Theorem 4242.2 (Modulus of total boundedness NameCert obligations)**.** *For every accepted* $\mathsf{ModulusOfTotalBoundedness}^{\uparrow}$ *carrier $M = (X, D, S, T, K, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ModulusOfTotalBoundedness}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-source exposure, dyadic tolerance exposure, finite-window exposure, total-bounded source exposure, finite center-bundle exposure, coverage-ledger exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 4242.1. Its visible rows are precisely $X, D, S, T, K, L, H, C, P, N$.

The tolerance schedule is read through D and S before any finite-net row is consumed. The total-bounded row T supplies the finite-net source, while K and L display the center bundle and coverage ledger for that tolerance.

The structural rows H, C, P, N transport, replay, source, and name the same finite surface. Since the carrier has no open-cover, selected-set, quotient-completion, choice, or ambient-completeness coordinate, the NameCert obligations are exactly the displayed schedule rows. □

Theorem 4242.3 (Modulus of total boundedness compact handoff)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$ *or continuous-route consumer of an accepted* $\mathsf{ModulusOfTotalBoundedness}^{\uparrow}$ *packet must read the dyadic tolerance row D, the StreamName schedule row S, the* $\mathsf{TotallyBounded}^{\uparrow}$ *source row T, the center bundle K, and the coverage ledger L before it consumes compact finite-net data. The handoff exports a schedule-indexed finite net and no open-cover compactness, selected subcover, countable choice, selected representative, or ambient completeness theorem.*

Proof. Start with the NameCert obligation theorem. It places the tolerance request, finite observation schedule, total-bounded source, center bundle, and coverage ledger among the visible rows of every accepted packet.

A compact-metric or continuous-route read needs the finite-net data. That data occurs only in T, K, L, and those rows are downstream of the dyadic tolerance and schedule rows D, S in the carrier.

Thus the consumer receives a finite dyadic epsilon-net schedule, not an open-cover compactness principle. The excluded coordinates do not occur in the carrier, so they cannot be exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusOfTotalBoundedness}^{\uparrow}}$.

Constructive story: A ModulusOfTotalBoundedness$^{\uparrow}$ packet is generated from a MetricSpace row, a DyadicRatCore positive tolerance request, a StreamName finite schedule, a TotallyBounded finite-net source, a ProbeBundle center row, a coverage ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ModulusOfTotalBoundedness}^{\uparrow}}$, seed)

Scope closed: Definition 4242.1, Definition 4242.2, and Definition 4242.3 seed the explicit dyadic epsilon-net schedule route for total-bounded and compact-metric consumers.

Formal verification: FormalStatus(NameCert$_{\text{ModulusOfTotalBoundedness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, selected representatives, quotient completion, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite schedule exposure, total-bounded source exposure, finite center-bundle exposure, coverage-ledger exposure, compact handoff, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ModulusOfTotalBoundednessUp.

Chapter 4243

A Concrete Naming Certificate for $\mathsf{PolishCauchyBasis}^{\uparrow}$

Following Alexandrov–Urysohn, Bourbaki, Kelley, and Bishop–Bridges, the $\mathsf{PolishCauchyBasis}^{\uparrow}$ packet records the basis-level handoff by which a complete separable metric source exposes Cauchy-filter basis data before any completion consumer reads a limit. It sits between the $\mathsf{PolishSpace}^{\uparrow}$ source of chapter 1490, the $\mathsf{CauchyFilterBasis}^{\uparrow}$ generator of chapter 1501, the $\mathsf{CompleteMetric}^{\uparrow}$ handoff of chapter 128, and the $\mathsf{SeparableMetric}^{\uparrow}$ dense schedule of chapter 1458. The packet is a finite BEDC handoff surface for Polish-space Cauchy bases, not a quotient completion, not a choice-selected dense sequence, and not an ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 4243.1 (Polish Cauchy basis carrier)**.** *A* $\mathsf{PolishCauchyBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, B, K, D, S, R, O, H, C, G, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{PolishSpace}^{\uparrow}$ *source row, carrying the complete separable metric packet over which every later basis read is interpreted.*
2. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *basis row, recording the directed finite basis generator used by Cauchy-filter consumers.*
3. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row attached to the same metric surface as X; it records the completion-facing route without selecting a limit point.*
4. *D is the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule row, stored as public finite name data rather than as a choice function over all balls.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to inspect dense names, basis requests, and Cauchy-window demands.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those stream windows, giving regular rational observations before any basis comparison is made.*
7. *O is the observation ledger joining dense-window requests, regular-rational readbacks, Cauchy-basis refinements, and completion-handoff checks.*
8. *H records componentwise* hsame *transport for X, B, K, D, S, R, O and for the local certificate rows.*

9. *C records displayed* Cont *replay from a Polish-source request through dense schedules, stream windows, regular readbacks, Cauchy-basis refinement, and the completion handoff.*

10. *G is the* Pkg *provenance over* $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PolishCauchyBasis}^{\uparrow}}$ *row.*

The classifier compares two accepted packets only after transporting these displayed rows to a common Polish source, Cauchy-basis generator, completion-handoff row, dense schedule, stream-window row, and regular readback ledger. It has no coordinate for choice-selected dense points, quotient completion equality, host point equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.PolishCauchyBasisUp.PolishCauchyBasisTasteGate single carrier alignment`

Theorem 4243.2 (Polish Cauchy basis NameCert obligations)**.** *For every accepted* $\mathsf{PolishCauchyBasis}^{\uparrow}$ *carrier $P = (X, B, K, D, S, R, O, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{PolishCauchyBasis}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the Polish source, Cauchy-filter basis, complete-metric handoff, separable dense schedule, stream windows, regular rational readback, observation ledger, transport, continuation, provenance, and local naming rows;*

2. *common-source classification, requiring the B, K, D, S, R, O rows to be read over the same transported* $\mathsf{PolishSpace}^{\uparrow}$ *source row X;*

3. *basis-directedness exposure, requiring every Cauchy-basis refinement consumed by B to be visible in S, R, O before the completion handoff K is read;*

4. *dense-schedule compatibility, requiring the separable row D and the Cauchy-basis row B to share the same stream-window and regular-readback surface;*

5. *completion-handoff non-escape, requiring every completion-facing consumer to pass through B, S, R, O before reaching K;*

6. *package provenance and local* NameCert *naming for exactly the displayed packet.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 4293.1. The projection exposes the Polish source, Cauchy-basis generator, complete-metric handoff, dense schedule, stream windows, regular readbacks, observation ledger, transport rows, continuation rows, provenance row, and local name.

The classifier route starts at X. Componentwise transport in H moves B, K, D, S, R, O together, so a consumer never compares a basis row over one Polish source with a completion handoff or dense schedule over another.

The observation ledger O fixes the finite read order. Dense requests and basis refinements are observed through S and R before either the Cauchy-filter basis or complete-metric handoff can be consumed.

Finally replay C and attach G, N. These rows route, source, and name the same displayed packet, with no additional coordinate for selected dense points, quotient completion equality, host point equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence the listed rows exhaust the local naming surface. □

Theorem 4243.3 (Polish Cauchy basis completion handoff)**.** *Let $P = (X, B, K, D, S, R, O, H, C, G, N)$ be an accepted* $\mathsf{PolishCauchyBasis}^{\uparrow}$ *packet. Every completion-facing consumer of the Polish source*

X reaches the $\mathsf{CompleteMetric}^{\uparrow}$ *handoff K only through the displayed Cauchy-filter basis row B, the separable dense schedule D, the* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the observation ledger O, transported by H and replayed by C.*

The visible route is

$$X, D, S, R, B, O \longmapsto K \longmapsto H, C, G, N.$$

It exports a finite completion handoff for downstream completion, Baire, and fixed-point packets; it does not export a quotient completion class, a selected dense sequence, host point equality, or an ambient real-completeness principle.

Proof. Read X from the carrier in Definition 4293.1. The Polish source supplies the common complete separable metric surface, while D, S, R display the finite dense-window observations available to the packet.

Use the NameCert obligations of Definition 4293.2. The basis-directedness and dense-schedule compatibility clauses force the Cauchy-filter basis row B to be read through the same stream windows, regular readbacks, and observation ledger as the dense schedule.

The completion-handoff clause then places K after B, S, R, O. Transport by H and replay by C preserve that order, while G, N package and name the same route. Therefore every completion-facing consumer receives only the displayed finite handoff and cannot bypass it through choice, quotient equality, host point equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{PolishCauchyBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{PolishCauchyBasis}^{\uparrow}$ packet is generated from a PolishSpace source, CauchyFilterBasis basis, CompleteMetric handoff, SeparableMetric dense schedule, StreamName windows, RegSeqRat readback, an observation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PolishCauchyBasis}^{\uparrow}}$, seed)

Scope closed: Definition 4293.1, Definition 4293.2, and Definition 4293.3 seed the basis-level Cauchy handoff from Polish-space data to completion-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PolishCauchyBasis}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close choice-selected dense points, quotient completions, host point equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-source classification, basis-directedness exposure, dense-schedule compatibility, completion-handoff non-escape, transport, replay, provenance, and local naming for the same packet.

Chapter 4244

A Concrete Naming Certificate for $\mathsf{SymmetryRestorationStabilizer}^{\uparrow}$

The $\mathsf{SymmetryRestorationStabilizer}^{\uparrow}$ packet realizes the hidden Q_6 stabilizer and orbit-persistence rows of Definition 9462.1352, Definition 9462.1354, Definition 9462.1356, and Definition 9462.1362 as finite BEDC NameCert data. It consumes the six-coordinate codon window of chapter 2234, the boundary tile packet of chapter 3393, the codon lift-orbit classifier of chapter 4059, and the median-closure surface of chapter 3545. The packet exposes support, stabilizer, orbit, and median-closure rows before any consumer may claim the hidden C_2 persistence or the restored $S_3 \times C_2$ surface.

Definition 4244.1 (Symmetry restoration stabilizer carrier)**.** *A* $\mathsf{SymmetryRestorationStabilizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, A, T, U, M, O, R, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite Q_6 codon-window row, including the six bit coordinates inspected by the stabilizer calculation.*
2. *A is the active-support row for $\mathcal{R}$ and its inactive-anchor closure, read through the boundary-tile packet.*
3. *T is the hidden C_2 stabilizer row, naming the identity and the coordinate transposition $\tau : s_1 \leftrightarrow f_2$ from Definition 9462.1352.*
4. *U is the orbit-persistence row, recording the active-support, inactive-anchor, and first-median-layer orbits of τ from Definition 9462.1354.*
5. *M is the median-closure stabilizer row, recording the displayed $S_3 \times C_2$ restoration surface of Definition 9462.1356.*
6. *O is the orbit ledger joining the nontrivial C_2 orbits, the median-closure orbit table, and the sealing-corner orbit-completion row.*
7. *R is the refusal row separating support symmetry from weighted reassignment symmetry, and excluding biological causality, stochastic fitness, host quotient codon semantics, and hidden enumeration oracles.*

8. *H records componentwise* hsame *transport for Q, A, T, U, M, O, R and for the local certificate rows.*

9. *C records displayed* Cont *replay from a support read through the stabilizer row, orbit-persistence row, median-closure row, orbit ledger, and refusal row.*

10. *P is the* Pkg *provenance over* $\mathsf{SymmetryRestorationStabilizer}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}$ $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$, $\mathsf{MedianClosure}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SymmetryRestorationStabilizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, A, T, U, M, O, R, H, C, P, N$. It has no coordinate for an unstated support set, an unrecorded stabilizer enumeration, a host quotient codon object, a biological mechanism, or a weighted-symmetry substitute for the support stabilizer.

Lean4 ✓ `BEDC.Derived.SymmetryRestorationStabilizerUp.SymmetryRestorationStabilizerTasteGate`
`single carrier alignment`

Theorem 4244.2 (Symmetry restoration stabilizer NameCert obligations)**.** *For every accepted* $\mathsf{SymmetryRestorationStabilizer}^{\uparrow}$ *carrier $S = (Q, A, T, U, M, O, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SymmetryRestorationStab}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the Q_6 codon window, active support, hidden C_2 stabilizer, orbit-persistence row, median-closure stabilizer, orbit ledger, refusal row, transport, continuation, provenance, and local naming row;*

2. *support visibility, requiring every stabilizer or orbit read to expose the active-support row A before reading T, U, M, or O;*

3. *stabilizer exactness, requiring the hidden C_2 row T to name only the identity and $\tau : s_1 \leftrightarrow f_2$ for the active-support and first-median-layer reads;*

4. *median-closure compatibility, requiring the restored $S_3 \times C_2$ row M to be read only after the median-closure surface and its orbit ledger are displayed;*

5. *orbit non-escape, requiring any hidden C_2 orbit claim to pass through $A, T, U, M, O, H, C, P, N$;*

6. *package provenance and local* NameCert *naming for exactly the displayed packet.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 4294.1. The projection exposes the codon window, active support, stabilizer row, orbit-persistence row, median-closure stabilizer, orbit ledger, refusal row, and the structural rows H, C, P, N.

Support visibility comes first. The row A is the source for the stabilizer calculation, so T, U, M, and O cannot be read as free group-theoretic objects detached from the displayed support.

The stabilizer exactness row is T. It records exactly the identity and the transposition $\tau : s_1 \leftrightarrow f_2$ for the active-support surface, while U records the same nonidentity element along the inactive-anchor and first-median-layer rows.

The median-closure compatibility row is M, with orbit data stored in O. Transport by H and replay by C preserve this order, and P, N package and name the same rows. Thus no hidden orbit claim escapes the displayed support, stabilizer, median-closure, transport, replay, provenance, and local naming surface. □

Theorem 4244.3 (Symmetry restoration orbit non-escape)**.** *Every consumer claiming the hidden C_2 orbit of an accepted* $\mathsf{SymmetryRestorationStabilizer}^{\uparrow}$ *packet must display the support row A,*

the stabilizer row T, the orbit-persistence row U, the median-closure row M, the orbit ledger O, componentwise transport H, displayed replay C, package provenance P, and local NameCert *row N. The visible route is*

$$Q, A \longmapsto T, U \longmapsto M, O \longmapsto H, C, P, N.$$

It cannot be replaced by a host stabilizer calculation, an unrecorded orbit enumeration, a weighted-reassignment symmetry, quotient codon semantics, or a biological mechanism claim.

Proof. Read Q, A from the carrier in Definition 4294.1. These rows provide the finite codon-window coordinates and the active support over which the stabilizer calculation is meaningful.

Apply the NameCert obligations of Definition 4294.2. Support visibility and stabilizer exactness place T and U after A, while median-closure compatibility places M and O after the displayed closure surface.

Finally use orbit non-escape. The rows H, C, P, N transport, replay, source, and name the same finite route, and the refusal row separates it from weighted reassignment symmetry or host enumeration. Therefore a hidden C_2 orbit consumer must pass through the displayed packet and cannot claim the orbit from outside it. □

Falsifiable prediction: Any consumer claiming the hidden C_2 orbit without displaying support, stabilizer, median-closure, hsame, Cont, Pkg, and NameCert rows refutes the SymmetryRestorationStabilizer$^{\uparrow}$ packet.

Independence witness: q-six orbit/classification, median-closure sibling slugs: SymmetryRestorationStabilizer$^{\uparrow}$ is not bijective to the orbit/classification or median-closure siblings because this packet jointly carries active support, hidden C_2 stabilizer, orbit persistence, restored median-closure stabilizer, orbit ledger, refusal, componentwise transport, replay, provenance, and local naming as one accepted surface.

The Lean TasteGate file for this packet must include Nontrivial and FieldFaithful instances. The field-faithfulness witness keeps $Q, A, T, U, M, O, R, H, C, P, N$ as distinct rows so a checked TasteGate theorem can rule out hidden-orbit claims that omit the support, stabilizer, or median-closure coordinates.

Closure status for NameCert$_{\text{SymmetryRestorationStabilizer}^{\uparrow}}$.

Constructive story: A SymmetryRestorationStabilizer$^{\uparrow}$ packet is generated from Q6 codon-window rows, active-support rows, hidden C2 stabilizer rows, orbit-persistence rows, median-closure stabilizer rows, orbit ledgers, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{SymmetryRestorationStabilizer}^{\uparrow}}$, seed)

Scope closed: Definition 4294.1, Definition 4294.2, and Definition 4294.3 seed the finite support-stabilizer packet for the hidden Q6 orbit and median-closure restoration surface.

Formal verification: FormalStatus(NameCert$_{\text{SymmetryRestorationStabilizer}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological causality, stochastic fitness, quotient codon semantics, host stabilizer enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked codon-window admission, support visibility, stabilizer exactness, orbit persistence, median-closure compatibility, orbit non-escape, refusal preservation, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.SymmetryRestorationStabilizerUp.

Chapter 4245

A Concrete Naming Certificate for $\mathsf{TaggedRealPartition}^{\uparrow}$

Following Bishop and Bridges constructive integration, the $\mathsf{TaggedRealPartition}^{\uparrow}$ packet records a finite partition of a located real interval together with a displayed tag inside each cell. It refines the located partition carrier of chapter 2248 and the oscillation-controlled partition carrier of chapter 3800; it also reads its endpoint and tag data through the $\mathsf{StreamName}^{\uparrow}$ source of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies the finite tag-bearing surface needed by L10 integration and oscillation routes without replacing it by an untagged mesh, a host partition object, selected representatives, quotient real equality, countable choice, or ambient completeness.

Definition 4245.1 (Tagged real partition carrier)**.** *A* $\mathsf{TaggedRealPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, M, A, G, O, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$ *row exposing the located interval, finite cell order, endpoint containment, and mesh precision.*
2. *M is the finite mesh row inherited from I, listing adjacent cells and the common refinement ledger used by later integration consumers.*
3. *A is the cell-containment row, certifying for every mesh cell that its endpoints and rational witness rows remain inside the located interval source.*
4. *G is the tag row family, assigning to every displayed cell a tag history whose* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *reads certify containment in that same cell before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*
5. *O is the oscillation and modulus ledger, recording the tolerance request, the cellwise oscillation bound, and the refinement compatibility supplied by* $\mathsf{FiniteOscillationPartition}^{\uparrow}$*.*
6. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened for interval endpoints, cell endpoints, and tags.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family for the same finite windows and mesh precision.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal family reached only after the source interval, cell containment, tag containment, oscillation ledger, window, and regular readback rows have been displayed.*

9. *H records componentwise* hsame *transport for I, M, A, G, O, S, R, E and for the replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a tagged-partition read through*

$$I, M, A, G, O, S, R, E \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$, $\mathsf{FiniteOscillationPartition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{TaggedRealPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these displayed interval-source, mesh, containment, tag, oscillation, window, readback, seal, transport, replay, provenance, and local naming rows. It has no coordinate for a host tagged partition, an unbounded tag selector, quotient real equality, chosen completed tag values, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.TaggedRealPartitionUp.TaggedRealPartitionTasteGate single carrier alignment`

Theorem 4245.2 (Tagged real partition NameCert obligations)**.** *For every accepted* $\mathsf{TaggedRealPartition}^{\uparrow}$ *carrier $T = (I, M, A, G, O, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TaggedRealPartition}^{\uparrow}}$ *surface consists exactly of carrier admission, located interval and mesh exposure through I, M, cell-containment certification through A, tag containment through G, oscillation and modulus accounting through O, finite* $\mathsf{StreamName}^{\uparrow}$ *windows through S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *seals through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Every integration-facing or oscillation-facing read of the tagged partition must therefore pass through the displayed finite mesh, tag-containment, oscillation, window, readback, and seal rows before any terminal real-value consumer is allowed to inspect the packet.

Proof. Project the carrier of Definition 4296.1. The tuple lists the only rows available to a tagged-partition consumer: the interval source, mesh, containment ledger, tag rows, oscillation ledger, finite windows, regular readbacks, real seals, transport, replay, provenance, and local naming rows.

The source interval and cell obligations are I, M, A. The located partition row supplies the interval and mesh; the containment row attaches each cell to the same source, so a tag cannot be read against a detached host interval.

The tag and oscillation obligations are G, O. The tag row certifies cell membership for each tag through the same finite-window and regular-readback route, while the oscillation row records the tolerance and refinement ledger inherited from the oscillation-partition packet.

The readback and seal obligations are S, R, E. A consumer reaches the StreamName windows only after the interval, cell, tag, and oscillation rows are visible, then reads the regular rational rows and finally the terminal Real seal.

The structural rows H, C, P, N transport, replay, package, and name exactly this route. Since the carrier has no coordinate for a host tagged partition, an unbounded selector, quotient real equality, chosen completed tag values, countable choice, or ambient completeness, the displayed NameCert obligations exhaust the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{TaggedRealPartition}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TaggedRealPartition}^{\uparrow}$ packet is generated from a LocatedRealIntervalPartitionUp source, finite mesh and cell-containment rows, per-cell tag rows, oscillation and modulus ledgers, StreamName windows, RegSeqRat readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{TaggedRealPartition}\uparrow}$, seed)

Scope closed: Definition 4296.1 and Definition 4296.2 seed the finite tag-bearing partition interface for L10 integration and oscillation consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{TaggedRealPartition}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close integration convergence, Darboux sums, quotient real equality, selected tag values, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cell containment, tag containment, oscillation-modulus accounting, StreamName windows, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.TaggedRealPartitionUp.

Chapter 4246

A Concrete Naming Certificate for $\mathsf{FiniteFanBarModulus}^{\uparrow}$

Following Brouwer's fan theorem and Bishop–Bridges finite-bar analysis, the $\mathsf{FiniteFanBarModulus}^{\uparrow}$ packet records the finite carrier that turns admitted fan-bar rows and local modulus rows into a tolerance-only uniform-modulus ledger. It sits over the fan certificate of chapter 400, the compact metric finite-net surface of chapter 129, the continuous-map carrier of chapter 130, the rational lower-bound fold of chapter 4118, the $\mathsf{Rat}^{\uparrow}$ arithmetic source of chapter 37, and the $\mathsf{UniformModulus}^{\uparrow}$ handoff of chapter 369. It realizes the compact-uniform-continuity route of chapter 9237 without importing open-cover compactness, selected infinite branches, countable choice, quotient function equality, selected limits, or ambient real completeness.

Definition 4246.1 (Finite fan-bar modulus carrier)**.** *A* $\mathsf{FiniteFanBarModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, K, L, Q, R, U, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite fan-bar admission row, recording the fan, decidable bar classifier, finite depth bound, and finite branch-prefix witness window.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-probe row, aligning the bar prefixes with the compact finite-net probes consumed by the compact-uniform-continuity route.*
3. *L is the local modulus row read from the* $\mathsf{ContinuousMap}^{\uparrow}$ *packet at each admitted bar or probe entry.*
4. *Q is the positive* $\mathsf{Rat}^{\uparrow}$ *radius and tolerance row, carrying the finitely many local radii and requested tolerances.*
5. *R is the lower-bound modulus extraction row, obtained by primitive recursion over the finite fan-bar and probe bundle and by certified rational comparison in Q.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row, exposing the extracted lower bound as a tolerance-only modulus ledger.*
7. *H records componentwise* hsame *transport for the bar, compact-probe, local-modulus, rational, extraction, uniform-modulus, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the finite route*

$$B, K, L, Q \longmapsto R \longmapsto U.$$

9. *P is the* Pkg *provenance over* FiniteFanBarModulus$^\uparrow$, FanTheorem$^\uparrow$, CompactMetric$^\uparrow$, ContinuousMap$^\uparrow$, UniformModulus$^\uparrow$, Rat$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{FiniteFanBarModulus}^\uparrow}$ *row.*

The classifier compares accepted packets only through $B, K, L, Q, R, U, H, C, P, N$. It has no coordinate for an open cover, a selected infinite branch, countable choice, quotient equality of maps, selected limits, a host compactness theorem, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.FiniteFanBarModulusUp.FiniteFanBarModulusTasteGate single carrier alignment`

Theorem 4246.2 (Finite fan-bar modulus NameCert obligations)**.** *For every accepted* FiniteFanBarModulus$^\uparrow$ *carrier $F = (B, K, L, Q, R, U, H, C, P, N)$, the local* NameCert$_{\text{FiniteFanBarModulus}^\uparrow}$ *surface consists exactly of carrier admission, finite bar admission through B, compact finite-probe alignment through K, local continuous-map modulus exposure through L, positive rational radius accounting through Q, lower-bound modulus extraction through R,* UniformModulus$^\uparrow$ *handoff through U, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

In particular, a compact-uniform-continuity consumer may read a uniform modulus from this packet only after the finite bar, compact-probe, local-modulus, rational-radius, and lower-bound extraction rows have all been displayed.

Proof. Project the carrier of Definition 4297.1. The tuple displays exactly the finite bar, compact-probe, local-modulus, rational-radius, lower-bound extraction, uniform-modulus, transport, replay, provenance, and local naming rows.

Finite bar admission is the row B. It supplies the decidable bar classifier and finite depth witness, so the argument ranges over displayed finite prefixes rather than selected infinite branches.

The compact and local-modulus data are K, L, Q. The compact-probe row aligns finite bar prefixes with compact finite-net probes, the continuous-map row supplies local moduli at those probes, and the rational row stores the positive local radii and tolerance requests.

Lower-bound extraction is the row R. It is obtained by primitive recursion over the finite bar and probe rows, using the positive rational comparisons in Q to retain a certified lower bound for all admitted local radii.

Finally, U, H, C, P, N expose, transport, replay, source, and name that extracted lower bound as a UniformModulus$^\uparrow$ ledger. Since the carrier has no coordinate for open-cover compactness, branch selection, countable choice, quotient function equality, selected limits, host compactness, or ambient completeness, the displayed obligations exhaust the accepted packet. □

Theorem 4246.3 (Finite fan-bar lower-bound modulus extraction)**.** *Every compact-uniform-continuity read of an accepted* FiniteFanBarModulus$^\uparrow$ *packet factors through*

$$B, K, L, Q, R, U, H, C, P, N.$$

The extracted row R is the only lower-bound modulus source available to the UniformModulus$^\uparrow$ *consumer: it is computed from finite fan-bar admission, compact finite-probe alignment, local continuous-map moduli, and positive* Rat$^\uparrow$ *radius comparisons, and it exports no open-cover subcover, selected branch, selected limit, quotient map equality, or ambient compactness datum.*

Proof. Start with the NameCert obligations of Definition 4297.2. They require every compact-uniform-continuity consumer to read B, K, L, Q before the lower-bound row R is available.

The extraction step is finite. The bar depth and compact probe rows determine the finite index family, and the positive rational ledger compares the finitely many local radii by primitive recursion to produce a certified lower bound.

Once R is displayed, the uniform-modulus row U may consume it as a tolerance-only ledger. The structural rows H, C, P, N preserve and name the same route under componentwise transport and replay.

No excluded datum can be read from the carrier. Open-cover compactness, selected branches, selected limits, quotient map equality, countable choice, and ambient compactness are absent from $B, K, L, Q, R, U, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteFanBarModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteFanBarModulus}^{\uparrow}$ packet is generated from finite fan-bar admission, compact finite-probe alignment, local ContinuousMap modulus rows, positive RatUp radius ledgers, lower-bound extraction, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteFanBarModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4297.1, Definition 4297.2, and Definition 4297.3 seed the finite fan-bar lower-bound route consumed by compact-uniform-continuity and UniformModulus rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteFanBarModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite branches, countable choice, quotient function equality, selected limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite bar admission, compact finite-probe alignment, local modulus exposure, RatUp lower-bound extraction, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteFanBarModulusUp.

Chapter 4247

A Concrete Naming Certificate for $\mathsf{EdelsteinFixedPoint}^{\uparrow}$

Following Edelstein's compact-metric fixed-point theorem and Bishop–Bridges constructive metric practice, the $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ packet records the finite NameCert surface for a strictly contractive self-map on a compact metric carrier. It sits after the metric source of chapter 57, the compact-metric finite inspection surface of chapter 129, the sequential map discipline of chapter 1466, the contraction comparison row of chapter 3529, and the displayed iteration route of chapter 2359. The packet names only the compact source, the strict distance-decrease row, the sequential-continuity row, the orbit comparison ledger, transport, replay, provenance, and local naming; it does not import choice, quotient completion, a selected host fixed point, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a Banach contraction ratio.

Definition 4247.1 (Edelstein fixed-point carrier)**.** *An* $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, K, F, O, C, S, H, R, P, N)$$

with the following displayed rows:

1. *X is the underlying* $\mathsf{Met}^{\uparrow}$ *source row, carrying the point classifier and the distance observations inspected by the fixed-point consumer.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *row over X, exposing only the finite compactness windows and cluster-service rows accepted by the compact-metric certificate.*
3. *F is the self-map row, presented through the same metric carrier and never as an untracked host function.*
4. *O is the orbit row generated from F, recording the displayed Picard-style finite prefix consumed by the fixed-point search.*
5. *C is the strict contraction-comparison row: whenever the inspected points are classified as distinct by the metric row, the displayed distance from $F(x)$ to $F(y)$ is strictly below the displayed distance from x to y.*
6. *S is the* $\mathsf{SequentialContinuity}^{\uparrow}$ *row for F, binding cluster reads of the orbit to the image row without adding a semantic continuity theorem outside the displayed packet.*
7. *H stores componentwise* hsame *transport for metric, compactness, self-map, orbit, contraction-comparison, sequential-continuity, continuation, provenance, and naming rows.*

8. *R stores displayed* Cont *replay from the orbit row to the compact cluster row, from the cluster row through sequential continuity, and from the strict comparison row to the fixed-point equality boundary.*

9. *P is the* Pkg *provenance over* $\mathsf{EdelsteinFixedPoint}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{SequentialContinuity}^{\uparrow}$, $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{EdelsteinFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, K, F, O, C, S, H, R, P, N$. It has no coordinate for quotient completion, countable choice, a Banach contraction constant, an ambient complete real line, or a host-selected fixed point.

Lean4 ✓ `BEDC.Derived.EdelsteinFixedPointUp.EdelsteinFixedPointTasteGate single carrier alignment`

Theorem 4247.2 (Edelstein fixed-point NameCert obligations)**.** *For every accepted* $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ *carrier $E = (X, K, F, O, C, S, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EdelsteinFixedPoint}^{\uparrow}}$ *surface consists exactly of metric carrier admission through X, compact-metric finite inspection through K, self-map admission through F, Picard-style orbit exposure through O, strict contraction comparison through C, sequential-continuity cluster transport through S, componentwise* hsame *transport through H, displayed* Cont *replay through R,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.EdelsteinFixedPointUp.EdelsteinFixedPointCarrier namecert obligations`

Proof. Project the carrier of Definition 4298.1. The metric row X and compact-metric row K are the only source rows available to the certificate, so every inspected point, distance comparison, and compactness read is routed through those two displayed surfaces.

The self-map row F and orbit row O provide the visible finite Picard-style prefix. The strict comparison row C is separate from the Banach contraction surface: it records pointwise distance decrease on distinct displayed pairs and carries no global contraction ratio.

The sequential-continuity row S is the only route from a compact cluster read of the orbit to an image read under F. Transport through H, replay through R, provenance through P, and naming through N preserve this same finite route, so the listed rows exhaust the local NameCert obligations. □

Theorem 4247.3 (Edelstein compact-route nonescape)**.** *Every fixed-point read exported by an accepted* $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ *packet factors through the internal route*

$$X \longmapsto K \longmapsto O \longmapsto S \longmapsto C$$

together with F, H, R, P, N. The route may compare with the $\mathsf{BanachContraction}^{\uparrow}$ *and* $\mathsf{PicardIteration}^{\uparrow}$ *neighbours as named dependency rows, but it does not consume a Banach contraction constant, quotient completion equality, selected subsequence principle, choice operator, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with a fixed-point read. The carrier first exposes the metric source X and the compactness service K, so the consumer can only inspect displayed finite compact-metric windows and the point classifier attached to X.

The orbit row O supplies the visible Picard-style finite prefix for the self-map F. Compactness is consumed only through K, and the image of a cluster read is transported only through the sequential-continuity row S.

The strict comparison row C is then the only row that can rule out a non-fixed distinct-pair boundary. Since C contains no global ratio and the remaining rows H, R, P, N only transport, replay, source, and name the same finite data, the exported route cannot leave the displayed Edelstein packet for choice, quotient completion, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ fixed-point read factors through one MetricUp source row, one CompactMetricUp finite inspection row, one self-map row, one PicardIterationUp-style orbit row, one strict comparison row, one SequentialContinuityUp cluster-transport row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compactmetric, sequentialcontinuity, banach-contraction, picard-iteration: $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact-metric cluster service, strict pointwise distance decrease, and sequential-continuity image transport without a Banach ratio, selected endpoint, quotient completion, or ambient completeness coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{EdelsteinFixedPoint}^{\uparrow}}$.

Constructive story: An $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ packet is generated from a MetricUp source row, a CompactMetricUp finite inspection row, a displayed self-map row, a PicardIterationUp-style orbit row, a strict distance-decrease comparison row, a SequentialContinuityUp cluster-transport row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EdelsteinFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4298.1, Definition 4298.2, and Definition 4298.3 bind the compact-metric strict-contraction route through the displayed orbit, cluster, sequential-continuity, and comparison rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EdelsteinFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point equality, uniqueness, quotient completion equality, Banach contraction constants, selected fixed points, choice principles, bridge checking, Lean verification, or ambient real completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-metric inspection, orbit exposure, strict comparison, sequential-continuity cluster transport, nonescape, replay, provenance, and local naming for BEDC.Derived.EdelsteinFixedPointUp

Chapter 4248

A Concrete Naming Certificate for $\mathsf{CompletionLadder}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CompletionLadder}^{\uparrow}$ packet records the finite BEDC naming surface that ties the current Real and Completion route into one phase object. It sits over the dyadic tolerance ledger of chapter 291, the finite-window stream surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the separated-completion boundary of chapter 1612, and the completion-unit handoff of chapter 1527. The ladder is a finite dependency packet for the phase route; it is not quotient stream equality, not a selected limit, not countable choice, not trichotomy, not open-cover compactness, and not a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4248.1 (Completion ladder carrier)**.** *A* $\mathsf{CompletionLadder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, W, R, E, S, U, H, C, P, N)$$

with the following visible rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic tolerance row naming the precision requests that enter the route.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *stream-window row listing the finite observations read at those tolerances.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row obtained from D and W.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the dyadic tolerance, stream window, and regular readback rows have been displayed.*
5. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *witness row that consumes the same displayed real-facing route as a separated completion boundary.*
6. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *unit row that records the source-to-completion handoff along the same finite route.*
7. *H records componentwise* hsame *transport for dyadic tolerance, stream window, regular readback, Real seal, separated-completion witness, Cauchy-completion unit, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$D, W \longmapsto R \longmapsto E \longmapsto S, U.$$

9. *P is the* Pkg *provenance over* $\mathsf{CompletionLadder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionLadder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, R, E, S, U, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CompletionLadderUp.CompletionLadderTasteGate single carrier alignment`

Theorem 4248.2 (Completion ladder NameCert obligations)**.** *For every accepted* $\mathsf{CompletionLadder}^{\uparrow}$ *carrier $L = (D, W, R, E, S, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionLadder}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic tolerance, stream window, regular readback, Real seal, separated-completion witness, Cauchy-completion unit, componentwise transport, continuation replay, package provenance, and local naming rows;*
2. *tolerance-window compatibility, requiring each finite stream read in W to be indexed by a dyadic tolerance request in D before regular readback is inspected;*
3. *regular-readback exactness, requiring every* $\mathsf{RegSeqRat}^{\uparrow}$ *read in R to consume only the displayed D, W route;*
4. *Real-seal order, requiring E to be read only after D, W, R have been displayed;*
5. *completion-boundary order, requiring S and U to consume the same D, W, R, E route through the stored continuation row C;*
6. *transport stability, requiring componentwise* hsame *transport in H to preserve the listed route and no other completion data;*
7. *ledger non-escape, excluding quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, and completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Carrier admission is projection from Definition 4299.1. The tuple lists the dyadic tolerance row, stream-window row, regular readback row, Real seal, separated-completion witness, Cauchy-completion unit, transport rows, replay row, provenance, and local name.

The first dependency step reads D and W. Since W is the only stream-window coordinate and D is the only tolerance coordinate, each finite observation entering the regular readback must pass through those two rows.

The regular readback row R is then downstream of D, W, and the Real seal row E is downstream of R. The replay row C records this order before either completion-facing row is inspected.

The separated-completion witness S and Cauchy-completion unit U therefore consume the same displayed D, W, R, E route. Componentwise transport by H preserves those rows, while P and N source and name the same packet.

No remaining coordinate can export quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness. Thus the listed rows exhaust the local NameCert surface. □

Theorem 4248.3 (Completion ladder separated Real route)**.** *Every accepted* $\mathsf{CompletionLadder}^{\uparrow}$ *carrier factors any separated-completion or completion-unit consumer through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{SeparatedCompletion}^{\uparrow},\quad \mathsf{CauchyCompletionUnit}^{\uparrow}.$$

Equivalently, a consumer of S or U must first read the displayed dyadic tolerance row D, stream-window row W, regular readback row R, and Real seal row E, with componentwise transport, continuation replay, provenance, and local naming supplied by H, C, P, N.

Proof. Start from an accepted carrier $L = (D, W, R, E, S, U, H, C, P, N)$. The only completion-facing rows are S and U, so any separated-completion or completion-unit consumer must inspect one of those coordinates.

The definition places both coordinates after D, W, R, E. The continuation row C records the same order, forcing each consumer read to pass from dyadic tolerance and finite window through regular rational readback before the Real seal is available.

Componentwise hsame transport by H may rename the rows, but it preserves the displayed route rather than adding a second stream, a chosen limit, or a host completion object. The package and local name rows P, N then record that the consumer is reading the same finite packet.

Since the carrier contains no row for quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness, the separated Real route above is the whole exported completion-facing surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionLadder}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionLadder}^{\uparrow}$ packet is generated from DyadicRatCore tolerance requests, StreamName finite windows, RegSeqRat readback, a RealUp seal, a SeparatedCompletion witness, a CauchyCompletionUnit handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompletionLadder}^{\uparrow}}$, seed)

Scope closed: Definition 4299.1, Definition 4299.2, and Definition 4299.3 seed the finite Real and Completion ladder over DyadicRatCore, StreamName, RegSeqRat, Real, SeparatedCompletion, CauchyCompletionUnit, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompletionLadder}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, bridge checking, Lean verification, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-window compatibility, regular readback exactness, Real-seal order, separated-completion routing, completion-unit routing, componentwise transport stability, and ledger non-escape for BEDC.Derived.CompletionLadderUp.

Chapter 4249

A Concrete Naming Certificate for $\mathsf{LocatedFormalBar}^{\uparrow}$

Following Brouwer, Troelstra–van Dalen, and Vickers, the $\mathsf{LocatedFormalBar}^{\uparrow}$ packet records a finite located bar/cover boundary for spread paths and formal-topology cover requests. It sits after the cover/refinement carrier of chapter 3967, the admissible-prefix discipline of chapter 1532, the bar-recursion route of chapter 1675, and the finite observation interface of chapter 126. The packet supplies Real and Completion consumers with a finite bar boundary without importing open-cover compactness, selected points, quotient opens, countable choice, or ambient completeness.

Definition 4249.1 (Located formal-bar carrier)**.** *A* $\mathsf{LocatedFormalBar}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, S, B, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FormalTopology}^{\uparrow}$ *cover/refinement row, read through chapter 3967, that names the finite basic neighbourhoods and refinement requests used by the bar.*
2. *S is the* $\mathsf{SpreadLaw}^{\uparrow}$ *admissible-prefix row, read through chapter 1532, that determines which finite path prefixes can enter the bar ledger.*
3. *B is the* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *bar-recursion row, read through chapter 1675, that records the finite induction surface consumed by bar-cover arguments.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, read through chapter 126, that exposes the inspected prefix windows for Real and Completion routes.*
5. *Q is the located-query row: each accepted request names a finite prefix, a formal basic neighbourhood, and the bar-cover decision boundary visible at that prefix.*
6. *R is the spread-cover row, recording the finite route from an admissible prefix through the formal cover row to the bar-recursion row.*
7. *H records componentwise* hsame *transport for formal-cover rows, spread-law prefixes, bar-recursion rows, StreamName windows, located-query rows, spread-cover rows, replay rows, provenance rows, and local naming rows.*
8. *C records displayed* Cont *replay from a Real or Completion finite-window request through $F, S, B, W, Q, R, H, P, N$*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedFormalBar}^{\uparrow}$, $\mathsf{FormalTopology}^{\uparrow}$, $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedFormalBar}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, a selected infinite path, a selected point of a cover, quotient-open equality, countable choice, host topological equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.LocatedFormalBarUp.LocatedFormalBarTasteGate single carrier alignment`

Theorem 4249.2 (Located formal-bar spread-cover route)**.** *Every accepted* $\mathsf{LocatedFormalBar}^{\uparrow}$ *carrier*

$$L = (F, S, B, W, Q, R, H, C, P, N)$$

routes a Real or Completion finite-window consumer through the same displayed spread-cover boundary:

$$F, S, B, W \longmapsto Q, R \longmapsto H, C, P, N.$$

The formal-topology cover row F, spread-law row S, Brouwer bar-induction row B, and StreamName window row W must be visible before the located-query row Q and spread-cover row R are consumed. The route exports no open-cover compactness theorem, selected infinite branch, selected cover point, quotient-open equality, countable-choice schedule, host real equality, or ambient completeness datum.

Proof. Project the carrier of Definition 4300.1. The source rows are F, S, B, W, and the located bar/cover rows are Q, R.

First read the formal-topology and spread-law surfaces. The finite cover/refinement row F supplies only displayed basic neighbourhoods, while S supplies only admissible finite prefixes.

Next pass through the bar-recursion and StreamName rows. Row B keeps the bar argument on the finite Brouwer induction surface, and W fixes the inspected finite windows used by Real and Completion consumers.

Finally replay through Q, R, H, C, P, N. The located query and spread-cover rows are transported componentwise and replayed with the same provenance and local NameCert row. Since the carrier contains no coordinate for compact open covers, selected branches, selected points, quotient opens, choice, host equality, or ambient completeness, no consumer can read those objects from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedFormalBar}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedFormalBar}^{\uparrow}$ packet is generated from FormalTopology cover/refinement rows, Spread-Law admissible-prefix rows, BrouwerBarInduction bar-recursion rows, StreamName finite-window rows, located-query rows, spread-cover rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedFormalBar}^{\uparrow}}$, seed)

Scope closed: Definition 4300.1 and Definition 4300.2 seed the finite located bar/cover boundary for Real and Completion consumers over formal covers, spread prefixes, bar recursion, finite windows, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedFormalBar}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite branches, selected cover points, quotient-open equality, countable choice, host topological equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, formal-cover exposure, spread-law prefix exposure, bar-recursion routing, StreamName finite-window replay, located-query exactness, spread-cover exactness, transport, provenance, and local naming for BEDC.Derived.LocatedFormalBarUp.

Chapter 4250

A Concrete Naming Certificate for CauchyModulusFunctoriality$^{\uparrow}$

Following Bishop and Bridges, the CauchyModulusFunctoriality$^{\uparrow}$ packet records the finite data needed to transport displayed Cauchy moduli along a BEDC route without turning that route into a host function equality. It sits between the dyadic tolerance source DyadicRatCore$^{\uparrow}$ of chapter 291, the finite observation route StreamName$^{\uparrow}$ of chapter 126, the regular rational readback RegSeqRat$^{\uparrow}$ of chapter 301, the real-name seal Real$^{\uparrow}$ of chapter 38, the pullback discipline CauchyModulusPullback$^{\uparrow}$ of chapter 1951, and the regular stability surface RegularCauchyModulusStability$^{\uparrow}$ of chapter 1927.

Definition 4250.1 (Cauchy modulus functoriality carrier)**.** *A* CauchyModulusFunctoriality$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, R, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source Cauchy-modulus row, naming the inspected source modulus and its finite request boundary.*
2. *T is the target Cauchy-modulus row, naming the target modulus after transport along the displayed route.*
3. *R is the route-map row, recording the finite BEDC route that carries source requests to target requests without asserting equality of host functions.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, read through chapter 291, that keeps each modulus comparison on dyadic rational bounds.*
5. *W is the* StreamName$^{\uparrow}$ *finite-window row, read through chapter 126, that records the observation window used by the transported modulus request.*
6. *Q is the* RegSeqRat$^{\uparrow}$ *readback row, read through chapter 301, that turns the transported window into a regular rational comparison.*
7. *E is the* Real$^{\uparrow}$ *seal, read through chapter 38, that exposes only the terminal real-name boundary reached by the finite route.*
8. *H records componentwise* hsame *transport for source modulus, target modulus, route map, dyadic tolerance ledger, StreamName window, RegSeqRat readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a transported modulus request through $S, T, R, D, W, Q, E, H, P, N$.*

10. *P is the* Pkg *provenance over* CauchyModulusFunctoriality$^{\uparrow}$, CauchyModulusPullback$^{\uparrow}$, RegularCauchyModulusStal DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CauchyModulusFunctoriality}^{\uparrow}}$ *row.*

The carrier has no coordinate for host function equality, a selected limit, quotient real equality, trichotomy, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusFunctorialityUp.CauchyModulusFunctorialityTasteGate single carrier alignment`

Theorem 4250.2 (Cauchy modulus functoriality NameCert obligations)**.** *For every accepted* CauchyModulusFunctoriality$^{\uparrow}$ *carrier*

$$F = (S, T, R, D, W, Q, E, H, C, P, N),$$

the local NameCert$_{\text{CauchyModulusFunctoriality}^{\uparrow}}$ *obligations are exactly the finite route obligations listed by the carrier: source-modulus admission, target-modulus admission, route-map exposure, dyadic tolerance preservation, StreamName window preservation, RegSeqRat readback preservation, Real-seal non-escape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The route may use the sibling certificates for* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, CauchyModulusPullback$^{\uparrow}$, *and* RegularCauchyModulusStability$^{\uparrow}$, *but it exports no host function equality, selected limit, quotient real equality, trichotomy, countable choice, or ambient* Real$^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 4301.1. The source and target modulus rows are S, T, and the finite transport route is the displayed row R.

The numeric side is then forced through D, W, Q. The dyadic ledger D supplies the tolerance comparisons, the StreamName window W supplies the finite observation boundary, and the RegSeqRat row Q supplies the regular rational readback.

The terminal read is sealed by E. It records only the Real-facing boundary reached by the same finite route, so it cannot introduce a selected limit or quotient-real equality.

Finally transport and replay through H, C, P, N. These rows preserve the same carrier components under hsame, Cont, package provenance, and local naming. Since the carrier contains no coordinates for host function equality, selected limits, quotient real equality, trichotomy, countable choice, or ambient completeness, the listed NameCert obligations exhaust the packet. □

Closure status for NameCert$_{\text{CauchyModulusFunctoriality}^{\uparrow}}$.

Constructive story: A CauchyModulusFunctoriality$^{\uparrow}$ packet is generated from source and target Cauchy-modulus rows, a finite route-map row, DyadicRatCore tolerance ledgers, StreamName windows, RegSeqRat readback rows, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyModulusFunctoriality}^{\uparrow}}$, seed)

Scope closed: Definition 4301.1 and Definition 4301.2 seed the finite modulus-transport certificate over DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, CauchyModulusPullback$^{\uparrow}$, RegularCauchyModulusStability$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchyModulusFunctoriality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function equality, selected limits, quotient real equality, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, route-map exposure, dyadic tolerance preservation, StreamName window preservation, RegSeqRat readback preservation, Real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusFunctorialityUp.

Chapter 4251

A Concrete Naming Certificate for $\mathsf{RealLimitStability}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RealLimitStability}^{\uparrow}$ packet records the finite data by which two displayed terminal $\mathsf{Real}^{\uparrow}$ limit seals remain stable under shared regular-Cauchy evidence. It sits after the terminal Real seal of chapter 38, the regular rational readback discipline of chapter 301, the finite stream-name windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the completion witness of chapter 3579. The packet names stability of displayed limit seals; it is not quotient stream equality, selected host limits, trichotomy, countable choice, or ambient Real completeness.

Definition 4251.1 (Real limit stability carrier)**.** *A* $\mathsf{RealLimitStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L_0, L_1, W, R, D, E_0, E_1, H, C, P, N)$$

with the following displayed rows:

1. L_0 *and* L_1 *are the two limit-presentation rows whose terminal seals are compared.*
2. W *is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which both presentations are inspected.*
3. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the shared window.*
4. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the common dyadic budgets used by the comparison.*
5. E_0 *and* E_1 *are the paired terminal* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after* L_0, L_1, W, R, D *have been displayed.*
6. H *records componentwise* hsame *transport for both limit presentations, the shared window, readback, tolerance ledger, paired Real seals, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from a stability request through* $L_0, L_1, W, R, D, E_0, E_1, H, P, N$.
8. P *is the* Pkg *provenance over* $\mathsf{RealLimitStability}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCompletenessWitness}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RealLimitStability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and their replay path. It has no coordinate for quotient stream equality, selected host limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RealLimitStabilityUp.RealLimitStabilityTasteGate single carrier alignment`

Theorem 4251.2 (Real limit stability NameCert obligations)**.** *For every accepted* $\mathsf{RealLimitStability}^{\uparrow}$ *carrier* $S = (L_0, L_1, W, R, D, E_0, E_1, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealLimitStability}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite packet, classifier stability under componentwise* hsame*, shared-window readback through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$*, dyadic tolerance nonescape through* $\mathsf{DyadicRatCore}^{\uparrow}$*, paired terminal* $\mathsf{Real}^{\uparrow}$ *seal admission, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 4303.1. The accepted packet exposes exactly two presentation rows, one shared window, one regular rational readback, one dyadic tolerance ledger, two terminal Real seals, transport, replay, provenance, and local naming.

Carrier admission and classifier stability are componentwise. The transport row H moves the two presentations, shared evidence, paired seals, and certificate rows together, while the replay row C preserves the same order of inspection for every stability request.

The provenance row P cites only the listed sibling surfaces and the local row N names the packet. Since the carrier contains no quotient equality, selected host limit, trichotomy oracle, choice schedule, ambient completeness coordinate, Lean certificate, or bridge row, the listed obligations exhaust the NameCert surface. □

Theorem 4251.3 (Real limit stability seal stability)**.** *Every comparison of the paired terminal seals in an accepted* $\mathsf{RealLimitStability}^{\uparrow}$ *packet factors through the displayed route*

$$L_0, L_1 \longmapsto W \longmapsto R \longmapsto D \longmapsto E_0, E_1.$$

Thus the two $\mathsf{Real}^{\uparrow}$ *seals may be reused only under the shared finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger displayed by the packet.*

Proof. Start with a consumer that reads the paired Real seals. The only Real-facing terminal coordinates in the carrier are E_0 and E_1, and both appear after the two presentation rows, shared finite window, regular rational readback, and dyadic ledger.

The consumer must therefore pass through W, R, D before either seal can be used. These rows give the finite observations, regular Cauchy readback, and common tolerance budget that make the two terminal seals comparable as displayed BEDC data.

Finally read H, C, P, N. These rows transport, replay, source, and name the same route, so they preserve seal stability without adding a selected host limit or quotient stream equality. □

Theorem 4251.4 (Real limit stability nonescape)**.** *No accepted* $\mathsf{RealLimitStability}^{\uparrow}$ *carrier exports quotient stream equality, a selected host limit, trichotomy, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, a detached Real seal, Lean verification, or bridge checking. Any downstream completion consumer receives only the two limit presentations, shared window, regular readback, dyadic ledger, paired seals, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Proof. Inspect the carrier inventory. The tuple contains no coordinate for quotient equality, selected host limits, trichotomy, choice, ambient completeness, detached seal data, Lean verification, or a bridge certificate.

The paired seals E_0, E_1 are downstream of the shared witness rows W, R, D. Hence a completion consumer can reuse the seals only through the displayed finite evidence and not through an external selected limit.

Transport, replay, provenance, and local naming preserve the same boundary. The rows H, C, P, N move and name only the finite packet, so every exported object remains inside the displayed Real-limit-stability surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealLimitStability}^{\uparrow}}$.

Constructive story: A $\mathsf{RealLimitStability}^{\uparrow}$ packet is generated from two limit-presentation rows, a shared StreamName window, a RegSeqRat readback row, a DyadicRatCore tolerance ledger, paired RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLimitStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4303.1, Definition 4303.2, Definition 4303.3, and Definition 4303.4 seed the finite stability packet for paired terminal Real limit seals under shared StreamName, RegSeqRat, DyadicRatCore, hsame, Cont, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLimitStability}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RealLimitStabilityUp.RealLimitStabilityTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, shared-window readback, dyadic ledger nonescape, paired Real-seal stability, transport, replay, provenance, and local naming for BEDC.Derived.RealLimitStabilityUp.

Chapter 4252

A Concrete Naming Certificate for $\mathsf{DecimalIntervalReal}^{\uparrow}$

Bishop–Bridges constructive analysis uses rational and decimal brackets as finite evidence before a real name is treated as complete. The $\mathsf{DecimalIntervalReal}^{\uparrow}$ packet records this decimal-bracket carrier as BEDC NameCert data. It sits after the decimal prefix surface of chapter 1417, the finite decimal stream of chapter 4191, the dyadic tolerance ledger of chapter 291, the finite window schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located interval source of chapter 1709. The packet gives L10 Real and Completion consumers a finite decimal interval carrier without quotient reals, trichotomy, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4252.1 (Decimal interval real carrier)**.** *A* $\mathsf{DecimalIntervalReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (A, B, D, W, Q, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the lower finite decimal-prefix row, read through* $\mathsf{DecimalExpansion}^{\uparrow}$ *and the finite* $\mathsf{DecimalStream}^{\uparrow}$ *schedule.*
2. *B is the upper finite decimal-prefix row, read through the same decimal surfaces and carrying the advertised bracket side.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger translating decimal place values into dyadic comparison margins.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule opened for endpoint-prefix reads, bracket comparison, and downstream replay.*
5. *Q is the bracket-order row, recording that the lower decimal prefix and upper decimal prefix are compared only through the displayed tolerance ledger.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the endpoint windows, decimal prefix rows, dyadic ledger, and bracket-order row.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regular rational readback has been displayed.*
8. *L is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *handoff row that consumes the same endpoint, tolerance, readback, and seal rows as a located interval boundary.*

9. *H records componentwise* hsame *transport for endpoint prefixes, tolerance rows, windows, bracket order, regular readback, real seal, located interval handoff, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a decimal-bracket request through endpoint prefixes, dyadic comparison, finite windows, regular readback, real sealing, and located interval handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{DecimalIntervalReal}^{\uparrow}$, $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{DecimalStream}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, D, W, Q, R, E, L, H, C, P, N$. It has no coordinate for a quotient real, a trichotomy decision, a selected decimal representative, host endpoint equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.DecimalIntervalRealUp.DecimalIntervalRealCarrier`
Lean4 ✓ `BEDC.Derived.DecimalIntervalRealUp.DecimalIntervalRealTasteGate single carrier alignment`

Theorem 4252.2 (Decimal interval real NameCert obligations)**.** *For every accepted* $\mathsf{DecimalIntervalReal}^{\uparrow}$ *carrier $J = (A, B, D, W, Q, R, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the lower decimal prefix, upper decimal prefix, dyadic tolerance ledger, stream windows, bracket-order row, regular rational readback, real seal, located interval handoff, transport, replay, provenance, and local naming rows;*
2. *decimal-prefix visibility, requiring endpoint reads to enter through A and B before any bracket comparison is inspected;*
3. *tolerance discipline, requiring the place-value comparison to use the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D and no hidden real-order oracle;*
4. *window discipline, requiring each endpoint and comparison read to be scheduled by the finite* $\mathsf{StreamName}^{\uparrow}$ *row W;*
5. *regular-readback order, requiring R to consume A, B, D, W, Q before any* $\mathsf{Real}^{\uparrow}$ *seal is available;*
6. *located-interval handoff, requiring L to consume the same endpoint, tolerance, readback, and seal route rather than a host interval;*
7. *componentwise* hsame *transport and displayed* Cont *replay for exactly the rows carried by H and C;*
8. *ledger non-escape, excluding quotient reals, trichotomy, selected decimal representatives, host endpoint equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4357.1. The projection exposes exactly the two decimal endpoint-prefix rows, the dyadic tolerance ledger, the finite window schedule, the bracket-order row, the regular readback, the terminal real seal, the located interval handoff, transport, replay, provenance, and local naming.

The endpoint reads are visible before comparison. Rows A and B carry the finite decimal prefixes, while D supplies the dyadic margin used to compare their place-value readings. The row W schedules the inspected prefixes and comparison windows, so the bracket-order row Q has no access to a hidden real-order decision.

The real-facing route is downstream of the finite bracket data. Row R is read only after A, B, D, W, Q have been displayed, and row E seals the result only after that regular rational readback.

Finally, the located interval handoff L consumes the same displayed route, while H, C, P, N transport, replay, source, and name the packet. Since no remaining coordinate stores quotient equality, trichotomy, a selected decimal representative, host endpoint equality, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.DecimalIntervalRealUp.DecimalIntervalRealCarrier semantic name certificate`

Theorem 4252.3 (Decimal interval real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{LocatedRealInterval}^{\uparrow}$ *read exported by an accepted* $\mathsf{DecimalIntervalReal}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DecimalExpansion}^{\uparrow},\ \mathsf{DecimalStream}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{LocatedRealInterval}^{\uparrow}.$$

Equivalently, a downstream Real and Completion consumer receives the two decimal endpoint-prefix rows, the dyadic comparison ledger, the finite window row, the regular rational readback, the terminal real seal, the located interval handoff, transport, replay, provenance, and local naming before it can use the bracket.

Proof. Start with an accepted carrier $J = (A, B, D, W, Q, R, E, L, H, C, P, N)$. The only real-facing row is E, and the only located-interval row is L.

The definition places E after the endpoint-prefix rows A, B, the dyadic tolerance ledger D, the window schedule W, the bracket-order row Q, and the regular rational readback R. Thus a $\mathsf{Real}^{\uparrow}$ consumer must first inspect the decimal, dyadic, window, and readback rows.

The located interval handoff is not an alternate route. Row L consumes the same A, B, D, W, Q, R, E path, and componentwise transport through H preserves that path under hsame.

The replay, provenance, and local naming rows only record the displayed carrier. They do not add quotient reals, trichotomy, selected representatives, host endpoint equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so the displayed route is the whole exported handoff. □

Falsifiable prediction: Every accepted $\mathsf{DecimalIntervalReal}^{\uparrow}$ read displays two finite decimal-prefix rows, one dyadic comparison ledger, one finite StreamName window row, one RegSeqRat readback row, one RealUp seal row, one LocatedRealIntervalUp handoff row, and local transport, replay, provenance, and naming rows before it is consumed as a decimal bracket.

Independence witness: decimalexpansion, decimal-stream, dyadicratcore, streamname, regseqrat, real, located-real-interval: $\mathsf{DecimalIntervalReal}^{\uparrow}$ is not bijective to any listed sibling because it binds two ordered decimal endpoint-prefix rows, one dyadic comparison ledger, finite observation windows, regular rational readback, RealUp sealing, located interval handoff, componentwise hsame, displayed Cont, Pkg, and local $\mathsf{NameCert}$ into one accepted bracket packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}$.

Constructive story: A $\mathsf{DecimalIntervalReal}^{\uparrow}$ packet is generated from lower and upper decimal-prefix rows, DecimalStream windows, a DyadicRatCore comparison ledger, a StreamName schedule, a RegSeqRat readback, a RealUp seal, a LocatedRealIntervalUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4357.1, Definition 4357.2, and Definition 4357.3 seed the finite decimal-bracket route over DecimalExpansionUp, DecimalStreamUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, LocatedRealIntervalUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.DecimalIntervalRealUp`

Bridge status: none

Not claimed: This chapter does not claim quotient reals, trichotomy, selected decimal representatives, host endpoint equality, countable choice, Lean verification, bridge checking, or ambient $\mathrm{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, decimal-prefix visibility, dyadic tolerance discipline, finite-window discipline, regular-readback order, Real seal handoff, located interval handoff, transport, replay, provenance, and ledger non-escape for BEDC.Derived.DecimalIntervalRealUp.

Chapter 4253

A Concrete Naming Certificate for $\mathsf{AttouchWetsTopology}^{\uparrow}$

Following Attouch and Wets on variational convergence, the $\mathsf{AttouchWetsTopology}^{\uparrow}$ packet records local Hausdorff-window convergence for closed metric figures as finite BEDC NameCert data over the metric-completion and L10 real-name surface. It sits after the metric carrier of chapter 57, the Hausdorff-distance surface of chapter 3653, the terminal real seal of chapter 38, the regular rational readback of chapter 301, and the finite stream windows of chapter 126. The packet names the finite observation topology; it does not import host closed-set topology, arbitrary hyperspace compactness, quotient closed sets, selected nearest points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4253.1 (Attouch-Wets topology carrier)**.** *An* $\mathsf{AttouchWetsTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A_{\mathrm{aw}} = (M, H, D, W, R, E, Q, T, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose metric, point windows, and bounded-window radii are the only ambient metric data available to the packet.*
2. *H is the* $\mathsf{HausdorffDistance}^{\uparrow}$ *local-window row, read only on displayed bounded metric windows rather than on an ambient hyperspace.*
3. *D is the dyadic tolerance ledger for window radius, Hausdorff comparison margin, and late-window precision.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected centers, bounded windows, comparison stages, and requested precision cells.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational Hausdorff-window comparisons obtained from M, H, D, W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the regular rational readback has been displayed.*
7. *Q records componentwise* hsame *transport for metric source rows, Hausdorff-window rows, dyadic ledgers, stream windows, regular readbacks, real seals, replay rows, provenance, and local naming.*
8. *T records displayed* Cont *replay from an Attouch–Wets observation request through M, H, D, W, R, E.*

9. *C is the local bounded-window classifier row comparing packets only through the displayed metric source, Hausdorff-window, tolerance, stream, readback, seal, transport, replay, provenance, and naming coordinates.*

10. *P is the* Pkg *provenance over* $\mathsf{AttouchWetsTopology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{HausdorffDistance}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}$ *row.*

The classifier has no coordinate for global closed-set topology, open-cover compactness, selected nearest points, quotient hyperspace equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.AttouchWetsTopologyUp.AttouchWetsTopologyTasteGate single carrier alignment`

Theorem 4253.2 (Attouch-Wets topology NameCert obligation surface)**.** *For every accepted* $\mathsf{AttouchWetsTopology}^{\uparrow}$ *carrier*

$$A_{\mathrm{aw}} = (M, H, D, W, R, E, Q, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *expose the* $\mathsf{Met}^{\uparrow}$ *source row M before any local Hausdorff comparison is read;*

2. *display the* $\mathsf{HausdorffDistance}^{\uparrow}$ *window row H only on bounded metric windows named by the packet;*

3. *bind all numerical precision to the dyadic tolerance ledger D, the* $\mathsf{StreamName}^{\uparrow}$ *row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E;*

4. *preserve the same finite route by componentwise* hsame *transport Q and displayed* Cont *replay T;*

5. *source and name the same packet through the bounded-window classifier C,* Pkg *provenance P, and the local* NameCert *row N.*

No obligation row is stored for a host hyperspace topology, arbitrary closed-set compactness, selected representatives, quotient closed-set equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 4358.1. The metric row M is the only source of ambient distance data, and the Hausdorff row H is read only after the bounded window has been displayed.

The numerical part is downstream of that window. The tolerance ledger D, finite window row W, regular readback R, and real seal E are the only precision and value rows available to an observation request.

Transport and replay keep the same route. Rows Q and T preserve the displayed metric, Hausdorff, tolerance, window, readback, and seal data, while C, P, N classify, source, and name the finite packet.

Since the carrier contains none of the excluded topology, compactness, selection, quotient, choice, or ambient-completeness coordinates, the displayed obligations exhaust the local NameCert surface. □

Theorem 4253.3 (Attouch-Wets local Hausdorff window)**.** *Every topology-facing read exported by an accepted* $\mathsf{AttouchWetsTopology}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{HausdorffDistance}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}.$$

Thus a downstream metric-completion consumer receives the displayed metric source, bounded local Hausdorff window, finite observation schedule, regular rational readback, terminal real seal, componentwise transport, replay, provenance, and local naming before it can use Attouch–Wets convergence data.

Proof. Start with a topology-facing read of the accepted carrier. The only available metric source is M, and the only Hausdorff comparison row is the local-window row H.

The observation is then forced through D, W, R, E. The dyadic ledger fixes the requested tolerance, the stream row displays the inspected bounded windows, the regular rational row records the readback, and the real row seals the reported Hausdorff-window value.

Finally Q, T, C, P, N transport, replay, classify, source, and name that same finite route. Because no row supplies host closed-set topology, arbitrary hyperspace compactness, selected nearest points, quotient closed-set equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every exported topology-facing read factors through the displayed local Hausdorff window. □

Closure status for $\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}$.

Constructive story: An $\mathsf{AttouchWetsTopology}^{\uparrow}$ packet is generated from a MetricSpace source row, a HausdorffDistance bounded-window row, a dyadic tolerance ledger, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, a bounded-window classifier row, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4358.1, Definition 4358.2, and Definition 4358.3 seed the local Hausdorff-window topology route over MetricSpaceUp, HausdorffDistanceUp, StreamNameUp, RegSeqRatUp, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.AttouchWetsTopologyUp`

Bridge status: none

Not claimed: This chapter does not claim host closed-set topology, arbitrary hyperspace compactness, quotient closed sets, selected nearest points, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded Hausdorff-window exposure, finite-window scheduling, regular readback, Real sealing, transport, replay, classifier exactness, provenance, and local naming for BEDC.Derived.AttouchWetsTopologyUp.

Chapter 4254

A Concrete Naming Certificate for $\mathsf{CantorIntersectionMetric}^{\uparrow}$

Following Cantor's intersection theorem and Bishop–Bridges constructive metric completion, the $\mathsf{CantorIntersectionMetric}^{\uparrow}$ packet records the metric nested-closed-set intersection route as finite BEDC NameCert data over the L10 completion surface. It sits after the complete-metric source of chapter 128, the metric-completion route of chapter 1506, the nested closed-ball packet of chapter 3526, the Cantor complete metric route of chapter 2199, the Cauchy-filter interface of chapter 333, and the L10 real-name route through chapter 291, chapter 126, chapter 301, and chapter 38. The metric packet is the metric-completion specialization of the finite Cantor-intersection route in chapter 1421 and the theorem-facing intersection route in chapter 2318; it consumes their nested-window and diagonal-readback rows before exposing complete-metric service. The packet names a nested metric intersection handoff; it does not assert open-cover compactness, arbitrary closed-set compactness, quotient stream equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4254.1 (CantorIntersectionMetric carrier)**.** *A* $\mathsf{CantorIntersectionMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I_{\mathrm{cim}} = (M, E, B, K, F, D, S, R, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row whose metric and convergence service are the only complete-metric data available to the packet.*
2. *E is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row naming the surrounding completion request before any intersection point is read.*
3. *B is the* $\mathsf{NestedClosedBall}^{\uparrow}$ *row, recording the descending closed metric ball spine and its finite containment witnesses.*
4. *K is the* $\mathsf{CantorCompleteMetric}^{\uparrow}$ *row, used only as the displayed nested closed-ball completion handoff.*
5. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row generated by the nested metric spine and read only through the displayed filter route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter and tolerance ledger, storing the shrink schedule, late-radius comparisons, and requested precision bounds.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected centers, radii, and containment data.*

8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the regular rational readback of the displayed center schedule.*
9. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after B, K, F, D, S, R have been displayed.*
10. *H records componentwise* hsame *transport for the complete-metric source, completion route, nested-ball row, Cantor handoff, filter, dyadic ledger, stream windows, regular readback, real seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a nested metric intersection request through $M, E, B, K, F, D, S, R, L$.*
12. *P is the* Pkg *provenance over* $\mathsf{CantorIntersectionMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{NestedClosedBall}^{\uparrow}$, $\mathsf{CantorCompleteMetric}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, B, K, F, D, S, R, L, H, C, P, N$. It has no coordinate for open-cover compactness, arbitrary closed-set compactness, quotient completion equality, a selected limit, host trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorIntersectionMetricUp.CantorIntersectionMetricTasteGate single carrier alignment`

Theorem 4254.2 (CantorIntersectionMetric NameCert obligations)**.** *For every accepted* $\mathsf{CantorIntersectionMetric}^{\uparrow}$ *carrier*

$$I_{\mathrm{cim}} = (M, E, B, K, F, D, S, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *expose the complete-metric and metric-completion source rows M, E before any intersection witness is read;*
2. *display the nested metric route through B, K, F, namely the nested closed-ball spine, Cantor complete-metric handoff, and generated Cauchy-filter row;*
3. *bind all numerical readback to the L10 rows D, S, R, L, namely the dyadic tolerance ledger, finite stream windows, regular rational handoff, and terminal real seal;*
4. *preserve the route by componentwise* hsame *transport and displayed* Cont *replay through H, C;*
5. *source and name the same finite packet through* Pkg *provenance P and the local* NameCert *row N.*

No obligation row is stored for open-cover compactness, arbitrary closed-set compactness, quotient completions, selected limits, trichotomy, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 4359.1. The rows M, E expose the metric and completion sources before the packet can read an intersection point.

The nested metric content is then displayed through B, K, F. The nested closed-ball row supplies the descending closed metric spine, the Cantor complete-metric row supplies the existing handoff, and the Cauchy-filter row records the generated filter route.

The L10 readback is downstream. The dyadic ledger D, stream windows S, regular rational row R, and real seal L are the only numerical coordinates available before a completion-facing consumer receives a named output.

Finally H, C, P, N transport, replay, source, and name that same finite route. Since the carrier contains none of the excluded compactness, quotient, selected-limit, trichotomy, or ambient-completeness coordinates, the five displayed obligations exhaust the local NameCert surface. □

Theorem 4254.3 (CantorIntersectionMetric complete handoff)**.** *Every completion-facing read exported by an accepted* $\mathsf{CantorIntersectionMetric}^{\uparrow}$ *carrier factors through the displayed nested metric route*

$\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{NestedClosedBall}^{\uparrow}$, $\mathsf{CantorCompleteMetric}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, S

Thus a consumer receives the complete-metric service, completion request, nested closed-ball spine, Cantor complete-metric handoff, Cauchy-filter row, dyadic tolerance ledger, finite stream windows, regular rational readback, terminal real seal, componentwise transport, replay, provenance, and local naming rows before it may use the intersection output. The handoff exports no $\mathsf{Real}^{\uparrow}$ *completeness principle, open-cover compactness theorem, arbitrary closed-set compactness, quotient stream equality, or selected limit.*

Proof. Begin with a completion-facing read of the accepted carrier. The first available rows are M and E, so the read is grounded in the displayed complete-metric service and the surrounding metric-completion request.

Next pass through the nested route B, K, F. The descending closed-ball spine is read through the $\mathsf{NestedClosedBall}^{\uparrow}$ row, the existing Cantor complete-metric handoff is read through K, and the generated filter is read through F.

The numerical output is then forced through the L10 readback rows D, S, R, L. The dyadic ledger supplies tolerance control, the stream row supplies finite windows, the regular rational row supplies readback, and the terminal real seal is reached only after those rows are present.

The structural rows H, C, P, N preserve the same route for downstream consumers. Because no row supplies full real completeness, open-cover compactness, arbitrary closed-set compactness, quotient stream equality, or a selected limit, every completion-facing read factors through the displayed nested metric route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorIntersectionMetric}^{\uparrow}$ packet is generated from a CompleteMetric source row, a MetricCompletion request row, a NestedClosedBall spine, a CantorCompleteMetric handoff, a CauchyFilter row, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$, seed)

Scope closed: Definition 4359.1, Definition 4359.2, and Definition 4359.3 seed the metric nested-closed-set intersection route over displayed completion, nested-ball, Cantor handoff, filter, dyadic, stream, regular readback, real seal, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, arbitrary closed-set compactness, quotient completions, selected limits, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested metric inclusion, Cantor handoff, Cauchy-filter generation, dyadic shrink exactness, finite-window readback, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CantorIntersectionMetricUp.

Chapter 4255

A Concrete Naming Certificate for $\mathsf{TightRealInterval}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{TightRealInterval}^{\uparrow}$ packet names a finite lower-upper real interval by displaying both endpoint names and every rational cell through which those endpoints are inspected. It sits downstream of the located endpoint surface of chapter 394 and the dyadic refinement surface of chapter 306: consumers may read a tight interval only after the lower endpoint, upper endpoint, rational cell ledger, dyadic refinement ledger, stream windows, regular rational readbacks, and Real seal rows have all been displayed.

Definition 4255.1 (TightRealInterval carrier)**.** *A* $\mathsf{TightRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (L, U, Q, D, S, R, E, H, C, P, N)$$

with the following visible rows:

1. *L is the lower* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint row and U is the upper* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint row.*
2. *Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger recording the finite rational windows that enclose the endpoint reads and witness lower-before-upper compatibility.*
3. *D is the* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger attached to the rational cells in Q.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming exactly the endpoint observations and interval cells inspected by the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those endpoint windows and cell refinements.*
6. *E is the paired* $\mathsf{Real}^{\uparrow}$ *seal row reached from L, U, S, R, Q, D.*
7. *H records componentwise* hsame *transport for endpoints, rational cells, dyadic refinements, stream windows, readbacks, Real seals, replay, provenance, and the local name.*
8. *C records displayed* Cont *replay through $L, U, Q, D, S, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}$ *row.*

The carrier has no coordinate for host interval equality, chosen endpoint values, quotient real equality, trichotomy, countable choice, or ambient real completeness.

Lean4 (definition) `BEDC.Derived.TightRealIntervalUp.TightRealIntervalUp`
Lean4 ✓ `BEDC.Derived.TightRealIntervalUp.TasteGate.TightRealIntervalTasteGate single carrier alignment`

Theorem 4255.2 (TightRealInterval NameCert obligations)**.** *For an accepted* $\mathsf{TightRealInterval}^{\uparrow}$ *carrier* $T = (L, U, Q, D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the lower and upper* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows, rational and dyadic interval ledgers, finite stream windows, regular rational readbacks, paired Real seal rows, componentwise transport, continuation replay, package provenance, and local naming; endpoint-order visibility through* Q*; dyadic refinement discipline through* D*; stream-readback exactness through* S, R*; and ledger non-escape from host intervals, selected endpoints, quotient real equality, choice, trichotomy, and ambient completeness.*

Proof. Project the carrier of Definition 4360.1. The lower and upper endpoint rows, the rational cell ledger, the dyadic refinement ledger, finite windows, regular readbacks, Real seals, transport rows, replay rows, provenance row, and local naming row are all visible before any interval consumer can read the packet.

Endpoint-order visibility is supplied by Q. Since each dyadic refinement in D is attached to a rational cell, the refinement discipline cannot detach from the endpoint ledger.

Stream-readback exactness is then read through S and R. The rows H, C, P, N transport, replay, source, and name the same finite route, while the excluded interval and completeness data have no carrier coordinate. □

Theorem 4255.3 (TightRealInterval Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{TightRealInterval}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{LocatedReal}^{\uparrow},\ \mathsf{RationalInterval}^{\uparrow},\ \mathsf{DyadicInterval}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Nam}$$

The read exposes lower and upper endpoint windows together with the rational and dyadic cell ledgers that bind them. It does not expose a host real interval, a selected endpoint value, quotient real equality, countable choice, trichotomy, or ambient real completeness.

Proof. Begin with the accepted carrier. The only seal-facing row is E, and it is displayed after L, U, Q, D, S, R in the finite packet.

Apply Definition 4360.2. Endpoint-order visibility forces the Real read to keep the rational cell ledger Q, dyadic refinement discipline forces any dyadic window through D, and stream-readback exactness forces finite observations through S, R.

Finally route through H, C, P, N. These rows preserve and name the same packet, so no host interval, endpoint selector, quotient equality, choice schedule, trichotomy row, or ambient completeness principle can enter the Real seal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TightRealInterval}^{\uparrow}$ packet is generated from lower and upper $\mathsf{LocatedReal}^{\uparrow}$ endpoint rows, a $\mathsf{RationalInterval}^{\uparrow}$ cell ledger, a $\mathsf{DyadicInterval}^{\uparrow}$ refinement ledger, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, paired $\mathsf{Real}^{\uparrow}$ seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4360.1, Definition 4360.2, and Definition 4360.3 seed the finite lower-upper Real interval packet over located endpoints, rational cells, dyadic refinements, stream windows, regular readbacks, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host interval equality, selected endpoint values, quotient real equality, trichotomy, countable choice, or ambient real completeness.

Upgrade path: Scoped closure requires a checked carrier-obligation package and a public consumer route for the same finite lower-upper interval packet.

