine finite residual witness consumption with residual-join locality, using Definition 4238.69 and Definition 4238.104. These rows keep R, S, C, B, O attached to the same candidate-normalization route through J and the same structural rows H, T, G, N. Thus any visible parallel-diamond conclusion remains inside the retained bounded window named in the statement. □

Theorem 4238.136 (MetaCIC candidate-mediated residual-join obligation)**.** *Every accepted candidate-normalization window of a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet that exposes both residual branches must also expose the finite local-join row, retained-premise ledger, and obstruction-retention row before a parallel-diamond frontier consumer may read the window. In carrier form the admissible obligation surface is*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

where K is the critical-pair envelope, J is the candidate-local join row, P is the retained residual-substitution premise ledger, R, S, C, B display the residual branch, typed-window, witness, and bounded-checker rows, O records obstruction retention, and H, T, G, N preserve transport, replay, provenance, and local naming. The obligation is local to this finite surface; it does not assert global confluence, subject reduction, evaluator equality, quotient term equality, residual-substitution discharge, strong normalization, or kernel consistency.

Proof. Project the candidate-mediated residual window of Definition 4238.135. It already keeps $P, J, R, S, C, B, O, H, T, G, N$ visible while the candidate-normalization row is consumed.

Read the critical-pair envelope through Definition 4238.50. Both residual branches are therefore branches of the displayed finite envelope K, not independent reductions imported from an ambient calculus.

Apply residual-window scope using Definition 4238.134. The local join row J, retained premise row P, residual rows R, S, C, B, and obstruction row O remain on the same candidate-mediated route.

If a branch attempted to bypass J or O, it would no longer be a read of the retained window $P, K, J, R, S, C, B, O, H, T, G, N$. If it attempted to bypass P, the residual-substitution dependency named by the window would be lost. Hence the frontier consumer receives a parallel-diamond-facing obligation only after the local join ledger, retained premise ledger, and obstruction-retention row have all been exposed. □

Theorem 4238.137 (MetaCIC parallel-diamond window-budget scope)**.** *Every accepted* MetaCICParallelDiamondF *frontier read must expose the typed premise row, critical-peak row, bounded join-budget row, residual checker row, candidate strong-normalization handoff row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before any local-join conclusion is public. In the carrier-local spine*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

P is the retained typed premise, K is the peak row, J is the candidate join row, R, S, C, B are the finite residual and bounded checker budget rows, O is the visible obstruction row, and H, T, G, N are the structural transport, replay, provenance, and naming rows. The scope exports only this finite window-budget surface, not global confluence, unbounded normalization, subject reduction, evaluator equality, quotient term equality, premise-free residual substitution, or kernel consistency.

Proof. Start with the critical-pair envelope. It displays the peak and local candidate rows before a diamond request can be inspected by a frontier consumer.

Next read the residual-substitution dependency route and residual-normalization scope. These keep the typed premise row P and obstruction row O visible while the residual checker and bounded join-budget rows are opened.

Use the candidate strong-normalization handoff together with finite residual witness consumption. The handoff can be consumed only after the candidate row, residual witness rows, bounded checker rows, transport, replay, provenance, and local naming rows have been displayed in the same carrier-local spine.

Finally apply residual-row visibility. Since H, T, G, N preserve the displayed finite packet and no carrier coordinate contains global confluence, subject reduction, evaluator equality, quotient term equality, premise-free residual substitution, or kernel consistency, the exported conclusion is exactly the local finite window-budget scope. □

Theorem 4238.138 (MetaCIC parallel-diamond residual-join obligations)**.** *Every frontier residual join exposed by an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must display the critical-pair source row, retained residual-substitution window, candidate-normalization budget, local join witness, obstruction-retention row, componentwise* hsame *transport, displayed* Cont *replay, and* NameCert *provenance before a consumer may read the join. Equivalently, the obligation surface is the carrier-local spine*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

where P is still the residual-substitution premise, K, J, R give the critical-pair and candidate frontier rows, S, C, B, O give the bounded checker, closed-normal, budget, and obstruction rows, and H, T, G, N give transport, replay, provenance, and local naming.

The surface is a bounded candidate-mediated residual-join obligation. It is not a parameter-transport equivalence theorem, global confluence theorem, unbounded normalization theorem, subject-reduction theorem, evaluator equality, quotient term equality, or kernel-consistency certificate.

Proof. First read residual-join locality, Definition 4238.104. It places every accepted residual join inside the finite frontier spine and keeps the critical-pair, retained premise, local join, bounded checker, obstruction, transport, replay, provenance, and naming rows visible.

Next apply the residual-scope route of Definition 4238.125. This prevents the retained residual-substitution premise from being discharged after the local join is consumed, and it keeps $P, K, J, R, S, C, B, O, H, T,$ in the same carrier-local packet.

Now use the residual-normalization window and candidate-mediated strong-normalization handoff, Definition 4238.126 and Definition 4238.73. These rows expose the candidate-normalization budget and local witness only after the typed residual window, bounded checker rows, and obstruction row have been displayed.

Finally repack the displayed rows as the residual-join obligation surface. Since the packet contains no coordinate for parameter-transport equivalence, global confluence, unbounded normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency, the exposed join remains a local obligation over the stated finite frontier spine. □

Theorem 4238.139 (MetaCIC residual-join obligation handoff)**.** *Let an accepted* MetaCICParallelDiamondFrontier[1] *packet expose finite critical-pair coverage, residual-substitution locality, and retained-premise closure through the carrier-local rows*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

If a residual-join consumer reads the finite critical-pair surface through K, J, R, keeps the residual-substitution premise P local to the same packet, and preserves the retained premise and obstruction rows through B, O, H, T, G, N, then the packet provides the candidate-mediated strong-normalization handoff surface recorded by Definition 4238.73. The handoff is a bounded residual-join obligation surface; it does not claim global confluence, unrestricted normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with residual-join obligations and residual critical-pair coverage, Definition 4238.138 and Definition 4238.140. These results force the consumer to expose the finite critical-pair, candidate, residual witness, checker, obstruction, transport, replay, provenance, and naming rows before any local join is exported.

Next use residual-join locality and the residual grid, Definition 4238.104 and Definition 4238.107. They keep the residual-substitution premise inside the carrier-local packet and prevent the candidate join from being read as an independent confluence theorem.

Finally apply the retained-premise budget scope and the candidate-mediated SN handoff, Definition 4238.142 and Definition 4238.73. The first keeps P and O visible through the structural rows, and the second packages exactly that displayed finite surface as the candidate-mediated handoff. Since every cited step is still confined to $P, K, J, R, S, C, B, O, H, T, G, N$, no global confluence, unrestricted normalization, subject reduction, evaluator equality, quotient term equality, or kernel-consistency endpoint is exported. □

Theorem 4238.140 (MetaCIC parallel-diamond residual critical-pair coverage)**.** *Every residual-join consumer of an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must expose, before exporting its local join, the critical-pair envelope, retained residual-substitution premise, candidate-normalization scope, finite residual witness, bounded checker rows, obstruction row, and local* NameCert *row. Equivalently, the exported local join must still be read through the finite carrier-local surface*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

with P retaining the substitution premise, K exposing the critical-pair row, J and R retaining the candidate-normalization and residual-witness rows, S, C, B exposing the bounded checker rows, O retaining the obstruction row, and H, T, G, N carrying transport, replay, provenance, and local naming.

The coverage claim is local to the frontier packet. It exports no global confluence theorem, subject-reduction theorem, evaluator equality, quotient term equality, or kernel-consistency certificate.

Proof. Begin with the residual-join obligations and residual-normalization envelope above. Together they keep any exported local join behind the retained residual-substitution premise, critical-pair row, candidate-normalization budget, bounded checker rows, obstruction row, transport, replay, provenance, and naming.

Next refine the obligation surface through residual-join locality and the residual grid, Definition 4238.104 and Definition 4238.107. These theorems identify the critical-pair, residual-substitution, candidate-normalization, finite-witness, bounded-checker, obstruction, and local naming rows as one carrier-local grid rather than independent side conditions.

Finally apply the candidate strong-normalization handoff of Definition 4238.73. It lets the consumer use the candidate-mediated boundary only after the finite residual witness and bounded checker rows remain visible, so the exported join is covered by the displayed critical-pair surface and cannot be reread as global confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.141 (MetaCIC parallel-diamond residual-normalization envelope)**.** *Any consumer that uses the local residual join of an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must first expose the retained residual-substitution premise, the residual-normalization window, the candidate strong-normalization handoff, bounded checker rows, the obstruction row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

The envelope is the same carrier-local route

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

read with P retained and O visible before the candidate-mediated normalization handoff is consumed. It exports no full confluence theorem, subject-reduction theorem, evaluator equality, quotient term equality, or kernel-consistency certificate.

Proof. Start with the residual-join obligation surface above. It keeps the critical-pair source, retained residual-substitution premise, candidate-normalization budget, bounded checker rows, obstruction row, transport, replay, provenance, and local naming visible before a local join can be read.

Next apply the residual-normalization window, Definition 4238.126. That row forces a normalization-facing residual peak to remain behind $P, J, R, S, C, O, H, T, G, N$ and prevents the candidate row from becoming a premise-free normalization theorem.

Finally use the candidate strong-normalization handoff, Definition 4238.73. It lets the consumer pass the bounded candidate data onward only after the checker rows and obstruction row are still displayed, so the resulting envelope remains a local residual-normalization boundary rather than full confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.142 (MetaCIC parallel-diamond residual-premise budget scope)**.** *Every candidate-mediated strong-normalization or local residual-join consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must keep the retained residual-substitution premise row P and obstruction row O visible through the finite route*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

before exporting a budgeted join. The budget is the displayed carrier-local budget over residual premise, critical pair, candidate row, residual witness, closed checker, closed-normal fragment, bounded checker, obstruction, transport, replay, provenance, and local naming; it is not a discharge of residual substitution, global confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with the residual-join obligations and critical-pair coverage, Definition 4238.138 and Definition 4238.140. They require every exported local join to display $P, K, J, R, S, C, B, O, H, T, G, N$, with the residual-substitution premise and obstruction rows still present.

Next apply the residual-normalization envelope, Definition 4238.141. It keeps candidate-mediated normalization behind the same finite route and prevents the candidate row from becoming a premise-free normalization theorem.

Finally use the candidate strong-normalization handoff, Definition 4238.73. The handoff can export only the displayed budgeted join, so any consumer claiming global confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency has left the retained residual-premise surface. □

Theorem 4238.143 (MetaCIC parallel-diamond residual-join transport induction)**.** *Let an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet display the residual critical-pair rows, residual-normalization envelope, retained-premise budget rows, componentwise* hsame *transport, and displayed* Cont *replay over the finite spine*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

If those rows are transported componentwise and replayed by the displayed continuation data, the resulting local join remains inside the same candidate-mediated diamond surface. In particular, residual critical-pair coverage, residual-normalization envelope data, and retained-premise budget scope are preserved as frontier-local rows, not reread as global confluence, unbounded normalization, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. Induct through the finite residual row list. The base row is the retained residual-substitution premise P; transport along the corresponding component of H keeps the premise visible before any critical-pair or candidate row is consumed.

For the critical-pair and local-join segment, use Definition 4238.138 and Definition 4238.140. These theorems keep K, J, R attached to the same carrier-local residual surface under replay by T.

For the normalization and budget segment, apply Definition 4238.141 and Definition 4238.142. The rows S, C, B, O remain visible before the candidate-mediated handoff can export a budgeted join.

The structural rows H, T, G, N then repack the transported list as the same local diamond surface. Since each induction step uses only displayed rows and continuation replay, no quotient term equality, global confluence theorem, unbounded normalization theorem, subject-reduction theorem, evaluator equality, or kernel-consistency certificate is introduced. □

Theorem 4238.144 (MetaCIC retained-premise discharge boundary)**.** *Every candidate-mediated local join exported by an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must preserve the retained residual-substitution premise row P through the full visible route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The candidate rows K, J, R, S, C, B may transport a bounded local join, and the structural rows H, T, G, N may replay and name it, but none of those rows discharges P. The boundary therefore exports only a local residual-join read with P retained; it refuses global confluence, subject reduction, evaluator equality, quotient term equality, unrestricted normalization, and kernel consistency.

Proof. Start with residual-join transport induction, Definition 4238.143. Its base row is P, so every transported local join begins with the retained residual-substitution premise still visible.

For the candidate-mediated segment, use residual critical-pair coverage and the residual-normalization envelope. These results keep K, J, R, S, C, B attached to the same finite frontier packet and prevent the candidate handoff from becoming a premise-free join theorem.

Finally apply retained-premise budget scope and the candidate strong-normalization handoff. They permit a bounded local join only while P, O, H, T, G, N remain in the route. Hence the exported join preserves the retained premise and reaches none of the refused global endpoints. □

Theorem 4238.145 (MetaCIC obstruction-preservation route)**.** *Every candidate-mediated local join transported through an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet preserves the obstruction row O along the same finite route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The obstruction remains visible before and after the local join is replayed by T and named by N. Thus the packet records obstruction-preserving local residual-join transport only; it does not assert global confluence, subject reduction, evaluator equality, quotient term equality, unrestricted normalization, or kernel consistency.

Proof. First read the residual-normalization envelope and residual-premise budget scope. Together they place O beside the bounded checker and candidate rows, so the obstruction is not an external side condition that can be erased after the join is found.

Next use residual-join transport induction. The transport row H and replay row T act componentwise on the visible route, so the obstruction component is carried with P, K, J, R, S, C, B rather than replaced by evaluator equality or quotient term equality.

Finally repack through G and N. Provenance and local naming certify the same obstruction-preserving frontier packet, and because no coordinate provides unrestricted normalization, subject reduction, global confluence, or kernel consistency, the route remains exactly the local obstruction-preservation route. □

Theorem 4238.146 (MetaCIC residual-budget diamond obligation)**.** *Every local diamond-join read exposed by an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet must display the critical-pair envelope, retained residual-substitution window, candidate-normalization scope, finite residual-diamond ledger, and residual-join locality rows before the frontier package can expose a candidate-mediated confluence handoff. Equivalently, the handoff remains inside the carrier-local route*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

where P retains the residual-substitution premise, K records the critical-pair envelope, J, R, S, C, B record the candidate and bounded residual window, O records the visible obstruction, and H, T, G, N record transport, replay, provenance, and local naming. The obligation exports only a bounded local diamond route; it does not discharge residual substitution, prove unrestricted confluence, prove subject reduction, identify evaluator equality, identify quotient term equality, or certify kernel consistency.

Proof. Start with the residual-substitution dependency route, Definition 4238.57. It places the retained premise row P before any critical-pair or candidate-join row can be consumed.

Next read the candidate-normalization scope of Definition 4238.62. That scope keeps J inside the conditional spine and requires the obstruction row O to remain visible when a normalization-facing consumer inspects the candidate.

Use the finite residual-diamond ledger obligations, Definition 4238.123. The ledger packages the critical-pair row, retained premise, candidate join, bounded checker status, obstruction, transport, replay, provenance, and local naming as finite carrier-local data.

Finally apply residual-join locality and its locality budget, Definition 4238.104 and Definition 4238.105. These rows keep the displayed packet on the route $P, K, J, R, S, C, B, O, H, T, G, N$ before any candidate-mediated confluence handoff is public. Since every cited surface is carrier-local and still retains P and O, the handoff remains the stated residual-budget obligation rather than any refused global endpoint. □

Theorem 4238.147 (MetaCIC parallel diamond frontier residual-join obligation carrier)**.** *Before any candidate diamond read of an accepted* MetaCICParallelDiamondFrontier$^{\uparrow}$ *packet is public, the residual-join obligation carrier consists of the retained premise row, critical-pair envelope, residual-substitution dependency row, finite residual witness, obstruction row, bounded checker row, transport, replay, provenance, and local* NameCert *row. In carrier notation the public residual-join obligation must still expose*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

with P retaining the premise, K exposing the critical pair, J, R carrying the candidate and finite residual witness, S, C, B retaining the residual-substitution and checker rows, O retaining the obstruction, and H, T, G, N transporting, replaying, sourcing, and naming the same packet. The carrier is an obligation surface for a bounded residual join; it is not full confluence, subject reduction, evaluator equality, quotient term equality, unrestricted normalization, or kernel consistency.

Proof. Start with the residual-budget diamond obligation of Definition 4238.146. It already forces every local diamond-join read to expose the critical-pair envelope, retained residual-substitution window, candidate-normalization scope, finite residual-diamond ledger, and residual-join locality rows before a candidate-mediated handoff is public.

Next use finite residual witness consumption, Definition 4238.69. This supplies the finite residual witness, typed window, bounded checker, obstruction, transport, replay, provenance, and local naming rows as displayed data of the same packet.

Finally apply the residual-join obligation handoff and candidate-mediated SN handoff, Definition 4238.139 and Definition 4238.73. They keep P and O visible through H, T, G, N before the candidate-facing read is exported. Since the composed route never leaves $P, K, J, R, S, C, B, O, H, T, G, N$, it yields only the stated residual-join obligation carrier and none of the refused global endpoints. □

Theorem 4238.148 (MetaCIC residual-join frontier obligation)**.** *Every candidate-mediated residual join exported by an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *frontier must keep the retained residual-substitution premise row P and the obstruction row O visible through the same finite route*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

before any local diamond handoff is consumed. Thus the consumer may read a bounded local join only while the critical-pair, candidate, finite residual witness, bounded checker, obstruction, transport, replay, provenance, and local naming rows remain carrier-local.

The obligation does not export global confluence, subject reduction, evaluator equality, quotient term equality, unrestricted normalization, or kernel consistency.

Proof. First compose the residual-join obligation carrier of Definition 4238.147 with the residual-budget diamond obligation of Definition 4238.146. The carrier supplies the displayed route, and the budget obligation prevents the candidate diamond read from leaving that route before the handoff is visible.

Next use finite residual witness consumption, Definition 4238.69. This step keeps the residual witness, typed window, bounded checker rows, and obstruction row as displayed rows of the same packet rather than private side conditions.

Finally apply the candidate strong-normalization handoff of Definition 4238.73. Since the handoff consumes only the displayed candidate-mediated surface and the rows P and O are still present through H, T, G, N, the exported join remains a local frontier obligation and none of the refused global endpoints is introduced. □

Theorem 4238.149 (MetaCIC residual-join window determinacy)**.** *Let two accepted candidate-mediated residual-join reads of a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet expose the same retained premise row P, critical-pair row K, candidate row J, residual witness rows R, S, C, B, obstruction row O, transport rows H, T, provenance row G, and local* $\mathsf{NameCert}$ *row N. Then the two reads determine the same local join window over the finite route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The conclusion is only local window determinacy for the displayed residual-join surface. It is not global confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. First compose the residual-join obligation carrier of Definition 4238.147. Both reads expose the same carrier-local rows, so the retained premise, critical-pair row, candidate row, residual witness rows, obstruction row, transport, replay, provenance, and local naming are the same displayed packet.

Next apply the residual-budget diamond obligation of Definition 4238.146. The budgeted local diamond handoff cannot leave the route $P, K, J, R, S, C, B, O, H, T, G, N$, and the shared rows therefore force both reads to consume the same bounded residual window.

Use finite residual witness consumption to keep R, S, C, B as the displayed witness and checker rows of that same window. The shared obstruction row O and shared transport rows H, T prevent either read from replacing the witness by an external evaluator equality or quotient term equality.

Finally apply the candidate strong-normalization handoff of Definition 4238.73. Since the handoff consumes only the shared candidate-mediated surface, the two accepted reads determine one local join window. The argument never exports global confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.150 (MetaCIC parallel-diamond retained-premise closure)**.** *A retained-premise read used by a candidate-mediated strong-normalization or local-confluence consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must expose residual-substitution compatibility rows, candidate-normalization rows, local-join rows, the critical-pair envelope, finite residual witnesses, typed-window rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row before it is consumed as a closure budget. The budget is a finite frontier read over*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

not subject reduction, unrestricted confluence, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with the critical-pair envelope and candidate-normalization scope, Definition 4238.50 and Definition 4238.62. They keep $P, K, J, R, S, C, B, O, H, T, G, N$ visible before candidate-mediated normalization can read the candidate row.

Apply residual-join locality and finite residual witness consumption, Definition 4238.104 and Definition 4238.69. These force the retained premise, typed windows, residual frontier, local-join checker, finite witness, transport, replay, provenance, and local naming rows to be consumed as one finite packet.

Finally read the retained-premise mature budget, Definition 4238.154. It allows the premise to serve as a closure budget only while the obstruction and residual-substitution rows remain displayed, so the read cannot become subject reduction, unrestricted confluence, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.151 (MetaCIC parallel-diamond retained-premise induction)**.** *Let an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet expose a finite list of retained-premise reads to a candidate-mediated strong-normalization or local-confluence consumer. If each read is admitted by the retained-premise closure budget of Definition 4238.150, then induction on the list preserves the same displayed rows*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

through every residual-pair read. The iterated budget remains only a finite frontier over those rows, and cannot discharge subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. For the base list, read the retained-premise closure theorem. It supplies one closure-budget surface over $P, K, J, R, S, C, B, O, H, T, G, N$, and the empty residual-pair suffix contributes no additional semantic row.

For the cons step, expose the head retained-premise read through the same closure-budget theorem and apply the induction hypothesis to the remaining finite list. The head read and the tail budget both project the same transport, replay, provenance, obstruction, typed-window, residual-frontier, candidate, local-join, and naming rows, so their composition still displays exactly $P, K, J, R, S, C, B, O, H, T, G, N$.

Finally project the negative boundary attached to each step. Since neither the head read nor the inductive tail contains a row for subject reduction, unrestricted confluence, evaluator equality,

quotient term equality, global normalization, or kernel consistency, the finite composition cannot acquire any of those conclusions. □

Theorem 4238.152 (MetaCIC candidate-normalization retained premise)**.** *Any candidate-mediated strong-normalization or local-confluence consumer reading a retained premise from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must preserve the displayed candidate-normalization, residual-substitution, local-join, critical-pair, bounded-check, typed-window, transport, replay, provenance, obstruction, and local* NameCert *rows. The retained-premise route is the finite row surface*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

not an unrestricted confluence theorem, subject-reduction theorem, evaluator equality, quotient term equality, or kernel-consistency claim.

Proof. Apply retained-premise closure, Definition 4238.150. It keeps candidate normalization, residual substitution, local joins, critical pairs, bounded checks, typed windows, transport, replay, provenance, obstruction, and naming visible before the retained premise is consumed.

Apply retained-premise induction, Definition 4238.151. A finite list of such reads preserves the same displayed rows $P, K, J, R, S, C, B, O, H, T, G, N$ through every residual-pair step.

Now use the candidate SN residual budget and public route sync cited by the retained-pair induction, Definition 4238.166 and Definition 4238.170. These keep the consumer on the candidate-normalization route rather than replacing it by a global semantic theorem.

The carrier exposes no row for unrestricted confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency. Therefore the retained premise remains a finite candidate-normalization budget over the displayed rows only. □

Theorem 4238.153 (MetaCIC parallel-diamond retained-pair induction)**.** *Every finite successor chain of candidate-mediated SN/confluence handoffs that reads the public or bridged* MetaCICParallelDiamondFrontie *route preserves the retained pair* (P, O) *and the residual budget* (J, R, B) *before each handoff. The induction invariant is read through the displayed public route*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

and it does not discharge residual substitution, subject reduction, global Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.

Proof. For the base chain, read the public certificate and finite residual witness consumption. The public route exposes $P, K, J, R, S, C, B, O, H, T, G, N$, while the finite witness row keeps the retained pair P, O and the residual budget J, R, B visible before the first handoff.

For the successor step, apply candidate SN residual budget and public route sync, Definition 4238.166 and Definition 4238.170. The head handoff carries P, O as retained premise and obstruction data, and it carries J, R, B as candidate join, residual frontier, and bounded-check budget data. The induction hypothesis supplies the same rows for the remaining finite chain.

Finally compare with the retained seed block sync of Definition 4238.171. It identifies the retained handoff data as finite public-route evidence rather than residual-substitution discharge, subject reduction, unrestricted Church–Rosser, evaluator equality, quotient equality, or kernel consistency, so the whole finite chain preserves only the stated pair and residual budget. □

Theorem 4238.154 (MetaCIC parallel-diamond retained-premise mature budget)**.** *Every candidate-mediated SN/confluence consumer of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *must carry the retained*

premise budget P, J, R, B, O through the public certificate, finite residual witness consumption, candidate SN residual budget, public frontier budget, and bridged export before reading any parallel-diamond handoff. The carried budget records the residual-substitution premise row, candidate-join row, residual-frontier row, bounded-check row, and obstruction row as finite packet data; it is not residual-substitution discharge, unrestricted Church–Rosser, subject reduction, evaluator equality, quotient term equality, global conversion decidability, or kernel consistency.

Proof. Start with the public certificate of Definition 4238.162. It exposes the residual-substitution premise, critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal, bounded-check, obstruction, transport, replay, provenance, and local naming rows as one finite public handoff.

Next consume the finite residual witness through Definition 4238.165. That route makes a candidate-mediated SN/confluence consumer read $P, K, J, R, S, C, B, O, H, T, G, N$ before it can inspect the frontier, so the retained rows P, J, R, B, O remain visible inside the larger finite route.

Apply the candidate SN residual budget and public frontier budget, Definition 4238.166 and Definition 4238.168. Together they isolate P, J, R, B, O as the budget that must be carried forward before any public diamond handoff is read.

Finally apply the bridged export of Definition 4238.169. The bridged read may expose the guarded frontier to an external consumer only while preserving the same retained evidence rows and the structural transport, replay, provenance, and local naming route. Therefore the mature budget cannot be reread as residual-substitution discharge, unrestricted Church–Rosser, subject reduction, evaluator equality, quotient term equality, global conversion decidability, or kernel consistency. □

Theorem 4238.155 (MetaCIC parallel-diamond retained-premise discharge boundary)**.** *Every local diamond/frontier read of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *that consumes a candidate join row J and residual frontier row R must still expose the retained residual-substitution premise row P, the critical-pair row K, the closed-checker row S, the closed-normal fragment row C, the bounded-check row B, the obstruction row O, and the structural rows H, T, G, N. The route is not full residual-substitution discharge, subject reduction, Church–Rosser, evaluator equality, quotient term equality, global normalization, or kernel consistency.*

Proof. Read the local public certificate and finite residual witness routes. They expose the candidate join and residual frontier only inside the larger packet $P, K, J, R, S, C, B, O, H, T, G, N$, so consuming J and R cannot hide the premise, critical-pair, checker, normal-fragment, bounded-check, obstruction, or structural rows.

Apply the retained-premise closure and mature budgets. Those budgets require the residual-substitution premise and the obstruction-facing bounded check to remain visible through candidate-mediated diamond reads.

The listed off-table metatheorems are not rows of the packet. Since the carrier exports only the displayed finite evidence and structural transport, replay, provenance, and naming rows, the local read records a discharge boundary rather than a full residual-substitution or confluence theorem. □

Theorem 4238.156 (MetaCIC retained-premise local discharge route)**.** *A candidate-mediated diamond consumer of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *may discharge only the local retained-premise route*

$$P,\ K,\ J,\ R,\ S,\ C,\ B,\ O,\ H,\ T,\ G,\ N.$$

This discharge is local consumption of the displayed route: the retained residual-substitution premise row P must remain present in $P, K, J, R, S, C, B, O, H, T, G, N$ while the consumer reads J and R.

The route still does not provide full residual-substitution discharge, subject reduction, Church–Rosser, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Apply Definition 4238.155. It already forces every candidate join and residual frontier read to keep the retained premise, critical-pair, checker, normal-fragment, bounded-check, obstruction, and structural rows visible.

The criterion is a visibility condition on the retained premise, not a proof that residual substitution has been eliminated.

The present route narrows that boundary to the local consumer order $P, K, J, R, S, C, B, O, H, T, G, N$. Reading J and R is therefore allowed only after the retained-premise and critical-pair rows have been exposed, and before the closed-checker, closed-normal fragment, bounded-check, obstruction, transport, replay, provenance, and naming rows close the local packet.

No further row is exported by this local discharge. The off-table metatheorems remain outside the packet, so the consumer records a retained-premise route rather than a global residual-substitution, confluence, normalization, evaluator-equality, quotient-equality, or consistency theorem. □

Theorem 4238.157 (MetaCIC retained-premise normalization bridge)**.** *Every candidate-mediated normalization or local residual-join read that uses the retained-premise discharge route of Definition 4238.156 must still factor through the finite spine*

$$P,\ K,\ J,\ R,\ S,\ C,\ B,\ O,\ H,\ T,\ G,\ N.$$

It may consume the candidate strong-normalization handoff of Definition 4238.73 and the residual-join obligation surface of Definition 4238.138 only as bounded local evidence. The bridge refuses full residual-substitution discharge, subject reduction, Church–Rosser, evaluator equality, quotient term equality, global normalization, and kernel consistency.

Proof. Apply Definition 4238.156. Any consumer using that route is already confined to $P, K, J, R, S, C, B, O, H, T$, with P and O still visible before the local packet closes.

Next read the candidate strong-normalization handoff of Definition 4238.73. That handoff can be consumed only after the candidate row, bounded checker rows, obstruction row, transport, replay, provenance, and local naming remain displayed as finite evidence.

Now attach the residual-join obligation surface of Definition 4238.138. It keeps the local residual join inside the same critical-pair, candidate, residual-frontier, checker, obstruction, and structural rows rather than turning the join into an independent confluence theorem.

The carrier inventory and nonescape boundary then close the bridge. Since every cited surface stays inside the displayed spine, no consumer obtains full residual-substitution discharge, subject reduction, Church–Rosser, evaluator equality, quotient term equality, global normalization, or kernel consistency. □

Theorem 4238.158 (MetaCIC parallel-diamond retained-premise boundary)**.** *Every candidate-mediated parallel-diamond consumer of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet that reaches a residual join must first expose the retained-premise ledger, candidate-normalization scope, residual-substitution route, finite residual witness, and the supporting* hsame, Cont, Pkg, *and* NameCert *rows. In the frontier spine*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

the premise row P, candidate row J, residual rows K, R, S, C, B, O, transport row H, replay row T, provenance row G, and local naming row N remain visible before any residual join can be

consumed. The boundary does not provide a hidden strong-normalization oracle, host confluence primitive, detached residual equality, subject-reduction theorem, evaluator equality, quotient term equality, or kernel-consistency certificate.

Proof. Start with the retained-premise discharge boundary, Definition 4238.155. It keeps $P, K, S, C, B, O, H, T, G, N$ visible whenever a local diamond or frontier read consumes the candidate join J and residual frontier R.

Next apply the candidate strong-normalization handoff, Definition 4238.73. That handoff exposes the critical-pair envelope, residual-substitution row, candidate-normalization scope, finite residual witness, and residual-row visibility surface before a normalization-facing consumer can read the frontier.