Chapter 4256

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$

Following Bishop-style compact metric uniform continuity, the $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$ packet records the finite handoff that transfers compact finite-net and pointwise continuity data into a uniform modulus row. It consumes the finite compact source of chapter 60, the compact metric net surface of chapter 129, the continuity interface of chapter 391, the finite stream and regular readback rows of chapter 126 and chapter 301, and the dyadic tolerance ledger of chapter 291. The packet is a finite modulus-transfer NameCert surface, not an open-cover compactness proof or a host modulus selector.

Definition 4256.1 (Compact uniform modulus transfer carrier)**.** *A* $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, G, U, S, R, D, F, H, C, P, N)$$

with the following visible rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-net source row.*
2. *G is the* $\mathsf{CompactMetric}^{\uparrow}$ *metric coverage row for the same finite centers and source distance witnesses.*
3. *U is the* $\mathsf{UniformContinuity}^{\uparrow}$ *pointwise-to-uniform continuity row consumed by the transfer.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing the inspected finite centers, tolerance requests, and pointwise-radius reads.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for finite radius comparison and shrinkage.*
7. *F is the modulus-transfer ledger that records the finite lower-bound handoff into the downstream uniform-modulus consumer row.*
8. *H records componentwise* hsame *transport for compact, compact-metric, uniform-continuity, stream, readback, dyadic, transfer, replay, provenance, and local-name rows.*
9. *C records displayed* Cont *replay through $K, G, U, S, R, D, F, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusTransfer}^{\uparrow}}$ *row.*
The carrier has no coordinate for open-cover compactness, selected centers, selected Lebesgue numbers, host modulus functions, quotient point equality, countable choice, or ambient metric completeness.

Lean4 ✓ `BEDC.Derived.CompactUniformModulusTransferUp.CompactUniformModulusTransferTasteGate`
`single carrier alignment`

Theorem 4256.2 (Compact uniform modulus transfer obligations)**.** *For an accepted* CompactUniformModulusTrans *carrier $M = (K, G, U, S, R, D, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusTransfer}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact finite-net row, compact-metric coverage row, uniform-continuity row, stream windows, regular rational readbacks, dyadic tolerance ledger, modulus-transfer ledger, componentwise transport, continuation replay, package provenance, and local naming; source lock between K, G, U; finite-window exactness through S, R; dyadic tolerance exactness through D; and non-escape from open-cover compactness, selected centers, selected Lebesgue numbers, host modulus functions, quotient equality, choice, and ambient completeness.*

Proof. Project the carrier of Definition 4361.1. The compact row, compact-metric row, continuity row, stream windows, readbacks, dyadic tolerance ledger, transfer ledger, transport rows, replay rows, provenance row, and local name are displayed as one finite packet.

The source lock is the shared read of K, G, U. A transfer consumer cannot use the compact finite-net row without the compact-metric distance surface and the continuity row that supplies pointwise radius data.

Finite-window and dyadic exactness are read through S, R, D. The ledger F can therefore transfer only the displayed finite lower-bound data, and H, C, P, N preserve that route without adding any excluded compactness or choice principle. □

Theorem 4256.3 (Compact uniform modulus transfer handoff)**.** *Every accepted* $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$ *packet hands a downstream uniform-modulus consumer only the finite route*

$$\mathsf{Compact}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{UniformContinuity}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont}$$

The handoff records compact finite-net coverage, pointwise continuity radius reads, finite stream windows, regular rational readbacks, dyadic tolerance comparison, and the transfer ledger. It exports no open-cover compactness theorem, selected net center, selected Lebesgue number, host modulus function, quotient equality, countable choice, or ambient completeness.

Proof. Start from the transfer obligations of Definition 4361.2. They identify the compact, compact-metric, continuity, stream, readback, dyadic, and transfer rows as the only NameCert-readable data.

Route the downstream consumer through F. The ledger can be consumed only after K, G, U, S, R, D have supplied the finite-net, pointwise-radius, window, readback, and tolerance rows.

Finally use H, C, P, N to transport, replay, source, and name the same packet. Since the excluded compactness, selection, equality, choice, and completeness data have no coordinate in the carrier, the downstream handoff is exactly the displayed finite modulus-transfer route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusTransfer}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$ packet is generated from compact finite-net rows, compact-metric coverage rows, uniform-continuity rows, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, a modulus-transfer ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactUniformModulusTransfer}\uparrow}$, seed)

Scope closed: Definition 4361.1, Definition 4361.2, and Definition 4361.3 seed the finite compact-net modulus-transfer packet for uniform-continuity consumers.

Formal verification: FormalStatus(NameCert$_{\text{CompactUniformModulusTransfer}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.CompactUniformModulusTransferUp.CompactUniformModulusTransferTasteGate\_single\_carrier`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected centers, selected Lebesgue numbers, host modulus functions, quotient point equality, countable choice, or ambient metric completeness.

Upgrade path: Scoped closure requires a checked transfer-obligation package and a public uniform-modulus consumer route for the same finite packet.

Chapter 4257

A Concrete Naming Certificate for $\mathsf{RealIntervalApartness}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealIntervalApartness}^{\uparrow}$ packet records located separation of two real intervals by a displayed positive dyadic gap rather than by a trichotomy decision on completed real endpoints. It sits after the terminal real-name seal of chapter 38, the located endpoint interval surface of chapter 1709, the dyadic tolerance ledger of chapter 291, the finite window discipline of chapter 126, the regular rational readback of chapter 301, and the separability boundary of chapter 1809. The packet names interval separation only through visible endpoint rows, gap rows, transport, replay, provenance, and local naming.

Definition 4257.1 (RealIntervalApartness carrier)**.** *A* $\mathsf{RealIntervalApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, J, L, U, L', U', G, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I and J are the two* $\mathsf{LocatedRealInterval}^{\uparrow}$ *endpoint packets whose lower and upper endpoint rows are exposed before any apartness read.*
2. *L, U are the lower and upper* $\mathsf{Real}^{\uparrow}$ *seal rows for I, and L', U' are the corresponding* $\mathsf{Real}^{\uparrow}$ *seal rows for J.*
3. *G is a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap witness, attached either to the displayed comparison $U + G \leq L'$ or to the displayed comparison $U' + G \leq L$.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming exactly the endpoint observations and gap inspections used by the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those endpoint windows and dyadic gap checks.*
6. *E records the* $\mathsf{RealSeparability}^{\uparrow}$ *boundary row witnessing that the two exposed endpoint intervals are separated by the displayed dyadic gap.*
7. *H records componentwise* hsame *transport for intervals, endpoint seals, dyadic gap rows, finite windows, readbacks, separability rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay through $I, J, L, U, L', U', G, S, R, E, H$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealIntervalApartness}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}$ *row.*

The carrier has no coordinate for real trichotomy, quotient real equality, a selected endpoint representative, a host interval order, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 4257.2 (RealIntervalApartness NameCert obligations)**.** *For every accepted* $\mathsf{RealIntervalApartness}^{\uparrow}$ *carrier*

$$A = (I, J, L, U, L', U', G, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *admit the two located real interval packets I, J and expose their lower and upper endpoint rows through L, U, L', U';*
2. *expose the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap witness G and the side on which the gap separates the displayed endpoint rows;*
3. *bind every endpoint and gap inspection to the finite* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows S, R;*
4. *preserve the interval, endpoint, gap, readback, and separability rows by componentwise* hsame *transport through H;*
5. *replay the same finite route through* Cont *row C, source it by* Pkg *provenance P, and name it by the local* NameCert *row N.*

No obligation row is stored for real trichotomy, quotient equality of completed real names, selected endpoint representatives, host interval order, or ambient real completeness.

Proof. Project the carrier of Definition 4362.1. The two located interval packets and their endpoint seals are the only interval data exposed to a consumer.

The separation datum is the row G. Positivity is read as a dyadic-row property, and the side of separation is part of the displayed ledger; no trichotomy comparison is consulted.

The numerical readback is forced through S and R, then through the separability row E. The structural rows H, C, P, N transport, replay, source, and name the same finite packet.

Since none of the excluded host-order, quotient-equality, representative-selection, trichotomy, or completeness data occurs as a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.RealIntervalApartnessUp.TasteGate.RealIntervalApartnessTasteGate single carrier alignment`

Theorem 4257.3 (RealIntervalApartness separability route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{RealIntervalApartness}^{\uparrow}$ *carrier factors through*

$\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, hsame, Cont, Pkg, Na

The route exports located interval separation only as a positive dyadic gap between displayed endpoint rows. It exports no real trichotomy, quotient real equality, host interval order, selected endpoint representative, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Begin with the NameCert obligations of Definition 4362.2. They force the two located interval packets and endpoint seals to be visible before a consumer may read an apartness claim.

Next read the dyadic gap row and its finite endpoint inspections through the stream and regular-rational rows. The separability row is therefore attached to the displayed positive gap, not to a host comparison of completed reals.

Finally route through transport, replay, provenance, and local naming. These rows preserve the same finite packet, so the consumer receives located interval apartness without importing any excluded trichotomy, quotient, selection, host-order, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}$.

Constructive story: A $\mathsf{RealIntervalApartness}^{\uparrow}$ packet is generated from two LocatedRealInterval endpoint packets, Real endpoint seal rows, a positive DyadicRatCore gap witness, finite StreamName windows, RegSeqRat readback, a RealSeparability boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4362.1, Definition 4362.2, and Definition 4362.3 seed the located interval separation packet over displayed endpoint, dyadic gap, finite-window, regular-readback, Real seal, separability, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim real trichotomy, quotient real equality, selected endpoint representatives, host interval order, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exposure, positive-gap exposure, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.RealIntervalApartnessUp.

Chapter 4258

A Concrete Naming Certificate for $\mathsf{PartitionBasinPolynomial}^{\uparrow}$

Following finite enumerative combinatorics, the $\mathsf{PartitionBasinPolynomial}^{\uparrow}$ packet records the partition-basin product formula of Definition 9462.1736 as displayed NameCert data over block sizes, legal decorations, defect exponents, incidence totals, transport, replay, provenance, and local naming. It sits after the partition carrier of chapter 201, the defect-flow partition skeleton of chapter 4236, and the partition-core incidence certificate of chapter 4214. The packet names a finite polynomial enumeration surface; it is not a biological stochastic model, a host generating-function oracle, or a quotient-level semantic identification.

Definition 4258.1 (PartitionBasinPolynomial carrier)**.** *A* $\mathsf{PartitionBasinPolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, S, D, E, F, Q, I, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite block-count row for the partition core, and S is the finite block-size ledger $(s_1, \ldots, s_m)$.*
2. *D is the legal-decoration row, recording for each coordinate of block i the admissible subset of the other $m-1$ rows and the private-coordinate exclusion.*
3. *E is the defect-exponent ledger that assigns exponent weight q^r to a coordinate receiving r additional rows.*
4. *F is the product-formula row*
$$\prod_{i=1}^{m} \left[(1+q)^{(m-1)s_i} - \left((1+q)^{m-1} - 1 \right)^{s_i} \right].$$
5. *Q is the four-coordinate specialization row for the five partition types 4, $3+1$, $2+2$, $2+1+1$, and $1+1+1+1$.*
6. *I is the incidence-total row that reads the quotient-level and codon-level totals from the displayed specialization.*
7. *T records the downstream defect-flow handoff to the partition skeleton and incidence certificate.*
8. *H records componentwise* hsame *transport for block sizes, legal decorations, defect exponents, product rows, specialization rows, incidence rows, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay through $M, S, D, E, F, Q, I, T, H$.*
10. *P is the* Pkg *provenance over* PartitionBasinPolynomial$^{\uparrow}$, Partition$^{\uparrow}$, DefectFlowPartitionSkeleton$^{\uparrow}$, PartitionCoreIncidenceCertificate$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$ *row.*

The carrier has no coordinate for a stochastic biology model, a host polynomial oracle, a quotient-semantic equality, an unbounded partition enumeration, or a hidden recurrence outside the displayed finite rows.

Lean4 ✓ `BEDC.Derived.PartitionBasinPolynomialUp.PartitionBasinPolynomialTasteGate single carrier alignment`

Theorem 4258.2 (PartitionBasinPolynomial NameCert obligations)**.** *For every accepted* PartitionBasinPolynomial$^{\uparrow}$ *carrier*

$$B = (M, S, D, E, F, Q, I, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$ *surface consists exactly of block-count and block-size admission through M, S, legal-decoration admission through D, defect-exponent admission through E, product-formula exposure through F, four-coordinate specialization through Q, incidence-total readback through I, defect-flow handoff through T, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4363.1. The block-count and block-size rows supply the finite partition core on which the enumeration is read.

The decoration and defect rows are then exposed coordinatewise. For block i, the all-decoration contribution is $(1+q)^{(m-1)s_i}$, and the excluded no-private-coordinate contribution is $\left((1+q)^{m-1}-1\right)^{s_i}$.

Multiplying the legal block rows gives the product row F. The specialization row Q evaluates the same finite formula on the five four-coordinate partition types, and the incidence row I sums the displayed rows with their finite multiplicities.

Finally T, H, C, P, N route the same polynomial surface to the defect-flow and incidence packets. Because no excluded stochastic, host-oracle, quotient-semantic, unbounded-enumeration, or hidden-recurrence coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 4258.3 (PartitionBasinPolynomial product specialization)**.** *Every defect-flow consumer of an accepted* PartitionBasinPolynomial$^{\uparrow}$ *carrier receives the product formula row for $\mathcal{B}_P(q)$ and the four-coordinate specialization row before reading quotient-level or codon-level incidence totals. The consumer sees only finite block-size, decoration, defect, product, specialization, incidence, transport, replay, provenance, and local NameCert rows.*

Proof. Start from the obligations of Definition 4363.2. They force the block-size ledger and legal-decoration rows to be displayed before the product formula can be consumed.

The four-coordinate row is a finite specialization of the same product row. Its incidence totals are read only after the partition types and finite multiplicities have been displayed.

The handoff through T, H, C, P, N preserves the same finite surface for the defect-flow skeleton and partition-core incidence certificate. Thus no stochastic model, host generating-function oracle, quotient-semantic equality, or hidden enumeration can be read from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$.

Constructive story: A PartitionBasinPolynomial$^{\uparrow}$ packet is generated from block-count rows, block-size ledgers, legal-decoration rows, defect-exponent ledgers, a product-formula row, a four-coordinate specialization row, incidence-total rows, a defect-flow handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$, seed)

Scope closed: Definition 4363.1, Definition 4363.2, and Definition 4363.3 seed the finite partition-basin polynomial packet over displayed block-size, decoration, defect, product, specialization, incidence, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a stochastic biology model, host generating-function oracle, quotient-level semantic equality, unbounded partition enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, product-formula exposure, four-coordinate specialization, incidence readback, transport, replay, provenance, and local naming for BEDC.Derived.PartitionBasinPolynomialUp.

Chapter 4259

A Concrete Naming Certificate for $\mathsf{DistanceToSet}^{\uparrow}$

Following Bishop and Bridges on located subsets in metric spaces, the $\mathsf{DistanceToSet}^{\uparrow}$ packet records the finite route by which a point-to-set distance request is read through displayed located-radius rows and closed-ball witnesses. It sits after the metric source of chapter 57, the located-set surface of chapter 1541, the metric closed-ball boundary of chapter 1451, the located closed-ball handoff of chapter 4063, and the terminal real-name seal of chapter 38. The packet names distance-to-set as finite BEDC data; it is not a host infimum, not a selected nearest point, not quotient real equality, and not a countable-choice construction.

Definition 4259.1 (Distance-to-set carrier)**.** *A* $\mathsf{DistanceToSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, A, x, r, B, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row over which point and subset reads are interpreted.*
2. *A is the* $\mathsf{LocatedSet}^{\uparrow}$ *row naming the subset by finite located-radius observations.*
3. *x is the displayed point row in the metric source.*
4. *r is the dyadic radius ledger recording the inspected tolerance windows.*
5. *B is the* $\mathsf{MetricClosedBall}^{\uparrow}$ *witness row attached to the point and radius ledger.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the exported distance name, read only after the located-set and closed-ball rows are displayed.*
7. *H records componentwise* hsame *transport for the metric source, located set, point row, dyadic ledger, closed-ball witness, Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from the metric source through located-set exposure, point inspection, dyadic-radius accounting, closed-ball handoff, and the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{DistanceToSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{LocatedClosedBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DistanceToSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, A, x, r, B, R, H, C, P, N$. It has no coordinate for a host infimum over all points of A, a selected nearest point, quotient real equality, countable choice, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.DistanceToSetUp.DistanceToSetTasteGate single carrier alignment`

Theorem 4259.2 (Distance-to-set NameCert obligations)**.** *For every accepted* $\mathsf{DistanceToSet}^{\uparrow}$ *carrier*

$$D = (X, A, x, r, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DistanceToSet}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the metric source, located set, point row, dyadic radius ledger, closed-ball witness, Real seal, transport, replay, provenance, and local naming;*
2. *located-set exposure, requiring every subset read to pass through the* $\mathsf{LocatedSet}^{\uparrow}$ *row A before a distance row is exported;*
3. *dyadic-radius monotonicity, requiring the tolerance ledger r to preserve the displayed radius order used by the located-set and closed-ball rows;*
4. *closed-ball handoff, requiring each ball membership or exclusion read to pass through the* $\mathsf{MetricClosedBall}^{\uparrow}$ *witness B and the located closed-ball sibling surface before the Real seal is read;*
5. *Real seal non-escape, requiring R to seal only the displayed distance name and not a host infimum or quotient real;*
6. *componentwise transport, displayed replay, package provenance, and local* NameCert *naming for exactly the displayed packet.*

No DistanceToSet obligation is stored outside these rows.

Proof. Project the carrier of Definition 4364.1. The metric source is X, the located subset is A, the inspected point is x, and the finite tolerance information is held by r.

The closed-ball witness B is read only after those rows are displayed. Its radius requests are therefore attached to the same metric source, located-set row, point row, and dyadic ledger.

The Real seal R comes after the located-radius and closed-ball rows. Transport H and replay C preserve the same order, while P and N record provenance and local naming.

Since no coordinate stores a host infimum, a nearest-point selector, quotient real equality, countable choice, or ambient completeness, those objects cannot become local NameCert obligations. □

Theorem 4259.3 (Distance-to-set located-radius handoff)**.** *Every consumer of an accepted* $\mathsf{DistanceToSet}^{\uparrow}$ *packet reads distance-to-set data only through the displayed located-radius row A, the dyadic radius ledger r, the closed-ball witness B, and the Real seal R, transported by H and replayed by C. The consumer cannot bypass these rows by reading a host infimum, a selected nearest point, quotient real equality, countable choice, or an ambient completeness principle.*

Proof. Read the carrier of Definition 4364.1. The only subset coordinate is the located-set row A, and the only radius coordinate is the dyadic ledger r.

The closed-ball witness B supplies the displayed ball boundary before the Real seal R is exposed. Thus a distance consumer reaches the exported real name only through the located-radius and closed-ball rows.

Apply Definition 4364.2. The transport, replay, provenance, and local naming rows preserve the same finite packet and add no host infimum, nearest-point selector, quotient real equality, countable choice, or ambient completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{DistanceToSet}\uparrow}$.

Constructive story: A $\mathsf{DistanceToSet}^{\uparrow}$ packet is generated from a metric source, located set row, point row, dyadic radius ledger, closed-ball witness, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DistanceToSet}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4364.1, Definition 4364.2, and Definition 4364.3 seed the finite located-radius and closed-ball interface for distance-to-set consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DistanceToSet}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host infimum construction, selected nearest points, quotient real equality, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, located-set exposure, dyadic-radius monotonicity, closed-ball handoff, Real seal non-escape, transport stability, replay stability, provenance, and local naming for BEDC.Derived.DistanceToSetUp.

Chapter 4260

A Concrete Naming Certificate for $\mathsf{JordanCurve}^{\uparrow}$

Following Jordan and constructive topology, the $\mathsf{JordanCurve}^{\uparrow}$ packet records the finite polygonal and winding-ledger route by which a displayed simple closed curve in the real plane may be consumed as a separation boundary. It sits after the terminal real-name seal of chapter 38, the circle carrier of chapter 58, the graph and modulus rows of chapter 130, the finite compact-metric source of chapter 129, and the simplex inventory of chapter 238. The packet names a constructive finite obligation surface; it does not import classical open-cover compactness, selected complementary components, quotient path equality, or a choice-dependent separation theorem.

Definition 4260.1 (Jordan curve carrier)**.** *A* $\mathsf{JordanCurve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, F, P, W, O, I, E, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{S}^{1\uparrow}$ *source row, recording the circle parameter ledger and its local classifier.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row into the displayed* $\mathsf{Real}^{\uparrow} \times \mathsf{Real}^{\uparrow}$ *plane, with graph and modulus observations visible.*
3. *P is the finite polygonal approximation row, read through a* $\mathsf{SimplicialComplex}^{\uparrow}$ *subdivision and its vertex-image ledger.*
4. *W is the winding ledger, recording the finite edge-crossing and sign-change data used to compare test points with the polygonal boundary.*
5. *O is the orientation row, recording the compatible cyclic order inherited from the* $\mathsf{S}^{1\uparrow}$ *row and the polygonal subdivision.*
6. *I is the injectivity-apartness row, stating that distinct inspected arcs carry displayed positive separation windows before they are used by the boundary read.*
7. *E is the exterior-interior ledger, recording only the finite side classification certified by the current polygonal and winding rows.*
8. *H records componentwise* hsame *transport for $S, F, P, W, O, I, E, C, Q, N$.*
9. *C records displayed* Cont *replay from circle, map, polygonal, winding, orientation, and apartness rows to the side-classification row.*

10. *Q is the* Pkg *provenance over* $\mathsf{JordanCurve}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{JordanCurve}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, F, P, W, O, I, E, H, C, Q, N$. It has no coordinate for a host Jordan curve theorem, selected complementary components, open-cover compactness, arbitrary path lifting, quotient path equality, or countable-choice separation.

Lean4 ✓ `BEDC.Derived.JordanCurveUp.JordanCurveTasteGate single carrier alignment`

Theorem 4260.2 (Jordan curve orientation ledger)**.** *For every accepted* $\mathsf{JordanCurve}^{\uparrow}$ *carrier*

$$J = (S, F, P, W, O, I, E, H, C, Q, N),$$

the orientation row O is determined by the finite $\mathsf{S}^{1\uparrow}$ *cyclic order, the* $\mathsf{SimplicialComplex}^{\uparrow}$ *subdivision in P, and the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *edge-image ledger in F. The winding ledger W can read orientation only through those rows, transported by H and replayed by C.*

Proof. Project the accepted carrier. The only circle-facing coordinate is S, and the only finite boundary skeleton is the polygonal row P together with the displayed edge images in F.

The orientation row O is therefore read by following the cyclic order of S across the subdivision cells of P. Each edge-image comparison is a finite real-plane observation supplied by F, not by an ambient topological orientation principle.

The winding ledger W consumes that ordered edge list. Componentwise transport H and replay C preserve the same ordered rows, while Q and N record provenance and local naming. Since the carrier contains no host orientation object or quotient path coordinate, the finite ledger is the entire orientation source. □

Theorem 4260.3 (Jordan curve winding separation boundary)**.** *Every side-classification read from an accepted* $\mathsf{JordanCurve}^{\uparrow}$ *packet factors through the finite route*

$$S, F, P, O, I, W \longmapsto E \longmapsto H, C, Q, N.$$

Thus the packet exposes polygonal approximation, injectivity-apartness, orientation, and winding ledgers before it names an interior or exterior row. It does not assert a blanket classical Jordan separation theorem, selected complementary components, open-cover compactness, quotient path equality, or choice-dependent planar separation.

Proof. Read the carrier of Definition 4365.1. The curve source is S, the displayed map is F, and the finite polygonal boundary is P.

Before a side row is exported, the packet requires the orientation ledger O, injectivity-apartness row I, and winding ledger W. These rows are finite BHist data: the winding read uses edge crossings and signs already attached to the polygonal boundary.

The exterior-interior row E is downstream of that route. Transport, replay, provenance, and naming through H, C, Q, N preserve the same finite packet. The excluded host theorem, selected components, open covers, quotient paths, and choice rows are not coordinates of the carrier, so they cannot be read from the local NameCert surface. □

Falsifiable prediction: A $\mathsf{JordanCurve}^{\uparrow}$ consumer that exports side separation without reading P, W, O, I refutes the carrier surface.

Independence witness: real, sone, continuousmap, compactmetric, simplicialcomplex: the sibling chapters supply real-plane coordinates, circle source data, continuous graph and modulus rows, compact-metric finite inspection, and subdivision cells separately, while $\mathsf{JordanCurve}^{\uparrow}$ binds them into the finite packet $J = (S, F, P, W, O, I, E, H, C, Q, N)$.

Closure status for $\mathsf{NameCert}_{\mathsf{JordanCurve}\uparrow}$.

Constructive story: A $\mathsf{JordanCurve}^{\uparrow}$ packet is generated from a circle source row, continuous real-plane map row, finite polygonal subdivision, winding ledger, orientation row, injectivity-apartness row, side-classification ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JordanCurve}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4365.1, Definition 4365.2, and Definition 4365.3 seed the finite polygonal, winding, orientation, apartness, side-classification, transport, replay, provenance, and local naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JordanCurve}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.JordanCurveUp.JordanCurveTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, the classical Jordan curve theorem, selected complementary components, open-cover compactness, arbitrary path lifting, quotient path equality, or choice-dependent separation.

Upgrade path: Obligation closure requires checked carrier admission, polygonal approximation exactness, winding-ledger stability, orientation transport, injectivity-apartness handoff, side-classification non-escape, replay, provenance, and local naming for BEDC.Derived.JordanCurveUp.

Chapter 4261

A Concrete Naming Certificate for MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$

The MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ packet realizes the normalization remaining question of chapter 9386 as finite NameCert data. It sits beside the candidate-set packet of chapter 2320 and the normalization router of chapter 1108: those siblings expose candidate evidence and route selection, while this packet records the boundary where empty-context closed typed terms may or may not enter the candidate interface. The packet names a closed-projection frontier only; it does not turn candidate-mediated normalization into an unconditional strong-normalization theorem for every closed MetaCIC term.

Definition 4261.1 (MetaCIC candidate closed-projection boundary carrier)**.** *A* MetaCICCandidateClosedProjection *carrier is a finite* BHist *packet*

$$B = (T, K, R, E, NF, O, H, C, P, L)$$

with the following displayed rows:

1. *T is the empty-context typed closed-term row whose projection into the candidate interface is being tested.*
2. *K is the candidate-set evidence row, read through* CandidateSetNormalization$^{\uparrow}$ *when the projection is admitted.*
3. *R is the router row, read through* MetaCICNormalizationCertificateRouter$^{\uparrow}$ *and recording which candidate, closed-candidate, or candidate-set route is exposed.*
4. *E is the bounded-normal endpoint seal row, recording the finite normal-output evidence available after candidate admission.*
5. *NF is the no-infinite-reduction row exported only downstream of K, R, E.*
6. *O is the obstruction row recording refusal when the closed term cannot be placed into the displayed candidate interface.*
7. *H records componentwise* hsame *transport for $T, K, R, E, NF, O, C, P, L$.*
8. *C records displayed* Cont *replay from the closed-term row through candidate admission, router selection, endpoint seal, no-infinite-reduction read, and obstruction retention.*

9. *P is the* Pkg *provenance over* MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$, CandidateSetNormalization$^{\uparrow}$, MetaCICNormalizationCertificateRouter$^{\uparrow}$, MetaCICOpenProblemLedger$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* NameCert$_{\text{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, K, R, E, NF, O, H, C, P, L$. It has no coordinate for evidence-free closed-term strong normalization, unrestricted subject reduction, host reduction equality, quotient conversion, or a global normalizer.

Lean4 ✓ `BEDC.Derived.MetaCICCandidateClosedProjectionBoundaryUp.MetaCICCandidateClosedProjectionBoundar`
`single carrier alignment`

Theorem 4261.2 (MetaCIC candidate-set closed projection frontier)**.** *For every accepted* MetaCICCandidateClosed *carrier*

$$B = (T, K, R, E, NF, O, H, C, P, L),$$

the closed-term row T reaches a strong-normalization-facing read only through candidate evidence K, router selection R, and bounded-normal endpoint seal E. If those rows do not place T inside the candidate interface, the obstruction row O is the only exported boundary datum.

Proof. Project the carrier. The closed-term row T is present as a finite syntactic and typing packet, but it is not itself a normalization theorem.

The positive route first reads K through chapter 2320. The router row R then records the candidate, closed-candidate, or candidate-set branch through chapter 1108. Only after those rows are displayed can the endpoint seal E and no-infinite-reduction row NF be consumed.

If candidate admission is absent, O records the refusal. Transport, replay, provenance, and local naming through H, C, P, L preserve that same finite boundary, so the packet exports no evidence-free closed-term strong-normalization claim. □

Theorem 4261.3 (MetaCIC candidate-set SN handoff boundary)**.** *Every strong-normalization handoff exported by an accepted* MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ *packet is a handoff for rows already inside the displayed candidate interface. It cannot be read as a blanket theorem that all empty-context typed closed MetaCIC terms are strongly normalizing.*

Proof. Start with the frontier theorem. It places the normalization-facing route behind K, R, E and keeps the obstruction row O visible when the candidate interface is not supplied.

For an admitted row, the handoff consumes candidate evidence from CandidateSetNormalization$^{\uparrow}$ and route evidence from MetaCICNormalizationCertificateRouter$^{\uparrow}$. The no-infinite-reduction row NF is therefore downstream of the admitted candidate branch rather than a second source of normalization evidence.

For a closed term outside that interface, the carrier has only T and the obstruction row O on the boundary. The structural rows H, C, P, L transport, replay, source, and name the boundary, but they do not add subject reduction, host conversion equality, quotient reduction equality, or a global normalizer. Hence the handoff is candidate-scoped. □

Theorem 4261.4 (MetaCIC candidate-set public boundary)**.** *Any public no-infinite-reduction or strong-normalization read from an accepted* MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ *packet must cite candidate-set membership or soundness, router selection, and bounded-normal endpoint rows. A bare empty-context typed closed-term row T is insufficient: the public boundary may expose NF only downstream of the candidate-set facts named by* closed_typed_term_sn_from_candidateSet, candidateSet_implies_sn, *and* canonicalCandidateSet_sound *together with the router row R and endpoint seal E.*

Proof. Start with Definition 4366.2. It places every normalization-facing read behind the candidate evidence row K, router row R, and endpoint seal E, and leaves the obstruction row O as the only datum when candidate admission is absent.

Next apply Definition 4366.3. That theorem identifies the handoff as a candidate-interface handoff rather than a theorem about all empty-context closed typed rows. Thus the public NF row cannot be projected from T alone.

Finally read the MetaCIC normalization audit map through the existing candidate-set facts closed_typed_term_sn_from_candidateSet, candidateSet_implies_sn, and canonicalCandidateSet_sound. Those facts supply the candidate membership and soundness side of the route, while R and E supply the public router and endpoint rows. The resulting boundary is therefore candidate-mediated and evidence-bearing, not an unconditional closed-term normalizer. □

Falsifiable prediction: A MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ consumer that exports strong normalization from T without reading K, R, E refutes the carrier surface.

Independence witness: candidate-set-normalization, metacicnormalizationcertificaterouter, metacicopenproblemledger: the candidate-set packet carries candidate evidence, the router selects the admissible normalization route, and the open-problem ledger records the frontier question; this packet binds those rows into a closed-projection boundary without adding an evidence-free normalization theorem.

Closure status for NameCert$_{\text{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}}$.

Constructive story: A MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ packet is generated from an empty-context typed closed-term row, candidate-set evidence, normalization-router selection, bounded-normal endpoint seal, no-infinite-reduction row, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 4366.1, Definition 4366.2, Definition 4366.3, and Definition 4366.4 seed the finite closed-projection, candidate-evidence, router-selection, endpoint-seal, obstruction, public-boundary, transport, replay, provenance, and local naming surface.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, unconditional strong normalization for all closed typed MetaCIC terms, unrestricted subject reduction, host reduction equality, quotient conversion, or a global normalizer.

Upgrade path: Obligation closure requires checked closed-term projection, candidate-evidence admission, router selection, bounded-normal endpoint sealing, no-infinite-reduction handoff, obstruction exactness, replay, provenance, and local naming for BEDC.Derived.MetaCICCandidateClosedProjectionBoundaryUp.

Chapter 4262

A Concrete Naming Certificate for $\mathsf{PointedMetricSpace}^{\uparrow}$

Following Bourbaki and Kelley on based metric spaces, the $\mathsf{PointedMetricSpace}^{\uparrow}$ packet records a metric carrier together with a named basepoint route before completion, loop-space, or embedding consumers are allowed to inspect point-level data. It sits over the $\mathsf{Met}^{\uparrow}$ carrier of chapter 57, reads names through the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, passes regular rational distance observations through chapter 301 and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and offers a based source for the distance-preserving consumer route of chapter 439. The certificate names only finite BEDC rows; it does not import host points, quotient metric equality, selected representatives, or ambient completeness.

Definition 4262.1 (Pointed metric space carrier)**.** *A* $\mathsf{PointedMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, b, D, S, R, E, H, C, P_0, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *metric carrier row.*
2. *b is the basepoint name row, stored as finite BEDC data attached to M rather than as a host-level point.*
3. *D is the basepoint distance ledger, recording the finite requests that compare b with inspected metric names.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which basepoint and metric names are inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed distance windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the basepoint-distance observations.*
7. *H records componentwise* hsame *transport for M, b, D, S, R, E and the local certificate rows.*
8. *C records displayed* Cont *replay from a based metric request through the stream windows, regular rational readback, and real-distance seal.*
9. *P_0 is the* Pkg *provenance over* $\mathsf{PointedMetricSpace}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only after transporting the metric carrier, basepoint name, distance ledger, stream windows, regular readback, real seal, replay, provenance, and local naming rows together.

Lean4 ✓ `BEDC.Derived.PointedMetricSpaceUp.PointedMetricSpaceTasteGate single carrier alignment`

Theorem 4262.2 (Pointed metric space NameCert obligations)**.** *For every accepted* $\mathsf{PointedMetricSpace}^{\uparrow}$ *carrier* $P = (M, b, D, S, R, E, H, C, P_0, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the metric row, basepoint name, basepoint distance ledger, stream windows, regular rational readback, real-distance seal, transport, replay, provenance, and local naming rows;*
2. *common-carrier classification, requiring every comparison of basepoint data to be read over the transported metric row* M*;*
3. *basepoint-distance exposure, requiring every basepoint comparison to pass through* D, S, R, E *before any completion-facing or embedding-facing consumer reads it;*
4. *package provenance and local naming for exactly the displayed finite packet.*

No NameCert obligation is stored in a host point, quotient metric equality, a selected representative, or an ambient completeness principle.

Proof. Project the carrier of Definition 4367.1. The projection exposes the metric row, basepoint name, distance ledger, stream windows, regular readback, real seal, transport, replay, provenance, and local name as the only available coordinates.

The classifier route is common-carrier. Componentwise transport in H moves M, b, D, S, R, E together, so a consumer cannot compare a basepoint name over one metric carrier with distance observations over another.

The distance ledger fixes the read order. A basepoint comparison is first a finite request in D, then a scheduled stream observation in S, then a regular rational readback in R, and only then a $\mathsf{Real}^{\uparrow}$ distance seal in E.

Finally replay C and attach P_0, N. Since the carrier has no coordinate for host points, quotient equality, selected representatives, or ambient completeness, the listed rows exhaust the local naming surface. □

Theorem 4262.3 (Pointed metric space basepoint nonescape)**.** *Let* $P = (M, b, D, S, R, E, H, C, P_0, N)$ *be an accepted* $\mathsf{PointedMetricSpace}^{\uparrow}$ *carrier. Every completion-facing, loop-space-facing, or isometric-embedding-facing consumer of the basepoint row* b *must read it through the displayed route*

$$M, b, D \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P_0, N.$$

Thus the basepoint is exported only as finite named metric data over M*, not as a host point, quotient representative, selected completion point, or ambient metric-equality witness.*

Proof. Begin with carrier admission. The only row naming the basepoint is b, and it is stored beside the metric carrier M and distance ledger D.

Read the inspection route next. The stream windows S and regular rational readback R display every observed distance from the basepoint before the $\mathsf{Real}^{\uparrow}$ seal E is available to downstream consumers.

Transport and replay preserve that same route. The rows H, C, P_0, N move, replay, source, and name the displayed packet; they do not add host points, quotient representatives, selected completion points, or ambient metric equality.

Therefore every based consumer receives exactly the finite route displayed in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{PointedMetricSpace}^{\uparrow}$ packet is generated from a $\mathsf{Met}^{\uparrow}$ carrier, a named basepoint row, a basepoint distance ledger, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ distance seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4367.1, Definition 4367.2, and Definition 4367.3 seed the based metric route over $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.PointedMetricSpaceUp.PointedMetricSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host point equality, quotient metric equality, selected completion points, loop-space closure, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, basepoint-distance exposure, classifier transport, basepoint nonescape, and downstream completion and isometric-embedding consumer alignment for BEDC.Derived.PointedMetricSpaceUp.

Chapter 4263

A Concrete Naming Certificate for $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$

Following Bourbaki and Kelley on based complete metric spaces, the $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ packet records a based metric carrier together with a displayed completion service before completion, loop-space, or embedding consumers are allowed to read a point as complete. It sits over the $\mathsf{Met}^{\uparrow}$ carrier of chapter 57, the $\mathsf{CompleteMetric}^{\uparrow}$ limit-service boundary of chapter 128, the $\mathsf{PointedMetricSpace}^{\uparrow}$ basepoint route of chapter 4367, the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ rational readback of chapter 301, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The certificate names only finite BEDC rows; it does not import host points, quotient metric equality, selected completion representatives, countable choice, or ambient order completeness.

Definition 4263.1 (Pointed complete metric space carrier)**.** *A* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, B, Q, S, R, E, L, H, C, P_0, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *metric carrier row.*
2. *B is the basepoint row, stored as finite named metric data over M rather than as a host-level point.*
3. *Q is the Cauchy-window route, listing the finite tail requests through which regular Cauchy names based at B are inspected.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *readback row for the basepoint and Cauchy windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational distance and modulus observations.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed metric-distance and limit-distance observations.*
7. *L is the* $\mathsf{CompleteMetric}^{\uparrow}$ *completion seal, exposing only the displayed limit-service handoff for the Cauchy-window route Q.*
8. *H records componentwise* hsame *transport for M, B, Q, S, R, E, L and the local certificate rows.*
9. *C records displayed* Cont *replay from a based complete-metric request through the Cauchy windows, stream observations, regular rational readback, real seal, and completion seal.*

10. *P_0 is the* Pkg *provenance over* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PointedMetricSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only after transporting the metric carrier, basepoint, Cauchy-window route, stream windows, regular rational readback, real seal, completion seal, replay, provenance, and local naming rows together.

Lean4 ✓ `BEDC.Derived.PointedCompleteMetricSpaceUp.TasteGate.PointedCompleteMetricSpaceTasteGate single carrier alignment`

Theorem 4263.2 (Pointed complete metric space NameCert obligations)**.** *For every accepted* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *carrier* $P = (M, B, Q, S, R, E, L, H, C, P_0, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSp}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the metric row, basepoint row, Cauchy-window route, stream windows, regular rational readback, real seal, completion seal, transport, replay, provenance, and local naming rows;*
2. *common-carrier classification, requiring the basepoint row, Cauchy windows, and completion seal to be read over the transported metric row M;*
3. *Cauchy-window exposure, requiring every completion-facing read to pass through Q, S, R, E, L before any downstream consumer may inspect the limit handoff;*
4. *package provenance and local naming for exactly the displayed finite packet.*

No NameCert obligation is stored in a host point, quotient metric equality, selected completion representative, countable-choice selector, or ambient order-completeness principle.

Proof. Project the carrier of Definition 4368.1. The projection exposes the metric row, basepoint, Cauchy-window route, stream windows, regular readback, real seal, completion seal, transport, replay, provenance, and local name as the only available coordinates.

The classifier route is common-carrier. Componentwise transport in H moves M, B, Q, S, R, E, L together, so a consumer cannot compare a based Cauchy route over one metric carrier with a completion seal over another.

The completion-facing read order is fixed by the route rows. A completion request begins as a finite Cauchy-window request in Q, becomes a scheduled stream observation in S, is read back as regular rational data in R, is sealed as real-distance data in E, and only then reaches the $\mathsf{CompleteMetric}^{\uparrow}$ limit-service row L.

Finally replay C and attach P_0, N. Since the carrier has no coordinate for host points, quotient equality, selected completion representatives, countable-choice selectors, or ambient order completeness, the listed rows exhaust the local naming surface. □

Theorem 4263.3 (Pointed complete metric space Cauchy basepoint route)**.** *Let* $P = (M, B, Q, S, R, E, L, H, C, P_0$ *be an accepted* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *carrier. Every based regular Cauchy request whose initial window is anchored at B is read through the displayed route*

$$M, B, Q \longmapsto S \longmapsto R \longmapsto E \longmapsto L \longmapsto H, C, P_0, N.$$

Thus the basepoint participates in completion only as named metric and Cauchy-window data over M, not as a selected host point or completed-limit representative.

Lean4 ✓ `BEDC.Derived.PointedCompleteMetricSpaceUp.PointedCompleteMetricSpaceCauchyBasepointRoute`

Proof. Begin with carrier admission. The only row naming the basepoint is B, and it is stored beside the metric row M and the Cauchy-window route Q.

Read the window route next. The stream row S schedules the inspected windows, the regular rational row R reads the tail and distance ledgers, and the $\mathsf{Real}^{\uparrow}$ row E seals the observed distances before the complete-metric row L can expose any limit-service handoff.

Transport and replay preserve that same path. The rows H, C, P_0, N move, replay, source, and name the displayed packet; they do not add a host basepoint, a selected limit representative, quotient equality, or a separate completion object.

Therefore every based Cauchy consumer receives exactly the finite route displayed in the statement. □

Theorem 4263.4 (Pointed complete metric basepoint completion handoff)**.** *Let $P = (M, B, Q, S, R, E, L, H, C, P_0$ and $P' = (M', B', Q', S', R', E', L', H', C', P'_0, N')$ be accepted* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *carriers. If the two packets transport M, B, Q, S, R, E through the same componentwise H row, then every* $\mathsf{CompleteMetric}^{\uparrow}$ *service read of L is taken over that same named basepoint route before any loop-space or embedding consumer may inspect a completed point.*

Equivalently, a consumer may inspect

$$L \quad \text{or} \quad L'$$

only after the route

$$M, B, Q, S, R, E \longmapsto H, C, P_0, N$$

has been displayed; it cannot detach completion service from the transported basepoint row.

Proof. Project both carriers. In each packet the completion-service coordinate is L, and the only rows upstream of it are the metric row M, the basepoint row B, the Cauchy-window row Q, the stream row S, the regular rational row R, and the real-distance seal E.

Apply Definition 4368.3 to the first packet. The displayed route forces every based Cauchy request to pass through M, B, Q, S, R, E before the service row L is visible.

Use the assumed componentwise transport row H to move the same route to the second packet. The replay row C then reproduces the transported route for the completion-facing consumer, and the provenance and local name rows P_0, N record no independent completed point.

Thus a loop-space or embedding consumer can inspect a completed point only after the transported basepoint route has been displayed. There is no carrier coordinate from which the consumer could read L apart from B. □

Theorem 4263.5 (Pointed complete metric space completion nonescape)**.** *Every completion-facing, loop-space-facing, or embedding-facing consumer of an accepted* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *packet factors its completed-point read through*

$$M, B, Q, S, R, E, L, H, C, P_0, N.$$

Consequently the packet exports a based complete metric certificate only as finite BEDC NameCert data; it exports neither host points nor quotient completion equality.

Proof. Inspect the carrier coordinates. The only completion coordinate is L, and the definition makes L a completion seal for the already displayed Cauchy-window route Q over the metric row M and basepoint row B.

The readback rows precede the completion seal. Any consumer must first pass through S, R, E to display stream windows, regular rational ledgers, and real distance seals, so no completed point can be read before the finite analytic route is visible.

The remaining rows are administrative in the BEDC sense. Transport H, replay C, provenance P_0, and local name N preserve and source the packet but do not create host points, quotient completion equality, selected representatives, or ambient completeness.

Thus every downstream completed-point read factors through the displayed finite packet, which proves completion nonescape. □

Closure status for $\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ packet is generated from a MetricUp carrier, a named basepoint row, a Cauchy-window route, StreamName windows, RegSeqRat readback, a RealUp seal, a CompleteMetricUp completion seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4368.1, Definition 4368.2, Definition 4368.3, and Definition 4368.5 seed the based complete-metric route over $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PointedMetricSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient completion equality, selected host endpoints, loop-space closure, embedding closure, or ambient order completeness.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-window exposure, classifier transport, basepoint completion routing, completion nonescape, and downstream completion, loop-space, and embedding consumer alignment for BEDC.Derived.PointedCompleteMetricSpaceUp.

Chapter 4264

A Concrete Naming Certificate for $\mathsf{IntervalConnectedness}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{IntervalConnectedness}^{\uparrow}$ packet records the finite constructive route by which a located real interval is inspected as one connected interval surface before intermediate-value, zero-envelope, or completion-facing consumers use it. It sits after the endpoint seal of chapter 38, the located interval carrier of chapter 1709, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the sandwich consumer surface of chapter 2163. The packet names interval connectedness as displayed finite BEDC data; it does not import host topology, open-cover compactness, trichotomy, quotient real equality, selected roots, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4264.1 (Interval connectedness carrier)**.** *An* $\mathsf{IntervalConnectedness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (E, L, D, S, R, T, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint-pair row, storing the lower and upper endpoint names through their displayed real seals.*
2. *L is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *witness row, carrying the located interval budget, locator reads, and endpoint-radius checks attached to E.*
3. *D is the finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *subdivision-chain ledger, recording the dyadic cells, adjacent-cell overlaps, and tolerance requests inspected inside L.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which endpoint, cell, and witness observations are scheduled.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the scheduled endpoint and subdivision observations.*
6. *T records componentwise* hsame *transport for endpoint pairs, located interval witnesses, dyadic subdivision chains, stream windows, regular readbacks, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from endpoint pairs through located interval exposure, dyadic subdivision, stream-window inspection, regular readback, and the interval-connectedness handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{IntervalConnectedness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{SqueezeTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{IntervalConnectedness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, L, D, S, R, T, C, P, N$. It has no coordinate for host topological connectedness, open-cover compactness, trichotomy, quotient real equality, selected intermediate points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.IntervalConnectednessUp.IntervalConnectednessTasteGate single carrier alignment`

Theorem 4264.2 (Interval connectedness NameCert obligations)**.** *For every accepted* $\mathsf{IntervalConnectedness}^{\uparrow}$ *carrier*

$$I = (E, L, D, S, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{IntervalConnectedness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the endpoint pair, located interval witness, dyadic subdivision chain, stream windows, regular readbacks, transport, replay, provenance, and local naming rows;*
2. *classifier transport, requiring endpoint, locatedness, subdivision, window, readback, replay, provenance, and naming data to move componentwise through T;*
3. *dyadic chain exactness, requiring every inspected subinterval and adjacent-cell overlap to be recorded in D before a connectedness consumer reads the packet;*
4. *endpoint handoff nonescape, requiring every consumer of interval endpoints to pass through E, L, D, S, R before using any* $\mathsf{Real}^{\uparrow}$ *seal;*
5. *ledger exhaustion, requiring the packet to expose no host topological connectedness theorem, open-cover compactness, trichotomy, quotient real equality, selected intermediate point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

The sibling routes through $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{SqueezeTheorem}^{\uparrow}$ *are the only named consumers of this local certificate surface.*

Proof. Project the carrier of Definition 4369.1. The endpoint pair is visible only in E, and the located interval evidence is visible only in L.

The subdivision data are then forced through D. Each finite cell, overlap, and tolerance request is read as dyadic data before any stream-window or regular-readback consumer can inspect it.

Transport and replay preserve the same route. The rows T and C move endpoint, locatedness, subdivision, window, and readback data componentwise, while P and N source and name exactly that displayed packet.

Since the carrier has no coordinate for the excluded host principles, the local certificate cannot export them. □

Falsifiable prediction: Every accepted $\mathsf{IntervalConnectedness}^{\uparrow}$ consumer reads endpoint pairs, located interval witnesses, dyadic subdivision chains, StreamName windows, RegSeqRat readbacks, hsame transport, Cont replay, Pkg provenance, and local naming before any interval-connectedness handoff is visible.

Independence witness: real, locatedrealinterval, dyadicratcore, streamname, regseqrat, squeezetheorem: $\mathsf{IntervalConnectedness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint pairs, located interval witnesses, finite dyadic subdivision chains, scheduled stream windows, regular rational readbacks, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalConnectedness}^{\uparrow}}$.

Constructive story: An IntervalConnectedness$^{\uparrow}$ packet is generated from Real endpoint pairs, a LocatedRealInterval witness, a finite DyadicRatCore subdivision chain, StreamName windows, RegSeqRat readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\text{IntervalConnectedness}^{\uparrow}}$, seed)

Scope closed: Definition 4369.1 and Definition 4369.2 seed the finite located-interval connectedness route over Real$^{\uparrow}$, LocatedRealInterval$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and SqueezeTheorem$^{\uparrow}$ rows.

Formal verification: FormalStatus(NameCert$_{\text{IntervalConnectedness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host topology, open-cover compactness, trichotomy, quotient real equality, selected intermediate points, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, dyadic chain exactness, endpoint handoff nonescape, ledger exhaustion, and downstream intermediate-value consumer alignment for BEDC.Derived.IntervalConnectedness

Chapter 4265

A Concrete Naming Certificate for MetaCICResidualSubstitutionCompatibility$^{\uparrow}$

Following Tait–Martin-Lof and Barendregt on residuals, parallel reduction, and confluence discipline, the MetaCICResidualSubstitutionCompatibility$^{\uparrow}$ packet records the finite boundary where a beta-parallel branch and a substitution replay must meet before the MetaCIC confluence route may use the conditional diamond bridge. It sits over the audit map of chapter 9378 and names the residual-substitution input as packet data rather than as a global Church–Rosser theorem. The packet does not claim full closed Church–Rosser, arbitrary closed-source confluence, or an unrestricted substitution theorem.

The residual-substitution packet is consumed by chapter 765 as a guarded input to candidate-mediated SN/confluence scheduling. The dependency is the residual join row together with the closedness guard data: it tells the scheduler which finite substitution replay may enter a candidate branch and which source windows are closed enough for that handoff, not that the full Church–Rosser theorem has already been completed.

Definition 4265.1 (MetaCIC residual-substitution compatibility carrier)**.** *A* MetaCICResidualSubstitutionCompatil *carrier is a finite* BHist *packet*

$$M = (s, t, b, j, g, a, h, c, p, n)$$

with the following displayed rows:

1. *s is the source term row whose beta-parallel residual branch is inspected.*
2. *t is the substituted term row, storing the finite substitution request and the target occurrence window.*
3. *b is the parallel branch row, displaying the left and right beta-parallel steps before any join is named.*
4. *j is the residual join row, recording the candidate common reduct obtained after substitution replay and residual transport.*
5. *g is the closedness guard row, saying exactly which source and substitution windows are closed enough for the guarded handoff.*
6. *a is the atom-shape separation row, keeping atom, application, lambda, Pi, and beta-redex cases visibly disjoint.*
7. *h records componentwise* hsame *transport for source, substitution, branch, residual join, closedness guard, atom-shape separation, replay, provenance, and local naming rows.*

8. *c records displayed* Cont *replay from the source term through substitution, parallel branching, residual join construction, closedness guarding, and atom-shape separation.*
9. *p is the* Pkg *provenance over* MetaCICResidualSubstitutionCompatibility$^{\uparrow}$*, MetaCIC beta-parallel reduction, residual joins, closedness guards, atom-shape separation,* BHist*,* hsame*,* Cont*, and* NameCert*.*
10. *n is the local* NameCert$_{\text{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $s, t, b, j, g, a, h, c, p, n$. It has no coordinate for a completed parallel diamond, full closed Church–Rosser, arbitrary closed-source confluence, or an unguarded substitution principle.

Lean4 ✓ BEDC.Derived.MetaCICResidualSubstitutionCompatibilityUp.MetaCICResidualSubstitutionCompatibilit
single carrier alignment

Theorem 4265.2 (MetaCIC residual-substitution compatibility NameCert obligations)**.** *For every accepted* MetaCICResidualSubstitutionCompatibility$^{\uparrow}$ *carrier*

$$M = (s, t, b, j, g, a, h, c, p, n),$$

the local NameCert$_{\text{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source term, substituted term, parallel branch, residual join, closedness guard, atom-shape separation, transport, replay, provenance, and local naming rows;*
2. *branch-shape disjointness, requiring atom, application, lambda, Pi, and beta-redex branches to be separated by a before a residual join row is accepted;*
3. *substitution residual replay, requiring c to display how the substituted term row and beta-parallel branch row reach the same candidate join j;*
4. *closed-source guard, requiring g to expose the exact closedness assumptions consumed by the guarded compatibility packet;*
5. *non-claim of full closed Church–Rosser, requiring the packet to remain an input boundary for the conditional confluence bridge rather than a proof of arbitrary closed-source confluence.*

No obligation is stored outside $s, t, b, j, g, a, h, c, p, n$.

Proof. Project the carrier of Definition 4370.1. The source term, substituted term, branch, residual join, closedness guard, and atom-shape separation rows are the only computational coordinates.

The branch-shape row a fixes the case split before the join row is read. Thus a beta-redex residual branch cannot be silently identified with an atom, application, lambda, or Pi shape.

Replay then supplies the compatibility boundary. The row c records the finite route from substitution and beta-parallel branching to the candidate join j, while g states the closedness guard consumed by that route.

Finally h, p, n transport, source, and name exactly the displayed packet. Since full closed Church–Rosser and arbitrary closed-source confluence are not carrier coordinates, they are not exported by this NameCert surface. □

Theorem 4265.3 (MetaCIC residual-substitution candidate projection route)**.** *Every accepted* MetaCICResidualSubstitutionCompatibility$^{\uparrow}$ *carrier*

$$M = (s, t, b, j, g, a, h, c, p, n)$$

exports a candidate-closed projection route to chapter 4366 only after the source term row s, substituted term row t, beta-parallel branch row b, residual join row j, closedness guard row g, and atom-shape separation row a have all been displayed. The downstream candidate boundary receives a guarded compatibility packet, not full Church–Rosser and not arbitrary closed-source confluence.

Proof. Project the carrier of Definition 4370.1. The rows s, t, b, j, g, a are the only computational rows available before the structural transport, replay, provenance, and local naming rows are read.

Use Definition 4370.2. Branch-shape disjointness exposes a, substitution residual replay exposes the route from t and b to j, and the closed-source guard exposes exactly the assumptions in g.

The candidate boundary of chapter 4366 is therefore reached through a guarded compatibility packet. The route supplies source, substitution, beta-parallel, residual-join, closedness, and atom-shape data, while h, c, p, n only transport, replay, source, and name those rows.

Since completed Church–Rosser and arbitrary closed-source confluence are absent from the carrier, the candidate-closed projection route cannot export them. It hands off only the displayed residual-substitution compatibility boundary. □

Theorem 4265.4 (MetaCIC residual-substitution obligation closure surface)**.** *For every accepted* $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ *carrier*

$$M = (s, t, b, j, g, a, h, c, p, n),$$

the obligation surface is exactly the displayed source term, substituted term, parallel branch, residual join, closedness guard, atom-shape separation, transport, replay, provenance, and naming rows. The candidate-closed projection boundary receives only this guarded compatibility packet.

Proof. Apply Definition 4370.2. It identifies carrier admission, branch-shape disjointness, substitution residual replay, closed-source guarding, transport, replay, provenance, and naming as rows of $s, t, b, j, g, a, h, c, p, n$.

Apply Definition 4370.3. The candidate boundary receives the source, substitution, beta-parallel branch, residual-join, closedness, and atom-shape data only through that guarded projection route.

Therefore the obligation surface packages the candidate handoff without exporting full closed Church–Rosser, arbitrary closed-source confluence, or unguarded substitution compatibility. Those claims are not coordinates of the carrier and are not supplied by the candidate projection. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ read displays source term, substituted term, parallel branch, residual join, closedness guard, atom-shape separation, hsame transport, Cont replay, Pkg provenance, and local naming rows before the conditional MetaCIC confluence bridge can consume it.

Independence witness: metacic-confluence-audit: $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ is not a completed confluence theorem because it carries only the finite residual-substitution compatibility boundary consumed by the conditional parallel-diamond route.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ packet is generated from source term, substituted term, parallel branch, residual join, closedness guard, atom-shape separation, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4370.1, Definition 4370.2, and Definition 4370.3 seed the finite residual-substitution compatibility boundary consumed by the conditional MetaCIC confluence bridge and the candidate-closed projection route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full closed Church–Rosser, arbitrary closed-source confluence, unguarded substitution compatibility, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch-shape disjointness, substitution residual replay, closed-source guard, and conditional confluence handoff alignment for BEDC.MetaCIC.BetaParallelSubstitutionCompatibility.

Chapter 4266

A Concrete Naming Certificate for $\mathsf{ComputableCompactMetric}^{\uparrow}$

Following Weihrauch-style computable analysis and the Bishop–Bridges compact metric arguments, the $\mathsf{ComputableCompactMetric}^{\uparrow}$ packet records the effective compact-metric surface as finite BEDC NameCert data. It sits after the compact metric carrier of chapter 129, the effective Polish source of chapter 1706, the total-bounded finite-net route of chapter 127, the complete metric source of chapter 128, and the L10 readback route through chapter 126, chapter 301, and chapter 38. The packet names the finite-cover realizer surface consumed by effective compact analysis; it does not assert open-cover compactness, selected subcovers, quotient completion equality, or an ambient real-completeness principle.

Definition 4266.1 (Computable compact metric carrier)**.** *A* $\mathsf{ComputableCompactMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K_{\mathrm{ccm}} = (K, E, T, C, S, R, L, H, Q, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row carrying the compact metric packet whose finite-net behavior is being made effective.*
2. *E is the* $\mathsf{EffectivePolishSpace}^{\uparrow}$ *source row exposing the effective dense-name and semidecidable basic-ball interface.*
3. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *row naming the finite-net source for each displayed dyadic tolerance request.*
4. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row recording the convergence service available to Cauchy and compact consumers.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for inspected dense names, finite net centers, tolerance requests, and cover indices.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the regular rational readback of distances and tolerance comparisons.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite windows and regular rational comparisons have been displayed.*

8. *H records componentwise* hsame *transport for compact metric, effective Polish, total-bounded, complete-metric, stream-window, regular-readback, real-seal, finite-cover realizer, provenance, and local naming rows.*
9. *Q records displayed* Cont *replay from an effective compactness request through K, E, T, C, S, R, L, H.*
10. *P is the* Pkg *provenance over* $\mathsf{ComputableCompactMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{EffectivePolishSpace}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, E, T, C, S, R, L, H, Q, P, N$. It has no coordinate for an open-cover subcover, a choice-selected finite set, quotient completion equality, excluded-middle compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ComputableCompactMetricUp.ComputableCompactMetricTasteGate single carrier alignment`

Theorem 4266.2 (Computable compact metric NameCert obligations)**.** *For every accepted* ComputableCompactMe *carrier*

$$K_{\mathrm{ccm}} = (K, E, T, C, S, R, L, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}$ *surface consists exactly of the displayed rows in Definition 4371.1. Carrier admission must expose the compact metric source, effective Polish source, total-bounded finite-net source, complete-metric convergence service, finite stream windows, regular rational readback, terminal real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Classifier transport is componentwise through those same rows, and ledger exhaustion says that every finite-cover or compact-analysis consumer can inspect only $K, E, T, C, S, R, L, H, Q, P, N$.*

Proof. Project the carrier of Definition 4371.1. The rows K, E, T, C are the only structural compactness sources, so carrier admission exposes compact metric data, effective Polish naming data, total-bounded finite nets, and complete-metric convergence before any realizer can be read.

The readback rows S, R, L then bind numerical access to finite windows, regular rational comparisons, and the terminal real seal. This is the same L10 readback discipline used by the StreamName, RegSeqRat, and Real siblings named in the chapter introduction.

Transport and replay are visible rows rather than hidden meta-operations. The row H records componentwise hsame transport, Q records displayed Cont replay, and P, N source and name the same finite packet.

For ledger exhaustion, read any compact-analysis consumer from the accepted packet. The carrier exposes only $K, E, T, C, S, R, L, H, Q, P, N$, so no open-cover subcover, selected finite set, quotient completion equality, excluded-middle compactness, or ambient real-completeness principle can be obtained from this NameCert surface. □

Theorem 4266.3 (Computable compact metric finite-cover realizer)**.** *Every effective finite-cover read exported by an accepted* $\mathsf{ComputableCompactMetric}^{\uparrow}$ *packet factors through the route*

$\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{EffectivePolishSpace}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsa

Thus a consumer receives a compact metric source, effective dense-name interface, total-bounded finite-net source, complete-metric convergence service, finite stream windows, regular rational tolerance comparisons, terminal real seal, componentwise transport, replay, provenance, and local

naming rows before it uses the finite-cover realizer. The packet exports no selected subcover, open-cover compactness theorem, quotient completion representative, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with an accepted carrier $K_{\mathrm{ccm}} = (K, E, T, C, S, R, L, H, Q, P, N)$. The compact metric row K and effective Polish row E name the metric and effective dense-name surfaces, while T supplies the finite-net source used for the requested tolerance.

The convergence row C keeps the compact route compatible with complete-metric consumers. A finite-cover realizer cannot leave these displayed sources, because the later rows are read only after the compact, effective, total-bounded, and complete rows are present.

The numerical readback is finite. The stream row S exposes inspected names, center windows, cover indices, and tolerance requests; the regular rational row R compares the displayed distances; and the terminal seal L is reached only after those windows and comparisons have been read.

Finally H, Q, P, N preserve the route under transport, replay, provenance, and local naming. Since selected subcovers, open-cover compactness theorems, quotient representatives, choice selectors, and ambient completeness witnesses are not carrier coordinates, the exported realizer is exactly the displayed finite-cover surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{ComputableCompactMetric}^{\uparrow}$ packet is generated from CompactMetric, EffectivePolishSpace, TotallyBounded, CompleteMetric, StreamName, RegSeqRat, RealUp, componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4371.1, Definition 4371.2, and Definition 4371.3 seed the effective finite-cover realizer route for computable compact metric consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected subcovers, open-cover compactness, quotient completion equality, countable-choice selectors, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, effective dense-name exposure, total-bounded finite-net exposure, complete-metric convergence exposure, finite-window readback, regular rational comparison, real sealing, finite-cover realizer nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ComputableCompactMetricUp.

Chapter 4267

A Concrete Naming Certificate for $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ packet records the separated-completion reflection route for regular Cauchy rational names as finite BEDC NameCert data. It sits over the regular rational readback surface of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the uniqueness boundary of chapter 3390. The packet lets a Real-facing consumer treat two representative regular Cauchy names as the same separated reflection point only after the displayed finite windows, dyadic budgets, and uniqueness ledger have been exposed.

Definition 4267.1 (Regular-Cauchy Hausdorff-reflection carrier)**.** *A* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, Y, S, T, D, U, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the first* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name row.*
2. *Y is the second* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name row presented to the same separated-reflection request.*
3. *S and T are the paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows through which X and Y are observed.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows.*
5. *U is the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *row witnessing that the displayed tail comparisons force separated agreement.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after X, Y, S, T, D, U have been displayed.*
7. *H records componentwise* hsame *transport for the two regular names, stream windows, dyadic ledger, uniqueness row, Real seal, and local certificate rows.*
8. *C records the displayed* Cont *replay from a reflection request to the paired windows, dyadic tolerance ledger, uniqueness row, and terminal Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyUniqueness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, S, T, D, U, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionCarrier admission surface`

Theorem 4267.2 (Regular-Cauchy Hausdorff-reflection NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *carrier* $R = (X, Y, S, T, D, U, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}}$ *surface consists exactly of carrier admission for two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, paired* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *separated-agreement row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation may replace these rows by quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionTasteGate single carrier alignment`

Proof. Project the carrier of Definition 4372.1. The only displayed coordinates are $X, Y, S, T, D, U, E, H, C, P, N$.

The two regular rational names are compared through the paired stream windows S, T and the dyadic tolerance ledger D. The separated-agreement row U is therefore a displayed uniqueness boundary, not a quotient of streams or a host equality proof.

The terminal Real seal E is downstream of that boundary. Transport, replay, provenance, and local naming are supplied by H, C, P, N, and no excluded quotient, selector, host-equality, choice, trichotomy, or ambient-completeness coordinate can be projected from the carrier. □

Theorem 4267.3 (Regular-Cauchy Hausdorff-reflection representative independence)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read accepted by a* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *packet is independent of the chosen representative regular Cauchy name in the following BEDC sense: if the two presented* $\mathsf{RegSeqRat}^{\uparrow}$ *rows are compared through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, then the terminal seal can distinguish them only through the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *row. The packet exports no quotient stream equality, selected representative, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionRepresentativel`

Proof. Begin with an accepted carrier $R = (X, Y, S, T, D, U, E, H, C, P, N)$. The rows X and Y are not presented as completed real objects; they are presented as regular rational names observed through finite stream windows.

The dyadic ledger D binds the comparison budget for those windows, and the uniqueness row U is the only row that can turn the displayed tail comparison into separated agreement. Thus any Real-facing read of E must pass through the same finite comparison route.

The rows H, C, P, N transport, replay, source, and name this route without adding analytic content. Since the carrier contains no further equality coordinate, changing representatives cannot be detected except through the displayed uniqueness row. □

Theorem 4267.4 (Regular-Cauchy Hausdorff-reflection Real seal non-escape)**.** *No terminal* $\mathsf{Real}^{\uparrow}$ *seal consumer accepted by a* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *packet can bypass the displayed route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegularCauchyUniqueness}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In particular, the separated reflection supplies representative independence for the Real seal without quotient streams, host real equality, selected representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionCarrier real seal nonescape`

Proof. Read the carrier coordinates in order. The terminal row E appears only after the two regular rational names, paired stream windows, dyadic tolerance ledger, and uniqueness row have been displayed.

Apply Definition 4372.2. The local NameCert surface exposes exactly those rows, with H, C, P, N preserving the same route for downstream consumers.

The advertised route is therefore the only public path to the Real seal. Since no excluded equality or choice coordinate occurs in the carrier, the seal cannot escape through quotient streams, host equality, representatives selected outside the packet, countable choice, trichotomy, or ambient completeness. □

Theorem 4267.5 (Regular-Cauchy Hausdorff-reflection finite-window uniqueness route)**.** *Suppose two accepted* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *packets display the same paired* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the same* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *row, and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal. Then every separated-reflection consumer factors through the same finite-window route on the underlying* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The factorization does not use quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionCarrier finite window uniqueness route`

Proof. Apply Definition 4372.3. Once the paired StreamName windows, dyadic tolerance ledger, and uniqueness row agree, the terminal Real seal cannot distinguish the two regular Cauchy representatives by any route other than the displayed uniqueness row.

Apply Definition 4372.4. The Real seal is downstream of the finite windows, dyadic ledger, and uniqueness row, so a separated-reflection consumer has no bypass around those displayed rows.

The remaining rows are structural. The hsame rows transport only the displayed components, the Cont rows replay the same finite-window request, and the Pkg and NameCert rows name that route inside BHist. Therefore the consumer factors through the same finite-window route. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ consumer that reaches the terminal RealUp seal without reading two RegSeqRat source rows, paired StreamName windows, a DyadicRatCore tolerance ledger, and a RegularCauchyUniqueness row refutes the carrier surface.

Independence witness: regseqrat, streamname, dyadicratcore, real, regularcauchyuniqueness: $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ is not bijective to any listed sibling because it binds two regular rational representatives to one separated uniqueness row and one downstream Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ packet is generated from two RegSeqRat source rows, paired StreamName finite windows, a DyadicRatCore tolerance ledger, a RegularCauchyUniqueness separated-agreement row, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4372.1, Definition 4372.2, Definition 4372.3, Definition 4372.4, and Definition 4372.5 seed the separated reflection route for regular Cauchy representatives and Real seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}\uparrow}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove the finite NameCert obligation surface, representative-independence handoff, and Real seal non-escape theorem.

Chapter 4268

A Concrete Naming Certificate for $\mathsf{WeakLawLargeNumbers}^{\uparrow}$

Following Kolmogorov and Bishop–Bridges on finite averages and probability estimates, the $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ packet names the displayed finite-average route behind the weak law of large numbers. It sits after the normalized probability surface of chapter 184, the measurable random-variable rows of chapter 185, the finite tail-bound carrier of chapter 6592, and the terminal real-name seal of chapter 38. The packet is a finite certificate for Chebyshev-controlled averages; it is not an almost-sure convergence theorem, a central limit theorem, a countable-choice subsequence selector, a host probability-limit principle, or an ambient $\mathsf{Real}^{\uparrow}$ completeness result.

Definition 4268.1 (Weak law finite-average carrier)**.** *A* $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, R, A, V, T, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the total-event normalization and event classifier. The row R is the finite family of* $\mathsf{RandomVar}^{\uparrow}$ *entries read over that same probability source. The row A records the displayed finite average of the entries in R, while V records the variance or uniform second-moment bound used by the estimate. The row T reads the Chebyshev tail row through* $\mathsf{ChebyshevInequality}^{\uparrow}$ *for the event where the finite average differs from its displayed center by more than the requested tolerance. The row E is the* $\mathsf{Real}^{\uparrow}$ *epsilon seal naming the positive tolerance and the final probability bound. The row H records componentwise* hsame *transport, C records* Cont *replay of the finite averaging route, Q records* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{ChebyshevInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$, *and N is the local* $\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these ten rows.*

Lean4 ✓ `BEDC.Derived.WeakLawLargeNumbersUp.WeakLawLargeNumbersTasteGate single carrier alignment`

Theorem 4268.2 (Weak law NameCert obligations)**.** *For every accepted* $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ *carrier $(P, R, A, V, T, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 4373.1. Carrier admission displays the probability source, the random-variable family, the finite-average row, the variance-bound row, the Chebyshev tail row, the epsilon seal, the transport and replay rows, the provenance row, and the local naming row. The packet imports no host law of large numbers, selected subsequence, external probability-limit operation, countable-choice principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Read the carrier rows in order. The probability source P supplies the measurable-event classifier and total-mass normalization, and the random-variable row R exposes only the finitely displayed variables over that source.

The average row A and variance row V are then internal finite data. They record the algebraic averaging expression and the bound used by the tail estimate before any limiting statement is visible.

Finally read T, E, H, C, Q, N. The Chebyshev tail row and epsilon seal name the probability estimate at the requested tolerance, while transport, replay, provenance, and local naming keep the same finite route under classifier replacement. Since no carrier coordinate stores an infinite limit or subsequence selector, the listed rows exhaust the local certificate surface. □

Theorem 4268.3 (Weak law Chebyshev handoff)**.** *Every accepted* $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ *Chebyshev read factors through the route*

$$P \longmapsto R \longmapsto A \longmapsto V \longmapsto T \longmapsto E \longmapsto H, C, Q, N$$

before any probability-bound consumer receives the finite-average estimate. Thus the Chebyshev step is handed to later probability and $\mathsf{Real}^{\uparrow}$ *formalization as a displayed finite source, finite random-variable row, average row, variance-bound row, tail-event row, epsilon seal, transport, replay, provenance, and local naming data.*

Proof. Start with a probability-bound request. The only probability source exposed by the packet is P, and the only random-variable data exposed over it are the finite rows in R.

The request must next read the average and variance-bound rows. The average row A fixes the finite expression being estimated, and V fixes the bound that the Chebyshev tail row may consume.

Only after these rows are displayed can T and E be read as a bound on the exceptional event. The structural rows H, C, Q, N then preserve that same route for downstream consumers, so the handoff is the finite Chebyshev estimate itself rather than a host-side convergence theorem. □

Theorem 4268.4 (Weak law finite-average nonescape)**.** *Every accepted* $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ *probability-limit-facing read remains inside the finite-average route of Definition 4373.1. In particular, a consumer can read a tail estimate only after displaying the source probability row, finite random-variable rows, average row, variance-bound row, Chebyshev tail row,* $\mathsf{Real}^{\uparrow}$ *epsilon seal, componentwise transport, replay, provenance, and local* $\mathsf{NameCert}$ *row. No accepted read may replace this route by almost-sure convergence, central limit normalization, countable-choice subsequence selection, a host probability-limit operator, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Let a consumer request the finite-average estimate from an accepted carrier. Projection of Definition 4373.1 shows that the request first meets P, R, A, V, T, E and has no independent coordinate for a limit object.

The displayed Chebyshev row T is downstream from the variance-bound row V and upstream from the epsilon seal E. Hence any probability bound read is already tied to the visible finite average and its tolerance.

The remaining rows H, C, Q, N do not add new analytic content. They transport equal displayed histories, replay the finite route, record the package provenance, and attach the local name. Therefore every accepted probability-limit-facing read stays inside the finite-average certificate surface and cannot escape to the excluded convergence or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}$.

Constructive story: A $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ packet is generated from a probability source row, finite random-variable rows, a finite-average row, a variance or second-moment bound row, a Chebyshev tail row, a RealUp epsilon seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4373.1, Definition 4373.2, Definition 4373.3, and Definition 4373.4 seed the finite-average probability route through ProbSpace, RandomVar, RealUp, Chebyshev tail, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close almost-sure convergence, the central limit theorem, countable-choice subsequence selection, host probability limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-average routing, variance-bound stability, Chebyshev tail handoff, epsilon-seal nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.WeakLawLargeNumbe

Chapter 4269

A Concrete Naming Certificate for $\mathsf{LocatedSubset}^{\uparrow}$

Following Bishop and Bridges on located subsets of metric and real spaces, the $\mathsf{LocatedSubset}^{\uparrow}$ packet records a displayed subset together with finite distance-witness rows. It sits after the real-valued metric route of chapter 1638, the Hausdorff comparison boundary of chapter 2086, the real-separability window surface of chapter 1809, the dyadic tolerance core of chapter 291, and the regular rational readback surface of chapter 301. The packet gives Real and Completion consumers a finite located-subset interface without host set extensionality, selected nearest points, quotient subset equality, or ambient completeness.

The located-subset distance route consumes chapter 1809 as its finite search-window source and consumes chapter 2086 only after the real-distance seal has been displayed.

Definition 4269.1 (LocatedSubset carrier)**.** *A* $\mathsf{LocatedSubset}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, W, D, R, E, K, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{RealMetric}^{\uparrow}$ *source row, carrying the ambient metric distance through finite real-name observations.*
2. *S is the subset-admission row, naming the displayed members read by the carrier and exporting no host powerset equality.*
3. *W is the* $\mathsf{RealSeparability}^{\uparrow}$ *search-window row, recording the countable dense or finite-window probes available to a distance request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to each positive distance query.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, packaging the rational comparison data produced from W and D.*
6. *E is the real distance seal row, read only after the metric source, subset admission, search windows, dyadic tolerances, and regular rational readback have been displayed.*
7. *K is the optional* $\mathsf{HausdorffMetric}^{\uparrow}$ *comparison boundary for compact or hyperspace consumers; it records only the finite directed comparisons visible through the preceding rows.*
8. *H records componentwise* hsame *transport for the metric source, subset admission, search windows, dyadic ledger, regular readback, real seal, Hausdorff boundary, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from an ambient point and tolerance request through subset admission, separability windows, dyadic comparison, regular rational readback, real sealing, and any Hausdorff-facing comparison.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedSubset}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSubset}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, S, W, D, R, E, K, H, C, P, N$. It has no coordinate for a host subset object, extensional equality of subsets, a selected nearest point, quotient real equality, countable choice, or an ambient completion theorem.

Lean4 ✓ `BEDC.Derived.LocatedSubsetUp.LocatedSubsetTasteGate single carrier alignment`

Theorem 4269.2 (LocatedSubset NameCert obligations)**.** *For every accepted* $\mathsf{LocatedSubset}^{\uparrow}$ *carrier*

$$L = (M, S, W, D, R, E, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedSubset}^{\uparrow}}$ *surface consists exactly of carrier admission, ambient real-metric visibility, subset-admission stability, separability-window exposure, dyadic-tolerance compatibility, regular-rational readback, real-distance sealing, optional Hausdorff comparison routing, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 4374.1. The displayed packet lists exactly the rows used by an ambient point, subset-membership, tolerance, rational-readback, real-seal, or Hausdorff-facing request.

The metric and subset rows M, S are read first. A distance query can inspect the ambient space only through $\mathsf{RealMetric}^{\uparrow}$, and it can inspect membership only through the displayed admission row S.