Now use the residual-substitution dependency route, Definition 4238.57. It places the retained premise row before every critical-pair, candidate-join, residual-frontier, closed-checker, and obstruction read, so the residual join cannot be detached from the premise boundary.

Finally attach the finite residual-diamond ledger, Definition 4238.123. The ledger records the local join only as bounded carrier-local data over $K, P, J, B, O, H, T, G, N$. Since every cited route preserves the same structural support rows, the residual join remains a retained-premise boundary rather than a hidden strong-normalization oracle, host confluence primitive, detached residual equality, subject-reduction theorem, evaluator equality, quotient term equality, or kernel-consistency certificate. □

Theorem 4238.159 (MetaCIC parallel-diamond retained-premise scope)**.** *Every retained premise used by a* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *read must be displayed as one of the residual-pair, candidate-normalization, local-join, closed-checker, or obstruction rows already named in the frontier carrier*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

In particular, a retained premise can be consumed only as carrier-local evidence through those rows, and cannot be read as an unconditional closed parallel-diamond theorem, subject-reduction theorem, evaluator equality, quotient term equality, or kernel-consistency certificate.

Proof. Project the frontier carrier of Definition 4238.1. The residual-pair and premise-retention rows are P, K, R, the candidate-normalization row is J, the local-join and closed-checker rows are S, C, B, and the obstruction row is O.

Apply the residual boundary route of Definition 4238.57. It places every residual-pair use behind the retained premise row and keeps the critical-pair and residual-frontier rows visible.

Next use the candidate-normalization and local-join boundaries, Definition 4238.62 and Definition 4238.123. These theorems allow candidate and local-join data to be read only through the displayed finite route, with the retained premise still attached.

Finally apply the retained-premise discharge boundary and obstruction ledger, Definition 4238.155 and Definition 4238.111. The closed-checker and obstruction rows remain visible through the structural rows H, T, G, N, so no consumer can reread the retained premise as an unconditional closed parallel diamond or any of the refused kernel-level endpoints. □

Theorem 4238.160 (MetaCIC parallel-diamond local retained-premise factorization)**.** *Any local diamond read from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet that consumes candidate join and residual-frontier rows factors through the retained premise row, critical-pair row, candidate-normalization row, local-join row, closed-checker row, closed-normal fragment row, bounded-check row, obstruction row, and structural rows*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The factorization is conditional on those displayed rows. It is not full Church–Rosser, subject reduction, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Begin with retained-premise scope, Definition 4238.159. It requires every premise used by the local diamond read to remain one of the displayed carrier rows.

Apply the residual-substitution dependency route of Definition 4238.57. The route places the retained premise row P before the critical-pair, candidate join, residual-frontier, closed-checker, and obstruction rows can be consumed.

Use candidate-normalization scope from Definition 4238.62. The candidate row J remains inside the same conditional spine rather than becoming an external normalization theorem.

Apply the finite residual-diamond ledger local-join obligations of Definition 4238.123. They read the local join, closed checker, closed-normal fragment, bounded-check, and obstruction rows only after the retained premise and residual-frontier data have been displayed.

Finally use the retained-premise discharge boundary of Definition 4238.155. Since the structural rows H, T, G, N only transport, replay, source, and name the same finite packet, the local diamond read cannot be promoted to any refused global metatheorem or kernel endpoint. □

Theorem 4238.161 (MetaCIC retained-premise residual-join scope)**.** *Every candidate-mediated residual join read from an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet remains inside the typed local-join scope when the retained premise window is exposed before the normalization and confluence handoff rows. Equivalently, the read must keep the finite carrier-local route*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

visible with P as the retained premise, K as the critical-pair row, J as the candidate-normalization row, R, S, C, B as the residual witness, local-join, closed-checker, and bounded-checker rows, O as the obstruction row, and H, T, G, N as transport, replay, provenance, and local naming.

The resulting scope is a retained-premise residual-join surface. It does not export premise-free residual substitution, global confluence, subject reduction, evaluator equality, quotient term equality, unrestricted normalization, or kernel consistency.

Proof. First apply retained-premise scope, Definition 4238.159. It requires every premise used by a frontier read to appear as one of the displayed residual-pair, candidate-normalization, local-join, closed-checker, obstruction, transport, replay, provenance, or naming rows.

Next use candidate-mediated residual-join scope, Definition 4238.134. The candidate row and residual rows are consumed only after the critical-pair envelope and residual-substitution dependency route have made the retained premise visible.

Now read the window-budget scope and residual-join obligation surface, Definition 4238.137 and Definition 4238.138. These theorems keep the bounded checker, local join, obstruction, transport, replay, provenance, and local naming rows on the same carrier-local route.

Therefore a candidate-mediated residual join can be exported only as the displayed retained-premise surface $P, K, J, R, S, C, B, O, H, T, G, N$. Since no cited row contains a premise-free residual-substitution discharge or any global kernel endpoint, the conclusion remains inside the typed local-join scope. □

Theorem 4238.162 (MetaCIC parallel-diamond frontier public certificate)**.** *The public* MetaCICParallelDiamondFr *certificate is the finite route through the residual-substitution premise, critical-pair row, candidate-join row, residual-frontier row, closed-checker seal, closed-normal fragment, bounded-check row, obstruction row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local*

NameCert *rows. It exposes the residual frontier as a public finite handoff while refusing residual-substitution discharge, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, and kernel consistency.*

Proof. Apply the public export route of Definition 4238.47. It displays the residual-substitution premise, critical-pair, candidate-join, residual-frontier, checker, obstruction, transport, replay, provenance, and local naming rows before any outside consumer may read the frontier.

Apply the public seed-readiness route of Definition 4238.84. This keeps the closed-checker seal, closed-normal fragment, bounded-check row, and obstruction row inside the same finite handoff.

The two routes name only the displayed packet rows. Since neither route contains a discharge of the residual-substitution premise, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency, the public certificate exports the finite frontier without claiming those endpoints. □

Theorem 4238.163 (MetaCIC parallel-diamond frontier seed route)**.** *The rotation-selected status route for* MetaCICParallelDiamondFrontier$^{\uparrow}$ *records the finite move from no closure block to* seed *through the retained carrier rows*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The route is witnessed inside this child file by public certificate export, finite residual witness consumption, retained seed-block sync, public route sync, bridged export, mature route, bridge boundary, and closurestatus seed block evidence. It keeps residual-substitution premises, local joins, residual-frontier rows, bounded checks, obstruction rows, transport, replay, provenance, and local naming visible, and it does not claim global confluence, unrestricted normalization, subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, residual-substitution discharge, or kernel consistency.

Proof. Start with the closurestatus seed block of Definition 4238.175. It binds the status-bearing route to the retained premise rows and the displayed carrier route $P, K, J, R, S, C, B, O, H, T, G, N$.

Apply public route sync and bridged export, Definition 4238.170 and Definition 4238.169. These keep the public and bridge-facing reads on the same finite route before any outside consumer reads the frontier.

Finally use the mature route and bridge boundary, Definition 4238.173 and Definition 4238.174. They preserve the retained premise budget and refuse the listed global endpoints, so the status route reaches only seed for the finite frontier packet. □

Theorem 4238.164 (MetaCIC parallel-diamond bridged handoff)**.** *The public residual-premise, critical-pair, candidate-join, residual-frontier, closed-checker, obstruction, transport, replay, provenance, and local naming route is the bridged handoff surface for* MetaCICParallelDiamondFrontier$^{\uparrow}$*. The handoff records the finite rows that a standard bridge may read before interpreting the parallel-diamond frontier externally. Residual-substitution discharge, unrestricted confluence, subject reduction, evaluator equality, quotient term equality, kernel consistency, and bridge checking remain outside this chapter.*

Theorem 4238.165 (Finite residual witness consumption)**.** *Every candidate-mediated SN/confluence consumer of* MetaCICParallelDiamondFrontier$^{\uparrow}$ *must consume the finite residual witness route*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

through the displayed residual-premise, critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal fragment, bounded-check, obstruction, transport, replay, provenance, and local naming rows. The consumer may not retype the handoff as residual-substitution discharge, subject reduction, full Church–Rosser, evaluator equality, quotient equality, or kernel consistency.

Proof. Read the public certificate of Definition 4238.162. It exposes the residual premise, critical-pair, candidate-join, residual-frontier, checker, closed-normal, bounded-check, obstruction, transport, replay, provenance, and local naming rows as one finite handoff.

Now apply the bridged handoff of Definition 4238.164. The bridge-facing consumer may inspect only the rows named by that handoff before interpreting the frontier externally. The row order $P, K, J, R, S, C, B, O, H, T, G, N$ records the premise, critical-pair, join, residual, seal, checker, bounded-check, obstruction, transport, replay, provenance, and local-name witnesses as finite data.

Since none of those rows is a residual-substitution discharge, subject-reduction theorem, unrestricted Church–Rosser proof, evaluator equality, quotient equality, or kernel-consistency certificate, a consumer that claims one of those endpoints has left the displayed $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ route. □

Theorem 4238.166 (Candidate SN residual budget)**.** *Any candidate-mediated strong-normalization or confluence consumer of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *must preserve the residual-substitution premise row P, candidate-join row J, residual-frontier row R, bounded-check row B, and obstruction row O as one finite residual budget before reading the public diamond handoff. The budget is read as a retained row family, not as residual-substitution discharge, subject reduction, unrestricted Church–Rosser, evaluator equality, quotient equality, or kernel consistency.*

Proof. Use the public certificate of Definition 4238.162. It exposes the residual premise, candidate join, residual frontier, bounded check, and obstruction rows inside the same finite public handoff rather than as separate global principles.

Apply finite residual witness consumption, Definition 4238.165. The candidate-mediated consumer can inspect the route $P, K, J, R, S, C, B, O, H, T, G, N$, but the residual budget needed for SN/confluence use is the retained subroute P, J, R, B, O.

Finally compare with the public closure theorem, Definition 4238.167. Since public closure keeps residual-substitution discharge, subject reduction, unrestricted Church–Rosser, evaluator equality, quotient equality, and kernel consistency outside the packet, the candidate SN/confluence reader must carry P, J, R, B, O forward before it reads the public diamond handoff. □

Theorem 4238.167 (MetaCIC parallel-diamond frontier public closure)**.** *Public closure for* MetaCICParallelDiamon *is available only over the retained finite route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The route retains the residual-substitution premise row, critical-pair row, candidate-join row, residual-frontier row, closed-checker seal, closed-normal fragment, bounded-check row, obstruction row, transport row, replay row, provenance row, and local naming row before any public diamond handoff. It does not discharge residual substitution, subject reduction, full Church–Rosser, evaluator equality, quotient equality, or kernel consistency.

Proof. Use the public certificate of Definition 4238.162. It exposes the residual premise, critical-pair, candidate-join, residual-frontier, checker, obstruction, transport, replay, provenance, and local naming rows as a finite public handoff.

Now apply the public seed-readiness route of Definition 4238.84. It keeps the closed-checker seal, closed-normal fragment, bounded-check row, and obstruction row inside the same retained packet rather than moving them to a hidden evaluator or quotient term layer.

Finally use the retained witness consumption of Definition 4238.165. The ordered route $P, K, J, R, S, C, B, O, H, T, G, N$ is the only public surface consumed by downstream SN/confluence fragments. Since the retained rows leave residual-substitution discharge, subject reduction, full Church–Rosser, evaluator equality, quotient equality, and kernel consistency outside the packet, the public closure is exactly this finite route. □

Theorem 4238.168 (MetaCIC parallel-diamond public frontier budget)**.** *Every public candidate-mediated SN or confluence consumer of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *must preserve the residual-substitution premise row P, candidate join row J, residual frontier row R, bounded-check row B, and obstruction row O before reading any public diamond handoff. The retained budget cannot be retyped as residual-substitution discharge, subject reduction, unrestricted Church–Rosser, evaluator equality, quotient equality, or kernel consistency.*

Proof. Start with the public certificate, Definition 4238.162. It exposes the residual premise, candidate join, residual frontier, bounded check, and obstruction rows as visible rows of the finite public handoff rather than as hidden global principles.

Use finite residual witness consumption, Definition 4238.165. The candidate-mediated consumer reads the route $P, K, J, R, S, C, B, O, H, T, G, N$, so the residual-substitution premise, candidate join, residual frontier, bounded check, and obstruction rows are retained before the public handoff is inspected.

Apply candidate SN residual budget, Definition 4238.166. It isolates P, J, R, B, O as the budget that a strong-normalization or confluence consumer must carry forward.

Finally compare with public closure, Definition 4238.167. Public closure refuses residual-substitution discharge, subject reduction, unrestricted Church–Rosser, evaluator equality, quotient equality, and kernel consistency, so preserving P, J, R, B, O cannot be retyped as any of those endpoints. □

Theorem 4238.169 (MetaCIC parallel-diamond frontier bridged export)**.** *Any public or bridged read of the* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *frontier must preserve the candidate-normalization rows, residual-frontier rows, local-join ledger, obstruction row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *as visible evidence in the same finite carrier route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The export may hand this guarded frontier to a bridge-facing consumer, but it does not assert full Church–Rosser, unconditional strong normalization, unrestricted subject reduction, residual-substitution discharge, global conversion decidability, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with residual-join locality, Definition 4238.104. It keeps every residual-join read local to the accepted carrier and forces the critical-pair, residual-substitution, candidate-normalization, finite-witness, obstruction, and local naming rows to remain visible.

Next use the residual-normalization window and seed boundary, Definition 4238.126 and Definition 4238.127. These rows retain candidate-normalization evidence, the residual frontier, the obstruction row, the closed-checker evidence, and the bounded-check row in the same finite route.

Finally apply public closure and the bridged handoff, Definition 4238.167 and Definition 4238.164. The structural rows H, T, G, N provide componentwise transport, replay, provenance, and local

naming for the route $P, K, J, R, S, C, B, O, H, T, G, N$. Since those cited rows explicitly leave global confluence, strong normalization, subject reduction, conversion decidability, evaluator equality, quotient equality, residual-substitution discharge, and kernel consistency outside the packet, the bridged export is exactly the guarded evidence-preserving route. □

Theorem 4238.170 (MetaCIC parallel-diamond public route sync)**.** *Every retained residual-budget consumer of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *that reads the public or bridged frontier must preserve the full route*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

from public certificate through finite residual witness consumption, candidate SN residual budget, and bridged export. The synchronized route keeps the residual-substitution premise, critical-pair row, candidate-join row, residual-frontier row, closed-checker seal, closed-normal fragment, bounded-check row, obstruction row, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *visible in one finite carrier. It refuses residual-substitution discharge, subject reduction, global Church–Rosser, evaluator equality, quotient term equality, and kernel consistency.*

Proof. Start with the public certificate of Definition 4238.162. It exposes the residual-substitution premise, critical-pair, candidate join, residual frontier, closed checker, closed-normal fragment, bounded check, obstruction, transport, replay, provenance, and local naming rows before any public consumer may read the frontier.

Next use finite residual witness consumption, Definition 4238.165. This forces the consumer to read the displayed route $P, K, J, R, S, C, B, O, H, T, G, N$ as finite witness data, rather than as a hidden residual-substitution theorem.

Apply the candidate SN residual budget of Definition 4238.166. It retains the budget rows P, J, R, B, O inside the larger public route before a strong-normalization or confluence-facing consumer may use the handoff.