The search, tolerance, and readback rows W, D, R then supply finite witnesses for the locatedness request. The real seal E is reached only after those rows have been displayed, while K is available only as a downstream comparison boundary.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no host subset, selected nearest point, quotient equality, countable-choice schedule, or ambient completion coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 4269.3 (LocatedSubset dyadic distance witness)**.** *Every distance read exported by an accepted* $\mathsf{LocatedSubset}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{RealMetric}^{\uparrow} \longmapsto \mathsf{RealSeparability}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto E.$$

The read may be handed to a $\mathsf{HausdorffMetric}^{\uparrow}$ *consumer only after the same route has produced the displayed real-distance seal, transported by H and replayed by C.*

Proof. Begin with a point-to-subset distance request. The ambient metric row M supplies the only metric observations, and the subset-admission row S supplies the only visible membership data.

The finite search window W names the inspected probes. The dyadic ledger D fixes the positive tolerance requests, and the regular rational row R records the resulting readback windows.

The real-distance seal E is therefore downstream of M, S, W, D, R. Any Hausdorff-facing row K can compare only the finite distance data already sealed by this route.

Transport and replay do not add another distance object. The componentwise hsame row H, the displayed Cont route C, the Pkg provenance P, and the local NameCert row N preserve the

same witness surface, so no nearest-point selector or host infimum can bypass the dyadic distance route. □

Falsifiable prediction: Every accepted LocatedSubsetUp distance read exposes RealMetricUp, subset admission, RealSeparabilityUp windows, DyadicRatCoreUp tolerance rows, RegSeqRatUp readback, and a real-distance seal before any HausdorffMetricUp or completion-facing consumer reads the packet.

Independence witness: realmetric, hausdorffmetric, realseparability, dyadicratcore, regseqrat: none of these siblings alone carries the full located-subset packet with subset admission, finite search windows, dyadic tolerance rows, regular rational readback, real-distance sealing, optional Hausdorff comparison, transport, replay, package provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSubset}\uparrow}$.

Constructive story: A $\mathsf{LocatedSubset}^{\uparrow}$ packet is generated from a RealMetricUp source, displayed subset admission, RealSeparabilityUp search windows, DyadicRatCoreUp tolerance rows, RegSeqRatUp readback, a real-distance seal, optional HausdorffMetricUp comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedSubset}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4374.1, Definition 4374.2, and Definition 4374.3 seed the finite located-subset interface for real-metric and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedSubset}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LocatedSubsetUp.LocatedSubsetTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host subset extensionality, selected nearest points, quotient subset equality, countable choice, open-cover compactness, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, real-metric visibility, subset-admission stability, separability-window exposure, dyadic-tolerance compatibility, regular-rational readback, real-distance sealing, Hausdorff comparison routing, transport stability, replay stability, provenance, and local naming for BEDC.Derived.LocatedSubsetUp.

Chapter 4270

A Concrete Naming Certificate for $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$

Following Heine, Borel, and Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ packet records the explicit finite dyadic closed-interval net route for regular Cauchy real names. It sits over the dyadic arithmetic core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the finite-net Heine–Borel surface of chapter 3471. The chapter is a finite dyadic closed-interval net route over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; it is not general Heine–Borel for arbitrary subsets of $\mathsf{Real}^{\uparrow}$, does not import open-cover compactness, and does not select limits outside the displayed interval-net data.

Definition 4270.1 (Regular Cauchy Heine–Borel route carrier)**.** *A* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, D, S, Q, E, W, F, H, C, P, N)$$

with the following displayed rows:

1. *I is the closed bounded regular-Cauchy interval row, exposing two endpoint* $\mathsf{RegSeqRat}^{\uparrow}$ *names, their* $\mathsf{StreamName}^{\uparrow}$ *finite windows, and the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seals.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh row, recording the finite dyadic subdivision, endpoint comparisons, cell widths, and requested tolerance bound.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that lists the finite observations used to compare each regular-Cauchy endpoint and each inspected interval cell.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the endpoint names and the retained dyadic cell names.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, Q have been displayed.*
6. *W is the closed-interval witness row, pairing every retained dyadic cell with its lower and upper endpoint comparisons inside I.*
7. *F is the finite net row, containing only the finite bundle of dyadic cell centers and radius witnesses read by the interval-net route.*
8. *H records componentwise* hsame *transport for the interval, dyadic mesh, stream windows, regular readback, real seal, cell witnesses, finite net, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a closed-interval net request through* I, D, S, Q, E, W, F, H.
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, Q, E, W, F, H, C, P, N$. *It has no coordinate for an arbitrary subset of* $\mathsf{Real}^{\uparrow}$, *arbitrary open covers, selected finite subcovers, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHeineBorelRouteUp.TasteGate.RegularCauchyHeineBorelRouteTasteGate single carrier alignment`

Theorem 4270.2 (Regular Cauchy Heine–Borel route obligations)**.** *For every accepted* RegularCauchyHeineBorelRo *carrier*

$$R = (I, D, S, Q, E, W, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *expose the closed bounded regular-Cauchy interval row I before any interval-net consumer reads a cell;*
2. *display the dyadic subdivision and tolerance ledger D as the only mesh source;*
3. *route endpoint and cell observations through the finite* $\mathsf{StreamName}^{\uparrow}$ *windows S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q;*
4. *reach the terminal* $\mathsf{Real}^{\uparrow}$ *seal E only after the dyadic, stream, and regular-rational rows have been displayed;*
5. *bind each retained dyadic interval cell to the closed interval by the witness row W and export the finite net bundle F;*
6. *preserve the route by componentwise* hsame *transport and displayed* Cont *replay through H, C;*
7. *source and name the same finite packet through* Pkg *provenance P and the local* NameCert *row N.*

No obligation row states general Heine–Borel compactness for arbitrary subsets of $\mathsf{Real}^{\uparrow}$, *arbitrary open-cover compactness, a selected subcover functional, quotient real equality, countable choice, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 5715.1. The interval row I is the only source for the closed bounded regular-Cauchy endpoints, and the route cannot inspect an interval cell before those endpoint rows are present.

Next read the dyadic mesh and observation rows. The dyadic ledger D supplies the finite subdivision and the tolerance comparison, while S and Q supply the finite windows and regular-rational readbacks needed to compare endpoint and cell data.

The Real-facing boundary is downstream. The terminal row E is reached only after the dyadic, stream, and regular-rational rows have been displayed, so the route exports a named real seal rather than a host-selected real limit or quotient equality.

Finally the finite-net part is exhausted by W and F. The witness row W binds each retained dyadic cell to the closed interval, and F lists the finite cell centers and radii. The structural rows H, C, P, N transport, replay, source, and name this same packet, so no arbitrary subset, open cover, selected subcover, choice, selected-limit, or ambient-completeness coordinate remains. □

Theorem 4270.3 (Regular Cauchy Heine–Borel finite interval-net route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer of an accepted* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{HeineBorelFiniteNet}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{RegularCauchy}}$$

The route supplies an explicit finite dyadic closed-interval net for closed bounded regular-Cauchy interval data. It supplies no compactness theorem for arbitrary subsets of $\mathsf{Real}^{\uparrow}$*, no arbitrary open-cover subcover extraction, no quotient real equality, no countable choice, and no* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with a consumer read of the carrier. The only numerical mesh coordinate is D, and every inspected endpoint or cell must be read through the finite windows S and regular-rational row Q before the terminal seal E is available.

The closed-interval part is then bound by W. Each retained dyadic cell is paired with displayed lower and upper endpoint comparisons, so the interval-net route remains a finite dyadic route inside the presented closed bounded interval.

The finite net export is exactly F. It lists the dyadic centers and radius witnesses read by the Heine–Borel finite-net surface, while H, C, P, N preserve and name the same route. Since the carrier contains none of the excluded arbitrary-subset, open-cover, quotient, choice, selected-limit, or completeness coordinates, every such consumer remains on the displayed finite interval-net route. □

Theorem 4270.4 (Regular Cauchy Heine–Borel inductive subcover route)**.** *Every finite interval-net consumer of an accepted* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ *carrier may build subcover reads only by induction over the displayed dyadic cell list* F*. The base read over the empty cell list exports no cover row. The successor read appends one displayed dyadic cell, routes endpoint and cell comparisons through* D, S, Q, E, W*, and preserves the same* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. No read imports arbitrary open-cover compactness, selected finite subcovers, countable choice, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5715.1. The finite net row F is the only coordinate that lists dyadic cells, and the rows D, S, Q, E, W are the only coordinates available for mesh, window, readback, Real seal, and closed-interval comparisons.

The induction base is the empty displayed cell list. With no cell in F, the consumer can read the interval, dyadic mesh, stream windows, regular readback, and structural rows, but it has no cover row to export.

For the successor step, append one displayed dyadic cell from F. Its endpoint and cell comparisons are routed through the dyadic mesh D, finite windows S, regular readback Q, terminal seal E, and witness row W before the consumer extends the finite read.

The structural rows H, C, P, N are preserved componentwise. They transport, replay, source, and name the same finite induction route, so no arbitrary open cover, selected subcover, countable-choice schedule, quotient equality, or ambient completeness principle is introduced. □

Theorem 4270.5 (Regular Cauchy Heine–Borel route obligation scope)**.** *Every accepted* $\mathsf{RegularCauchyHeineBorelR}$ *carrier*

$$R = (I, D, S, Q, E, W, F, H, C, P, N)$$

scopes its obligation rows through finite BEDC primitives as follows:

1. *I is scoped by the* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint rows and the closed bounded regular-Cauchy interval data;*
2. *D is scoped by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh and tolerance rows;*
3. *S is scoped by finite* $\mathsf{StreamName}^{\uparrow}$ *windows;*
4. *Q is scoped by* $\mathsf{RegSeqRat}^{\uparrow}$ *readback;*
5. *E is scoped by the terminal* $\mathsf{Real}^{\uparrow}$ *seal;*
6. *W, F are scoped by the* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *finite closed-interval net route;*
7. *H, C, P, N are scoped respectively by componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row.*

The scoped surface exports no arbitrary subset compactness, open-cover subcover selector, quotient real equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5715.1. Its rows are exactly $I, D, S, Q, E, W, F, H, C, P, N$, so the obligation theorem can inspect no coordinate outside the displayed packet.

Apply Definition 5715.2. The interval row, dyadic mesh, finite stream windows, regular-rational readback, Real seal, closed-interval witnesses, finite net bundle, transport, replay, provenance, and local naming rows are precisely the finite obligations available to the local certificate.

Use Definition 5715.3. It identifies the consumer route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, with hsame, Cont, Pkg, and $\mathsf{NameCert}$ preserving the same displayed packet. The excluded compactness, quotient, selector, choice, selected-limit, and completeness readings therefore have no scoped row. □

Theorem 4270.6 (Regular Cauchy Heine–Borel closed-interval net scope)**.** *Every closed-interval net consumer of an accepted* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ *carrier*

$$R = (I, D, S, Q, E, W, F, H, C, P, N)$$

must read the displayed rows in the order

$$I,\ D,\ S,\ Q,\ E,\ W,\ F,\ H,\ C,\ P,\ N.$$

Here I binds the closed bounded $\mathsf{RegSeqRat}^{\uparrow}$ *interval, D supplies the dyadic mesh, S and Q provide the finite* $\mathsf{StreamName}^{\uparrow}$ *observations and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and W, F are the finite closed-interval witness row and finite interval-net bundle. The remaining rows H, C, P, N transport, replay, source, and name the same route. Thus the consumer sees only the displayed closed-interval net data and imports no arbitrary open-cover compactness, selected subcover functional, quotient real equality, countable choice, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5715.1. Its row list is exactly $I, D, S, Q, E, W, F, H, C, P, N$, and there is no coordinate before I from which a consumer could infer a cell, mesh, cover, or selected limit.

Apply Definition 5715.2. The obligation surface forces the closed bounded interval row I to be exposed before any interval-net read, then forces the mesh D, finite windows S, regular-rational readback Q, and terminal Real seal E before the closed-interval witness and finite-net rows can be exported.

Use Definition 5715.3 and Definition 5715.4. They identify W, F as the finite closed-interval net surface and restrict subcover reads to induction over the displayed dyadic cell list, with endpoint and cell comparisons routed through D, S, Q, E, W.

Finally apply Definition 5715.5. It scopes H, C, P, N as componentwise transport, displayed replay, provenance, and local naming for the same packet. The composed read order is therefore the displayed order $I, D, S, Q, E, W, F, H, C, P, N$, and the excluded compactness, quotient, selector, choice, selected-limit, and completeness principles have no row to enter through. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ packet is generated from a closed bounded regular-Cauchy interval row, a DyadicRatCore mesh row, StreamName windows, RegSeqRat readback, a RealUp seal, closed-interval cell witnesses, a finite dyadic net row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 5715.1, Definition 5715.2, and Definition 5715.3 seed the explicit finite dyadic closed-interval net route over DyadicRatCore, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim general Heine–Borel compactness for arbitrary subsets of $\mathsf{Real}^{\uparrow}$, arbitrary open-cover compactness, selected finite subcovers, quotient real equality, countable choice, selected limits, Lean verification, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, dyadic mesh exactness, finite stream-window readback, regular-rational endpoint routing, Real seal nonescape, finite interval-net exposure, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyHeineBorelRouteUp.

Chapter 4271

A Concrete Naming Certificate for $\mathsf{CauchyApproximationTree}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyApproximationTree}^{\uparrow}$ packet records a finite branching approximation surface over the L10 Cauchy spine: each active branch carries a displayed tolerance window, a dyadic approximation row, a regular-rational readback row, and a terminal Real seal. It sits between the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback surface of chapter 301, the real-name seal of chapter 38, and the Cauchy route of chapter 3413. The packet gives Real and Completion consumers a finite approximation tree without quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient completeness.

Definition 4271.1 (Cauchy approximation tree carrier)**.** *A* $\mathsf{CauchyApproximationTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (V, E, B, D, S, R, L, H, C, P, N)$$

with the following displayed rows:

1. *V is the finite tree-node row, listing the nodes presently opened by the approximation packet.*
2. *E is the finite edge and parenthood row, recording the branch relation among the nodes in V.*
3. *B is the branch-window row, assigning each active branch the finite tolerance window currently inspected.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic approximants, radius comparisons, and the error rows attached to each branch window.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by the branch windows and no hidden stream coordinates.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and dyadic tolerance rows.*
7. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the node, branch-window, dyadic, stream, and regular-readback rows have been exposed.*
8. *H records componentwise* hsame *transport for tree nodes, branch windows, dyadic rows, stream schedules, regular readbacks, Real seals, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a finite tree branch through B, D, S, R and into the terminal Real seal L.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyApproximationTree}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, E, B, D, S, R, L, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyApproximationTreeUp.CauchyApproximationTreeTasteGate single carrier alignment`

Theorem 4271.2 (Cauchy approximation tree NameCert obligations)**.** *For every accepted* CauchyApproximationTre *carrier $T = (V, E, B, D, S, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the tree-node row, edge row, branch windows, dyadic tolerance ledger, stream schedule, regular readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *tree finiteness, requiring every inspected branch to be generated by the finite node and edge rows V, E;*
3. *branch-window exactness, requiring each active branch to read its tolerance window from B before any dyadic approximation in D is accepted;*
4. *dyadic and stream exactness, requiring D and S to expose only the dyadic approximants and finite observations demanded by the displayed branch windows;*
5. *regular readback and Real-seal boundary, requiring R and L to remain downstream of V, E, B, D, S and never to serve as selected limits or host equality objects;*
6. *componentwise transport and replay, requiring H and C to preserve exactly the displayed finite branch route;*
7. *provenance and local naming, requiring P and N to export the route over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{Cauchy}^{\uparrow}$ *without adding quotient equality, choice, trichotomy, or ambient completeness.*

No approximation-tree obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5716.1. The accepted packet displays exactly the finite node row V, edge row E, branch windows B, dyadic ledger D, stream schedule S, regular readback R, Real seal L, and structural rows H, C, P, N.

Tree finiteness and branch-window exactness follow from the row order. A consumer first reads a node and its branch relation from V, E; only then may it inspect the branch tolerance window B and the dyadic approximation row D attached to that branch.

The stream and readback rows are downstream of the same branch window. The schedule S opens only the finite observations demanded by B, and R records the regular-rational data justified by D and S.

Finally, the Real seal row L is terminal for this finite branch route. The transport row H, replay row C, provenance row P, and local naming row N preserve and name the same displayed packet, so no quotient stream equality, selected limit, countable-choice selector, host real equality, trichotomy principle, or ambient completeness theorem can become a local obligation. □

Theorem 4271.3 (Cauchy approximation tree branch readback)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Cauchy}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyApproximationTree}^{\uparrow}$ *carrier reads a branch only through the displayed route*

$$V, E, B, D, S, R, L, H, C, P, N.$$

Consequently each consumed branch exposes finite tree nodes, branch windows, dyadic tolerance rows, StreamName observations, RegSeqRat readbacks, a Real seal, componentwise transport, displayed replay, provenance, and local naming data. It exposes no quotient stream equality, selected limit, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Let a Real-facing or Cauchy-facing consumer read an accepted packet $T = (V, E, B, D, S, R, L, H, C, P, N)$. Carrier projection gives access only to the rows named in Definition 5716.1.

The read begins with the finite tree rows V, E and then chooses a displayed branch window in B. The dyadic ledger D supplies the approximant and tolerance comparison for that branch, the stream schedule S opens the finite observation windows, and the regular readback row R exposes the rational data that the Real seal may consume.

The terminal row L is therefore reached only after the finite route through V, E, B, D, S, R has been displayed. The structural rows H, C, P, N transport, replay, source, and name the same route without adding any second equality or limit coordinate.

Since the packet has no carrier row for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, a Real-facing or Cauchy-facing consumer cannot read any of those objects from the local certificate. □

Falsifiable prediction: Every $\mathsf{CauchyApproximationTree}^{\uparrow}$ Real-facing or Cauchy-facing read factors through finite tree nodes, branch windows, a DyadicRatCore tolerance ledger, selected StreamName observations, RegSeqRat readbacks, a RealUp seal row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy: $\mathsf{CauchyApproximationTree}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite tree nodes, branch windows, dyadic tolerance rows, finite stream schedules, regular-rational readback, a terminal Real seal, transport, replay, provenance, and local naming in one branch-indexed packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyApproximationTree}^{\uparrow}$ packet is generated from finite tree nodes, branch windows, a DyadicRatCore tolerance ledger, StreamName finite observations, RegSeqRat readback rows, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5716.1, Definition 5716.2, and Definition 5716.3 seed the finite branch-indexed route from L10 Cauchy approximation windows to RealUp endpoint consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tree finiteness, branch-window exactness, dyadic ledger exactness, stream and readback exactness, Real seal boundary, componentwise transport, replay, provenance, and local naming for BEDC.Derived.CauchyApproximationTreeUp.

Chapter 4272

A Concrete Naming Certificate for $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$ packet records the finite comparison surface between Bishop-style Cauchy representations and the BEDC real-name ladder. It sits after the Cauchy-representation route of chapter 1680, the precision ledger of chapter 4141, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names the comparison route as finite NameCert data; it is not quotient stream equality, selected host limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4272.1 (Bishop Cauchy representation comparison carrier)**.** *A* $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, B, S, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{CauchyRepresentation}^{\uparrow}$ *row whose decoder route supplies the representation-facing observations.*
2. *B is the* $\mathsf{BishopRealPrecision}^{\uparrow}$ *row recording the requested constructive precision discipline for the comparison.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row shared by the representation and precision reads.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed stream windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the precision and regular-readback rows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after R, B, S, Q, D have been displayed.*
7. *H records componentwise* hsame *transport for the representation row, precision row, stream windows, regular readback, dyadic ledger, terminal seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a comparison request through $R, B, S, Q, D, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$, $\mathsf{CauchyRepresentation}^{\uparrow}$, $\mathsf{BishopRealPrecision}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite comparison packet. It has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCauchyRepresentationComparisonUp.BishopCauchyRepresentationComparisonTasteGa`
`single carrier alignment`

Theorem 4272.2 (Bishop Cauchy representation comparison NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$ *carrier* $K = (R, B, S, Q, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, representation decoding through* R*, constructive precision exposure through* B*, shared finite-window access through* S*, regular rational readback through* Q*, dyadic tolerance accounting through* D*, terminal real-name sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The visible analytic data are the representation decoder R, precision row B, shared stream window S, regular rational readback Q, dyadic tolerance ledger D, and terminal real seal E.

The comparison obligations are componentwise. A representation-facing consumer first reads R, then the requested Bishop precision surface B, and then the common finite-window, regular-readback, and dyadic-tolerance route S, Q, D.

Only after these rows are displayed may the consumer inspect the terminal seal E. The support rows H, C, P, N transport, replay, source, and name the same finite route, so no further NameCert obligation remains outside the listed coordinates. □

Theorem 4272.3 (Bishop Cauchy representation comparison nonescape)**.** *No accepted* BishopCauchyRepresentatio*n carrier exports quotient streams, selected host limits, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every downstream Real or Completion consumer receives only the displayed representation row, Bishop precision row, stream-window row, regular readback row, dyadic tolerance ledger, terminal real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Proof. Inspect the carrier inventory. The tuple contains only $R, B, S, Q, D, E, H, C, P, N$.

The rows R, B, S, Q, D are the complete comparison route before the terminal Real seal can be consumed. Thus the seal E is not a selected host limit; it is the downstream endpoint of the displayed representation, precision, window, readback, and tolerance data.

Transport, replay, provenance, and local naming preserve the same boundary. Since no coordinate stores quotient stream equality, a choice schedule, a trichotomy branch, host real equality, or an ambient completeness principle, none can escape from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$ packet is generated from a CauchyRepresentation decoder, a BishopRealPrecision row, a StreamName finite window, a RegSeqRat readback row, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$, seed)

Scope closed: Definition 5717.1, Definition 5717.2, and Definition 5717.3 seed the finite representation-comparison route from CauchyRepresentation and BishopRealPrecision data to StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, representation-decoder exactness, precision-row exposure, shared-window readback, dyadic tolerance accounting, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyRepresentationComparisonUp.

The SeparableSpace$^{\uparrow}$ hub routes its countable dense schedule through chapter 1809 for Real-facing L10 density consumers.

Chapter 4273

A Concrete Naming Certificate for $\mathsf{SeparableSpace}^{\uparrow}$

Following Bourbaki's countable-base presentation and Bishop and Bridges' constructive dense-sequence discipline, the $\mathsf{SeparableSpace}^{\uparrow}$ packet names a countable dense schedule as finite BEDC data. It sits over the metric carrier of chapter 57, the finite window surface of chapter 126, the regular rational readback route of chapter 301, the terminal real-name surface of chapter 38, and the complete-separable consumer of chapter 1490. Its Real-facing dense schedule is also consumed by the downstream sibling dependency chapter 1809. The packet exports a dense schedule visible to L10 completion consumers without host set equality, selected dense points, countable choice, or ambient completeness.

Definition 4273.1 (Separable-space carrier)**.** *A* $\mathsf{SeparableSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, S, R, D, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *row containing the admitted metric carrier, distance classifier, and metric local* $\mathsf{NameCert}$*.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row that schedules finite dense-name probes and radius requests.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row that reads the rational windows attached to those probes.*
4. *D is the countable-density ledger, recording that every displayed metric-radius request reaches an admitted stream probe with a regular rational distance bound.*
5. *W is the observation ledger joining stream positions, regular rational windows, metric-radius requests, and terminal* $\mathsf{Real}^{\uparrow}$ *seal reads.*
6. *H records componentwise* hsame *transport for M, S, R, D, W and the local certificate rows.*
7. *C records displayed* Cont *replay from a density request to the corresponding stream and regular-rational readback rows.*
8. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparableSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a host dense subset, selected nearest point, quotient point equality, or external enumeration.

Theorem 4273.2 (Separable-space NameCert obligations)**.** *For every accepted* $\mathsf{SeparableSpace}^{\uparrow}$ *carrier* $Q = (M, S, R, D, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SeparableSpace}^{\uparrow}}$ *surface consists exactly of six obligation rows: carrier admission for* $M, S, R, D, W, H, C, P, N$*; classifier transport to a common* $\mathsf{Met}^{\uparrow}$ *row before density is read; stability of the stream schedule and regular rational readback under* H*; exactness of* W *as the only route from a radius request to finite stream and rational-window data; displayed* Cont *replay from density requests through* S, R, D, W*; and* Pkg *provenance with local naming for precisely this packet. No additional obligation stores a selected dense point, countable-choice function, host set equality, or ambient completion datum.*

Proof. Project the carrier of Definition 5718.1. Carrier admission exposes the metric row, stream schedule, regular rational readback, density ledger, observation ledger, transport, replay, provenance, and local name.

The classifier route begins at M. Componentwise transport in H moves M, S, R, D, W together, so a dense schedule cannot be compared after changing the metric source.

The exactness row is W. Every radius request reaches a finite stream position in S, reads its rational window through R, and records the density witness in D before any terminal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Finally replay the request through C and source it through P, N. Since no row names a selected point, host dense subset, countable-choice selector, or ambient completion, the six listed rows exhaust the NameCert obligations. □

Theorem 4273.3 (Separable-space StreamName dense readback)**.** *Let* $Q = (M, S, R, D, W, H, C, P, N)$ *be an accepted* $\mathsf{SeparableSpace}^{\uparrow}$ *carrier. Every dense-readback consumer reads the countable schedule only through* $\mathsf{StreamName}^{\uparrow}$ *row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, observation ledger* W*, and density ledger* D *over the common* $\mathsf{Met}^{\uparrow}$ *row* M*. When the read is Real-facing it may consume only the terminal* $\mathsf{Real}^{\uparrow}$ *seal already displayed by* R, W*; when it is completion-facing, a* $\mathsf{PolishSpace}^{\uparrow}$ *or* $\mathsf{SeparableMetric}^{\uparrow}$ *consumer receives the same finite schedule route and no selected dense point, quotient point equality, host enumeration, or ambient completeness principle.*

Proof. Expose the accepted carrier. The only scheduling coordinate is S, and the only regular rational readback coordinate attached to the schedule is R.

Use Definition 5718.2. Observation exactness forces a dense-readback request through W before the density ledger D is available, while H keeps the route over the same metric row M.

The Real-facing boundary is downstream of the regular rational observations. Thus any $\mathsf{Real}^{\uparrow}$ seal is read after S, R, W, D, not as a separate host-real shortcut.

Finally pass the displayed route to the complete-separable consumers. The $\mathsf{PolishSpace}^{\uparrow}$ and $\mathsf{SeparableMetric}^{\uparrow}$ packets may inspect the same finite schedule rows, but the carrier contains no coordinate for selected dense points, quotient equality, host enumeration, or ambient completeness. □

Theorem 4273.4 (Separable-space finite dense-schedule induction)**.** *Let* $Q = (M, S, R, D, W, H, C, P, N)$ *be an accepted* $\mathsf{SeparableSpace}^{\uparrow}$ *carrier. Any finite list of dense-readback requests over* Q *is discharged by induction through the same* $\mathsf{StreamName}^{\uparrow}$ *schedule row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, observation ledger* W*, density ledger* D*, and common* $\mathsf{Met}^{\uparrow}$ *row* M*. The induction exports only the displayed finite schedule route and no selected dense point, host enumeration, quotient equality, or countable-choice selector.*

Proof. Induct on the displayed finite list of dense-readback requests.

For the empty list, no dense point is selected and no host enumeration is opened. The carrier projection of Definition 5718.1 leaves only the common rows $M, S, R, D, W, H, C, P, N$, so the empty schedule is discharged by the displayed packet itself.

For a cons list, apply Definition 5718.3 to the head request. The head is routed through S, R, W, D over the fixed metric row M, and any Real-facing read remains behind the already displayed regular rational observations.

Apply the induction hypothesis to the tail list using the same accepted carrier. Componentwise transport through H and replay through C keep every tail request on the same S, R, W, D, M route. Since no step introduces a selected dense point, host enumeration, quotient equality, or countable-choice selector, the whole finite list is discharged inside the finite dense-schedule packet. □

Theorem 4273.5 (Separable-space RealSeparability forward route)**.** *Any* $\mathsf{RealSeparability}^{\uparrow}$ *consumer reading a* $\mathsf{SeparableSpace}^{\uparrow}$ *dense schedule must factor the read through the* $\mathsf{Met}^{\uparrow}$ *row* M*, the* $\mathsf{StreamName}^{\uparrow}$ *row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal displayed by* R, W*, and the countable-density ledger* D *before the* $\mathsf{RealSeparability}^{\uparrow}$ *row of chapter 1809 is consumed. The route exports a finite dense-readback dependency, not a selected dense point, quotient point equality, host enumeration, countable-choice selector, or ambient completeness principle.*

Proof. Start with the accepted carrier $Q = (M, S, R, D, W, H, C, P, N)$. The metric source is M, the finite schedule is S, and the regular rational readback is R.

Use Definition 5718.3. It forces every dense read through S, R, W, D over the same metric row M before any Real-facing seal is consumed.

Now route the downstream sibling dependency through chapter 1809. The $\mathsf{RealSeparability}^{\uparrow}$ row receives the displayed countable-density ledger only after the metric, stream, regular rational, and $\mathsf{Real}^{\uparrow}$ rows are visible.

Because the carrier has no coordinate for selected dense points, quotient point equality, host enumeration, countable choice, or ambient completeness, the forward route remains a finite dependency edge. □

Theorem 4273.6 (SeparableSpace real-metric dependency route)**.** *Every completion, compactness, or real-facing consumer of an accepted* $\mathsf{SeparableSpace}^{\uparrow}$ *dense schedule reads the metric carrier data of chapter 57 and the Real-density route of chapter 1809 before it may inspect the downstream separability surface. The route exposes countable dense data only through displayed* $\mathsf{Met}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows; it exports no host enumeration, selected dense point, quotient point equality, countable-choice selector, or ambient completeness principle.*

Proof. Project the accepted dense schedule. Its metric source is the row that supplies distance observations, while the real-separability row supplies the Real-facing density readback.

The existing forward route through Definition 5718.5 places the Real-density consumer after the metric, stream, regular rational, terminal Real, and countable-density ledgers. Thus the child dependency route is not a separate carrier; it records the horizontal lattice edge through which completion and compactness consumers must enter the same finite packet.

Since the carrier has no coordinate for a host enumeration, selected dense point, quotient equality, countable-choice selector, or ambient completeness theorem, every such consumer remains inside the displayed metric and Real-separability dependency route. □

Chapter 4274

A Concrete Naming Certificate for $\mathsf{FormalBallDomain}^{\uparrow}$

Following Edalat and Heckmann on formal balls and domain-theoretic completion, the $\mathsf{FormalBallDomain}^{\uparrow}$ packet records the rounded, directed, radius-ordered domain surface used by constructive completion arguments. It sits over the formal-ball carrier of chapter 1510, the basis refinement route of chapter 3943, the radius-order ledger of chapter 3968, the completion route of chapter 2012, the metric completion boundary of chapter 1506, and the terminal real-name seal of chapter 38. The packet gives L10 completion consumers a finite domain-neighbour route without quotienting Cauchy names, selecting limits, invoking host point equality, using countable choice, or assuming ambient completeness.

Definition 4274.1 (FormalBallDomain carrier)**.** *A* $\mathsf{FormalBallDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, R, Q, I, C, E, H, T, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FormalBall}^{\uparrow}$ *observation row, carrying the visible centre-radius windows used by the domain packet.*
2. *R is the* $\mathsf{FormalBallRadiusOrder}^{\uparrow}$ *row, recording the finite radius refinement and order comparisons available before any rounded-domain read is exported.*
3. *Q is the* $\mathsf{FormalBallBasis}^{\uparrow}$ *row, exposing the basis elements and basis-refinement route inspected by the domain surface.*
4. *I is the directed-ideal row, listing the finite compatible formal-ball windows retained by the rounded domain read.*
5. *C is the* $\mathsf{FormalBallCompletion}^{\uparrow}$ *row, reached only after the formal-ball, radius-order, basis, and directed-ideal rows have been displayed.*
6. *E is the completion endpoint row, read through* $\mathsf{MetricCompletion}^{\uparrow}$ *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rather than through host point equality.*
7. *H records componentwise* hsame *transport for formal balls, radius orders, bases, directed ideals, completion rows, endpoint seals, replay, provenance, and local naming.*
8. *T records displayed* Cont *replay from a rounded-domain request through $B, R, Q, I, C, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{FormalBallDomain}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{FormalBallBasis}^{\uparrow}$, $\mathsf{FormalBallRadiusOrder}^{\uparrow}$, $\mathsf{FormalBallCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FormalBallDomain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, R, Q, I, C, E, H, T, P, N$. It has no coordinate for quotient completion, selected representatives, host point equality, countable choice, trichotomy, or ambient completeness.

Lean4 (definition) `BEDC.Derived.FormalBallDomainUp.FormalBallDomainUp`

Theorem 4274.2 (FormalBallDomain NameCert obligations)**.** *For every accepted* $\mathsf{FormalBallDomain}^{\uparrow}$ *carrier $D = (B, R, Q, I, C, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FormalBallDomain}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the formal-ball row, radius-order row, basis row, directed-ideal row, formal-ball-completion row, endpoint row, transport row, replay row, provenance row, and local naming row;*
2. *radius-order exactness, requiring every refinement or rounded containment used by the domain read to be recorded in R before any ideal or completion row is consumed;*
3. *basis coverage, requiring each retained formal-ball window to be inspected through Q and then recorded in the directed row I;*
4. *completion handoff, requiring C and E to remain downstream of B, R, Q, I and to expose only the displayed* $\mathsf{FormalBallCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *route;*
5. *structural stability, requiring H and T to preserve the same component rows under* hsame *transport and displayed* Cont *replay;*
6. *provenance and local naming through P and N, with no obligation row for quotient completion, selected representatives, host point equality, countable choice, trichotomy, or ambient completeness.*

No $\mathsf{FormalBallDomain}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5723.1. The accepted packet exposes exactly the formal-ball, radius-order, basis, directed-ideal, completion, endpoint, transport, replay, provenance, and naming rows.

Radius-order exactness and basis coverage are forced by the row order. A domain read must first inspect B through the finite comparisons in R, then use Q to identify the displayed basis route before the retained directed row I is available.

The completion handoff is downstream of those rows. The formal-ball-completion row C and endpoint row E can be read only after B, R, Q, I have been displayed, so they cannot supply a quotient-completion representative or host point equality on their own.

Finally H and T transport and replay the same finite packet, while P and N source and name it. Since the carrier has no coordinate for quotient completion, selected representatives, countable choice, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 4274.3 (FormalBallDomain Cauchy completion handoff)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{FormalBallCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{FormalBallDomain}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{FormalBall}^{\uparrow} \longmapsto \mathsf{FormalBallRadiusOrder}^{\uparrow} \longmapsto \mathsf{FormalBallBasis}^{\uparrow} \longmapsto I \longmapsto \mathsf{FormalBallCompletion}^{\uparrow} \longmapsto \mathsf{MetricComplet}$$

The handoff exports rounded formal-ball domain data, directed finite coverage, and completion-facing endpoint seals, but it exports no quotient completion, selected Cauchy representative, host point equality, countable-choice selector, trichotomy, or ambient completeness principle.

Proof. Start with an accepted carrier $D = (B, R, Q, I, C, E, H, T, P, N)$. A Cauchy-facing or completion-facing request can first read only the formal-ball row B and the displayed radius-order comparisons in R.

The basis and directed stages are then forced through Q and I. The basis row identifies the finite neighbourhood data retained by the packet, and the directed row records the compatible finite family used by the rounded-domain read.

The completion rows are terminal for this route. The row C supplies the formal-ball-completion handoff, while E records the metric-completion and Real-seal endpoint data that downstream consumers may inspect.

Componentwise transport and replay through H, T preserve the same route, and P, N record provenance and local naming. Since no excluded quotient, selected representative, host equality, choice, trichotomy, or ambient-completeness coordinate exists in the carrier, the handoff exposes only the displayed domain data. □

Theorem 4274.4 (FormalBallDomain Real seal boundary)**.** *For every accepted* $\mathsf{FormalBallDomain}^{\uparrow}$ *carrier* $D = (B, R, Q, I, C, E, H, T, P, N)$*, each* $\mathsf{Real}^{\uparrow}$*-facing read exported by* D *remains downstream of the formal-ball row* B*, radius-order row* R*, basis row* Q*, directed-ideal row* I*, and formal-ball-completion row* C*. The Real seal is therefore a terminal endpoint of the displayed completion route, not a detached real point, quotient-completion class, selected representative, host point equality, countable-choice selector, or ambient completeness witness.*

Proof. Read the endpoint row E from the carrier. By Definition 5723.1, E is exposed only after the formal-ball, radius-order, basis, directed-ideal, and formal-ball-completion rows have been displayed.

Apply the NameCert obligations of Definition 5723.2. Radius-order exactness keeps every refinement inside R, basis coverage keeps retained windows inside Q, I, and completion handoff keeps C, E downstream of that finite route.

The replay row T and transport row H preserve the same component order. The provenance row P and local naming row N name no second Real route, no representative selector, and no host point-equality witness.

Thus any $\mathsf{Real}^{\uparrow}$ read exported by the packet is terminal for $B, R, Q, I, C, E, H, T, P, N$. The excluded detached real point, quotient class, selected representative, choice schedule, and ambient completeness data have no carrier coordinate from which a consumer could read them. □

Falsifiable prediction: Every accepted $\mathsf{FormalBallDomain}^{\uparrow}$ completion-facing read factors through displayed FormalBallUp windows, FormalBallRadiusOrderUp comparisons, FormalBallBasisUp coverage, a directed finite row, FormalBallCompletionUp handoff, MetricCompletionUp endpoint data, RealUp sealing, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: formalball, formalballbasis, formalballradiusorder, formalballcompletion, metriccompletion, real: $\mathsf{FormalBallDomain}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries formal-ball windows, radius-order comparisons, basis coverage, directed finite domain data, completion handoff, endpoint sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FormalBallDomain}^{\uparrow}}$.

Constructive story: A FormalBallDomain$^{\uparrow}$ packet is generated from FormalBallUp windows, FormalBallRadiusOrderUp comparisons, FormalBallBasisUp coverage, directed finite domain rows, FormalBallCompletionUp handoff, MetricCompletionUp and RealUp endpoint rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FormalBallDomain}^{\uparrow}}$, seed)

Scope closed: Definition 5723.1, Definition 5723.2, Definition 5723.3, and Definition 5723.4 seed the finite formal-ball domain route from rounded neighbourhood data to completion and Real endpoint consumers.

Formal verification: FormalStatus(NameCert$_{\text{FormalBallDomain}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, host point equality, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius-order exactness, basis coverage, directed-row stability, completion handoff, Real seal boundary, componentwise transport, replay, provenance, and local naming for BEDC.Derived.FormalBallDomainUp.

The DedekindCutStream$^{\uparrow}$ route points its finite readback through chapter 301 and its terminal seal through chapter 38.

Chapter 4275

A Concrete Naming Certificate for $\mathsf{DedekindCutStream}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DedekindCutStream}^{\uparrow}$ packet records a located cut-observation stream over the L10 stream-name substrate, not the forbidden Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$. It sits after the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the rounded located cut interface of chapter 436. The packet names the finite stream route by which lower and upper cut observations can be sampled before any Real-facing consumer treats them as regular Cauchy data.

Definition 4275.1 (Dedekind-cut stream carrier)**.** *A* $\mathsf{DedekindCutStream}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S_{\mathrm{cut}} = (D, L, U, W, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row, recording the finite dyadic rational endpoints, radii, and comparison budgets used by the cut observation.*
2. *L is the located lower-cut observation row, carrying finite evidence that the displayed endpoints lie on the lower side of the cut.*
3. *U is the located upper-cut observation row, carrying finite evidence that the displayed endpoints lie on the upper side of the cut.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing exactly the finite observation windows through which L and U are sampled.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the stream windows and dyadic endpoint budgets have been displayed.*
6. *H records componentwise* hsame *transport for dyadic endpoints, lower observations, upper observations, stream windows, regular readbacks, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located cut-observation request through D, L, U, W, R.*
8. *P is the* Pkg *provenance over* $\mathsf{DedekindCutStream}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, L, U, W, R, H, C, P, N$. It has no coordinate for quotient cuts, quotient stream equality, trichotomy, selected suprema, selected real limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4275.2 (Dedekind-cut stream NameCert obligations)**.** *For every accepted* $\mathsf{DedekindCutStream}^{\uparrow}$ *carrier* $S_{\mathrm{cut}} = (D, L, U, W, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic endpoint ledger, located lower observations, located upper observations, stream windows, regular rational readback, transport, replay, provenance, and local naming rows;*
2. *endpoint exactness, requiring every lower or upper cut observation to name its rational endpoint and comparison budget through D;*
3. *located observation separation, requiring L and U to remain displayed lower and upper observations rather than a quotient cut object;*
4. *stream-window exactness, requiring every cut observation consumed downstream to pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *row W;*
5. *regular-readback boundary, requiring R to be read only after D, L, U, W have been exposed;*
6. *componentwise transport and replay, requiring H and C to preserve the same endpoint, observation, stream, and readback route;*
7. *provenance and local naming, requiring P and N to source the packet through* $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *without adding quotient cuts, trichotomy, completeness, or host real equality.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5719.1. The accepted packet exposes only the dyadic endpoint row D, the lower and upper observation rows L, U, the stream window row W, the regular readback row R, and the structural rows H, C, P, N.

Endpoint exactness and located observation separation are read from the same projection. The rows L and U can mention a rational observation only through the dyadic endpoint and budget data in D, and they remain two displayed observation ledgers rather than a quotient cut.

The stream and readback obligations are downstream. A consumer first opens the finite windows in W, then obtains the regular rational readback R justified by those windows and the endpoint budget.

Finally, H and C transport and replay that same finite route, while P and N source and name it. Since the carrier contains no row for quotient cuts, trichotomy, completeness, host real equality, or selected real limits, the listed rows exhaust the local NameCert surface. □

Theorem 4275.3 (Dedekind-cut stream regular-Cauchy handoff)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{DedekindCutStream}^{\uparrow}$ *carrier must pass through the* $\mathsf{StreamName}^{\uparrow}$ *window row W and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before the cut-observation stream can be consumed. Equivalently, the only Real-facing route exported by the packet is*

$$\mathsf{DedekindCut}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}.$$

The handoff supplies located cut observations as finite stream-name data; it supplies no Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$*, quotient cut, trichotomy branch, completeness theorem, selected supremum, selected limit, or host real equality.*

This handoff is a source route for chapter 4372 when a downstream Real-facing consumer compares two regular-Cauchy presentations through the shared $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows, because the comparison sees displayed stream windows and dyadic tolerance ledgers rather than a quotient cut or host real equality.

Proof. Let a downstream Real-facing consumer read an accepted carrier $S_{\mathrm{cut}} = (D, L, U, W, R, H, C, P, N)$. By carrier projection, the only cut-facing data available before readback are the endpoint ledger D and the displayed lower and upper observation rows L, U.

The consumer cannot reach a regular rational datum directly from L or U. The finite stream-name row W records the observation windows that are opened, and the readback row R records the regular rational data obtained from those windows and the dyadic endpoint budget.

Thus any Real-facing use of the cut-observation stream is downstream of W and R. The remaining rows H, C, P, N preserve, replay, source, and name the same route.

Because no carrier coordinate stores quotient cuts, a Dedekind construction of reals, trichotomy, completeness, selected suprema, selected limits, or host real equality, the handoff is exactly the displayed stream-name and regular-Cauchy boundary. □

Falsifiable prediction: Every accepted $\mathsf{DedekindCutStream}^{\uparrow}$ Real-facing read factors through DyadicRatCore endpoints, located lower and upper cut observations, StreamName windows, RegSeqRat readback, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: dedekindcut, dyadicratcore, streamname, regseqrat, real: $\mathsf{DedekindCutStream}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries located lower and upper cut observations, dyadic endpoint budgets, stream windows, regular rational readback, transport, replay, provenance, and local naming in one stream-observation packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}$.

Constructive story: A $\mathsf{DedekindCutStream}^{\uparrow}$ packet is generated from DyadicRatCore endpoint rows, located lower and upper cut observations, StreamName finite windows, RegSeqRat readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5719.1, Definition 5719.2, and Definition 5719.3 seed the located cut-observation stream route over DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, DedekindCutUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$, quotient cuts, trichotomy, completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, located observation separation, stream-window exactness, regular-readback boundary, transport, replay, provenance, and local naming for BEDC.Derived.DedekindCutStreamUp.

Theorem 4275.4 (Dedekind-cut stream RegSeqRat forward route)**.** *Every* $\mathsf{DedekindCutStream}^{\uparrow}$ *Real-facing consumer that exports a comparison must first display the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{Real}^{\uparrow}$ *seal row of the accepted packet. The forward route is*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

inside the same BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}$ *surface. It exports no quotient cut, quotient stream equality, trichotomy branch, selected supremum, selected limit, ambient real completeness, or host comparison outside the displayed route.*

Proof. Start with the carrier of Definition 5719.1. A Real-facing comparison can read endpoint budgets only through the $\mathsf{DyadicRatCore}^{\uparrow}$ row D, and it can inspect cut observations only through the finite $\mathsf{StreamName}^{\uparrow}$ window row W.

Apply the regular-Cauchy handoff of Definition 5719.3. It places the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R downstream of the displayed stream windows and dyadic endpoint budgets before any Real-facing read consumes the cut-observation stream.

Finally pass through the terminal $\mathsf{Real}^{\uparrow}$ seal while preserving the transport, replay, provenance, and local naming rows H, C, P, N. Since the packet has no coordinate for quotient cuts, selected suprema, selected limits, trichotomy, ambient completeness, or host comparison, the exported comparison route is exactly the displayed forward dependency chain. □

The $\mathsf{DedekindCutStream}^{\uparrow}$ dependency lattice consumes the finite-window $\mathsf{StreamName}^{\uparrow}$ spine of chapter 126 and the $\mathsf{RegSeqRat}^{\uparrow}$ readback route of chapter 301 before any $\mathsf{Real}^{\uparrow}$-facing cut stream is inspected through chapter 38. Thus the cut-observation packet remains a horizontal L10 route through displayed stream windows and regular rational readback, not a kernel-only pointer to a selected real limit or quotient cut.

Chapter 4276

A Concrete Naming Certificate for $\mathsf{StokesTheorem}^{\uparrow}$

Following Cartan and de Rham, the $\mathsf{StokesTheorem}^{\uparrow}$ packet names the finite BEDC surface on which exterior differentiation, oriented boundary, and integration over a carried chain can be consumed as one certificate. It reads differential forms from chapter 136, the cochain boundary route from chapter 137, the charted domain surface from chapter 96, and the scalar integral handoff from chapter 1526. The packet is only a naming certificate for the displayed Stokes boundary route; it does not supply a host smooth manifold, a selected triangulation, a quotient de Rham class, a measure completion, or an ambient real-completeness theorem.

Definition 4276.1 (Stokes theorem carrier)**.** *A* $\mathsf{StokesTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, F, B, E, I, H, C, P, N)$$

whose rows have the following BEDC-facing meaning.

- M *is the carried* $\mathsf{Manifold}^{\uparrow}$ *chart-and-orientation source row for the integration domain.*
- F *is the carried* $\mathsf{DiffForm}^{\uparrow}$ *form row together with the exterior-derivative row consumed by the Stokes boundary read.*
- B *is the oriented boundary-chain row whose source and target faces are read through the same displayed manifold surface.*
- E *is the* $\mathsf{DeRham}^{\uparrow}$ *boundary route identifying the exterior derivative and boundary pairing as one chain-complex comparison.*
- I *is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *scalar-integration handoff for the displayed domain, boundary, form, and derivative rows.*
- H *records componentwise* hsame *transport for* M, F, B, E, I *and the structural rows.*
- C *records displayed* Cont *replay of the route from manifold charts through form rows, boundary-chain rows, de Rham boundary data, and integration handoff.*
- P *is the* Pkg *provenance over* $\mathsf{Manifold}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{DeRham}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
- N *is the local* $\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.StokesTheoremUp.StokesTheoremTasteGate single carrier alignment`

Theorem 4276.2 (Stokes theorem NameCert obligations)**.** *For every accepted* $\mathsf{StokesTheorem}^{\uparrow}$ *carrier* $K = (M, F, B, E, I, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}$ *surface is exhausted by carrier admission for* M, F, B, E, I*, boundary-chain compatibility between* B *and* E*, integral-handoff compatibility between* E *and* I*, componentwise* hsame *transport in* H*, displayed* Cont *replay in* C*, provenance in* P*, and local naming in* N*. The certificate exports no host smooth map, no selected chain representative, no quotient de Rham class, no measure-completion object, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 5720.1. The analytic rows are exactly the manifold row M, differential-form row F, boundary-chain row B, de Rham boundary row E, and integration handoff row I.

The boundary compatibility is local: B supplies the displayed oriented boundary route, while E supplies the de Rham chain-complex comparison over the same form data. The integration compatibility is also local: I is read only after those rows have been displayed.

Finally attach H, C, P, N. These rows transport, replay, source, and name the same finite route. Since the carrier has no coordinate for the excluded host objects, the listed rows exhaust the local NameCert obligations. □

Theorem 4276.3 (Stokes boundary-chain route)**.** *Let* $K = (M, F, B, E, I, H, C, P, N)$ *be an accepted* $\mathsf{StokesTheorem}^{\uparrow}$ *carrier. Any consumer of the Stokes boundary comparison must first read the manifold row* M*, the differential-form row* F*, and the oriented boundary-chain row* B *before it can consume the de Rham boundary row* E *or the integration handoff* I*. The comparison is therefore a finite BEDC route through* $M, F, B, E, I, H, C, P, N$*, not an appeal to a host boundary operator or an unlogged smooth-chain equality.*

Proof. Read the carrier inventory. The row B is the only boundary-chain coordinate, and it is stated over the manifold and form rows M, F.

Apply Definition 5720.2. Boundary-chain compatibility places B before the de Rham row E, and integral-handoff compatibility places I downstream from the same displayed route.

The structural rows H, C, P, N preserve and name this route without adding a second boundary source. Hence no consumer can bypass M, F, B when reading the Stokes comparison. □

Theorem 4276.4 (Stokes closed-form nonescape)**.** *Let* $K = (M, F, B, E, I, H, C, P, N)$ *be an accepted* $\mathsf{StokesTheorem}^{\uparrow}$ *carrier whose displayed* $\mathsf{DiffForm}^{\uparrow}$ *row* F *is read as closed along the de Rham route* E*. Then every zero-boundary integral read exported by the packet remains inside* $M, F, B, E, I, H, C, P, N$*. It may use the carried closed-form row, the boundary-chain route, the de Rham boundary comparison, and the Riemann-integral handoff, but it cannot introduce a quotient cohomology representative, a host Stokes theorem, a measure-completion argument, selected charts outside* M*, or ambient real completeness.*

Proof. Begin with the closed-form read inside F and E. The form row supplies the exterior data, and the de Rham row supplies the boundary comparison over the same displayed form.

The zero-boundary integral is then read through B and I. The boundary row supplies the oriented chain surface, and the integral row supplies only the scalar handoff already tied to M, F, B, E.

Transport and replay are confined to H and C, while P and N attach provenance and local naming. None of these rows contains a quotient representative, host theorem, measure-completion carrier, external chart selector, or ambient completeness coordinate, so the closed-form read cannot escape the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{StokesTheorem}^{\uparrow}$ packet records a displayed manifold-and-orientation row, carried differential-form row, oriented boundary-chain row, de Rham boundary route, Riemann-integral handoff, componentwise transport, continuation replay, provenance, and local naming. The packet names the Stokes boundary comparison only through these finite rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed scope covers the displayed $\mathsf{Manifold}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{DeRham}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local NameCert rows of Definition 5720.1.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close a public Stokes bridge, a host smooth-chain theorem, quotient cohomology, measure completion, selected triangulations, or ambient real completeness.

Upgrade path: Obligation closure requires checked carrier admission, boundary-chain compatibility, integral-handoff compatibility, transport, replay, provenance, and ledger non-escape for BEDC.Derived.StokesTheoremUp.

Chapter 4277

A Concrete Naming Certificate for $\mathsf{ConstructiveImplicitFunction}^{\uparrow}$

Following Bishop and Bridges on constructive inverse and implicit function reasoning, the ConstructiveImplicitFunctio packet records a local solution graph as finite BEDC data rather than as a host-level selection of a function. It sits between the real-name surface of chapter 38, the metric ball and interval windows of chapter 1450, chapter 1638, and chapter 1709, the continuous-map rows of chapter 130, and the derivative boundary of chapter 122. The certificate exposes the local graph, nondegenerate derivative row, located window, contraction or modulus replay, Real readback, transport, provenance, and local naming rows before any consumer may read a local solve.

Definition 4277.1 (Constructive implicit function carrier)**.** *A* $\mathsf{ConstructiveImplicitFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, J, A, M, I, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Real}^{\uparrow}$ *graph row for the equation and its local output coordinate, read only through displayed real-name endpoints.*
2. *J is the derivative or Jacobian row, including the apartness or nondegeneracy witness used by the local solve.*
3. *A is the located interval or metric-ball window row, naming the input cell, output cell, and base point through* $\mathsf{LocatedRealInterval}^{\uparrow}$*,* $\mathsf{RealMetric}^{\uparrow}$*, or* $\mathsf{MetricBall}^{\uparrow}$ *data.*
4. *M is the contraction, Lipschitz, or continuity-modulus replay row that bounds the local correction inside A.*
5. *I is the terminal* $\mathsf{Real}^{\uparrow}$ *readback and seal row for the solved graph point.*
6. *H records componentwise* hsame *transport for graph rows, derivative rows, apartness witnesses, located windows, modulus rows, Real seals, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from F, J, A, M, I to the local solve row, including the* $\mathsf{ContinuousMap}^{\uparrow}$ *and* $\mathsf{Derivative}^{\uparrow}$ *reads used by the graph.*
8. *P is the* Pkg *provenance over* $\mathsf{ConstructiveImplicitFunction}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricBall}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Derivative}^{\uparrow}$*,* $\mathsf{LocatedRealInterval}^{\uparrow}$*,* $\mathsf{RealMetric}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveImplicitFunction}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host implicit function, a selected germ, quotient function equality, global inverse theorem, ambient completeness principle, or classical choice.

Lean4 ✓ `BEDC.Derived.ConstructiveImplicitFunctionUp.ConstructiveImplicitFunctionTasteGate`
`single carrier alignment`

Theorem 4277.2 (Constructive implicit function NameCert obligations)**.** *For every accepted carrier $U = (F, J, A, M, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveImplicitFunction}^{\uparrow}}$ *surface consists of the following finite obligations:*

1. *carrier admission for the displayed graph, derivative, located-window, modulus, Real seal, transport, replay, provenance, and local name rows;*
2. *local graph exactness, requiring every solved point read to pass through the graph row F and terminal Real seal I;*
3. *apartness or nondegeneracy stability, requiring J to transport its derivative witness through H without replacing it by host equality;*
4. *contraction or modulus replay, requiring M and C to keep correction steps inside the located window A;*
5. *uniqueness nonescape, requiring any two local solve reads with the same displayed rows to return to the same $F, J, A, M, I, H, C, P, N$ packet.*

No obligation is stored in a detached function object or an ambient completeness theorem.

Proof. Carrier admission is projection from Definition 4277.1. The packet lists exactly the graph, derivative, located-window, modulus, Real seal, transport, replay, provenance, and local name rows.

The analytic obligations are local to the displayed rows. The graph exactness read uses F and I, while derivative stability uses J together with the componentwise transports in H.

The local solve is kept inside the named window by A, M, C. Since the carrier has no host implicit-function coordinate, selected germ, quotient function equality, or ambient completeness row, uniqueness is a nonescape statement about the same finite packet. □

Theorem 4277.3 (Constructive implicit function local solve route)**.** *Every* $\mathsf{ConstructiveImplicitFunction}^{\uparrow}$ *local-solve read factors through the displayed finite route*

$$\mathsf{ContinuousMap}^{\uparrow}, \mathsf{Derivative}^{\uparrow}, \mathsf{LocatedRealInterval}^{\uparrow}, \mathsf{MetricBall}^{\uparrow}, \mathsf{RealMetric}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$$

The consumer must open the graph row F, derivative or Jacobian row J, located window A, contraction or modulus row M, Real seal I, transport row H, replay row C, provenance row P, and local name row N before it can export a solved graph point.

Proof. Project the accepted carrier. The local-solve read has no available coordinate except $F, J, A, M, I, H, C, P, N$.

The graph and derivative rows are the analytic source. The located interval or metric-ball row names the window, and the contraction or modulus row records why the replay stays in that window.

Finally the Real seal and structural rows finish the route. The solve is therefore a displayed finite certificate over the named sibling chapters, not a host implicit function, selected germ, quotient of local functions, or classical existence principle. □

Falsifiable prediction: Every $\mathsf{ConstructiveImplicitFunction}^{\uparrow}$ local-solve read opens a displayed Real graph row, a derivative or Jacobian apartness row, a located interval or metric-ball row, a contraction or modulus row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before exporting a solved graph point.

Independence witness: real, metricball, continuousmap, derivative, located-real-interval, real-metric: $\mathsf{ConstructiveImplicitFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries local graph exactness, derivative nondegeneracy, located-window control, modulus replay, Real sealing, transport, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveImplicitFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveImplicitFunction}^{\uparrow}$ packet is generated from a displayed Real graph row, a derivative or Jacobian row with apartness data, a located interval or metric-ball window, a contraction or modulus replay row, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveImplicitFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4277.1, Definition 4277.2, and Definition 4277.3 seed the finite constructive implicit-function certificate over graph, derivative, located-window, modulus, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveImplicitFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host implicit functions, selected germs, quotient function equality, global inverse or implicit theorem packages, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, graph exactness, apartness stability, modulus replay, uniqueness nonescape, and local naming for BEDC.Derived.ConstructiveImplicitFunctionUp.

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ hub routes completion existence through the diagonal-window handoff of chapter 4080 and the pointwise stream metric boundary of chapter 4139 before its child files expose the completion seal.

Chapter 4278

A Concrete Naming Certificate for $\mathsf{MetricCompletionExistence}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{MetricCompletionExistence}^{\uparrow}$ packet records the finite BEDC surface by which a displayed metric source receives a completion-facing existence certificate without selecting quotient classes or host representatives. It sits between the metric carrier of chapter 4230, the Cauchy route of chapter 3413, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the real seal of chapter 38, the completion object surface of chapter 1506, and the complete-metric consumer row of chapter 128. The selected finite windows used by the completion-existence seal are compatible with the diagonal-selection route of chapter 4080 before any completion consumer treats the seal as public. The packet names existence as finite certificate data; it is not an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4278.1 (Metric completion existence carrier)**.** *A* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, S, D, W, R, Y, U, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row whose metric observations are to be completed.*
2. *S is the* $\mathsf{Cauchy}^{\uparrow}$ *schedule row naming the finite Cauchy requests admitted from M.*
3. *D is the dense-embedding row that presents source points inside the completion-facing surface without choosing representatives.*
4. *W is the selected* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the schedule is inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the inspected windows.*
6. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that bounds the readback by finite dyadic budgets.*
7. *U is the completion seal row, tying the preceding route to* $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{CompleteMetric}^{\uparrow}$ *consumers while preserving the displayed* $\mathsf{Real}^{\uparrow}$ *distance boundary.*
8. *H records componentwise* hsame *transport for the source metric, Cauchy schedule, dense embedding, windows, readback, dyadic ledger, completion seal, uniqueness ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$M, S, D \longmapsto W \longmapsto R \longmapsto Y \longmapsto U.$$

10. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionExistence}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows, their uniqueness ledger inside H, and the replay path C. It has no coordinate for quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4278.2 (Metric completion existence NameCert obligations)**.** *For every accepted* MetricCompletionExiste *carrier $E = (M, S, D, W, R, Y, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed source metric, Cauchy schedule, dense embedding, selected finite stream windows, regular rational readback, dyadic tolerance ledger, completion seal, uniqueness ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The certificate refuses quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5721.1. Its rows expose the source $\mathsf{Met}^{\uparrow}$ data, the $\mathsf{Cauchy}^{\uparrow}$ schedule, the dense embedding, selected $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, completion seal, transport, replay, provenance, and local name.

The NameCert obligations follow the displayed order. The schedule is read from M, the embedding row D is inspected before any window, W and R provide finite observations and regular rational readback, and Y bounds them by dyadic tolerances before the completion seal U is available.

Transport and replay supply the uniqueness ledger. The row H moves the same coordinates componentwise, and C repeats the same inspection route for each consumer request; neither row introduces a host equality test or a chosen quotient representative.

Finally, P and N source and name the packet. Since the carrier contains no quotient-completion coordinate, selected representative, choice schedule, host equality oracle, trichotomy row, open-cover compactness row, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 4278.3 (Metric completion existence completion-seal nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier $E = (M, S, D, W, R, Y, U, H, C, P, N)$ reaches the completion seal U only after reading M, S, D, W, R, Y through the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, hsame, Cont, Pkg, *and local* NameCert *route. The seal cannot be replaced by quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5721.1. The only route to U first exposes the source metric row M, the Cauchy schedule S, the dense embedding row D, selected finite windows W, regular rational readback R, and dyadic tolerance ledger Y.

Apply the NameCert obligations theorem, Definition 5721.2. It orders those rows before the completion seal and binds the same route through componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ row.

The refused objects are absent from the carrier. Quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no coordinate in E, so no completion-facing consumer can substitute them for the displayed seal row U. □

Theorem 4278.4 (Metric completion existence CompleteMetric consumer route)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier* $E = (M, S, D, W, R, Y, U, H, C, P, N)$ *may use the completion seal* U *only after the* $\mathsf{Met}^{\uparrow}$ *source row,* $\mathsf{Cauchy}^{\uparrow}$ *schedule, dense embedding row,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *boundary,* $\mathsf{MetricCompletion}^{\uparrow}$ *surface, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows have been displayed. The route exports no quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier $E = (M, S, D, W, R, Y, U, H, C, P, N)$. The rows M, S, D, W, R, Y display the source metric, Cauchy schedule, dense embedding, finite windows, regular rational readback, and dyadic tolerance ledger before the completion seal row can be read.

Invoke Definition 5721.2. It binds the same rows to the $\mathsf{Real}^{\uparrow}$ boundary, the $\mathsf{MetricCompletion}^{\uparrow}$ surface, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ row.

Invoke Definition 5721.3. It prevents any completion-facing consumer from replacing U by quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Finally read the consumer side through chapter 128. A $\mathsf{CompleteMetric}^{\uparrow}$ consumer receives only the displayed completion seal and the rows that precede it, so its use of U factors through $M, S, D, W, R, Y, U, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetricCompletionExistence}^{\uparrow}$ packet is generated from a MetricSpace source row, a Cauchy schedule, dense embedding data, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a completion seal, uniqueness transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$, seed)

Scope closed: Definition 5721.1, Definition 5721.2, Definition 5721.3, and Definition 5721.4 seed the finite completion-existence packet over MetricSpace, Cauchy, StreamName, RegSeqRat, DyadicRatCore, Real, MetricCompletion, CompleteMetric, hsame, Cont, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-embedding order, finite-window readback, dyadic tolerance nonescape, completion-seal routing, CompleteMetric consumer routing, uniqueness transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionExistenceUp.

Every $\mathsf{MetricCompletionExistence}^{\uparrow}$ existence seal is read after the separated uniqueness boundary of chapter 1796, the universal-mapping row of chapter 1456, and the reflective completion route of chapter 1793. The handoff is finite completion-existence data: a source metric row, completion-facing route rows, uniqueness transport, universal-mapping visibility, reflective visibility, replay, provenance, and local $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ naming. It is not quotient completion, selected representative equality, host limit choice, or an ambient completeness construction.

Theorem 4278.5 (Metric completion existence sibling handoff)**.** *For every accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *packet* $E = (M, S, D, W, R, Y, U, H, C, P, N)$*, a completion-existence consumer may use* U *only after the uniqueness route of chapter 1796, the universal-mapping route of chapter 1456, and the*

reflective-subcategory route of chapter 1793 have been displayed through the same finite packet. The consumer receives the completion seal, uniqueness transport, universal-mapping visibility, reflective visibility, replay, provenance, and local naming rows; it receives no quotient completion, choice-selected limit, or host completeness theorem.

Proof. Project the carrier of Definition 5721.1. The packet exposes $M, S, D, W, R, Y, U, H, C, P, N$ as the only completion-existence surface.

Use the local obligations of Definition 5721.2 to order every read of U through the source metric, Cauchy schedule, dense embedding, finite stream windows, rational readback, dyadic tolerance ledger, uniqueness ledger, transport, replay, provenance, and local naming rows.

The three sibling chapters supply the horizontal route: metric-completion uniqueness contributes the separated comparison boundary, Cauchy-completion adjunction contributes the universal-mapping row, and Cauchy-completion reflective subcategory contributes the reflective visibility boundary. The adjunction row forces completion-facing consumers and source finite-window consumers through the same dense embedding and uniqueness ledger before reflection is read.

Since all three are consumed as displayed rows inside the same finite handoff, no quotient completion or choice-selected limit construction can be substituted for the packet. □

Theorem 4278.6 (Metric completion existence Cauchy-filter basis route)**.** *Every accepted* MetricCompletionExisten *completion seal is read only after the Cauchy-filter basis row and the separated metric reflection boundary have been displayed with the same finite completion packet. In particular, a public completion seal must expose* $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{SeparatedMetricReflection}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before any completion consumer treats the seal as public. The route exports no quotient completion, selected representative, host limit choice, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 5721.1. Its finite route already displays the source metric, Cauchy schedule, dense embedding, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real-facing completion seal, transport, replay, provenance, and local naming rows.

Insert the Cauchy-filter basis boundary before the completion seal is consumed. The basis row refines the Cauchy schedule into finite filter requests, while the separated metric reflection row fixes the equality boundary through which the completion consumer may read the result.

The remaining rows are then forced in order: $\mathsf{MetricCompletion}^{\uparrow}$ supplies the completion target, $\mathsf{CompletionEmbedding}^{\uparrow}$ supplies the dense embedding boundary, and the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows supply the finite readback and tolerance seal. Since none of those rows contains a quotient object, selected representative, host limit selector, choice schedule, or ambient completeness principle, the public completion seal has exactly the stated dependency route. □

Theorem 4278.7 (Metric completion existence finite basis-read route)**.** *Every completion-facing read of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier first normalizes the Cauchy schedule into a finite* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *basis before exposing the public* $\mathsf{MetricCompletion}^{\uparrow}$ *seal. Only after that basis row is displayed may the consumer read the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *row attached to the same completion packet.*

The basis-read route exports no quotient completion, selected representative, host limit choice, countable-choice schedule, excluded ambient completeness row, or separated metric shortcut outside the displayed basis packet.

Proof. Project the carrier of Definition 5721.1. Its completion-facing coordinates already include the Cauchy schedule, finite readback rows, completion seal, embedding boundary, transport, replay, provenance, and local naming.

Apply Definition 5721.6. That route inserts the $\mathsf{CauchyFilterBasis}^{\uparrow}$ boundary before the completion seal is public, so the Cauchy schedule is read as finite basis data rather than as an ambient filter object.

Now expose the consumer rows in order. The $\mathsf{MetricCompletion}^{\uparrow}$ seal can be inspected only after the basis row, and the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are the finite observation, rational readback, tolerance, and terminal seal rows of that same packet.

The excluded rows have no coordinate in the carrier. There is no quotient completion row, selected representative row, host limit-choice row, countable-choice schedule row, or ambient completeness row from which the consumer could read additional data. □

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ completion-existence packet consumes the finite Cauchy-filter basis route of chapter 1501 and the completion-facing filter handoff of chapter 1569 before exporting its own seal to the complete-metric consumer surface of chapter 128. The dependency is horizontal: the basis rows choose the finite requests, the completion rows bind the public completion route, and the complete-metric rows receive only the displayed existence packet, not quotient completion, selected representatives, host limit choice, or ambient completeness.

Theorem 4278.8 (Metric completion existence separated forward route)**.** *Every* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *completion-seal row U is consumed by the separated-completion route of chapter 1612 only after the* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Cauchy}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, and* $\mathsf{CompleteMetric}^{\uparrow}$ *rows are visible. The forward link exports a displayed completion-existence seal into* $\mathsf{SeparatedCompletion}^{\uparrow}$ *as finite route evidence, not as quotient completion equality, selected representatives, host point equality, countable choice, or an ambient complete metric space.*

Proof. Project the accepted carrier of Definition 5721.1. Its completion-seal row is not isolated; it is read downstream of the metric-space source, Cauchy request, StreamName observation schedule, RegSeqRat readback, DyadicRatCore tolerance row, Real seal, MetricCompletion row, CompleteMetric row, transport, replay, provenance, and local naming rows.

Apply Definition 5721.2. The obligation surface forces the seal consumer to expose those prerequisite rows before the completion-existence claim can be replayed or named.

The separated-completion sibling then reads the displayed completion-existence seal as route evidence for chapter 1612. Since the carrier and obligation theorem have no coordinate for quotient completion equality, selected representatives, host point equality, countable choice, or an ambient complete metric space, the forward route exports none of those endpoints. □

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ seal is read only after the Cauchy-filter basis route of chapter 1501 and the separated-completion route of chapter 1612 have both been displayed for the same completion packet. Thus a completion-existence consumer first sees the finite Cauchy-basis rows, then the separated-completion boundary, and only then treats the $\mathsf{MetricCompletionExistence}^{\uparrow}$ row as a seal for a complete metric forward route.

Theorem 4278.9 (Metric completion existence uniqueness-reflective route)**.** *Every accepted* MetricCompletionExist *read factors first through the existence carrier of Definition 5721.1. Before any completion consumer receives the completion seal U, the read must display the separated comparison boundary of* $\mathsf{MetricCompletionUniqueness}^{\uparrow}$ *and the reflective visibility boundary of* $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$

over the same finite source, Cauchy schedule, dense embedding, window, readback, dyadic, transport, replay, provenance, and local naming rows. It exports no quotient completion, selected representative, host limit choice, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the existence carrier. Its rows $M, S, D, W, R, Y, U, H, C, P, N$ are the whole route by which the source metric and Cauchy schedule reach a completion seal.

Use Definition 5721.2 to keep the source metric, schedule, dense embedding, finite windows, regular rational readback, dyadic tolerance, completion seal, transport, replay, provenance, and local naming in the displayed order.

Now read the sibling surfaces named in the packet provenance. The separated comparison boundary of chapter 1796 supplies the uniqueness side, and the reflective visibility boundary of chapter 1793 supplies the reflective side.

Because both sibling reads are consumed through the same finite carrier route, the completion consumer receives a uniqueness-reflective handoff rather than a quotient object, selected representative, host limit choice, countable-choice schedule, or ambient completeness theorem. □

Theorem 4278.10 (Metric completion existence to Cauchy completion monad law forward link)**.** *Every* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *completion seal consumed by a completion-law reader must pass through the finite* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Cauchy}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, and* $\mathsf{CompleteMetric}^{\uparrow}$ *rows before the* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *law surface of chapter 3834 is read. The forward link exports only this displayed completion-existence route, together with componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ *row.*

Proof. Project the carrier of Definition 5721.1. The source metric row M, Cauchy schedule S, selected stream windows W, regular rational readback R, dyadic tolerance ledger Y, and completion seal U form the ordered finite route toward $\mathsf{MetricCompletion}^{\uparrow}$ and $\mathsf{CompleteMetric}^{\uparrow}$ consumers.

Apply Definition 5721.2. It states that the local certificate is exhausted by carrier admission, the displayed completion-existence rows, transport, replay, provenance, and local naming. Hence a completion-law reader cannot bypass those rows when reaching the law surface.

Finally read the structural rows H, C, P, N. They preserve and replay the same finite route for the consumer, so the $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ handoff is a forward sibling dependency through the completion-existence carrier rather than a quotient completion, selected representative, or ambient completeness principle. □

Theorem 4278.11 (Metric completion existence Real-consumer route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier must read the* $\mathsf{Met}^{\uparrow}$ *source row,* $\mathsf{Cauchy}^{\uparrow}$ *schedule row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *distance seal,* $\mathsf{MetricCompletion}^{\uparrow}$ *completion row, and* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer row before using the completion seal. The route is a finite L10 dependency route through the displayed completion-existence packet, not a quotient completion, selected representative, countable-choice schedule, host equality oracle, trichotomy row, open-cover compactness row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the carrier of Definition 5721.1. Its only completion seal is the row U, and the route to U first displays the metric source M, Cauchy schedule S, dense embedding D, finite windows W, regular rational readback R, and dyadic tolerance ledger Y.

Apply the NameCert obligation theorem Definition 5721.2. It keeps $\mathsf{Met}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CompleteMetric}^{\uparrow}$ as separate source and consumer rows before the completion seal is exposed.

The sibling routes then keep the same boundary for downstream consumers. The complete-metric forward route and the completion uniqueness reflective route preserve the completion seal as packet data, while the Cauchy completion monad-law forward link reads the same finite source rows before any algebraic consumer uses the seal.

Since none of these rows contains quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every Real/completion consumer remains on the displayed L10 route. □

Theorem 4278.12 (MetricCompletionExistence pointwise-stream lattice route)**.** *Any* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *read consumed by* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *or by a regular Cauchy completion consumer first exposes the finite lattice*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{PointwiseStreamMetric}^{\uparrow}$$

before it reaches the completion-existence boundary. Thus the read travels through displayed stream windows, regular rational readback, terminal real-name sealing, the metric carrier, and the pointwise stream metric row; it is not a quotient completion, a selected limit, an ambient completeness theorem, or a host equality of real streams.

Proof. Read the pointwise-stream metric consumer first. Its distance observations are stream-indexed, so the consumer must display the $\mathsf{StreamName}^{\uparrow}$ row and the $\mathsf{PointwiseStreamMetric}^{\uparrow}$ row before any completion-existence seal can be used.

For a regular Cauchy completion consumer, the same route exposes the $\mathsf{RegSeqRat}^{\uparrow}$ readback and the terminal $\mathsf{Real}^{\uparrow}$ seal on top of the ambient $\mathsf{Met}^{\uparrow}$ row. These rows are the finite completion-facing lattice visible to the consumer.

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ boundary is therefore reached only after the displayed lattice has been opened. Since none of those rows carries quotient completion, selected limits, ambient completeness, or host stream equality, the handoff cannot export those conclusions. □

Theorem 4278.13 (MetricCompletionExistence pointwise-stream factorization)**.** *Every completion-existence read consumed through* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *factors through the displayed order*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{PointwiseStreamMetric}^{\uparrow}$$

before it reaches the $\mathsf{MetricCompletionExistence}^{\uparrow}$ *boundary. The factorization exposes finite stream windows, regular rational readback, the terminal Real seal, metric-space carrier rows, and the pointwise-stream distance row in that order; it exports no quotient completion, selected limit, ambient completeness theorem, or host equality of streams.*

Proof. Project the lattice route of Definition 5721.12. It already displays the only rows available to a pointwise-stream metric consumer before the completion-existence boundary.

The first factor is the finite stream read. A consumer sees $\mathsf{StreamName}^{\uparrow}$ windows and then the $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to those windows before any Real or metric row can be used.

The second factor is the completion-facing metric read. The terminal $\mathsf{Real}^{\uparrow}$ seal is exposed before the ambient $\mathsf{Met}^{\uparrow}$ row, and the $\mathsf{PointwiseStreamMetric}^{\uparrow}$ distance row is downstream of both.

Since the route contains only these displayed rows, it has no coordinate for quotient completions, selected limits, ambient completeness, or host stream equality. The completion-existence handoff therefore consumes the pointwise-stream factorization rather than a hidden completion principle. □

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ seal consumes $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ before exposing completion-facing rows: finite tail thresholds enter through chapter 1487, then travel along the existing metric-completion sibling handoff of Definition 5721.5. Thus a completion consumer sees the tail estimate as displayed threshold and readback data attached to the same $\mathsf{Met}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CompleteMetric}^{\uparrow}$ route, not as a quotient completion or ambient completeness principle.

Theorem 4278.14 (Metric completion existence Cauchy-convergence dependency route)**.** *Every* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *completion-seal consumer that uses Cauchy-convergence data first reads the Cauchy filter basis of chapter 1501, the regular Cauchy tail row, the separated-completion boundary of chapter 1612, and the terminal real-name readback row before the completion seal is public. Thus the consumer receives finite basis, tail, separated-completion, and* $\mathsf{Real}^{\uparrow}$ *rows attached to the same displayed completion packet, not quotient completion, selected representatives, host limit choice, or ambient completeness.*

Proof. Project the accepted $\mathsf{MetricCompletionExistence}^{\uparrow}$ carrier. Its existing route displays the source metric, Cauchy schedule, dense embedding, finite stream windows, regular rational readback, dyadic tolerance ledger, completion seal, transport, replay, provenance, and local naming rows.