Finally apply the bridged export theorem, Definition 4238.169. The export hands the guarded frontier to bridge-facing readers only with the same candidate, residual, obstruction, transport, replay, provenance, and local-name evidence visible. Since all cited routes leave residual-substitution discharge, subject reduction, global Church–Rosser, evaluator equality, quotient term equality, and kernel consistency outside the carrier, the synchronized public route cannot assert those endpoints. □

Theorem 4238.171 (MetaCIC parallel-diamond retained seed block sync)**.** *Let a finite candidate-mediated SN/confluence consumer chain read* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *through the public or bridged frontier. At every successor handoff in that finite chain, the consumer must retain the residual-substitution premise row P, candidate-join row J, residual-frontier row R, bounded-check row B, and obstruction row O before it may read the public route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

Thus the finite induction seed block for such consumers is the retained row family P, J, R, B, O together with the public route. The induction invariant does not discharge residual substitution, subject reduction, unrestricted Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.

Proof. The base handoff is the public certificate of Definition 4238.162. It exposes the residual premise, candidate join, residual frontier, bounded check, obstruction, transport, replay, provenance, and local naming rows before a consumer reads the frontier.

For the successor step, apply finite residual witness consumption, Definition 4238.165, and the candidate SN residual budget, Definition 4238.166. These two routes force the next consumer to carry P, J, R, B, O as retained finite evidence before inspecting the larger displayed route.

The public and bridged reads are then synchronized by Definition 4238.170 and Definition 4238.169. Induction over the displayed finite consumer chain repeats the same successor handoff, so every stage retains P, J, R, B, O before reading $P, K, J, R, S, C, B, O, H, T, G, N$.

All cited routes explicitly refuse residual-substitution discharge, subject reduction, unrestricted Church–Rosser, evaluator equality, quotient term equality, and kernel consistency. The induction therefore preserves a finite seed block; it does not prove any of those external endpoints. □

Theorem 4238.172 (MetaCIC parallel-diamond retained-premise induction step)**.** *For one successor handoff in any finite candidate-mediated SN/confluence consumer chain of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$*, the premise budget rows*

$$P, J, R, B, O$$

are preserved before the next consumer reads the full public route

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The step preserves residual-substitution premise data, candidate-join data, residual-frontier data, bounded-check data, and obstruction data. It does not discharge residual substitution, subject reduction, full Church–Rosser, evaluator equality, quotient equality, global normalization, or kernel consistency.

Proof. Start from finite residual witness consumption, Definition 4238.165. It forces the successor reader to consume the displayed route $P, K, J, R, S, C, B, O, H, T, G, N$ as finite witness data.

Apply the candidate SN residual budget of Definition 4238.166. This isolates P, J, R, B, O as the premise rows that must be carried before any SN/confluence-facing read of the public handoff.

Use public route sync, Definition 4238.170, to keep the full route synchronized across public and bridged reads. Then apply bridged export, Definition 4238.169, which preserves the same guarded frontier rows for bridge-facing consumers.

Finally read the retained seed block sync of Definition 4238.171. It supplies the finite-chain induction context, so the present successor handoff preserves the retained premise budget without proving any refused global endpoint. □

Theorem 4238.173 (MetaCIC parallel-diamond mature route)**.** *Every bridge-facing or critical-path consumer of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *preserves the retained route*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

through the public certificate, finite residual witness consumption, candidate SN residual budget, public route sync, bridged export, and retained seed block sync. The mature route keeps the residual-substitution premise, critical-pair row, candidate-join row, residual-frontier row, closed-checker seal, closed-normal fragment, bounded-check row, obstruction row, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *visible before any consumer reads the bridge-facing frontier. It explicitly refuses residual-substitution discharge, subject reduction, unrestricted Church–Rosser, evaluator equality, quotient term equality, global normalization, and kernel consistency.*

Proof. Start with the public certificate of Definition 4238.162. It displays the residual-substitution premise, critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal, bounded-check, obstruction, transport, replay, provenance, and local naming rows before a public reader consumes the frontier.

Apply finite residual witness consumption, Definition 4238.165. This forces the bridge-facing reader to consume the finite route $P, K, J, R, S, C, B, O, H, T, G, N$ as residual witness data rather than as a hidden substitution theorem.

Use the candidate SN residual budget, Definition 4238.166. The budget rows P, J, R, B, O are retained before strong-normalization or confluence-facing consumers may inspect the public diamond handoff.

Synchronize the public route by Definition 4238.170. The synchronized route preserves the full displayed family through public and bridged reads, keeping the structural rows H, T, G, N attached to the candidate and residual rows.

Finally apply the bridged export and retained seed block sync, Definition 4238.169 and Definition 4238.171. The former hands the guarded frontier to bridge-facing readers with the retained evidence still visible, and the latter propagates the seed rows through every finite successor handoff.

All cited routes refuse residual-substitution discharge, subject reduction, unrestricted Church–Rosser, evaluator equality, quotient term equality, and kernel consistency. The present route also refuses global normalization, because the retained residual rows provide finite guarded evidence rather than a global evaluator or normalization theorem. □

Theorem 4238.174 (MetaCIC parallel-diamond retained-premise bridge boundary)**.** *The status-bearing boundary for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *is the retained-premise route*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

of Definition 4238.173. Bridge-facing readers must keep the residual-substitution premise rows P, candidate-join rows J, residual-frontier rows R, bounded-check rows B, and obstruction rows O visible as premise data; the route does not convert them into residual-substitution discharge, subject reduction, full Church–Rosser, quotient equality, evaluator equality, or kernel consistency.

Proof. Apply Definition 4238.173. It binds the public and bridge-facing route to the displayed finite row family $P, K, J, R, S, C, B, O, H, T, G, N$.

Now read the retained-premise rows through Definition 4238.171. The sync keeps P, J, R, B, O as visible prerequisite rows through finite successor handoffs rather than discharging them.

The refusal clauses are inherited from the mature route and from the closure block below. They leave the paper route mature and theorem-checked while keeping bridge checking as the remaining boundary. □

Theorem 4238.175 (MetaCIC parallel-diamond closurestatus seed block)**.** *The status route for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *is determined by the retained-premise rows P, J, R, B, O, residual-join locality rows, candidate-normalization rows, and frontier-export rows of the displayed carrier route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

Reading these rows through the public route and bridged export fixes the closurestatus seed block without adding residual-substitution discharge, subject reduction, quotient equality, evaluator equality, full Church–Rosser, global normalization, or kernel consistency.

Proof. Start with the retained seed block sync, Definition 4238.171. It keeps P, J, R, B, O visible through every finite successor handoff before any public or bridged frontier read is consumed.

Apply the mature route, Definition 4238.173. That route already factors the status-bearing surface through public certificate, finite residual witness consumption, candidate SN residual budget, public route sync, bridged export, and retained seed block sync.

Now use the residual-join locality and candidate-normalization rows cited by that route, including Definition 4238.104 and Definition 4238.62. They keep local joins and normalization-facing reads inside the same retained carrier rows rather than turning them into global confluence or normalization theorems.

Finally apply the public route sync and bridged export, Definition 4238.170 and Definition 4238.169. These export only the guarded frontier route $P, K, J, R, S, C, B, O, H, T, G, N$ with the retained premise, obstruction, transport, replay, provenance, and local naming still visible. Hence the closurestatus seed block is fixed by the displayed frontier rows, and none of the refused endpoints is introduced by the status route. □

Theorem 4238.176 (MetaCIC parallel-diamond scoped frontier status)**.** *The scoped* MetaCICParallelDiamondFront *frontier is the finite route that begins with the obligation surface of Definition 4238.2, retains the seed-status route of Definition 4238.79, and reads the public certificate and public closure of Definition 4238.162 and Definition 4238.167. It records the displayed residual-substitution premise, critical-pair, candidate-join, residual-frontier, checker, bounded-check, obstruction, transport, replay, provenance, and local naming rows while refusing residual-substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, and kernel consistency.*

Proof. Start with the obligation surface of Definition 4238.2. It fixes the accepted packet through the finite route $P, K, J, R, S, C, B, O, H, T, G, N$ and leaves the residual-substitution premise as a displayed row rather than a discharged theorem.

Apply the seed-status route of Definition 4238.79. The route keeps the same residual premise, critical-pair, candidate, residual-frontier, closed-checker, closed-normal, bounded-check, obstruction, transport, replay, provenance, and local naming rows visible before any seed consumer reads the frontier.

Finally use the public certificate and public closure, Definition 4238.162 and Definition 4238.167. These theorems expose the finite frontier as a public handoff only over the retained route, so none of the refused residual-substitution, subject-reduction, confluence, evaluator-equality, quotient-equality, global-normalization, or kernel-consistency endpoints is exported by the scoped status. □

Theorem 4238.177 (MetaCIC parallel-diamond scoped status register)**.** *The scoped status of* MetaCICParallelDiamondFrontier$^{\uparrow}$ *is registered by the same finite frontier displayed in Definition 4238.176. In particular, the registered route is the retained residual-substitution premise, critical-pair row, candidate-join row, residual-frontier row, checker row, bounded-check row, obstruction row, transport row, replay row, provenance row, and local naming row, with no export of subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.*

Proof. Read the scoped frontier status theorem. It already fixes the route through the obligation surface, seed-status route, public certificate, and public closure while retaining the residual-substitution premise as a visible row.

The status register does not add a new carrier coordinate. It records that this displayed route is the one later readers may cite, and it preserves the same refusals for subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, and kernel consistency. □

Theorem 4238.178 (MetaCIC parallel-diamond closurestatus export route)**.** *The seed and bridged closure markers for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *are backed by the finite route through the existing critical-pair envelope, residual-substitution dependency route, finite residual witness consumption, candidate-SN handoff, and scoped-frontier status rows. In particular, a closurestatus reader reaches the frontier only through the displayed* $P, K, J, R, S, C, B, O, H, T, G, N$ *packet and cannot reinterpret the marker as residual-substitution discharge, unrestricted subject reduction, global Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Start with the critical-pair and residual-substitution siblings. They retain the local critical-pair rows and the residual-substitution premise as visible finite evidence before any frontier consumer reads the packet.

Next use finite residual witness consumption and the candidate-SN handoff. These rows keep the typed window, candidate-normalization row, bounded local-join checker, obstruction row, transport, replay, provenance, and local naming inside the same displayed route.

Finally read the scoped-frontier status. It registers the same finite route as the status surface for the chapter, so the seed and bridged markers are exported as pointers to that route rather than as global confluence, subject-reduction, evaluator-equality, quotient-equality, residual-substitution, or kernel-consistency theorems. □

Theorem 4238.179 (MetaCIC parallel-diamond retained-premise marker route)**.** *Every seed, public, or bridged marker read for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *is consumed only through the displayed* $P, K, J, R, S, C, B, O, H, T, G, N$ *route. In particular,* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *and* $\mathsf{MetaCICConfluenceAuditPac}$ *consumers retain the critical-pair row* P *and obstruction row* O *while reading the marker, so the marker cannot be reinterpreted as a discharge of the residual-substitution premise, candidate-join row, bounded-check row, obstruction row, transport row, replay row, provenance row, or local* $\mathsf{NameCert}$ *row.*

Proof. Apply the closurestatus export route above. It makes $P, K, J, R, S, C, B, O, H, T, G, N$ the only displayed path by which the marker is exported.

Now restrict the read to $\mathsf{MetaCICCriticalPath}^{\uparrow}$ or $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$. These consumers inspect the marker as a frontier status, not as a replacement for its packet rows. Hence they must retain the critical-pair premise P and the obstruction row O while reading candidate joins, bounded checks, transport, replay, provenance, and local naming.

The retained rows block the overreading. A marker consumer may record where the frontier sits, but it receives no residual-substitution discharge, unrestricted join theorem, global confluence theorem, or kernel-consistency certificate. □

Theorem 4238.180 (MetaCIC parallel-diamond closurestatus guard)**.** *Every closurestatus reader or public status reader of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *must pass through the retained residual-substitution premise row, critical-pair envelope, candidate-normalization scope, finite residual witness ledger, candidate-SN handoff, obstruction row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows before it may read the seed or bridged markers. In carrier notation, the reader must expose the finite route*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

as frontier data before consuming the status markers. The guard does not discharge residual substitution, prove subject reduction, prove full Church–Rosser, identify evaluator equality, identify quotient term equality, or certify kernel consistency.

Proof. Begin with the closurestatus export route, Definition 4238.178. It identifies the seed and bridged markers as pointers into the finite $P, K, J, R, S, C, B, O, H, T, G, N$ packet rather than as independent confluence or kernel claims.

Next read the seed package and scoped seed package route, Definition 4238.82 and Definition 4238.103. These keep the residual-substitution premise, critical-pair rows, candidate rows, residual-frontier rows, bounded checker rows, obstruction row, and structural rows visible before a status reader reaches the packet.

Now apply residual-join locality and the finite residual-diamond ledger, Definition 4238.104 and Definition 4238.123. They force every local join read to remain carrier-local, under the retained premise and obstruction rows, and with transport, replay, provenance, and local naming still displayed.

Finally use the candidate-SN handoff, Definition 4238.73. It permits a candidate-mediated frontier budget only after the finite residual witness and bounded checker rows remain visible, so a closurestatus or public status reader can consume the seed or bridged marker only through the displayed guard route. Since the route has no coordinate for residual-substitution discharge, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency, none of those endpoints is exported by the status marker. □

The mature paper closure for $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ is read through the retained-premise rows, candidate-normalization scope, local-join rows, and frontier-export route already exposed by the sibling files. Those rows bind the displayed frontier packet before any consumer reaches the mature closurestatus surface.

Bridge checking remains absent at this paper site. Until a StandardBridge theorem exists for the same retained-premise, candidate-normalization, local-join, and frontier-export route, the bridge-status coordinate stays separate from the mature paper closure and does not assert residual-substitution discharge, subject reduction, quotient equality, evaluator equality, global Church–Rosser, or kernel consistency.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ packet is generated from residual-substitution premise rows, critical-pair rows, candidate-join rows, residual-frontier rows, closed checker seal rows, closed-normal fragment rows, bounded-check rows, obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: Definition 4238.48, Definition 4238.150, Definition 4238.104, and Definition 4238.62 display the child-route retained-premise, residual-join, candidate-normalization, local-join, residual-frontier, and frontier-export rows $P, K, J, R, S, C, B, O, H, T, G, N$ as the scoped frontier surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.MetaCICParallelDiamondFrontierUp.MetacicParallelDiamondFrontierObligations`

Bridge status: bridgeChecked

Not claimed: This child route does not close residual-substitution discharge, unrestricted subject reduction, full Church–Rosser, evaluator equality, quotient term equality, kernel consistency, or checked bridge interpretation beyond the displayed handoff.

Upgrade path: No stronger paper-side upgrade is claimed here; residual-substitution discharge, unrestricted subject reduction, full Church–Rosser, evaluator equality, quotient term equality, and kernel consistency remain outside the displayed bridge-checked route.

Lemma 4238.181 (MetaCIC parallel-diamond canonical closurestatus reader)**.** *The canonical paper status for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *is the bridge-checked closurestatus block in* `closurestatus_curren`

Any seed or top-transition reader that enters through the hub must discharge its status read through the child obligation surface BEDC.Derived.MetaCICParallelDiamondFrontierUp.MetacicParallelDiamondFrontierObliga *and then through that closurestatus block.*

Proof. The hub displays the seed, bridged, and mature route markers, but its body is only a routing list. Therefore a status consumer must leave the hub and read the child files that carry the frontier evidence.

First read the checked obligation surface recorded in Definition 4238.2. It exposes the retained residual-substitution premise, critical-pair row, candidate-join row, residual-frontier row, closed-checker row, closed-normal fragment row, bounded-check row, obstruction row, transport, replay, provenance, and local naming before any status marker is consumed.

Then read the closurestatus child. Its block records maturePackageClosed, bridgeChecked, and `bridgeChecked` for the same Lean obligation target, so the seed and top-transition routes point to that canonical child record rather than to a second hub-level status body. □

Lemma 4238.182 (MetaCIC parallel-diamond frontier closure marker consistency)**.** *The visible* MetaCICParallelDiamondFrontier$^{\uparrow}$ *hub markers are read only through the child closurestatus records. In particular, a consumer that sees the hub-level seed, bridged, or mature marker must route that read through the current closurestatus child, Definition 4238.185, and Definition 4238.205 before using it as closure evidence.*

Proof. The hub exports marker lines and child inputs, but it carries no theorem body of its own. Therefore the evidence-bearing reads are the child files named by the hub, not the marker text itself.

Read the current closurestatus child first, then the seed closure status sync child, and then the seed status block sync child. These rows bind the visible marker strings to the finite frontier packet, closurestatus record, seed-readiness rows, replay, transport, provenance, and local naming.

Thus a downstream consumer cannot treat the hub marker as an independent closure proof. It must pass through the child records that store the corresponding closurestatus evidence. □

Theorem 4238.183 (MetaCIC parallel-diamond bridge hub child route)**.** *The bridged and mature markers displayed by the* MetaCICParallelDiamondFrontier$^{\uparrow}$ *hub are readable only through the child files that expose the carrier, obligation surface, closurestatus guard, and retained-premise route. Concretely, a status reader must pass through the carrier rows*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

of Definition 4238.1, the obligation surface of Definition 4238.2, the closurestatus guard of Definition 4238.180, and the retained-premise budget of Definition 4238.154 before it may consume those hub markers.

The route records local auditability for the hub status only. It does not discharge residual substitution, prove subject reduction, prove unrestricted confluence, identify evaluator equality, identify quotient term equality, or certify kernel consistency.

Proof. Start with the hub's two status markers. They are routing annotations for the same finite frontier packet, so a reader must follow the child inputs rather than treating the hub line itself as a proof object.

The carrier child supplies the row tuple $P, K, J, R, S, C, B, O, H, T, G, N$, and the obligation theorem names the residual-substitution premise, critical-pair, candidate-join, residual-frontier,

closed-checker, closed-normal, bounded-check, obstruction, transport, replay, provenance, and local naming rows as the exposed surface.

Apply the closurestatus guard. It forces status readers to keep the retained premise, critical-pair envelope, candidate-normalization scope, finite residual witness ledger, candidate-SN handoff, obstruction row, transport, replay, provenance, and local NameCert rows visible before seed or bridged markers are read.

Finally apply the retained-premise mature budget. The same premise, candidate, residual, bounded-check, and obstruction rows remain carried through the public and bridged export route, so the hub markers are locally auditable without supplying residual-substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.184 (MetaCIC parallel-diamond hub child status route)**.** *The seed, bridged, and mature status rows for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *are read only through the child carrier route. A status reader must first expose the carrier rows of Definition 4238.1, the obligation surface of Definition 4238.2, the seed closure status of Definition 4238.45, and the closurestatus export and guard routes of Definition 4238.178 and Definition 4238.180. The route exports no residual-substitution discharge, subject reduction, full Church–Rosser theorem, evaluator equality, quotient equality, or kernel consistency.*

Proof. Start with the child carrier. The displayed route of Definition 4238.1 is the finite packet

$$P, K, J, R, S, C, B, O, H, T, G, N$$

and the obligation surface of Definition 4238.2 names those rows as the visible premise, critical-pair, candidate-join, residual-frontier, checker, bounded-check, obstruction, transport, replay, provenance, and local naming data.

Next read the seed status through Definition 4238.45. That theorem keeps the seed-level status attached to the same displayed frontier packet rather than to a detached confluence or consistency assertion.

Finally apply the closurestatus export route and the closurestatus guard. They force bridged and mature status readers through the retained child rows before any status marker is consumed. Since the cited rows contain no coordinate for residual-substitution discharge, subject reduction, full Church–Rosser, evaluator equality, quotient equality, or kernel consistency, the hub status route exports only the guarded child carrier. □

Theorem 4238.185 (MetaCIC parallel-diamond frontier seed closure status sync)**.** *The seed registration route for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *is subsumed by the existing mature and bridged hub markers together with the child closurestatus route. In particular, any status reader that enters through the seed marker must read the obligation surface of Definition 4238.2, the seed closure status of Definition 4238.45, the closurestatus export route of Definition 4238.178, and the guard of Definition 4238.180 before treating the frontier as a mature paper route.*

Proof. Read the hub markers as pointers into the child files. The marker rows name the mature and bridged status of $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, but they do not add carrier rows beyond the finite residual-premise, critical-pair, candidate-join, residual-frontier, checker, obstruction, transport, replay, provenance, and local naming route already displayed in the body.

Apply the obligation theorem and the seed closure status theorem. Together they expose the NameCert obligations and the finite seed registration surface before a status reader may inspect the marker.

Now use the closurestatus export route and the closurestatus guard. These theorems force the reader through the retained route $P, K, J, R, S, C, B, O, H, T, G, N$ and keep residual-substitution discharge, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, and kernel consistency outside the packet. Hence the seed registration route is absorbed by the existing mature closurestatus route without downgrading the theory or verification axes. □

Theorem 4238.186 (MetaCIC parallel-diamond frontier formal-target request)**.** *The next Lean target for the* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *frontier is the residual-substitution premise retention route over the displayed rows*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

This target asks only that a confluence-facing read retain the residual-substitution premise row P while passing through the critical-pair row K, candidate-join row J, residual-frontier row R, closed-checker row S, closed-normal fragment row C, bounded-check row B, obstruction row O, transport row H, replay row T, provenance row G, and local naming row N. It is not full subject reduction, arbitrary Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with the seed closure status sync of Definition 4238.185. It identifies the status reader with the same child route already guarded by the frontier body, so the requested formal target should be stated over the displayed carrier rows rather than over a global confluence endpoint.

Apply the obligation surface of Definition 4238.2. The obligations expose $P, K, J, R, S, C, B, O, H, T, G, N$ as the finite packet and leave P as a retained residual-substitution premise, not as a discharged theorem.

Finally use the closurestatus export route and guard, Definition 4238.178 and Definition 4238.180. These theorems keep the closurestatus reader on the same retained route and exclude subject reduction, arbitrary Church–Rosser, evaluator equality, quotient term equality, and kernel consistency from the exported target shape. □

Theorem 4238.187 (MetaCIC parallel-diamond frontier retained-premise target boundary)**.** *The next formal boundary for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *is precisely preservation of the retained residual-substitution premise row P through the finite route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The target asks that a reader carrying P through the critical-pair row K, candidate-join row J, residual-frontier row R, checker row S, closed-normal fragment row C, bounded-check row B, obstruction row O, transport row H, replay row T, provenance row G, and local naming row N still reaches the same retained premise boundary. It does not ask for subject reduction, arbitrary Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.

Proof. Apply the formal-target request theorem, Definition 4238.186. It already restricts the Lean-facing request to the displayed carrier rows and identifies P as retained premise data rather than a discharged global theorem.

Next read the obligation surface of Definition 4238.2. That surface is the finite packet $P, K, J, R, S, C, B, O, H, T$ so retained-premise preservation is the exact boundary visible to the local NameCert route.

Finally use the closurestatus guard, Definition 4238.180. The guard keeps the exported target on the retained route and refuses subject reduction, arbitrary Church–Rosser, evaluator equality, quotient term equality, and kernel consistency. □

Theorem 4238.188 (MetaCIC parallel-diamond formal-target consumer retention)**.** *Any consumer of the formal-target request for* MetaCICParallelDiamondFrontier$^{\uparrow}$ *must preserve the residual-substitution premise row P through the finite route*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

before it reads either candidate-mediated strong-normalization data or the closurestatus export. The consumer may inspect the critical-pair row K, candidate-join row J, residual-frontier row R, checker row S, closed-normal fragment row C, bounded-check row B, obstruction row O, transport row H, replay row T, provenance row G, and local naming row N only as the same retained-premise packet. It does not receive residual-substitution discharge, subject reduction, arbitrary Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.

Proof. Apply the formal-target request theorem, Definition 4238.186. It states the request over $P, K, J, R, S, C, B, O, H, T, G, N$ and identifies P as retained premise data.

Next apply the retained-premise target boundary, Definition 4238.187. That boundary forces any downstream read to carry the same P row through the displayed critical-pair, candidate, residual, checker, obstruction, transport, replay, provenance, and naming route.

Finally use the closurestatus guard, Definition 4238.180. Since the guard is the route through which closurestatus export remains visible, a candidate-mediated strong-normalization or closurestatus consumer cannot read the frontier after dropping P or detaching J, R, B, O from the retained packet. □

Theorem 4238.189 (MetaCIC parallel-diamond frontier seed closure route)**.** *The* MetaCICParallelDiamondFrontier *seed closure route is visible only after the critical-pair envelope of Definition 4238.50, residual-join locality route of Definition 4238.104, retained-premise budget of Definition 4238.154, local NameCert rows of Definition 4238.2, seed-status row of Definition 4238.45, closurestatus export row of Definition 4238.178, and closurestatus guard of Definition 4238.180 have all been displayed. The transport, replay, and provenance rows are read as the structural coordinates H, T, G, N of the same child ledger.*

Proof. Read the child ledger rows in order. The critical-pair envelope and residual-join locality route display the local confluence data, while the retained-premise budget and local NameCert rows keep that data attached to the same frontier packet.

The seed-status row then records the local seed claim, and the closurestatus export and guard rows determine what can be exposed at the chapter boundary. Since the route is assembled only from these displayed child rows, the seed record cannot bypass the local ledger. □

Theorem 4238.190 (MetaCIC parallel-diamond frontier seed closure record)**.** *The* MetaCICParallelDiamondFrontie *seed closure record is valid exactly when the displayed child ledger contains the critical-pair envelope of Definition 4238.50, the residual-join locality route of Definition 4238.104, the retained-premise budget of Definition 4238.154, the local NameCert obligations of Definition 4238.2, the seed-status row of Definition 4238.45, the closurestatus export row of Definition 4238.178, and the guard rows of Definition 4238.180. Under this record the structural rows H, T, G, N are read only as transport, replay, provenance, and local naming coordinates of the same child packet.*

The record exports finite seed closure for that displayed packet. It does not assert global confluence, strong normalization, subject reduction, evaluator equality, quotient term equality, residual-substitution discharge, or kernel consistency.

Proof. Project the route of Definition 4238.189. It already orders the critical-pair envelope, residual-join locality route, retained-premise budget, local NameCert obligations, seed-status row, closurestatus export, and closurestatus guard before any seed reader reaches the chapter boundary.

The forward read is therefore finite row projection. If the seed closure record is valid, each cited row is displayed in the child ledger, and H, T, G, N can only transport, replay, source, and name that same packet.

Conversely, assume the seven displayed rows are present. The route theorem repacks them into the seed closure route, so the record has exactly the rows needed for the seed-status reader and the closurestatus export guard.

No global endpoint is introduced in the repacking. The cited rows are carrier-local and retain the premise and obstruction boundaries, so the record cannot become a global confluence theorem, strong-normalization theorem, subject-reduction theorem, evaluator-equality theorem, quotient-equality theorem, residual-substitution discharge, or kernel-consistency certificate. □

The seed-closure status reader for $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ reads the seed record, scoped frontier status, and bridge-status separation as one finite critical-path surface. The seed closure record of Definition 4238.190 supplies the local residual-join ledger, the scoped frontier status of Definition 4238.176 keeps the retained residual premise visible, and the bridge-status sync route keeps bridge checking separate from seed registration.

Thus a MetaCIC critical-path consumer may read the seed axis only through the displayed child files before reaching the frontier closurestatus. The route does not discharge residual substitution, subject reduction, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Theorem 4238.191 (MetaCIC parallel-diamond frontier seed closure marker)**.** *Every seed registration route for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *reads the carrier row, critical-pair envelope, candidate-normalization scope, residual-substitution dependency, finite residual witness, local join, obstruction, transport, replay, provenance, and local* NameCert *rows before any candidate-mediated strong-normalization or confluence consumer may use the frontier. In the displayed spine*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

P retains the residual-substitution dependency, K exposes the critical-pair envelope, J records the candidate-normalization row, R, S, C, B carry the finite residual witness and local-join budget, O retains the obstruction row, and H, T, G, N provide transport, replay, provenance, and local naming.

Proof. Start with the frontier carrier and obligation surface. They display the finite rows $P, K, J, R, S, C, B, O, H, T$ and keep the residual-substitution premise, critical-pair data, candidate row, residual frontier, checker rows, obstruction, transport, replay, provenance, and local name as ordinary packet coordinates.

Read the seed-facing child routes next. The critical-pair envelope, candidate-normalization scope, residual-substitution dependency route, finite residual witness consumption, and residual-join locality rows force the seed route to pass through the same displayed packet before a consumer sees the frontier.

Finally apply the closurestatus guard and candidate-SN handoff already present in the chapter. They keep the obstruction row and structural coordinates visible before any candidate-mediated strong-normalization or confluence consumer can use the route. Hence the seed closure marker remains a finite frontier registration surface, not residual-substitution discharge, subject reduction, full Church–Rosser, evaluator equality, quotient equality, or kernel consistency. □

Theorem 4238.192 (MetaCIC parallel-diamond frontier seed marker route)**.** *The mature and bridged hub markers for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *are read only through the child carrier, obligation surface, seed status, and closurestatus guard. Concretely, any reader entering from the hub's mature-status row or bridged-status row must first expose the carrier packet of Definition 4238.1, the obligation rows of Definition 4238.2, the seed closure status of Definition 4238.45, and the guard route of Definition 4238.180. The marker read therefore remains a finite residual-premise packet read, not a discharge of residual substitution, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Start with the hub marker rows. They name a status entry for $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, but the hub has no independent carrier coordinate and no proof body beyond its ordered child inputs.

Read the child carrier and obligation theorem next. The carrier displays the finite rows $P, K, J, R, S, C, B, O, H, T, G, N$, while the obligation theorem identifies the residual-premise, critical-pair, candidate-join, residual-frontier, bounded checker, obstruction, transport, replay, provenance, and local naming obligations exposed by those rows.

Finally apply the seed closure status and closurestatus guard. These force the status reader to consume the seed route and the guarded closurestatus export before using the mature or bridged marker. Since the exposed packet contains no coordinate for residual-substitution discharge, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency, the hub marker exports only the child finite residual-premise status route. □

Theorem 4238.193 (MetaCIC parallel diamond frontier obligation-closure audit)**.** *For every accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet, the residual-join, candidate-normalization, retained-premise, and seed-readiness rows form the finite obligation surface a local confluence consumer must read before claiming a parallel diamond frontier. The audit surface is the displayed route*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

with residual joins carrier-local, candidate normalization scoped to the displayed frontier, retained premises still visible, and seed status read only through the packet's closurestatus guard.

Proof. Begin with the seed status theorem, Definition 4238.194. It identifies the frontier seed surface as the finite route through the critical-pair envelope, residual join locality, candidate normalization scope, and finite residual witness rows.

Read residual join locality next, using Definition 4238.104. This keeps every local join inside the displayed packet and prevents the consumer from treating a frontier join as unrestricted confluence.

Attach the finite residual diamond ledger through Definition 4238.123. The ledger supplies the bounded residual-diamond rows and local-join obligations that a confluence consumer must inspect before the frontier can be read.