Insert the Cauchy-filter and separated-completion dependencies before the seal is read. The basis row fixes the finite Cauchy requests, the regular tail row supplies the readback thresholds, and the separated-completion boundary fixes the equality route that downstream consumers may inspect.

The final readback remains terminal. The $\mathsf{Real}^{\uparrow}$ row is reached only through the same displayed packet, so the completion-seal consumer cannot replace the dependency route by quotient completion, selected representatives, host limit choice, or ambient completeness. □

Theorem 4278.15 (MetricCompletionExistence to CauchyRealSpread route)**.** *Every* $\mathsf{CauchyRealSpread}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *packet receives the completion-facing seal only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *boundary, and* $\mathsf{MetricCompletion}^{\uparrow}$ *completion row of Definition 5721.1. The route supplies a finite completion-facing seal for chapter 4161; it does not add quotient completion, selected representatives, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, host equality, trichotomy, or a choice principle.*

Proof. Project the carrier of Definition 5721.1. The only completion-facing route is the displayed chain from the source metric and Cauchy schedule through selected stream windows, regular rational readback, dyadic tolerance data, and the completion seal.

Apply Definition 5721.2. It requires the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{MetricCompletion}^{\uparrow}$ rows to remain visible before the seal is consumed.

The $\mathsf{CauchyRealSpread}^{\uparrow}$ consumer reads exactly that seal as finite spread data. Since the carrier has no quotient-completion coordinate, selected representative, ambient completeness theorem, host equality oracle, trichotomy row, or choice schedule, the route cannot export any of the excluded objects. □

The $\mathsf{FiniteLimitSeal}^{\uparrow}$ route is consumed by the regular Cauchy gluing boundary of chapter 5899, so this hub records the finite seal as a sibling dependency before routing the child files.

Chapter 4279

A Concrete Naming Certificate for $\mathsf{FiniteLimitSeal}^{\uparrow}$

Following Bishop regular-Cauchy completion, the $\mathsf{FiniteLimitSeal}^{\uparrow}$ packet records the finite seal used by diagonal-limit arguments before any selected limit or quotient stream equality can be mentioned. It is anchored in the finite-window route through chapter 126, chapter 301, chapter 291, and chapter 38. The packet packages the local Real-completion limit service as displayed BEDC data; it is not a global completeness theorem for $\mathsf{Real}^{\uparrow}$.

Its downstream role is fixed by the sibling routes Definition 5722.4 and Definition 5722.5: CategoryUp finite-limit consumers must first pass through the same M, W, R, D, E seal rows, and RealUp limit-seal consumers receive only that finite modulus-window-readback-tolerance-seal route. The Cauchy-filter forward route of Definition 5722.9 is consumed through the same finite seal rows, so completion-facing filter reads do not acquire a selected limit or quotient stream equality outside the local packet.

Definition 4279.1 (Finite limit seal carrier)**.** *A* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus schedule row naming the finite tail and tolerance requests used by the diagonal-limit route.*
2. *W is the selected* $\mathsf{StreamName}^{\uparrow}$ *window row containing exactly the finite observations requested by M.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger against which the readback is checked.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after M, W, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the modulus schedule, selected windows, readback, tolerance ledger, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$M \longmapsto W \longmapsto R \longmapsto D \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{FiniteLimitSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by the displayed modulus schedule, window reads, rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local name. It has no coordinate for selected limits, quotient stream equality, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4279.2 (Finite limit seal route nonescape)**.** *Every accepted* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *carrier exports its diagonal-limit service only through the finite route*

$$M \longmapsto W \longmapsto R \longmapsto D \longmapsto E.$$

It exports no selected limit, quotient stream equality, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Inspect the carrier of Definition 5722.1. The only limit-facing row is the terminal $\mathsf{Real}^{\uparrow}$ seal E, and the definition places it after the modulus schedule, selected stream windows, regular rational readback, and dyadic tolerance ledger.

Thus any consumer of the seal must first read M, W, R, D. The transport row H and replay row C preserve this same route under componentwise renaming and repeated consumer requests.

The provenance row P and local name N source the packet without adding mathematical content. Since the tuple contains no selected-limit coordinate, quotient equality relation, choice schedule, host real equality oracle, trichotomy branch, or ambient completeness theorem, the displayed route is the whole exported surface. □

Theorem 4279.3 (Finite limit seal bounded regular Cauchy route)**.** *When the modulus schedule M and the selected* $\mathsf{StreamName}^{\uparrow}$ *windows W of an accepted* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *carrier*

$$L = (M, W, R, D, E, H, C, P, N)$$

are supplied by an accepted $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *packet, the finite-limit seal route factors through the bounded tail envelope of chapter 1697 before reaching M, W, R, D, E. The handoff first reads the bounded regular Cauchy threshold and late-window rows, then repacks the displayed windows as the local* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the seal. It exports no selected limit, quotient stream equality, countable choice, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the accepted $\mathsf{FiniteLimitSeal}^{\uparrow}$ carrier and the supplying accepted $\mathsf{BoundedRegularCauchy}^{\uparrow}$ packet. The bounded regular Cauchy chapter provides the finite tail-envelope route before any Real-facing seal is consumed.

Read that envelope into the local coordinates M, W, R, D, E. The supplied threshold schedule becomes the modulus row M, the supplied late stream windows become W, and their regular rational and dyadic tolerance readbacks become the local rows R and D before the terminal seal E is exposed.

Finally apply Definition 5722.2. The structural rows H, C, P, N preserve the displayed route from M through E, and the local classifier has no coordinate for a selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^\uparrow}$.

Constructive story: A $\mathsf{FiniteLimitSeal}^\uparrow$ packet is generated from a modulus schedule, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^\uparrow}$, seed)

Scope closed: Definition 5722.1, Definition 5722.2, and Definition 5722.3 seed the finite diagonal-limit seal over StreamName, RegSeqRat, DyadicRatCore, Real, hsame, Cont, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window selection, regular readback, dyadic tolerance nonescape, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteLimitSealUp.

Theorem 4279.4 (Finite limit seal categorical consumer route)**.** *Every categorical or completion-facing consumer of an accepted* $\mathsf{FiniteLimitSeal}^\uparrow$ *carrier reads the seal through the finite-window route*

$$M \longmapsto W \longmapsto R \longmapsto D \longmapsto E$$

of Definition 5722.2, then through downstream completion siblings such as chapter 1276 and chapter 3701 before it can use the terminal $\mathsf{Real}^\uparrow$ *seal. The consumer receives a finite categorical handoff over the displayed StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and local NameCert rows; it receives no selected limits, quotient stream equality, countable choice, host real equality, trichotomy, or ambient Real completeness.*

Proof. Start with the carrier of Definition 5722.1. Its only completion-facing route places the modulus schedule, finite stream windows, regular readback, dyadic tolerance ledger, and terminal Real seal in the ordered rows M, W, R, D, E.

Apply Definition 5722.2. This prevents a categorical consumer from bypassing the finite-window rows or reading a selected limit directly from the seal.

Use Definition 5722.3 to align bounded regular Cauchy data with the same route. The bounded threshold and late-window rows are repacked as M, W, R, D before the Real seal E is visible.

Finally pass through the downstream envelope and classifier-lock chapters. chapter 1276 records the finite envelope consumed by Real and Completion routes, while chapter 3701 keeps the diagonal limit classifier on a single displayed seal route. Since none of these rows adds a selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient completeness theorem, the categorical consumer remains on the finite-window lattice. □

Theorem 4279.5 (Finite limit seal real dependency route)**.** *Every public* $\mathsf{FiniteLimitSeal}^\uparrow$ *seal consumes its real-facing rows in the displayed dependency order*

$$\mathsf{Real}^\uparrow,\ \mathsf{RegSeqRat}^\uparrow,\ \mathsf{StreamName}^\uparrow,\ \mathsf{MetricCompletion}^\uparrow$$

only through the finite modulus, window, readback, tolerance, and completion-envelope rows of Definition 5722.1. A limit consumer must first read the $\mathsf{StreamName}^\uparrow$ *observation windows, then the* $\mathsf{RegSeqRat}^\uparrow$ *rational readback, then the* $\mathsf{Real}^\uparrow$ *seal and* $\mathsf{MetricCompletion}^\uparrow$ *envelope route before the local* $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^\uparrow}$ *row is public; it receives no selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient completeness theorem.*

Proof. Project the accepted carrier from Definition 5722.1. The only real-facing path is the finite route from the modulus schedule through stream windows, regular rational readback, dyadic tolerance, and terminal Real seal.

Apply Definition 5722.2 and Definition 5722.4. They force completion-facing consumers to remain behind the displayed M, W, R, D, E rows before any categorical or completion envelope can read the seal.

The added dependency order records the same lattice edge: $\mathsf{StreamName}^{\uparrow}$ supplies the finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the rational readback, $\mathsf{Real}^{\uparrow}$ supplies the terminal seal, and $\mathsf{MetricCompletion}^{\uparrow}$ consumes that seal only through the completion route. Since the local packet has no coordinate for a selected limit or ambient completeness theorem, the dependency route is exactly the finite readback route already named by the carrier. □

Theorem 4279.6 (FiniteLimitSeal MetricCompletionFinite forward link)**.** *Every finite-limit seal consumed by a completion-facing route must expose its* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows before entering* $\mathsf{MetricCompletionFinite}^{\uparrow}$*. The forward link into chapter 1559 is a finite readback route, not a selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient Real completeness theorem.*

Proof. Start with the real dependency route above. It already forces a public $\mathsf{FiniteLimitSeal}^{\uparrow}$ consumer to read finite stream windows, regular rational readback, terminal Real sealing, and the completion envelope before any local naming row is public.

Next project the structural rows of Definition 5722.1. The same route carries hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ data, so a completion-facing consumer cannot bypass the finite seal packet.

Finally compose this route with chapter 1559. A $\mathsf{MetricCompletionFinite}^{\uparrow}$ consumer therefore receives the finite-limit seal only after the StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and naming rows are exposed, with no selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient Real completeness. □

Theorem 4279.7 (FiniteLimitSeal Real-completion route)**.** *Every accepted* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *completion-facing consumer factors through the route*

$$M, W, R, D, E, H, C, P, N.$$

Here W *is supplied by* $\mathsf{StreamName}^{\uparrow}$*,* R *by* $\mathsf{RegSeqRat}^{\uparrow}$*,* D *by* $\mathsf{DyadicRatCore}^{\uparrow}$*,* E *by* $\mathsf{Real}^{\uparrow}$*, and downstream completion is read only through* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletionFinite}^{\uparrow}$*. No selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient Real completeness enters the route.*

Proof. Project the carrier of Definition 5722.1. The completion-facing rows available to a consumer are the displayed modulus, window, readback, dyadic tolerance, Real seal, transport, replay, provenance, and local naming rows.

Use route nonescape, Definition 5722.2. It prevents a completion consumer from bypassing M, W, R, D, E or replacing them by a selected limit, quotient stream equality, host equality, trichotomy branch, or ambient completeness theorem.

Apply the real dependency route above. It identifies W as the $\mathsf{StreamName}^{\uparrow}$ window row, R as the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, D as the dyadic tolerance row, and E as the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally use the $\mathsf{MetricCompletionFinite}^{\uparrow}$ forward link, Definition 5722.6. It records the finite completion handoff and leaves downstream completion only through $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{MetricCompletionFinite}^{\uparrow}$, so the displayed route is exhausted by $M, W, R, D, E, H, C, P, N$. □

Theorem 4279.8 (FiniteLimitSeal PointwiseStreamMetric reverse route)**.** *Any* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *consumer entering* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *must expose* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{Met}^{\uparrow}$ *row,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *before the finite seal is read. The route from chapter 4139 is therefore the reverse completion-facing edge to the finite-limit seal routes above, not a selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient Real completeness theorem.*

Proof. Project the completion-facing route of Definition 5722.7. It requires the finite seal to expose $M, W, R, D, E, H, C, P, N$ before downstream completion data can be read.

Now read the $\mathsf{PointwiseStreamMetric}^{\uparrow}$ consumer through chapter 4139. Its stream metric input already carries a displayed $\mathsf{Met}^{\uparrow}$ row and pointwise StreamName observations, so entry into $\mathsf{FiniteLimitSeal}^{\uparrow}$ must align those observations with the seal rows W, R, D, E.

Finally apply the real dependency route and the $\mathsf{MetricCompletionFinite}^{\uparrow}$ forward link. They identify W as the $\mathsf{StreamName}^{\uparrow}$ window row, R as the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, D as the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and E as the $\mathsf{Real}^{\uparrow}$ seal, while H, C, P, N keep transport, replay, provenance, and naming visible. Thus the reverse route contributes only the displayed finite rows and no selected limit, quotient stream equality, choice schedule, host equality, trichotomy branch, or ambient Real completeness. □

Real-facing $\mathsf{FiniteLimitSeal}^{\uparrow}$ consumers of finite limits must read the $\mathsf{StreamName}^{\uparrow}$ observation windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ sealing boundary of chapter 38 before exporting finite-limit rows. This dependency route keeps the finite seal on displayed windows, regular rational readback, dyadic tolerance, and Real-name sealing; it does not supply selected limits, quotient stream equality, trichotomy, countable choice, or ambient Real completeness.

Theorem 4279.9 (FiniteLimitSeal CauchyFilterLimit forward route)**.** *Let*

$$L = (M, W, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteLimitSeal}^{\uparrow}$ *carrier. Every completion-facing read of* L *that is consumed as a* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *route first projects the displayed modulus schedule* M*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and only then enters the Cauchy-filter limit surface of chapter 1558. The handoff preserves the componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^{\uparrow}}$ *row* N*. It exports no selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient completeness theorem.*

Proof. Project the carrier of Definition 5722.1. Its only completion-facing route is the finite sequence M, W, R, D, E together with H, C, P, N.

Apply Definition 5722.2. This keeps the seal read behind the displayed StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, and Real seal rather than behind a selected limit or quotient stream equality.

Now use the real dependency route of Definition 5722.5. It records the same L10 path from $\mathsf{StreamName}^{\uparrow}$ through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$, so a $\mathsf{CauchyFilterLimit}^{\uparrow}$ consumer can only receive the finite seal after those rows have been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since no excluded coordinate is present in L, the route into chapter 1558 is a substantive dependency of the finite seal and not an external citation. □

Theorem 4279.10 (FiniteLimitSeal regular Cauchy gluing route)**.** *Every* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *consumer that reads a glued regular-Cauchy limit must expose the finite-limit seal rows* $M, W, R, D, E, H, C, P, N$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the sibling* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *route before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is public. The route exports no selected representatives, quotient stream equality, countable choice, or ambient Real completeness.*

Proof. Project the finite-limit seal carrier of Definition 5722.1. Its public limit-facing route is the displayed sequence from the modulus schedule through stream windows, regular rational readback, dyadic tolerance, and terminal Real seal, together with transport, replay, provenance, and local naming rows.

Apply the real-limit dependency route and the Cauchy-filter forward route, Definition 5722.5 and Definition 5722.9. These require every completion-facing seal read to pass through the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before the local $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^{\uparrow}}$ row is public.

For a glued regular-Cauchy limit, cite the substantive sibling dependency chapter 5899. The gluing packet supplies the compatible-window route, but the finite-limit seal still exposes its own $M, W, R, D, E, H, C, P, N$ rows before the terminal seal can be consumed.

The carrier and the cited sibling route contain no coordinate for selected representatives, quotient stream equality, countable choice, or ambient Real completeness. Thus a glued regular-Cauchy limit is read only through the finite seal route and the $\mathsf{RegularCauchyGluing}^{\uparrow}$ dependency. □

Chapter 4280

A Concrete Naming Certificate for CauchyCompletionReflectiveLocalization$^{\uparrow}$

Mac Lane reflective subcategories and Bishop–Bridges constructive completion present Cauchy completion as a reflector whose completed objects form a saturated boundary of the metric-name world. The CauchyCompletionReflectiveLocalization$^{\uparrow}$ packet isolates that boundary as finite BEDC NameCert data: it reads the reflective subcategory of chapter 1793, the reflector of chapter 1585, the functorial route of chapter 423, the universal property of chapter 397, the stream-name surface of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The chapter names the L10 localization boundary used by completion adjoint and universal-reflector consumers; it does not add a quotient completion carrier, selected limit representative, host equality on completed objects, countable-choice selector, ambient completeness theorem, or full Real$^{\uparrow}$ completeness principle.

Definition 4280.1 (CauchyCompletionReflectiveLocalization carrier)**.** *A* CauchyCompletionReflectiveLocalization$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, Q, I, U, F, K, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the source metric and source name-data row, including the displayed metric classifier, finite Cauchy observations,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *reads, and* DyadicRatCore$^{\uparrow}$ *tolerance ledger available before localization is read.*

2. *Q is the Cauchy completion reflector row, read through* CauchyCompletionReflector$^{\uparrow}$ *and* CauchyCompletionFunctc *naming the completed-object surface without exposing a quotient carrier or selected host limit.*

3. *I is the reflective subcategory inclusion row, read through* CauchyCompletionReflectiveSubcategory$^{\uparrow}$*, exposing completed objects as the public inclusion boundary.*

4. *U is the universal-property factorization row, read through* CompletionUniversalProperty$^{\uparrow}$ *after S, Q, I have all been displayed.*

5. *F is the saturated complete-object localization row, saying that a second completion-facing read returns to the same included complete-object surface rather than creating a second host completion.*

6. *K is the StreamName–RegSeqRat–DyadicRatCore–Real transport row, carrying finite windows, regular rational readback, dyadic tolerance accounting, and the terminal* Real$^{\uparrow}$ *seal used by S, Q, I, U, F.*

7. *T stores componentwise* hsame *transport for source metric/name data, the reflector, the inclusion, universal factorization, saturated localization, the local name route, continuation replay, provenance, and local naming.*

8. *H stores the displayed* Cont *replay from source observations through reflector admission, reflective inclusion, universal-property factorization, localization return, and the local StreamName–RegSeqRat–DyadicRatCore–Real route.*

9. *C stores the* Pkg *provenance over* $\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}$, $\mathsf{CauchyCompletionReflectiveSubcatego}$ $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *P is the local provenance ledger tying the source, reflector, inclusion, factorization, localization, transport, replay, and naming rows to the same finite history.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It contains no coordinate for quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

`single carrier alignment`

Theorem 4280.2 (CauchyCompletionReflectiveLocalization NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}$ *carrier* $L = (S, Q, I, U, F, K, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed source metric/name data, Cauchy completion reflector, reflective subcategory inclusion, universal-property factorization, saturated complete-object localization, StreamName–RegSeqRat–DyadicRatCore–Real transport,* hsame *transport,* Cont *replay,* Pkg *provenance, local provenance, and local naming rows;*

2. *reflector visibility, requiring every completion-facing read to pass through Q after the source row S has displayed the relevant finite windows and tolerance ledger;*

3. *inclusion exactness, requiring every completed-object consumer to pass through I as the reflective subcategory boundary;*

4. *universal factorization, requiring every finite-window continuous consumer to reach its extension route only through U after S, Q, I have been projected;*

5. *localization saturation, requiring repeated completion-facing reads or already-complete reads to return through F to the same included complete-object surface;*

6. *local name-route discipline, requiring* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *data to be consumed only through K;*

7. *transport and replay nonescape, requiring T, H, C, P, N to preserve the displayed dependency surface and to export no quotient completion, selected limit, host equality, countable choice, ambient completeness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside $S, Q, I, U, F, K, T, H, C, P, N$.

Proof. Project the carrier of Definition 5724.1. The displayed rows are the only data available to the local classifier: source metric/name data, reflector, reflective inclusion, universal factorization,

saturated localization, local name transport, structural transport, replay, provenance, and local naming.

The reflector and inclusion obligations are read in order. The row Q supplies the Cauchy completion reflector and functor route from the source data, while I exposes the completed objects only as the reflective-subcategory boundary.

The universal-property and saturation obligations are downstream from those rows. The row U is the sole factorization surface for finite-window continuous consumers, and F records that already-complete or repeated completion-facing reads remain on the same included complete-object surface.

Finally K, T, H, C, P, N preserve and name the route. Since the carrier has no coordinate for quotient completion equality, selected limits, host equality, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ completeness, the NameCert surface cannot export any of those objects. □

Theorem 4280.3 (CauchyCompletionReflectiveLocalization universal exhaustion)**.** *Let $L = (S, Q, I, U, F, K, T, H$ be an accepted* $\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}$ *carrier. Every L10 completion consumer that reads a reflector, completed-object inclusion, universal factorization, or repeated-completion return factors through the finite localization route*

$$S \longmapsto Q \longmapsto I \longmapsto U \longmapsto F \longmapsto K \longmapsto T, H, C, P, N.$$

Thus the completion route is exhausted by the source metric/name data, Cauchy completion reflector, reflective subcategory inclusion, universal-property factorization, saturated complete-object localization, StreamName–RegSeqRat–DyadicRatCore–Real transport, hsame *transport,* Cont *replay,* Pkg *provenance, and local NameCert rows of the carrier.*

Proof. Start with an L10 completion consumer and project the source row S. The finite source observations, stream windows, regular rational readbacks, and dyadic tolerances are visible before the consumer reaches any completed-object surface.

Next project the reflector and inclusion rows. The consumer enters completion data through Q and reads completed objects through I, so the reflective subcategory boundary is part of the same finite route rather than an external host collection.

The row U supplies universal-property factorization, and F supplies the saturated return to the same complete-object surface. Hence extension reads and repeated completion-facing reads have no second completion coordinate.

The local transport row K and structural rows T, H, C, P, N close the route. They carry StreamName, RegSeqRat, DyadicRatCore, and Real data together with transport, replay, provenance, and local naming, so the listed carrier rows exhaust every public completion read. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}$ packet is generated from source metric/name data, a Cauchy completion reflector, reflective subcategory inclusion, universal-property factorization, saturated complete-object localization, StreamName-RegSeqRat-DyadicRatCore-Real transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, local provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$, seed)

Scope closed: Definition 5724.1, Definition 5724.2, and Definition 5724.3 seed the finite reflective-localization boundary for the L10 completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host equality on completed objects, countable choice, ambient completeness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reflector visibility, inclusion exactness, universal factorization, localization saturation, local name-route discipline, and transport-replay nonescape for BEDC.Derived.CauchyCompletionReflecti

Chapter 4281

A Concrete Naming Certificate for $\mathsf{HoeffdingFiniteSum}^{\uparrow}$

Following Hoeffding's finite bounded-sum inequality, the $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ packet records the finite concentration route by which independent bounded random variables yield an exponential tail estimate. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the law and range summaries of chapter 186, the independence ledger of chapter 187, the dyadic exponential-bound arithmetic of chapter 291, the terminal seal of chapter 38, and the finite-average probability route of chapter 4373. The packet names a bounded finite-sum concentration certificate; it is not a martingale inequality, a Chernoff optimization principle, an almost-sure convergence theorem, a host measure-theoretic limit, or an ambient $\mathsf{Real}^{\uparrow}$ completeness result.

Definition 4281.1 (Hoeffding finite-sum carrier)**.** *A* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, V, I, B, S, D, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row V is the finite family of* $\mathsf{RandomVar}^{\uparrow}$ *entries read over P. The row I is the* $\mathsf{Independence}^{\uparrow}$ *ledger certifying that the displayed family is independent in the finite index range under inspection. The row B is the bounded-range ledger: for each displayed variable it records lower and upper* $\mathsf{Real}^{\uparrow}$ *seals and the corresponding* $\mathsf{Distribution}^{\uparrow}$ *range summary. The row S records the centered finite-sum expression and the positive deviation request. The row D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *exponential-bound row naming the finite dyadic numerator, denominator, square, range-width sum, and slack comparison used by the displayed Hoeffding bound. The row E is the terminal* $\mathsf{Real}^{\uparrow}$ *tail seal naming the probability estimate for the exceptional event. The row H records componentwise* hsame *transport, C records* Cont *replay of the finite concentration route, Q records* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Independence}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert, *and N is the local* $\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these eleven rows.*

Lean4 ✓ `BEDC.Derived.HoeffdingFiniteSumUp.HoeffdingFiniteSumTasteGate single carrier alignment`

Theorem 4281.2 (Hoeffding finite-sum NameCert obligations)**.** *For every accepted* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *carrier $(P, V, I, B, S, D, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 5726.1. Carrier admission displays the probability source, finite random-variable family, independence ledger, bounded-range ledger, finite-sum row, dyadic*

exponential-bound row, $\mathsf{Real}^{\uparrow}$ *tail seal, transport, replay, provenance, and local naming row. The certificate imports no host concentration theorem, martingale filtration, Chernoff variational optimizer, countable-choice schedule, external probability-limit operation, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Read the carrier rows in order. The source row P supplies the event classifier and normalization, while V exposes only a finite family of random variables over that same probability source.

The independence row I and bounded-range row B are then finite ledgers. They state exactly which variables are independent and which displayed lower and upper seals bound each variable before any exponential estimate is available.

The finite-sum row S fixes the centered sum and requested deviation. The dyadic row D records the arithmetic denominator, squared deviation, accumulated range-width budget, and slack comparison used by the exponential estimate, and the $\mathsf{Real}^{\uparrow}$ row E seals the resulting tail bound.

Finally H, C, Q, N transport, replay, source, and name the same route. Since the carrier has no coordinate for a host concentration theorem, variational optimizer, infinite limit, or completeness principle, these displayed rows exhaust the local certificate surface. □

Theorem 4281.3 (Hoeffding finite tail-bound route)**.** *Every accepted* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *tail-bound read factors through the route*

$$\mathsf{ProbSpace}^{\uparrow},\ \mathsf{RandomVar}^{\uparrow},\ \mathsf{Independence}^{\uparrow},\ \mathsf{Distribution}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by the carrier rows $P, V, I, B, S, D, E, H, C, Q, N$*. A probability-bound consumer can inspect the exceptional-event estimate only after the finite probability source, random-variable family, independence ledger, bounded-range ledger, centered-sum row, dyadic exponential-bound row, terminal real seal, transport, replay, provenance, and local naming row have been displayed.*

Proof. Start with an accepted carrier and project the source rows. The probability source P and finite random-variable family V provide the only measurable data available to the tail-bound request.

Next read I and B. The independence ledger is the only route by which the product-event step enters the packet, and the bounded-range ledger is the only route by which distributional lower and upper seals enter the range-width budget.

The centered-sum row S then determines the finite event being bounded. The dyadic row D supplies the exponential-bound arithmetic for that event, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream from the same displayed dyadic comparison.

The structural rows H, C, Q, N preserve that route under classifier replacement and local naming. Therefore every tail-bound read is the finite Hoeffding handoff itself, not a hidden appeal to an external concentration theorem or ambient real-completeness principle. □

Theorem 4281.4 (Hoeffding finite-sum nonescape)**.** *For every accepted* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *packet, every concentration-facing read remains inside the displayed rows* $P, V, I, B, S, D, E, H, C, Q, N$*. In particular, the packet exports no martingale filtration, Chernoff optimizer, almost-sure convergence claim, host probability-limit operator, countable-choice selection, quotient equality of real names, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. The carrier of Definition 5726.1 has no coordinate beyond the eleven displayed rows. Thus a concentration-facing request can only project the probability source, finite variables, independence

ledger, range ledger, sum row, dyadic estimate, real tail seal, transport, replay, provenance, and local name.

The analytic content of the request is concentrated in I, B, S, D, E. Independence, bounded ranges, the finite centered sum, dyadic exponential arithmetic, and the terminal tail seal appear as explicit rows, so no further theorem object can be read from the packet.

The remaining rows H, C, Q, N are structural. They preserve displayed histories, replay the finite route, record package provenance, and attach the local certificate. Hence the accepted packet cannot export any of the excluded limit, optimizer, quotient, choice, or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}$.

Constructive story: A $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ packet is generated from a probability source row, finite random-variable family, independence ledger, bounded-range ledger, centered finite-sum row, dyadic exponential-bound row, RealUp tail seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5726.1, Definition 5726.2, Definition 5726.3, and Definition 5726.4 seed the bounded finite-sum concentration route through ProbSpace, RandomVar, Independence, Distribution, DyadicRatCore, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close martingale inequalities, Chernoff optimization, almost-sure convergence, host probability limits, countable-choice selection, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite independence routing, bounded-range stability, dyadic exponential-bound handoff, tail-seal nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.HoeffdingFiniteSumUp.

Chapter 4282

A Concrete Naming Certificate for RegularCauchyLatticeOperations$^{\uparrow}$

Following Bishop and Bridges, the RegularCauchyLatticeOperations$^{\uparrow}$ packet records the finite constructive lattice-operation surface for regular Cauchy real names. It reads the regular rational route of chapter 301, the terminal real-name seal of chapter 38, the dyadic arithmetic surface of chapter 291, the lower-member packet of chapter 1832, and the upper-member packet of chapter 1833. The certificate gives downstream Real$^{\uparrow}$ consumers one finite min/max interface without importing trichotomy, quotient real equality, selected limits, countable choice, host order completeness, or ambient Real$^{\uparrow}$ completeness.

Definition 4282.1 (Regular Cauchy lattice operations carrier)**.** *A* RegularCauchyLatticeOperations$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, Y, T, D, M, A, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two accepted* Real$^{\uparrow}$ *rows presented by regular Cauchy names, exposing only their finite* RegSeqRat$^{\uparrow}$ *readbacks and terminal real seals.*
2. *T is the shared tolerance row used to align the lower-member and upper-member requests.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *ledger for the displayed comparison scale, branch budgets, and readback arithmetic consumed by both operation rows.*
4. *M is the* RegularCauchyMinimum$^{\uparrow}$ *lower-member row.*
5. *A is the* RegularCauchyMaximum$^{\uparrow}$ *upper-member row.*
6. *R is the paired regular rational readback row for the two operation outputs.*
7. *E is the paired* Real$^{\uparrow}$ *seal row, reached only after M, A, R have been displayed.*
8. *H records componentwise* hsame *transport for the two input names, tolerance, dyadic arithmetic, minimum row, maximum row, readback, seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from a lattice-operation request through $X, Y, T, D, M, A, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* RegularCauchyLatticeOperations$^{\uparrow}$*,* RegularCauchyMinimum$^{\uparrow}$*,* RegularCauchyMaximu RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, T, D, M, A, R, E, H, C, P, N$. The carrier has no coordinate for trichotomy, quotient real equality, host order completeness, selected limits, countable choice, a host lattice structure, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularCauchyLatticeOperationsUp.RegularCauchyLatticeOperationsTasteGate`
`single carrier alignment`

Theorem 4282.2 (Regular Cauchy lattice operations NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ *carrier*

$$L = (X, Y, T, D, M, A, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two regular Cauchy real rows, shared tolerance row, dyadic arithmetic ledger, minimum row, maximum row, paired readback, paired seal, transport, replay, provenance, and local name;*
2. *shared-scale exposure, requiring T and D to be displayed before either M or A may be consumed;*
3. *lower-member routing, requiring the minimum output to be read through the* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *row M;*
4. *upper-member routing, requiring the maximum output to be read through the* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *row A;*
5. *readback and seal ordering, requiring R to expose the paired regular rational outputs before E exposes the paired* $\mathsf{Real}^{\uparrow}$ *seals;*
6. *classifier stability, requiring componentwise* hsame *transport of $X, Y, T, D, M, A, R, E, C, P, N$ to preserve the accepted operation route;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no trichotomy, quotient real equality, host order completeness, selected limit, countable choice, host lattice structure, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5727.1. Its displayed rows are exactly the two regular Cauchy real inputs, the shared tolerance row, the dyadic ledger, the two operation rows, the paired readback and seal rows, and the structural rows.

Shared-scale exposure follows because M and A have no independent tolerance coordinate inside this packet. Both operation rows read the same T, D surface before any output row can be consumed.

The lower-member and upper-member obligations are inherited as named rows, not as host operations. The packet can read the lower member only through M and the upper member only through A.

Readback and seal ordering is forced by R, E. The real-facing consumer first receives the paired regular rational readback and only then the paired $\mathsf{Real}^{\uparrow}$ seal. Transport, replay, provenance, and local naming are exhausted by H, C, P, N, so no excluded host or quotient object is available. □

Theorem 4282.3 (Regular Cauchy lattice operations min-max readback)**.** *Let* $L = (X, Y, T, D, M, A, R, E, H, C, P$ *be an accepted* $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the lattice-operation output factors through the finite route*

$$X, Y, T, D \longmapsto M, A \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the packet exports the lower and upper regular Cauchy operation outputs only as paired $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *and* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *readbacks over the same dyadic scale. It exports no trichotomy, quotient real equality, host order completeness, selected limit, countable choice, or host lattice operation.*

Proof. Start with a real-facing read of the carrier. The only input rows are X, Y, and the only scale rows are T, D, so the consumer must read those coordinates before either operation row is available.

The operation rows are M and A. By Definition 5727.1, M names the lower-member route and A names the upper-member route; neither row carries a separate host order principle.

After the operation rows are displayed, the readback row R exposes the paired regular rational outputs and the seal row E exposes the paired $\mathsf{Real}^{\uparrow}$ boundary. The structural rows H, C, P, N preserve and name this route without adding any coordinate beyond it. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5727.1, Definition 5727.2, and Definition 5727.3 seed a finite min/max operation route for two regular Cauchy real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, host order completeness, selected limits, countable choice, host lattice operations, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-scale exposure, lower-member routing, upper-member routing, readback ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLatticeOperationsUp.

Constructive story: A $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ packet is generated from two regular Cauchy Real rows, a shared dyadic tolerance surface, RegularCauchyMinimum and RegularCauchyMaximum rows, paired regular rational readback, a paired RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4283

A Concrete Naming Certificate for $\mathsf{CauchyCompletionRoute}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyCompletionRoute}^{\uparrow}$ packet records the regular-Cauchy completion path as finite NameCert data rather than as a scattered analytic slogan. It reads the dyadic tolerance core of chapter 291, the finite observation interface of chapter 126, the regular rational sequence surface of chapter 301, the terminal real-name seal of chapter 38, and the Bishop regular-Cauchy completion packet of chapter 1639. The route names exactly the L10 path by which finite dyadic observations become a completion-facing real-name handoff; it does not assert ambient completeness of $\mathsf{Real}^{\uparrow}$, identify quotient streams, select limits, or import countable choice.

Definition 4283.1 (Cauchy completion route carrier)**.** *A* $\mathsf{CauchyCompletionRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, S, Q, E, B, T, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording endpoints, dyadic comparisons, precision requests, and the finite gap ledger used by the route.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, exposing only finite windows of the source stream before any regular-Cauchy read is admitted.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, recording the rational sequence data and tail modulus visible through D and S.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint row, read only as the terminal seal produced from the displayed regular-Cauchy data.*
5. *B is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *route row, tying D, S, Q, E to the established regular-Cauchy completion packet.*
6. *T records componentwise* hsame *transport for dyadic tolerances, stream windows, regular rational readback, terminal real seal, Bishop completion route, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a completion request through D, S, Q, B and then to E.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionRoute}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionRoute}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these displayed rows. It has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionRouteUp.CauchyCompletionRouteTasteGate single carrier alignment`

Theorem 4283.2 (Cauchy completion route NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionRoute}^{\uparrow}$ *carrier* $R = (D, S, Q, E, B, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionRoute}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed dyadic tolerance, stream-window, regular rational, real seal, Bishop completion, transport, replay, provenance, and local naming rows;*
2. *dyadic observation discipline, requiring every completion-facing read to expose* D *and* S *before any regular rational or real seal row is consumed;*
3. *regularity routing, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* Q *to be the only passage from finite windows to a completion-facing regular sequence;*
4. *Bishop route compatibility, requiring* B *to identify the same dyadic, stream, regular rational, and real rows as the Bishop regular-Cauchy completion packet;*
5. *terminal seal discipline, requiring the* $\mathsf{Real}^{\uparrow}$ *row* E *to be read only after* D, S, Q, B *have been displayed;*
6. *transport and replay non-escape, requiring* T, C, P, N *to preserve the listed rows and to export no quotient stream equality, selected limit, host real equality, countable choice, or ambient completeness theorem.*

No NameCert obligation is stored outside $D, S, Q, E, B, T, C, P, N$*.*

Proof. Project the carrier of Definition 4283.1. The finite packet exposes only the dyadic tolerance row, stream-window row, regular rational row, terminal real seal, Bishop completion route, transport, replay, provenance, and local naming.

The dyadic and stream rows are upstream. Any completion-facing consumer first reads the displayed tolerance and finite observation data, so the regular rational row is not a detached sequence or a host limit object.

The Bishop route row then checks compatibility with the established regular-Cauchy completion packet. It ties the same dyadic, stream, regular rational, and real rows to the route and prevents a second completion carrier from being inserted.

Finally T, C, P, N transport, replay, source, and name the displayed route. Since the carrier lacks quotient, selected-limit, host-equality, choice, and ambient-completeness coordinates, the listed rows exhaust the local NameCert surface. □

Theorem 4283.3 (Cauchy completion route real boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyCompletionRoute}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{BishopRegularCauchyCompletion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exposes only dyadic tolerance rows, finite stream windows, regular rational readback, the Bishop regular-Cauchy completion route, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows. It does not export quotient stream equality, selected limits, host real equality, countable choice, or an ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$*.*

Proof. Begin with Definition 4283.2. It places every completion-facing read behind the displayed dyadic tolerance row D and stream-window row S.

The regularity route is then unique inside the carrier. The row Q is the only regular rational passage, and B confirms that the same D, S, Q, E rows are the rows consumed by the Bishop regular-Cauchy completion packet.

The terminal handoff is the row E. Transport by T, replay by C, provenance by P, and local naming by N preserve the route without adding new analytic data, so the $\mathsf{Real}^{\uparrow}$ consumer receives exactly the displayed finite boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionRoute}^{\uparrow}$ packet is generated from DyadicRatCore tolerances, StreamName finite observations, RegSeqRat regularity, a Bishop regular-Cauchy completion row, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionRoute}^{\uparrow}}$, seed)

Scope closed: Definition 4283.1, Definition 4283.2, and Definition 4283.3 seed the finite L10 completion route from dyadic observations to the Real boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionRoute}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, host real equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic observation discipline, regularity routing, Bishop route compatibility, terminal seal discipline, and transport-replay nonescape for BEDC.Derived.CauchyCompletionRouteUp.

Chapter 4284

A Concrete Naming Certificate for $\mathsf{MetaCICProofSearchFrontier}^{\uparrow}$

The $\mathsf{MetaCICProofSearchFrontier}^{\uparrow}$ packet realizes the proof-search boundary in section 9386.4 as finite NameCert data. It sits beside the critical-path packet of chapter 765, the subject-reduction discharge socket of chapter 719, the normalization frontier of chapter 892, and the bounded normal-conversion bridge of chapter 3439. The packet names the exact frontier at which candidate evidence, bounded normal endpoints, discharge sockets, obstruction rows, transport, replay, provenance, and local naming may be consumed by a proof-search reader without claiming unrestricted closed consistency.

Falsifiable prediction: Any accepted proof-search consumer reaching a closed-consistency read without first exposing the discharge socket row refutes the $\mathsf{MetaCICProofSearchFrontier}^{\uparrow}$ carrier.

Independence witness: metaciccriticalpath, subjectreductiondischargesocket, metacicnormalizationfrontier, boundednormalconversionbridge: the critical path records dependency pressure without local proof-search candidates; the discharge socket records subject-reduction inputs without bounded normal endpoints; the normalization frontier records candidate evidence without proof-search replay; and the bounded normal-conversion bridge records endpoint comparison without the discharge socket. None is bijective to $\mathsf{MetaCICProofSearchFrontier}^{\uparrow}$.

Definition 4284.1 (MetaCIC proof-search frontier carrier)**.** *A* $\mathsf{MetaCICProofSearchFrontier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, D, N, B, A, E, O, T, C, P, L)$$

with the following displayed rows:

1. *K is the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *row, retaining the closed-consistency dependency pressure over subject reduction, normalization, decidability, confluence, and examples.*
2. *D is the* $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ *row, recording the socket through which proof-search evidence must pass before a closed-consistency consumer may read the subject-reduction boundary.*
3. *N is the* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *row, exposing candidate evidence, closed-candidate evidence, finished-normal endpoints, and retained normalization obstruction data.*
4. *B is the* $\mathsf{BoundedNormalConversionBridge}^{\uparrow}$ *row, recording the bounded normal endpoint bridge used by conversion-facing proof-search checks.*

5. *A is the candidate-evidence row, storing the finite proof-search candidates, their local support rows, and the bounded normal endpoint they claim to reach.*
6. *E is the discharge-socket evidence row, pairing each accepted candidate with the socket read needed before closed-consistency handoff.*
7. *O is the obstruction row, retaining the excluded endpoints: unrestricted subject reduction, unrestricted closed normalization, global conversion decidability, kernel consistency, and proof-search completeness.*
8. *T records componentwise* hsame *transport for K, D, N, B, A, E, O and the local naming row.*
9. *C records displayed* Cont *replay from proof-search candidate admission through the critical path, discharge socket, normalization frontier, bounded bridge, evidence, obstruction, provenance, and local naming rows.*
10. *P is the* Pkg *provenance over* $\mathsf{MetaCICProofSearchFrontier}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, SubjectReductionDischargeSoc $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{BoundedNormalConversionBridge}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICProofSearchFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, D, N, B, A, E, O, T, C, P, L$. It has no coordinate for unrestricted subject reduction, unrestricted closed normalization, global conversion decidability, kernel consistency, proof-search completeness, or an unmediated closed-consistency read.

Lean4 ✓ `BEDC.Derived.MetaCICProofSearchFrontierUp.MetaCICProofSearchFrontierTasteGate single carrier alignment`

Theorem 4284.2 (MetaCIC proof-search frontier NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICProofSearchFrontier}^{\uparrow}$ *carrier $F = (K, D, N, B, A, E, O, T, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICProofSearchFrontie}}$ *surface consists exactly of the following finite obligation rows:*

1. *critical-path exposure through K;*
2. *subject-reduction discharge-socket exposure through D;*
3. *normalization-frontier exposure through N;*
4. *bounded normal-conversion bridge exposure through B;*
5. *candidate-evidence admission through A;*
6. *discharge-socket evidence pairing through E;*
7. *obstruction retention through O;*
8. *componentwise transport through T;*
9. *displayed replay through C;*
10. *provenance through P and local naming through L.*

No accepted proof-search read may skip the discharge socket row, and no local obligation is stored outside $K, D, N, B, A, E, O, T, C, P, L$.

Proof. Project the carrier of Definition 4284.1. Rows K, D, N, B are the already named frontier surfaces, while A and E store the local candidate and discharge-socket evidence.

The closed-consistency-facing read must pass through D and E. Candidate evidence in A may reach a bounded normal endpoint through N and B, but it is not eligible for the consistency handoff until the discharge socket row has been exposed.

The obstruction row O remains part of the packet throughout the read. It prevents the bounded proof-search frontier from being cited as unrestricted subject reduction, unrestricted normalization, global conversion decidability, kernel consistency, or proof-search completeness.

Finally T, C, P, L transport, replay, source, and name the same finite route. Since the carrier has no coordinate for the excluded endpoints or for an unmediated closed-consistency read, the listed rows exhaust the NameCert surface. □

Theorem 4284.3 (MetaCIC proof-search frontier discharge boundary)**.** *Every closed-consistency-facing consumer of an accepted* $\mathsf{MetaCICProofSearchFrontier}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{MetaCICCriticalPath}^{\uparrow} \longmapsto \mathsf{SubjectReductionDischargeSocket}^{\uparrow} \longmapsto \mathsf{MetaCICNormalizationFrontier}^{\uparrow} \longmapsto \mathsf{BoundedNorm}$$

and then through the local candidate-evidence, discharge-socket evidence, obstruction, transport, replay, provenance, and NameCert rows. The route exports a bounded proof-search frontier only; it does not prove unrestricted subject reduction, unrestricted closed normalization, global conversion decidability, kernel consistency, or proof-search completeness. Future Lean work in TasteGate.lean *must provide* Nontrivial *and* FieldFaithful *instances before the carrier can be used as a checked proof-search taste gate.*

Proof. Start from Definition 4284.2. It forces the proof-search consumer to expose the critical path and the subject-reduction discharge socket before candidate evidence is treated as consistency-facing data.

The normalization and bounded conversion rows then bound the endpoint. The rows N and B justify only the displayed finished-normal and bounded-normal comparison reads, so the proof-search route remains a finite candidate route rather than a global theorem.

The local rows A, E, O, T, C, P, L preserve the discharge boundary. Candidate evidence is paired with the socket read, the obstruction row remains visible, and transport plus replay keep the consumer on the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICProofSearchFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICProofSearchFrontier}^{\uparrow}$ packet is generated from MetaCICCriticalPath, SubjectReductionDischargeSocket, MetaCICNormalizationFrontier, BoundedNormalConversionBridge, candidate evidence, discharge-socket evidence, obstruction, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICProofSearchFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4284.1, Definition 4284.2, and Definition 4284.3 seed the finite proof-search frontier for MetaCIC closed-consistency consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICProofSearchFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unrestricted subject reduction, unrestricted closed normalization, global conversion decidability, kernel consistency, proof-search completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked candidate admission, bounded-normal endpoint routing, discharge-socket exposure, obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICProofSearchFrontierUp.

Chapter 4285

A Concrete Naming Certificate for $\mathsf{DyadicIntervalHull}^{\uparrow}$

Following Moore interval analysis and Bishop–Bridges constructive interval arithmetic, the $\mathsf{DyadicIntervalHull}^{\uparrow}$ packet records the finite lower-upper dyadic enclosure route used before Real and Completion consumers inspect an interval hull. It sits next to the endpoint carrier of chapter 306, the interval-operation packet of chapter 1645, the located hull surface of chapter 2327, and the located endpoint route of chapter 394. The packet names a constructive enclosure certificate for displayed dyadic endpoints; it is not a host interval primitive, not a selected real endpoint pair, and not an appeal to ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4285.1 (Dyadic interval hull carrier)**.** *A* $\mathsf{DyadicIntervalHull}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (L, U, O, A, B, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *L is the lower dyadic endpoint row accepted by* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *U is the upper dyadic endpoint row accepted by* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *O is the endpoint-order witness, recording the displayed comparison $L \leq U$ through the same dyadic scale ledger.*
4. *A is the hull enclosure ledger, listing every inspected source endpoint or cell and its containment proof inside the displayed dyadic interval.*
5. *B is the* $\mathsf{DyadicInterval}^{\uparrow}$ *handoff row, packaging L, U, O, A as the dyadic interval consumed by interval-arithmetic neighbours.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which located endpoint observers may read finite endpoint approximations.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same endpoint windows.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the dyadic interval row, located-real hull row, stream windows, and regular rational readbacks have been displayed.*
9. *T records componentwise* hsame *transport for endpoints, order witnesses, enclosure ledgers, located-real handoff rows, stream windows, readbacks, real seals, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from endpoint requests through L, U, O, A, B, S, R and then to E.*

11. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalHull}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedRealIntervalHull}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalHull}^{\uparrow}}$ *row.*

The classifier compares accepted hulls only through these rows. It has no coordinate for host intervals, selected real endpoints, quotient stream equality, trichotomy, countable choice, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.DyadicIntervalHullUp.DyadicIntervalHullTasteGate single carrier alignment`

Theorem 4285.2 (Dyadic interval hull NameCert obligations)**.** *For every accepted* $\mathsf{DyadicIntervalHull}^{\uparrow}$ *carrier $H = (L, U, O, A, B, S, R, E, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalHull}^{\uparrow}}$ *surface consists exactly of carrier admission, endpoint ordering, hull containment, located-real route, non-escape, transport, replay, provenance, and local naming obligations. Carrier admission displays the lower endpoint, upper endpoint, order witness, enclosure ledger,* $\mathsf{DyadicInterval}^{\uparrow}$ *handoff,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local NameCert row. No obligation is stored outside those displayed rows.*

Proof. Project the accepted carrier. The lower and upper endpoint rows L, U are both dyadic rational core rows, and O is the only order witness available to the packet.

The enclosure ledger A is then read before any interval consumer sees the hull. It records finite containment of the displayed source endpoints or cells in the same lower-upper dyadic boundary.

The located-real route is the ordered handoff through B, S, R, E. The dyadic interval row packages the endpoint ledger, the stream row exposes finite endpoint windows, the regular rational row records readback, and the real row seals the terminal boundary.

Finally T, C, P, N preserve and name the route. Since the carrier has no coordinate for a host interval, selected endpoint pair, quotient stream, trichotomy, choice principle, or ambient completeness theorem, the listed obligations exhaust the local certificate. □

Theorem 4285.3 (Dyadic interval hull located-real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*- or Completion-facing consumer of an accepted* $\mathsf{DyadicIntervalHull}^{\uparrow}$ *packet factors through the route*

$$\mathsf{DyadicInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{LocatedRealIntervalHull}^{\uparrow} \longmapsto \mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSe}$$

as displayed by the rows $L, U, O, A, B, S, R, E, T, C, P, N$. The consumer may inspect a hull only after the dyadic endpoints, order witness, containment ledger, located interval handoff, stream windows, regular rational readback, terminal real seal, transport, replay, provenance, and local naming rows have all been displayed.

Proof. Start from Definition 4285.2. It places every accepted read behind L, U, O, A, so the consumer first sees a finite dyadic lower-upper enclosure.

The row B is the dyadic interval handoff. It is the only route from endpoint rows to interval consumers, and it keeps the hull attached to the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ comparisons.

The located-real portion then runs through the finite windows S and readbacks R before the seal E is exposed. This is exactly the located interval route consumed by the surrounding located-real hull and located-interval chapters.

Transport, replay, provenance, and local naming preserve the row order. Therefore no Real or Completion consumer can bypass the dyadic interval, dyadic core, located hull, located interval, stream, regular rational, and real-seal rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalHull}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalHull}^{\uparrow}$ packet is generated from lower and upper DyadicRatCore endpoint rows, an endpoint-order witness, a hull enclosure ledger, DyadicInterval and located-real handoff rows, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalHull}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4285.1, Definition 4285.2, and Definition 4285.3 seed the finite dyadic hull route from endpoint rows to Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicIntervalHull}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host interval primitives, selected real endpoint pairs, quotient stream equality, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint ordering, hull containment, located-real routing, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicIntervalHullUp.

Chapter 4286

A Concrete Naming Certificate for $\mathsf{CellularCarrierSwitchCost}^{\uparrow}$

The $\mathsf{CellularCarrierSwitchCost}^{\uparrow}$ packet realizes the carrier-switch audit surface of chapter 9391 as finite BEDC data. It sits beside the carrier encoding of chapter 943, the BHist cell-row embedding of chapter 948, the substrate classifier of chapter 945, the cellular window trace of chapter 3481, and the carrier comparison of chapter 3998. The packet names the finite cost of retargeting theorem families, kernel verbs, proof scripts, and audit gates to a cellular carrier; it is not a replacement kernel carrier.

Definition 4286.1 (Cellular carrier switch-cost carrier)**.** *A* $\mathsf{CellularCarrierSwitchCost}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, O, V, R, A, K, H, C, P, N)$$

with the following displayed rows:

1. *B is the BHist theorem-family row, listing the finite family of BHist-facing statements under inspection.*
2. *O is the cellular orbit row, exposing the finite cellular rows and orbit windows to which the statements would be retargeted.*
3. *V is the verb-realignment row, recording how Mark, Hist, Ext, and Cont reads are translated to cellular classifier, orbit, extension, and continuation reads.*
4. *R is the proof-retarget budget row, recording the displayed proof obligations that must be rebuilt after the carrier change.*
5. *A is the audit-regeneration ledger, listing the checks that must be regenerated for the cellular statements and their NameCert markers.*
6. *K is the non-escape row, recording that the packet measures the switch cost without replacing the public BEDC* BHist *carrier.*
7. *H records componentwise* hsame *transport for theorem-family, orbit, verb, proof-budget, audit, non-escape, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through B, O, V, R, A, K before any switch-cost read reaches the local certificate.*

9. *P is the* Pkg *provenance over* CellularCarrierSwitchCost$^{\uparrow}$, CellularCarrierEncoding$^{\uparrow}$, BHistCellRowEmbedding$^{\uparrow}$, CellularSubstrateClassifier$^{\uparrow}$, CellularWindowTrace$^{\uparrow}$, CellularVerbRealignment$^{\uparrow}$, CellularCarrierBHistEquivalence$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{CellularCarrierSwitchCost}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, O, V, R, A, K, H, C, P, N$. It has no coordinate for a kernel-carrier replacement, infinite cellular semantics, host evaluator equivalence, hidden proof synthesis, or an audit gate outside the displayed ledger.

Lean4 ✓ `BEDC.Derived.CellularCarrierSwitchCostUp.CellularCarrierSwitchCostTasteGate single carrier alignment`

Theorem 4286.2 (Cellular carrier switch-cost NameCert obligations)**.** *For every accepted* CellularCarrierSwitchCost *carrier $S = (B, O, V, R, A, K, H, C, P, N)$, the local* NameCert$_{\text{CellularCarrierSwitchCost}^{\uparrow}}$ *surface consists exactly of carrier admission, BHist theorem-family exposure, cellular orbit exposure, verb realignment, proof-retarget budgeting, audit-regeneration accounting, non-escape, transport, replay, provenance, and local naming obligations. A valid switch-cost read must display both the proof-retarget budget row R and the audit-regeneration ledger A before it reaches the local certificate.*

Proof. Carrier admission is projection from Definition 4286.1. The rows B and O expose the two carriers being compared as finite theorem-family and orbit-window data.

The verb row V records the syntactic realignment of Mark, Hist, Ext, and Cont. It does not itself measure the engineering cost, because statement retargeting and proof rebuilding are separate rows.

The proof-retarget budget R and audit-regeneration ledger A are therefore mandatory. A packet omitting either row cannot certify the displayed switch cost, since it would hide either the proof obligations or the audit gates that must be regenerated.

Finally K, H, C, P, N preserve the non-replacement boundary, replay the finite route, record provenance, and name the packet. No hidden carrier replacement, infinite orbit semantics, host evaluator equivalence, or external audit gate is available outside those rows. □

Theorem 4286.3 (Cellular carrier switch-cost finite audit route)**.** *Every accepted* CellularCarrierSwitchCost$^{\uparrow}$ *read factors through the finite route*

$$B, O, V, R, A, K, H, C, P, N.$$

The route measures a BHist theorem-family transposition by first displaying the theorem family, then the cellular orbit window, then the verb-realignment row, then the proof-retarget budget, and then the audit-regeneration ledger. It cannot export carrier replacement, host bisimulation, unbounded cellular traces, hidden proof repair, or completed audit success outside the displayed packet.

Proof. Read B first to identify the theorem-family surface whose statements are being retargeted. Read O next to expose the finite cellular orbit window available to the target carrier.

The row V aligns the verbs but does not discharge the work. It only states which BHist reads correspond to which cellular classifier and orbit reads.

The rows R and A then carry the cost. Proof retargeting is visible in R, while audit regeneration is visible in A, so the packet measures both proof work and gate work before local naming.

The non-escape and structural rows K, H, C, P, N keep this as a finite audit NameCert packet. Because no other coordinate exists, the route cannot export a carrier replacement, host bisimulation, unbounded trace, hidden proof repair, or completed audit success. □

Falsifiable prediction: A valid $\mathsf{CellularCarrierSwitchCost}^{\uparrow}$ packet is refuted if it omits the proof-retarget budget row or the audit-regeneration ledger.

Independence witness: cellularcarrierencoding, bhist-cell-row-embedding, cellularsubstrateclassifier, cellular-window-trace: $\mathsf{CellularCarrierSwitchCost}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries BHist theorem-family, cellular orbit, verb-realignment, proof-retarget, audit-regeneration, non-escape, transport, replay, provenance, and local naming rows.

Lean TasteGate coverage for this packet must provide Nontrivial and FieldFaithful instances in BEDC.Derived.CellularCarrierSwitchCostUp.TasteGate.

Closure status for $\mathsf{NameCert}_{\mathsf{CellularCarrierSwitchCost}^{\uparrow}}$.

Constructive story: A $\mathsf{CellularCarrierSwitchCost}^{\uparrow}$ packet is generated from BHist theorem-family rows, cellular orbit rows, verb-realignment rows, proof-retarget budget rows, audit-regeneration ledgers, non-escape rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CellularCarrierSwitchCost}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4286.1, Definition 4286.2, and Definition 4286.3 seed the finite audit object for cellular carrier-switch cost.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CellularCarrierSwitchCost}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close kernel-carrier replacement, infinite cellular semantics, host evaluator equivalence, hidden proof synthesis, completed audit success, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, theorem-family exposure, cellular orbit exposure, verb realignment, proof-retarget budgeting, audit-regeneration accounting, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CellularCarrierSwitchCostUp.

The sequence-level shared-modulus route is a downstream consumer of chapter 2299 and chapter 4356 before finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ windows are exposed.

Chapter 4287

A Concrete Naming Certificate for $\mathsf{UniformlyContinuousSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ packet records a sequence of maps whose continuity data share one displayed modulus ledger. It sits over the metric source row of chapter 57, the continuous-map surface of chapter 130, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The point of the packet is the shared-modulus route: a downstream consumer may inspect finitely many sequence entries only after the same uniform-control row has been displayed for all inspected maps.

The sequence carrier consumes the continuous-map rows of chapter 130 and the uniform-modulus handoff rows of chapter 369 before it exposes its own sequence-level carrier, so each inspected entry inherits a map row and the shared modulus remains a visible sibling dependency rather than a detached continuity family.

The $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ route first consumes the single-modulus surface of chapter 391 and the exported precision ledger of chapter 369; only after those two sibling rows are displayed can the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows be read as sequence-level data.

The compact-source read uses the route through chapter 2299, and the equicontinuous sequence comparison uses chapter 4356 before the shared-modulus row can be consumed.

The shared-modulus route is also a downstream consumer of chapter 2299 and chapter 4356: compact finite-net moduli and equicontinuity family rows supply the same tolerance-only handoff that $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ exposes to $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ windows.

Definition 4287.1 (Uniformly continuous sequence carrier)**.** *A* $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, Y, F, M, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row used by every displayed map in the sequence.*
3. *F is the finite family of* $\mathsf{ContinuousMap}^{\uparrow}$ *sequence-entry rows available to the packet.*
4. *M is the shared* $\mathsf{UniformModulus}^{\uparrow}$ *row, read once and then reused by every displayed entry in F.*

5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the inspected indices, source probes, and requested tolerances.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and to the shared modulus ledger.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal for the target readings reached only after S, Q, M have been displayed.*
8. *H records componentwise* hsame *transport for source metric, target metric, sequence-entry, shared-modulus, stream-window, regular-readback, real-seal, replay, provenance, and local-name rows.*
9. *C records displayed* Cont *replay from an inspected sequence index and tolerance request through X, Y, F, M, S, Q, E.*
10. *P is the* Pkg *provenance over* $\mathsf{UniformlyContinuousSequence}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformlyContinuousSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, F, M, S, Q, E, H, C, P, N$. It has no coordinate for host function extensionality, quotient stream equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached pointwise continuity proof for a sequence entry.*

Theorem 4287.2 (Uniformly continuous sequence NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ *carrier $U = (X, Y, F, M, S, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformlyContinuousSequ}}$ *surface consists exactly of carrier admission for the two metric rows, continuous-map sequence-entry rows, shared uniform-modulus row, finite stream windows, regular rational readback, real-name seal, componentwise transport, continuation replay, package provenance, and local naming; shared-modulus exactness requiring each inspected entry of F to consume the same M row; finite-window exactness through S; readback exactness through Q; real-seal boundary through E; and non-escape from host function extensionality, quotient streams, selected limits, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and detached pointwise continuity data.*

Proof. Project the carrier of Definition 4287.1. The only source, target, sequence-entry, shared-modulus, stream, readback, and real-seal data available to the classifier are the displayed rows X, Y, F, M, S, Q, E.

The shared-modulus clause is read before any inspected sequence entry reaches a downstream Real-facing consumer. Each entry in F is a $\mathsf{ContinuousMap}^{\uparrow}$ row, but the packet exposes it to a tolerance request only through the common $\mathsf{UniformModulus}^{\uparrow}$ row M and the finite windows in S.

Readback and sealing are downstream of that shared route. The $\mathsf{RegSeqRat}^{\uparrow}$ row Q records only the rational data obtained from the displayed windows and shared modulus, and the $\mathsf{Real}^{\uparrow}$ row E is reached only after S, Q, M have been exposed.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no row for host function extensionality, quotient stream equality, selected limits, countable choice, ambient real completeness, or detached pointwise continuity proofs, the listed rows exhaust the local NameCert surface. □

Theorem 4287.3 (Uniformly continuous sequence shared-modulus handoff)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

The route supplies a shared modulus for all inspected sequence entries, finite stream windows for those inspections, regular rational readback, and the terminal real-name seal. It exports no host

function extensionality, quotient stream equality, selected limit, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or hidden complete metric space.*

Proof. Start from the obligation surface of Definition 4287.2. It identifies the continuous-map entries and the shared uniform-modulus ledger as carrier rows, not as host functions or external continuity facts.

A Real-facing consumer next opens only the finite windows in S. Those windows determine the regular rational readback Q under the shared modulus M, and only then can the terminal seal E be consumed.

The transport, continuation, provenance, and local naming rows preserve that same order. Therefore every public read is a shared-modulus sequence-of-maps route through the displayed BEDC rows, with the excluded extensionality, quotient, choice, completeness, and hidden-completion objects absent from the packet. □

Theorem 4287.4 (Uniformly continuous sequence obligation-closure package)**.** *The carrier of Definition 4287.1, the local NameCert obligations of Definition 4287.2, the shared-modulus handoff of Definition 4287.3, and the compact/uniform-modulus child routes assemble one obligation surface for* $\mathsf{UniformlyContinuousSequence}^{\uparrow}$*. A consumer may read source data through* $\mathsf{CompactMetric}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *rows, sequence entries through* $\mathsf{ContinuousMap}^{\uparrow}$*, uniform control through* $\mathsf{UniformModulus}^{\uparrow}$*, inspected indices through* $\mathsf{StreamName}^{\uparrow}$ *windows, rational readback through* $\mathsf{RegSeqRat}^{\uparrow}$*, terminal sealing through* $\mathsf{Real}^{\uparrow}$*, and structural movement through* hsame*,* Cont*,* Pkg*, and* NameCert*.*

This package exports no host function extensionality, quotient stream equality, selected limit, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness, hidden complete metric space, or detached pointwise-continuity proof.*

Proof. Start from the carrier row $U = (X, Y, F, M, S, Q, E, H, C, P, N)$. The source and target metric rows, the finite sequence-entry row, the shared modulus row, the stream-window row, the regular rational readback row, and the real-seal row are the only analytic data visible to the packet.

Apply the NameCert obligations. They assign carrier admission, shared-modulus exactness, finite-window exactness, readback exactness, real-seal boundary, transport, replay, provenance, and local naming to the displayed rows.

Use the shared-modulus handoff together with the compact-source and uniform-modulus routes named in the chapter introduction. Those routes force every inspected $\mathsf{ContinuousMap}^{\uparrow}$ entry to consume the same $\mathsf{UniformModulus}^{\uparrow}$ row before the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows can be read.

Therefore the obligation package is exactly the finite BEDC surface listed in the statement. Since no carrier coordinate names host extensionality, quotient streams, selected limits, countable choice, ambient completeness, hidden complete metrics, or detached pointwise proofs, none of those endpoints is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyContinuousSequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ packet is generated from source and target MetricSpace rows, ContinuousMap sequence-entry rows, one shared UniformModulus row, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformlyContinuousSequence}^{\uparrow}}$, seed)

Scope closed: Definition 4287.1, Definition 4287.2, and Definition 4287.3 seed the shared-modulus sequence-of-maps packet for Real-facing finite-window consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformlyContinuousSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient streams, selected limits, countable choice, ambient RealUp completeness, hidden complete metric spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-modulus exactness, finite-window exactness, regular-readback boundary, Real-seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.UniformlyContinuousSe

The UniformlyContinuousSequence$^{\uparrow}$ route consumes chapter 2299, chapter 369, and chapter 130 as load-bearing rows before any sequence endpoint is public. The compact-uniform-modulus sibling supplies the finite compact-window fold, the uniform-modulus sibling supplies the shared tolerance-to-precision row, and the continuous-map sibling supplies the pointwise graph and modulus readback that the sequence packet transports along hsame and replays through Cont.

Thus a sequence-level uniform-continuity packet reads compact cover data, finite modulus rows, tolerance readbacks, and terminal Real-facing seals through the sibling modulus lattice rather than through a host continuity theorem or an external compactness oracle.

Theorem 4287.5 (Compact uniform-modulus route for uniformly continuous sequences)**.** *Every Real-facing read of an accepted* UniformlyContinuousSequence$^{\uparrow}$ *carrier whose source is displayed through the compact route must consume the shared* UniformModulus$^{\uparrow}$ *row through the compact-uniform modulus packet of chapter 2299. The read factors through the visible route*

$$\mathsf{CompactUniformModulus}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hs}$$

It exports no detached pointwise continuity family, host compactness theorem, selected limit, quotient stream equality, countable-choice schedule, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4287.1. The sequence entries are available only as ContinuousMap$^{\uparrow}$ rows, the inspected indices only through StreamName$^{\uparrow}$ windows, and the target values only after RegSeqRat$^{\uparrow}$ readback and the terminal Real$^{\uparrow}$ seal.

When the source row is compact, the shared modulus row is not read as an external theorem. It is consumed through the compact-uniform modulus route of chapter 2299, which packages compact source coverage and the downstream UniformModulus$^{\uparrow}$ handoff before any Real-facing sequence read is public.

The transport, replay, provenance, and local naming rows then preserve the same route. Since the carrier has no coordinate for detached pointwise continuity, host compactness, selected limits, quotient stream equality, countable choice, or ambient real completeness, a Real-facing compact-source read must pass through the displayed compact-uniform modulus dependency. □

Theorem 4287.6 (Uniformly continuous sequence compact-metric forward dependency)**.** *Every* CompactMetric$^{\uparrow}$ *consumer of an accepted* UniformlyContinuousSequence$^{\uparrow}$ *packet must first read the visible source and observation route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Only after the metric source row, continuous-map entry rows, shared uniform-modulus row, finite stream windows, regular rational readback, and terminal real seal are displayed may the consumer inspect compact-metric modulus data.

Proof. Project the carrier of Definition 4287.1. The compact-facing consumer receives the source metric row X, target metric row Y, continuous-map entry rows F, shared modulus row M, stream-window row S, readback row Q, and real-seal row E before any structural transport or provenance row can be used.

The compact-metric dependency route then reads the compact source through chapter 129. That route is downstream of the displayed Met$^{\uparrow}$ source and the same UniformModulus$^{\uparrow}$ row used

by the sequence packet, so compact-metric modulus data cannot be consumed before the shared sequence modulus and finite windows are visible.

Finally the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows seal the consumer-facing values. Since the carrier has no coordinate for detached pointwise continuity, selected limits, quotient stream equality, countable choice, or ambient real completeness, the compact-metric consumer is forced through the displayed forward dependency. □

The compact-metric consumer reads $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ through chapter 129 and chapter 369 before using the shared sequence modulus. This keeps the sequence ledger attached to compact finite-net data and the finite modulus row, rather than to an external pointwise continuity family, open-cover compactness theorem, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Theorem 4287.7 (UniformlyContinuousSequence equicontinuous dependency)**.** *Every accepted* $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ *shared-modulus packet supplies the common modulus row consumed by* $\mathsf{EquicontinuousSequence}^{\uparrow}$*. The dependency is read through* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{CompactMetric}^{\uparrow}$ *source rows of chapter 129, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of chapter 301, and the* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before the equicontinuity consumer of chapter 4356 may inspect the shared sequence modulus.*

Proof. Start with the carrier of Definition 4287.1. Its finite sequence route displays the source and target metric rows, continuous-map entries, one shared $\mathsf{UniformModulus}^{\uparrow}$ row, finite $\mathsf{StreamName}^{\uparrow}$ windows, regular rational readback, terminal $\mathsf{Real}^{\uparrow}$ seal, transport, replay, provenance, and local naming.

The compact-metric dependency route keeps the same shared modulus attached to compact source rows before downstream compact-uniform consumers read it. Thus an $\mathsf{EquicontinuousSequence}^{\uparrow}$ consumer receives a common modulus only after the compact source, stream window, rational readback, and real seal rows have been displayed.

Finally use the equicontinuous-sequence carrier of Definition 4356.1. Its common schedule and equicontinuity rows consume exactly the kind of shared finite modulus exported by the $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ packet, while selected subsequences, quotient stream equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness remain outside both carriers. □

Theorem 4287.8 (Uniformly continuous sequence equicontinuity handoff)**.** *Every accepted* UniformlyContinuousSe *packet read over a displayed finite sequence window may be consumed as a finite family-modulus route for chapter 4076. The read first exposes the shared* $\mathsf{UniformModulus}^{\uparrow}$ *row, the finite* $\mathsf{StreamName}^{\uparrow}$ *window, the compact-metric source boundary, regular rational readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row; only then may an* $\mathsf{Equicontinuity}^{\uparrow}$ *consumer inspect the same window as a finite family indexed by the displayed sequence positions.*

Proof. Project the uniformly continuous sequence carrier through Definition 4287.1. Its shared modulus is already attached to the displayed sequence window, so the finite family read does not choose a new radius schedule.

Read the equicontinuity carrier through Definition 4076.1. That carrier asks for a finite family ledger, a common tolerance-radius handoff, transport, replay, provenance, and local naming. The sequence window supplies exactly that route when its displayed indices are treated as the family index set.

Thus the dependency is a forward consumer edge from the sequence packet to $\mathsf{Equicontinuity}^{\uparrow}$. It does not add selected subsequences, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 4287.9 (Uniformly continuous sequence located-modulus dependency route)**.** *Every* $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ *read that reaches a sequence-level* $\mathsf{Real}^{\uparrow}$ *consumer must first expose a substantive modulus sibling: either the* $\mathsf{UniformModulus}^{\uparrow}$ *route of chapter 369 or the compact handoff through* $\mathsf{CompactUniformModulus}^{\uparrow}$ *in chapter 2299. The sequence packet therefore exports a finite modulus-mediated read surface before any Real-facing sequence value is consumed, and it provides no detached pointwise-continuity family, selected limit, quotient stream equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted uniformly continuous sequence packet. Its sequence rows can be inspected only through displayed finite windows, and a Real-facing consumer can read values only after the regular rational and terminal Real rows have been exposed.

The modulus row supplies the horizontal dependency. A general sequence read consumes $\mathsf{UniformModulus}^{\uparrow}$ through chapter 369; a compact-source read consumes the compact route through chapter 2299 before it presents the same uniform-modulus handoff.

Thus the sequence carrier is not a kernel-only island. Its downstream Real route is mediated by a displayed modulus sibling, so the packet cannot supply a detached pointwise family, selected limit, quotient stream equality, countable-choice schedule, or ambient real completeness. □

Theorem 4287.10 (Uniformly continuous sequence pointwise stream metric route)**.** *Every accepted* $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ *packet whose finite windows are consumed pointwise by a metric-stream reader must expose the same source and target* $\mathsf{Met}^{\uparrow}$ *rows, shared* $\mathsf{UniformModulus}^{\uparrow}$ *row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before it can invoke the* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *comparison route of chapter 4139. The read is a shared-modulus stream route, not detached pointwise continuity, quotient stream equality, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4287.1. The pointwise metric-stream reader receives only $X, Y, F, M, S, Q, E, H, C, P, N$, so the source and target metric rows and the shared uniform-modulus row remain visible before any inspected sequence entry is read.

Use the NameCert obligations and shared-modulus handoff. They force each finite window to pass through the same $\mathsf{UniformModulus}^{\uparrow}$ row M, then through $\mathsf{StreamName}^{\uparrow}$ windows S and $\mathsf{RegSeqRat}^{\uparrow}$ readback Q before the $\mathsf{Real}^{\uparrow}$ seal E can be consumed.

Finally route the visible windows through chapter 4139. The $\mathsf{PointwiseStreamMetric}^{\uparrow}$ comparison can inspect the displayed metric-stream rows, but the uniformly continuous sequence packet has no coordinate for detached pointwise continuity proofs, quotient stream equality, selected limits, countable-choice schedules, or ambient Real completeness. □

The $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ completion-facing route reads the regular-Cauchy metric boundary through chapter 8164 and the compact uniform-modulus route of chapter 2299 before any sequence-level Real seal is public. This keeps compact finite-net data, pointwise-stream observations, shared $\mathsf{UniformModulus}^{\uparrow}$ rows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seals on one displayed sibling route rather than on a detached host continuity theorem, selected limit, quotient stream equality, or ambient completion principle.

Theorem 4287.11 (Uniformly continuous sequence sibling dependency)**.** *Every* $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ *consumer first reads the uniform-modulus surface of chapter 391 and the compact-uniform handoff of chapter 388 before it routes pointwise stream metrics into sequence-level uniformity. Thus the sibling surface is a finite lattice of uniform-control rows, compact handoff rows, stream windows,*

transport, replay, provenance, and local naming, not detached pointwise continuity, selected limits, countable choice, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the route through the two sibling chapters named in the statement. The uniform-continuity row supplies the modulus that every sequence-level consumer must keep visible, and the compact-uniform row supplies the handoff that turns compact-domain control into a stable sequence surface.

The remaining rows are bookkeeping for that route. Stream windows present the finite observations, hsame transport preserves the selected control data, Cont replay replays the same rows, Pkg records provenance, and the local naming row records the resulting $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ certificate. No extra pointwise or quotient-level equality is introduced. □

Every public sequence-level uniform-continuity read from $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ must first pass through the sibling lattice formed by compact finite-net rows from chapter 129, the shared $\mathsf{UniformModulus}^{\uparrow}$ row of chapter 369, pointwise stream-metric rows from chapter 4139, $\mathsf{StreamName}^{\uparrow}$ window rows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seals. The lattice gives the consumer finite compact coverage, one reusable modulus, stream-local metric observations, windowed rational reads, and sealed target values before any sequence-level uniform continuity claim is public; it exports no detached pointwise-continuity family, selected limit, quotient stream equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Every $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ consumer that reads sequence-level uniform continuity must pass through the finite modulus surface of chapter 2228 or chapter 5128 before it can inspect the shared sequence ledger. Completion-facing uses then continue through the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readback route of chapter 38, so the packet exposes a finite uniform-modulus dependency rather than a host pointwise-continuity family, a selected limit, or an ambient completeness principle.

Chapter 4288

A Concrete Naming Certificate for $\mathsf{LocatedIntervalHalving}^{\uparrow}$

Following Bishop and Bridges constructive interval-halving analysis, the $\mathsf{LocatedIntervalHalving}^{\uparrow}$ packet isolates the one-step finite halving certificate that later bisection and convergence chapters consume. It reads the midpoint route of chapter 1712, the retained-child route of chapter 1711, the finite-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the downstream convergence consumer of chapter 1804. The certificate names one visible halving step, not an infinite branch, a selected limit, host interval equality, or ambient completeness.

Definition 4288.1 (Located interval halving carrier)**.** *A* $\mathsf{LocatedIntervalHalving}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (I, M, L, R, S, D, Q, E, T, C, P, N)$$

with the following displayed rows:

1. *I is the source located real interval row. It supplies the lower endpoint, upper endpoint, radius budget, locator reads, locatedness modulus, and endpoint-order observations for the parent interval.*
2. *M is the* $\mathsf{LocatedIntervalMidpoint}^{\uparrow}$ *row. It records the displayed midpoint route and the two child endpoint-transport rows before any retained side is selected.*
3. *L and R are the left-child and right-child interval rows opened from M.*
4. *S is the side row. It records the finite locator, sign, containment, or requested-side datum that selects which of L, R is retained for this halving step.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the common scale, half-radius budget, and dyadic comparison data used by the one-step diameter estimate.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the retained child endpoints and midpoint windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, M, L, R, S, D, Q have been displayed.*
8. *T records componentwise* hsame *transport for the source interval, midpoint row, child intervals, side row, dyadic tolerance row, regular readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a halving request through source inspection, midpoint construction, child exposure, side retention, dyadic tolerance checking, regular readback, and the Real-facing seal.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedIntervalHalving}^{\uparrow}$, $\mathsf{LocatedIntervalMidpoint}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedIntervalHalving}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one located interval halving packet. It has no coordinate for host interval equality, real trichotomy, quotient representatives, countable choice, an infinite branch, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Lean4 ✓ `BEDC.Derived.LocatedIntervalHalvingUp.LocatedIntervalHalvingTasteGate single carrier alignment`

Theorem 4288.2 (LocatedIntervalHalving NameCert obligations)**.** *For every accepted* $\mathsf{LocatedIntervalHalving}^{\uparrow}$ *carrier*

$$H = (I, M, L, R, S, D, Q, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedIntervalHalving}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source located interval, midpoint row, two child intervals, side row, dyadic tolerance row, regular readback, Real seal, transport, replay, provenance, and local naming;*

2. *source discipline, requiring every endpoint, radius, locator, locatedness, and order read to factor through I before midpoint or side data are inspected;*

3. *midpoint exposure, requiring M to display the midpoint and both child endpoint-transport routes before the retained side is read;*

4. *side retention, requiring S to choose only between the displayed children L and R and to export no infinite branch selector;*

5. *dyadic halving exactness, requiring D to attach the retained child to the common scale and half-radius budget used by the one-step diameter estimate;*

6. *Real-facing handoff, requiring Q, E, T, C, P, N to route the retained child through regular rational readback, the terminal Real seal, transport, replay, provenance, and local naming;*

7. *ledger exhaustion, excluding host interval equality, real trichotomy, quotient representatives, countable choice, infinite branches, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge data.*

No located interval halving obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 4288.1. The displayed tuple exposes the source interval, midpoint route, two child intervals, side row, dyadic tolerance row, regular readback, Real seal, and structural rows as finite BHist coordinates.