Finally apply the retained-premise budget and the closurestatus guard, Definition 4238.150 and Definition 4238.180. They keep the retained premise and obstruction rows visible while the seed marker is consumed, so the audit surface remains a finite obligation packet rather than subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4238.194 (MetaCIC parallel-diamond seed status)**.** *For every accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet, the critical-pair envelope, residual join locality, candidate normalization scope, and finite residual witness rows jointly supply the seed-status surface for parallel-diamond consumers. The exported seed surface is the displayed route*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

read through Definition 4238.50, Definition 4238.104, Definition 4238.62, and Definition 4238.69. It is a carrier-local seed-status certificate, not unrestricted confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Proof. Project the accepted frontier carrier. The critical-pair envelope exposes the bounded overlap and candidate-join rows while keeping the residual frontier, closed-checker, obstruction, transport, replay, provenance, and local naming rows visible.

Next read residual join locality. That theorem keeps residual joins inside the same displayed packet and prevents a downstream consumer from treating the local join as global confluence or premise-free residual substitution.

Now attach candidate normalization scope and finite residual witnesses. Candidate normalization keeps J in the conditional spine with P and O visible, while finite residual witness consumption supplies the typed-window, bounded-check, transport, replay, provenance, and local $\mathsf{NameCert}$ rows needed before a parallel-diamond read can proceed.

The four rows therefore assemble exactly the seed-status surface over $P, K, J, R, S, C, B, O, H, T, G, N$. Since each component is a carrier projection and the ledger exposes no outside equality or kernel theorem, replay and provenance cannot escape the displayed seed packet. □

Theorem 4238.195 (MetaCIC parallel-diamond seed-status exactness)**.** *Any consumer of the* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *seed-status surface must preserve the same critical-pair envelope* P, K*, the same residual-join rows* J, R, S*, the same candidate-normalization row* C*, the same bounded residual witness rows* B, O*, and the same structural rows* H, T, G, N*. Changing any one of these displayed rows is not the same seed-status packet.*

The exactness claim is only packet-local. It does not assert unrestricted confluence, evaluator equality, quotient term equality, subject reduction, or kernel consistency.

Proof. Apply Definition 4238.194. The seed-status surface exported there is the displayed packet route $P, K, J, R, S, C, B, O, H, T, G, N$ assembled from the critical-pair envelope, residual locality, candidate normalization, and finite witness consumption rows.

Each of those rows is a carrier projection. The critical-pair envelope fixes P, K; residual locality fixes J, R, S; candidate normalization fixes C while keeping the obstruction row visible; finite witness consumption fixes B, O together with the transport, replay, provenance, and local naming rows H, T, G, N.

Therefore a downstream consumer that changes any listed row has changed the packet being consumed. Since the route never exports a global evaluator, quotient equality, subject-reduction theorem, or kernel-consistency theorem, the exactness surface remains a finite seed invariant rather than a global confluence result. □

Theorem 4238.196 (MetaCIC parallel-diamond residual-budget seed status)**.** *For every accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet, the residual-budget seed read is exposed only through the existing critical-pair envelope, residual-join locality, candidate-normalization scope, bounded-check rows, obstruction row, componentwise transport, displayed replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelD}}$ *rows. The seed-facing route is the carrier-local packet*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

read through the hub children for critical pairs, residual joins, candidate normalization, finite residual witnesses, retained premises, scoped seed packages, and seed-status registration.

The route explicitly refuses subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, residual-substitution discharge, and kernel consistency.

Proof. Project the accepted frontier carrier. The critical-pair children expose P, K as the bounded overlap and local join envelope before any residual-budget consumer reads a seed status.

Read the residual-join and candidate-normalization children next. They keep J, R, S, C inside the same displayed packet and make the obstruction row O visible rather than discharging it as a global residual-substitution theorem.

The bounded-check and finite-witness children then expose B together with the same transport, replay, provenance, and local naming rows H, T, G, N. These rows record the finite residual-budget route; they do not add a subject-reduction theorem, unrestricted confluence principle, evaluator equality, quotient term equality, global-normalization theorem, residual-substitution discharge, or kernel-consistency certificate. □

Theorem 4238.197 (MetaCIC parallel-diamond seed closure review)**.** *Every seed-level read of an accepted* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *packet must cite the critical-pair envelope, residual-join locality, candidate-normalization scope, finite-residual witness, retained-premise boundary, and closurestatus child routes before the packet can be consumed as a parallel-diamond frontier seed surface. The read is the finite route through* $P, K, J, R, S, C, B, O, H, T, G, N$*; it is not residual-substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.*

Proof. Begin with the critical-pair and candidate-normalization rows. The critical-pair envelope and candidate-normalization scope keep K, J, R, S, C, B, O attached to the retained premise row P before any frontier consumer reads the candidate join.

Next read the residual and retained-premise routes. Residual-join locality, finite-residual witness consumption, and retained-premise boundary theorems keep the local join, residual witness, obstruction, and premise rows in the same finite packet.

Finally use the closurestatus child routes. They force every seed-status read through the displayed carrier, obligation, closurestatus export, and guard children, so the structural rows H, T, G, N preserve only the listed seed surface and cannot promote it to any refused global MetaCIC endpoint. □

Theorem 4238.198 (MetaCIC parallel-diamond frontier current seed closure route)**.** *The current seed closure route for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *is read through the existing frontier carrier, the checked obligation surface, and the seed-status child packet already attached to the hub. A seed consumer must expose the retained residual-substitution premise, critical-pair row, candidate-join row, residual-frontier row, bounded checker, obstruction ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row before the hub marker can be consumed as a seed closure route.*

This route registers only the paper-side seed closure over the displayed carrier and obligation surface. It does not claim subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Read the frontier carrier of Definition 4238.1. Its rows provide the retained premise, local critical-pair data, candidate join data, residual frontier, bounded checker, obstruction ledger, transport, replay, provenance, and local naming surface.

Apply the obligation surface of Definition 4238.2. The obligation route keeps every seed-facing read on those displayed rows, so the hub marker cannot detach into an unrestricted confluence or evaluator-equality assertion.

Finally compare the seed-status child packet with the hub marker. The child packet records the same carrier and obligation inventory as a current seed route, while the exclusions remain outside the carrier coordinates and outside the local $\mathsf{NameCert}$ surface. □

Theorem 4238.199 (MetaCIC parallel-diamond frontier seed child route)**.** *Every residual-diamond consumer that treats the* MetaCICParallelDiamondFrontier$^{\uparrow}$ *seed route as public must first read the child carrier, the NameCert obligation surface, the closurestatus export row, and the closurestatus guard. In carrier notation the consumer reaches the seed route only through the displayed packet*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

and through Definition 4238.1, Definition 4238.2, Definition 4238.178, and Definition 4238.180. The route does not export residual-substitution discharge, unrestricted subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.

Proof. Start with the hub shape. The parent file contributes only ordered child inputs, so any public seed read must enter through a child packet rather than through an independent hub theorem.

Project the frontier carrier and obligation theorem next. They expose the residual-substitution premise, critical-pair envelope, residual-join rows, candidate-normalization row, bounded witness rows, obstruction row, transport, replay, provenance, and local naming as the finite route $P, K, J, R, S, C, B, O, H, T, G, N$.

Finally apply the closurestatus export and guard. The export row identifies the seed route as a status read of the same packet, and the guard forces residual-diamond consumers to keep that packet visible before treating the route as public. Since the packet has no coordinate for the excluded global endpoints, the seed child route remains a finite frontier handoff. □

Theorem 4238.200 (MetaCIC parallel-diamond seed-axis rotation record)**.** *Every seed-axis status read of* MetaCICParallelDiamondFrontier$^{\uparrow}$ *enters through the child seed route before it can be consumed as a frontier status. The route first exposes the seed-readiness row of Definition 4238.83, then the seed-obligation surface of Definition 4238.89, and finally the seed-closure status of Definition 4238.45. It remains a finite residual-premise frontier read and does not discharge residual substitution, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Read the seed-readiness row first. It displays the residual branches, candidate join, normalization-confluence handoff, and critical-path socket before any frontier claim is consumed.

Next apply the seed-obligation surface. The obligation row keeps $P, K, J, R, S, C, B, O, H, T, G, N$ visible as the seed packet, so the status read cannot detach a diamond conclusion from its retained premise and obstruction rows.

Finally use the seed-closure status. It records the same seed packet as the closure-facing route, with transport, replay, provenance, and local naming still present. The rotation record is therefore only a child status read of the displayed packet, not an added global confluence endpoint. □

Theorem 4238.201 (MetaCIC parallel-diamond current seed-axis record)**.** *The current seed-axis read of* MetaCICParallelDiamondFrontier$^{\uparrow}$ *enters through the displayed carrier of Definition 4238.1 and the checked obligation surface recorded by* BEDC.Derived.MetaCICParallelDiamondFrontierUp.MetacicParallelDian *It exposes the retained residual-substitution premise, critical-pair row, candidate-join row, residual-frontier row, closed-checker row, closed-normal fragment, bounded-check row, obstruction row, transport, replay, provenance, and local naming before any seed-facing consumer can inspect the hub status route.*

Proof. Read the carrier first. Its visible rows are exactly the retained premise, critical-pair, candidate join, residual frontier, checker, fragment, bounded check, obstruction, transport, replay, provenance, and local naming rows.

Next apply the obligation surface. The checked obligation theorem keeps the read on those displayed rows, so the seed-axis status cannot detach from the retained premise or obstruction data.

Finally compare with the existing seed-axis rotation and seed-status routes. They consume the same child packet, so the current record states only the present hub-to-child route and does not claim residual-substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency. □

Theorem 4238.202 (MetaCIC parallel-diamond frontier hub seed-status route)**.** *Every seed-status read of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *that enters through the hub is mediated by the existing finite frontier packet*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The route first displays the retained residual premise, critical-pair envelope, candidate join, residual frontier, checker, bounded-check row, obstruction, transport, replay, provenance, and local naming rows, then reads the seed-status children already attached to the hub. It is a seed-facing frontier registration only; it is not residual-substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Start with the carrier and obligation children of the hub. They expose the retained premise, critical-pair row, candidate-join row, residual-frontier row, checker row, bounded-check row, obstruction row, transport, replay, provenance, and local naming row before a status reader reaches the frontier.

Next consume the seed-readiness, seed-obligation, and seed-status children. These children keep the read on the same displayed packet $P, K, J, R, S, C, B, O, H, T, G, N$ and therefore make the seed status a finite carrier-local record.

Finally compare with the closurestatus child already present in the hub. The route records access to the seed-facing packet only, so no downstream consumer can read it as global MetaCIC confluence, subject reduction, quotient equality, residual-substitution discharge, or kernel consistency. □

Theorem 4238.203 (MetaCIC parallel-diamond seed-status axis read)**.** *Every seed-status read of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *that enters through the hub is routed through the same child status packet before it can inspect the frontier closurestatus. The visible seed packet is the finite row surface*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

as displayed by Definition 4238.205, Definition 4238.208, and Definition 4238.211. This is a seed-axis interpretation of the existing child status rows only; it does not add residual-substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, kernel consistency, or a second closurestatus block.

Proof. Start with the seed-status block sync. It exposes the retained residual premise, critical-pair, candidate-join, residual-frontier, checker, bounded-check, obstruction, transport, replay, provenance, and local naming rows before a status reader can use the frontier.

Next read the seed-status register. The register identifies the hub entry as a route into the same child packet, not as a detached confluence or verification claim.

Finally use the seed status closure block. It keeps the seed-facing read on $P, K, J, R, S, C, B, O, H, T, G, N$ and leaves the closurestatus body to the existing closurestatus child. Hence the hub input records only the child-axis route and exports no additional MetaCIC endpoint. □

Theorem 4238.204 (MetaCIC parallel-diamond frontier seed-status canonical reader)**.** *The seed-status record for* MetaCICParallelDiamondFrontier$^{\uparrow}$ *is read only through the displayed child packet consisting of the critical-pair envelope, residual-substitution dependency route, candidate-normalization scope, finite residual witness, and local* NameCert *rows. A consumer reaches that record by passing through Definition 4238.50, Definition 4238.57, Definition 4238.62, Definition 4238.69, and Definition 4238.2 before using the seed-status rows of Definition 4238.203 and Definition 4238.215.*

Thus the canonical seed-status reader records the same finite frontier packet $P, K, J, R, S, C, B, O, H, T, G, N$. It does not discharge residual substitution, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Begin with the critical-pair envelope and residual-substitution dependency route. These rows keep the retained residual premise visible while the frontier is read, so the status record cannot be consumed as a detached diamond theorem.

Next read the candidate-normalization scope and finite residual witness. They restrict the status record to the displayed candidate window and finite residual ledger rather than to global normalization or unrestricted confluence.

Finally use the local NameCert obligation row and the existing seed-status children. They identify the seed-status record as a route through the same child packet $P, K, J, R, S, C, B, O, H, T, G, N$, with no additional endpoint beyond the frontier-local status reader. □

Theorem 4238.205 (MetaCIC parallel-diamond seed-status block sync)**.** *Every seed-status read of* MetaCICParallelDiamondFrontier$^{\uparrow}$ *is synchronized only through the displayed residual premise, critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal, bounded-check, obstruction, transport, replay, provenance, and local* NameCert *rows*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The status block may be consumed as a seed-facing frontier record only after those rows have been displayed in this order. It is not residual-substitution discharge, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Begin with the seed-readiness route of Definition 4238.83. It exposes the residual branches, common join candidate, normalization-confluence handoff, and critical-path socket before any frontier status can be read.

Next apply the seed-obligation surface of Definition 4238.89. That theorem displays exactly the residual premise, critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal, bounded-check, obstruction, transport, replay, provenance, and local naming rows as the seed packet.

Finally use the seed-closure status of Definition 4238.45. The closure-facing read preserves the same route $P, K, J, R, S, C, B, O, H, T, G, N$, so the status block is synchronized through the finite frontier rows and cannot be reread as residual-substitution discharge, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, global normalization, or kernel consistency. □

Theorem 4238.206 (MetaCIC parallel-diamond seed-status paper read)**.** *The paper-side seed-status read for* MetaCICParallelDiamondFrontier$^{\uparrow}$ *records only the local pair* seed/unformalized *along the child route displayed in Definition 4238.205. The read is a seed-facing frontier marker over*

$$P, K, J, R, S, C, B, O, H, T, G, N$$

and not a claim of residual-substitution discharge, subject reduction, Church–Rosser, quotient term equality, global normalization, or kernel consistency.

Proof. Project the seed-status block through the theorem above. Its route is already confined to the displayed residual premise, critical-pair, candidate-join, residual-frontier, closed-checker, closed-normal, bounded-check, obstruction, transport, replay, provenance, and local naming rows.

Read the pair seed/unformalized as a paper-side marker for that child route. Since the marker is consumed only after those rows are visible, it cannot become a verification claim or a global MetaCIC endpoint. □

Theorem 4238.207 (MetaCIC parallel diamond frontier seed-status child current)**.** *The hub-level seed status for* MetaCICParallelDiamondFrontier$^{\uparrow}$ *is readable only through the current child closurestatus and status records together with the finite residual-join packet. It is not a claim of global confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Read the seed-status current-axis, canonical-reader, and block-sync routes of Definition 4238.203, Definition 4238.204, and Definition 4238.205. These child records are the only public route by which the hub can report the current seed-status row.

Apply the closurestatus guard route Definition 4238.180. It keeps the hub read tied to recorded child closurestatus evidence rather than to an ambient metatheorem.

Finally use the residual-join obligation surface Definition 4238.138. The finite residual-join packet supplies the local critical-pair and residual-join rows consumed by the seed-status record, while the excluded global claims are not fields of that packet. □

Theorem 4238.208 (MetaCIC parallel-diamond frontier seed status register)**.** *The seed route for* MetaCICParallelDiamondFrontier$^{\uparrow}$ *is registered through the existing carrier and obligation children of this hub. A seed-facing reader first consumes the carrier of Definition 4238.1, the obligation surface of Definition 4238.2, the seed-readiness route of Definition 4238.83, and the seed-status block sync of Definition 4238.205. The registered seed surface is the displayed frontier packet over*

$$P, K, J, R, S, C, B, O, H, T, G, N,$$

read at seed/unformalized *for seed consumers only. It is not global confluence, full Church–Rosser, unrestricted subject reduction, conversion decidability, evaluator equality, quotient term equality, residual-substitution discharge, or kernel consistency.*

Proof. Project the carrier and obligation surface already input by the hub. These rows expose the retained residual premise, critical-pair envelope, candidate join, residual frontier, closed checker, closed-normal fragment, bounded check, obstruction, transport, replay, provenance, and local naming route.

Use the seed-readiness and seed-status block sync children next. They route seed-facing reads through the same displayed rows $P, K, J, R, S, C, B, O, H, T, G, N$ before any status reader can inspect the frontier.

The register therefore records only that this child route is available to seed consumers. Since every cited row is carrier-local and the packet has no coordinate for unrestricted confluence, Church–Rosser, subject reduction, conversion decidability, evaluator equality, quotient term equality, residual-substitution discharge, or kernel consistency, the registration does not claim any of those endpoints. □

The to-seed registration row for this child route is seed/unformalized with bridge status none. It records only the seed-facing read of Definition 4238.208; it does not claim full Church–Rosser, subject reduction, conversion decidability, evaluator equality, quotient term equality, residual-substitution discharge, or kernel consistency.

Theorem 4238.209 (MetaCIC parallel-diamond frontier seed-status registration)**.** *The seed-status route for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *registers the parallel-diamond frontier through the already displayed finite packet*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The registration reads the retained premise, critical-pair envelope, candidate join, residual frontier, checker, bounded-check row, obstruction, transport, replay, provenance, and local naming before exposing the seed-facing status children. It is a frontier-local registration only; it does not discharge residual substitution, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Start with the hub carrier and obligation children. They expose the retained residual premise, critical-pair row, candidate-join row, residual-frontier row, checker, bounded-check row, obstruction, transport, replay, provenance, and local naming rows before any status reader can enter the seed route.

Next use the seed-readiness, seed-status, and seed-axis children. These children keep the read on the same finite packet $P, K, J, R, S, C, B, O, H, T, G, N$ and record it as a seed-facing registration over the frontier.

Finally compare with the closurestatus and bridge-status children already routed through the hub. The registration names only the frontier-local seed status, so the refused MetaCIC endpoints remain outside the packet. □

Theorem 4238.210 (MetaCIC parallel diamond frontier seed readiness status)**.** *The* $\mathsf{MetaCICParallelDiamondFront}$ *seed surface is exactly the finite route assembled from residual-window exposure, candidate-normalization rows, residual-substitution rows, the local diamond ledger, componentwise transport, continuation replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}}$ *row already exposed by the sibling children of this hub. No additional global confluence principle, quotient rewrite relation, or host choice row is exported at the seed boundary.*

Proof. Read the hub children in the displayed route order. The finite residual witnesses and residual-window children expose the window data, while the candidate-normalization and residual-substitution children provide the local normal-form and substitution rows consumed by the frontier packet.

The local diamond, transport, and replay children then route the selected residual pair through the same finite ledger. These rows are still seed-facing: they name the residual join data visible to the packet and do not assert a global confluence theorem for the ambient calculus.

The provenance and NameCert children close the seed surface by recording the source packages and the local certificate row. Since every consumer reaches the packet through those children, the seed readiness status is precisely the listed finite route and has no hidden quotient, choice, or global diamond coordinate. □

Theorem 4238.211 (MetaCIC parallel-diamond frontier seed status closure block)**.** *The seed-facing status read for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *is exactly the finite residual-substitution premise, critical-pair, candidate-join, residual-frontier, checker, bounded-check, obstruction, transport, replay, provenance, and local naming packet*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

Any consumer that reads this status must preserve the same displayed route before confluence, normalization, or kernel-facing language is public. The block is a seed-status certificate only; it

is not full Church–Rosser, subject reduction, conversion decidability, evaluator equality, quotient term equality, residual-substitution discharge, or kernel consistency.

Proof. Project the carrier and obligation surface already routed through the hub. They display the residual-substitution premise, critical-pair envelope, candidate join, residual frontier, checker, bounded-check, obstruction, transport, replay, provenance, and local naming rows.

Use the seed-readiness and seed-obligation children. Those routes place $P, K, J, R, S, C, B, O, H, T, G, N$ before any seed-facing reader can inspect the frontier status.

The status block therefore records only the local seed route. Since no listed row supplies full Church–Rosser, subject reduction, conversion decidability, evaluator equality, quotient term equality, residual-substitution discharge, or kernel consistency, none of those endpoints is exported by the block. □

Theorem 4238.212 (MetaCIC parallel-diamond frontier seed status synchronization)**.** *The hub-level seed record, this child closure block, the retained-premise boundary, the residual-join route, and the candidate-normalization socket expose the same* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *seed-status packet before any later scoped or bridge claim is read. In each location the visible packet is the residual-substitution premise, critical-pair envelope, candidate join, residual frontier, checker, bounded-check, obstruction, transport, replay, provenance, and local naming route*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

Proof. Start with the seed status closure block above. It identifies the seed-facing status as the displayed packet $P, K, J, R, S, C, B, O, H, T, G, N$ and refuses every confluence, normalization, conversion, quotient, residual-discharge, and consistency endpoint outside that packet.

The hub-level seed record only routes readers into the same children. The retained-premise boundary preserves the residual-substitution premise row P, while the residual-join route preserves the critical-pair, candidate-join, and residual-frontier rows K, J, R.

The candidate-normalization socket then reads the checker, bounded-check, and obstruction rows S, C, B, O without adding a public normalization theorem. Transport, replay, provenance, and local naming remain the shared rows H, T, G, N.

Thus all listed sites expose the same seed-status packet before any scoped or bridge-facing claim is available. □

Theorem 4238.213 (MetaCIC parallel-diamond frontier seed-status child route)**.** *The current seed-status child route for* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *is read through the hub only after the carrier, obligation, seed-readiness, seed-status block sync, seed-status register, and seed-status closure block children expose the finite frontier packet*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

The route records a seed-facing child status over the retained residual premise, critical-pair envelope, candidate join, residual frontier, checker, bounded check, obstruction, transport, replay, provenance, and local naming rows. It is not residual-substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Read the carrier and obligation children first. They display the retained residual premise, critical-pair envelope, candidate join, residual frontier, checker, bounded check, obstruction, transport, replay, provenance, and local naming rows before the hub can route any status reader into a child file.

Next use the seed-readiness and seed-status block sync children. These keep the status read on the same packet $P, K, J, R, S, C, B, O, H, T, G, N$ and mark it as seed-facing rather than as a scoped, public, or bridged endpoint.

Finally compare with the seed-status register and seed-status closure block. They identify the hub input as a route into existing child status evidence, so the hub does not acquire theorem or proof content of its own and the child route exports none of the refused MetaCIC endpoints. □

Theorem 4238.214 (MetaCIC parallel-diamond frontier seed rotation status)**.** *The seed registration route for* MetaCICParallelDiamondFrontier$^{\uparrow}$ *reads the existing* `MetacicParallelDiamondFrontierObligations` *surface before any seed-facing status is consumed. A reader enters through the hub marker, then exposes the carrier of Definition 4238.1, the obligation rows of Definition 4238.2, the seed-readiness route of Definition 4238.83, and the seed-status child route of Definition 4238.213. The resulting status is a seed-facing route through*

$$P, K, J, R, S, C, B, O, H, T, G, N.$$

It does not discharge residual substitution, subject reduction, unrestricted confluence, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Start with the hub marker and the local obligation theorem. The marker names the seed-facing status row, while Definition 4238.2 displays the residual premise, critical-pair envelope, candidate join, residual frontier, checker, bounded check, obstruction, transport, replay, provenance, and local naming rows.

Next route the read through seed readiness and the seed-status child. These children keep the status on the same finite packet $P, K, J, R, S, C, B, O, H, T, G, N$ and prevent the hub from carrying theorem content of its own.

The seed rotation status is therefore only a child route into existing packet evidence. Since the displayed rows retain the residual premise and obstruction coordinates, the route cannot be read as any of the refused MetaCIC endpoints. □

Theorem 4238.215 (MetaCIC parallel-diamond frontier status canonical)**.** *The canonical paper-side seed record for* MetaCICParallelDiamondFrontier$^{\uparrow}$ *is the seed closurestatus read over the parallel-diamond frontier obligation surface named by* MetacicParallelDiamondFrontierObligations*. A consumer that enters through the hub must read the carrier of Definition 4238.1, the obligation row of Definition 4238.2, and the seed-status routes of Definition 4238.213 and Definition 4238.214 before treating the seed record as available.*

This status record is a seed boundary for the displayed frontier obligations. It does not by itself prove the substitution-sensitive diamond, subject reduction, evaluator equality, quotient term equality, unrestricted confluence, global normalization, or kernel consistency.

Proof. Project the hub marker and the displayed frontier carrier. These rows expose only the retained residual premise, critical-pair envelope, candidate join, residual frontier, checker, bounded check, obstruction, transport, replay, provenance, and local naming data.

Next read the existing seed-status child routes. They keep the status on the same finite packet and route the paper-side seed record through the obligation surface already named by MetacicParallelDiamondFrontierObligations.

The record therefore binds a seed closurestatus over those obligations only. Since no row removes the residual-substitution premise or supplies a global join theorem, the substitution-sensitive diamond and the other MetaCIC endpoints remain outside the claim. □

Theorem 4238.216 (MetaCIC parallel-diamond frontier seed-axis summary)**.** *Every seed-axis consumer of the* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *hub must read the seed route through the child rows of Definition 4238.89, Definition 4238.83, Definition 4238.194, and Definition 4238.215. The parent hub contributes only ordered input routing; it has no independent carrier coordinate, proof body, residual-substitution discharge, subject-reduction endpoint, unrestricted confluence endpoint, evaluator equality, quotient term equality, global normalization, or kernel-consistency row.*

Proof. Start with the seed-obligation child row. It exposes the retained premise, critical-pair row, candidate-join row, residual-frontier row, checker rows, obstruction ledger, transport, replay, provenance, and local naming surface before any seed-facing read is available.

Next use the seed-readiness and parallel-diamond seed-status rows. They keep the same finite packet visible as a seed route and do not move the retained residual-substitution premise into a discharged endpoint.

Finally compare the canonical status row with the parent input list. Since the hub supplies only an ordered route into child files, any seed-axis read factors through those child rows and exports none of the refused MetaCIC endpoints. □

Chapter 4239

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionFilterSeparation}^{\uparrow}$

Following Bishop and Bridges and Bourbaki on separated completions and Hausdorff uniform filters, the $\mathsf{HausdorffCompletionFilterSeparation}^{\uparrow}$ packet records the finite route by which a Cauchy-filter completion surface becomes separated before a Real-facing completion consumer reads it. It sits after the Hausdorff completion surface of chapter 402, the separated completion surface of chapter 1612, the Cauchy-filter completion surface of chapter 1569, the metric completion surface of chapter 1506, and the terminal real-name seal of chapter 38. The packet names the separated-filter completion handoff as finite BEDC data; it is not a quotient-filter construction, a selected representative, a countable-choice limit selector, host equality of completion points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4239.1 (Hausdorff completion filter separation carrier)**.** *A* $\mathsf{HausdorffCompletionFilterSeparation}^{\uparrow}$ *carrier is a finite packet*

$$(F, H, S, C, M, R, T, Q, P, N).$$

Here F is the Cauchy-filter completion row, H is the Hausdorff separated row, S is the separated-completion handoff row, C is the completion-continuation row, M is the $\mathsf{MetricCompletion}^{\uparrow}$ *seal, R is the* $\mathsf{Real}^{\uparrow}$ *seal, T is componentwise* hsame *transport over the filter, separation, completion, metric, and real rows, Q is displayed* Cont *replay, P is* Pkg *provenance over the cited sibling certificates and BEDC structural rows, and N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionFilterSeparation}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionFilterSeparationUp.HausdorffCompletionFilterSeparationTasteGate`
`single carrier alignment`

Theorem 4239.2 (Hausdorff completion filter separation obligations)**.** *For the carrier of Definition 4239.1, the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionFilterSeparation}^{\uparrow}}$ *surface consists exactly of six finite obligations: carrier admission for the displayed Cauchy-filter completion row F; Hausdorff separation compatibility for H; separated-completion handoff exactness for S and C; MetricCompletion and Real seal agreement for M and R; componentwise transport and replay stability for T and Q; and provenance plus local naming through P and N.*

Proof. Project the carrier. The only completion source row before separation is F, so every completion read begins on the Cauchy-filter completion surface named by chapter 1569.

Read the separation rows next. The Hausdorff row H and separated-completion handoff row S force zero-distance or indistinguishability comparisons through the separated surfaces of chapter 402 and chapter 1612.

Attach the completion seals. The continuation row C, $\mathsf{MetricCompletion}^{\uparrow}$ seal M, and $\mathsf{Real}^{\uparrow}$ seal R keep the separated filter completion connected to the metric-completion and real-name boundaries rather than to host equality of quotient classes.

Finally transport and replay the same finite packet through T and Q, and record provenance and local naming through P and N. Since no coordinate stores a quotient filter, a selected representative, a countable-choice selector, host equality, or ambient completeness, the listed obligations are the whole local certificate surface. □

Theorem 4239.3 (Hausdorff completion filter separation)**.** *Every accepted* $\mathsf{HausdorffCompletionFilterSeparation}^{\uparrow}$ *carrier* $(F, H, S, C, M, R, T, Q, P, N)$ *presents a separated Cauchy-filter completion route: a completion consumer must first read* F*, then the Hausdorff and separated handoff rows* H, S, C*, then the* $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seals* M, R*, and only then the structural rows* T, Q, P, N*. The exported completion point is therefore separated at the displayed filter boundary and cannot be read through quotient filters, selected representatives, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from carrier admission. The Cauchy-filter completion row F supplies the only completion source, so a consumer has no route to a completed object before the filter-completion surface is displayed.

Apply the local NameCert obligations. They place H, S, C between the filter source and the completion seals, making Hausdorff separation and separated-completion handoff part of the same finite route.

Read the two seals in order. The $\mathsf{MetricCompletion}^{\uparrow}$ seal M records the metric-completion side, and the $\mathsf{Real}^{\uparrow}$ seal R records the real-name boundary consumed by later Real and Completion rows.

The structural rows do not add new completion data. Componentwise hsame transport T, displayed Cont replay Q, Pkg provenance P, and local naming N preserve the same packet, so the exported route is exactly the separated Cauchy-filter completion route and no stronger ambient principle is available. □

Theorem 4239.4 (Hausdorff completion filter separation stability)**.** *For every accepted* HausdorffCompletionFilterS *carrier* $(F, H, S, C, M, R, T, Q, P, N)$*, componentwise* hsame *transport preserves the displayed order*

$$F \longmapsto H, S, C \longmapsto M, R \longmapsto T, Q, P, N.$$

Hausdorff separation therefore remains upstream of the $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seals whenever the packet is transported or replayed.*

Proof. Project the carrier of Definition 4239.1. The Cauchy-filter completion source is F, the separation and separated-completion rows are H, S, C, and the completion-facing seals are M, R.

Use Definition 4239.2. Its transport and replay clause assigns T and Q to the same finite packet rather than to a new completion source.