Source discipline is supplied by I. The halving request starts from the source located interval row, so endpoint, radius, locator, locatedness, and order observations cannot be replaced by a host closed interval object.

Midpoint exposure is supplied by M, L, R. The midpoint row displays the two child endpoint-transport routes, and the child interval rows make those two finite cells available before any retained side is read.

Side retention and dyadic exactness are supplied by S and D. The side row selects only between the displayed children, while the dyadic row records the common scale and half-radius budget for that retained child.

Finally Q, E, T, C, P, N carry the retained child to regular rational readback, the terminal Real seal, componentwise transport, displayed replay, provenance, and local naming. Since every visible coordinate has already been listed, the excluded host equality, trichotomy, quotient, choice, branch, limit, completeness, verification, and bridge objects cannot be projected. □

Theorem 4288.3 (LocatedIntervalHalving RegSeqRat and Real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedIntervalHalving}^{\uparrow}$ *carrier reads the retained child only after the finite route*

$$I \longmapsto M, L, R \longmapsto S, D \longmapsto Q \longmapsto E$$

has been displayed. Consequently the handoff consumed by chapter 1711 and chapter 1804 is a one-step located halving certificate over $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows, not a selected branch, a quotient representative, or an ambient completeness principle.*

Proof. Start with the accepted carrier $H = (I, M, L, R, S, D, Q, E, T, C, P, N)$. The only source coordinate is I, so a readback or Real-facing consumer first receives the displayed located interval data.

Next the consumer reads M, L, R. These rows display the midpoint and both child intervals before the retained child is selected, so the later route cannot hide a midpoint construction or child endpoint transport.

The retained side is then fixed by S and measured by D. The side row chooses between the displayed children, and the dyadic tolerance row records the common-scale half-radius estimate for that child.

Only after those rows are displayed does Q expose the regular rational readback and E expose the terminal Real seal. The structural rows T, C, P, N replay, transport, record provenance, and name the same finite route. Thus downstream bisection and convergence consumers receive a visible one-step halving certificate and no selected infinite branch, quotient representative, or ambient completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalHalving}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntervalHalving}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4288.1, Definition 4288.2, and Definition 4288.3 seed the one-step located interval halving route through source interval, midpoint, child interval, side-retention, dyadic tolerance, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedIntervalHalving}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host interval equality, real trichotomy, quotient representatives, countable choice, infinite branches, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, midpoint exposure, side retention, dyadic halving exactness, RegSeqRat and Real handoff, and non-escape proofs for BEDC.Derived.LocatedIntervalHalvingUp.

Constructive story: A $\mathsf{LocatedIntervalHalving}^{\uparrow}$ packet is generated from one source located interval row, one LocatedIntervalMidpointUp row, two child interval rows, one finite side-retention row, one DyadicRatCoreUp tolerance row, one RegSeqRatUp readback row, one RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4289

A Concrete Naming Certificate for $\mathsf{BishopLocatedRoot}^{\uparrow}$

Following Bishop and Bridges constructive located-root arguments, the $\mathsf{BishopLocatedRoot}^{\uparrow}$ packet records the finite bisection route by which a located sign-changing bracket is read as a terminal $\mathsf{Real}^{\uparrow}$ root seal. It sits after the bisection convergence surface of chapter 1804, the located intermediate-value route of chapter 1402, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a constructive root certificate over displayed finite rows; it does not assert full $\mathsf{Real}^{\uparrow}$ completeness, classical trichotomy, quotient real equality, selected host roots, or countable choice.

Definition 4289.1 (Bishop located root carrier)**.** *A* $\mathsf{BishopLocatedRoot}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, O, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the located bracket row naming two displayed endpoint windows and the retained interval boundary.*
2. *O is the opposite-sign witness row, read as positive apartness data for the two endpoint evaluations.*
3. *S is the bisection schedule row selecting the retained subintervals and midpoint tests.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording widths, midpoint radii, sign-test budgets, and the requested terminal precision.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the finite bisection windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after B, O, S, D, Q have been displayed.*
7. *H records componentwise* hsame *transport for the bracket, sign witness, bisection schedule, dyadic ledger, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a root request through $B, O, S, D, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedRoot}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRoot}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their replay path. It has no coordinate for a host root object, real trichotomy, quotient real equality, ambient completeness, countable choice, or a detached limit point.

Lean4 ✓ `BEDC.Derived.BishopLocatedRootUp.TasteGate.BishopLocatedRootTasteGate single carrier alignment`

Theorem 4289.2 (Bishop located root NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedRoot}^{\uparrow}$ *carrier*

$$R = (B, O, S, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedRoot}^{\uparrow}}$ *surface consists exactly of carrier admission for the located bracket, opposite-sign witness, bisection schedule, dyadic tolerance ledger, regular rational readback, terminal Real seal, componentwise transport, displayed continuation replay, provenance, and local naming row; bisection-route exposure; Real-seal nonescape; and refusal of host roots, trichotomy, quotient real equality, ambient completeness, countable choice, and detached limit points.*

Proof. Project the carrier of Definition 4289.1. The accepted packet exposes exactly the bracket, sign witness, schedule, dyadic ledger, regular readback, Real seal, and structural rows H, C, P, N.

The bisection route is forced by the displayed order. A root-facing consumer must inspect the located bracket and opposite-sign row before it can read midpoint choices, dyadic widths, or the regular readback.

The terminal Real seal is downstream of those rows. Since the carrier has no coordinate for a host root, trichotomy, quotient equality, ambient completeness, countable choice, or a detached limit, the listed rows exhaust the local NameCert surface. □

Theorem 4289.3 (Bishop located root bisection route)**.** *Every accepted* $\mathsf{BishopLocatedRoot}^{\uparrow}$ *root read factors through the finite route*

$$B \longmapsto O \longmapsto S \longmapsto D \longmapsto Q \longmapsto E$$

before any downstream Real or Completion consumer can inspect the root seal. In particular, the read uses the bisection convergence route of chapter 1804, the finite-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ *seal of chapter 38.*

Proof. Start with an accepted root read. The located bracket row B and opposite-sign witness O are the only sources for the retained interval and sign-change data.

Apply the bisection schedule row S and dyadic ledger D. These rows record the finite midpoint choices, interval widths, and tolerance budgets consumed by the bisection convergence route.

Read Q and E only after the finite schedule and ledger have been displayed. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular rational source, and the $\mathsf{Real}^{\uparrow}$ seal records the terminal root-facing name. The structural rows H, C, P, N transport, replay, source, and name the same packet, so no host root, trichotomy, quotient equality, countable choice, or ambient completeness coordinate can enter between the bracket and the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRoot}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRoot}^{\uparrow}$ packet is generated from a located bracket, opposite-sign witness, bisection schedule, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedRoot}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4289.1, Definition 4289.2, and Definition 4289.3 seed the finite located-root certificate over bisection, StreamName, DyadicRatCore, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopLocatedRoot}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full RealUp completeness, classical trichotomy, quotient real equality, selected host roots, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, opposite-sign stability, bisection-route exposure, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedRootUp.

Chapter 4290

A Concrete Naming Certificate for $\mathsf{RealCompletenessWitness}^{\uparrow}$

The $\mathsf{RealCompletenessWitness}^{\uparrow}$ packet realizes the four-face Real and Completion route as finite BEDC data: the $\mathsf{StreamName}^{\uparrow}$ finite-window face, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance face, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and classifier face, and the terminal $\mathsf{Real}^{\uparrow}$ seal face. It records the completion witness used by Real-facing consumers without turning that witness into ambient completeness, quotient stream equality, selected limits, trichotomy, or countable choice.

Definition 4290.1 (Real completeness witness carrier)**.** *A* $\mathsf{RealCompletenessWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule naming the requested observations.*
2. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger of endpoint rows, radii, comparison distances, and tolerance budgets.*
3. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier row read from the same finite schedule and dyadic ledger.*
4. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after* S, D, R *have been displayed.*
5. H *records componentwise* hsame *transport for the four faces, replay, provenance, and local naming rows.*
6. C *records displayed* Cont *replay from a completion-facing request through* S, D, R, E, H, P, N.
7. P *is the* Pkg *provenance over* $\mathsf{RealCompletenessWitness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. N *is the local* $\mathsf{NameCert}_{\mathsf{RealCompletenessWitness}^{\uparrow}}$ *row.*

The classifier compares accepted witnesses only through the displayed four-face route and the structural rows. It has no coordinate for quotient streams, selected host limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, countable choice, field completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RealCompletenessWitnessUp.RealCompletenessWitnessTasteGate single carrier alignment`

Theorem 4290.2 (Real completeness witness NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletenessWitness}$ *carrier* $W = (S, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealCompletenessWitness}^{\uparrow}}$ *surface consists exactly of carrier admission for the StreamName finite-window face, DyadicRatCore tolerance face, RegSeqRat regularity and classifier face, terminal RealUp seal face, componentwise transport, displayed continuation replay, provenance, and local naming; four-face route exposure; and refusal of quotient streams, selected limits, ambient completeness, trichotomy, countable choice, detached field structure, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 4290.1. The accepted packet has exactly four mathematical faces, followed by transport, replay, provenance, and naming rows.

The route exposure is ordered. A completion-facing consumer reads S before dyadic tolerances, D before regular readback, R before the terminal Real seal, and E before any downstream seal consumer.

The exclusions are an inventory check. No coordinate stores quotient stream equality, a selected host limit, an ambient completeness theorem, trichotomy, countable choice, a field-faithfulness proof, Lean verification, or a bridge certificate. Therefore the displayed rows exhaust the local NameCert surface. □

Theorem 4290.3 (Real completeness witness four-face route)**.** *Every accepted* $\mathsf{RealCompletenessWitness}^{\uparrow}$ *consumer reaches completion-facing Real data only through the finite route*

$$S \longmapsto D \longmapsto R \longmapsto E$$

and then through H, C, P, N*. Thus the witness is a finite four-face packet over chapter 126, chapter 291, chapter 301, and chapter 38, not an assertion of full* $\mathsf{Real}^{\uparrow}$ *completeness or a field-completeness theorem.*

Proof. Start with an accepted completion-facing read. The only source face is S, the finite $\mathsf{StreamName}^{\uparrow}$ schedule, so the read first fixes the visible windows.

Next read D and R. The dyadic face supplies endpoint, radius, distance, and tolerance rows; the regular-rational face reads those rows as the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and classifier surface.

Finally read E as the terminal $\mathsf{Real}^{\uparrow}$ seal and pass through H, C, P, N for transport, replay, source, and local naming. Since no field-faithfulness, nontriviality, quotient stream, selected limit, or ambient completeness coordinate is present in the carrier, those later Lean obligations must be supplied separately by ‘TasteGate.lean‘, with ‘Nontrivial RealCompletenessWitnessUp‘ and ‘FieldFaithful RealCompletenessWitnessUp‘ recorded as independent evidence rather than projected from this packet. □

Falsifiable prediction: Any accepted $\mathsf{RealCompletenessWitness}^{\uparrow}$ read that reaches Real-completion data while bypassing the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ seal rows refutes the carrier.

Independence witness: streamname, dyadicratcore, regseqrat, real, finite-real-section: $\mathsf{RealCompletenessWitness}$ is not bijective to any listed sibling because it jointly carries the finite-window schedule, dyadic tolerance ledger, regularity and classifier readback, terminal Real seal, structural transport, replay, provenance, and local NameCert rows as one four-face packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletenessWitness}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{RealCompletenessWitness}^{\uparrow}$ packet is generated from a StreamName finite-window face, DyadicRatCore tolerance face, RegSeqRat regularity and classifier face, terminal RealUp seal face, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RealCompletenessWitness}\uparrow}$, seed)

Scope closed: Definition 4290.1, Definition 4290.2, and Definition 4290.3 seed the finite four-face completion witness over StreamName, DyadicRatCore, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealCompletenessWitness}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full RealUp completeness, quotient stream equality, selected limits, field-faithfulness, nontriviality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked four-face carrier admission, route exposure, nonescape, transport, replay, provenance, local naming, and separate TasteGate evidence for BEDC.Derived.RealCompletenessWitnessUp.

Chapter 4291

A Concrete Naming Certificate for $\mathsf{SmoothManifold}^{\uparrow}$

Following John M. Lee's smooth manifold presentation, the $\mathsf{SmoothManifold}^{\uparrow}$ packet records a finite atlas, overlap, transition, and replay surface for a manifold object already routed through chapter 96, chapter 88, chapter 47, chapter 130, and chapter 97. It names the differentiable atlas boundary used by later bundle, connection, and metric consumers; it is not a host smooth-space primitive, not a global coordinate choice, and not an ambient classical maximal-atlas theorem.

Definition 4291.1 (Smooth manifold carrier)**.** *A* $\mathsf{SmoothManifold}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, T, V, A, O, S, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the underlying* $\mathsf{Manifold}^{\uparrow}$ *carrier row.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *chart-domain ledger, recording the displayed open-domain data used by the atlas.*
3. *V is the finite* $\mathsf{VecSpace}^{\uparrow}$ *model row for the chart codomains.*
4. *A is the atlas-admission row, listing the chart names, domains, codomain windows, and coverage witnesses accepted by the packet.*
5. *O is the chart-overlap ledger, recording the finite intersections on which transition comparisons are requested.*
6. *S is the smooth-transition classifier row, whose entries are read through* $\mathsf{ContinuousMap}^{\uparrow}$ *and the displayed finite differentiability tests available on the model* $\mathsf{VecSpace}^{\uparrow}$ *windows.*
7. *R is the* $\mathsf{Bundle}^{\uparrow}$ *readiness row, exposing the atlas route that downstream tangent, frame, and coordinate-bundle packets may consume.*
8. *H records componentwise* hsame *transport for the manifold carrier, topology ledger, model vector space rows, atlas, overlaps, smooth-transition classifiers, bundle-readiness row, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from chart requests through B, T, V, A, O, S, R.*
10. *P is the* Pkg *provenance over* $\mathsf{SmoothManifold}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Bundle}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SmoothManifold}^\uparrow}$ *row.*
The classifier compares accepted packets only through $B, T, V, A, O, S, R, H, C, P, N$. It has no coordinate for a selected maximal atlas, ambient set-theoretic smooth structure, global chart, classical paracompactness theorem, connection form, or Riemannian metric.

Lean4 ✓ `BEDC.Derived.SmoothManifoldUp.SmoothManifoldTasteGate single carrier alignment`

Theorem 4291.2 (Smooth manifold NameCert obligations)**.** *For every accepted* $\mathsf{SmoothManifold}^\uparrow$ *carrier $M = (B, T, V, A, O, S, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SmoothManifold}^\uparrow}$ *surface consists exactly of carrier admission, atlas admission, chart-overlap smoothness, transition compatibility,* hsame *transport,* Cont *replay, package provenance, and local naming obligations. In particular, the atlas row must display finite chart admission, the overlap row must display every inspected intersection, the transition row must display smooth compatibility on those overlaps, and the replay row must reproduce the same route before any* $\mathsf{Bundle}^\uparrow$ *consumer reads R.*

Proof. Project the accepted carrier. The base rows B, T, V expose the topological manifold boundary, chart-domain ledger, and model vector-space windows before the atlas can be read.

The atlas row A is then checked against those rows. Its chart names, displayed domains, codomain windows, and finite coverage witnesses are the only admission data available to the packet.

On each displayed overlap in O, the transition classifier S reads the corresponding coordinate changes through $\mathsf{ContinuousMap}^\uparrow$ and the finite differentiability tests attached to the model $\mathsf{VecSpace}^\uparrow$ windows. Transition compatibility is therefore stored in S rather than in a hidden maximal-atlas object.

Finally H, C, P, N transport, replay, source, and name the same rows, and R exposes only that displayed atlas route to $\mathsf{Bundle}^\uparrow$ consumers. Since the carrier has no coordinate for a selected maximal atlas, global chart, connection form, or metric tensor, the listed obligations exhaust the local certificate. □

Lean4 ✓ `BEDC.Derived.SmoothManifoldUp.SmoothManifoldNamecertObligations`

Theorem 4291.3 (Smooth manifold bundle-readiness route)**.** *Every* $\mathsf{Bundle}^\uparrow$*-facing consumer of an accepted* $\mathsf{SmoothManifold}^\uparrow$ *packet factors through the displayed route*

$$\mathsf{Manifold}^\uparrow \longmapsto \mathsf{Topology}^\uparrow \longmapsto \mathsf{VecSpace}^\uparrow \longmapsto \mathsf{ContinuousMap}^\uparrow \longmapsto \mathsf{Bundle}^\uparrow$$

as represented by the rows $B, T, V, A, O, S, R, H, C, P, N$. The consumer may read coordinate-bundle readiness only after atlas admission, overlap smoothness, transition compatibility, transport, replay, provenance, and local naming rows have all been displayed.

Proof. Start with the NameCert obligation theorem. It places every accepted bundle-facing read behind the carrier, topology, model-space, atlas, overlap, and transition rows.

The row R is downstream of S, so a bundle consumer cannot inspect a smooth coordinate route before transition compatibility has been displayed on each overlap requested by O. The rows H and C preserve the same order under transport and replay.

The package and local naming rows record that the exposed route is the finite $\mathsf{SmoothManifold}^\uparrow$ atlas surface. Therefore later bundle, connection, and metric packets consume a named differentiable-atlas boundary rather than an ambient maximal atlas or a global smooth-space primitive. □

Lean4 ✓ `BEDC.Derived.SmoothManifoldUp.SmoothManifoldBundleReadinessRoute`

Falsifiable prediction: Every accepted $\mathsf{SmoothManifold}^{\uparrow}$ consumer that reaches $\mathsf{Bundle}^{\uparrow}$ readiness without reading atlas admission, chart-overlap smoothness, transition compatibility, hsame transport, Cont replay, Pkg provenance, and local NameCert rows refutes this packet surface.

Closure status for $\mathsf{NameCert}_{\mathsf{SmoothManifold}^{\uparrow}}$.

Constructive story: A $\mathsf{SmoothManifold}^{\uparrow}$ packet is generated from a Manifold carrier row, Topology chart-domain ledger, VecSpace model windows, atlas admission, chart-overlap ledger, smooth-transition classifier, Bundle readiness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SmoothManifold}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4291.1, Definition 4291.2, and Definition 4291.3 seed the finite smooth-atlas route from manifold and topology rows to Bundle consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SmoothManifold}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, selected maximal atlases, ambient smooth-space primitives, global charts, paracompactness, connections, or Riemannian metrics.

Upgrade path: Obligation closure requires checked carrier admission, atlas admission, overlap smoothness, transition compatibility, transport, replay, provenance, and local naming for BEDC.Derived.SmoothManifoldUp.

Chapter 4292

A Concrete Naming Certificate for $\mathsf{MetaCICNormalEndpointBudget}^{\uparrow}$

The $\mathsf{MetaCICNormalEndpointBudget}^{\uparrow}$ packet realizes the normal-endpoint budget from the MetaCIC normalization frontier as finite NameCert data. It sits beside chapter 3954, chapter 731, chapter 737, chapter 936, and chapter 3439. The packet names the accepted endpoint budget that consistency consumers may inspect; it does not erase the obstruction against blanket strong normalization.

Definition 4292.1 (MetaCIC normal-endpoint budget carrier)**.** *A* $\mathsf{MetaCICNormalEndpointBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, K, B, F, O, H, C, P, N, G)$$

with the following displayed rows:

1. *T is the typed closed-term or typed fragment row whose normal endpoint is being budgeted.*
2. *K is the candidate-evidence row, read before any normalization-facing consumer sees an endpoint.*
3. *B is the bounded-normal endpoint row, recording the finite fuel, reduction trace, and bounded checker evidence available for T.*
4. *F is the finished-normal seal row, exposing the normal endpoint only after candidate evidence and bounded computation rows have been displayed.*
5. *O is the obstruction row, recording the retained subject-reduction or confluence boundary when the endpoint budget is unavailable for a wider theorem.*
6. *H records componentwise* hsame *transport for typed rows, candidate evidence, bounded endpoints, finished-normal seals, obstruction rows, replay, provenance, local naming, and gate rows.*
7. *C records displayed* Cont *replay from endpoint requests through T, K, B, F, O.*
8. *P is the* Pkg *provenance over* $\mathsf{MetaCICNormalEndpointBudget}^{\uparrow}$*, the MetaCIC strong-normalization boundary, the subject-reduction obstruction, the confluence-normal fragment,* $\mathsf{ZNormal}^{\uparrow}$*, the bounded-normal conversion bridge,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalEndpointBudget}^{\uparrow}}$ *row.*

10. *G is the TasteGate landing row requiring* Nontrivial *and* FieldFaithful *instances for the displayed carrier surface before the packet is treated as a closed audit object.*

The classifier compares accepted packets only through $T, K, B, F, O, H, C, P, N, G$. It has no coordinate for evidence-free strong normalization, unrestricted subject reduction, quotient conversion equality, hidden fuel, or an unbounded normalizer.

Theorem 4292.2 (MetaCIC normal-endpoint budget NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICNormalEndpointBudget}^{\uparrow}$ *carrier $E = (T, K, B, F, O, H, C, P, N, G)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalEndpointBu}}$ *surface consists exactly of candidate evidence, bounded-normal endpoint, finished-normal seal, obstruction retention,* hsame *transport,* Cont *replay,* Pkg *provenance, local naming, and TasteGate landing obligations. Every consistency-facing consumer must display those rows before it reads the endpoint budget.*

Proof. Project the accepted carrier. The typed row T is only a source row; it is not a normalization theorem by itself.

The candidate row K is read before the bounded endpoint row B. The finished-normal seal F is downstream of both rows, so a consumer cannot reach the normal endpoint without candidate evidence and bounded computation evidence.

The obstruction row O remains part of the same packet. It records the subject-reduction or confluence boundary that blocks reading the endpoint budget as a blanket strong-normalization theorem.

Finally H, C, P, N, G transport, replay, source, name, and gate the same carrier. Since the classifier has no hidden fuel coordinate, unbounded normalizer, quotient conversion equality, or evidence-free theorem row, the listed obligations exhaust the endpoint budget surface. □

Theorem 4292.3 (MetaCIC normal-endpoint budget consistency boundary)**.** *Every consistency-facing read from an accepted* $\mathsf{MetaCICNormalEndpointBudget}^{\uparrow}$ *packet factors through the finite route from chapter 3954 through chapter 731, chapter 737, chapter 936, and chapter 3439, as mediated by the rows $T, K, B, F, O, H, C, P, N, G$. Thus the endpoint can support a bounded normal-consistency read only while candidate evidence, obstruction retention, and finished-normal sealing remain displayed.*

Proof. Use the obligation theorem to expose the row order. Candidate evidence K and bounded endpoint evidence B precede the finished-normal seal F.

The obstruction row O remains visible between the strong-normalization boundary and the subject-reduction or confluence frontier. Therefore the route through the confluence-normal fragment, $\mathsf{ZNormal}^{\uparrow}$ endpoint, and bounded-normal conversion bridge is a finite endpoint budget, not a full subject-reduction or strong-normalization theorem.

Transport, replay, provenance, local naming, and the TasteGate landing row preserve the same dependency order. A consistency consumer therefore reads the normal endpoint only as a displayed budget with retained obstruction evidence. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICNormalEndpointBudget}^{\uparrow}$ packet must display candidate evidence, bounded-normal endpoint, finished-normal seal, obstruction, hsame, Cont, Pkg, and NameCert rows before any consistency consumer reads it.

Independence witness: metacic-strong-normalization-boundary, metacic-subject-reduction-obstruction, metacicconfluencenormalfragment, znormal, bounded-normal-conversion-bridge: the normal-endpoint budget consumes those sibling frontiers as independent rows and does not collapse them into a blanket strong-normalization or subject-reduction theorem.

The Lean TasteGate landing condition for MetaCICNormalEndpointBudget$^{\uparrow}$ includes explicit Nontrivial and FieldFaithful instances for the displayed carrier surface.

Closure status for NameCert$_{\text{MetaCICNormalEndpointBudget}^{\uparrow}}$.

Constructive story: A MetaCICNormalEndpointBudget$^{\uparrow}$ packet is generated from typed MetaCIC source rows, candidate evidence, bounded-normal endpoint evidence, a finished-normal seal, obstruction retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, local NameCert data, and TasteGate landing rows.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICNormalEndpointBudget}^{\uparrow}}$, seed)

Scope closed: Definition 4292.1, Definition 4292.2, and Definition 4292.3 seed the finite normal-endpoint budget for consistency-facing MetaCIC consumers.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICNormalEndpointBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, blanket strong normalization, unrestricted subject reduction, quotient conversion equality, hidden fuel, or an unbounded normalizer.

Upgrade path: Obligation closure requires checked candidate evidence, bounded-normal endpoint, finished-normal seal, obstruction retention, transport, replay, provenance, local naming, and TasteGate Nontrivial and FieldFaithful rows for BEDC.Derived.MetaCICNormalEndpointBudgetUp.

Chapter 4293

A Concrete Naming Certificate for $\mathsf{PolishCauchyBasis}^{\uparrow}$

Following Alexandrov–Urysohn, Bourbaki, Kelley, and Bishop–Bridges, the $\mathsf{PolishCauchyBasis}^{\uparrow}$ packet records the basis-level handoff by which a complete separable metric source exposes Cauchy-filter basis data before any completion consumer reads a limit. It sits between the $\mathsf{PolishSpace}^{\uparrow}$ source of chapter 1490, the $\mathsf{CauchyFilterBasis}^{\uparrow}$ generator of chapter 1501, the $\mathsf{CompleteMetric}^{\uparrow}$ handoff of chapter 128, and the $\mathsf{SeparableMetric}^{\uparrow}$ dense schedule of chapter 1458. The packet is a finite BEDC handoff surface for Polish-space Cauchy bases, not a quotient completion, not a choice-selected dense sequence, and not an ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 4293.1 (Polish Cauchy basis carrier)**.** *A* $\mathsf{PolishCauchyBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, B, K, D, S, R, O, H, C, G, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{PolishSpace}^{\uparrow}$ *source row, carrying the complete separable metric packet over which every later basis read is interpreted.*
2. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *basis row, recording the directed finite basis generator used by Cauchy-filter consumers.*
3. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row attached to the same metric surface as X; it records the completion-facing route without selecting a limit point.*
4. *D is the* $\mathsf{SeparableMetric}^{\uparrow}$ *dense schedule row, stored as public finite name data rather than as a choice function over all balls.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to inspect dense names, basis requests, and Cauchy-window demands.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those stream windows, giving regular rational observations before any basis comparison is made.*
7. *O is the observation ledger joining dense-window requests, regular-rational readbacks, Cauchy-basis refinements, and completion-handoff checks.*
8. *H records componentwise* hsame *transport for X, B, K, D, S, R, O and for the local certificate rows.*

9. *C records displayed* Cont *replay from a Polish-source request through dense schedules, stream windows, regular readbacks, Cauchy-basis refinement, and the completion handoff.*
10. *G is the* Pkg *provenance over* $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PolishCauchyBasis}^{\uparrow}}$ *row.*

The classifier compares two accepted packets only after transporting these displayed rows to a common Polish source, Cauchy-basis generator, completion-handoff row, dense schedule, stream-window row, and regular readback ledger. It has no coordinate for choice-selected dense points, quotient completion equality, host point equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.PolishCauchyBasisUp.PolishCauchyBasisTasteGate single carrier alignment`

Theorem 4293.2 (Polish Cauchy basis NameCert obligations)**.** *For every accepted* $\mathsf{PolishCauchyBasis}^{\uparrow}$ *carrier $P = (X, B, K, D, S, R, O, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{PolishCauchyBasis}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the Polish source, Cauchy-filter basis, complete-metric handoff, separable dense schedule, stream windows, regular rational readback, observation ledger, transport, continuation, provenance, and local naming rows;*
2. *common-source classification, requiring the B, K, D, S, R, O rows to be read over the same transported* $\mathsf{PolishSpace}^{\uparrow}$ *source row X;*
3. *basis-directedness exposure, requiring every Cauchy-basis refinement consumed by B to be visible in S, R, O before the completion handoff K is read;*
4. *dense-schedule compatibility, requiring the separable row D and the Cauchy-basis row B to share the same stream-window and regular-readback surface;*
5. *completion-handoff non-escape, requiring every completion-facing consumer to pass through B, S, R, O before reaching K;*
6. *package provenance and local* NameCert *naming for exactly the displayed packet.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 4293.1. The projection exposes the Polish source, Cauchy-basis generator, complete-metric handoff, dense schedule, stream windows, regular readbacks, observation ledger, transport rows, continuation rows, provenance row, and local name.

The classifier route starts at X. Componentwise transport in H moves B, K, D, S, R, O together, so a consumer never compares a basis row over one Polish source with a completion handoff or dense schedule over another.

The observation ledger O fixes the finite read order. Dense requests and basis refinements are observed through S and R before either the Cauchy-filter basis or complete-metric handoff can be consumed.

Finally replay C and attach G, N. These rows route, source, and name the same displayed packet, with no additional coordinate for selected dense points, quotient completion equality, host point equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence the listed rows exhaust the local naming surface. □

Theorem 4293.3 (Polish Cauchy basis completion handoff)**.** *Let $P = (X, B, K, D, S, R, O, H, C, G, N)$ be an accepted* $\mathsf{PolishCauchyBasis}^{\uparrow}$ *packet. Every completion-facing consumer of the Polish source*

X reaches the $\mathsf{CompleteMetric}^{\uparrow}$ *handoff K only through the displayed Cauchy-filter basis row B, the separable dense schedule D, the* $\mathsf{StreamName}^{\uparrow}$ *windows S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the observation ledger O, transported by H and replayed by C.*

The visible route is

$$X, D, S, R, B, O \longmapsto K \longmapsto H, C, G, N.$$

It exports a finite completion handoff for downstream completion, Baire, and fixed-point packets; it does not export a quotient completion class, a selected dense sequence, host point equality, or an ambient real-completeness principle.

Proof. Read X from the carrier in Definition 4293.1. The Polish source supplies the common complete separable metric surface, while D, S, R display the finite dense-window observations available to the packet.

Use the NameCert obligations of Definition 4293.2. The basis-directedness and dense-schedule compatibility clauses force the Cauchy-filter basis row B to be read through the same stream windows, regular readbacks, and observation ledger as the dense schedule.

The completion-handoff clause then places K after B, S, R, O. Transport by H and replay by C preserve that order, while G, N package and name the same route. Therefore every completion-facing consumer receives only the displayed finite handoff and cannot bypass it through choice, quotient equality, host point equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{PolishCauchyBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{PolishCauchyBasis}^{\uparrow}$ packet is generated from a PolishSpace source, CauchyFilterBasis basis, CompleteMetric handoff, SeparableMetric dense schedule, StreamName windows, RegSeqRat readback, an observation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PolishCauchyBasis}^{\uparrow}}$, seed)

Scope closed: Definition 4293.1, Definition 4293.2, and Definition 4293.3 seed the basis-level Cauchy handoff from Polish-space data to completion-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PolishCauchyBasis}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close choice-selected dense points, quotient completions, host point equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-source classification, basis-directedness exposure, dense-schedule compatibility, completion-handoff non-escape, transport, replay, provenance, and local naming for the same packet.

Chapter 4294

A Concrete Naming Certificate for $\mathsf{SymmetryRestorationStabilizer}^{\uparrow}$

The $\mathsf{SymmetryRestorationStabilizer}^{\uparrow}$ packet realizes the hidden Q_6 stabilizer and orbit-persistence rows of Definition 9462.1352, Definition 9462.1354, Definition 9462.1356, and Definition 9462.1362 as finite BEDC NameCert data. It consumes the six-coordinate codon window of chapter 2234, the boundary tile packet of chapter 3393, the codon lift-orbit classifier of chapter 4059, and the median-closure surface of chapter 3545. The packet exposes support, stabilizer, orbit, and median-closure rows before any consumer may claim the hidden C_2 persistence or the restored $S_3 \times C_2$ surface.

Definition 4294.1 (Symmetry restoration stabilizer carrier)**.** *A* $\mathsf{SymmetryRestorationStabilizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, A, T, U, M, O, R, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite Q_6 codon-window row, including the six bit coordinates inspected by the stabilizer calculation.*
2. *A is the active-support row for $\mathcal{R}$ and its inactive-anchor closure, read through the boundary-tile packet.*
3. *T is the hidden C_2 stabilizer row, naming the identity and the coordinate transposition $\tau : s_1 \leftrightarrow f_2$ from Definition 9462.1352.*
4. *U is the orbit-persistence row, recording the active-support, inactive-anchor, and first-median-layer orbits of τ from Definition 9462.1354.*
5. *M is the median-closure stabilizer row, recording the displayed $S_3 \times C_2$ restoration surface of Definition 9462.1356.*
6. *O is the orbit ledger joining the nontrivial C_2 orbits, the median-closure orbit table, and the sealing-corner orbit-completion row.*
7. *R is the refusal row separating support symmetry from weighted reassignment symmetry, and excluding biological causality, stochastic fitness, host quotient codon semantics, and hidden enumeration oracles.*

8. *H records componentwise* hsame *transport for Q, A, T, U, M, O, R and for the local certificate rows.*

9. *C records displayed* Cont *replay from a support read through the stabilizer row, orbit-persistence row, median-closure row, orbit ledger, and refusal row.*

10. *P is the* Pkg *provenance over* $\mathsf{SymmetryRestorationStabilizer}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}$ $\mathsf{CodonLiftOrbitClassifier}^{\uparrow}$, $\mathsf{MedianClosure}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SymmetryRestorationStabilizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, A, T, U, M, O, R, H, C, P, N$. It has no coordinate for an unstated support set, an unrecorded stabilizer enumeration, a host quotient codon object, a biological mechanism, or a weighted-symmetry substitute for the support stabilizer.

Lean4 ✓ `BEDC.Derived.SymmetryRestorationStabilizerUp.SymmetryRestorationStabilizerTasteGate`
`single carrier alignment`

Theorem 4294.2 (Symmetry restoration stabilizer NameCert obligations)**.** *For every accepted* $\mathsf{SymmetryRestorationStabilizer}^{\uparrow}$ *carrier $S = (Q, A, T, U, M, O, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SymmetryRestorationStab}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the Q_6 codon window, active support, hidden C_2 stabilizer, orbit-persistence row, median-closure stabilizer, orbit ledger, refusal row, transport, continuation, provenance, and local naming row;*

2. *support visibility, requiring every stabilizer or orbit read to expose the active-support row A before reading T, U, M, or O;*

3. *stabilizer exactness, requiring the hidden C_2 row T to name only the identity and $\tau : s_1 \leftrightarrow f_2$ for the active-support and first-median-layer reads;*

4. *median-closure compatibility, requiring the restored $S_3 \times C_2$ row M to be read only after the median-closure surface and its orbit ledger are displayed;*

5. *orbit non-escape, requiring any hidden C_2 orbit claim to pass through $A, T, U, M, O, H, C, P, N$;*

6. *package provenance and local* NameCert *naming for exactly the displayed packet.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 4294.1. The projection exposes the codon window, active support, stabilizer row, orbit-persistence row, median-closure stabilizer, orbit ledger, refusal row, and the structural rows H, C, P, N.

Support visibility comes first. The row A is the source for the stabilizer calculation, so T, U, M, and O cannot be read as free group-theoretic objects detached from the displayed support.

The stabilizer exactness row is T. It records exactly the identity and the transposition $\tau : s_1 \leftrightarrow f_2$ for the active-support surface, while U records the same nonidentity element along the inactive-anchor and first-median-layer rows.

The median-closure compatibility row is M, with orbit data stored in O. Transport by H and replay by C preserve this order, and P, N package and name the same rows. Thus no hidden orbit claim escapes the displayed support, stabilizer, median-closure, transport, replay, provenance, and local naming surface. □

Theorem 4294.3 (Symmetry restoration orbit non-escape)**.** *Every consumer claiming the hidden C_2 orbit of an accepted* $\mathsf{SymmetryRestorationStabilizer}^{\uparrow}$ *packet must display the support row A,*

the stabilizer row T, the orbit-persistence row U, the median-closure row M, the orbit ledger O, componentwise transport H, displayed replay C, package provenance P, and local NameCert *row N. The visible route is*

$$Q, A \longmapsto T, U \longmapsto M, O \longmapsto H, C, P, N.$$

It cannot be replaced by a host stabilizer calculation, an unrecorded orbit enumeration, a weighted-reassignment symmetry, quotient codon semantics, or a biological mechanism claim.

Proof. Read Q, A from the carrier in Definition 4294.1. These rows provide the finite codon-window coordinates and the active support over which the stabilizer calculation is meaningful.

Apply the NameCert obligations of Definition 4294.2. Support visibility and stabilizer exactness place T and U after A, while median-closure compatibility places M and O after the displayed closure surface.

Finally use orbit non-escape. The rows H, C, P, N transport, replay, source, and name the same finite route, and the refusal row separates it from weighted reassignment symmetry or host enumeration. Therefore a hidden C_2 orbit consumer must pass through the displayed packet and cannot claim the orbit from outside it. □

Falsifiable prediction: Any consumer claiming the hidden C_2 orbit without displaying support, stabilizer, median-closure, hsame, Cont, Pkg, and NameCert rows refutes the SymmetryRestorationStabilizer$^{\uparrow}$ packet.

Independence witness: q-six orbit/classification, median-closure sibling slugs: SymmetryRestorationStabilizer$^{\uparrow}$ is not bijective to the orbit/classification or median-closure siblings because this packet jointly carries active support, hidden C_2 stabilizer, orbit persistence, restored median-closure stabilizer, orbit ledger, refusal, componentwise transport, replay, provenance, and local naming as one accepted surface.

The Lean TasteGate file for this packet must include Nontrivial and FieldFaithful instances. The field-faithfulness witness keeps $Q, A, T, U, M, O, R, H, C, P, N$ as distinct rows so a checked TasteGate theorem can rule out hidden-orbit claims that omit the support, stabilizer, or median-closure coordinates.

Closure status for NameCert$_{\text{SymmetryRestorationStabilizer}^{\uparrow}}$.

Constructive story: A SymmetryRestorationStabilizer$^{\uparrow}$ packet is generated from Q6 codon-window rows, active-support rows, hidden C2 stabilizer rows, orbit-persistence rows, median-closure stabilizer rows, orbit ledgers, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{SymmetryRestorationStabilizer}^{\uparrow}}$, seed)

Scope closed: Definition 4294.1, Definition 4294.2, and Definition 4294.3 seed the finite support-stabilizer packet for the hidden Q6 orbit and median-closure restoration surface.

Formal verification: FormalStatus(NameCert$_{\text{SymmetryRestorationStabilizer}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological causality, stochastic fitness, quotient codon semantics, host stabilizer enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked codon-window admission, support visibility, stabilizer exactness, orbit persistence, median-closure compatibility, orbit non-escape, refusal preservation, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.SymmetryRestorationStabilizerUp.

Chapter 4295

A Concrete Naming Certificate for $\mathsf{KolmogorovContinuity}^{\uparrow}$

Following Kolmogorov's continuity criterion, the $\mathsf{KolmogorovContinuity}^{\uparrow}$ packet records a finite-modulus continuity test for stochastic-process windows as displayed BEDC data. It consumes the probability carrier of chapter 184, the random-variable preimage surface of chapter 185, the metric-space rows of chapter 4230, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the finite difference and modulus ledger; it is not a host path-continuity theorem, a choice of continuous modification, a quotient sample-path object, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 4295.1 (Kolmogorov continuity carrier)**.** *A* $\mathsf{KolmogorovContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, M, S, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite difference ledger, listing inspected process windows, endpoint pairs, random-variable rows, metric-distance requests, and the probability-space row used for each two-time difference.*
2. *M is the moment and finite-modulus ledger. It records the displayed exponent, scale, tolerance, and decay rows that certify the Kolmogorov bound on the inspected two-time differences.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that names the finite time and sample observations read by the process consumer.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational moment and modulus bounds extracted from I, M, S.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the real-valued bound reached only after the displayed regular rational readback.*
6. *E is the* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{RandomVar}^{\uparrow}$ *endpoint-exposure row, keeping metric distance and random-variable measurability attached to the same inspected two-time difference.*
7. *H records componentwise* hsame *transport for two-time difference rows, moment/modulus rows, StreamName windows, RegSeqRat readback, Real seals, metric/random-variable exposure, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay of the finite route*

$$I, M, S \longmapsto Q \longmapsto R \longmapsto E \longmapsto H.$$

9. *P is the* Pkg *provenance over* $\mathsf{KolmogorovContinuity}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{KolmogorovContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, M, S, Q, R, E, H, C, P, N$. It has no coordinate for ambient path continuity, a selected continuous modification, quotient sample paths, countable-choice schedules, host equality of stochastic processes, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.KolmogorovContinuityUp.KolmogorovContinuityTasteGate single carrier alignment`
Lean4 (definition) `BEDC.Derived.KolmogorovContinuityUp.KolmogorovContinuityCarrier`

Theorem 4295.2 (KolmogorovContinuityUp NameCert obligations)**.** *For every accepted* $\mathsf{KolmogorovContinuity}^{\uparrow}$ *carrier*

$$K = (I, M, S, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KolmogorovContinuity}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *two-time difference admission for I, requiring every inspected endpoint pair, process row, random-variable row, metric-distance request, and probability-space row to be displayed;*
2. *moment and modulus admission for M, requiring the exponent, scale, tolerance, and decay rows used by the criterion to be named as finite ledger data;*
3. *StreamName observation for S, requiring all time and sample windows consumed by the two-time difference rows to be displayed before any regular-rational readback;*
4. *regular-rational readback for Q, requiring moment and modulus bounds to pass through the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *surface;*
5. *Real seal exposure for R, requiring every real-valued bound to be reached only after Q;*
6. *metric and random-variable endpoint exposure for E, requiring distance and measurability rows to remain attached to the same inspected two-time difference;*
7. *transport, replay, provenance, and local naming through H, C, P, N, preserving exactly the displayed continuity-criterion packet.*

No Kolmogorov continuity obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 4295.1. The two-time difference ledger I supplies the only endpoint pairs and stochastic-process rows available to a consumer, and each such row already displays its $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, and $\mathsf{Met}^{\uparrow}$ support.

Read the moment and finite-modulus ledger M together with the observation row S. These rows name the inspected windows, exponents, scales, tolerances, and decay data before any readback can be exported.

The regular-rational row Q is the only route from the finite moment/modulus ledger to a numerical bound, and the real seal R is downstream of Q. The endpoint-exposure row E keeps the metric and random-variable coordinates attached to the same two-time difference rather than letting them become ambient path data.

Finally H, C, P, N transport, replay, source, and name the same tuple. Since the carrier has no coordinate for ambient path continuity, selected modifications, quotient sample paths, countable

choice, host process equality, or $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the local naming surface. □

Theorem 4295.3 (KolmogorovContinuityUp finite-modulus route)**.** *Every continuity-facing consumer of an accepted* $\mathsf{KolmogorovContinuity}^{\uparrow}$ *packet reads the criterion through the finite route*

$$\mathsf{ProbSpace}^{\uparrow},\ \mathsf{RandomVar}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Concretely, a two-time difference row first displays its probability-space, random-variable, and metric-distance support; the same request then exposes a finite StreamName window, a moment/modulus ledger, a regular rational readback, and only then a terminal real seal. The route exports a finite-modulus continuity criterion, not ambient path continuity, a chosen continuous modification, quotient sample paths, host process equality, countable choice, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $K = (I, M, S, Q, R, E, H, C, P, N)$. By Definition 4295.2, a two-time difference read must first display the rows in I and the endpoint support in E, so the probability, random-variable, and metric data are fixed before a continuity-facing consumer sees a bound.

The same obligation surface places the finite StreamName window S and moment/modulus ledger M before the regular-rational readback Q. Thus the criterion is read from displayed windows and finite decay rows rather than from an infinite sample path.

The real-facing step is controlled by R, which is downstream of Q. Componentwise hsame transport and Cont replay preserve this order, while Pkg provenance and the local NameCert row name exactly the same route.

Therefore every consumer factors through the displayed finite-modulus path. The excluded path-continuity, modification-choice, quotient-sample-path, host-equality, countable-choice, and completeness claims are absent from the carrier and cannot be recovered from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{KolmogorovContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{KolmogorovContinuity}^{\uparrow}$ packet is generated from finite two-time difference rows, moment and modulus ledger rows, StreamName windows, RegSeqRat readback, Real seals, metric and random-variable endpoint exposure, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KolmogorovContinuity}^{\uparrow}}$, seed)

Scope closed: Definition 4295.1, Definition 4295.2, and Definition 4295.3 seed the finite-modulus continuity criterion over probability, random-variable, metric, StreamName, RegSeqRat, Real, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KolmogorovContinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient path continuity, chosen continuous modifications, quotient sample paths, countable choice, host process equality, RealUp completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked two-time difference admission, moment/modulus admission, StreamName observation, RegSeqRat readback, Real seal exposure, endpoint exposure, and transport/provenance/name exhaustion for BEDC.Derived.KolmogorovContinuityUp.

Chapter 4296

A Concrete Naming Certificate for $\mathsf{TaggedRealPartition}^{\uparrow}$

Following Bishop and Bridges constructive integration, the $\mathsf{TaggedRealPartition}^{\uparrow}$ packet records a finite partition of a located real interval together with a displayed tag inside each cell. It refines the located partition carrier of chapter 2248 and the oscillation-controlled partition carrier of chapter 3800; it also reads its endpoint and tag data through the $\mathsf{StreamName}^{\uparrow}$ source of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies the finite tag-bearing surface needed by L10 integration and oscillation routes without replacing it by an untagged mesh, a host partition object, selected representatives, quotient real equality, countable choice, or ambient completeness.

Definition 4296.1 (Tagged real partition carrier)**.** *A* $\mathsf{TaggedRealPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, M, A, G, O, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$ *row exposing the located interval, finite cell order, endpoint containment, and mesh precision.*
2. *M is the finite mesh row inherited from I, listing adjacent cells and the common refinement ledger used by later integration consumers.*
3. *A is the cell-containment row, certifying for every mesh cell that its endpoints and rational witness rows remain inside the located interval source.*
4. *G is the tag row family, assigning to every displayed cell a tag history whose* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *reads certify containment in that same cell before any* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*
5. *O is the oscillation and modulus ledger, recording the tolerance request, the cellwise oscillation bound, and the refinement compatibility supplied by* $\mathsf{FiniteOscillationPartition}^{\uparrow}$*.*
6. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened for interval endpoints, cell endpoints, and tags.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family for the same finite windows and mesh precision.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal family reached only after the source interval, cell containment, tag containment, oscillation ledger, window, and regular readback rows have been displayed.*

9. *H records componentwise* hsame *transport for I, M, A, G, O, S, R, E and for the replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a tagged-partition read through*

$$I, M, A, G, O, S, R, E \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{LocatedRealIntervalPartition}^{\uparrow}$, $\mathsf{FiniteOscillationPartition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{TaggedRealPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these displayed interval-source, mesh, containment, tag, oscillation, window, readback, seal, transport, replay, provenance, and local naming rows. It has no coordinate for a host tagged partition, an unbounded tag selector, quotient real equality, chosen completed tag values, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.TaggedRealPartitionUp.TaggedRealPartitionTasteGate single carrier alignment`

Theorem 4296.2 (Tagged real partition NameCert obligations)**.** *For every accepted* $\mathsf{TaggedRealPartition}^{\uparrow}$ *carrier $T = (I, M, A, G, O, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TaggedRealPartition}^{\uparrow}}$ *surface consists exactly of carrier admission, located interval and mesh exposure through I, M, cell-containment certification through A, tag containment through G, oscillation and modulus accounting through O, finite* $\mathsf{StreamName}^{\uparrow}$ *windows through S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *seals through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Every integration-facing or oscillation-facing read of the tagged partition must therefore pass through the displayed finite mesh, tag-containment, oscillation, window, readback, and seal rows before any terminal real-value consumer is allowed to inspect the packet.

Proof. Project the carrier of Definition 4296.1. The tuple lists the only rows available to a tagged-partition consumer: the interval source, mesh, containment ledger, tag rows, oscillation ledger, finite windows, regular readbacks, real seals, transport, replay, provenance, and local naming rows.

The source interval and cell obligations are I, M, A. The located partition row supplies the interval and mesh; the containment row attaches each cell to the same source, so a tag cannot be read against a detached host interval.

The tag and oscillation obligations are G, O. The tag row certifies cell membership for each tag through the same finite-window and regular-readback route, while the oscillation row records the tolerance and refinement ledger inherited from the oscillation-partition packet.

The readback and seal obligations are S, R, E. A consumer reaches the StreamName windows only after the interval, cell, tag, and oscillation rows are visible, then reads the regular rational rows and finally the terminal Real seal.

The structural rows H, C, P, N transport, replay, package, and name exactly this route. Since the carrier has no coordinate for a host tagged partition, an unbounded selector, quotient real equality, chosen completed tag values, countable choice, or ambient completeness, the displayed NameCert obligations exhaust the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{TaggedRealPartition}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TaggedRealPartition}^{\uparrow}$ packet is generated from a LocatedRealIntervalPartitionUp source, finite mesh and cell-containment rows, per-cell tag rows, oscillation and modulus ledgers, StreamName windows, RegSeqRat readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{TaggedRealPartition}\uparrow}$, seed)

Scope closed: Definition 4296.1 and Definition 4296.2 seed the finite tag-bearing partition interface for L10 integration and oscillation consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{TaggedRealPartition}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close integration convergence, Darboux sums, quotient real equality, selected tag values, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cell containment, tag containment, oscillation-modulus accounting, StreamName windows, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.TaggedRealPartitionUp.

Chapter 4297

A Concrete Naming Certificate for $\mathsf{FiniteFanBarModulus}^{\uparrow}$

Following Brouwer's fan theorem and Bishop–Bridges finite-bar analysis, the $\mathsf{FiniteFanBarModulus}^{\uparrow}$ packet records the finite carrier that turns admitted fan-bar rows and local modulus rows into a tolerance-only uniform-modulus ledger. It sits over the fan certificate of chapter 400, the compact metric finite-net surface of chapter 129, the continuous-map carrier of chapter 130, the rational lower-bound fold of chapter 4118, the $\mathsf{Rat}^{\uparrow}$ arithmetic source of chapter 37, and the $\mathsf{UniformModulus}^{\uparrow}$ handoff of chapter 369. It realizes the compact-uniform-continuity route of chapter 9237 without importing open-cover compactness, selected infinite branches, countable choice, quotient function equality, selected limits, or ambient real completeness.

Definition 4297.1 (Finite fan-bar modulus carrier)**.** *A* $\mathsf{FiniteFanBarModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, K, L, Q, R, U, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite fan-bar admission row, recording the fan, decidable bar classifier, finite depth bound, and finite branch-prefix witness window.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-probe row, aligning the bar prefixes with the compact finite-net probes consumed by the compact-uniform-continuity route.*
3. *L is the local modulus row read from the* $\mathsf{ContinuousMap}^{\uparrow}$ *packet at each admitted bar or probe entry.*
4. *Q is the positive* $\mathsf{Rat}^{\uparrow}$ *radius and tolerance row, carrying the finitely many local radii and requested tolerances.*
5. *R is the lower-bound modulus extraction row, obtained by primitive recursion over the finite fan-bar and probe bundle and by certified rational comparison in Q.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row, exposing the extracted lower bound as a tolerance-only modulus ledger.*
7. *H records componentwise* hsame *transport for the bar, compact-probe, local-modulus, rational, extraction, uniform-modulus, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the finite route*

$$B, K, L, Q \longmapsto R \longmapsto U.$$

9. *P is the* Pkg *provenance over* FiniteFanBarModulus$^\uparrow$, FanTheorem$^\uparrow$, CompactMetric$^\uparrow$, ContinuousMap$^\uparrow$, UniformModulus$^\uparrow$, Rat$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{FiniteFanBarModulus}^\uparrow}$ *row.*

The classifier compares accepted packets only through $B, K, L, Q, R, U, H, C, P, N$. It has no coordinate for an open cover, a selected infinite branch, countable choice, quotient equality of maps, selected limits, a host compactness theorem, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.FiniteFanBarModulusUp.FiniteFanBarModulusTasteGate single carrier alignment`

Theorem 4297.2 (Finite fan-bar modulus NameCert obligations)**.** *For every accepted* FiniteFanBarModulus$^\uparrow$ *carrier $F = (B, K, L, Q, R, U, H, C, P, N)$, the local* NameCert$_{\text{FiniteFanBarModulus}^\uparrow}$ *surface consists exactly of carrier admission, finite bar admission through B, compact finite-probe alignment through K, local continuous-map modulus exposure through L, positive rational radius accounting through Q, lower-bound modulus extraction through R,* UniformModulus$^\uparrow$ *handoff through U, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

In particular, a compact-uniform-continuity consumer may read a uniform modulus from this packet only after the finite bar, compact-probe, local-modulus, rational-radius, and lower-bound extraction rows have all been displayed.

Proof. Project the carrier of Definition 4297.1. The tuple displays exactly the finite bar, compact-probe, local-modulus, rational-radius, lower-bound extraction, uniform-modulus, transport, replay, provenance, and local naming rows.

Finite bar admission is the row B. It supplies the decidable bar classifier and finite depth witness, so the argument ranges over displayed finite prefixes rather than selected infinite branches.

The compact and local-modulus data are K, L, Q. The compact-probe row aligns finite bar prefixes with compact finite-net probes, the continuous-map row supplies local moduli at those probes, and the rational row stores the positive local radii and tolerance requests.

Lower-bound extraction is the row R. It is obtained by primitive recursion over the finite bar and probe rows, using the positive rational comparisons in Q to retain a certified lower bound for all admitted local radii.

Finally, U, H, C, P, N expose, transport, replay, source, and name that extracted lower bound as a UniformModulus$^\uparrow$ ledger. Since the carrier has no coordinate for open-cover compactness, branch selection, countable choice, quotient function equality, selected limits, host compactness, or ambient completeness, the displayed obligations exhaust the accepted packet. □

Theorem 4297.3 (Finite fan-bar lower-bound modulus extraction)**.** *Every compact-uniform-continuity read of an accepted* FiniteFanBarModulus$^\uparrow$ *packet factors through*

$$B, K, L, Q, R, U, H, C, P, N.$$

The extracted row R is the only lower-bound modulus source available to the UniformModulus$^\uparrow$ *consumer: it is computed from finite fan-bar admission, compact finite-probe alignment, local continuous-map moduli, and positive* Rat$^\uparrow$ *radius comparisons, and it exports no open-cover subcover, selected branch, selected limit, quotient map equality, or ambient compactness datum.*

Proof. Start with the NameCert obligations of Definition 4297.2. They require every compact-uniform-continuity consumer to read B, K, L, Q before the lower-bound row R is available.

The extraction step is finite. The bar depth and compact probe rows determine the finite index family, and the positive rational ledger compares the finitely many local radii by primitive recursion to produce a certified lower bound.

Once R is displayed, the uniform-modulus row U may consume it as a tolerance-only ledger. The structural rows H, C, P, N preserve and name the same route under componentwise transport and replay.

No excluded datum can be read from the carrier. Open-cover compactness, selected branches, selected limits, quotient map equality, countable choice, and ambient compactness are absent from $B, K, L, Q, R, U, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteFanBarModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteFanBarModulus}^{\uparrow}$ packet is generated from finite fan-bar admission, compact finite-probe alignment, local ContinuousMap modulus rows, positive RatUp radius ledgers, lower-bound extraction, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteFanBarModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4297.1, Definition 4297.2, and Definition 4297.3 seed the finite fan-bar lower-bound route consumed by compact-uniform-continuity and UniformModulus rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteFanBarModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite branches, countable choice, quotient function equality, selected limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite bar admission, compact finite-probe alignment, local modulus exposure, RatUp lower-bound extraction, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteFanBarModulusUp.

Chapter 4298

A Concrete Naming Certificate for $\mathsf{EdelsteinFixedPoint}^{\uparrow}$

Following Edelstein's compact-metric fixed-point theorem and Bishop–Bridges constructive metric practice, the $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ packet records the finite NameCert surface for a strictly contractive self-map on a compact metric carrier. It sits after the metric source of chapter 57, the compact-metric finite inspection surface of chapter 129, the sequential map discipline of chapter 1466, the contraction comparison row of chapter 3529, and the displayed iteration route of chapter 2359. The packet names only the compact source, the strict distance-decrease row, the sequential-continuity row, the orbit comparison ledger, transport, replay, provenance, and local naming; it does not import choice, quotient completion, a selected host fixed point, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a Banach contraction ratio.

Definition 4298.1 (Edelstein fixed-point carrier)**.** *An* $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, K, F, O, C, S, H, R, P, N)$$

with the following displayed rows:

1. *X is the underlying* $\mathsf{Met}^{\uparrow}$ *source row, carrying the point classifier and the distance observations inspected by the fixed-point consumer.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *row over X, exposing only the finite compactness windows and cluster-service rows accepted by the compact-metric certificate.*
3. *F is the self-map row, presented through the same metric carrier and never as an untracked host function.*
4. *O is the orbit row generated from F, recording the displayed Picard-style finite prefix consumed by the fixed-point search.*
5. *C is the strict contraction-comparison row: whenever the inspected points are classified as distinct by the metric row, the displayed distance from $F(x)$ to $F(y)$ is strictly below the displayed distance from x to y.*
6. *S is the* $\mathsf{SequentialContinuity}^{\uparrow}$ *row for F, binding cluster reads of the orbit to the image row without adding a semantic continuity theorem outside the displayed packet.*
7. *H stores componentwise* hsame *transport for metric, compactness, self-map, orbit, contraction-comparison, sequential-continuity, continuation, provenance, and naming rows.*

8. *R stores displayed* Cont *replay from the orbit row to the compact cluster row, from the cluster row through sequential continuity, and from the strict comparison row to the fixed-point equality boundary.*

9. *P is the* Pkg *provenance over* $\mathsf{EdelsteinFixedPoint}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{SequentialContinuity}^{\uparrow}$, $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{EdelsteinFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, K, F, O, C, S, H, R, P, N$. It has no coordinate for quotient completion, countable choice, a Banach contraction constant, an ambient complete real line, or a host-selected fixed point.

Lean4 ✓ `BEDC.Derived.EdelsteinFixedPointUp.EdelsteinFixedPointTasteGate single carrier alignment`

Theorem 4298.2 (Edelstein fixed-point NameCert obligations)**.** *For every accepted* $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ *carrier $E = (X, K, F, O, C, S, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EdelsteinFixedPoint}^{\uparrow}}$ *surface consists exactly of metric carrier admission through X, compact-metric finite inspection through K, self-map admission through F, Picard-style orbit exposure through O, strict contraction comparison through C, sequential-continuity cluster transport through S, componentwise* hsame *transport through H, displayed* Cont *replay through R,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.EdelsteinFixedPointUp.EdelsteinFixedPointCarrier namecert obligations`

Proof. Project the carrier of Definition 4298.1. The metric row X and compact-metric row K are the only source rows available to the certificate, so every inspected point, distance comparison, and compactness read is routed through those two displayed surfaces.

The self-map row F and orbit row O provide the visible finite Picard-style prefix. The strict comparison row C is separate from the Banach contraction surface: it records pointwise distance decrease on distinct displayed pairs and carries no global contraction ratio.

The sequential-continuity row S is the only route from a compact cluster read of the orbit to an image read under F. Transport through H, replay through R, provenance through P, and naming through N preserve this same finite route, so the listed rows exhaust the local NameCert obligations. □

Theorem 4298.3 (Edelstein compact-route nonescape)**.** *Every fixed-point read exported by an accepted* $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ *packet factors through the internal route*

$$X \longmapsto K \longmapsto O \longmapsto S \longmapsto C$$

together with F, H, R, P, N. The route may compare with the $\mathsf{BanachContraction}^{\uparrow}$ *and* $\mathsf{PicardIteration}^{\uparrow}$ *neighbours as named dependency rows, but it does not consume a Banach contraction constant, quotient completion equality, selected subsequence principle, choice operator, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with a fixed-point read. The carrier first exposes the metric source X and the compactness service K, so the consumer can only inspect displayed finite compact-metric windows and the point classifier attached to X.

The orbit row O supplies the visible Picard-style finite prefix for the self-map F. Compactness is consumed only through K, and the image of a cluster read is transported only through the sequential-continuity row S.

The strict comparison row C is then the only row that can rule out a non-fixed distinct-pair boundary. Since C contains no global ratio and the remaining rows H, R, P, N only transport, replay, source, and name the same finite data, the exported route cannot leave the displayed Edelstein packet for choice, quotient completion, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ fixed-point read factors through one MetricUp source row, one CompactMetricUp finite inspection row, one self-map row, one PicardIterationUp-style orbit row, one strict comparison row, one SequentialContinuityUp cluster-transport row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compactmetric, sequentialcontinuity, banach-contraction, picard-iteration: $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact-metric cluster service, strict pointwise distance decrease, and sequential-continuity image transport without a Banach ratio, selected endpoint, quotient completion, or ambient completeness coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{EdelsteinFixedPoint}^{\uparrow}}$.

Constructive story: An $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ packet is generated from a MetricUp source row, a CompactMetricUp finite inspection row, a displayed self-map row, a PicardIterationUp-style orbit row, a strict distance-decrease comparison row, a SequentialContinuityUp cluster-transport row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EdelsteinFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4298.1, Definition 4298.2, and Definition 4298.3 bind the compact-metric strict-contraction route through the displayed orbit, cluster, sequential-continuity, and comparison rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EdelsteinFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point equality, uniqueness, quotient completion equality, Banach contraction constants, selected fixed points, choice principles, bridge checking, Lean verification, or ambient real completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-metric inspection, orbit exposure, strict comparison, sequential-continuity cluster transport, nonescape, replay, provenance, and local naming for BEDC.Derived.EdelsteinFixedPointUp

Chapter 4299

A Concrete Naming Certificate for $\mathsf{CompletionLadder}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CompletionLadder}^{\uparrow}$ packet records the finite BEDC naming surface that ties the current Real and Completion route into one phase object. It sits over the dyadic tolerance ledger of chapter 291, the finite-window stream surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the separated-completion boundary of chapter 1612, and the completion-unit handoff of chapter 1527. The ladder is a finite dependency packet for the phase route; it is not quotient stream equality, not a selected limit, not countable choice, not trichotomy, not open-cover compactness, and not a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4299.1 (Completion ladder carrier)**.** *A* $\mathsf{CompletionLadder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, W, R, E, S, U, H, C, P, N)$$

with the following visible rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic tolerance row naming the precision requests that enter the route.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *stream-window row listing the finite observations read at those tolerances.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row obtained from D and W.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the dyadic tolerance, stream window, and regular readback rows have been displayed.*
5. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *witness row that consumes the same displayed real-facing route as a separated completion boundary.*
6. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *unit row that records the source-to-completion handoff along the same finite route.*
7. *H records componentwise* hsame *transport for dyadic tolerance, stream window, regular readback, Real seal, separated-completion witness, Cauchy-completion unit, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$D, W \longmapsto R \longmapsto E \longmapsto S, U.$$

9. *P is the* Pkg *provenance over* $\mathsf{CompletionLadder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionLadder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, R, E, S, U, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CompletionLadderUp.CompletionLadderTasteGate single carrier alignment`

Theorem 4299.2 (Completion ladder NameCert obligations)**.** *For every accepted* $\mathsf{CompletionLadder}^{\uparrow}$ *carrier $L = (D, W, R, E, S, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionLadder}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic tolerance, stream window, regular readback, Real seal, separated-completion witness, Cauchy-completion unit, componentwise transport, continuation replay, package provenance, and local naming rows;*
2. *tolerance-window compatibility, requiring each finite stream read in W to be indexed by a dyadic tolerance request in D before regular readback is inspected;*
3. *regular-readback exactness, requiring every* $\mathsf{RegSeqRat}^{\uparrow}$ *read in R to consume only the displayed D, W route;*
4. *Real-seal order, requiring E to be read only after D, W, R have been displayed;*
5. *completion-boundary order, requiring S and U to consume the same D, W, R, E route through the stored continuation row C;*
6. *transport stability, requiring componentwise* hsame *transport in H to preserve the listed route and no other completion data;*
7. *ledger non-escape, excluding quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, and completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Carrier admission is projection from Definition 4299.1. The tuple lists the dyadic tolerance row, stream-window row, regular readback row, Real seal, separated-completion witness, Cauchy-completion unit, transport rows, replay row, provenance, and local name.

The first dependency step reads D and W. Since W is the only stream-window coordinate and D is the only tolerance coordinate, each finite observation entering the regular readback must pass through those two rows.

The regular readback row R is then downstream of D, W, and the Real seal row E is downstream of R. The replay row C records this order before either completion-facing row is inspected.

The separated-completion witness S and Cauchy-completion unit U therefore consume the same displayed D, W, R, E route. Componentwise transport by H preserves those rows, while P and N source and name the same packet.

No remaining coordinate can export quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness. Thus the listed rows exhaust the local NameCert surface. □

Theorem 4299.3 (Completion ladder separated Real route)**.** *Every accepted* $\mathsf{CompletionLadder}^{\uparrow}$ *carrier factors any separated-completion or completion-unit consumer through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{SeparatedCompletion}^{\uparrow},\quad \mathsf{CauchyCompletionUnit}^{\uparrow}.$$

Equivalently, a consumer of S or U must first read the displayed dyadic tolerance row D, stream-window row W, regular readback row R, and Real seal row E, with componentwise transport, continuation replay, provenance, and local naming supplied by H, C, P, N.

Proof. Start from an accepted carrier $L = (D, W, R, E, S, U, H, C, P, N)$. The only completion-facing rows are S and U, so any separated-completion or completion-unit consumer must inspect one of those coordinates.

The definition places both coordinates after D, W, R, E. The continuation row C records the same order, forcing each consumer read to pass from dyadic tolerance and finite window through regular rational readback before the Real seal is available.

Componentwise hsame transport by H may rename the rows, but it preserves the displayed route rather than adding a second stream, a chosen limit, or a host completion object. The package and local name rows P, N then record that the consumer is reading the same finite packet.

Since the carrier contains no row for quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, or $\mathsf{Real}^{\uparrow}$ completeness, the separated Real route above is the whole exported completion-facing surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionLadder}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionLadder}^{\uparrow}$ packet is generated from DyadicRatCore tolerance requests, StreamName finite windows, RegSeqRat readback, a RealUp seal, a SeparatedCompletion witness, a CauchyCompletionUnit handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionLadder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4299.1, Definition 4299.2, and Definition 4299.3 seed the finite Real and Completion ladder over DyadicRatCore, StreamName, RegSeqRat, Real, SeparatedCompletion, CauchyCompletionUnit, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionLadder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, bridge checking, Lean verification, or completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-window compatibility, regular readback exactness, Real-seal order, separated-completion routing, completion-unit routing, componentwise transport stability, and ledger non-escape for BEDC.Derived.CompletionLadderUp.

Chapter 4300

A Concrete Naming Certificate for $\mathsf{LocatedFormalBar}^{\uparrow}$

Following Brouwer, Troelstra–van Dalen, and Vickers, the $\mathsf{LocatedFormalBar}^{\uparrow}$ packet records a finite located bar/cover boundary for spread paths and formal-topology cover requests. It sits after the cover/refinement carrier of chapter 3967, the admissible-prefix discipline of chapter 1532, the bar-recursion route of chapter 1675, and the finite observation interface of chapter 126. The packet supplies Real and Completion consumers with a finite bar boundary without importing open-cover compactness, selected points, quotient opens, countable choice, or ambient completeness.

Definition 4300.1 (Located formal-bar carrier)**.** *A* $\mathsf{LocatedFormalBar}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, S, B, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FormalTopology}^{\uparrow}$ *cover/refinement row, read through chapter 3967, that names the finite basic neighbourhoods and refinement requests used by the bar.*
2. *S is the* $\mathsf{SpreadLaw}^{\uparrow}$ *admissible-prefix row, read through chapter 1532, that determines which finite path prefixes can enter the bar ledger.*
3. *B is the* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *bar-recursion row, read through chapter 1675, that records the finite induction surface consumed by bar-cover arguments.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, read through chapter 126, that exposes the inspected prefix windows for Real and Completion routes.*
5. *Q is the located-query row: each accepted request names a finite prefix, a formal basic neighbourhood, and the bar-cover decision boundary visible at that prefix.*
6. *R is the spread-cover row, recording the finite route from an admissible prefix through the formal cover row to the bar-recursion row.*
7. *H records componentwise* hsame *transport for formal-cover rows, spread-law prefixes, bar-recursion rows, StreamName windows, located-query rows, spread-cover rows, replay rows, provenance rows, and local naming rows.*
8. *C records displayed* Cont *replay from a Real or Completion finite-window request through $F, S, B, W, Q, R, H, P, N$*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedFormalBar}^{\uparrow}$, $\mathsf{FormalTopology}^{\uparrow}$, $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedFormalBar}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, a selected infinite path, a selected point of a cover, quotient-open equality, countable choice, host topological equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.LocatedFormalBarUp.LocatedFormalBarTasteGate single carrier alignment`

Theorem 4300.2 (Located formal-bar spread-cover route)**.** *Every accepted* $\mathsf{LocatedFormalBar}^{\uparrow}$ *carrier*

$$L = (F, S, B, W, Q, R, H, C, P, N)$$

routes a Real or Completion finite-window consumer through the same displayed spread-cover boundary:

$$F, S, B, W \longmapsto Q, R \longmapsto H, C, P, N.$$

The formal-topology cover row F, spread-law row S, Brouwer bar-induction row B, and StreamName window row W must be visible before the located-query row Q and spread-cover row R are consumed. The route exports no open-cover compactness theorem, selected infinite branch, selected cover point, quotient-open equality, countable-choice schedule, host real equality, or ambient completeness datum.

Proof. Project the carrier of Definition 4300.1. The source rows are F, S, B, W, and the located bar/cover rows are Q, R.

First read the formal-topology and spread-law surfaces. The finite cover/refinement row F supplies only displayed basic neighbourhoods, while S supplies only admissible finite prefixes.

Next pass through the bar-recursion and StreamName rows. Row B keeps the bar argument on the finite Brouwer induction surface, and W fixes the inspected finite windows used by Real and Completion consumers.

Finally replay through Q, R, H, C, P, N. The located query and spread-cover rows are transported componentwise and replayed with the same provenance and local NameCert row. Since the carrier contains no coordinate for compact open covers, selected branches, selected points, quotient opens, choice, host equality, or ambient completeness, no consumer can read those objects from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedFormalBar}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedFormalBar}^{\uparrow}$ packet is generated from FormalTopology cover/refinement rows, SpreadLaw admissible-prefix rows, BrouwerBarInduction bar-recursion rows, StreamName finite-window rows, located-query rows, spread-cover rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedFormalBar}^{\uparrow}}$, seed)

Scope closed: Definition 4300.1 and Definition 4300.2 seed the finite located bar/cover boundary for Real and Completion consumers over formal covers, spread prefixes, bar recursion, finite windows, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedFormalBar}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite branches, selected cover points, quotient-open equality, countable choice, host topological equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, formal-cover exposure, spread-law prefix exposure, bar-recursion routing, StreamName finite-window replay, located-query exactness, spread-cover exactness, transport, provenance, and local naming for BEDC.Derived.LocatedFormalBarUp.

Chapter 4301

A Concrete Naming Certificate for CauchyModulusFunctoriality$^{\uparrow}$

Following Bishop and Bridges, the CauchyModulusFunctoriality$^{\uparrow}$ packet records the finite data needed to transport displayed Cauchy moduli along a BEDC route without turning that route into a host function equality. It sits between the dyadic tolerance source DyadicRatCore$^{\uparrow}$ of chapter 291, the finite observation route StreamName$^{\uparrow}$ of chapter 126, the regular rational readback RegSeqRat$^{\uparrow}$ of chapter 301, the real-name seal Real$^{\uparrow}$ of chapter 38, the pullback discipline CauchyModulusPullback$^{\uparrow}$ of chapter 1951, and the regular stability surface RegularCauchyModulusStability$^{\uparrow}$ of chapter 1927.

Definition 4301.1 (Cauchy modulus functoriality carrier)**.** *A* CauchyModulusFunctoriality$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, R, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source Cauchy-modulus row, naming the inspected source modulus and its finite request boundary.*
2. *T is the target Cauchy-modulus row, naming the target modulus after transport along the displayed route.*
3. *R is the route-map row, recording the finite BEDC route that carries source requests to target requests without asserting equality of host functions.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, read through chapter 291, that keeps each modulus comparison on dyadic rational bounds.*
5. *W is the* StreamName$^{\uparrow}$ *finite-window row, read through chapter 126, that records the observation window used by the transported modulus request.*
6. *Q is the* RegSeqRat$^{\uparrow}$ *readback row, read through chapter 301, that turns the transported window into a regular rational comparison.*
7. *E is the* Real$^{\uparrow}$ *seal, read through chapter 38, that exposes only the terminal real-name boundary reached by the finite route.*
8. *H records componentwise* hsame *transport for source modulus, target modulus, route map, dyadic tolerance ledger, StreamName window, RegSeqRat readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a transported modulus request through* $S, T, R, D, W, Q, E, H, P, N$.

10. *P is the* Pkg *provenance over* CauchyModulusFunctoriality$^{\uparrow}$, CauchyModulusPullback$^{\uparrow}$, RegularCauchyModulusStal DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{CauchyModulusFunctoriality}^{\uparrow}}$ *row.*

The carrier has no coordinate for host function equality, a selected limit, quotient real equality, trichotomy, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusFunctorialityUp.CauchyModulusFunctorialityTasteGate single carrier alignment`

Theorem 4301.2 (Cauchy modulus functoriality NameCert obligations)**.** *For every accepted* CauchyModulusFunctoriality$^{\uparrow}$ *carrier*

$$F = (S, T, R, D, W, Q, E, H, C, P, N),$$

the local NameCert$_{\text{CauchyModulusFunctoriality}^{\uparrow}}$ *obligations are exactly the finite route obligations listed by the carrier: source-modulus admission, target-modulus admission, route-map exposure, dyadic tolerance preservation, StreamName window preservation, RegSeqRat readback preservation, Real-seal non-escape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The route may use the sibling certificates for* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, CauchyModulusPullback$^{\uparrow}$, *and* RegularCauchyModulusStability$^{\uparrow}$, *but it exports no host function equality, selected limit, quotient real equality, trichotomy, countable choice, or ambient* Real$^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 4301.1. The source and target modulus rows are S, T, and the finite transport route is the displayed row R.

The numeric side is then forced through D, W, Q. The dyadic ledger D supplies the tolerance comparisons, the StreamName window W supplies the finite observation boundary, and the RegSeqRat row Q supplies the regular rational readback.

The terminal read is sealed by E. It records only the Real-facing boundary reached by the same finite route, so it cannot introduce a selected limit or quotient-real equality.

Finally transport and replay through H, C, P, N. These rows preserve the same carrier components under hsame, Cont, package provenance, and local naming. Since the carrier contains no coordinates for host function equality, selected limits, quotient real equality, trichotomy, countable choice, or ambient completeness, the listed NameCert obligations exhaust the packet. □

Closure status for NameCert$_{\text{CauchyModulusFunctoriality}^{\uparrow}}$.

Constructive story: A CauchyModulusFunctoriality$^{\uparrow}$ packet is generated from source and target Cauchy-modulus rows, a finite route-map row, DyadicRatCore tolerance ledgers, StreamName windows, RegSeqRat readback rows, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyModulusFunctoriality}^{\uparrow}}$, seed)

Scope closed: Definition 4301.1 and Definition 4301.2 seed the finite modulus-transport certificate over DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, CauchyModulusPullback$^{\uparrow}$, RegularCauchyModulusStability$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchyModulusFunctoriality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function equality, selected limits, quotient real equality, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, route-map exposure, dyadic tolerance preservation, StreamName window preservation, RegSeqRat readback preservation, Real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusFunctorialityUp.

The finite gauge presentation routes the metric distance surface of chapter 57 through the entourage interface of chapter 339 and the missing-symmetry boundary of chapter 2334.

Chapter 4302

A Concrete Naming Certificate for $\mathsf{GaugeSpace}^{\uparrow}$

Following Bourbaki and Willard, the $\mathsf{GaugeSpace}^{\uparrow}$ packet records a uniform structure by a finite family of gauge seminorm rows rather than by a primitive entourage filter. It sits between the metric distance certificate of chapter 57, the entourage interface of chapter 339, and the directional variant of chapter 2334. The chapter names the finite presentation used by uniform-completion consumers without importing a selected completion, quotient equality, or ambient uniformity oracle.

Definition 4302.1 (Gauge-space carrier)**.** *A* $\mathsf{GaugeSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Q, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying point-name carrier read through the ambient finite source rows.*
2. *Q is the finite list of gauge rows, each row naming a nonnegative comparison surface for a displayed point pair.*
3. *D is the diagonal row, stating that each displayed gauge row admits the named diagonal pair.*
4. *R is the refinement row, stating that a requested finite tolerance may be met by a displayed subfamily and smaller tolerance row.*
5. *S is the symmetry row for the uniform case; in a quasi-uniform presentation it is replaced by the directional row of chapter 2334.*
6. *H stores componentwise* hsame *transport for the point carrier, gauge list, diagonal, refinement, symmetry, continuation, provenance, and local naming rows.*
7. *C stores the* Cont *replay route from finite gauge requests to generated entourage rows.*
8. *P is the* Pkg *provenance over* $\mathsf{GaugeSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{GaugeSpace}^{\uparrow}}$ *row.*

The carrier exports only the finite gauge presentation. It contains no primitive entourage filter, no selected uniform completion, no quotient equality of Cauchy data, and no ambient choice of separating gauges.

Theorem 4302.2 (Gauge-space entourage generation)**.** *For every accepted* $\mathsf{GaugeSpace}^{\uparrow}$ *carrier* $G = (X, Q, D, R, S, H, C, P, N)$*, the displayed gauge rows generate the diagonal, refinement, and symmetry surface required by the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage interface:* D *supplies diagonal admission for every named gauge row,* R *supplies finite refinement of gauge tolerances, and* S *supplies the uniform symmetry row. The generated surface is transported by* H*, replayed by* C*, packaged by* P*, and locally named by* N*, and it does not add a primitive entourage filter, selected completion point, quotient Cauchy equality, or host uniformity principle.*

Proof. Start with the finite gauge list Q. Each gauge row is a displayed comparison surface over the carrier X, so any entourage request must first name a finite subfamily of Q and a tolerance row.

The diagonal face is provided by D. It admits the named diagonal pair for each displayed gauge row and therefore gives the same diagonal surface that a metric ball entourage obtains from zero self-distance in chapter 57.

Refinement is provided by R. A request for a smaller entourage is answered by a finite subfamily and smaller tolerance row, then replayed through C as the generated entourage route. This is the finite counterpart of the refinement surface in chapter 339.

The symmetry row S closes the uniform case. If the row is replaced by a directional row, the same carrier becomes a quasi-uniform presentation of the kind recorded in chapter 2334; with S present, the route is the ordinary uniform gauge surface.

Finally, H, P, N preserve the same generated route under transport, package provenance, and local naming. No step introduces a primitive entourage filter, selected completion, quotient Cauchy equality, or ambient uniformity oracle, so the generated surface is exactly the finite BEDC gauge presentation. □

Theorem 4302.3 (Gauge-space L10 metric completion dependency)**.** *Every L10 consumer of an accepted* $\mathsf{GaugeSpace}^{\uparrow}$ *carrier* $G = (X, Q, D, R, S, H, C, P, N)$ *factors its gauge entourages through the displayed* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{UniformSpace}^{\uparrow}$ *rows before reaching completion-facing* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows. The dependency route first reads the finite gauge list* Q*, diagonal row* D*, refinement row* R*, and symmetry row* S*; then it replays those rows as generated uniform entourages; only then may finite windows, regular rational readback, dyadic tolerance ledgers, and Real seals be consumed through chapter 126, chapter 301, chapter 291, and chapter 38.*

Thus the gauge carrier enters the L10 dependency lattice through chapter 57 and chapter 339. It does not export a primitive entourage filter, selected completion point, quotient Cauchy equality, host uniformity principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Unpack the carrier of Definition 4302.1. The only entourage-generating analytic rows are the finite gauge list Q, the diagonal row D, the refinement row R, and the symmetry row S; the rows H, C, P, N transport, replay, package, and name that finite presentation.

Apply Definition 4302.2. It turns the displayed gauge data into the uniform entourage surface and identifies the metric-facing route through the same finite diagonal, refinement, and symmetry rows. Consequently a completion consumer cannot read StreamName windows or regular rational data before the gauge route has passed through the $\mathsf{Met}^{\uparrow}$ and $\mathsf{UniformSpace}^{\uparrow}$ interfaces.

The L10 completion-facing rows are then downstream. StreamName supplies finite observation windows, RegSeqRat supplies readback, DyadicRatCore supplies tolerance ledgers, and Real supplies the terminal seal. Since each of these rows is reached after the generated entourage route, the gauge packet remains a finite dependency surface rather than a primitive completion or quotient-equality principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{GaugeSpace}^\uparrow}$.

Constructive story: A $\mathsf{GaugeSpace}^\uparrow$ packet is generated from a displayed point carrier, finite gauge rows, diagonal admission, refinement rows, a symmetry row, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GaugeSpace}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 4302.1 and Definition 4302.2 seed the finite gauge-row presentation of diagonal, refinement, and symmetry entourage generation.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GaugeSpace}^\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a selected completion, quotient Cauchy equality, a primitive entourage filter, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal generation, refinement generation, symmetry transport, and standard uniform-space handoff for the displayed finite packet.

Every $\mathsf{GaugeSpace}^\uparrow$ packet consumes the $\mathsf{Met}^\uparrow$ distance-witness rows of chapter 57 together with the $\mathsf{UniformSpace}^\uparrow$ entourage rows of chapter 339. The dependency route presents gauge families as finite NameCert data: each gauge observation is read as a metric-controlled distance row, each comparison is replayed through a uniform entourage row, and the visible BHist, hsame, Cont, Pkg, and NameCert rows keep the gauge carrier from exporting an ambient topology or quotient uniformity not displayed by those siblings. Every $\mathsf{GaugeSpace}^\uparrow$ read first receives metric distance rows from chapter 57, then packages the generated entourage rows consumed by chapter 339. The same carrier boundary is compared against the missing-symmetry surface of chapter 2334: with the symmetry row present it is a uniform gauge presentation, and without that row it remains a directional quasi-uniform presentation rather than a primitive entourage filter.

Theorem 4302.4 (Gauge-space uniformity dependency route)**.** *Every accepted* $\mathsf{GaugeSpace}^\uparrow$ *packet consumes the* $\mathsf{Met}^\uparrow$ *distance rows,* $\mathsf{UniformSpace}^\uparrow$ *entourage rows, and* $\mathsf{QuasiUniformSpace}^\uparrow$ *directional rows before it exports finite gauge uniformity. The dependency is substantive: the gauge-family comparison first reads the* $\mathsf{UniformSpace}^\uparrow$ *local-base row through chapter 339 and the* $\mathsf{Met}^\uparrow$ *distance-window row through chapter 57, then exposes gauge-family comparisons only after those sibling rows have fixed the uniformity boundary. In carrier notation, the point row* X*, gauge list* Q*, diagonal row* D*, refinement row* R*, symmetry or directional row* S*, transport row* H*, continuation row* C*, provenance row* P*, and local naming row* N *must all be displayed before any uniform-completion consumer may use the generated gauge surface.*

Proof. Project the carrier of Definition 4302.1. The gauge rows Q do not stand alone: the carrier description places them beside metric distance input, generated uniform entourage data, and the directional quasi-uniform boundary.

Apply Definition 4302.2. The diagonal and refinement rows D, R are the finite entourage-generation surface, while S distinguishes the ordinary $\mathsf{UniformSpace}^\uparrow$ route from the $\mathsf{QuasiUniformSpace}^\uparrow$ directional route.

Finally use Definition 4302.6. It identifies the generated gauge rows as the sibling handoff to the uniform and quasi-uniform interfaces, and the structural rows H, C, P, N preserve that handoff without adding a primitive entourage filter, selected completion, quotient equality, or ambient uniformity oracle. □

Theorem 4302.5 (Gauge-space UniformSpace local-base dependency)**.** *Every accepted* $\mathsf{GaugeSpace}^\uparrow$ *packet consumes the* $\mathsf{UniformSpace}^\uparrow$ *entourage rows of chapter 339 before its gauge seminorm family is read as a local base. In carrier notation, the point row* X*, finite gauge list* Q*, diagonal row* D*, refinement row* R*, symmetry row* S*, transport row* H*, replay row* C*, provenance row* P*, and local naming row* N *are not enough by themselves to export a uniform local base; the generated*

entourage surface must first display finite entourage, classifier, transport, replay, provenance, and local naming rows from the uniform-space sibling.

Proof. Project the carrier of Definition 4302.1. The gauge family Q is a finite list of comparison rows, but it becomes a local base only after diagonal, refinement, and symmetry data have been read as entourage-generation data.

Apply Definition 4302.2. That theorem reads D, R, S as the generated uniform interface and routes the result through the $\mathsf{UniformSpace}^{\uparrow}$ sibling. The route is therefore an entourage route before it is a local-base route.

Now use Definition 4302.6. It identifies the generated gauge rows with the UniformSpace entourage surface and keeps the quasi-uniform alternative visible when the symmetry row is absent. Thus the accepted packet consumes finite entourage rows, classifier rows, componentwise transport, replay, provenance, and local naming before any gauge seminorm family is read as a uniform local base. □

Theorem 4302.6 (GaugeSpace UniformSpace sibling anchor)**.** *Every accepted* $\mathsf{GaugeSpace}^{\uparrow}$ *packet exposes its finite gauge rows as a generated* $\mathsf{UniformSpace}^{\uparrow}$ *entourage surface, and exposes the missing-symmetry boundary as the corresponding* $\mathsf{QuasiUniformSpace}^{\uparrow}$ *directional surface. The carrier of Definition 4302.1 supplies the point row X, gauge rows Q, diagonal row D, refinement row R, optional symmetry row S, transport row H, continuation row C, provenance row P, and local naming row N. The entourage-generation theorem Definition 4302.2 reads D, R, S as the uniform interface of chapter 339; when S is absent or replaced by a directional row, the same generated gauge surface lands at the quasi-uniform boundary of chapter 2334.*

Proof. Project the accepted carrier through Definition 4302.1. The gauge list Q is finite, and every generated entourage request must pass through the displayed diagonal and refinement rows D and R.

Apply Definition 4302.2. With the symmetry row S present, the generated route is exactly the $\mathsf{UniformSpace}^{\uparrow}$ entourage surface: diagonal admission, finite refinement, symmetry transport, continuation replay, provenance, and local naming.

If the symmetry row is not present as a uniform row, the same carrier data still gives the directional diagonal-and-refinement route. That is the $\mathsf{QuasiUniformSpace}^{\uparrow}$ boundary, because the omitted symmetry coordinate is precisely the distinction between the uniform sibling and the quasi-uniform sibling. □

Chapter 4303

A Concrete Naming Certificate for $\mathsf{RealLimitStability}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RealLimitStability}^{\uparrow}$ packet records the finite data by which two displayed terminal $\mathsf{Real}^{\uparrow}$ limit seals remain stable under shared regular-Cauchy evidence. It sits after the terminal Real seal of chapter 38, the regular rational readback discipline of chapter 301, the finite stream-name windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the completion witness of chapter 3579. The packet names stability of displayed limit seals; it is not quotient stream equality, selected host limits, trichotomy, countable choice, or ambient Real completeness.

Definition 4303.1 (Real limit stability carrier)**.** *A* $\mathsf{RealLimitStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L_0, L_1, W, R, D, E_0, E_1, H, C, P, N)$$

with the following displayed rows:

1. L_0 *and* L_1 *are the two limit-presentation rows whose terminal seals are compared.*
2. W *is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which both presentations are inspected.*
3. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the shared window.*
4. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the common dyadic budgets used by the comparison.*
5. E_0 *and* E_1 *are the paired terminal* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after* L_0, L_1, W, R, D *have been displayed.*
6. H *records componentwise* hsame *transport for both limit presentations, the shared window, readback, tolerance ledger, paired Real seals, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from a stability request through* $L_0, L_1, W, R, D, E_0, E_1, H, P, N$.
8. P *is the* Pkg *provenance over* $\mathsf{RealLimitStability}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCompletenessWitness}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RealLimitStability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and their replay path. It has no coordinate for quotient stream equality, selected host limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RealLimitStabilityUp.RealLimitStabilityTasteGate single carrier alignment`

Theorem 4303.2 (Real limit stability NameCert obligations)**.** *For every accepted* $\mathsf{RealLimitStability}^{\uparrow}$ *carrier* $S = (L_0, L_1, W, R, D, E_0, E_1, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealLimitStability}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite packet, classifier stability under componentwise* hsame*, shared-window readback through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$*, dyadic tolerance nonescape through* $\mathsf{DyadicRatCore}^{\uparrow}$*, paired terminal* $\mathsf{Real}^{\uparrow}$ *seal admission, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 4303.1. The accepted packet exposes exactly two presentation rows, one shared window, one regular rational readback, one dyadic tolerance ledger, two terminal Real seals, transport, replay, provenance, and local naming.

Carrier admission and classifier stability are componentwise. The transport row H moves the two presentations, shared evidence, paired seals, and certificate rows together, while the replay row C preserves the same order of inspection for every stability request.

The provenance row P cites only the listed sibling surfaces and the local row N names the packet. Since the carrier contains no quotient equality, selected host limit, trichotomy oracle, choice schedule, ambient completeness coordinate, Lean certificate, or bridge row, the listed obligations exhaust the NameCert surface. □

Theorem 4303.3 (Real limit stability seal stability)**.** *Every comparison of the paired terminal seals in an accepted* $\mathsf{RealLimitStability}^{\uparrow}$ *packet factors through the displayed route*

$$L_0, L_1 \longmapsto W \longmapsto R \longmapsto D \longmapsto E_0, E_1.$$

Thus the two $\mathsf{Real}^{\uparrow}$ *seals may be reused only under the shared finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger displayed by the packet.*

Proof. Start with a consumer that reads the paired Real seals. The only Real-facing terminal coordinates in the carrier are E_0 and E_1, and both appear after the two presentation rows, shared finite window, regular rational readback, and dyadic ledger.

The consumer must therefore pass through W, R, D before either seal can be used. These rows give the finite observations, regular Cauchy readback, and common tolerance budget that make the two terminal seals comparable as displayed BEDC data.

Finally read H, C, P, N. These rows transport, replay, source, and name the same route, so they preserve seal stability without adding a selected host limit or quotient stream equality. □

Theorem 4303.4 (Real limit stability nonescape)**.** *No accepted* $\mathsf{RealLimitStability}^{\uparrow}$ *carrier exports quotient stream equality, a selected host limit, trichotomy, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, a detached Real seal, Lean verification, or bridge checking. Any downstream completion consumer receives only the two limit presentations, shared window, regular readback, dyadic ledger, paired seals, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row.*

Proof. Inspect the carrier inventory. The tuple contains no coordinate for quotient equality, selected host limits, trichotomy, choice, ambient completeness, detached seal data, Lean verification, or a bridge certificate.

The paired seals E_0, E_1 are downstream of the shared witness rows W, R, D. Hence a completion consumer can reuse the seals only through the displayed finite evidence and not through an external selected limit.

Transport, replay, provenance, and local naming preserve the same boundary. The rows H, C, P, N move and name only the finite packet, so every exported object remains inside the displayed Real-limit-stability surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealLimitStability}^{\uparrow}}$.

Constructive story: A $\mathsf{RealLimitStability}^{\uparrow}$ packet is generated from two limit-presentation rows, a shared StreamName window, a RegSeqRat readback row, a DyadicRatCore tolerance ledger, paired RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLimitStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4303.1, Definition 4303.2, Definition 4303.3, and Definition 4303.4 seed the finite stability packet for paired terminal Real limit seals under shared StreamName, RegSeqRat, DyadicRatCore, hsame, Cont, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLimitStability}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RealLimitStabilityUp.RealLimitStabilityTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, shared-window readback, dyadic ledger nonescape, paired Real-seal stability, transport, replay, provenance, and local naming for BEDC.Derived.RealLimitStabilityUp.

Chapter 4304

A Concrete Naming Certificate for $\mathsf{DecimalIntervalReal}^{\uparrow}$

Bishop–Bridges constructive analysis uses rational and decimal brackets as finite evidence before a real name is treated as complete. The $\mathsf{DecimalIntervalReal}^{\uparrow}$ packet records this decimal-bracket carrier as BEDC NameCert data. It sits after the decimal prefix surface of chapter 1417, the finite decimal stream of chapter 4191, the dyadic tolerance ledger of chapter 291, the finite window schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located interval source of chapter 1709. The packet gives L10 Real and Completion consumers a finite decimal interval carrier without quotient reals, trichotomy, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4304.1 (Decimal interval real carrier)**.** *A* $\mathsf{DecimalIntervalReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (A, B, D, W, Q, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the lower finite decimal-prefix row, read through* $\mathsf{DecimalExpansion}^{\uparrow}$ *and the finite* $\mathsf{DecimalStream}^{\uparrow}$ *schedule.*
2. *B is the upper finite decimal-prefix row, read through the same decimal surfaces and carrying the advertised bracket side.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger translating decimal place values into dyadic comparison margins.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule opened for endpoint-prefix reads, bracket comparison, and downstream replay.*
5. *Q is the bracket-order row, recording that the lower decimal prefix and upper decimal prefix are compared only through the displayed tolerance ledger.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the endpoint windows, decimal prefix rows, dyadic ledger, and bracket-order row.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regular rational readback has been displayed.*
8. *L is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *handoff row that consumes the same endpoint, tolerance, readback, and seal rows as a located interval boundary.*

9. *H records componentwise* hsame *transport for endpoint prefixes, tolerance rows, windows, bracket order, regular readback, real seal, located interval handoff, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a decimal-bracket request through endpoint prefixes, dyadic comparison, finite windows, regular readback, real sealing, and located interval handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{DecimalIntervalReal}^{\uparrow}$, $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{DecimalStream}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, D, W, Q, R, E, L, H, C, P, N$. It has no coordinate for a quotient real, a trichotomy decision, a selected decimal representative, host endpoint equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.DecimalIntervalRealUp.DecimalIntervalRealCarrier`
Lean4 ✓ `BEDC.Derived.DecimalIntervalRealUp.DecimalIntervalRealTasteGate single carrier alignment`

Theorem 4304.2 (Decimal interval real NameCert obligations)**.** *For every accepted* $\mathsf{DecimalIntervalReal}^{\uparrow}$ *carrier $J = (A, B, D, W, Q, R, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the lower decimal prefix, upper decimal prefix, dyadic tolerance ledger, stream windows, bracket-order row, regular rational readback, real seal, located interval handoff, transport, replay, provenance, and local naming rows;*
2. *decimal-prefix visibility, requiring endpoint reads to enter through A and B before any bracket comparison is inspected;*
3. *tolerance discipline, requiring the place-value comparison to use the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D and no hidden real-order oracle;*
4. *window discipline, requiring each endpoint and comparison read to be scheduled by the finite* $\mathsf{StreamName}^{\uparrow}$ *row W;*
5. *regular-readback order, requiring R to consume A, B, D, W, Q before any* $\mathsf{Real}^{\uparrow}$ *seal is available;*
6. *located-interval handoff, requiring L to consume the same endpoint, tolerance, readback, and seal route rather than a host interval;*
7. *componentwise* hsame *transport and displayed* Cont *replay for exactly the rows carried by H and C;*
8. *ledger non-escape, excluding quotient reals, trichotomy, selected decimal representatives, host endpoint equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4357.1. The projection exposes exactly the two decimal endpoint-prefix rows, the dyadic tolerance ledger, the finite window schedule, the bracket-order row, the regular readback, the terminal real seal, the located interval handoff, transport, replay, provenance, and local naming.

The endpoint reads are visible before comparison. Rows A and B carry the finite decimal prefixes, while D supplies the dyadic margin used to compare their place-value readings. The row W schedules the inspected prefixes and comparison windows, so the bracket-order row Q has no access to a hidden real-order decision.

The real-facing route is downstream of the finite bracket data. Row R is read only after A, B, D, W, Q have been displayed, and row E seals the result only after that regular rational readback.

Finally, the located interval handoff L consumes the same displayed route, while H, C, P, N transport, replay, source, and name the packet. Since no remaining coordinate stores quotient equality, trichotomy, a selected decimal representative, host endpoint equality, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.DecimalIntervalRealUp.DecimalIntervalRealCarrier semantic name certificate`

Theorem 4304.3 (Decimal interval real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{LocatedRealInterval}^{\uparrow}$ *read exported by an accepted* $\mathsf{DecimalIntervalReal}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DecimalExpansion}^{\uparrow},\ \mathsf{DecimalStream}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{LocatedRealInterval}^{\uparrow}.$$

Equivalently, a downstream Real and Completion consumer receives the two decimal endpoint-prefix rows, the dyadic comparison ledger, the finite window row, the regular rational readback, the terminal real seal, the located interval handoff, transport, replay, provenance, and local naming before it can use the bracket.

Proof. Start with an accepted carrier $J = (A, B, D, W, Q, R, E, L, H, C, P, N)$. The only real-facing row is E, and the only located-interval row is L.

The definition places E after the endpoint-prefix rows A, B, the dyadic tolerance ledger D, the window schedule W, the bracket-order row Q, and the regular rational readback R. Thus a $\mathsf{Real}^{\uparrow}$ consumer must first inspect the decimal, dyadic, window, and readback rows.

The located interval handoff is not an alternate route. Row L consumes the same A, B, D, W, Q, R, E path, and componentwise transport through H preserves that path under hsame.

The replay, provenance, and local naming rows only record the displayed carrier. They do not add quotient reals, trichotomy, selected representatives, host endpoint equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so the displayed route is the whole exported handoff. □

Falsifiable prediction: Every accepted $\mathsf{DecimalIntervalReal}^{\uparrow}$ read displays two finite decimal-prefix rows, one dyadic comparison ledger, one finite StreamName window row, one RegSeqRat readback row, one RealUp seal row, one LocatedRealIntervalUp handoff row, and local transport, replay, provenance, and naming rows before it is consumed as a decimal bracket.

Independence witness: decimalexpansion, decimal-stream, dyadicratcore, streamname, regseqrat, real, located-real-interval: $\mathsf{DecimalIntervalReal}^{\uparrow}$ is not bijective to any listed sibling because it binds two ordered decimal endpoint-prefix rows, one dyadic comparison ledger, finite observation windows, regular rational readback, RealUp sealing, located interval handoff, componentwise hsame, displayed Cont, Pkg, and local $\mathsf{NameCert}$ into one accepted bracket packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}$.

Constructive story: A $\mathsf{DecimalIntervalReal}^{\uparrow}$ packet is generated from lower and upper decimal-prefix rows, DecimalStream windows, a DyadicRatCore comparison ledger, a StreamName schedule, a RegSeqRat readback, a RealUp seal, a LocatedRealIntervalUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4357.1, Definition 4357.2, and Definition 4357.3 seed the finite decimal-bracket route over DecimalExpansionUp, DecimalStreamUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, LocatedRealIntervalUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.DecimalIntervalRealUp`

Bridge status: none

Not claimed: This chapter does not claim quotient reals, trichotomy, selected decimal representatives, host endpoint equality, countable choice, Lean verification, bridge checking, or ambient $\mathrm{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, decimal-prefix visibility, dyadic tolerance discipline, finite-window discipline, regular-readback order, Real seal handoff, located interval handoff, transport, replay, provenance, and ledger non-escape for BEDC.Derived.DecimalIntervalRealUp.

Chapter 4305

A Concrete Naming Certificate for $\mathsf{AttouchWetsTopology}^{\uparrow}$

Following Attouch and Wets on variational convergence, the $\mathsf{AttouchWetsTopology}^{\uparrow}$ packet records local Hausdorff-window convergence for closed metric figures as finite BEDC NameCert data over the metric-completion and L10 real-name surface. It sits after the metric carrier of chapter 57, the Hausdorff-distance surface of chapter 3653, the terminal real seal of chapter 38, the regular rational readback of chapter 301, and the finite stream windows of chapter 126. The packet names the finite observation topology; it does not import host closed-set topology, arbitrary hyperspace compactness, quotient closed sets, selected nearest points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4305.1 (Attouch-Wets topology carrier)**.** *An* $\mathsf{AttouchWetsTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A_{\mathrm{aw}} = (M, H, D, W, R, E, Q, T, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose metric, point windows, and bounded-window radii are the only ambient metric data available to the packet.*
2. *H is the* $\mathsf{HausdorffDistance}^{\uparrow}$ *local-window row, read only on displayed bounded metric windows rather than on an ambient hyperspace.*
3. *D is the dyadic tolerance ledger for window radius, Hausdorff comparison margin, and late-window precision.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected centers, bounded windows, comparison stages, and requested precision cells.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational Hausdorff-window comparisons obtained from M, H, D, W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the regular rational readback has been displayed.*
7. *Q records componentwise* hsame *transport for metric source rows, Hausdorff-window rows, dyadic ledgers, stream windows, regular readbacks, real seals, replay rows, provenance, and local naming.*
8. *T records displayed* Cont *replay from an Attouch–Wets observation request through M, H, D, W, R, E.*

9. *C is the local bounded-window classifier row comparing packets only through the displayed metric source, Hausdorff-window, tolerance, stream, readback, seal, transport, replay, provenance, and naming coordinates.*

10. *P is the* Pkg *provenance over* $\mathsf{AttouchWetsTopology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{HausdorffDistance}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}$ *row.*

The classifier has no coordinate for global closed-set topology, open-cover compactness, selected nearest points, quotient hyperspace equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.AttouchWetsTopologyUp.AttouchWetsTopologyTasteGate single carrier alignment`

Theorem 4305.2 (Attouch-Wets topology NameCert obligation surface)**.** *For every accepted* $\mathsf{AttouchWetsTopology}^{\uparrow}$ *carrier*

$$A_{\mathrm{aw}} = (M, H, D, W, R, E, Q, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *expose the* $\mathsf{Met}^{\uparrow}$ *source row M before any local Hausdorff comparison is read;*

2. *display the* $\mathsf{HausdorffDistance}^{\uparrow}$ *window row H only on bounded metric windows named by the packet;*

3. *bind all numerical precision to the dyadic tolerance ledger D, the* $\mathsf{StreamName}^{\uparrow}$ *row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E;*

4. *preserve the same finite route by componentwise* hsame *transport Q and displayed* Cont *replay T;*

5. *source and name the same packet through the bounded-window classifier C,* Pkg *provenance P, and the local* NameCert *row N.*

No obligation row is stored for a host hyperspace topology, arbitrary closed-set compactness, selected representatives, quotient closed-set equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 4358.1. The metric row M is the only source of ambient distance data, and the Hausdorff row H is read only after the bounded window has been displayed.

The numerical part is downstream of that window. The tolerance ledger D, finite window row W, regular readback R, and real seal E are the only precision and value rows available to an observation request.

Transport and replay keep the same route. Rows Q and T preserve the displayed metric, Hausdorff, tolerance, window, readback, and seal data, while C, P, N classify, source, and name the finite packet.

Since the carrier contains none of the excluded topology, compactness, selection, quotient, choice, or ambient-completeness coordinates, the displayed obligations exhaust the local NameCert surface. □

Theorem 4305.3 (Attouch-Wets local Hausdorff window)**.** *Every topology-facing read exported by an accepted* $\mathsf{AttouchWetsTopology}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{HausdorffDistance}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}.$$

Thus a downstream metric-completion consumer receives the displayed metric source, bounded local Hausdorff window, finite observation schedule, regular rational readback, terminal real seal, componentwise transport, replay, provenance, and local naming before it can use Attouch–Wets convergence data.

Proof. Start with a topology-facing read of the accepted carrier. The only available metric source is M, and the only Hausdorff comparison row is the local-window row H.

The observation is then forced through D, W, R, E. The dyadic ledger fixes the requested tolerance, the stream row displays the inspected bounded windows, the regular rational row records the readback, and the real row seals the reported Hausdorff-window value.

Finally Q, T, C, P, N transport, replay, classify, source, and name that same finite route. Because no row supplies host closed-set topology, arbitrary hyperspace compactness, selected nearest points, quotient closed-set equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every exported topology-facing read factors through the displayed local Hausdorff window. □

Closure status for $\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}$.

Constructive story: An $\mathsf{AttouchWetsTopology}^{\uparrow}$ packet is generated from a MetricSpace source row, a HausdorffDistance bounded-window row, a dyadic tolerance ledger, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, a bounded-window classifier row, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4358.1, Definition 4358.2, and Definition 4358.3 seed the local Hausdorff-window topology route over MetricSpaceUp, HausdorffDistanceUp, StreamNameUp, RegSeqRatUp, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.AttouchWetsTopologyUp`

Bridge status: none

Not claimed: This chapter does not claim host closed-set topology, arbitrary hyperspace compactness, quotient closed sets, selected nearest points, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded Hausdorff-window exposure, finite-window scheduling, regular readback, Real sealing, transport, replay, classifier exactness, provenance, and local naming for BEDC.Derived.AttouchWetsTopologyUp.

Chapter 4306

A Concrete Naming Certificate for $\mathsf{CantorIntersectionMetric}^{\uparrow}$

Following Cantor's intersection theorem and Bishop–Bridges constructive metric completion, the $\mathsf{CantorIntersectionMetric}^{\uparrow}$ packet records the metric nested-closed-set intersection route as finite BEDC NameCert data over the L10 completion surface. It sits after the complete-metric source of chapter 128, the metric-completion route of chapter 1506, the nested closed-ball packet of chapter 3526, the Cantor complete metric route of chapter 2199, the Cauchy-filter interface of chapter 333, and the L10 real-name route through chapter 291, chapter 126, chapter 301, and chapter 38. The metric packet is the metric-completion specialization of the finite Cantor-intersection route in chapter 1421 and the theorem-facing intersection route in chapter 2318; it consumes their nested-window and diagonal-readback rows before exposing complete-metric service. The packet names a nested metric intersection handoff; it does not assert open-cover compactness, arbitrary closed-set compactness, quotient stream equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4306.1 (CantorIntersectionMetric carrier)**.** *A* $\mathsf{CantorIntersectionMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I_{\mathrm{cim}} = (M, E, B, K, F, D, S, R, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row whose metric and convergence service are the only complete-metric data available to the packet.*
2. *E is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row naming the surrounding completion request before any intersection point is read.*
3. *B is the* $\mathsf{NestedClosedBall}^{\uparrow}$ *row, recording the descending closed metric ball spine and its finite containment witnesses.*
4. *K is the* $\mathsf{CantorCompleteMetric}^{\uparrow}$ *row, used only as the displayed nested closed-ball completion handoff.*
5. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row generated by the nested metric spine and read only through the displayed filter route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter and tolerance ledger, storing the shrink schedule, late-radius comparisons, and requested precision bounds.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected centers, radii, and containment data.*

8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the regular rational readback of the displayed center schedule.*
9. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after B, K, F, D, S, R have been displayed.*
10. *H records componentwise* hsame *transport for the complete-metric source, completion route, nested-ball row, Cantor handoff, filter, dyadic ledger, stream windows, regular readback, real seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a nested metric intersection request through $M, E, B, K, F, D, S, R, L$.*
12. *P is the* Pkg *provenance over* $\mathsf{CantorIntersectionMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{NestedClosedBall}^{\uparrow}$, $\mathsf{CantorCompleteMetric}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, B, K, F, D, S, R, L, H, C, P, N$. It has no coordinate for open-cover compactness, arbitrary closed-set compactness, quotient completion equality, a selected limit, host trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorIntersectionMetricUp.CantorIntersectionMetricTasteGate single carrier alignment`

Theorem 4306.2 (CantorIntersectionMetric NameCert obligations)**.** *For every accepted* $\mathsf{CantorIntersectionMetric}^{\uparrow}$ *carrier*

$$I_{\mathrm{cim}} = (M, E, B, K, F, D, S, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *expose the complete-metric and metric-completion source rows M, E before any intersection witness is read;*
2. *display the nested metric route through B, K, F, namely the nested closed-ball spine, Cantor complete-metric handoff, and generated Cauchy-filter row;*
3. *bind all numerical readback to the L10 rows D, S, R, L, namely the dyadic tolerance ledger, finite stream windows, regular rational handoff, and terminal real seal;*
4. *preserve the route by componentwise* hsame *transport and displayed* Cont *replay through H, C;*
5. *source and name the same finite packet through* Pkg *provenance P and the local* NameCert *row N.*

No obligation row is stored for open-cover compactness, arbitrary closed-set compactness, quotient completions, selected limits, trichotomy, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 4359.1. The rows M, E expose the metric and completion sources before the packet can read an intersection point.

The nested metric content is then displayed through B, K, F. The nested closed-ball row supplies the descending closed metric spine, the Cantor complete-metric row supplies the existing handoff, and the Cauchy-filter row records the generated filter route.

The L10 readback is downstream. The dyadic ledger D, stream windows S, regular rational row R, and real seal L are the only numerical coordinates available before a completion-facing consumer receives a named output.

Finally H, C, P, N transport, replay, source, and name that same finite route. Since the carrier contains none of the excluded compactness, quotient, selected-limit, trichotomy, or ambient-completeness coordinates, the five displayed obligations exhaust the local NameCert surface. □

Theorem 4306.3 (CantorIntersectionMetric complete handoff)**.** *Every completion-facing read exported by an accepted* $\mathsf{CantorIntersectionMetric}^{\uparrow}$ *carrier factors through the displayed nested metric route*

$\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{NestedClosedBall}^{\uparrow}$, $\mathsf{CantorCompleteMetric}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, S

Thus a consumer receives the complete-metric service, completion request, nested closed-ball spine, Cantor complete-metric handoff, Cauchy-filter row, dyadic tolerance ledger, finite stream windows, regular rational readback, terminal real seal, componentwise transport, replay, provenance, and local naming rows before it may use the intersection output. The handoff exports no $\mathsf{Real}^{\uparrow}$ *completeness principle, open-cover compactness theorem, arbitrary closed-set compactness, quotient stream equality, or selected limit.*

Proof. Begin with a completion-facing read of the accepted carrier. The first available rows are M and E, so the read is grounded in the displayed complete-metric service and the surrounding metric-completion request.

Next pass through the nested route B, K, F. The descending closed-ball spine is read through the $\mathsf{NestedClosedBall}^{\uparrow}$ row, the existing Cantor complete-metric handoff is read through K, and the generated filter is read through F.

The numerical output is then forced through the L10 readback rows D, S, R, L. The dyadic ledger supplies tolerance control, the stream row supplies finite windows, the regular rational row supplies readback, and the terminal real seal is reached only after those rows are present.

The structural rows H, C, P, N preserve the same route for downstream consumers. Because no row supplies full real completeness, open-cover compactness, arbitrary closed-set compactness, quotient stream equality, or a selected limit, every completion-facing read factors through the displayed nested metric route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorIntersectionMetric}^{\uparrow}$ packet is generated from a CompleteMetric source row, a MetricCompletion request row, a NestedClosedBall spine, a CantorCompleteMetric handoff, a CauchyFilter row, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$, seed)

Scope closed: Definition 4359.1, Definition 4359.2, and Definition 4359.3 seed the metric nested-closed-set intersection route over displayed completion, nested-ball, Cantor handoff, filter, dyadic, stream, regular readback, real seal, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, arbitrary closed-set compactness, quotient completions, selected limits, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested metric inclusion, Cantor handoff, Cauchy-filter generation, dyadic shrink exactness, finite-window readback, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CantorIntersectionMetricUp.

Chapter 4307

A Concrete Naming Certificate for $\mathsf{TightRealInterval}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{TightRealInterval}^{\uparrow}$ packet names a finite lower-upper real interval by displaying both endpoint names and every rational cell through which those endpoints are inspected. It sits downstream of the located endpoint surface of chapter 394 and the dyadic refinement surface of chapter 306: consumers may read a tight interval only after the lower endpoint, upper endpoint, rational cell ledger, dyadic refinement ledger, stream windows, regular rational readbacks, and Real seal rows have all been displayed.

Definition 4307.1 (TightRealInterval carrier)**.** *A* $\mathsf{TightRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (L, U, Q, D, S, R, E, H, C, P, N)$$

with the following visible rows:

1. *L is the lower* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint row and U is the upper* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint row.*
2. *Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger recording the finite rational windows that enclose the endpoint reads and witness lower-before-upper compatibility.*
3. *D is the* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger attached to the rational cells in Q.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming exactly the endpoint observations and interval cells inspected by the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those endpoint windows and cell refinements.*
6. *E is the paired* $\mathsf{Real}^{\uparrow}$ *seal row reached from L, U, S, R, Q, D.*
7. *H records componentwise* hsame *transport for endpoints, rational cells, dyadic refinements, stream windows, readbacks, Real seals, replay, provenance, and the local name.*
8. *C records displayed* Cont *replay through $L, U, Q, D, S, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}$ *row.*

The carrier has no coordinate for host interval equality, chosen endpoint values, quotient real equality, trichotomy, countable choice, or ambient real completeness.

Lean4 (definition) `BEDC.Derived.TightRealIntervalUp.TightRealIntervalUp`
Lean4 ✓ `BEDC.Derived.TightRealIntervalUp.TasteGate.TightRealIntervalTasteGate single carrier alignment`

Theorem 4307.2 (TightRealInterval NameCert obligations)**.** *For an accepted* $\mathsf{TightRealInterval}^{\uparrow}$ *carrier* $T = (L, U, Q, D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the lower and upper* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows, rational and dyadic interval ledgers, finite stream windows, regular rational readbacks, paired Real seal rows, componentwise transport, continuation replay, package provenance, and local naming; endpoint-order visibility through* Q*; dyadic refinement discipline through* D*; stream-readback exactness through* S, R*; and ledger non-escape from host intervals, selected endpoints, quotient real equality, choice, trichotomy, and ambient completeness.*

Proof. Project the carrier of Definition 4360.1. The lower and upper endpoint rows, the rational cell ledger, the dyadic refinement ledger, finite windows, regular readbacks, Real seals, transport rows, replay rows, provenance row, and local naming row are all visible before any interval consumer can read the packet.

Endpoint-order visibility is supplied by Q. Since each dyadic refinement in D is attached to a rational cell, the refinement discipline cannot detach from the endpoint ledger.

Stream-readback exactness is then read through S and R. The rows H, C, P, N transport, replay, source, and name the same finite route, while the excluded interval and completeness data have no carrier coordinate. □

Theorem 4307.3 (TightRealInterval Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{TightRealInterval}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{LocatedReal}^{\uparrow},\ \mathsf{RationalInterval}^{\uparrow},\ \mathsf{DyadicInterval}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Nam}$$

The read exposes lower and upper endpoint windows together with the rational and dyadic cell ledgers that bind them. It does not expose a host real interval, a selected endpoint value, quotient real equality, countable choice, trichotomy, or ambient real completeness.

Proof. Begin with the accepted carrier. The only seal-facing row is E, and it is displayed after L, U, Q, D, S, R in the finite packet.

Apply Definition 4360.2. Endpoint-order visibility forces the Real read to keep the rational cell ledger Q, dyadic refinement discipline forces any dyadic window through D, and stream-readback exactness forces finite observations through S, R.

Finally route through H, C, P, N. These rows preserve and name the same packet, so no host interval, endpoint selector, quotient equality, choice schedule, trichotomy row, or ambient completeness principle can enter the Real seal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TightRealInterval}^{\uparrow}$ packet is generated from lower and upper $\mathsf{LocatedReal}^{\uparrow}$ endpoint rows, a $\mathsf{RationalInterval}^{\uparrow}$ cell ledger, a $\mathsf{DyadicInterval}^{\uparrow}$ refinement ledger, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, paired $\mathsf{Real}^{\uparrow}$ seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4360.1, Definition 4360.2, and Definition 4360.3 seed the finite lower-upper Real interval packet over located endpoints, rational cells, dyadic refinements, stream windows, regular readbacks, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host interval equality, selected endpoint values, quotient real equality, trichotomy, countable choice, or ambient real completeness.

Upgrade path: Scoped closure requires a checked carrier-obligation package and a public consumer route for the same finite lower-upper interval packet.

Chapter 4308

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$

Following Bishop-style compact metric uniform continuity, the $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$ packet records the finite handoff that transfers compact finite-net and pointwise continuity data into a uniform modulus row. It consumes the finite compact source of chapter 60, the compact metric net surface of chapter 129, the continuity interface of chapter 391, the finite stream and regular readback rows of chapter 126 and chapter 301, and the dyadic tolerance ledger of chapter 291. The packet is a finite modulus-transfer NameCert surface, not an open-cover compactness proof or a host modulus selector.

Definition 4308.1 (Compact uniform modulus transfer carrier)**.** *A* $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, G, U, S, R, D, F, H, C, P, N)$$

with the following visible rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-net source row.*
2. *G is the* $\mathsf{CompactMetric}^{\uparrow}$ *metric coverage row for the same finite centers and source distance witnesses.*
3. *U is the* $\mathsf{UniformContinuity}^{\uparrow}$ *pointwise-to-uniform continuity row consumed by the transfer.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing the inspected finite centers, tolerance requests, and pointwise-radius reads.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for finite radius comparison and shrinkage.*
7. *F is the modulus-transfer ledger that records the finite lower-bound handoff into the downstream uniform-modulus consumer row.*
8. *H records componentwise* hsame *transport for compact, compact-metric, uniform-continuity, stream, readback, dyadic, transfer, replay, provenance, and local-name rows.*
9. *C records displayed* Cont *replay through $K, G, U, S, R, D, F, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusTransfer}^{\uparrow}}$ *row.*
The carrier has no coordinate for open-cover compactness, selected centers, selected Lebesgue numbers, host modulus functions, quotient point equality, countable choice, or ambient metric completeness.

Lean4 ✓ `BEDC.Derived.CompactUniformModulusTransferUp.CompactUniformModulusTransferTasteGate`
`single carrier alignment`

Theorem 4308.2 (Compact uniform modulus transfer obligations)**.** *For an accepted* CompactUniformModulusTrans *carrier $M = (K, G, U, S, R, D, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusTransfer}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact finite-net row, compact-metric coverage row, uniform-continuity row, stream windows, regular rational readbacks, dyadic tolerance ledger, modulus-transfer ledger, componentwise transport, continuation replay, package provenance, and local naming; source lock between K, G, U; finite-window exactness through S, R; dyadic tolerance exactness through D; and non-escape from open-cover compactness, selected centers, selected Lebesgue numbers, host modulus functions, quotient equality, choice, and ambient completeness.*

Proof. Project the carrier of Definition 4361.1. The compact row, compact-metric row, continuity row, stream windows, readbacks, dyadic tolerance ledger, transfer ledger, transport rows, replay rows, provenance row, and local name are displayed as one finite packet.

The source lock is the shared read of K, G, U. A transfer consumer cannot use the compact finite-net row without the compact-metric distance surface and the continuity row that supplies pointwise radius data.

Finite-window and dyadic exactness are read through S, R, D. The ledger F can therefore transfer only the displayed finite lower-bound data, and H, C, P, N preserve that route without adding any excluded compactness or choice principle. □

Theorem 4308.3 (Compact uniform modulus transfer handoff)**.** *Every accepted* $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$ *packet hands a downstream uniform-modulus consumer only the finite route*

$$\mathsf{Compact}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{UniformContinuity}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont}$$

The handoff records compact finite-net coverage, pointwise continuity radius reads, finite stream windows, regular rational readbacks, dyadic tolerance comparison, and the transfer ledger. It exports no open-cover compactness theorem, selected net center, selected Lebesgue number, host modulus function, quotient equality, countable choice, or ambient completeness.

Proof. Start from the transfer obligations of Definition 4361.2. They identify the compact, compact-metric, continuity, stream, readback, dyadic, and transfer rows as the only NameCert-readable data.

Route the downstream consumer through F. The ledger can be consumed only after K, G, U, S, R, D have supplied the finite-net, pointwise-radius, window, readback, and tolerance rows.

Finally use H, C, P, N to transport, replay, source, and name the same packet. Since the excluded compactness, selection, equality, choice, and completeness data have no coordinate in the carrier, the downstream handoff is exactly the displayed finite modulus-transfer route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusTransfer}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$ packet is generated from compact finite-net rows, compact-metric coverage rows, uniform-continuity rows, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, a modulus-transfer ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactUniformModulusTransfer}\uparrow}$, seed)

Scope closed: Definition 4361.1, Definition 4361.2, and Definition 4361.3 seed the finite compact-net modulus-transfer packet for uniform-continuity consumers.

Formal verification: FormalStatus(NameCert$_{\text{CompactUniformModulusTransfer}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.CompactUniformModulusTransferUp.CompactUniformModulusTransferTasteGate\_single\_carrier`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected centers, selected Lebesgue numbers, host modulus functions, quotient point equality, countable choice, or ambient metric completeness.

Upgrade path: Scoped closure requires a checked transfer-obligation package and a public uniform-modulus consumer route for the same finite packet.

Chapter 4309

A Concrete Naming Certificate for $\mathsf{RealIntervalApartness}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealIntervalApartness}^{\uparrow}$ packet records located separation of two real intervals by a displayed positive dyadic gap rather than by a trichotomy decision on completed real endpoints. It sits after the terminal real-name seal of chapter 38, the located endpoint interval surface of chapter 1709, the dyadic tolerance ledger of chapter 291, the finite window discipline of chapter 126, the regular rational readback of chapter 301, and the separability boundary of chapter 1809. The packet names interval separation only through visible endpoint rows, gap rows, transport, replay, provenance, and local naming.

Definition 4309.1 (RealIntervalApartness carrier)**.** *A* $\mathsf{RealIntervalApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, J, L, U, L', U', G, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I and J are the two* $\mathsf{LocatedRealInterval}^{\uparrow}$ *endpoint packets whose lower and upper endpoint rows are exposed before any apartness read.*
2. *L, U are the lower and upper* $\mathsf{Real}^{\uparrow}$ *seal rows for I, and L', U' are the corresponding* $\mathsf{Real}^{\uparrow}$ *seal rows for J.*
3. *G is a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap witness, attached either to the displayed comparison $U + G \leq L'$ or to the displayed comparison $U' + G \leq L$.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming exactly the endpoint observations and gap inspections used by the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those endpoint windows and dyadic gap checks.*
6. *E records the* $\mathsf{RealSeparability}^{\uparrow}$ *boundary row witnessing that the two exposed endpoint intervals are separated by the displayed dyadic gap.*
7. *H records componentwise* hsame *transport for intervals, endpoint seals, dyadic gap rows, finite windows, readbacks, separability rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay through $I, J, L, U, L', U', G, S, R, E, H$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealIntervalApartness}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}$ *row.*

The carrier has no coordinate for real trichotomy, quotient real equality, a selected endpoint representative, a host interval order, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 4309.2 (RealIntervalApartness NameCert obligations)**.** *For every accepted* $\mathsf{RealIntervalApartness}^{\uparrow}$ *carrier*

$$A = (I, J, L, U, L', U', G, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *admit the two located real interval packets I, J and expose their lower and upper endpoint rows through L, U, L', U';*
2. *expose the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap witness G and the side on which the gap separates the displayed endpoint rows;*
3. *bind every endpoint and gap inspection to the finite* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows S, R;*
4. *preserve the interval, endpoint, gap, readback, and separability rows by componentwise* hsame *transport through H;*
5. *replay the same finite route through* Cont *row C, source it by* Pkg *provenance P, and name it by the local* NameCert *row N.*

No obligation row is stored for real trichotomy, quotient equality of completed real names, selected endpoint representatives, host interval order, or ambient real completeness.

Proof. Project the carrier of Definition 4362.1. The two located interval packets and their endpoint seals are the only interval data exposed to a consumer.

The separation datum is the row G. Positivity is read as a dyadic-row property, and the side of separation is part of the displayed ledger; no trichotomy comparison is consulted.

The numerical readback is forced through S and R, then through the separability row E. The structural rows H, C, P, N transport, replay, source, and name the same finite packet.

Since none of the excluded host-order, quotient-equality, representative-selection, trichotomy, or completeness data occurs as a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.RealIntervalApartnessUp.TasteGate.RealIntervalApartnessTasteGate single carrier alignment`

Theorem 4309.3 (RealIntervalApartness separability route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{RealIntervalApartness}^{\uparrow}$ *carrier factors through*

$\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, hsame, Cont, Pkg, Na

The route exports located interval separation only as a positive dyadic gap between displayed endpoint rows. It exports no real trichotomy, quotient real equality, host interval order, selected endpoint representative, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Begin with the NameCert obligations of Definition 4362.2. They force the two located interval packets and endpoint seals to be visible before a consumer may read an apartness claim.

Next read the dyadic gap row and its finite endpoint inspections through the stream and regular-rational rows. The separability row is therefore attached to the displayed positive gap, not to a host comparison of completed reals.

Finally route through transport, replay, provenance, and local naming. These rows preserve the same finite packet, so the consumer receives located interval apartness without importing any excluded trichotomy, quotient, selection, host-order, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}$.

Constructive story: A $\mathsf{RealIntervalApartness}^{\uparrow}$ packet is generated from two LocatedRealInterval endpoint packets, Real endpoint seal rows, a positive DyadicRatCore gap witness, finite StreamName windows, RegSeqRat readback, a RealSeparability boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4362.1, Definition 4362.2, and Definition 4362.3 seed the located interval separation packet over displayed endpoint, dyadic gap, finite-window, regular-readback, Real seal, separability, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim real trichotomy, quotient real equality, selected endpoint representatives, host interval order, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exposure, positive-gap exposure, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.RealIntervalApartnessUp.

Chapter 4310

A Concrete Naming Certificate for $\mathsf{PartitionBasinPolynomial}^{\uparrow}$

Following finite enumerative combinatorics, the $\mathsf{PartitionBasinPolynomial}^{\uparrow}$ packet records the partition-basin product formula of Definition 9462.1736 as displayed NameCert data over block sizes, legal decorations, defect exponents, incidence totals, transport, replay, provenance, and local naming. It sits after the partition carrier of chapter 201, the defect-flow partition skeleton of chapter 4236, and the partition-core incidence certificate of chapter 4214. The packet names a finite polynomial enumeration surface; it is not a biological stochastic model, a host generating-function oracle, or a quotient-level semantic identification.

Definition 4310.1 (PartitionBasinPolynomial carrier)**.** *A* $\mathsf{PartitionBasinPolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, S, D, E, F, Q, I, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite block-count row for the partition core, and S is the finite block-size ledger $(s_1, \ldots, s_m)$.*
2. *D is the legal-decoration row, recording for each coordinate of block i the admissible subset of the other $m-1$ rows and the private-coordinate exclusion.*
3. *E is the defect-exponent ledger that assigns exponent weight q^r to a coordinate receiving r additional rows.*
4. *F is the product-formula row*
$$\prod_{i=1}^{m} \left[(1+q)^{(m-1)s_i} - \left((1+q)^{m-1} - 1 \right)^{s_i} \right].$$
5. *Q is the four-coordinate specialization row for the five partition types 4, $3+1$, $2+2$, $2+1+1$, and $1+1+1+1$.*
6. *I is the incidence-total row that reads the quotient-level and codon-level totals from the displayed specialization.*
7. *T records the downstream defect-flow handoff to the partition skeleton and incidence certificate.*
8. *H records componentwise* hsame *transport for block sizes, legal decorations, defect exponents, product rows, specialization rows, incidence rows, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay through $M, S, D, E, F, Q, I, T, H$.*
10. *P is the* Pkg *provenance over* PartitionBasinPolynomial$^{\uparrow}$, Partition$^{\uparrow}$, DefectFlowPartitionSkeleton$^{\uparrow}$, PartitionCoreIncidenceCertificate$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$ *row.*

The carrier has no coordinate for a stochastic biology model, a host polynomial oracle, a quotient-semantic equality, an unbounded partition enumeration, or a hidden recurrence outside the displayed finite rows.

Lean4 ✓ `BEDC.Derived.PartitionBasinPolynomialUp.PartitionBasinPolynomialTasteGate single carrier alignment`

Theorem 4310.2 (PartitionBasinPolynomial NameCert obligations)**.** *For every accepted* PartitionBasinPolynomial$^{\uparrow}$ *carrier*

$$B = (M, S, D, E, F, Q, I, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$ *surface consists exactly of block-count and block-size admission through M, S, legal-decoration admission through D, defect-exponent admission through E, product-formula exposure through F, four-coordinate specialization through Q, incidence-total readback through I, defect-flow handoff through T, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4363.1. The block-count and block-size rows supply the finite partition core on which the enumeration is read.

The decoration and defect rows are then exposed coordinatewise. For block i, the all-decoration contribution is $(1+q)^{(m-1)s_i}$, and the excluded no-private-coordinate contribution is $\left((1+q)^{m-1}-1\right)^{s_i}$.

Multiplying the legal block rows gives the product row F. The specialization row Q evaluates the same finite formula on the five four-coordinate partition types, and the incidence row I sums the displayed rows with their finite multiplicities.

Finally T, H, C, P, N route the same polynomial surface to the defect-flow and incidence packets. Because no excluded stochastic, host-oracle, quotient-semantic, unbounded-enumeration, or hidden-recurrence coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 4310.3 (PartitionBasinPolynomial product specialization)**.** *Every defect-flow consumer of an accepted* PartitionBasinPolynomial$^{\uparrow}$ *carrier receives the product formula row for $\mathcal{B}_P(q)$ and the four-coordinate specialization row before reading quotient-level or codon-level incidence totals. The consumer sees only finite block-size, decoration, defect, product, specialization, incidence, transport, replay, provenance, and local NameCert rows.*

Proof. Start from the obligations of Definition 4363.2. They force the block-size ledger and legal-decoration rows to be displayed before the product formula can be consumed.

The four-coordinate row is a finite specialization of the same product row. Its incidence totals are read only after the partition types and finite multiplicities have been displayed.

The handoff through T, H, C, P, N preserves the same finite surface for the defect-flow skeleton and partition-core incidence certificate. Thus no stochastic model, host generating-function oracle, quotient-semantic equality, or hidden enumeration can be read from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$.

Constructive story: A PartitionBasinPolynomial$^{\uparrow}$ packet is generated from block-count rows, block-size ledgers, legal-decoration rows, defect-exponent ledgers, a product-formula row, a four-coordinate specialization row, incidence-total rows, a defect-flow handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$, seed)

Scope closed: Definition 4363.1, Definition 4363.2, and Definition 4363.3 seed the finite partition-basin polynomial packet over displayed block-size, decoration, defect, product, specialization, incidence, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a stochastic biology model, host generating-function oracle, quotient-level semantic equality, unbounded partition enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, product-formula exposure, four-coordinate specialization, incidence readback, transport, replay, provenance, and local naming for BEDC.Derived.PartitionBasinPolynomialUp.

Chapter 4311

A Concrete Naming Certificate for $\mathsf{DistanceToSet}^{\uparrow}$

Following Bishop and Bridges on located subsets in metric spaces, the $\mathsf{DistanceToSet}^{\uparrow}$ packet records the finite route by which a point-to-set distance request is read through displayed located-radius rows and closed-ball witnesses. It sits after the metric source of chapter 57, the located-set surface of chapter 1541, the metric closed-ball boundary of chapter 1451, the located closed-ball handoff of chapter 4063, and the terminal real-name seal of chapter 38. The packet names distance-to-set as finite BEDC data; it is not a host infimum, not a selected nearest point, not quotient real equality, and not a countable-choice construction.

Definition 4311.1 (Distance-to-set carrier)**.** *A* $\mathsf{DistanceToSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, A, x, r, B, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row over which point and subset reads are interpreted.*
2. *A is the* $\mathsf{LocatedSet}^{\uparrow}$ *row naming the subset by finite located-radius observations.*
3. *x is the displayed point row in the metric source.*
4. *r is the dyadic radius ledger recording the inspected tolerance windows.*
5. *B is the* $\mathsf{MetricClosedBall}^{\uparrow}$ *witness row attached to the point and radius ledger.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the exported distance name, read only after the located-set and closed-ball rows are displayed.*
7. *H records componentwise* hsame *transport for the metric source, located set, point row, dyadic ledger, closed-ball witness, Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from the metric source through located-set exposure, point inspection, dyadic-radius accounting, closed-ball handoff, and the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{DistanceToSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{LocatedClosedBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DistanceToSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, A, x, r, B, R, H, C, P, N$. It has no coordinate for a host infimum over all points of A, a selected nearest point, quotient real equality, countable choice, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.DistanceToSetUp.DistanceToSetTasteGate single carrier alignment`

Theorem 4311.2 (Distance-to-set NameCert obligations)**.** *For every accepted* $\mathsf{DistanceToSet}^{\uparrow}$ *carrier*

$$D = (X, A, x, r, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DistanceToSet}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the metric source, located set, point row, dyadic radius ledger, closed-ball witness, Real seal, transport, replay, provenance, and local naming;*
2. *located-set exposure, requiring every subset read to pass through the* $\mathsf{LocatedSet}^{\uparrow}$ *row A before a distance row is exported;*
3. *dyadic-radius monotonicity, requiring the tolerance ledger r to preserve the displayed radius order used by the located-set and closed-ball rows;*
4. *closed-ball handoff, requiring each ball membership or exclusion read to pass through the* $\mathsf{MetricClosedBall}^{\uparrow}$ *witness B and the located closed-ball sibling surface before the Real seal is read;*
5. *Real seal non-escape, requiring R to seal only the displayed distance name and not a host infimum or quotient real;*
6. *componentwise transport, displayed replay, package provenance, and local* NameCert *naming for exactly the displayed packet.*

No DistanceToSet obligation is stored outside these rows.

Proof. Project the carrier of Definition 4364.1. The metric source is X, the located subset is A, the inspected point is x, and the finite tolerance information is held by r.

The closed-ball witness B is read only after those rows are displayed. Its radius requests are therefore attached to the same metric source, located-set row, point row, and dyadic ledger.

The Real seal R comes after the located-radius and closed-ball rows. Transport H and replay C preserve the same order, while P and N record provenance and local naming.

Since no coordinate stores a host infimum, a nearest-point selector, quotient real equality, countable choice, or ambient completeness, those objects cannot become local NameCert obligations. □

Theorem 4311.3 (Distance-to-set located-radius handoff)**.** *Every consumer of an accepted* $\mathsf{DistanceToSet}^{\uparrow}$ *packet reads distance-to-set data only through the displayed located-radius row A, the dyadic radius ledger r, the closed-ball witness B, and the Real seal R, transported by H and replayed by C. The consumer cannot bypass these rows by reading a host infimum, a selected nearest point, quotient real equality, countable choice, or an ambient completeness principle.*

Proof. Read the carrier of Definition 4364.1. The only subset coordinate is the located-set row A, and the only radius coordinate is the dyadic ledger r.

The closed-ball witness B supplies the displayed ball boundary before the Real seal R is exposed. Thus a distance consumer reaches the exported real name only through the located-radius and closed-ball rows.

Apply Definition 4364.2. The transport, replay, provenance, and local naming rows preserve the same finite packet and add no host infimum, nearest-point selector, quotient real equality, countable choice, or ambient completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{DistanceToSet}\uparrow}$.

Constructive story: A $\mathsf{DistanceToSet}^{\uparrow}$ packet is generated from a metric source, located set row, point row, dyadic radius ledger, closed-ball witness, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DistanceToSet}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4364.1, Definition 4364.2, and Definition 4364.3 seed the finite located-radius and closed-ball interface for distance-to-set consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DistanceToSet}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host infimum construction, selected nearest points, quotient real equality, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, located-set exposure, dyadic-radius monotonicity, closed-ball handoff, Real seal non-escape, transport stability, replay stability, provenance, and local naming for BEDC.Derived.DistanceToSetUp.

Chapter 4312

A Concrete Naming Certificate for $\mathsf{JordanCurve}^{\uparrow}$

Following Jordan and constructive topology, the $\mathsf{JordanCurve}^{\uparrow}$ packet records the finite polygonal and winding-ledger route by which a displayed simple closed curve in the real plane may be consumed as a separation boundary. It sits after the terminal real-name seal of chapter 38, the circle carrier of chapter 58, the graph and modulus rows of chapter 130, the finite compact-metric source of chapter 129, and the simplex inventory of chapter 238. The packet names a constructive finite obligation surface; it does not import classical open-cover compactness, selected complementary components, quotient path equality, or a choice-dependent separation theorem.

Definition 4312.1 (Jordan curve carrier)**.** *A* $\mathsf{JordanCurve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, F, P, W, O, I, E, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{S}^{1\uparrow}$ *source row, recording the circle parameter ledger and its local classifier.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row into the displayed* $\mathsf{Real}^{\uparrow} \times \mathsf{Real}^{\uparrow}$ *plane, with graph and modulus observations visible.*
3. *P is the finite polygonal approximation row, read through a* $\mathsf{SimplicialComplex}^{\uparrow}$ *subdivision and its vertex-image ledger.*
4. *W is the winding ledger, recording the finite edge-crossing and sign-change data used to compare test points with the polygonal boundary.*
5. *O is the orientation row, recording the compatible cyclic order inherited from the* $\mathsf{S}^{1\uparrow}$ *row and the polygonal subdivision.*
6. *I is the injectivity-apartness row, stating that distinct inspected arcs carry displayed positive separation windows before they are used by the boundary read.*
7. *E is the exterior-interior ledger, recording only the finite side classification certified by the current polygonal and winding rows.*
8. *H records componentwise* hsame *transport for $S, F, P, W, O, I, E, C, Q, N$.*
9. *C records displayed* Cont *replay from circle, map, polygonal, winding, orientation, and apartness rows to the side-classification row.*

10. *Q is the* Pkg *provenance over* $\mathsf{JordanCurve}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{JordanCurve}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, F, P, W, O, I, E, H, C, Q, N$. It has no coordinate for a host Jordan curve theorem, selected complementary components, open-cover compactness, arbitrary path lifting, quotient path equality, or countable-choice separation.

Lean4 ✓ `BEDC.Derived.JordanCurveUp.JordanCurveTasteGate single carrier alignment`

Theorem 4312.2 (Jordan curve orientation ledger)**.** *For every accepted* $\mathsf{JordanCurve}^{\uparrow}$ *carrier*

$$J = (S, F, P, W, O, I, E, H, C, Q, N),$$

the orientation row O is determined by the finite $\mathsf{S}^{1\uparrow}$ *cyclic order, the* $\mathsf{SimplicialComplex}^{\uparrow}$ *subdivision in P, and the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *edge-image ledger in F. The winding ledger W can read orientation only through those rows, transported by H and replayed by C.*

Proof. Project the accepted carrier. The only circle-facing coordinate is S, and the only finite boundary skeleton is the polygonal row P together with the displayed edge images in F.

The orientation row O is therefore read by following the cyclic order of S across the subdivision cells of P. Each edge-image comparison is a finite real-plane observation supplied by F, not by an ambient topological orientation principle.

The winding ledger W consumes that ordered edge list. Componentwise transport H and replay C preserve the same ordered rows, while Q and N record provenance and local naming. Since the carrier contains no host orientation object or quotient path coordinate, the finite ledger is the entire orientation source. □

Theorem 4312.3 (Jordan curve winding separation boundary)**.** *Every side-classification read from an accepted* $\mathsf{JordanCurve}^{\uparrow}$ *packet factors through the finite route*

$$S, F, P, O, I, W \longmapsto E \longmapsto H, C, Q, N.$$

Thus the packet exposes polygonal approximation, injectivity-apartness, orientation, and winding ledgers before it names an interior or exterior row. It does not assert a blanket classical Jordan separation theorem, selected complementary components, open-cover compactness, quotient path equality, or choice-dependent planar separation.

Proof. Read the carrier of Definition 4365.1. The curve source is S, the displayed map is F, and the finite polygonal boundary is P.

Before a side row is exported, the packet requires the orientation ledger O, injectivity-apartness row I, and winding ledger W. These rows are finite BHist data: the winding read uses edge crossings and signs already attached to the polygonal boundary.

The exterior-interior row E is downstream of that route. Transport, replay, provenance, and naming through H, C, Q, N preserve the same finite packet. The excluded host theorem, selected components, open covers, quotient paths, and choice rows are not coordinates of the carrier, so they cannot be read from the local NameCert surface. □

Falsifiable prediction: A $\mathsf{JordanCurve}^{\uparrow}$ consumer that exports side separation without reading P, W, O, I refutes the carrier surface.

Independence witness: real, sone, continuousmap, compactmetric, simplicialcomplex: the sibling chapters supply real-plane coordinates, circle source data, continuous graph and modulus rows, compact-metric finite inspection, and subdivision cells separately, while $\mathsf{JordanCurve}^{\uparrow}$ binds them into the finite packet $J = (S, F, P, W, O, I, E, H, C, Q, N)$.

Closure status for $\mathsf{NameCert}_{\mathsf{JordanCurve}\uparrow}$.

Constructive story: A $\mathsf{JordanCurve}^{\uparrow}$ packet is generated from a circle source row, continuous real-plane map row, finite polygonal subdivision, winding ledger, orientation row, injectivity-apartness row, side-classification ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JordanCurve}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4365.1, Definition 4365.2, and Definition 4365.3 seed the finite polygonal, winding, orientation, apartness, side-classification, transport, replay, provenance, and local naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JordanCurve}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.JordanCurveUp.JordanCurveTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, the classical Jordan curve theorem, selected complementary components, open-cover compactness, arbitrary path lifting, quotient path equality, or choice-dependent separation.

Upgrade path: Obligation closure requires checked carrier admission, polygonal approximation exactness, winding-ledger stability, orientation transport, injectivity-apartness handoff, side-classification non-escape, replay, provenance, and local naming for BEDC.Derived.JordanCurveUp.

Chapter 4313

A Concrete Naming Certificate for MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$

The MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ packet realizes the normalization remaining question of chapter 9386 as finite NameCert data. It sits beside the candidate-set packet of chapter 2320 and the normalization router of chapter 1108: those siblings expose candidate evidence and route selection, while this packet records the boundary where empty-context closed typed terms may or may not enter the candidate interface. The packet names a closed-projection frontier only; it does not turn candidate-mediated normalization into an unconditional strong-normalization theorem for every closed MetaCIC term.

Definition 4313.1 (MetaCIC candidate closed-projection boundary carrier)**.** *A* MetaCICCandidateClosedProjection *carrier is a finite* BHist *packet*

$$B = (T, K, R, E, NF, O, H, C, P, L)$$

with the following displayed rows:

1. *T is the empty-context typed closed-term row whose projection into the candidate interface is being tested.*
2. *K is the candidate-set evidence row, read through* CandidateSetNormalization$^{\uparrow}$ *when the projection is admitted.*
3. *R is the router row, read through* MetaCICNormalizationCertificateRouter$^{\uparrow}$ *and recording which candidate, closed-candidate, or candidate-set route is exposed.*
4. *E is the bounded-normal endpoint seal row, recording the finite normal-output evidence available after candidate admission.*
5. *NF is the no-infinite-reduction row exported only downstream of K, R, E.*
6. *O is the obstruction row recording refusal when the closed term cannot be placed into the displayed candidate interface.*
7. *H records componentwise* hsame *transport for $T, K, R, E, NF, O, C, P, L$.*
8. *C records displayed* Cont *replay from the closed-term row through candidate admission, router selection, endpoint seal, no-infinite-reduction read, and obstruction retention.*

9. *P is the* Pkg *provenance over* MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$, CandidateSetNormalization$^{\uparrow}$, MetaCICNormalizationCertificateRouter$^{\uparrow}$, MetaCICOpenProblemLedger$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* NameCert$_{\text{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, K, R, E, NF, O, H, C, P, L$. It has no coordinate for evidence-free closed-term strong normalization, unrestricted subject reduction, host reduction equality, quotient conversion, or a global normalizer.

Lean4 ✓ `BEDC.Derived.MetaCICCandidateClosedProjectionBoundaryUp.MetaCICCandidateClosedProjectionBoundar`
`single carrier alignment`

Theorem 4313.2 (MetaCIC candidate-set closed projection frontier)**.** *For every accepted* MetaCICCandidateClosed *carrier*

$$B = (T, K, R, E, NF, O, H, C, P, L),$$

the closed-term row T reaches a strong-normalization-facing read only through candidate evidence K, router selection R, and bounded-normal endpoint seal E. If those rows do not place T inside the candidate interface, the obstruction row O is the only exported boundary datum.

Proof. Project the carrier. The closed-term row T is present as a finite syntactic and typing packet, but it is not itself a normalization theorem.

The positive route first reads K through chapter 2320. The router row R then records the candidate, closed-candidate, or candidate-set branch through chapter 1108. Only after those rows are displayed can the endpoint seal E and no-infinite-reduction row NF be consumed.

If candidate admission is absent, O records the refusal. Transport, replay, provenance, and local naming through H, C, P, L preserve that same finite boundary, so the packet exports no evidence-free closed-term strong-normalization claim. □

Theorem 4313.3 (MetaCIC candidate-set SN handoff boundary)**.** *Every strong-normalization handoff exported by an accepted* MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ *packet is a handoff for rows already inside the displayed candidate interface. It cannot be read as a blanket theorem that all empty-context typed closed MetaCIC terms are strongly normalizing.*

Proof. Start with the frontier theorem. It places the normalization-facing route behind K, R, E and keeps the obstruction row O visible when the candidate interface is not supplied.

For an admitted row, the handoff consumes candidate evidence from CandidateSetNormalization$^{\uparrow}$ and route evidence from MetaCICNormalizationCertificateRouter$^{\uparrow}$. The no-infinite-reduction row NF is therefore downstream of the admitted candidate branch rather than a second source of normalization evidence.

For a closed term outside that interface, the carrier has only T and the obstruction row O on the boundary. The structural rows H, C, P, L transport, replay, source, and name the boundary, but they do not add subject reduction, host conversion equality, quotient reduction equality, or a global normalizer. Hence the handoff is candidate-scoped. □

Theorem 4313.4 (MetaCIC candidate-set public boundary)**.** *Any public no-infinite-reduction or strong-normalization read from an accepted* MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ *packet must cite candidate-set membership or soundness, router selection, and bounded-normal endpoint rows. A bare empty-context typed closed-term row T is insufficient: the public boundary may expose NF only downstream of the candidate-set facts named by* closed_typed_term_sn_from_candidateSet, candidateSet_implies_sn, *and* canonicalCandidateSet_sound *together with the router row R and endpoint seal E.*

Proof. Start with Definition 4366.2. It places every normalization-facing read behind the candidate evidence row K, router row R, and endpoint seal E, and leaves the obstruction row O as the only datum when candidate admission is absent.

Next apply Definition 4366.3. That theorem identifies the handoff as a candidate-interface handoff rather than a theorem about all empty-context closed typed rows. Thus the public NF row cannot be projected from T alone.

Finally read the MetaCIC normalization audit map through the existing candidate-set facts closed_typed_term_sn_from_candidateSet, candidateSet_implies_sn, and canonicalCandidateSet_sound. Those facts supply the candidate membership and soundness side of the route, while R and E supply the public router and endpoint rows. The resulting boundary is therefore candidate-mediated and evidence-bearing, not an unconditional closed-term normalizer. □

Falsifiable prediction: A MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ consumer that exports strong normalization from T without reading K, R, E refutes the carrier surface.

Independence witness: candidate-set-normalization, metacicnormalizationcertificaterouter, metacicopenproblemledger: the candidate-set packet carries candidate evidence, the router selects the admissible normalization route, and the open-problem ledger records the frontier question; this packet binds those rows into a closed-projection boundary without adding an evidence-free normalization theorem.

Closure status for NameCert$_{\text{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}}$.

Constructive story: A MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ packet is generated from an empty-context typed closed-term row, candidate-set evidence, normalization-router selection, bounded-normal endpoint seal, no-infinite-reduction row, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 4366.1, Definition 4366.2, Definition 4366.3, and Definition 4366.4 seed the finite closed-projection, candidate-evidence, router-selection, endpoint-seal, obstruction, public-boundary, transport, replay, provenance, and local naming surface.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, unconditional strong normalization for all closed typed MetaCIC terms, unrestricted subject reduction, host reduction equality, quotient conversion, or a global normalizer.

Upgrade path: Obligation closure requires checked closed-term projection, candidate-evidence admission, router selection, bounded-normal endpoint sealing, no-infinite-reduction handoff, obstruction exactness, replay, provenance, and local naming for BEDC.Derived.MetaCICCandidateClosedProjectionBoundaryUp.

Chapter 4314

A Concrete Naming Certificate for $\mathsf{PointedMetricSpace}^{\uparrow}$

Following Bourbaki and Kelley on based metric spaces, the $\mathsf{PointedMetricSpace}^{\uparrow}$ packet records a metric carrier together with a named basepoint route before completion, loop-space, or embedding consumers are allowed to inspect point-level data. It sits over the $\mathsf{Met}^{\uparrow}$ carrier of chapter 57, reads names through the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, passes regular rational distance observations through chapter 301 and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and offers a based source for the distance-preserving consumer route of chapter 439. The certificate names only finite BEDC rows; it does not import host points, quotient metric equality, selected representatives, or ambient completeness.

Definition 4314.1 (Pointed metric space carrier)**.** *A* $\mathsf{PointedMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, b, D, S, R, E, H, C, P_0, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *metric carrier row.*
2. *b is the basepoint name row, stored as finite BEDC data attached to M rather than as a host-level point.*
3. *D is the basepoint distance ledger, recording the finite requests that compare b with inspected metric names.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which basepoint and metric names are inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed distance windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the basepoint-distance observations.*
7. *H records componentwise* hsame *transport for M, b, D, S, R, E and the local certificate rows.*
8. *C records displayed* Cont *replay from a based metric request through the stream windows, regular rational readback, and real-distance seal.*
9. *P_0 is the* Pkg *provenance over* $\mathsf{PointedMetricSpace}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only after transporting the metric carrier, basepoint name, distance ledger, stream windows, regular readback, real seal, replay, provenance, and local naming rows together.

Lean4 ✓ `BEDC.Derived.PointedMetricSpaceUp.PointedMetricSpaceTasteGate single carrier alignment`

Theorem 4314.2 (Pointed metric space NameCert obligations)**.** *For every accepted* $\mathsf{PointedMetricSpace}^{\uparrow}$ *carrier* $P = (M, b, D, S, R, E, H, C, P_0, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the metric row, basepoint name, basepoint distance ledger, stream windows, regular rational readback, real-distance seal, transport, replay, provenance, and local naming rows;*
2. *common-carrier classification, requiring every comparison of basepoint data to be read over the transported metric row* M*;*
3. *basepoint-distance exposure, requiring every basepoint comparison to pass through* D, S, R, E *before any completion-facing or embedding-facing consumer reads it;*
4. *package provenance and local naming for exactly the displayed finite packet.*

No NameCert obligation is stored in a host point, quotient metric equality, a selected representative, or an ambient completeness principle.

Proof. Project the carrier of Definition 4367.1. The projection exposes the metric row, basepoint name, distance ledger, stream windows, regular readback, real seal, transport, replay, provenance, and local name as the only available coordinates.

The classifier route is common-carrier. Componentwise transport in H moves M, b, D, S, R, E together, so a consumer cannot compare a basepoint name over one metric carrier with distance observations over another.

The distance ledger fixes the read order. A basepoint comparison is first a finite request in D, then a scheduled stream observation in S, then a regular rational readback in R, and only then a $\mathsf{Real}^{\uparrow}$ distance seal in E.

Finally replay C and attach P_0, N. Since the carrier has no coordinate for host points, quotient equality, selected representatives, or ambient completeness, the listed rows exhaust the local naming surface. □

Theorem 4314.3 (Pointed metric space basepoint nonescape)**.** *Let* $P = (M, b, D, S, R, E, H, C, P_0, N)$ *be an accepted* $\mathsf{PointedMetricSpace}^{\uparrow}$ *carrier. Every completion-facing, loop-space-facing, or isometric-embedding-facing consumer of the basepoint row* b *must read it through the displayed route*

$$M, b, D \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P_0, N.$$

Thus the basepoint is exported only as finite named metric data over M*, not as a host point, quotient representative, selected completion point, or ambient metric-equality witness.*

Proof. Begin with carrier admission. The only row naming the basepoint is b, and it is stored beside the metric carrier M and distance ledger D.