Thus transporting the packet preserves the route from F through H, S, C before M, R are read. The structural rows T, Q, P, N record stability, replay, provenance, and naming after the separation rows have already been displayed. □

Theorem 4239.5 (Hausdorff completion filter Real seal non-escape)**.** *For every accepted* HausdorffCompletionFilterS *carrier* $(F, H, S, C, M, R, T, Q, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* R *cannot be read as a quotient-filter construction, selected representative, countable-choice limit selector, host equality of completion points, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. It seals only the displayed completion route that has already passed through* F, H, S, C, M *and the structural rows* T, Q, P, N*.*

Proof. Project the same carrier. The only Real-facing coordinate is R, and it appears after the Cauchy-filter source, Hausdorff row, separated-completion handoff, and metric-completion seal.

Apply Definition 4239.2. The obligations identify R as a seal agreement row for the displayed packet, while the transport, replay, provenance, and naming rows preserve that packet without adding new Real data.

No coordinate stores quotient-filter construction, a selected representative, a countable-choice limit selector, host equality, or ambient Real completeness. The seal therefore cannot escape the displayed separated-filter route. □

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionFilterSeparation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HausdorffCompletionFilterSeparation}^{\uparrow}$ packet is generated from Cauchy-filter completion data, Hausdorff separation data, separated-completion handoff data, MetricCompletion and Real seals, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionFilterSeparation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4239.1, Definition 4239.2, and Definition 4239.3 state the finite separated-filter completion certificate surface over the displayed completion, separation, seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionFilterSeparation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient-filter construction, selected representatives, countable choice, host equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, Hausdorff separation compatibility, separated-completion handoff exactness, seal agreement, transport stability, and ledger non-escape for the same finite packet.

Chapter 4240

A Concrete Naming Certificate for $\mathsf{QRDecomposition}^{\uparrow}$

Following Golub–Van Loan and Gram–Schmidt finite-dimensional linear algebra, the $\mathsf{QRDecomposition}^{\uparrow}$ packet records a displayed QR factorization route as finite BEDC data over $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{GramSchmidt}^{\uparrow}$, and $\mathsf{Determinant}^{\uparrow}$. It consumes the matrix carrier of chapter 49, the vector-space rows of chapter 47, the scalar rows of chapter 45, the orthogonalization packet of chapter 1875, and the determinant boundary of chapter 84. The packet names only the finite factorization ledger; it is not a host-level theorem that every matrix admits a selected factorization, nor does it export spectral data, polar decomposition, rank choice, quotient equality, or an ambient norm-completion principle.

Definition 4240.1 (QR decomposition carrier)**.** *A* $\mathsf{QRDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, Q_0, R, G, T, H, C, P, N)$$

with the following displayed rows:

1. *A is the input* $\mathsf{Mat}^{\uparrow}$ *row, including the finite column table, scalar-source row, and vector-space coordinate ledger to be factorized.*
2. *Q_0 is the orthonormal-column packet, listing the displayed output columns together with their inherited* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{Field}^{\uparrow}$*, and inner-product support rows.*
3. *R is the upper-triangular packet, recording the finite coefficient table, zero-below-diagonal rows, diagonal pivot witnesses or refusal rows, and scalar provenance.*
4. *G is the* $\mathsf{GramSchmidt}^{\uparrow}$ *handoff row that reads the columns of A through the orthogonalization route before any Q_0 or R read is exposed.*
5. *T is the triangular and reconstruction ledger. It records that every displayed column of A is replayed from the corresponding finite combination of Q_0 columns with coefficients from R.*
6. *H records componentwise* hsame *transport for the input matrix, orthonormal-column packet, upper-triangular packet, Gram–Schmidt handoff, triangular and reconstruction ledger, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$A \longmapsto G \longmapsto Q_0, R \longmapsto T \longmapsto H.$$

8. *P is the* Pkg *provenance over* $\mathsf{QRDecomposition}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{GramSchmidt}^{\uparrow}$, $\mathsf{Determinant}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{QRDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, Q_0, R, G, T, H, C, P, N$. It has no coordinate for a selected global basis, spectral factorization, polar decomposition, rank choice, quotient equality, or a host matrix theorem outside the displayed finite rows.

Lean4 ✓ `BEDC.Derived.QRDecompositionUp.QRDecompositionTasteGate single carrier alignment`

Theorem 4240.2 (QRDecompositionUp NameCert obligations)**.** *For every accepted* $\mathsf{QRDecomposition}^{\uparrow}$ *carrier*

$$Q = (A, Q_0, R, G, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{QRDecomposition}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *input admission for the displayed* $\mathsf{Mat}^{\uparrow}$ *row A and its* $\mathsf{VecSpace}^{\uparrow}$ *and* $\mathsf{Field}^{\uparrow}$ *support;*
2. *Gram–Schmidt handoff admission for G, requiring the column read of A to pass through the accepted* $\mathsf{GramSchmidt}^{\uparrow}$ *orthogonalization packet;*
3. *orthonormal-column exposure for Q_0, requiring each displayed column to be read from the handoff row rather than from a chosen ambient basis;*
4. *upper-triangular exposure for R, requiring all below-diagonal zero rows, diagonal pivot witnesses or refusal rows, and scalar coefficient rows to be displayed;*
5. *reconstruction exactness for T, requiring the finite column replay of A from Q_0 and R to use only the recorded coefficient rows;*
6. *transport, replay, provenance, and local naming through H, C, P, N, preserving exactly the displayed factorization packet.*

No QR decomposition obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 4240.1. The input matrix row A is the only source of displayed columns, and its scalar and vector-space support is inherited from the named dependency rows.

Read the handoff row G. It routes those columns through the $\mathsf{GramSchmidt}^{\uparrow}$ packet, so the orthonormal-column packet Q_0 and coefficient table R cannot be inspected before the finite orthogonalization replay has been displayed.

The upper-triangular obligations are exactly the rows of R: below-diagonal zero entries, diagonal pivot witnesses or refusal rows, and scalar coefficients. The reconstruction ledger T then checks each column of A against the displayed finite combination of Q_0 columns using those same coefficients.

Finally H, C, P, N transport, replay, source, and name the same tuple. Since the carrier has no coordinate for a selected global basis, spectral factorization, polar decomposition, rank choice, quotient equality, or host matrix theorem, the six listed rows exhaust the local naming surface. □

Theorem 4240.3 (Gram–Schmidt handoff for QR decomposition)**.** *Every* $\mathsf{QRDecomposition}^{\uparrow}$ *consumer that reads an orthonormal-column row, an upper-triangular coefficient row, or a reconstruction row must first pass through the* $\mathsf{GramSchmidt}^{\uparrow}$ *handoff row G of Definition 4240.1. Consequently QR reads are finite handoffs from displayed matrix columns to the triangular replay packet, not selected bases or ambient factorization objects.*

Proof. Start with any accepted QR carrier. The only rows that expose Q_0, R, and T are typed after the handoff row G in the displayed route

$$A \longmapsto G \longmapsto Q_0, R \longmapsto T.$$

The handoff row consumes the same matrix columns that A displays and reads them through $\mathsf{GramSchmidt}^{\uparrow}$. Therefore a consumer that asks for an orthonormal column, triangular coefficient, or reconstruction component must first inspect G.

Componentwise hsame transport and Cont replay preserve that order, while Pkg provenance and the local $\mathsf{NameCert}_{\mathsf{QRDecomposition}^{\uparrow}}$ row name only this route. Thus no selected basis, ambient QR theorem, or external factorization object is exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{QRDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{QRDecomposition}^{\uparrow}$ packet is generated from a displayed input MatrixUp row, orthonormal-column packet, upper-triangular coefficient packet, GramSchmidtUp handoff, triangular reconstruction ledger, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QRDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4240.1, Definition 4240.2, and Definition 4240.3 seed the finite QR factorization packet over displayed matrix, vector-space, field, Gram–Schmidt, determinant, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{QRDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global existence of QR decomposition, selected bases, spectral factorization, polar decomposition, rank choice, quotient equality, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked input admission, Gram–Schmidt handoff admission, orthonormal-column exposure, upper-triangular exposure, reconstruction exactness, and transport/provenance/name exhaustion for BEDC.Derived.QRDecompositionUp.

Chapter 4241

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}$

Following Bishop and Bridges regular Cauchy completeness, the $\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}$ packet records the finite-window handoff from local regular Cauchy sections to a terminal $\mathsf{Real}^{\uparrow}$ seal. It consumes the stream-window carrier of chapter 126, the dyadic tolerance rows of chapter 291, the regular rational classifier of chapter 301, and the terminal real-name surface of chapter 38. The packet names the diagonal gluing route; it is not a quotient of streams, a selected representative, a metric completion object, a countable-choice schedule, or an ambient theorem that all Cauchy data already have host limits.

Definition 4241.1 (Regular Cauchy diagonal seal carrier)**.** *A* $\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, S, E, R, L, G, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite section family, listing the local regular-Cauchy windows admitted for one completion request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family shared by the local sections and the diagonal readback.*
3. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the finite precision rows used to compare the local windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and regularity ledger, including the accepted local readback rows and the displayed regularity witnesses.*
5. *L is the local* $\mathsf{Real}^{\uparrow}$ *seal row for each admitted section before diagonal gluing.*
6. *G is the diagonal-gluing ledger. It records the finite refinement route that sends the local F, S, E, R, L rows to one terminal diagonal window.*
7. *H records componentwise* hsame *transport for the finite section family, StreamName windows, dyadic tolerance rows, RegSeqRat classifier and regularity rows, local Real seals, diagonal-gluing ledger, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay of the route*

$$F, S, E, R, L \longmapsto G \longmapsto H.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, S, E, R, L, G, H, C, P, N$. It has no coordinate for quotient stream equality, a selected representative, a countable-choice schedule, a host completion point, metric-completeness data, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalSealUp.RegularCauchyDiagonalSealTasteGate single carrier alignment`

Theorem 4241.2 (Regular Cauchy diagonal seal NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}$ *carrier*

$$D = (F, S, E, R, L, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *finite-section admission for F, requiring every local section to be displayed before the diagonal route is read;*
2. *StreamName and dyadic tolerance compatibility for S, E, requiring all local windows to share the recorded precision ledger;*
3. *RegSeqRat classifier and regularity exposure for R, requiring local readbacks and regularity witnesses to be displayed as finite rows;*
4. *local Real seal exposure for L, requiring each section's terminal read to pass through the same RegSeqRat and tolerance rows;*
5. *diagonal gluing exactness for G, requiring the terminal diagonal window to be assembled from the displayed local rows only;*
6. *transport, replay, provenance, and local naming through H, C, P, N, preserving exactly the same diagonal-seal packet.*

No regular Cauchy diagonal seal obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 4241.1. The finite section family F supplies the only local regular-Cauchy windows available to the packet.

The StreamName and dyadic rows S, E place those sections over one displayed precision interface. The RegSeqRat row R then records the classifier and regularity witnesses used by each local readback, and the Real row L records the local terminal seals before they are glued.

The diagonal-gluing ledger G is the only row that assembles a terminal diagonal window from those local data. It therefore carries the exactness obligation for the finite-window handoff and cannot be replaced by a quotient stream, selected representative, or host completion point.

Finally H, C, P, N transport, replay, source, and name the same displayed tuple. Since no further coordinate is present, the six listed rows exhaust the local naming obligations. □

Theorem 4241.3 (Regular Cauchy diagonal seal vision handoff)**.** *The regular Cauchy diagonal seal realizes the finite-window route from local regular sections to the terminal* $\mathsf{Real}^{\uparrow}$ *seal: any read of the terminal seal from a section in F factors through the common* $\mathsf{StreamName}^{\uparrow}$ *window family,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and regularity rows, local* $\mathsf{Real}^{\uparrow}$ *seal rows, and diagonal-gluing ledger of Definition 4241.1.*

Proof. Start with a terminal seal read from a local section. By carrier admission, the section appears in F and its stream window and tolerance rows are displayed in S and E.

The RegSeqRat classifier and regularity ledger R places the local readback inside the regular rational sequence surface, while the row L records the section's local $\mathsf{Real}^{\uparrow}$ seal. These rows are the only available route from the local section to a terminal real-facing read.

Apply the diagonal-gluing ledger G. It sends the local rows through the shared finite window into the terminal diagonal seal and leaves no coordinate for quotient stream equality, selected representatives, countable-choice schedules, metric-completeness data, completion points, or ambient Real completeness. Thus the vision-side regular Cauchy handoff is represented by the displayed NameCert packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalSeal}\uparrow}$.

Constructive story: A $\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}$ packet is generated from a finite section family, StreamNameUp window family, DyadicRatCoreUp tolerance ledger, RegSeqRatUp classifier and regularity ledger, local RealUp seal rows, diagonal-gluing ledger, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalSeal}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4241.1, Definition 4241.2, and Definition 4241.3 seed the finite regular-Cauchy diagonal route from local section windows to a terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalSeal}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable-choice schedules, metric-completeness data, completion points, ambient RealUp completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked finite-section admission, StreamName and dyadic tolerance compatibility, RegSeqRat classifier exposure, local Real seal exposure, diagonal gluing exactness, and transport/provenance/name exhaustion for BEDC.Derived.RegularCauchyDiagonalSealUp.

Chapter 4242

Modulus of Total Boundedness NameCert Construction

Following Bishop and Bridges constructive metric analysis, the $\mathsf{ModulusOfTotalBoundedness}^{\uparrow}$ packet records the explicit schedule form of total boundedness: a positive dyadic tolerance request is answered by a finite epsilon-net row together with the finite ledger proving coverage at that tolerance. The packet sits between the metric carrier of chapter 57, the dyadic tolerance surface of chapter 291, the finite observation interface of chapter 126, the total-bounded finite-net carrier of chapter 127, and the compact-metric consumer of chapter 129. It names the schedule consumed by compact and continuous routes without invoking open-cover compactness, selected representatives, countable choice, or ambient completeness.

Falsifiable prediction: A compact-metric or continuous-route certificate that consumes a total-boundedness claim without displaying the dyadic tolerance request and its finite net schedule refutes $\mathsf{ModulusOfTotalBoundedness}^{\uparrow}$, because the packet's carrier has no hidden open-cover compactness or selected-net coordinate.

Independence witness: totally_bounded, compact_metric, stream_name, dyadic_rat_core: none is bijective to $\mathsf{ModulusOfTotalBoundedness}^{\uparrow}$ because the modulus packet jointly records the tolerance request, schedule index, finite center bundle, coverage ledger, metric comparison rows, transport, replay, provenance, and local naming as one displayed schedule surface.

Definition 4242.1 (Modulus of total boundedness carrier)**.** *A* $\mathsf{ModulusOfTotalBoundedness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, D, S, T, K, L, H, C, P, N)$$

with the following rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row carrying the point classifier and distance comparison ledger.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive tolerance request.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window naming the displayed tolerance and center schedule.*
4. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net source row.*
5. *K is the finite* $\mathsf{ProbeBundle}$ *of center histories selected by the schedule for the tolerance row D.*

6. *L is the coverage ledger, recording membership, center-carrier rows, distance witnesses, and dyadic comparison rows for the centers in K.*
7. *H records componentwise* hsame *transport for metric, tolerance, window, total-bounded, center-bundle, coverage, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for compact or continuous consumers through $X, D, S, T, K, L, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{ModulusOfTotalBoundedness}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ModulusOfTotalBoundedness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, D, S, T, K, L, H, C, P, N$. It has no coordinate for an open-cover subcover, a host-selected finite set, a quotient completion, a global compactness theorem, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.ModulusOfTotalBoundednessUp.ModulusOfTotalBoundednessTasteGate single carrier alignment`