Read the inspection route next. The stream windows S and regular rational readback R display every observed distance from the basepoint before the $\mathsf{Real}^{\uparrow}$ seal E is available to downstream consumers.

Transport and replay preserve that same route. The rows H, C, P_0, N move, replay, source, and name the displayed packet; they do not add host points, quotient representatives, selected completion points, or ambient metric equality.

Therefore every based consumer receives exactly the finite route displayed in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{PointedMetricSpace}^{\uparrow}$ packet is generated from a $\mathsf{Met}^{\uparrow}$ carrier, a named basepoint row, a basepoint distance ledger, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ distance seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4367.1, Definition 4367.2, and Definition 4367.3 seed the based metric route over $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.PointedMetricSpaceUp.PointedMetricSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host point equality, quotient metric equality, selected completion points, loop-space closure, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, basepoint-distance exposure, classifier transport, basepoint nonescape, and downstream completion and isometric-embedding consumer alignment for BEDC.Derived.PointedMetricSpaceUp.

Chapter 4315

A Concrete Naming Certificate for $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$

Following Bourbaki and Kelley on based complete metric spaces, the $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ packet records a based metric carrier together with a displayed completion service before completion, loop-space, or embedding consumers are allowed to read a point as complete. It sits over the $\mathsf{Met}^{\uparrow}$ carrier of chapter 57, the $\mathsf{CompleteMetric}^{\uparrow}$ limit-service boundary of chapter 128, the $\mathsf{PointedMetricSpace}^{\uparrow}$ basepoint route of chapter 4367, the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ rational readback of chapter 301, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The certificate names only finite BEDC rows; it does not import host points, quotient metric equality, selected completion representatives, countable choice, or ambient order completeness.

Definition 4315.1 (Pointed complete metric space carrier)**.** *A* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, B, Q, S, R, E, L, H, C, P_0, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *metric carrier row.*
2. *B is the basepoint row, stored as finite named metric data over M rather than as a host-level point.*
3. *Q is the Cauchy-window route, listing the finite tail requests through which regular Cauchy names based at B are inspected.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *readback row for the basepoint and Cauchy windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational distance and modulus observations.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed metric-distance and limit-distance observations.*
7. *L is the* $\mathsf{CompleteMetric}^{\uparrow}$ *completion seal, exposing only the displayed limit-service handoff for the Cauchy-window route Q.*
8. *H records componentwise* hsame *transport for M, B, Q, S, R, E, L and the local certificate rows.*
9. *C records displayed* Cont *replay from a based complete-metric request through the Cauchy windows, stream observations, regular rational readback, real seal, and completion seal.*

10. *P_0 is the* Pkg *provenance over* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PointedMetricSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only after transporting the metric carrier, basepoint, Cauchy-window route, stream windows, regular rational readback, real seal, completion seal, replay, provenance, and local naming rows together.

Lean4 ✓ `BEDC.Derived.PointedCompleteMetricSpaceUp.TasteGate.PointedCompleteMetricSpaceTasteGate single carrier alignment`

Theorem 4315.2 (Pointed complete metric space NameCert obligations)**.** *For every accepted* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *carrier* $P = (M, B, Q, S, R, E, L, H, C, P_0, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSp}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the metric row, basepoint row, Cauchy-window route, stream windows, regular rational readback, real seal, completion seal, transport, replay, provenance, and local naming rows;*
2. *common-carrier classification, requiring the basepoint row, Cauchy windows, and completion seal to be read over the transported metric row M;*
3. *Cauchy-window exposure, requiring every completion-facing read to pass through Q, S, R, E, L before any downstream consumer may inspect the limit handoff;*
4. *package provenance and local naming for exactly the displayed finite packet.*

No NameCert obligation is stored in a host point, quotient metric equality, selected completion representative, countable-choice selector, or ambient order-completeness principle.

Proof. Project the carrier of Definition 4368.1. The projection exposes the metric row, basepoint, Cauchy-window route, stream windows, regular readback, real seal, completion seal, transport, replay, provenance, and local name as the only available coordinates.

The classifier route is common-carrier. Componentwise transport in H moves M, B, Q, S, R, E, L together, so a consumer cannot compare a based Cauchy route over one metric carrier with a completion seal over another.

The completion-facing read order is fixed by the route rows. A completion request begins as a finite Cauchy-window request in Q, becomes a scheduled stream observation in S, is read back as regular rational data in R, is sealed as real-distance data in E, and only then reaches the $\mathsf{CompleteMetric}^{\uparrow}$ limit-service row L.

Finally replay C and attach P_0, N. Since the carrier has no coordinate for host points, quotient equality, selected completion representatives, countable-choice selectors, or ambient order completeness, the listed rows exhaust the local naming surface. □

Theorem 4315.3 (Pointed complete metric space Cauchy basepoint route)**.** *Let $P = (M, B, Q, S, R, E, L, H, C, P_0$ be an accepted* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *carrier. Every based regular Cauchy request whose initial window is anchored at B is read through the displayed route*

$$M, B, Q \longmapsto S \longmapsto R \longmapsto E \longmapsto L \longmapsto H, C, P_0, N.$$

Thus the basepoint participates in completion only as named metric and Cauchy-window data over M, not as a selected host point or completed-limit representative.

Lean4 ✓ `BEDC.Derived.PointedCompleteMetricSpaceUp.PointedCompleteMetricSpaceCauchyBasepointRoute`

Proof. Begin with carrier admission. The only row naming the basepoint is B, and it is stored beside the metric row M and the Cauchy-window route Q.

Read the window route next. The stream row S schedules the inspected windows, the regular rational row R reads the tail and distance ledgers, and the $\mathsf{Real}^{\uparrow}$ row E seals the observed distances before the complete-metric row L can expose any limit-service handoff.

Transport and replay preserve that same path. The rows H, C, P_0, N move, replay, source, and name the displayed packet; they do not add a host basepoint, a selected limit representative, quotient equality, or a separate completion object.

Therefore every based Cauchy consumer receives exactly the finite route displayed in the statement. □

Theorem 4315.4 (Pointed complete metric basepoint completion handoff)**.** *Let $P = (M, B, Q, S, R, E, L, H, C, P_0$ and $P' = (M', B', Q', S', R', E', L', H', C', P'_0, N')$ be accepted* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *carriers. If the two packets transport M, B, Q, S, R, E through the same componentwise H row, then every* $\mathsf{CompleteMetric}^{\uparrow}$ *service read of L is taken over that same named basepoint route before any loop-space or embedding consumer may inspect a completed point.*

Equivalently, a consumer may inspect

$$L \quad \text{or} \quad L'$$

only after the route

$$M, B, Q, S, R, E \longmapsto H, C, P_0, N$$

has been displayed; it cannot detach completion service from the transported basepoint row.

Proof. Project both carriers. In each packet the completion-service coordinate is L, and the only rows upstream of it are the metric row M, the basepoint row B, the Cauchy-window row Q, the stream row S, the regular rational row R, and the real-distance seal E.

Apply Definition 4368.3 to the first packet. The displayed route forces every based Cauchy request to pass through M, B, Q, S, R, E before the service row L is visible.

Use the assumed componentwise transport row H to move the same route to the second packet. The replay row C then reproduces the transported route for the completion-facing consumer, and the provenance and local name rows P_0, N record no independent completed point.

Thus a loop-space or embedding consumer can inspect a completed point only after the transported basepoint route has been displayed. There is no carrier coordinate from which the consumer could read L apart from B. □

Theorem 4315.5 (Pointed complete metric space completion nonescape)**.** *Every completion-facing, loop-space-facing, or embedding-facing consumer of an accepted* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *packet factors its completed-point read through*

$$M, B, Q, S, R, E, L, H, C, P_0, N.$$

Consequently the packet exports a based complete metric certificate only as finite BEDC NameCert data; it exports neither host points nor quotient completion equality.

Proof. Inspect the carrier coordinates. The only completion coordinate is L, and the definition makes L a completion seal for the already displayed Cauchy-window route Q over the metric row M and basepoint row B.

The readback rows precede the completion seal. Any consumer must first pass through S, R, E to display stream windows, regular rational ledgers, and real distance seals, so no completed point can be read before the finite analytic route is visible.

The remaining rows are administrative in the BEDC sense. Transport H, replay C, provenance P_0, and local name N preserve and source the packet but do not create host points, quotient completion equality, selected representatives, or ambient completeness.

Thus every downstream completed-point read factors through the displayed finite packet, which proves completion nonescape. □

Closure status for $\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ packet is generated from a MetricUp carrier, a named basepoint row, a Cauchy-window route, StreamName windows, RegSeqRat readback, a RealUp seal, a CompleteMetricUp completion seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4368.1, Definition 4368.2, Definition 4368.3, and Definition 4368.5 seed the based complete-metric route over $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PointedMetricSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient completion equality, selected host endpoints, loop-space closure, embedding closure, or ambient order completeness.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-window exposure, classifier transport, basepoint completion routing, completion nonescape, and downstream completion, loop-space, and embedding consumer alignment for BEDC.Derived.PointedCompleteMetricSpaceUp.

Chapter 4316

A Concrete Naming Certificate for $\mathsf{IntervalConnectedness}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{IntervalConnectedness}^{\uparrow}$ packet records the finite constructive route by which a located real interval is inspected as one connected interval surface before intermediate-value, zero-envelope, or completion-facing consumers use it. It sits after the endpoint seal of chapter 38, the located interval carrier of chapter 1709, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the sandwich consumer surface of chapter 2163. The packet names interval connectedness as displayed finite BEDC data; it does not import host topology, open-cover compactness, trichotomy, quotient real equality, selected roots, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4316.1 (Interval connectedness carrier)**.** *An* $\mathsf{IntervalConnectedness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (E, L, D, S, R, T, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint-pair row, storing the lower and upper endpoint names through their displayed real seals.*
2. *L is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *witness row, carrying the located interval budget, locator reads, and endpoint-radius checks attached to E.*
3. *D is the finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *subdivision-chain ledger, recording the dyadic cells, adjacent-cell overlaps, and tolerance requests inspected inside L.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which endpoint, cell, and witness observations are scheduled.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the scheduled endpoint and subdivision observations.*
6. *T records componentwise* hsame *transport for endpoint pairs, located interval witnesses, dyadic subdivision chains, stream windows, regular readbacks, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from endpoint pairs through located interval exposure, dyadic subdivision, stream-window inspection, regular readback, and the interval-connectedness handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{IntervalConnectedness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{SqueezeTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{IntervalConnectedness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, L, D, S, R, T, C, P, N$. It has no coordinate for host topological connectedness, open-cover compactness, trichotomy, quotient real equality, selected intermediate points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.IntervalConnectednessUp.IntervalConnectednessTasteGate single carrier alignment`

Theorem 4316.2 (Interval connectedness NameCert obligations)**.** *For every accepted* $\mathsf{IntervalConnectedness}^{\uparrow}$ *carrier*

$$I = (E, L, D, S, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{IntervalConnectedness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the endpoint pair, located interval witness, dyadic subdivision chain, stream windows, regular readbacks, transport, replay, provenance, and local naming rows;*
2. *classifier transport, requiring endpoint, locatedness, subdivision, window, readback, replay, provenance, and naming data to move componentwise through T;*
3. *dyadic chain exactness, requiring every inspected subinterval and adjacent-cell overlap to be recorded in D before a connectedness consumer reads the packet;*
4. *endpoint handoff nonescape, requiring every consumer of interval endpoints to pass through E, L, D, S, R before using any* $\mathsf{Real}^{\uparrow}$ *seal;*
5. *ledger exhaustion, requiring the packet to expose no host topological connectedness theorem, open-cover compactness, trichotomy, quotient real equality, selected intermediate point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

The sibling routes through $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{SqueezeTheorem}^{\uparrow}$ *are the only named consumers of this local certificate surface.*

Proof. Project the carrier of Definition 4369.1. The endpoint pair is visible only in E, and the located interval evidence is visible only in L.

The subdivision data are then forced through D. Each finite cell, overlap, and tolerance request is read as dyadic data before any stream-window or regular-readback consumer can inspect it.

Transport and replay preserve the same route. The rows T and C move endpoint, locatedness, subdivision, window, and readback data componentwise, while P and N source and name exactly that displayed packet.

Since the carrier has no coordinate for the excluded host principles, the local certificate cannot export them. □

Falsifiable prediction: Every accepted $\mathsf{IntervalConnectedness}^{\uparrow}$ consumer reads endpoint pairs, located interval witnesses, dyadic subdivision chains, StreamName windows, RegSeqRat readbacks, hsame transport, Cont replay, Pkg provenance, and local naming before any interval-connectedness handoff is visible.

Independence witness: real, locatedrealinterval, dyadicratcore, streamname, regseqrat, squeezetheorem: $\mathsf{IntervalConnectedness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint pairs, located interval witnesses, finite dyadic subdivision chains, scheduled stream windows, regular rational readbacks, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalConnectedness}^{\uparrow}}$.

Constructive story: An IntervalConnectedness$^{\uparrow}$ packet is generated from Real endpoint pairs, a LocatedRealInterval witness, a finite DyadicRatCore subdivision chain, StreamName windows, RegSeqRat readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\text{IntervalConnectedness}^{\uparrow}}$, seed)

Scope closed: Definition 4369.1 and Definition 4369.2 seed the finite located-interval connectedness route over Real$^{\uparrow}$, LocatedRealInterval$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and SqueezeTheorem$^{\uparrow}$ rows.

Formal verification: FormalStatus(NameCert$_{\text{IntervalConnectedness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host topology, open-cover compactness, trichotomy, quotient real equality, selected intermediate points, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, dyadic chain exactness, endpoint handoff nonescape, ledger exhaustion, and downstream intermediate-value consumer alignment for BEDC.Derived.IntervalConnectedness

Chapter 4317

A Concrete Naming Certificate for MetaCICResidualSubstitutionCompatibility$^{\uparrow}$

Following Tait–Martin-Lof and Barendregt on residuals, parallel reduction, and confluence discipline, the MetaCICResidualSubstitutionCompatibility$^{\uparrow}$ packet records the finite boundary where a beta-parallel branch and a substitution replay must meet before the MetaCIC confluence route may use the conditional diamond bridge. It sits over the audit map of chapter 9378 and names the residual-substitution input as packet data rather than as a global Church–Rosser theorem. The packet does not claim full closed Church–Rosser, arbitrary closed-source confluence, or an unrestricted substitution theorem.

The residual-substitution packet is consumed by chapter 765 as a guarded input to candidate-mediated SN/confluence scheduling. The dependency is the residual join row together with the closedness guard data: it tells the scheduler which finite substitution replay may enter a candidate branch and which source windows are closed enough for that handoff, not that the full Church–Rosser theorem has already been completed.

Definition 4317.1 (MetaCIC residual-substitution compatibility carrier)**.** *A* MetaCICResidualSubstitutionCompatil *carrier is a finite* BHist *packet*

$$M = (s, t, b, j, g, a, h, c, p, n)$$

with the following displayed rows:

1. *s is the source term row whose beta-parallel residual branch is inspected.*
2. *t is the substituted term row, storing the finite substitution request and the target occurrence window.*
3. *b is the parallel branch row, displaying the left and right beta-parallel steps before any join is named.*
4. *j is the residual join row, recording the candidate common reduct obtained after substitution replay and residual transport.*
5. *g is the closedness guard row, saying exactly which source and substitution windows are closed enough for the guarded handoff.*
6. *a is the atom-shape separation row, keeping atom, application, lambda, Pi, and beta-redex cases visibly disjoint.*
7. *h records componentwise* hsame *transport for source, substitution, branch, residual join, closedness guard, atom-shape separation, replay, provenance, and local naming rows.*

8. *c records displayed* Cont *replay from the source term through substitution, parallel branching, residual join construction, closedness guarding, and atom-shape separation.*
9. *p is the* Pkg *provenance over* MetaCICResidualSubstitutionCompatibility$^{\uparrow}$*, MetaCIC beta-parallel reduction, residual joins, closedness guards, atom-shape separation,* BHist*,* hsame*,* Cont*, and* NameCert*.*
10. *n is the local* NameCert$_{\text{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $s, t, b, j, g, a, h, c, p, n$. It has no coordinate for a completed parallel diamond, full closed Church–Rosser, arbitrary closed-source confluence, or an unguarded substitution principle.

Lean4 ✓ BEDC.Derived.MetaCICResidualSubstitutionCompatibilityUp.MetaCICResidualSubstitutionCompatibilit
single carrier alignment

Theorem 4317.2 (MetaCIC residual-substitution compatibility NameCert obligations)**.** *For every accepted* MetaCICResidualSubstitutionCompatibility$^{\uparrow}$ *carrier*

$$M = (s, t, b, j, g, a, h, c, p, n),$$

the local NameCert$_{\text{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source term, substituted term, parallel branch, residual join, closedness guard, atom-shape separation, transport, replay, provenance, and local naming rows;*
2. *branch-shape disjointness, requiring atom, application, lambda, Pi, and beta-redex branches to be separated by a before a residual join row is accepted;*
3. *substitution residual replay, requiring c to display how the substituted term row and beta-parallel branch row reach the same candidate join j;*
4. *closed-source guard, requiring g to expose the exact closedness assumptions consumed by the guarded compatibility packet;*
5. *non-claim of full closed Church–Rosser, requiring the packet to remain an input boundary for the conditional confluence bridge rather than a proof of arbitrary closed-source confluence.*

No obligation is stored outside $s, t, b, j, g, a, h, c, p, n$.

Proof. Project the carrier of Definition 4370.1. The source term, substituted term, branch, residual join, closedness guard, and atom-shape separation rows are the only computational coordinates.

The branch-shape row a fixes the case split before the join row is read. Thus a beta-redex residual branch cannot be silently identified with an atom, application, lambda, or Pi shape.

Replay then supplies the compatibility boundary. The row c records the finite route from substitution and beta-parallel branching to the candidate join j, while g states the closedness guard consumed by that route.

Finally h, p, n transport, source, and name exactly the displayed packet. Since full closed Church–Rosser and arbitrary closed-source confluence are not carrier coordinates, they are not exported by this NameCert surface. □

Theorem 4317.3 (MetaCIC residual-substitution candidate projection route)**.** *Every accepted* MetaCICResidualSubstitutionCompatibility$^{\uparrow}$ *carrier*

$$M = (s, t, b, j, g, a, h, c, p, n)$$

exports a candidate-closed projection route to chapter 4366 only after the source term row s, substituted term row t, beta-parallel branch row b, residual join row j, closedness guard row g, and atom-shape separation row a have all been displayed. The downstream candidate boundary receives a guarded compatibility packet, not full Church–Rosser and not arbitrary closed-source confluence.

Proof. Project the carrier of Definition 4370.1. The rows s, t, b, j, g, a are the only computational rows available before the structural transport, replay, provenance, and local naming rows are read.

Use Definition 4370.2. Branch-shape disjointness exposes a, substitution residual replay exposes the route from t and b to j, and the closed-source guard exposes exactly the assumptions in g.

The candidate boundary of chapter 4366 is therefore reached through a guarded compatibility packet. The route supplies source, substitution, beta-parallel, residual-join, closedness, and atom-shape data, while h, c, p, n only transport, replay, source, and name those rows.

Since completed Church–Rosser and arbitrary closed-source confluence are absent from the carrier, the candidate-closed projection route cannot export them. It hands off only the displayed residual-substitution compatibility boundary. □

Theorem 4317.4 (MetaCIC residual-substitution obligation closure surface)**.** *For every accepted* $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ *carrier*

$$M = (s, t, b, j, g, a, h, c, p, n),$$

the obligation surface is exactly the displayed source term, substituted term, parallel branch, residual join, closedness guard, atom-shape separation, transport, replay, provenance, and naming rows. The candidate-closed projection boundary receives only this guarded compatibility packet.

Proof. Apply Definition 4370.2. It identifies carrier admission, branch-shape disjointness, substitution residual replay, closed-source guarding, transport, replay, provenance, and naming as rows of $s, t, b, j, g, a, h, c, p, n$.

Apply Definition 4370.3. The candidate boundary receives the source, substitution, beta-parallel branch, residual-join, closedness, and atom-shape data only through that guarded projection route.

Therefore the obligation surface packages the candidate handoff without exporting full closed Church–Rosser, arbitrary closed-source confluence, or unguarded substitution compatibility. Those claims are not coordinates of the carrier and are not supplied by the candidate projection. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ read displays source term, substituted term, parallel branch, residual join, closedness guard, atom-shape separation, hsame transport, Cont replay, Pkg provenance, and local naming rows before the conditional MetaCIC confluence bridge can consume it.

Independence witness: metacic-confluence-audit: $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ is not a completed confluence theorem because it carries only the finite residual-substitution compatibility boundary consumed by the conditional parallel-diamond route.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ packet is generated from source term, substituted term, parallel branch, residual join, closedness guard, atom-shape separation, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4370.1, Definition 4370.2, and Definition 4370.3 seed the finite residual-substitution compatibility boundary consumed by the conditional MetaCIC confluence bridge and the candidate-closed projection route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full closed Church–Rosser, arbitrary closed-source confluence, unguarded substitution compatibility, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch-shape disjointness, substitution residual replay, closed-source guard, and conditional confluence handoff alignment for BEDC.MetaCIC.BetaParallelSubstitutionCompatibility.

Chapter 4318

A Concrete Naming Certificate for $\mathsf{ComputableCompactMetric}^{\uparrow}$

Following Weihrauch-style computable analysis and the Bishop–Bridges compact metric arguments, the $\mathsf{ComputableCompactMetric}^{\uparrow}$ packet records the effective compact-metric surface as finite BEDC NameCert data. It sits after the compact metric carrier of chapter 129, the effective Polish source of chapter 1706, the total-bounded finite-net route of chapter 127, the complete metric source of chapter 128, and the L10 readback route through chapter 126, chapter 301, and chapter 38. The packet names the finite-cover realizer surface consumed by effective compact analysis; it does not assert open-cover compactness, selected subcovers, quotient completion equality, or an ambient real-completeness principle.

Definition 4318.1 (Computable compact metric carrier)**.** *A* $\mathsf{ComputableCompactMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K_{\mathrm{ccm}} = (K, E, T, C, S, R, L, H, Q, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row carrying the compact metric packet whose finite-net behavior is being made effective.*
2. *E is the* $\mathsf{EffectivePolishSpace}^{\uparrow}$ *source row exposing the effective dense-name and semidecidable basic-ball interface.*
3. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *row naming the finite-net source for each displayed dyadic tolerance request.*
4. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row recording the convergence service available to Cauchy and compact consumers.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for inspected dense names, finite net centers, tolerance requests, and cover indices.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the regular rational readback of distances and tolerance comparisons.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite windows and regular rational comparisons have been displayed.*

8. *H records componentwise* hsame *transport for compact metric, effective Polish, total-bounded, complete-metric, stream-window, regular-readback, real-seal, finite-cover realizer, provenance, and local naming rows.*
9. *Q records displayed* Cont *replay from an effective compactness request through K, E, T, C, S, R, L, H.*
10. *P is the* Pkg *provenance over* $\mathsf{ComputableCompactMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{EffectivePolishSpace}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, E, T, C, S, R, L, H, Q, P, N$. It has no coordinate for an open-cover subcover, a choice-selected finite set, quotient completion equality, excluded-middle compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ComputableCompactMetricUp.ComputableCompactMetricTasteGate single carrier alignment`

Theorem 4318.2 (Computable compact metric NameCert obligations)**.** *For every accepted* ComputableCompactMe *carrier*

$$K_{\mathrm{ccm}} = (K, E, T, C, S, R, L, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}$ *surface consists exactly of the displayed rows in Definition 4371.1. Carrier admission must expose the compact metric source, effective Polish source, total-bounded finite-net source, complete-metric convergence service, finite stream windows, regular rational readback, terminal real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Classifier transport is componentwise through those same rows, and ledger exhaustion says that every finite-cover or compact-analysis consumer can inspect only $K, E, T, C, S, R, L, H, Q, P, N$.*

Proof. Project the carrier of Definition 4371.1. The rows K, E, T, C are the only structural compactness sources, so carrier admission exposes compact metric data, effective Polish naming data, total-bounded finite nets, and complete-metric convergence before any realizer can be read.

The readback rows S, R, L then bind numerical access to finite windows, regular rational comparisons, and the terminal real seal. This is the same L10 readback discipline used by the StreamName, RegSeqRat, and Real siblings named in the chapter introduction.

Transport and replay are visible rows rather than hidden meta-operations. The row H records componentwise hsame transport, Q records displayed Cont replay, and P, N source and name the same finite packet.

For ledger exhaustion, read any compact-analysis consumer from the accepted packet. The carrier exposes only $K, E, T, C, S, R, L, H, Q, P, N$, so no open-cover subcover, selected finite set, quotient completion equality, excluded-middle compactness, or ambient real-completeness principle can be obtained from this NameCert surface. □

Theorem 4318.3 (Computable compact metric finite-cover realizer)**.** *Every effective finite-cover read exported by an accepted* $\mathsf{ComputableCompactMetric}^{\uparrow}$ *packet factors through the route*

$\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{EffectivePolishSpace}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsa

Thus a consumer receives a compact metric source, effective dense-name interface, total-bounded finite-net source, complete-metric convergence service, finite stream windows, regular rational tolerance comparisons, terminal real seal, componentwise transport, replay, provenance, and local

naming rows before it uses the finite-cover realizer. The packet exports no selected subcover, open-cover compactness theorem, quotient completion representative, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with an accepted carrier $K_{\mathrm{ccm}} = (K, E, T, C, S, R, L, H, Q, P, N)$. The compact metric row K and effective Polish row E name the metric and effective dense-name surfaces, while T supplies the finite-net source used for the requested tolerance.

The convergence row C keeps the compact route compatible with complete-metric consumers. A finite-cover realizer cannot leave these displayed sources, because the later rows are read only after the compact, effective, total-bounded, and complete rows are present.

The numerical readback is finite. The stream row S exposes inspected names, center windows, cover indices, and tolerance requests; the regular rational row R compares the displayed distances; and the terminal seal L is reached only after those windows and comparisons have been read.

Finally H, Q, P, N preserve the route under transport, replay, provenance, and local naming. Since selected subcovers, open-cover compactness theorems, quotient representatives, choice selectors, and ambient completeness witnesses are not carrier coordinates, the exported realizer is exactly the displayed finite-cover surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{ComputableCompactMetric}^{\uparrow}$ packet is generated from CompactMetric, EffectivePolishSpace, TotallyBounded, CompleteMetric, StreamName, RegSeqRat, RealUp, componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4371.1, Definition 4371.2, and Definition 4371.3 seed the effective finite-cover realizer route for computable compact metric consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected subcovers, open-cover compactness, quotient completion equality, countable-choice selectors, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, effective dense-name exposure, total-bounded finite-net exposure, complete-metric convergence exposure, finite-window readback, regular rational comparison, real sealing, finite-cover realizer nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ComputableCompactMetricUp.

Chapter 4319

A Concrete Naming Certificate for $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ packet records the separated-completion reflection route for regular Cauchy rational names as finite BEDC NameCert data. It sits over the regular rational readback surface of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the uniqueness boundary of chapter 3390. The packet lets a Real-facing consumer treat two representative regular Cauchy names as the same separated reflection point only after the displayed finite windows, dyadic budgets, and uniqueness ledger have been exposed.

Definition 4319.1 (Regular-Cauchy Hausdorff-reflection carrier)**.** *A* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, Y, S, T, D, U, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the first* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name row.*
2. *Y is the second* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name row presented to the same separated-reflection request.*
3. *S and T are the paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows through which X and Y are observed.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows.*
5. *U is the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *row witnessing that the displayed tail comparisons force separated agreement.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after X, Y, S, T, D, U have been displayed.*
7. *H records componentwise* hsame *transport for the two regular names, stream windows, dyadic ledger, uniqueness row, Real seal, and local certificate rows.*
8. *C records the displayed* Cont *replay from a reflection request to the paired windows, dyadic tolerance ledger, uniqueness row, and terminal Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyUniqueness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, S, T, D, U, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionCarrier admission surface`

Theorem 4319.2 (Regular-Cauchy Hausdorff-reflection NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *carrier* $R = (X, Y, S, T, D, U, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}}$ *surface consists exactly of carrier admission for two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, paired* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *separated-agreement row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation may replace these rows by quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionTasteGate single carrier alignment`

Proof. Project the carrier of Definition 4372.1. The only displayed coordinates are $X, Y, S, T, D, U, E, H, C, P, N$.

The two regular rational names are compared through the paired stream windows S, T and the dyadic tolerance ledger D. The separated-agreement row U is therefore a displayed uniqueness boundary, not a quotient of streams or a host equality proof.

The terminal Real seal E is downstream of that boundary. Transport, replay, provenance, and local naming are supplied by H, C, P, N, and no excluded quotient, selector, host-equality, choice, trichotomy, or ambient-completeness coordinate can be projected from the carrier. □

Theorem 4319.3 (Regular-Cauchy Hausdorff-reflection representative independence)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read accepted by a* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *packet is independent of the chosen representative regular Cauchy name in the following BEDC sense: if the two presented* $\mathsf{RegSeqRat}^{\uparrow}$ *rows are compared through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, then the terminal seal can distinguish them only through the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *row. The packet exports no quotient stream equality, selected representative, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionRepresentativel`

Proof. Begin with an accepted carrier $R = (X, Y, S, T, D, U, E, H, C, P, N)$. The rows X and Y are not presented as completed real objects; they are presented as regular rational names observed through finite stream windows.

The dyadic ledger D binds the comparison budget for those windows, and the uniqueness row U is the only row that can turn the displayed tail comparison into separated agreement. Thus any Real-facing read of E must pass through the same finite comparison route.

The rows H, C, P, N transport, replay, source, and name this route without adding analytic content. Since the carrier contains no further equality coordinate, changing representatives cannot be detected except through the displayed uniqueness row. □

Theorem 4319.4 (Regular-Cauchy Hausdorff-reflection Real seal non-escape)**.** *No terminal* $\mathsf{Real}^{\uparrow}$ *seal consumer accepted by a* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *packet can bypass the displayed route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegularCauchyUniqueness}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In particular, the separated reflection supplies representative independence for the Real seal without quotient streams, host real equality, selected representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionCarrier real seal nonescape`

Proof. Read the carrier coordinates in order. The terminal row E appears only after the two regular rational names, paired stream windows, dyadic tolerance ledger, and uniqueness row have been displayed.

Apply Definition 4372.2. The local NameCert surface exposes exactly those rows, with H, C, P, N preserving the same route for downstream consumers.

The advertised route is therefore the only public path to the Real seal. Since no excluded equality or choice coordinate occurs in the carrier, the seal cannot escape through quotient streams, host equality, representatives selected outside the packet, countable choice, trichotomy, or ambient completeness. □

Theorem 4319.5 (Regular-Cauchy Hausdorff-reflection finite-window uniqueness route)**.** *Suppose two accepted* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *packets display the same paired* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the same* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *row, and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal. Then every separated-reflection consumer factors through the same finite-window route on the underlying* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The factorization does not use quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionCarrier finite window uniqueness route`

Proof. Apply Definition 4372.3. Once the paired StreamName windows, dyadic tolerance ledger, and uniqueness row agree, the terminal Real seal cannot distinguish the two regular Cauchy representatives by any route other than the displayed uniqueness row.

Apply Definition 4372.4. The Real seal is downstream of the finite windows, dyadic ledger, and uniqueness row, so a separated-reflection consumer has no bypass around those displayed rows.

The remaining rows are structural. The hsame rows transport only the displayed components, the Cont rows replay the same finite-window request, and the Pkg and NameCert rows name that route inside BHist. Therefore the consumer factors through the same finite-window route. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ consumer that reaches the terminal RealUp seal without reading two RegSeqRat source rows, paired StreamName windows, a DyadicRatCore tolerance ledger, and a RegularCauchyUniqueness row refutes the carrier surface.

Independence witness: regseqrat, streamname, dyadicratcore, real, regularcauchyuniqueness: $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ is not bijective to any listed sibling because it binds two regular rational representatives to one separated uniqueness row and one downstream Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ packet is generated from two RegSeqRat source rows, paired StreamName finite windows, a DyadicRatCore tolerance ledger, a RegularCauchyUniqueness separated-agreement row, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4372.1, Definition 4372.2, Definition 4372.3, Definition 4372.4, and Definition 4372.5 seed the separated reflection route for regular Cauchy representatives and Real seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}\uparrow}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove the finite NameCert obligation surface, representative-independence handoff, and Real seal non-escape theorem.

Chapter 4320

A Concrete Naming Certificate for $\mathsf{WeakLawLargeNumbers}^{\uparrow}$

Following Kolmogorov and Bishop–Bridges on finite averages and probability estimates, the $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ packet names the displayed finite-average route behind the weak law of large numbers. It sits after the normalized probability surface of chapter 184, the measurable random-variable rows of chapter 185, the finite tail-bound carrier of chapter 6592, and the terminal real-name seal of chapter 38. The packet is a finite certificate for Chebyshev-controlled averages; it is not an almost-sure convergence theorem, a central limit theorem, a countable-choice subsequence selector, a host probability-limit principle, or an ambient $\mathsf{Real}^{\uparrow}$ completeness result.

Definition 4320.1 (Weak law finite-average carrier)**.** *A* $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, R, A, V, T, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the total-event normalization and event classifier. The row R is the finite family of* $\mathsf{RandomVar}^{\uparrow}$ *entries read over that same probability source. The row A records the displayed finite average of the entries in R, while V records the variance or uniform second-moment bound used by the estimate. The row T reads the Chebyshev tail row through* $\mathsf{ChebyshevInequality}^{\uparrow}$ *for the event where the finite average differs from its displayed center by more than the requested tolerance. The row E is the* $\mathsf{Real}^{\uparrow}$ *epsilon seal naming the positive tolerance and the final probability bound. The row H records componentwise* hsame *transport, C records* Cont *replay of the finite averaging route, Q records* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{ChebyshevInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$, *and N is the local* $\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these ten rows.*

Lean4 ✓ `BEDC.Derived.WeakLawLargeNumbersUp.WeakLawLargeNumbersTasteGate single carrier alignment`

Theorem 4320.2 (Weak law NameCert obligations)**.** *For every accepted* $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ *carrier $(P, R, A, V, T, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 4373.1. Carrier admission displays the probability source, the random-variable family, the finite-average row, the variance-bound row, the Chebyshev tail row, the epsilon seal, the transport and replay rows, the provenance row, and the local naming row. The packet imports no host law of large numbers, selected subsequence, external probability-limit operation, countable-choice principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Read the carrier rows in order. The probability source P supplies the measurable-event classifier and total-mass normalization, and the random-variable row R exposes only the finitely displayed variables over that source.

The average row A and variance row V are then internal finite data. They record the algebraic averaging expression and the bound used by the tail estimate before any limiting statement is visible.

Finally read T, E, H, C, Q, N. The Chebyshev tail row and epsilon seal name the probability estimate at the requested tolerance, while transport, replay, provenance, and local naming keep the same finite route under classifier replacement. Since no carrier coordinate stores an infinite limit or subsequence selector, the listed rows exhaust the local certificate surface. □

Theorem 4320.3 (Weak law Chebyshev handoff)**.** *Every accepted* $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ *Chebyshev read factors through the route*

$$P \longmapsto R \longmapsto A \longmapsto V \longmapsto T \longmapsto E \longmapsto H, C, Q, N$$

before any probability-bound consumer receives the finite-average estimate. Thus the Chebyshev step is handed to later probability and $\mathsf{Real}^{\uparrow}$ *formalization as a displayed finite source, finite random-variable row, average row, variance-bound row, tail-event row, epsilon seal, transport, replay, provenance, and local naming data.*

Proof. Start with a probability-bound request. The only probability source exposed by the packet is P, and the only random-variable data exposed over it are the finite rows in R.

The request must next read the average and variance-bound rows. The average row A fixes the finite expression being estimated, and V fixes the bound that the Chebyshev tail row may consume.

Only after these rows are displayed can T and E be read as a bound on the exceptional event. The structural rows H, C, Q, N then preserve that same route for downstream consumers, so the handoff is the finite Chebyshev estimate itself rather than a host-side convergence theorem. □

Theorem 4320.4 (Weak law finite-average nonescape)**.** *Every accepted* $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ *probability-limit-facing read remains inside the finite-average route of Definition 4373.1. In particular, a consumer can read a tail estimate only after displaying the source probability row, finite random-variable rows, average row, variance-bound row, Chebyshev tail row,* $\mathsf{Real}^{\uparrow}$ *epsilon seal, componentwise transport, replay, provenance, and local* $\mathsf{NameCert}$ *row. No accepted read may replace this route by almost-sure convergence, central limit normalization, countable-choice subsequence selection, a host probability-limit operator, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Let a consumer request the finite-average estimate from an accepted carrier. Projection of Definition 4373.1 shows that the request first meets P, R, A, V, T, E and has no independent coordinate for a limit object.

The displayed Chebyshev row T is downstream from the variance-bound row V and upstream from the epsilon seal E. Hence any probability bound read is already tied to the visible finite average and its tolerance.

The remaining rows H, C, Q, N do not add new analytic content. They transport equal displayed histories, replay the finite route, record the package provenance, and attach the local name. Therefore every accepted probability-limit-facing read stays inside the finite-average certificate surface and cannot escape to the excluded convergence or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ packet is generated from a probability source row, finite random-variable rows, a finite-average row, a variance or second-moment bound row, a Chebyshev tail row, a RealUp epsilon seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4373.1, Definition 4373.2, Definition 4373.3, and Definition 4373.4 seed the finite-average probability route through ProbSpace, RandomVar, RealUp, Chebyshev tail, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close almost-sure convergence, the central limit theorem, countable-choice subsequence selection, host probability limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-average routing, variance-bound stability, Chebyshev tail handoff, epsilon-seal nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.WeakLawLargeNumbe

Chapter 4321

A Concrete Naming Certificate for $\mathsf{LocatedSubset}^{\uparrow}$

Following Bishop and Bridges on located subsets of metric and real spaces, the $\mathsf{LocatedSubset}^{\uparrow}$ packet records a displayed subset together with finite distance-witness rows. It sits after the real-valued metric route of chapter 1638, the Hausdorff comparison boundary of chapter 2086, the real-separability window surface of chapter 1809, the dyadic tolerance core of chapter 291, and the regular rational readback surface of chapter 301. The packet gives Real and Completion consumers a finite located-subset interface without host set extensionality, selected nearest points, quotient subset equality, or ambient completeness.

The located-subset distance route consumes chapter 1809 as its finite search-window source and consumes chapter 2086 only after the real-distance seal has been displayed.

Definition 4321.1 (LocatedSubset carrier)**.** *A* $\mathsf{LocatedSubset}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, W, D, R, E, K, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{RealMetric}^{\uparrow}$ *source row, carrying the ambient metric distance through finite real-name observations.*
2. *S is the subset-admission row, naming the displayed members read by the carrier and exporting no host powerset equality.*
3. *W is the* $\mathsf{RealSeparability}^{\uparrow}$ *search-window row, recording the countable dense or finite-window probes available to a distance request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to each positive distance query.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, packaging the rational comparison data produced from W and D.*
6. *E is the real distance seal row, read only after the metric source, subset admission, search windows, dyadic tolerances, and regular rational readback have been displayed.*
7. *K is the optional* $\mathsf{HausdorffMetric}^{\uparrow}$ *comparison boundary for compact or hyperspace consumers; it records only the finite directed comparisons visible through the preceding rows.*
8. *H records componentwise* hsame *transport for the metric source, subset admission, search windows, dyadic ledger, regular readback, real seal, Hausdorff boundary, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from an ambient point and tolerance request through subset admission, separability windows, dyadic comparison, regular rational readback, real sealing, and any Hausdorff-facing comparison.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedSubset}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSubset}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, S, W, D, R, E, K, H, C, P, N$. It has no coordinate for a host subset object, extensional equality of subsets, a selected nearest point, quotient real equality, countable choice, or an ambient completion theorem.

Lean4 ✓ `BEDC.Derived.LocatedSubsetUp.LocatedSubsetTasteGate single carrier alignment`

Theorem 4321.2 (LocatedSubset NameCert obligations)**.** *For every accepted* $\mathsf{LocatedSubset}^{\uparrow}$ *carrier*

$$L = (M, S, W, D, R, E, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedSubset}^{\uparrow}}$ *surface consists exactly of carrier admission, ambient real-metric visibility, subset-admission stability, separability-window exposure, dyadic-tolerance compatibility, regular-rational readback, real-distance sealing, optional Hausdorff comparison routing, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 4374.1. The displayed packet lists exactly the rows used by an ambient point, subset-membership, tolerance, rational-readback, real-seal, or Hausdorff-facing request.

The metric and subset rows M, S are read first. A distance query can inspect the ambient space only through $\mathsf{RealMetric}^{\uparrow}$, and it can inspect membership only through the displayed admission row S.

The search, tolerance, and readback rows W, D, R then supply finite witnesses for the locatedness request. The real seal E is reached only after those rows have been displayed, while K is available only as a downstream comparison boundary.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no host subset, selected nearest point, quotient equality, countable-choice schedule, or ambient completion coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 4321.3 (LocatedSubset dyadic distance witness)**.** *Every distance read exported by an accepted* $\mathsf{LocatedSubset}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{RealMetric}^{\uparrow} \longmapsto \mathsf{RealSeparability}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto E.$$

The read may be handed to a $\mathsf{HausdorffMetric}^{\uparrow}$ *consumer only after the same route has produced the displayed real-distance seal, transported by H and replayed by C.*

Proof. Begin with a point-to-subset distance request. The ambient metric row M supplies the only metric observations, and the subset-admission row S supplies the only visible membership data.

The finite search window W names the inspected probes. The dyadic ledger D fixes the positive tolerance requests, and the regular rational row R records the resulting readback windows.

The real-distance seal E is therefore downstream of M, S, W, D, R. Any Hausdorff-facing row K can compare only the finite distance data already sealed by this route.

Transport and replay do not add another distance object. The componentwise hsame row H, the displayed Cont route C, the Pkg provenance P, and the local NameCert row N preserve the

same witness surface, so no nearest-point selector or host infimum can bypass the dyadic distance route. □

Falsifiable prediction: Every accepted LocatedSubsetUp distance read exposes RealMetricUp, subset admission, RealSeparabilityUp windows, DyadicRatCoreUp tolerance rows, RegSeqRatUp readback, and a real-distance seal before any HausdorffMetricUp or completion-facing consumer reads the packet.

Independence witness: realmetric, hausdorffmetric, realseparability, dyadicratcore, regseqrat: none of these siblings alone carries the full located-subset packet with subset admission, finite search windows, dyadic tolerance rows, regular rational readback, real-distance sealing, optional Hausdorff comparison, transport, replay, package provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSubset}\uparrow}$.

Constructive story: A $\mathsf{LocatedSubset}^{\uparrow}$ packet is generated from a RealMetricUp source, displayed subset admission, RealSeparabilityUp search windows, DyadicRatCoreUp tolerance rows, RegSeqRatUp readback, a real-distance seal, optional HausdorffMetricUp comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedSubset}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4374.1, Definition 4374.2, and Definition 4374.3 seed the finite located-subset interface for real-metric and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedSubset}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LocatedSubsetUp.LocatedSubsetTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host subset extensionality, selected nearest points, quotient subset equality, countable choice, open-cover compactness, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, real-metric visibility, subset-admission stability, separability-window exposure, dyadic-tolerance compatibility, regular-rational readback, real-distance sealing, Hausdorff comparison routing, transport stability, replay stability, provenance, and local naming for BEDC.Derived.LocatedSubsetUp.

Chapter 4322

A Concrete Naming Certificate for $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$

Following Heine, Borel, and Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ packet records the explicit finite dyadic closed-interval net route for regular Cauchy real names. It sits over the dyadic arithmetic core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the finite-net Heine–Borel surface of chapter 3471. The chapter is a finite dyadic closed-interval net route over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; it is not general Heine–Borel for arbitrary subsets of $\mathsf{Real}^{\uparrow}$, does not import open-cover compactness, and does not select limits outside the displayed interval-net data.

Definition 4322.1 (Regular Cauchy Heine–Borel route carrier)**.** *A* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, D, S, Q, E, W, F, H, C, P, N)$$

with the following displayed rows:

1. *I is the closed bounded regular-Cauchy interval row, exposing two endpoint* $\mathsf{RegSeqRat}^{\uparrow}$ *names, their* $\mathsf{StreamName}^{\uparrow}$ *finite windows, and the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seals.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh row, recording the finite dyadic subdivision, endpoint comparisons, cell widths, and requested tolerance bound.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that lists the finite observations used to compare each regular-Cauchy endpoint and each inspected interval cell.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the endpoint names and the retained dyadic cell names.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, Q have been displayed.*
6. *W is the closed-interval witness row, pairing every retained dyadic cell with its lower and upper endpoint comparisons inside I.*
7. *F is the finite net row, containing only the finite bundle of dyadic cell centers and radius witnesses read by the interval-net route.*
8. *H records componentwise* hsame *transport for the interval, dyadic mesh, stream windows, regular readback, real seal, cell witnesses, finite net, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a closed-interval net request through* I, D, S, Q, E, W, F, H.
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, Q, E, W, F, H, C, P, N$. *It has no coordinate for an arbitrary subset of* $\mathsf{Real}^{\uparrow}$, *arbitrary open covers, selected finite subcovers, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHeineBorelRouteUp.TasteGate.RegularCauchyHeineBorelRouteTasteGate single carrier alignment`

Theorem 4322.2 (Regular Cauchy Heine–Borel route obligations)**.** *For every accepted* RegularCauchyHeineBorelRo *carrier*

$$R = (I, D, S, Q, E, W, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *expose the closed bounded regular-Cauchy interval row I before any interval-net consumer reads a cell;*
2. *display the dyadic subdivision and tolerance ledger D as the only mesh source;*
3. *route endpoint and cell observations through the finite* $\mathsf{StreamName}^{\uparrow}$ *windows S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q;*
4. *reach the terminal* $\mathsf{Real}^{\uparrow}$ *seal E only after the dyadic, stream, and regular-rational rows have been displayed;*
5. *bind each retained dyadic interval cell to the closed interval by the witness row W and export the finite net bundle F;*
6. *preserve the route by componentwise* hsame *transport and displayed* Cont *replay through H, C;*
7. *source and name the same finite packet through* Pkg *provenance P and the local* NameCert *row N.*

No obligation row states general Heine–Borel compactness for arbitrary subsets of $\mathsf{Real}^{\uparrow}$, *arbitrary open-cover compactness, a selected subcover functional, quotient real equality, countable choice, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 5715.1. The interval row I is the only source for the closed bounded regular-Cauchy endpoints, and the route cannot inspect an interval cell before those endpoint rows are present.

Next read the dyadic mesh and observation rows. The dyadic ledger D supplies the finite subdivision and the tolerance comparison, while S and Q supply the finite windows and regular-rational readbacks needed to compare endpoint and cell data.

The Real-facing boundary is downstream. The terminal row E is reached only after the dyadic, stream, and regular-rational rows have been displayed, so the route exports a named real seal rather than a host-selected real limit or quotient equality.

Finally the finite-net part is exhausted by W and F. The witness row W binds each retained dyadic cell to the closed interval, and F lists the finite cell centers and radii. The structural rows H, C, P, N transport, replay, source, and name this same packet, so no arbitrary subset, open cover, selected subcover, choice, selected-limit, or ambient-completeness coordinate remains. □

Theorem 4322.3 (Regular Cauchy Heine–Borel finite interval-net route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer of an accepted* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{HeineBorelFiniteNet}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{RegularCauchy}}$$

The route supplies an explicit finite dyadic closed-interval net for closed bounded regular-Cauchy interval data. It supplies no compactness theorem for arbitrary subsets of $\mathsf{Real}^{\uparrow}$*, no arbitrary open-cover subcover extraction, no quotient real equality, no countable choice, and no* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with a consumer read of the carrier. The only numerical mesh coordinate is D, and every inspected endpoint or cell must be read through the finite windows S and regular-rational row Q before the terminal seal E is available.

The closed-interval part is then bound by W. Each retained dyadic cell is paired with displayed lower and upper endpoint comparisons, so the interval-net route remains a finite dyadic route inside the presented closed bounded interval.

The finite net export is exactly F. It lists the dyadic centers and radius witnesses read by the Heine–Borel finite-net surface, while H, C, P, N preserve and name the same route. Since the carrier contains none of the excluded arbitrary-subset, open-cover, quotient, choice, selected-limit, or completeness coordinates, every such consumer remains on the displayed finite interval-net route. □

Theorem 4322.4 (Regular Cauchy Heine–Borel inductive subcover route)**.** *Every finite interval-net consumer of an accepted* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ *carrier may build subcover reads only by induction over the displayed dyadic cell list* F*. The base read over the empty cell list exports no cover row. The successor read appends one displayed dyadic cell, routes endpoint and cell comparisons through* D, S, Q, E, W*, and preserves the same* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. No read imports arbitrary open-cover compactness, selected finite subcovers, countable choice, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5715.1. The finite net row F is the only coordinate that lists dyadic cells, and the rows D, S, Q, E, W are the only coordinates available for mesh, window, readback, Real seal, and closed-interval comparisons.

The induction base is the empty displayed cell list. With no cell in F, the consumer can read the interval, dyadic mesh, stream windows, regular readback, and structural rows, but it has no cover row to export.

For the successor step, append one displayed dyadic cell from F. Its endpoint and cell comparisons are routed through the dyadic mesh D, finite windows S, regular readback Q, terminal seal E, and witness row W before the consumer extends the finite read.

The structural rows H, C, P, N are preserved componentwise. They transport, replay, source, and name the same finite induction route, so no arbitrary open cover, selected subcover, countable-choice schedule, quotient equality, or ambient completeness principle is introduced. □

Theorem 4322.5 (Regular Cauchy Heine–Borel route obligation scope)**.** *Every accepted* $\mathsf{RegularCauchyHeineBorelR}$ *carrier*

$$R = (I, D, S, Q, E, W, F, H, C, P, N)$$

scopes its obligation rows through finite BEDC primitives as follows:

1. *I is scoped by the* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint rows and the closed bounded regular-Cauchy interval data;*
2. *D is scoped by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh and tolerance rows;*
3. *S is scoped by finite* $\mathsf{StreamName}^{\uparrow}$ *windows;*
4. *Q is scoped by* $\mathsf{RegSeqRat}^{\uparrow}$ *readback;*
5. *E is scoped by the terminal* $\mathsf{Real}^{\uparrow}$ *seal;*
6. *W, F are scoped by the* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *finite closed-interval net route;*
7. *H, C, P, N are scoped respectively by componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row.*

The scoped surface exports no arbitrary subset compactness, open-cover subcover selector, quotient real equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5715.1. Its rows are exactly $I, D, S, Q, E, W, F, H, C, P, N$, so the obligation theorem can inspect no coordinate outside the displayed packet.

Apply Definition 5715.2. The interval row, dyadic mesh, finite stream windows, regular-rational readback, Real seal, closed-interval witnesses, finite net bundle, transport, replay, provenance, and local naming rows are precisely the finite obligations available to the local certificate.

Use Definition 5715.3. It identifies the consumer route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, with hsame, Cont, Pkg, and $\mathsf{NameCert}$ preserving the same displayed packet. The excluded compactness, quotient, selector, choice, selected-limit, and completeness readings therefore have no scoped row. □

Theorem 4322.6 (Regular Cauchy Heine–Borel closed-interval net scope)**.** *Every closed-interval net consumer of an accepted* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ *carrier*

$$R = (I, D, S, Q, E, W, F, H, C, P, N)$$

must read the displayed rows in the order

$$I,\ D,\ S,\ Q,\ E,\ W,\ F,\ H,\ C,\ P,\ N.$$

Here I binds the closed bounded $\mathsf{RegSeqRat}^{\uparrow}$ *interval, D supplies the dyadic mesh, S and Q provide the finite* $\mathsf{StreamName}^{\uparrow}$ *observations and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and W, F are the finite closed-interval witness row and finite interval-net bundle. The remaining rows H, C, P, N transport, replay, source, and name the same route. Thus the consumer sees only the displayed closed-interval net data and imports no arbitrary open-cover compactness, selected subcover functional, quotient real equality, countable choice, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5715.1. Its row list is exactly $I, D, S, Q, E, W, F, H, C, P, N$, and there is no coordinate before I from which a consumer could infer a cell, mesh, cover, or selected limit.

Apply Definition 5715.2. The obligation surface forces the closed bounded interval row I to be exposed before any interval-net read, then forces the mesh D, finite windows S, regular-rational readback Q, and terminal Real seal E before the closed-interval witness and finite-net rows can be exported.

Use Definition 5715.3 and Definition 5715.4. They identify W, F as the finite closed-interval net surface and restrict subcover reads to induction over the displayed dyadic cell list, with endpoint and cell comparisons routed through D, S, Q, E, W.

Finally apply Definition 5715.5. It scopes H, C, P, N as componentwise transport, displayed replay, provenance, and local naming for the same packet. The composed read order is therefore the displayed order $I, D, S, Q, E, W, F, H, C, P, N$, and the excluded compactness, quotient, selector, choice, selected-limit, and completeness principles have no row to enter through. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ packet is generated from a closed bounded regular-Cauchy interval row, a DyadicRatCore mesh row, StreamName windows, RegSeqRat readback, a RealUp seal, closed-interval cell witnesses, a finite dyadic net row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 5715.1, Definition 5715.2, and Definition 5715.3 seed the explicit finite dyadic closed-interval net route over DyadicRatCore, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim general Heine–Borel compactness for arbitrary subsets of $\mathsf{Real}^{\uparrow}$, arbitrary open-cover compactness, selected finite subcovers, quotient real equality, countable choice, selected limits, Lean verification, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, dyadic mesh exactness, finite stream-window readback, regular-rational endpoint routing, Real seal nonescape, finite interval-net exposure, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyHeineBorelRouteUp.

Chapter 4323

A Concrete Naming Certificate for $\mathsf{CauchyApproximationTree}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyApproximationTree}^{\uparrow}$ packet records a finite branching approximation surface over the L10 Cauchy spine: each active branch carries a displayed tolerance window, a dyadic approximation row, a regular-rational readback row, and a terminal Real seal. It sits between the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback surface of chapter 301, the real-name seal of chapter 38, and the Cauchy route of chapter 3413. The packet gives Real and Completion consumers a finite approximation tree without quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient completeness.

Definition 4323.1 (Cauchy approximation tree carrier)**.** *A* $\mathsf{CauchyApproximationTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (V, E, B, D, S, R, L, H, C, P, N)$$

with the following displayed rows:

1. *V is the finite tree-node row, listing the nodes presently opened by the approximation packet.*
2. *E is the finite edge and parenthood row, recording the branch relation among the nodes in V.*
3. *B is the branch-window row, assigning each active branch the finite tolerance window currently inspected.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic approximants, radius comparisons, and the error rows attached to each branch window.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by the branch windows and no hidden stream coordinates.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and dyadic tolerance rows.*
7. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the node, branch-window, dyadic, stream, and regular-readback rows have been exposed.*
8. *H records componentwise* hsame *transport for tree nodes, branch windows, dyadic rows, stream schedules, regular readbacks, Real seals, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a finite tree branch through B, D, S, R and into the terminal Real seal L.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyApproximationTree}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, E, B, D, S, R, L, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyApproximationTreeUp.CauchyApproximationTreeTasteGate single carrier alignment`

Theorem 4323.2 (Cauchy approximation tree NameCert obligations)**.** *For every accepted* CauchyApproximationTre *carrier $T = (V, E, B, D, S, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the tree-node row, edge row, branch windows, dyadic tolerance ledger, stream schedule, regular readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *tree finiteness, requiring every inspected branch to be generated by the finite node and edge rows V, E;*
3. *branch-window exactness, requiring each active branch to read its tolerance window from B before any dyadic approximation in D is accepted;*
4. *dyadic and stream exactness, requiring D and S to expose only the dyadic approximants and finite observations demanded by the displayed branch windows;*
5. *regular readback and Real-seal boundary, requiring R and L to remain downstream of V, E, B, D, S and never to serve as selected limits or host equality objects;*
6. *componentwise transport and replay, requiring H and C to preserve exactly the displayed finite branch route;*
7. *provenance and local naming, requiring P and N to export the route over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{Cauchy}^{\uparrow}$ *without adding quotient equality, choice, trichotomy, or ambient completeness.*

No approximation-tree obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5716.1. The accepted packet displays exactly the finite node row V, edge row E, branch windows B, dyadic ledger D, stream schedule S, regular readback R, Real seal L, and structural rows H, C, P, N.

Tree finiteness and branch-window exactness follow from the row order. A consumer first reads a node and its branch relation from V, E; only then may it inspect the branch tolerance window B and the dyadic approximation row D attached to that branch.

The stream and readback rows are downstream of the same branch window. The schedule S opens only the finite observations demanded by B, and R records the regular-rational data justified by D and S.

Finally, the Real seal row L is terminal for this finite branch route. The transport row H, replay row C, provenance row P, and local naming row N preserve and name the same displayed packet, so no quotient stream equality, selected limit, countable-choice selector, host real equality, trichotomy principle, or ambient completeness theorem can become a local obligation. □

Theorem 4323.3 (Cauchy approximation tree branch readback)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Cauchy}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyApproximationTree}^{\uparrow}$ *carrier reads a branch only through the displayed route*

$$V, E, B, D, S, R, L, H, C, P, N.$$

Consequently each consumed branch exposes finite tree nodes, branch windows, dyadic tolerance rows, StreamName observations, RegSeqRat readbacks, a Real seal, componentwise transport, displayed replay, provenance, and local naming data. It exposes no quotient stream equality, selected limit, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Let a Real-facing or Cauchy-facing consumer read an accepted packet $T = (V, E, B, D, S, R, L, H, C, P, N)$. Carrier projection gives access only to the rows named in Definition 5716.1.

The read begins with the finite tree rows V, E and then chooses a displayed branch window in B. The dyadic ledger D supplies the approximant and tolerance comparison for that branch, the stream schedule S opens the finite observation windows, and the regular readback row R exposes the rational data that the Real seal may consume.

The terminal row L is therefore reached only after the finite route through V, E, B, D, S, R has been displayed. The structural rows H, C, P, N transport, replay, source, and name the same route without adding any second equality or limit coordinate.

Since the packet has no carrier row for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, a Real-facing or Cauchy-facing consumer cannot read any of those objects from the local certificate. □

Falsifiable prediction: Every $\mathsf{CauchyApproximationTree}^{\uparrow}$ Real-facing or Cauchy-facing read factors through finite tree nodes, branch windows, a DyadicRatCore tolerance ledger, selected StreamName observations, RegSeqRat readbacks, a RealUp seal row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy: $\mathsf{CauchyApproximationTree}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite tree nodes, branch windows, dyadic tolerance rows, finite stream schedules, regular-rational readback, a terminal Real seal, transport, replay, provenance, and local naming in one branch-indexed packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyApproximationTree}^{\uparrow}$ packet is generated from finite tree nodes, branch windows, a DyadicRatCore tolerance ledger, StreamName finite observations, RegSeqRat readback rows, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5716.1, Definition 5716.2, and Definition 5716.3 seed the finite branch-indexed route from L10 Cauchy approximation windows to RealUp endpoint consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tree finiteness, branch-window exactness, dyadic ledger exactness, stream and readback exactness, Real seal boundary, componentwise transport, replay, provenance, and local naming for BEDC.Derived.CauchyApproximationTreeUp.

Chapter 4324

A Concrete Naming Certificate for $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$ packet records the finite comparison surface between Bishop-style Cauchy representations and the BEDC real-name ladder. It sits after the Cauchy-representation route of chapter 1680, the precision ledger of chapter 4141, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names the comparison route as finite NameCert data; it is not quotient stream equality, selected host limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4324.1 (Bishop Cauchy representation comparison carrier)**.** *A* $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, B, S, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{CauchyRepresentation}^{\uparrow}$ *row whose decoder route supplies the representation-facing observations.*
2. *B is the* $\mathsf{BishopRealPrecision}^{\uparrow}$ *row recording the requested constructive precision discipline for the comparison.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row shared by the representation and precision reads.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed stream windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the precision and regular-readback rows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after R, B, S, Q, D have been displayed.*
7. *H records componentwise* hsame *transport for the representation row, precision row, stream windows, regular readback, dyadic ledger, terminal seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a comparison request through $R, B, S, Q, D, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$, $\mathsf{CauchyRepresentation}^{\uparrow}$, $\mathsf{BishopRealPrecision}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite comparison packet. It has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCauchyRepresentationComparisonUp.BishopCauchyRepresentationComparisonTasteGa`
`single carrier alignment`

Theorem 4324.2 (Bishop Cauchy representation comparison NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$ *carrier* $K = (R, B, S, Q, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, representation decoding through* R*, constructive precision exposure through* B*, shared finite-window access through* S*, regular rational readback through* Q*, dyadic tolerance accounting through* D*, terminal real-name sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The visible analytic data are the representation decoder R, precision row B, shared stream window S, regular rational readback Q, dyadic tolerance ledger D, and terminal real seal E.

The comparison obligations are componentwise. A representation-facing consumer first reads R, then the requested Bishop precision surface B, and then the common finite-window, regular-readback, and dyadic-tolerance route S, Q, D.

Only after these rows are displayed may the consumer inspect the terminal seal E. The support rows H, C, P, N transport, replay, source, and name the same finite route, so no further NameCert obligation remains outside the listed coordinates. □

Theorem 4324.3 (Bishop Cauchy representation comparison nonescape)**.** *No accepted* BishopCauchyRepresentatio*n carrier exports quotient streams, selected host limits, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every downstream Real or Completion consumer receives only the displayed representation row, Bishop precision row, stream-window row, regular readback row, dyadic tolerance ledger, terminal real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Proof. Inspect the carrier inventory. The tuple contains only $R, B, S, Q, D, E, H, C, P, N$.

The rows R, B, S, Q, D are the complete comparison route before the terminal Real seal can be consumed. Thus the seal E is not a selected host limit; it is the downstream endpoint of the displayed representation, precision, window, readback, and tolerance data.

Transport, replay, provenance, and local naming preserve the same boundary. Since no coordinate stores quotient stream equality, a choice schedule, a trichotomy branch, host real equality, or an ambient completeness principle, none can escape from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$ packet is generated from a CauchyRepresentation decoder, a BishopRealPrecision row, a StreamName finite window, a RegSeqRat readback row, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$, seed)

Scope closed: Definition 5717.1, Definition 5717.2, and Definition 5717.3 seed the finite representation-comparison route from CauchyRepresentation and BishopRealPrecision data to StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, representation-decoder exactness, precision-row exposure, shared-window readback, dyadic tolerance accounting, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyRepresentationComparisonUp.

The SeparableSpace$^{\uparrow}$ hub routes its countable dense schedule through chapter 1809 for Real-facing L10 density consumers.

Chapter 4325

A Concrete Naming Certificate for $\mathsf{SeparableSpace}^{\uparrow}$

Following Bourbaki's countable-base presentation and Bishop and Bridges' constructive dense-sequence discipline, the $\mathsf{SeparableSpace}^{\uparrow}$ packet names a countable dense schedule as finite BEDC data. It sits over the metric carrier of chapter 57, the finite window surface of chapter 126, the regular rational readback route of chapter 301, the terminal real-name surface of chapter 38, and the complete-separable consumer of chapter 1490. Its Real-facing dense schedule is also consumed by the downstream sibling dependency chapter 1809. The packet exports a dense schedule visible to L10 completion consumers without host set equality, selected dense points, countable choice, or ambient completeness.

Definition 4325.1 (Separable-space carrier)**.** *A* $\mathsf{SeparableSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, S, R, D, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *row containing the admitted metric carrier, distance classifier, and metric local* $\mathsf{NameCert}$*.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row that schedules finite dense-name probes and radius requests.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row that reads the rational windows attached to those probes.*
4. *D is the countable-density ledger, recording that every displayed metric-radius request reaches an admitted stream probe with a regular rational distance bound.*
5. *W is the observation ledger joining stream positions, regular rational windows, metric-radius requests, and terminal* $\mathsf{Real}^{\uparrow}$ *seal reads.*
6. *H records componentwise* hsame *transport for M, S, R, D, W and the local certificate rows.*
7. *C records displayed* Cont *replay from a density request to the corresponding stream and regular-rational readback rows.*
8. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparableSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a host dense subset, selected nearest point, quotient point equality, or external enumeration.

Theorem 4325.2 (Separable-space NameCert obligations)**.** *For every accepted* $\mathsf{SeparableSpace}^{\uparrow}$ *carrier* $Q = (M, S, R, D, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SeparableSpace}^{\uparrow}}$ *surface consists exactly of six obligation rows: carrier admission for* $M, S, R, D, W, H, C, P, N$*; classifier transport to a common* $\mathsf{Met}^{\uparrow}$ *row before density is read; stability of the stream schedule and regular rational readback under* H*; exactness of* W *as the only route from a radius request to finite stream and rational-window data; displayed* Cont *replay from density requests through* S, R, D, W*; and* Pkg *provenance with local naming for precisely this packet. No additional obligation stores a selected dense point, countable-choice function, host set equality, or ambient completion datum.*

Proof. Project the carrier of Definition 5718.1. Carrier admission exposes the metric row, stream schedule, regular rational readback, density ledger, observation ledger, transport, replay, provenance, and local name.

The classifier route begins at M. Componentwise transport in H moves M, S, R, D, W together, so a dense schedule cannot be compared after changing the metric source.

The exactness row is W. Every radius request reaches a finite stream position in S, reads its rational window through R, and records the density witness in D before any terminal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Finally replay the request through C and source it through P, N. Since no row names a selected point, host dense subset, countable-choice selector, or ambient completion, the six listed rows exhaust the NameCert obligations. □

Theorem 4325.3 (Separable-space StreamName dense readback)**.** *Let* $Q = (M, S, R, D, W, H, C, P, N)$ *be an accepted* $\mathsf{SeparableSpace}^{\uparrow}$ *carrier. Every dense-readback consumer reads the countable schedule only through* $\mathsf{StreamName}^{\uparrow}$ *row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, observation ledger* W*, and density ledger* D *over the common* $\mathsf{Met}^{\uparrow}$ *row* M*. When the read is Real-facing it may consume only the terminal* $\mathsf{Real}^{\uparrow}$ *seal already displayed by* R, W*; when it is completion-facing, a* $\mathsf{PolishSpace}^{\uparrow}$ *or* $\mathsf{SeparableMetric}^{\uparrow}$ *consumer receives the same finite schedule route and no selected dense point, quotient point equality, host enumeration, or ambient completeness principle.*

Proof. Expose the accepted carrier. The only scheduling coordinate is S, and the only regular rational readback coordinate attached to the schedule is R.

Use Definition 5718.2. Observation exactness forces a dense-readback request through W before the density ledger D is available, while H keeps the route over the same metric row M.

The Real-facing boundary is downstream of the regular rational observations. Thus any $\mathsf{Real}^{\uparrow}$ seal is read after S, R, W, D, not as a separate host-real shortcut.

Finally pass the displayed route to the complete-separable consumers. The $\mathsf{PolishSpace}^{\uparrow}$ and $\mathsf{SeparableMetric}^{\uparrow}$ packets may inspect the same finite schedule rows, but the carrier contains no coordinate for selected dense points, quotient equality, host enumeration, or ambient completeness. □

Theorem 4325.4 (Separable-space finite dense-schedule induction)**.** *Let* $Q = (M, S, R, D, W, H, C, P, N)$ *be an accepted* $\mathsf{SeparableSpace}^{\uparrow}$ *carrier. Any finite list of dense-readback requests over* Q *is discharged by induction through the same* $\mathsf{StreamName}^{\uparrow}$ *schedule row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, observation ledger* W*, density ledger* D*, and common* $\mathsf{Met}^{\uparrow}$ *row* M*. The induction exports only the displayed finite schedule route and no selected dense point, host enumeration, quotient equality, or countable-choice selector.*

Proof. Induct on the displayed finite list of dense-readback requests.

For the empty list, no dense point is selected and no host enumeration is opened. The carrier projection of Definition 5718.1 leaves only the common rows $M, S, R, D, W, H, C, P, N$, so the empty schedule is discharged by the displayed packet itself.

For a cons list, apply Definition 5718.3 to the head request. The head is routed through S, R, W, D over the fixed metric row M, and any Real-facing read remains behind the already displayed regular rational observations.

Apply the induction hypothesis to the tail list using the same accepted carrier. Componentwise transport through H and replay through C keep every tail request on the same S, R, W, D, M route. Since no step introduces a selected dense point, host enumeration, quotient equality, or countable-choice selector, the whole finite list is discharged inside the finite dense-schedule packet. □

Theorem 4325.5 (Separable-space RealSeparability forward route)**.** *Any* $\mathsf{RealSeparability}^{\uparrow}$ *consumer reading a* $\mathsf{SeparableSpace}^{\uparrow}$ *dense schedule must factor the read through the* $\mathsf{Met}^{\uparrow}$ *row* M*, the* $\mathsf{StreamName}^{\uparrow}$ *row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal displayed by* R, W*, and the countable-density ledger* D *before the* $\mathsf{RealSeparability}^{\uparrow}$ *row of chapter 1809 is consumed. The route exports a finite dense-readback dependency, not a selected dense point, quotient point equality, host enumeration, countable-choice selector, or ambient completeness principle.*

Proof. Start with the accepted carrier $Q = (M, S, R, D, W, H, C, P, N)$. The metric source is M, the finite schedule is S, and the regular rational readback is R.

Use Definition 5718.3. It forces every dense read through S, R, W, D over the same metric row M before any Real-facing seal is consumed.

Now route the downstream sibling dependency through chapter 1809. The $\mathsf{RealSeparability}^{\uparrow}$ row receives the displayed countable-density ledger only after the metric, stream, regular rational, and $\mathsf{Real}^{\uparrow}$ rows are visible.

Because the carrier has no coordinate for selected dense points, quotient point equality, host enumeration, countable choice, or ambient completeness, the forward route remains a finite dependency edge. □

Theorem 4325.6 (SeparableSpace real-metric dependency route)**.** *Every completion, compactness, or real-facing consumer of an accepted* $\mathsf{SeparableSpace}^{\uparrow}$ *dense schedule reads the metric carrier data of chapter 57 and the Real-density route of chapter 1809 before it may inspect the downstream separability surface. The route exposes countable dense data only through displayed* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{RealSeparability}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows; it exports no host enumeration, selected dense point, quotient point equality, countable-choice selector, or ambient completeness principle.*

Proof. Project the accepted dense schedule. Its metric source is the row that supplies distance observations, while the real-separability row supplies the Real-facing density readback.

The existing forward route through Definition 5718.5 places the Real-density consumer after the metric, stream, regular rational, terminal Real, and countable-density ledgers. Thus the child dependency route is not a separate carrier; it records the horizontal lattice edge through which completion and compactness consumers must enter the same finite packet.

Since the carrier has no coordinate for a host enumeration, selected dense point, quotient equality, countable-choice selector, or ambient completeness theorem, every such consumer remains inside the displayed metric and Real-separability dependency route. □

The $\mathsf{DedekindCutStream}^{\uparrow}$ route points its finite readback through chapter 301 and its terminal seal through chapter 38.

Chapter 4326

A Concrete Naming Certificate for $\mathsf{DedekindCutStream}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DedekindCutStream}^{\uparrow}$ packet records a located cut-observation stream over the L10 stream-name substrate, not the forbidden Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$. It sits after the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the rounded located cut interface of chapter 436. The packet names the finite stream route by which lower and upper cut observations can be sampled before any Real-facing consumer treats them as regular Cauchy data.

Definition 4326.1 (Dedekind-cut stream carrier)**.** *A* $\mathsf{DedekindCutStream}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S_{\mathrm{cut}} = (D, L, U, W, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row, recording the finite dyadic rational endpoints, radii, and comparison budgets used by the cut observation.*
2. *L is the located lower-cut observation row, carrying finite evidence that the displayed endpoints lie on the lower side of the cut.*
3. *U is the located upper-cut observation row, carrying finite evidence that the displayed endpoints lie on the upper side of the cut.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing exactly the finite observation windows through which L and U are sampled.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the stream windows and dyadic endpoint budgets have been displayed.*
6. *H records componentwise* hsame *transport for dyadic endpoints, lower observations, upper observations, stream windows, regular readbacks, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located cut-observation request through D, L, U, W, R.*
8. *P is the* Pkg *provenance over* $\mathsf{DedekindCutStream}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, L, U, W, R, H, C, P, N$. It has no coordinate for quotient cuts, quotient stream equality, trichotomy, selected suprema, selected real limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4326.2 (Dedekind-cut stream NameCert obligations)**.** *For every accepted* $\mathsf{DedekindCutStream}^{\uparrow}$ *carrier* $S_{\mathrm{cut}} = (D, L, U, W, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic endpoint ledger, located lower observations, located upper observations, stream windows, regular rational readback, transport, replay, provenance, and local naming rows;*
2. *endpoint exactness, requiring every lower or upper cut observation to name its rational endpoint and comparison budget through D;*
3. *located observation separation, requiring L and U to remain displayed lower and upper observations rather than a quotient cut object;*
4. *stream-window exactness, requiring every cut observation consumed downstream to pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *row W;*
5. *regular-readback boundary, requiring R to be read only after D, L, U, W have been exposed;*
6. *componentwise transport and replay, requiring H and C to preserve the same endpoint, observation, stream, and readback route;*
7. *provenance and local naming, requiring P and N to source the packet through* $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *without adding quotient cuts, trichotomy, completeness, or host real equality.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5719.1. The accepted packet exposes only the dyadic endpoint row D, the lower and upper observation rows L, U, the stream window row W, the regular readback row R, and the structural rows H, C, P, N.

Endpoint exactness and located observation separation are read from the same projection. The rows L and U can mention a rational observation only through the dyadic endpoint and budget data in D, and they remain two displayed observation ledgers rather than a quotient cut.

The stream and readback obligations are downstream. A consumer first opens the finite windows in W, then obtains the regular rational readback R justified by those windows and the endpoint budget.

Finally, H and C transport and replay that same finite route, while P and N source and name it. Since the carrier contains no row for quotient cuts, trichotomy, completeness, host real equality, or selected real limits, the listed rows exhaust the local NameCert surface. □

Theorem 4326.3 (Dedekind-cut stream regular-Cauchy handoff)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{DedekindCutStream}^{\uparrow}$ *carrier must pass through the* $\mathsf{StreamName}^{\uparrow}$ *window row W and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before the cut-observation stream can be consumed. Equivalently, the only Real-facing route exported by the packet is*

$$\mathsf{DedekindCut}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}.$$

The handoff supplies located cut observations as finite stream-name data; it supplies no Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$*, quotient cut, trichotomy branch, completeness theorem, selected supremum, selected limit, or host real equality.*

This handoff is a source route for chapter 4372 when a downstream Real-facing consumer compares two regular-Cauchy presentations through the shared $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows, because the comparison sees displayed stream windows and dyadic tolerance ledgers rather than a quotient cut or host real equality.

Proof. Let a downstream Real-facing consumer read an accepted carrier $S_{\mathrm{cut}} = (D, L, U, W, R, H, C, P, N)$. By carrier projection, the only cut-facing data available before readback are the endpoint ledger D and the displayed lower and upper observation rows L, U.

The consumer cannot reach a regular rational datum directly from L or U. The finite stream-name row W records the observation windows that are opened, and the readback row R records the regular rational data obtained from those windows and the dyadic endpoint budget.

Thus any Real-facing use of the cut-observation stream is downstream of W and R. The remaining rows H, C, P, N preserve, replay, source, and name the same route.

Because no carrier coordinate stores quotient cuts, a Dedekind construction of reals, trichotomy, completeness, selected suprema, selected limits, or host real equality, the handoff is exactly the displayed stream-name and regular-Cauchy boundary. □

Falsifiable prediction: Every accepted $\mathsf{DedekindCutStream}^{\uparrow}$ Real-facing read factors through DyadicRatCore endpoints, located lower and upper cut observations, StreamName windows, RegSeqRat readback, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: dedekindcut, dyadicratcore, streamname, regseqrat, real: $\mathsf{DedekindCutStream}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries located lower and upper cut observations, dyadic endpoint budgets, stream windows, regular rational readback, transport, replay, provenance, and local naming in one stream-observation packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}$.

Constructive story: A $\mathsf{DedekindCutStream}^{\uparrow}$ packet is generated from DyadicRatCore endpoint rows, located lower and upper cut observations, StreamName finite windows, RegSeqRat readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5719.1, Definition 5719.2, and Definition 5719.3 seed the located cut-observation stream route over DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, DedekindCutUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$, quotient cuts, trichotomy, completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, located observation separation, stream-window exactness, regular-readback boundary, transport, replay, provenance, and local naming for BEDC.Derived.DedekindCutStreamUp.

Theorem 4326.4 (Dedekind-cut stream RegSeqRat forward route)**.** *Every* $\mathsf{DedekindCutStream}^{\uparrow}$ *Real-facing consumer that exports a comparison must first display the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{Real}^{\uparrow}$ *seal row of the accepted packet. The forward route is*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

inside the same BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}$ *surface. It exports no quotient cut, quotient stream equality, trichotomy branch, selected supremum, selected limit, ambient real completeness, or host comparison outside the displayed route.*

Proof. Start with the carrier of Definition 5719.1. A Real-facing comparison can read endpoint budgets only through the $\mathsf{DyadicRatCore}^{\uparrow}$ row D, and it can inspect cut observations only through the finite $\mathsf{StreamName}^{\uparrow}$ window row W.

Apply the regular-Cauchy handoff of Definition 5719.3. It places the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R downstream of the displayed stream windows and dyadic endpoint budgets before any Real-facing read consumes the cut-observation stream.

Finally pass through the terminal $\mathsf{Real}^{\uparrow}$ seal while preserving the transport, replay, provenance, and local naming rows H, C, P, N. Since the packet has no coordinate for quotient cuts, selected suprema, selected limits, trichotomy, ambient completeness, or host comparison, the exported comparison route is exactly the displayed forward dependency chain. □

The $\mathsf{DedekindCutStream}^{\uparrow}$ dependency lattice consumes the finite-window $\mathsf{StreamName}^{\uparrow}$ spine of chapter 126 and the $\mathsf{RegSeqRat}^{\uparrow}$ readback route of chapter 301 before any $\mathsf{Real}^{\uparrow}$-facing cut stream is inspected through chapter 38. Thus the cut-observation packet remains a horizontal L10 route through displayed stream windows and regular rational readback, not a kernel-only pointer to a selected real limit or quotient cut.

Chapter 4327

A Concrete Naming Certificate for $\mathsf{StokesTheorem}^{\uparrow}$

Following Cartan and de Rham, the $\mathsf{StokesTheorem}^{\uparrow}$ packet names the finite BEDC surface on which exterior differentiation, oriented boundary, and integration over a carried chain can be consumed as one certificate. It reads differential forms from chapter 136, the cochain boundary route from chapter 137, the charted domain surface from chapter 96, and the scalar integral handoff from chapter 1526. The packet is only a naming certificate for the displayed Stokes boundary route; it does not supply a host smooth manifold, a selected triangulation, a quotient de Rham class, a measure completion, or an ambient real-completeness theorem.

Definition 4327.1 (Stokes theorem carrier)**.** *A* $\mathsf{StokesTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, F, B, E, I, H, C, P, N)$$

whose rows have the following BEDC-facing meaning.

- *M is the carried* $\mathsf{Manifold}^{\uparrow}$ *chart-and-orientation source row for the integration domain.*
- *F is the carried* $\mathsf{DiffForm}^{\uparrow}$ *form row together with the exterior-derivative row consumed by the Stokes boundary read.*
- *B is the oriented boundary-chain row whose source and target faces are read through the same displayed manifold surface.*
- *E is the* $\mathsf{DeRham}^{\uparrow}$ *boundary route identifying the exterior derivative and boundary pairing as one chain-complex comparison.*
- *I is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *scalar-integration handoff for the displayed domain, boundary, form, and derivative rows.*
- *H records componentwise* hsame *transport for M, F, B, E, I and the structural rows.*
- *C records displayed* Cont *replay of the route from manifold charts through form rows, boundary-chain rows, de Rham boundary data, and integration handoff.*
- *P is the* Pkg *provenance over* $\mathsf{Manifold}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{DeRham}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
- *N is the local* $\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.StokesTheoremUp.StokesTheoremTasteGate single carrier alignment`

Theorem 4327.2 (Stokes theorem NameCert obligations)**.** *For every accepted* $\mathsf{StokesTheorem}^{\uparrow}$ *carrier* $K = (M, F, B, E, I, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}$ *surface is exhausted by carrier admission for* M, F, B, E, I*, boundary-chain compatibility between* B *and* E*, integral-handoff compatibility between* E *and* I*, componentwise* hsame *transport in* H*, displayed* Cont *replay in* C*, provenance in* P*, and local naming in* N*. The certificate exports no host smooth map, no selected chain representative, no quotient de Rham class, no measure-completion object, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 5720.1. The analytic rows are exactly the manifold row M, differential-form row F, boundary-chain row B, de Rham boundary row E, and integration handoff row I.

The boundary compatibility is local: B supplies the displayed oriented boundary route, while E supplies the de Rham chain-complex comparison over the same form data. The integration compatibility is also local: I is read only after those rows have been displayed.

Finally attach H, C, P, N. These rows transport, replay, source, and name the same finite route. Since the carrier has no coordinate for the excluded host objects, the listed rows exhaust the local NameCert obligations. □

Theorem 4327.3 (Stokes boundary-chain route)**.** *Let* $K = (M, F, B, E, I, H, C, P, N)$ *be an accepted* $\mathsf{StokesTheorem}^{\uparrow}$ *carrier. Any consumer of the Stokes boundary comparison must first read the manifold row* M*, the differential-form row* F*, and the oriented boundary-chain row* B *before it can consume the de Rham boundary row* E *or the integration handoff* I*. The comparison is therefore a finite BEDC route through* $M, F, B, E, I, H, C, P, N$*, not an appeal to a host boundary operator or an unlogged smooth-chain equality.*

Proof. Read the carrier inventory. The row B is the only boundary-chain coordinate, and it is stated over the manifold and form rows M, F.

Apply Definition 5720.2. Boundary-chain compatibility places B before the de Rham row E, and integral-handoff compatibility places I downstream from the same displayed route.

The structural rows H, C, P, N preserve and name this route without adding a second boundary source. Hence no consumer can bypass M, F, B when reading the Stokes comparison. □

Theorem 4327.4 (Stokes closed-form nonescape)**.** *Let* $K = (M, F, B, E, I, H, C, P, N)$ *be an accepted* $\mathsf{StokesTheorem}^{\uparrow}$ *carrier whose displayed* $\mathsf{DiffForm}^{\uparrow}$ *row* F *is read as closed along the de Rham route* E*. Then every zero-boundary integral read exported by the packet remains inside* $M, F, B, E, I, H, C, P, N$*. It may use the carried closed-form row, the boundary-chain route, the de Rham boundary comparison, and the Riemann-integral handoff, but it cannot introduce a quotient cohomology representative, a host Stokes theorem, a measure-completion argument, selected charts outside* M*, or ambient real completeness.*

Proof. Begin with the closed-form read inside F and E. The form row supplies the exterior data, and the de Rham row supplies the boundary comparison over the same displayed form.

The zero-boundary integral is then read through B and I. The boundary row supplies the oriented chain surface, and the integral row supplies only the scalar handoff already tied to M, F, B, E.

Transport and replay are confined to H and C, while P and N attach provenance and local naming. None of these rows contains a quotient representative, host theorem, measure-completion carrier, external chart selector, or ambient completeness coordinate, so the closed-form read cannot escape the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{StokesTheorem}^{\uparrow}$ packet records a displayed manifold-and-orientation row, carried differential-form row, oriented boundary-chain row, de Rham boundary route, Riemann-integral handoff, componentwise transport, continuation replay, provenance, and local naming. The packet names the Stokes boundary comparison only through these finite rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed scope covers the displayed $\mathsf{Manifold}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{DeRham}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local NameCert rows of Definition 5720.1.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close a public Stokes bridge, a host smooth-chain theorem, quotient cohomology, measure completion, selected triangulations, or ambient real completeness.

Upgrade path: Obligation closure requires checked carrier admission, boundary-chain compatibility, integral-handoff compatibility, transport, replay, provenance, and ledger non-escape for BEDC.Derived.StokesTheoremUp.

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ hub routes completion existence through the diagonal-window handoff of chapter 4080 and the pointwise stream metric boundary of chapter 4139 before its child files expose the completion seal.

Chapter 4328

A Concrete Naming Certificate for $\mathsf{MetricCompletionExistence}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{MetricCompletionExistence}^{\uparrow}$ packet records the finite BEDC surface by which a displayed metric source receives a completion-facing existence certificate without selecting quotient classes or host representatives. It sits between the metric carrier of chapter 4230, the Cauchy route of chapter 3413, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the real seal of chapter 38, the completion object surface of chapter 1506, and the complete-metric consumer row of chapter 128. The selected finite windows used by the completion-existence seal are compatible with the diagonal-selection route of chapter 4080 before any completion consumer treats the seal as public. The packet names existence as finite certificate data; it is not an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4328.1 (Metric completion existence carrier)**.** *A* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, S, D, W, R, Y, U, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row whose metric observations are to be completed.*
2. *S is the* $\mathsf{Cauchy}^{\uparrow}$ *schedule row naming the finite Cauchy requests admitted from M.*
3. *D is the dense-embedding row that presents source points inside the completion-facing surface without choosing representatives.*
4. *W is the selected* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the schedule is inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the inspected windows.*
6. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that bounds the readback by finite dyadic budgets.*
7. *U is the completion seal row, tying the preceding route to* $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{CompleteMetric}^{\uparrow}$ *consumers while preserving the displayed* $\mathsf{Real}^{\uparrow}$ *distance boundary.*
8. *H records componentwise* hsame *transport for the source metric, Cauchy schedule, dense embedding, windows, readback, dyadic ledger, completion seal, uniqueness ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$M, S, D \longmapsto W \longmapsto R \longmapsto Y \longmapsto U.$$

10. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionExistence}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows, their uniqueness ledger inside H, and the replay path C. It has no coordinate for quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4328.2 (Metric completion existence NameCert obligations)**.** *For every accepted* MetricCompletionExiste *carrier $E = (M, S, D, W, R, Y, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed source metric, Cauchy schedule, dense embedding, selected finite stream windows, regular rational readback, dyadic tolerance ledger, completion seal, uniqueness ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The certificate refuses quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5721.1. Its rows expose the source $\mathsf{Met}^{\uparrow}$ data, the $\mathsf{Cauchy}^{\uparrow}$ schedule, the dense embedding, selected $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, completion seal, transport, replay, provenance, and local name.

The NameCert obligations follow the displayed order. The schedule is read from M, the embedding row D is inspected before any window, W and R provide finite observations and regular rational readback, and Y bounds them by dyadic tolerances before the completion seal U is available.

Transport and replay supply the uniqueness ledger. The row H moves the same coordinates componentwise, and C repeats the same inspection route for each consumer request; neither row introduces a host equality test or a chosen quotient representative.

Finally, P and N source and name the packet. Since the carrier contains no quotient-completion coordinate, selected representative, choice schedule, host equality oracle, trichotomy row, open-cover compactness row, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 4328.3 (Metric completion existence completion-seal nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier $E = (M, S, D, W, R, Y, U, H, C, P, N)$ reaches the completion seal U only after reading M, S, D, W, R, Y through the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, hsame, Cont, Pkg, *and local* NameCert *route. The seal cannot be replaced by quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5721.1. The only route to U first exposes the source metric row M, the Cauchy schedule S, the dense embedding row D, selected finite windows W, regular rational readback R, and dyadic tolerance ledger Y.

Apply the NameCert obligations theorem, Definition 5721.2. It orders those rows before the completion seal and binds the same route through componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ row.

The refused objects are absent from the carrier. Quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no coordinate in E, so no completion-facing consumer can substitute them for the displayed seal row U. □

Theorem 4328.4 (Metric completion existence CompleteMetric consumer route)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier* $E = (M, S, D, W, R, Y, U, H, C, P, N)$ *may use the completion seal* U *only after the* $\mathsf{Met}^{\uparrow}$ *source row,* $\mathsf{Cauchy}^{\uparrow}$ *schedule, dense embedding row,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *boundary,* $\mathsf{MetricCompletion}^{\uparrow}$ *surface, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows have been displayed. The route exports no quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier $E = (M, S, D, W, R, Y, U, H, C, P, N)$. The rows M, S, D, W, R, Y display the source metric, Cauchy schedule, dense embedding, finite windows, regular rational readback, and dyadic tolerance ledger before the completion seal row can be read.

Invoke Definition 5721.2. It binds the same rows to the $\mathsf{Real}^{\uparrow}$ boundary, the $\mathsf{MetricCompletion}^{\uparrow}$ surface, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ row.

Invoke Definition 5721.3. It prevents any completion-facing consumer from replacing U by quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Finally read the consumer side through chapter 128. A $\mathsf{CompleteMetric}^{\uparrow}$ consumer receives only the displayed completion seal and the rows that precede it, so its use of U factors through $M, S, D, W, R, Y, U, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetricCompletionExistence}^{\uparrow}$ packet is generated from a MetricSpace source row, a Cauchy schedule, dense embedding data, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a completion seal, uniqueness transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$, seed)

Scope closed: Definition 5721.1, Definition 5721.2, Definition 5721.3, and Definition 5721.4 seed the finite completion-existence packet over MetricSpace, Cauchy, StreamName, RegSeqRat, DyadicRatCore, Real, MetricCompletion, CompleteMetric, hsame, Cont, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-embedding order, finite-window readback, dyadic tolerance nonescape, completion-seal routing, CompleteMetric consumer routing, uniqueness transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionExistenceUp.

Every $\mathsf{MetricCompletionExistence}^{\uparrow}$ existence seal is read after the separated uniqueness boundary of chapter 1796, the universal-mapping row of chapter 1456, and the reflective completion route of chapter 1793. The handoff is finite completion-existence data: a source metric row, completion-facing route rows, uniqueness transport, universal-mapping visibility, reflective visibility, replay, provenance, and local $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ naming. It is not quotient completion, selected representative equality, host limit choice, or an ambient completeness construction.

Theorem 4328.5 (Metric completion existence sibling handoff)**.** *For every accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *packet* $E = (M, S, D, W, R, Y, U, H, C, P, N)$*, a completion-existence consumer may use* U *only after the uniqueness route of chapter 1796, the universal-mapping route of chapter 1456, and the*

reflective-subcategory route of chapter 1793 have been displayed through the same finite packet. The consumer receives the completion seal, uniqueness transport, universal-mapping visibility, reflective visibility, replay, provenance, and local naming rows; it receives no quotient completion, choice-selected limit, or host completeness theorem.

Proof. Project the carrier of Definition 5721.1. The packet exposes $M, S, D, W, R, Y, U, H, C, P, N$ as the only completion-existence surface.

Use the local obligations of Definition 5721.2 to order every read of U through the source metric, Cauchy schedule, dense embedding, finite stream windows, rational readback, dyadic tolerance ledger, uniqueness ledger, transport, replay, provenance, and local naming rows.

The three sibling chapters supply the horizontal route: metric-completion uniqueness contributes the separated comparison boundary, Cauchy-completion adjunction contributes the universal-mapping row, and Cauchy-completion reflective subcategory contributes the reflective visibility boundary. The adjunction row forces completion-facing consumers and source finite-window consumers through the same dense embedding and uniqueness ledger before reflection is read.

Since all three are consumed as displayed rows inside the same finite handoff, no quotient completion or choice-selected limit construction can be substituted for the packet. □

Theorem 4328.6 (Metric completion existence Cauchy-filter basis route)**.** *Every accepted* MetricCompletionExisten *completion seal is read only after the Cauchy-filter basis row and the separated metric reflection boundary have been displayed with the same finite completion packet. In particular, a public completion seal must expose* $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{SeparatedMetricReflection}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before any completion consumer treats the seal as public. The route exports no quotient completion, selected representative, host limit choice, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 5721.1. Its finite route already displays the source metric, Cauchy schedule, dense embedding, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real-facing completion seal, transport, replay, provenance, and local naming rows.

Insert the Cauchy-filter basis boundary before the completion seal is consumed. The basis row refines the Cauchy schedule into finite filter requests, while the separated metric reflection row fixes the equality boundary through which the completion consumer may read the result.

The remaining rows are then forced in order: $\mathsf{MetricCompletion}^{\uparrow}$ supplies the completion target, $\mathsf{CompletionEmbedding}^{\uparrow}$ supplies the dense embedding boundary, and the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows supply the finite readback and tolerance seal. Since none of those rows contains a quotient object, selected representative, host limit selector, choice schedule, or ambient completeness principle, the public completion seal has exactly the stated dependency route. □

Theorem 4328.7 (Metric completion existence finite basis-read route)**.** *Every completion-facing read of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier first normalizes the Cauchy schedule into a finite* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *basis before exposing the public* $\mathsf{MetricCompletion}^{\uparrow}$ *seal. Only after that basis row is displayed may the consumer read the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *row attached to the same completion packet.*

The basis-read route exports no quotient completion, selected representative, host limit choice, countable-choice schedule, excluded ambient completeness row, or separated metric shortcut outside the displayed basis packet.

Proof. Project the carrier of Definition 5721.1. Its completion-facing coordinates already include the Cauchy schedule, finite readback rows, completion seal, embedding boundary, transport, replay, provenance, and local naming.

Apply Definition 5721.6. That route inserts the $\mathsf{CauchyFilterBasis}^{\uparrow}$ boundary before the completion seal is public, so the Cauchy schedule is read as finite basis data rather than as an ambient filter object.

Now expose the consumer rows in order. The $\mathsf{MetricCompletion}^{\uparrow}$ seal can be inspected only after the basis row, and the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are the finite observation, rational readback, tolerance, and terminal seal rows of that same packet.

The excluded rows have no coordinate in the carrier. There is no quotient completion row, selected representative row, host limit-choice row, countable-choice schedule row, or ambient completeness row from which the consumer could read additional data. □

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ completion-existence packet consumes the finite Cauchy-filter basis route of chapter 1501 and the completion-facing filter handoff of chapter 1569 before exporting its own seal to the complete-metric consumer surface of chapter 128. The dependency is horizontal: the basis rows choose the finite requests, the completion rows bind the public completion route, and the complete-metric rows receive only the displayed existence packet, not quotient completion, selected representatives, host limit choice, or ambient completeness.

Theorem 4328.8 (Metric completion existence separated forward route)**.** *Every* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *completion-seal row U is consumed by the separated-completion route of chapter 1612 only after the* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Cauchy}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, and* $\mathsf{CompleteMetric}^{\uparrow}$ *rows are visible. The forward link exports a displayed completion-existence seal into* $\mathsf{SeparatedCompletion}^{\uparrow}$ *as finite route evidence, not as quotient completion equality, selected representatives, host point equality, countable choice, or an ambient complete metric space.*

Proof. Project the accepted carrier of Definition 5721.1. Its completion-seal row is not isolated; it is read downstream of the metric-space source, Cauchy request, StreamName observation schedule, RegSeqRat readback, DyadicRatCore tolerance row, Real seal, MetricCompletion row, CompleteMetric row, transport, replay, provenance, and local naming rows.

Apply Definition 5721.2. The obligation surface forces the seal consumer to expose those prerequisite rows before the completion-existence claim can be replayed or named.

The separated-completion sibling then reads the displayed completion-existence seal as route evidence for chapter 1612. Since the carrier and obligation theorem have no coordinate for quotient completion equality, selected representatives, host point equality, countable choice, or an ambient complete metric space, the forward route exports none of those endpoints. □

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ seal is read only after the Cauchy-filter basis route of chapter 1501 and the separated-completion route of chapter 1612 have both been displayed for the same completion packet. Thus a completion-existence consumer first sees the finite Cauchy-basis rows, then the separated-completion boundary, and only then treats the $\mathsf{MetricCompletionExistence}^{\uparrow}$ row as a seal for a complete metric forward route.

Theorem 4328.9 (Metric completion existence uniqueness-reflective route)**.** *Every accepted* MetricCompletionExist *read factors first through the existence carrier of Definition 5721.1. Before any completion consumer receives the completion seal U, the read must display the separated comparison boundary of* $\mathsf{MetricCompletionUniqueness}^{\uparrow}$ *and the reflective visibility boundary of* $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$

over the same finite source, Cauchy schedule, dense embedding, window, readback, dyadic, transport, replay, provenance, and local naming rows. It exports no quotient completion, selected representative, host limit choice, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the existence carrier. Its rows $M, S, D, W, R, Y, U, H, C, P, N$ are the whole route by which the source metric and Cauchy schedule reach a completion seal.

Use Definition 5721.2 to keep the source metric, schedule, dense embedding, finite windows, regular rational readback, dyadic tolerance, completion seal, transport, replay, provenance, and local naming in the displayed order.

Now read the sibling surfaces named in the packet provenance. The separated comparison boundary of chapter 1796 supplies the uniqueness side, and the reflective visibility boundary of chapter 1793 supplies the reflective side.

Because both sibling reads are consumed through the same finite carrier route, the completion consumer receives a uniqueness-reflective handoff rather than a quotient object, selected representative, host limit choice, countable-choice schedule, or ambient completeness theorem. □

Theorem 4328.10 (Metric completion existence to Cauchy completion monad law forward link)**.** *Every* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *completion seal consumed by a completion-law reader must pass through the finite* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Cauchy}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, and* $\mathsf{CompleteMetric}^{\uparrow}$ *rows before the* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *law surface of chapter 3834 is read. The forward link exports only this displayed completion-existence route, together with componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ *row.*

Proof. Project the carrier of Definition 5721.1. The source metric row M, Cauchy schedule S, selected stream windows W, regular rational readback R, dyadic tolerance ledger Y, and completion seal U form the ordered finite route toward $\mathsf{MetricCompletion}^{\uparrow}$ and $\mathsf{CompleteMetric}^{\uparrow}$ consumers.

Apply Definition 5721.2. It states that the local certificate is exhausted by carrier admission, the displayed completion-existence rows, transport, replay, provenance, and local naming. Hence a completion-law reader cannot bypass those rows when reaching the law surface.

Finally read the structural rows H, C, P, N. They preserve and replay the same finite route for the consumer, so the $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ handoff is a forward sibling dependency through the completion-existence carrier rather than a quotient completion, selected representative, or ambient completeness principle. □

Theorem 4328.11 (Metric completion existence Real-consumer route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier must read the* $\mathsf{Met}^{\uparrow}$ *source row,* $\mathsf{Cauchy}^{\uparrow}$ *schedule row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *distance seal,* $\mathsf{MetricCompletion}^{\uparrow}$ *completion row, and* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer row before using the completion seal. The route is a finite L10 dependency route through the displayed completion-existence packet, not a quotient completion, selected representative, countable-choice schedule, host equality oracle, trichotomy row, open-cover compactness row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the carrier of Definition 5721.1. Its only completion seal is the row U, and the route to U first displays the metric source M, Cauchy schedule S, dense embedding D, finite windows W, regular rational readback R, and dyadic tolerance ledger Y.

Apply the NameCert obligation theorem Definition 5721.2. It keeps $\mathsf{Met}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CompleteMetric}^{\uparrow}$ as separate source and consumer rows before the completion seal is exposed.

The sibling routes then keep the same boundary for downstream consumers. The complete-metric forward route and the completion uniqueness reflective route preserve the completion seal as packet data, while the Cauchy completion monad-law forward link reads the same finite source rows before any algebraic consumer uses the seal.

Since none of these rows contains quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every Real/completion consumer remains on the displayed L10 route. □

Theorem 4328.12 (MetricCompletionExistence pointwise-stream lattice route)**.** *Any* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *read consumed by* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *or by a regular Cauchy completion consumer first exposes the finite lattice*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{PointwiseStreamMetric}^{\uparrow}$$

before it reaches the completion-existence boundary. Thus the read travels through displayed stream windows, regular rational readback, terminal real-name sealing, the metric carrier, and the pointwise stream metric row; it is not a quotient completion, a selected limit, an ambient completeness theorem, or a host equality of real streams.

Proof. Read the pointwise-stream metric consumer first. Its distance observations are stream-indexed, so the consumer must display the $\mathsf{StreamName}^{\uparrow}$ row and the $\mathsf{PointwiseStreamMetric}^{\uparrow}$ row before any completion-existence seal can be used.

For a regular Cauchy completion consumer, the same route exposes the $\mathsf{RegSeqRat}^{\uparrow}$ readback and the terminal $\mathsf{Real}^{\uparrow}$ seal on top of the ambient $\mathsf{Met}^{\uparrow}$ row. These rows are the finite completion-facing lattice visible to the consumer.

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ boundary is therefore reached only after the displayed lattice has been opened. Since none of those rows carries quotient completion, selected limits, ambient completeness, or host stream equality, the handoff cannot export those conclusions. □

Theorem 4328.13 (MetricCompletionExistence pointwise-stream factorization)**.** *Every completion-existence read consumed through* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *factors through the displayed order*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{PointwiseStreamMetric}^{\uparrow}$$

before it reaches the $\mathsf{MetricCompletionExistence}^{\uparrow}$ *boundary. The factorization exposes finite stream windows, regular rational readback, the terminal Real seal, metric-space carrier rows, and the pointwise-stream distance row in that order; it exports no quotient completion, selected limit, ambient completeness theorem, or host equality of streams.*

Proof. Project the lattice route of Definition 5721.12. It already displays the only rows available to a pointwise-stream metric consumer before the completion-existence boundary.

The first factor is the finite stream read. A consumer sees $\mathsf{StreamName}^{\uparrow}$ windows and then the $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to those windows before any Real or metric row can be used.

The second factor is the completion-facing metric read. The terminal $\mathsf{Real}^{\uparrow}$ seal is exposed before the ambient $\mathsf{Met}^{\uparrow}$ row, and the $\mathsf{PointwiseStreamMetric}^{\uparrow}$ distance row is downstream of both.

Since the route contains only these displayed rows, it has no coordinate for quotient completions, selected limits, ambient completeness, or host stream equality. The completion-existence handoff therefore consumes the pointwise-stream factorization rather than a hidden completion principle. □

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ seal consumes $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ before exposing completion-facing rows: finite tail thresholds enter through chapter 1487, then travel along the existing metric-completion sibling handoff of Definition 5721.5. Thus a completion consumer sees the tail estimate as displayed threshold and readback data attached to the same $\mathsf{Met}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CompleteMetric}^{\uparrow}$ route, not as a quotient completion or ambient completeness principle.

Theorem 4328.14 (Metric completion existence Cauchy-convergence dependency route)**.** *Every* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *completion-seal consumer that uses Cauchy-convergence data first reads the Cauchy filter basis of chapter 1501, the regular Cauchy tail row, the separated-completion boundary of chapter 1612, and the terminal real-name readback row before the completion seal is public. Thus the consumer receives finite basis, tail, separated-completion, and* $\mathsf{Real}^{\uparrow}$ *rows attached to the same displayed completion packet, not quotient completion, selected representatives, host limit choice, or ambient completeness.*

Proof. Project the accepted $\mathsf{MetricCompletionExistence}^{\uparrow}$ carrier. Its existing route displays the source metric, Cauchy schedule, dense embedding, finite stream windows, regular rational readback, dyadic tolerance ledger, completion seal, transport, replay, provenance, and local naming rows.

Insert the Cauchy-filter and separated-completion dependencies before the seal is read. The basis row fixes the finite Cauchy requests, the regular tail row supplies the readback thresholds, and the separated-completion boundary fixes the equality route that downstream consumers may inspect.

The final readback remains terminal. The $\mathsf{Real}^{\uparrow}$ row is reached only through the same displayed packet, so the completion-seal consumer cannot replace the dependency route by quotient completion, selected representatives, host limit choice, or ambient completeness. □

Theorem 4328.15 (MetricCompletionExistence to CauchyRealSpread route)**.** *Every* $\mathsf{CauchyRealSpread}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *packet receives the completion-facing seal only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *boundary, and* $\mathsf{MetricCompletion}^{\uparrow}$ *completion row of Definition 5721.1. The route supplies a finite completion-facing seal for chapter 4161; it does not add quotient completion, selected representatives, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, host equality, trichotomy, or a choice principle.*

Proof. Project the carrier of Definition 5721.1. The only completion-facing route is the displayed chain from the source metric and Cauchy schedule through selected stream windows, regular rational readback, dyadic tolerance data, and the completion seal.

Apply Definition 5721.2. It requires the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{MetricCompletion}^{\uparrow}$ rows to remain visible before the seal is consumed.

The $\mathsf{CauchyRealSpread}^{\uparrow}$ consumer reads exactly that seal as finite spread data. Since the carrier has no quotient-completion coordinate, selected representative, ambient completeness theorem, host equality oracle, trichotomy row, or choice schedule, the route cannot export any of the excluded objects. □

The $\mathsf{FiniteLimitSeal}^{\uparrow}$ route is consumed by the regular Cauchy gluing boundary of chapter 5899, so this hub records the finite seal as a sibling dependency before routing the child files.

Chapter 4329

A Concrete Naming Certificate for $\mathsf{FiniteLimitSeal}^{\uparrow}$

Following Bishop regular-Cauchy completion, the $\mathsf{FiniteLimitSeal}^{\uparrow}$ packet records the finite seal used by diagonal-limit arguments before any selected limit or quotient stream equality can be mentioned. It is anchored in the finite-window route through chapter 126, chapter 301, chapter 291, and chapter 38. The packet packages the local Real-completion limit service as displayed BEDC data; it is not a global completeness theorem for $\mathsf{Real}^{\uparrow}$.

Its downstream role is fixed by the sibling routes Definition 5722.4 and Definition 5722.5: CategoryUp finite-limit consumers must first pass through the same M, W, R, D, E seal rows, and RealUp limit-seal consumers receive only that finite modulus-window-readback-tolerance-seal route. The Cauchy-filter forward route of Definition 5722.9 is consumed through the same finite seal rows, so completion-facing filter reads do not acquire a selected limit or quotient stream equality outside the local packet.

Definition 4329.1 (Finite limit seal carrier)**.** *A* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus schedule row naming the finite tail and tolerance requests used by the diagonal-limit route.*
2. *W is the selected* $\mathsf{StreamName}^{\uparrow}$ *window row containing exactly the finite observations requested by M.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger against which the readback is checked.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after M, W, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the modulus schedule, selected windows, readback, tolerance ledger, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$M \longmapsto W \longmapsto R \longmapsto D \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{FiniteLimitSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by the displayed modulus schedule, window reads, rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local name. It has no coordinate for selected limits, quotient stream equality, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4329.2 (Finite limit seal route nonescape)**.** *Every accepted* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *carrier exports its diagonal-limit service only through the finite route*

$$M \longmapsto W \longmapsto R \longmapsto D \longmapsto E.$$

It exports no selected limit, quotient stream equality, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Inspect the carrier of Definition 5722.1. The only limit-facing row is the terminal $\mathsf{Real}^{\uparrow}$ seal E, and the definition places it after the modulus schedule, selected stream windows, regular rational readback, and dyadic tolerance ledger.

Thus any consumer of the seal must first read M, W, R, D. The transport row H and replay row C preserve this same route under componentwise renaming and repeated consumer requests.

The provenance row P and local name N source the packet without adding mathematical content. Since the tuple contains no selected-limit coordinate, quotient equality relation, choice schedule, host real equality oracle, trichotomy branch, or ambient completeness theorem, the displayed route is the whole exported surface. □

Theorem 4329.3 (Finite limit seal bounded regular Cauchy route)**.** *When the modulus schedule M and the selected* $\mathsf{StreamName}^{\uparrow}$ *windows W of an accepted* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *carrier*

$$L = (M, W, R, D, E, H, C, P, N)$$

are supplied by an accepted $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *packet, the finite-limit seal route factors through the bounded tail envelope of chapter 1697 before reaching M, W, R, D, E. The handoff first reads the bounded regular Cauchy threshold and late-window rows, then repacks the displayed windows as the local* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the seal. It exports no selected limit, quotient stream equality, countable choice, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the accepted $\mathsf{FiniteLimitSeal}^{\uparrow}$ carrier and the supplying accepted $\mathsf{BoundedRegularCauchy}^{\uparrow}$ packet. The bounded regular Cauchy chapter provides the finite tail-envelope route before any Real-facing seal is consumed.

Read that envelope into the local coordinates M, W, R, D, E. The supplied threshold schedule becomes the modulus row M, the supplied late stream windows become W, and their regular rational and dyadic tolerance readbacks become the local rows R and D before the terminal seal E is exposed.

Finally apply Definition 5722.2. The structural rows H, C, P, N preserve the displayed route from M through E, and the local classifier has no coordinate for a selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^\uparrow}$.

Constructive story: A $\mathsf{FiniteLimitSeal}^\uparrow$ packet is generated from a modulus schedule, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^\uparrow}$, seed)

Scope closed: Definition 5722.1, Definition 5722.2, and Definition 5722.3 seed the finite diagonal-limit seal over StreamName, RegSeqRat, DyadicRatCore, Real, hsame, Cont, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window selection, regular readback, dyadic tolerance nonescape, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteLimitSealUp.

Theorem 4329.4 (Finite limit seal categorical consumer route)**.** *Every categorical or completion-facing consumer of an accepted* $\mathsf{FiniteLimitSeal}^\uparrow$ *carrier reads the seal through the finite-window route*

$$M \longmapsto W \longmapsto R \longmapsto D \longmapsto E$$

of Definition 5722.2, then through downstream completion siblings such as chapter 1276 and chapter 3701 before it can use the terminal $\mathsf{Real}^\uparrow$ *seal. The consumer receives a finite categorical handoff over the displayed StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and local NameCert rows; it receives no selected limits, quotient stream equality, countable choice, host real equality, trichotomy, or ambient Real completeness.*

Proof. Start with the carrier of Definition 5722.1. Its only completion-facing route places the modulus schedule, finite stream windows, regular readback, dyadic tolerance ledger, and terminal Real seal in the ordered rows M, W, R, D, E.

Apply Definition 5722.2. This prevents a categorical consumer from bypassing the finite-window rows or reading a selected limit directly from the seal.

Use Definition 5722.3 to align bounded regular Cauchy data with the same route. The bounded threshold and late-window rows are repacked as M, W, R, D before the Real seal E is visible.

Finally pass through the downstream envelope and classifier-lock chapters. chapter 1276 records the finite envelope consumed by Real and Completion routes, while chapter 3701 keeps the diagonal limit classifier on a single displayed seal route. Since none of these rows adds a selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient completeness theorem, the categorical consumer remains on the finite-window lattice. □

Theorem 4329.5 (Finite limit seal real dependency route)**.** *Every public* $\mathsf{FiniteLimitSeal}^\uparrow$ *seal consumes its real-facing rows in the displayed dependency order*

$$\mathsf{Real}^\uparrow,\ \mathsf{RegSeqRat}^\uparrow,\ \mathsf{StreamName}^\uparrow,\ \mathsf{MetricCompletion}^\uparrow$$

only through the finite modulus, window, readback, tolerance, and completion-envelope rows of Definition 5722.1. A limit consumer must first read the $\mathsf{StreamName}^\uparrow$ *observation windows, then the* $\mathsf{RegSeqRat}^\uparrow$ *rational readback, then the* $\mathsf{Real}^\uparrow$ *seal and* $\mathsf{MetricCompletion}^\uparrow$ *envelope route before the local* $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^\uparrow}$ *row is public; it receives no selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient completeness theorem.*

Proof. Project the accepted carrier from Definition 5722.1. The only real-facing path is the finite route from the modulus schedule through stream windows, regular rational readback, dyadic tolerance, and terminal Real seal.

Apply Definition 5722.2 and Definition 5722.4. They force completion-facing consumers to remain behind the displayed M, W, R, D, E rows before any categorical or completion envelope can read the seal.

The added dependency order records the same lattice edge: $\mathsf{StreamName}^{\uparrow}$ supplies the finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the rational readback, $\mathsf{Real}^{\uparrow}$ supplies the terminal seal, and $\mathsf{MetricCompletion}^{\uparrow}$ consumes that seal only through the completion route. Since the local packet has no coordinate for a selected limit or ambient completeness theorem, the dependency route is exactly the finite readback route already named by the carrier. □

Theorem 4329.6 (FiniteLimitSeal MetricCompletionFinite forward link)**.** *Every finite-limit seal consumed by a completion-facing route must expose its* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows before entering* $\mathsf{MetricCompletionFinite}^{\uparrow}$*. The forward link into chapter 1559 is a finite readback route, not a selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient Real completeness theorem.*

Proof. Start with the real dependency route above. It already forces a public $\mathsf{FiniteLimitSeal}^{\uparrow}$ consumer to read finite stream windows, regular rational readback, terminal Real sealing, and the completion envelope before any local naming row is public.

Next project the structural rows of Definition 5722.1. The same route carries hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ data, so a completion-facing consumer cannot bypass the finite seal packet.

Finally compose this route with chapter 1559. A $\mathsf{MetricCompletionFinite}^{\uparrow}$ consumer therefore receives the finite-limit seal only after the StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and naming rows are exposed, with no selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient Real completeness. □

Theorem 4329.7 (FiniteLimitSeal Real-completion route)**.** *Every accepted* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *completion-facing consumer factors through the route*

$$M, W, R, D, E, H, C, P, N.$$

Here W *is supplied by* $\mathsf{StreamName}^{\uparrow}$*,* R *by* $\mathsf{RegSeqRat}^{\uparrow}$*,* D *by* $\mathsf{DyadicRatCore}^{\uparrow}$*,* E *by* $\mathsf{Real}^{\uparrow}$*, and downstream completion is read only through* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletionFinite}^{\uparrow}$*. No selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient Real completeness enters the route.*

Proof. Project the carrier of Definition 5722.1. The completion-facing rows available to a consumer are the displayed modulus, window, readback, dyadic tolerance, Real seal, transport, replay, provenance, and local naming rows.

Use route nonescape, Definition 5722.2. It prevents a completion consumer from bypassing M, W, R, D, E or replacing them by a selected limit, quotient stream equality, host equality, trichotomy branch, or ambient completeness theorem.

Apply the real dependency route above. It identifies W as the $\mathsf{StreamName}^{\uparrow}$ window row, R as the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, D as the dyadic tolerance row, and E as the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally use the $\mathsf{MetricCompletionFinite}^{\uparrow}$ forward link, Definition 5722.6. It records the finite completion handoff and leaves downstream completion only through $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{MetricCompletionFinite}^{\uparrow}$, so the displayed route is exhausted by $M, W, R, D, E, H, C, P, N$. □

Theorem 4329.8 (FiniteLimitSeal PointwiseStreamMetric reverse route)**.** *Any* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *consumer entering* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *must expose* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{Met}^{\uparrow}$ *row,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *before the finite seal is read. The route from chapter 4139 is therefore the reverse completion-facing edge to the finite-limit seal routes above, not a selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient Real completeness theorem.*

Proof. Project the completion-facing route of Definition 5722.7. It requires the finite seal to expose $M, W, R, D, E, H, C, P, N$ before downstream completion data can be read.

Now read the $\mathsf{PointwiseStreamMetric}^{\uparrow}$ consumer through chapter 4139. Its stream metric input already carries a displayed $\mathsf{Met}^{\uparrow}$ row and pointwise StreamName observations, so entry into $\mathsf{FiniteLimitSeal}^{\uparrow}$ must align those observations with the seal rows W, R, D, E.

Finally apply the real dependency route and the $\mathsf{MetricCompletionFinite}^{\uparrow}$ forward link. They identify W as the $\mathsf{StreamName}^{\uparrow}$ window row, R as the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, D as the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and E as the $\mathsf{Real}^{\uparrow}$ seal, while H, C, P, N keep transport, replay, provenance, and naming visible. Thus the reverse route contributes only the displayed finite rows and no selected limit, quotient stream equality, choice schedule, host equality, trichotomy branch, or ambient Real completeness. □

Real-facing $\mathsf{FiniteLimitSeal}^{\uparrow}$ consumers of finite limits must read the $\mathsf{StreamName}^{\uparrow}$ observation windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ sealing boundary of chapter 38 before exporting finite-limit rows. This dependency route keeps the finite seal on displayed windows, regular rational readback, dyadic tolerance, and Real-name sealing; it does not supply selected limits, quotient stream equality, trichotomy, countable choice, or ambient Real completeness.

Theorem 4329.9 (FiniteLimitSeal CauchyFilterLimit forward route)**.** *Let*

$$L = (M, W, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteLimitSeal}^{\uparrow}$ *carrier. Every completion-facing read of* L *that is consumed as a* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *route first projects the displayed modulus schedule* M*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and only then enters the Cauchy-filter limit surface of chapter 1558. The handoff preserves the componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^{\uparrow}}$ *row* N*. It exports no selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient completeness theorem.*

Proof. Project the carrier of Definition 5722.1. Its only completion-facing route is the finite sequence M, W, R, D, E together with H, C, P, N.

Apply Definition 5722.2. This keeps the seal read behind the displayed StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, and Real seal rather than behind a selected limit or quotient stream equality.

Now use the real dependency route of Definition 5722.5. It records the same L10 path from $\mathsf{StreamName}^{\uparrow}$ through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$, so a $\mathsf{CauchyFilterLimit}^{\uparrow}$ consumer can only receive the finite seal after those rows have been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since no excluded coordinate is present in L, the route into chapter 1558 is a substantive dependency of the finite seal and not an external citation. □

Theorem 4329.10 (FiniteLimitSeal regular Cauchy gluing route)**.** *Every* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *consumer that reads a glued regular-Cauchy limit must expose the finite-limit seal rows* $M, W, R, D, E, H, C, P, N$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the sibling* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *route before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is public. The route exports no selected representatives, quotient stream equality, countable choice, or ambient Real completeness.*

Proof. Project the finite-limit seal carrier of Definition 5722.1. Its public limit-facing route is the displayed sequence from the modulus schedule through stream windows, regular rational readback, dyadic tolerance, and terminal Real seal, together with transport, replay, provenance, and local naming rows.

Apply the real-limit dependency route and the Cauchy-filter forward route, Definition 5722.5 and Definition 5722.9. These require every completion-facing seal read to pass through the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before the local $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^{\uparrow}}$ row is public.

For a glued regular-Cauchy limit, cite the substantive sibling dependency chapter 5899. The gluing packet supplies the compatible-window route, but the finite-limit seal still exposes its own $M, W, R, D, E, H, C, P, N$ rows before the terminal seal can be consumed.

The carrier and the cited sibling route contain no coordinate for selected representatives, quotient stream equality, countable choice, or ambient Real completeness. Thus a glued regular-Cauchy limit is read only through the finite seal route and the $\mathsf{RegularCauchyGluing}^{\uparrow}$ dependency. □

Chapter 4330

A Concrete Naming Certificate for $\mathsf{FormalBallDomain}^{\uparrow}$

Following Edalat and Heckmann on formal balls and domain-theoretic completion, the $\mathsf{FormalBallDomain}^{\uparrow}$ packet records the rounded, directed, radius-ordered domain surface used by constructive completion arguments. It sits over the formal-ball carrier of chapter 1510, the basis refinement route of chapter 3943, the radius-order ledger of chapter 3968, the completion route of chapter 2012, the metric completion boundary of chapter 1506, and the terminal real-name seal of chapter 38. The packet gives L10 completion consumers a finite domain-neighbour route without quotienting Cauchy names, selecting limits, invoking host point equality, using countable choice, or assuming ambient completeness.

Definition 4330.1 (FormalBallDomain carrier)**.** *A* $\mathsf{FormalBallDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, R, Q, I, C, E, H, T, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FormalBall}^{\uparrow}$ *observation row, carrying the visible centre-radius windows used by the domain packet.*
2. *R is the* $\mathsf{FormalBallRadiusOrder}^{\uparrow}$ *row, recording the finite radius refinement and order comparisons available before any rounded-domain read is exported.*
3. *Q is the* $\mathsf{FormalBallBasis}^{\uparrow}$ *row, exposing the basis elements and basis-refinement route inspected by the domain surface.*
4. *I is the directed-ideal row, listing the finite compatible formal-ball windows retained by the rounded domain read.*
5. *C is the* $\mathsf{FormalBallCompletion}^{\uparrow}$ *row, reached only after the formal-ball, radius-order, basis, and directed-ideal rows have been displayed.*
6. *E is the completion endpoint row, read through* $\mathsf{MetricCompletion}^{\uparrow}$ *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rather than through host point equality.*
7. *H records componentwise* hsame *transport for formal balls, radius orders, bases, directed ideals, completion rows, endpoint seals, replay, provenance, and local naming.*
8. *T records displayed* Cont *replay from a rounded-domain request through $B, R, Q, I, C, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{FormalBallDomain}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{FormalBallBasis}^{\uparrow}$, $\mathsf{FormalBallRadiusOrder}^{\uparrow}$, $\mathsf{FormalBallCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FormalBallDomain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, R, Q, I, C, E, H, T, P, N$. It has no coordinate for quotient completion, selected representatives, host point equality, countable choice, trichotomy, or ambient completeness.

Lean4 (definition) `BEDC.Derived.FormalBallDomainUp.FormalBallDomainUp`

Theorem 4330.2 (FormalBallDomain NameCert obligations)**.** *For every accepted* $\mathsf{FormalBallDomain}^{\uparrow}$ *carrier $D = (B, R, Q, I, C, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FormalBallDomain}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the formal-ball row, radius-order row, basis row, directed-ideal row, formal-ball-completion row, endpoint row, transport row, replay row, provenance row, and local naming row;*
2. *radius-order exactness, requiring every refinement or rounded containment used by the domain read to be recorded in R before any ideal or completion row is consumed;*
3. *basis coverage, requiring each retained formal-ball window to be inspected through Q and then recorded in the directed row I;*
4. *completion handoff, requiring C and E to remain downstream of B, R, Q, I and to expose only the displayed* $\mathsf{FormalBallCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *route;*
5. *structural stability, requiring H and T to preserve the same component rows under* hsame *transport and displayed* Cont *replay;*
6. *provenance and local naming through P and N, with no obligation row for quotient completion, selected representatives, host point equality, countable choice, trichotomy, or ambient completeness.*

No $\mathsf{FormalBallDomain}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5723.1. The accepted packet exposes exactly the formal-ball, radius-order, basis, directed-ideal, completion, endpoint, transport, replay, provenance, and naming rows.

Radius-order exactness and basis coverage are forced by the row order. A domain read must first inspect B through the finite comparisons in R, then use Q to identify the displayed basis route before the retained directed row I is available.

The completion handoff is downstream of those rows. The formal-ball-completion row C and endpoint row E can be read only after B, R, Q, I have been displayed, so they cannot supply a quotient-completion representative or host point equality on their own.

Finally H and T transport and replay the same finite packet, while P and N source and name it. Since the carrier has no coordinate for quotient completion, selected representatives, countable choice, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 4330.3 (FormalBallDomain Cauchy completion handoff)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{FormalBallCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{FormalBallDomain}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{FormalBall}^{\uparrow} \longmapsto \mathsf{FormalBallRadiusOrder}^{\uparrow} \longmapsto \mathsf{FormalBallBasis}^{\uparrow} \longmapsto I \longmapsto \mathsf{FormalBallCompletion}^{\uparrow} \longmapsto \mathsf{MetricComplet}$$

The handoff exports rounded formal-ball domain data, directed finite coverage, and completion-facing endpoint seals, but it exports no quotient completion, selected Cauchy representative, host point equality, countable-choice selector, trichotomy, or ambient completeness principle.

Proof. Start with an accepted carrier $D = (B, R, Q, I, C, E, H, T, P, N)$. A Cauchy-facing or completion-facing request can first read only the formal-ball row B and the displayed radius-order comparisons in R.

The basis and directed stages are then forced through Q and I. The basis row identifies the finite neighbourhood data retained by the packet, and the directed row records the compatible finite family used by the rounded-domain read.

The completion rows are terminal for this route. The row C supplies the formal-ball-completion handoff, while E records the metric-completion and Real-seal endpoint data that downstream consumers may inspect.

Componentwise transport and replay through H, T preserve the same route, and P, N record provenance and local naming. Since no excluded quotient, selected representative, host equality, choice, trichotomy, or ambient-completeness coordinate exists in the carrier, the handoff exposes only the displayed domain data. □

Theorem 4330.4 (FormalBallDomain Real seal boundary)**.** *For every accepted* $\mathsf{FormalBallDomain}^{\uparrow}$ *carrier* $D = (B, R, Q, I, C, E, H, T, P, N)$*, each* $\mathsf{Real}^{\uparrow}$*-facing read exported by* D *remains downstream of the formal-ball row* B*, radius-order row* R*, basis row* Q*, directed-ideal row* I*, and formal-ball-completion row* C*. The Real seal is therefore a terminal endpoint of the displayed completion route, not a detached real point, quotient-completion class, selected representative, host point equality, countable-choice selector, or ambient completeness witness.*

Proof. Read the endpoint row E from the carrier. By Definition 5723.1, E is exposed only after the formal-ball, radius-order, basis, directed-ideal, and formal-ball-completion rows have been displayed.

Apply the NameCert obligations of Definition 5723.2. Radius-order exactness keeps every refinement inside R, basis coverage keeps retained windows inside Q, I, and completion handoff keeps C, E downstream of that finite route.

The replay row T and transport row H preserve the same component order. The provenance row P and local naming row N name no second Real route, no representative selector, and no host point-equality witness.

Thus any $\mathsf{Real}^{\uparrow}$ read exported by the packet is terminal for $B, R, Q, I, C, E, H, T, P, N$. The excluded detached real point, quotient class, selected representative, choice schedule, and ambient completeness data have no carrier coordinate from which a consumer could read them. □

Falsifiable prediction: Every accepted $\mathsf{FormalBallDomain}^{\uparrow}$ completion-facing read factors through displayed FormalBallUp windows, FormalBallRadiusOrderUp comparisons, FormalBallBasisUp coverage, a directed finite row, FormalBallCompletionUp handoff, MetricCompletionUp endpoint data, RealUp sealing, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: formalball, formalballbasis, formalballradiusorder, formalballcompletion, metriccompletion, real: $\mathsf{FormalBallDomain}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries formal-ball windows, radius-order comparisons, basis coverage, directed finite domain data, completion handoff, endpoint sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FormalBallDomain}^{\uparrow}}$.

Constructive story: A FormalBallDomain$^{\uparrow}$ packet is generated from FormalBallUp windows, FormalBallRadiusOrderUp comparisons, FormalBallBasisUp coverage, directed finite domain rows, FormalBallCompletionUp handoff, MetricCompletionUp and RealUp endpoint rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FormalBallDomain}^{\uparrow}}$, seed)

Scope closed: Definition 5723.1, Definition 5723.2, Definition 5723.3, and Definition 5723.4 seed the finite formal-ball domain route from rounded neighbourhood data to completion and Real endpoint consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{FormalBallDomain}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, host point equality, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius-order exactness, basis coverage, directed-row stability, completion handoff, Real seal boundary, componentwise transport, replay, provenance, and local naming for BEDC.Derived.FormalBallDomainUp.

Chapter 4331

A Concrete Naming Certificate for CauchyCompletionReflectiveLocalization$^{\uparrow}$

Mac Lane reflective subcategories and Bishop–Bridges constructive completion present Cauchy completion as a reflector whose completed objects form a saturated boundary of the metric-name world. The CauchyCompletionReflectiveLocalization$^{\uparrow}$ packet isolates that boundary as finite BEDC NameCert data: it reads the reflective subcategory of chapter 1793, the reflector of chapter 1585, the functorial route of chapter 423, the universal property of chapter 397, the stream-name surface of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The chapter names the L10 localization boundary used by completion adjoint and universal-reflector consumers; it does not add a quotient completion carrier, selected limit representative, host equality on completed objects, countable-choice selector, ambient completeness theorem, or full Real$^{\uparrow}$ completeness principle.

Definition 4331.1 (CauchyCompletionReflectiveLocalization carrier)**.** *A* CauchyCompletionReflectiveLocalization$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, Q, I, U, F, K, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the source metric and source name-data row, including the displayed metric classifier, finite Cauchy observations,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *reads, and* DyadicRatCore$^{\uparrow}$ *tolerance ledger available before localization is read.*

2. *Q is the Cauchy completion reflector row, read through* CauchyCompletionReflector$^{\uparrow}$ *and* CauchyCompletionFunctc *naming the completed-object surface without exposing a quotient carrier or selected host limit.*

3. *I is the reflective subcategory inclusion row, read through* CauchyCompletionReflectiveSubcategory$^{\uparrow}$*, exposing completed objects as the public inclusion boundary.*

4. *U is the universal-property factorization row, read through* CompletionUniversalProperty$^{\uparrow}$ *after S, Q, I have all been displayed.*

5. *F is the saturated complete-object localization row, saying that a second completion-facing read returns to the same included complete-object surface rather than creating a second host completion.*

6. *K is the StreamName–RegSeqRat–DyadicRatCore–Real transport row, carrying finite windows, regular rational readback, dyadic tolerance accounting, and the terminal* Real$^{\uparrow}$ *seal used by S, Q, I, U, F.*

7. *T stores componentwise* hsame *transport for source metric/name data, the reflector, the inclusion, universal factorization, saturated localization, the local name route, continuation replay, provenance, and local naming.*

8. *H stores the displayed* Cont *replay from source observations through reflector admission, reflective inclusion, universal-property factorization, localization return, and the local StreamName–RegSeqRat–DyadicRatCore–Real route.*

9. *C stores the* Pkg *provenance over* $\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}$, $\mathsf{CauchyCompletionReflectiveSubcatego}$ $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *P is the local provenance ledger tying the source, reflector, inclusion, factorization, localization, transport, replay, and naming rows to the same finite history.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It contains no coordinate for quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectiveLocalizationUp.CauchyCompletionReflectiveLocalizationTas`
`single carrier alignment`

Theorem 4331.2 (CauchyCompletionReflectiveLocalization NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}$ *carrier* $L = (S, Q, I, U, F, K, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed source metric/name data, Cauchy completion reflector, reflective subcategory inclusion, universal-property factorization, saturated complete-object localization, StreamName–RegSeqRat–DyadicRatCore–Real transport,* hsame *transport,* Cont *replay,* Pkg *provenance, local provenance, and local naming rows;*

2. *reflector visibility, requiring every completion-facing read to pass through Q after the source row S has displayed the relevant finite windows and tolerance ledger;*

3. *inclusion exactness, requiring every completed-object consumer to pass through I as the reflective subcategory boundary;*

4. *universal factorization, requiring every finite-window continuous consumer to reach its extension route only through U after S, Q, I have been projected;*

5. *localization saturation, requiring repeated completion-facing reads or already-complete reads to return through F to the same included complete-object surface;*

6. *local name-route discipline, requiring* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *data to be consumed only through K;*

7. *transport and replay nonescape, requiring T, H, C, P, N to preserve the displayed dependency surface and to export no quotient completion, selected limit, host equality, countable choice, ambient completeness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside $S, Q, I, U, F, K, T, H, C, P, N$.

Proof. Project the carrier of Definition 5724.1. The displayed rows are the only data available to the local classifier: source metric/name data, reflector, reflective inclusion, universal factorization,

saturated localization, local name transport, structural transport, replay, provenance, and local naming.

The reflector and inclusion obligations are read in order. The row Q supplies the Cauchy completion reflector and functor route from the source data, while I exposes the completed objects only as the reflective-subcategory boundary.

The universal-property and saturation obligations are downstream from those rows. The row U is the sole factorization surface for finite-window continuous consumers, and F records that already-complete or repeated completion-facing reads remain on the same included complete-object surface.

Finally K, T, H, C, P, N preserve and name the route. Since the carrier has no coordinate for quotient completion equality, selected limits, host equality, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ completeness, the NameCert surface cannot export any of those objects. □

Theorem 4331.3 (CauchyCompletionReflectiveLocalization universal exhaustion)**.** *Let $L = (S, Q, I, U, F, K, T, H$ be an accepted* $\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}$ *carrier. Every L10 completion consumer that reads a reflector, completed-object inclusion, universal factorization, or repeated-completion return factors through the finite localization route*

$$S \longmapsto Q \longmapsto I \longmapsto U \longmapsto F \longmapsto K \longmapsto T, H, C, P, N.$$

Thus the completion route is exhausted by the source metric/name data, Cauchy completion reflector, reflective subcategory inclusion, universal-property factorization, saturated complete-object localization, StreamName–RegSeqRat–DyadicRatCore–Real transport, hsame *transport,* Cont *replay,* Pkg *provenance, and local NameCert rows of the carrier.*

Proof. Start with an L10 completion consumer and project the source row S. The finite source observations, stream windows, regular rational readbacks, and dyadic tolerances are visible before the consumer reaches any completed-object surface.

Next project the reflector and inclusion rows. The consumer enters completion data through Q and reads completed objects through I, so the reflective subcategory boundary is part of the same finite route rather than an external host collection.

The row U supplies universal-property factorization, and F supplies the saturated return to the same complete-object surface. Hence extension reads and repeated completion-facing reads have no second completion coordinate.

The local transport row K and structural rows T, H, C, P, N close the route. They carry StreamName, RegSeqRat, DyadicRatCore, and Real data together with transport, replay, provenance, and local naming, so the listed carrier rows exhaust every public completion read. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}$ packet is generated from source metric/name data, a Cauchy completion reflector, reflective subcategory inclusion, universal-property factorization, saturated complete-object localization, StreamName-RegSeqRat-DyadicRatCore-Real transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, local provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$, seed)

Scope closed: Definition 5724.1, Definition 5724.2, and Definition 5724.3 seed the finite reflective-localization boundary for the L10 completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host equality on completed objects, countable choice, ambient completeness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reflector visibility, inclusion exactness, universal factorization, localization saturation, local name-route discipline, and transport-replay nonescape for BEDC.Derived.CauchyCompletionReflecti

$\mathsf{RieszThorinInterpolation}^{\uparrow}$ reads endpoint bounded-operator and strip-estimate rows through chapter 1644, chapter 3893, and chapter 38 before any interpolated norm-bound ledger is exposed.

Chapter 4332

A Concrete Naming Certificate for $\mathsf{RieszThorinInterpolation}^{\uparrow}$

Following Riesz, Thorin, and Stein-Weiss, the $\mathsf{RieszThorinInterpolation}^{\uparrow}$ packet records the finite interpolation certificate by which two endpoint bounded-operator rows and a Hadamard three-lines strip estimate expose one interpolated norm bound. It sits after the strip-bound packet of chapter 3893, the endpoint normed-space surface of chapter 1950, the bounded-operator row of chapter 1644, the interpolation carrier of chapter 224, and the terminal real-name seal of chapter 38. The chapter names the displayed certificate only; it does not import a host interpolation functor, quotient operator equality, selected extremal analytic family, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Every interpolated-bound consumer must read endpoint bounded-operator rows through chapter 1644 and the strip estimate through chapter 3893 before the $\mathsf{Real}^{\uparrow}$ norm-bound ledger is visible.

Definition 4332.1 (Riesz-Thorin interpolation carrier)**.** *A* $\mathsf{RieszThorinInterpolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B, H, C, P, N)$$

with the following displayed rows:

1. X_0, X_1, Y_0, Y_1 *are endpoint* $\mathsf{NormedSpace}^{\uparrow}$ *rows for the source and target normed spaces at the two endpoints.*
2. A_0, A_1 *are endpoint* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *rows, recording the same displayed operator action with endpoint norm bounds over the corresponding normed-space rows.*
3. E_0, E_1 *are endpoint exponent rows, storing the source and target exponent ledgers and their rational comparison data.*
4. S *is the* $\mathsf{HadamardThreeLines}^{\uparrow}$ *strip-estimate row used to compare the endpoint bounds along the displayed interpolation strip.*
5. Θ *is the interpolation-parameter row, storing the inspected parameter, its endpoint incidence, and the convex-weight ledger consumed by* S*.*
6. B *is the* $\mathsf{Real}^{\uparrow}$ *norm-bound ledger exporting the interpolated bound only after* $A_0, A_1, E_0, E_1, S, \Theta$ *have been displayed.*

7. *H records componentwise* hsame *transport for endpoint normed spaces, bounded operators, exponent rows, strip estimate, interpolation parameter, norm-bound ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an interpolated-bound request through $X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B$*
9. *P is the* Pkg *provenance over* $\mathsf{RieszThorinInterpolation}^{\uparrow}$, $\mathsf{HadamardThreeLines}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Interpolation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows. It has no coordinate for a host interpolation space, quotient equality of operators, selected extremal analytic family, non-displayed exponent completion, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4332.2 (Riesz-Thorin interpolation NameCert obligations)**.** *For every accepted* $\mathsf{RieszThorinInterpolation}^{\uparrow}$ *carrier*

$$T = (X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}$ *surface consists exactly of endpoint normed-space admission through X_0, X_1, Y_0, Y_1, bounded-operator endpoint admission through A_0, A_1, endpoint exponent admission through E_0, E_1, Hadamard three-lines strip-estimate compatibility through S, interpolation-parameter admission through Θ, interpolated* $\mathsf{Real}^{\uparrow}$ *norm-bound export through B, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5725.1. The rows X_0, X_1, Y_0, Y_1 provide the endpoint normed-space surfaces, and A_0, A_1 are the only bounded-operator coordinates available to the classifier.

The exponent and strip data are then forced by row order. The endpoint exponent rows E_0, E_1 and the interpolation parameter Θ determine the displayed convex weights, while the $\mathsf{HadamardThreeLines}^{\uparrow}$ row S is the sole strip-estimate route that can compare endpoint bounds.

The bound row B reads only after those endpoint and strip rows are displayed. It exports the interpolated $\mathsf{Real}^{\uparrow}$ norm-bound ledger, not a selected analytic family or a host interpolation space.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since every excluded host object lacks a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 4332.3 (Riesz-Thorin horizontal dependency route)**.** *Every accepted interpolated-bound read for a* $\mathsf{RieszThorinInterpolation}^{\uparrow}$ *packet exposes the Hadamard three-lines strip row, endpoint* $\mathsf{NormedSpace}^{\uparrow}$ *rows, endpoint* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *rows, interpolation-parameter row, and terminal* $\mathsf{Real}^{\uparrow}$ *bound row before the interpolated estimate is visible. Equivalently, every consumer route factors through the displayed dependency lattice*

$$X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B, H, C, P, N$$

and through the sibling certificate surfaces of chapter 3893, chapter 1950, chapter 1644, chapter 224, and chapter 38.

Proof. Project the carrier $T = (X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B, H, C, P, N)$ of Definition 5725.1. The rows X_0, X_1, Y_0, Y_1 are exactly the endpoint normed-space rows, and A_0, A_1 are exactly the endpoint bounded-operator rows over those spaces.

The rows E_0, E_1, Θ record the endpoint exponent and interpolation-parameter data consumed by the strip comparison. The only strip-estimate coordinate is S, so the interpolated estimate cannot be read before the Hadamard three-lines surface named in chapter 3893 is displayed.

The terminal bound row B is downstream of the endpoint, operator, exponent, strip, and interpolation-parameter rows. The structural rows H, C, P, N transport, replay, package, and name that same dependency lattice, and they introduce no bypass around the sibling NormedSpace, BoundedLinearOperator, Interpolation, HadamardThreeLines, or Real surfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}$.

Constructive story: A $\mathsf{RieszThorinInterpolation}^{\uparrow}$ packet is generated from endpoint NormedSpace rows, endpoint BoundedLinearOperator rows, endpoint exponent rows, a HadamardThreeLines strip-estimate row, an interpolation-parameter row, a RealUp norm-bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5725.1, Definition 5725.2, and Definition 5725.3 seed the finite Riesz-Thorin interpolation carrier over endpoint normed spaces, bounded operators, exponent rows, strip estimates, interpolation parameters, norm-bound ledgers, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host interpolation spaces, quotient operator equality, selected extremal analytic families, non-displayed exponent completion, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint normed-space admission, bounded-operator admission, endpoint exponent compatibility, HadamardThreeLines strip-estimate compatibility, interpolation-parameter admission, RealUp norm-bound export, transport, replay, provenance, and local naming for BEDC.Derived.RieszThorinInterpolationUp.

The top-level $\mathsf{RieszThorinInterpolation}^{\uparrow}$ route records the sibling lattice that every interpolated norm-bound read must traverse. The proof surface is anchored in the three-lines estimate of chapter 3893, the normed source and target rows of chapter 1950, the operator-action rows of chapter 1644, the interpolation-family carrier of chapter 224, and the scalar seal of chapter 38.

Lemma 4332.4 (Riesz–Thorin sibling lattice route)**.** *Every accepted* $\mathsf{RieszThorinInterpolation}^{\uparrow}$ *consumer reads its endpoint bounds, analytic-strip comparison, interpolation parameter, bounded-linear-operator action, norm rows, and terminal* $\mathsf{Real}^{\uparrow}$ *scalar estimate through the displayed sibling lattice before the interpolated bound is public. The route exports no host complex interpolation theorem, quotient operator equality, selected analytic family, or ambient completeness coordinate beyond those sibling rows.*

Chapter 4333

A Concrete Naming Certificate for $\mathsf{HoeffdingFiniteSum}^{\uparrow}$

Following Hoeffding's finite bounded-sum inequality, the $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ packet records the finite concentration route by which independent bounded random variables yield an exponential tail estimate. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the law and range summaries of chapter 186, the independence ledger of chapter 187, the dyadic exponential-bound arithmetic of chapter 291, the terminal seal of chapter 38, and the finite-average probability route of chapter 4373. The packet names a bounded finite-sum concentration certificate; it is not a martingale inequality, a Chernoff optimization principle, an almost-sure convergence theorem, a host measure-theoretic limit, or an ambient $\mathsf{Real}^{\uparrow}$ completeness result.

Definition 4333.1 (Hoeffding finite-sum carrier)**.** *A* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, V, I, B, S, D, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row V is the finite family of* $\mathsf{RandomVar}^{\uparrow}$ *entries read over P. The row I is the* $\mathsf{Independence}^{\uparrow}$ *ledger certifying that the displayed family is independent in the finite index range under inspection. The row B is the bounded-range ledger: for each displayed variable it records lower and upper* $\mathsf{Real}^{\uparrow}$ *seals and the corresponding* $\mathsf{Distribution}^{\uparrow}$ *range summary. The row S records the centered finite-sum expression and the positive deviation request. The row D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *exponential-bound row naming the finite dyadic numerator, denominator, square, range-width sum, and slack comparison used by the displayed Hoeffding bound. The row E is the terminal* $\mathsf{Real}^{\uparrow}$ *tail seal naming the probability estimate for the exceptional event. The row H records componentwise* hsame *transport, C records* Cont *replay of the finite concentration route, Q records* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Independence}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert, *and N is the local* $\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these eleven rows.*

Lean4 ✓ `BEDC.Derived.HoeffdingFiniteSumUp.HoeffdingFiniteSumTasteGate single carrier alignment`

Theorem 4333.2 (Hoeffding finite-sum NameCert obligations)**.** *For every accepted* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *carrier $(P, V, I, B, S, D, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 5726.1. Carrier admission displays the probability source, finite random-variable family, independence ledger, bounded-range ledger, finite-sum row, dyadic*

exponential-bound row, $\mathsf{Real}^{\uparrow}$ *tail seal, transport, replay, provenance, and local naming row. The certificate imports no host concentration theorem, martingale filtration, Chernoff variational optimizer, countable-choice schedule, external probability-limit operation, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Read the carrier rows in order. The source row P supplies the event classifier and normalization, while V exposes only a finite family of random variables over that same probability source.

The independence row I and bounded-range row B are then finite ledgers. They state exactly which variables are independent and which displayed lower and upper seals bound each variable before any exponential estimate is available.

The finite-sum row S fixes the centered sum and requested deviation. The dyadic row D records the arithmetic denominator, squared deviation, accumulated range-width budget, and slack comparison used by the exponential estimate, and the $\mathsf{Real}^{\uparrow}$ row E seals the resulting tail bound.

Finally H, C, Q, N transport, replay, source, and name the same route. Since the carrier has no coordinate for a host concentration theorem, variational optimizer, infinite limit, or completeness principle, these displayed rows exhaust the local certificate surface. □

Theorem 4333.3 (Hoeffding finite tail-bound route)**.** *Every accepted* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *tail-bound read factors through the route*

$$\mathsf{ProbSpace}^{\uparrow},\ \mathsf{RandomVar}^{\uparrow},\ \mathsf{Independence}^{\uparrow},\ \mathsf{Distribution}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by the carrier rows $P, V, I, B, S, D, E, H, C, Q, N$*. A probability-bound consumer can inspect the exceptional-event estimate only after the finite probability source, random-variable family, independence ledger, bounded-range ledger, centered-sum row, dyadic exponential-bound row, terminal real seal, transport, replay, provenance, and local naming row have been displayed.*

Proof. Start with an accepted carrier and project the source rows. The probability source P and finite random-variable family V provide the only measurable data available to the tail-bound request.

Next read I and B. The independence ledger is the only route by which the product-event step enters the packet, and the bounded-range ledger is the only route by which distributional lower and upper seals enter the range-width budget.

The centered-sum row S then determines the finite event being bounded. The dyadic row D supplies the exponential-bound arithmetic for that event, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream from the same displayed dyadic comparison.

The structural rows H, C, Q, N preserve that route under classifier replacement and local naming. Therefore every tail-bound read is the finite Hoeffding handoff itself, not a hidden appeal to an external concentration theorem or ambient real-completeness principle. □

Theorem 4333.4 (Hoeffding finite-sum nonescape)**.** *For every accepted* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *packet, every concentration-facing read remains inside the displayed rows* $P, V, I, B, S, D, E, H, C, Q, N$*. In particular, the packet exports no martingale filtration, Chernoff optimizer, almost-sure convergence claim, host probability-limit operator, countable-choice selection, quotient equality of real names, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. The carrier of Definition 5726.1 has no coordinate beyond the eleven displayed rows. Thus a concentration-facing request can only project the probability source, finite variables, independence

ledger, range ledger, sum row, dyadic estimate, real tail seal, transport, replay, provenance, and local name.

The analytic content of the request is concentrated in I, B, S, D, E. Independence, bounded ranges, the finite centered sum, dyadic exponential arithmetic, and the terminal tail seal appear as explicit rows, so no further theorem object can be read from the packet.

The remaining rows H, C, Q, N are structural. They preserve displayed histories, replay the finite route, record package provenance, and attach the local certificate. Hence the accepted packet cannot export any of the excluded limit, optimizer, quotient, choice, or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}$.

Constructive story: A $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ packet is generated from a probability source row, finite random-variable family, independence ledger, bounded-range ledger, centered finite-sum row, dyadic exponential-bound row, RealUp tail seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5726.1, Definition 5726.2, Definition 5726.3, and Definition 5726.4 seed the bounded finite-sum concentration route through ProbSpace, RandomVar, Independence, Distribution, DyadicRatCore, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close martingale inequalities, Chernoff optimization, almost-sure convergence, host probability limits, countable-choice selection, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite independence routing, bounded-range stability, dyadic exponential-bound handoff, tail-seal nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.HoeffdingFiniteSumUp.

Chapter 4334

A Concrete Naming Certificate for RegularCauchyLatticeOperations$^{\uparrow}$

Following Bishop and Bridges, the RegularCauchyLatticeOperations$^{\uparrow}$ packet records the finite constructive lattice-operation surface for regular Cauchy real names. It reads the regular rational route of chapter 301, the terminal real-name seal of chapter 38, the dyadic arithmetic surface of chapter 291, the lower-member packet of chapter 1832, and the upper-member packet of chapter 1833. The certificate gives downstream Real$^{\uparrow}$ consumers one finite min/max interface without importing trichotomy, quotient real equality, selected limits, countable choice, host order completeness, or ambient Real$^{\uparrow}$ completeness.

Definition 4334.1 (Regular Cauchy lattice operations carrier)**.** *A* RegularCauchyLatticeOperations$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, Y, T, D, M, A, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two accepted* Real$^{\uparrow}$ *rows presented by regular Cauchy names, exposing only their finite* RegSeqRat$^{\uparrow}$ *readbacks and terminal real seals.*
2. *T is the shared tolerance row used to align the lower-member and upper-member requests.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *ledger for the displayed comparison scale, branch budgets, and readback arithmetic consumed by both operation rows.*
4. *M is the* RegularCauchyMinimum$^{\uparrow}$ *lower-member row.*
5. *A is the* RegularCauchyMaximum$^{\uparrow}$ *upper-member row.*
6. *R is the paired regular rational readback row for the two operation outputs.*
7. *E is the paired* Real$^{\uparrow}$ *seal row, reached only after M, A, R have been displayed.*
8. *H records componentwise* hsame *transport for the two input names, tolerance, dyadic arithmetic, minimum row, maximum row, readback, seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from a lattice-operation request through $X, Y, T, D, M, A, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* RegularCauchyLatticeOperations$^{\uparrow}$*,* RegularCauchyMinimum$^{\uparrow}$*,* RegularCauchyMaximu RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, T, D, M, A, R, E, H, C, P, N$. The carrier has no coordinate for trichotomy, quotient real equality, host order completeness, selected limits, countable choice, a host lattice structure, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularCauchyLatticeOperationsUp.RegularCauchyLatticeOperationsTasteGate`
`single carrier alignment`

Theorem 4334.2 (Regular Cauchy lattice operations NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ *carrier*

$$L = (X, Y, T, D, M, A, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two regular Cauchy real rows, shared tolerance row, dyadic arithmetic ledger, minimum row, maximum row, paired readback, paired seal, transport, replay, provenance, and local name;*
2. *shared-scale exposure, requiring T and D to be displayed before either M or A may be consumed;*
3. *lower-member routing, requiring the minimum output to be read through the* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *row M;*
4. *upper-member routing, requiring the maximum output to be read through the* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *row A;*
5. *readback and seal ordering, requiring R to expose the paired regular rational outputs before E exposes the paired* $\mathsf{Real}^{\uparrow}$ *seals;*
6. *classifier stability, requiring componentwise* hsame *transport of $X, Y, T, D, M, A, R, E, C, P, N$ to preserve the accepted operation route;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no trichotomy, quotient real equality, host order completeness, selected limit, countable choice, host lattice structure, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5727.1. Its displayed rows are exactly the two regular Cauchy real inputs, the shared tolerance row, the dyadic ledger, the two operation rows, the paired readback and seal rows, and the structural rows.

Shared-scale exposure follows because M and A have no independent tolerance coordinate inside this packet. Both operation rows read the same T, D surface before any output row can be consumed.

The lower-member and upper-member obligations are inherited as named rows, not as host operations. The packet can read the lower member only through M and the upper member only through A.

Readback and seal ordering is forced by R, E. The real-facing consumer first receives the paired regular rational readback and only then the paired $\mathsf{Real}^{\uparrow}$ seal. Transport, replay, provenance, and local naming are exhausted by H, C, P, N, so no excluded host or quotient object is available. □

Theorem 4334.3 (Regular Cauchy lattice operations min-max readback)**.** *Let* $L = (X, Y, T, D, M, A, R, E, H, C, P$ *be an accepted* $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the lattice-operation output factors through the finite route*

$$X, Y, T, D \longmapsto M, A \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the packet exports the lower and upper regular Cauchy operation outputs only as paired $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *and* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *readbacks over the same dyadic scale. It exports no trichotomy, quotient real equality, host order completeness, selected limit, countable choice, or host lattice operation.*

Proof. Start with a real-facing read of the carrier. The only input rows are X, Y, and the only scale rows are T, D, so the consumer must read those coordinates before either operation row is available.

The operation rows are M and A. By Definition 5727.1, M names the lower-member route and A names the upper-member route; neither row carries a separate host order principle.

After the operation rows are displayed, the readback row R exposes the paired regular rational outputs and the seal row E exposes the paired $\mathsf{Real}^{\uparrow}$ boundary. The structural rows H, C, P, N preserve and name this route without adding any coordinate beyond it. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5727.1, Definition 5727.2, and Definition 5727.3 seed a finite min/max operation route for two regular Cauchy real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, host order completeness, selected limits, countable choice, host lattice operations, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-scale exposure, lower-member routing, upper-member routing, readback ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLatticeOperationsUp.

Constructive story: A $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ packet is generated from two regular Cauchy Real rows, a shared dyadic tolerance surface, RegularCauchyMinimum and RegularCauchyMaximum rows, paired regular rational readback, a paired RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4335

A Concrete Naming Certificate for $\mathsf{CauchyModulusBridge}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyModulusBridge}^{\uparrow}$ packet records the finite handoff by which a displayed Cauchy-criterion request becomes an explicit modulus schedule before any regular-rational readback or real-name seal is consumed. It sits after the effective criterion packet of chapter 3695, the modulus schedule surface of chapter 292, the regular rational readback of chapter 301, the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the L10 bridge from criterion-facing reads to explicit schedules as finite NameCert data; it is not quotient stream equality, a selected host limit, countable choice, trichotomy, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4335.1 (Cauchy modulus bridge carrier)**.** *A* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, M, E, S, D, R, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyCriterion}^{\uparrow}$ *request row naming the late-pair comparison surface to be served by the bridge.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row assigning the displayed precision request to a finite tail threshold.*
3. *E is the* $\mathsf{EffectiveCauchyCriterion}^{\uparrow}$ *row tying the same criterion request and modulus schedule to a finite effective handoff.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the criterion request and scheduled by the modulus row.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the radius, tail comparison, and endpoint budget used by the request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row available only after Q, M, E, S, D have been displayed.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the criterion, modulus, effective handoff, window, tolerance, and regular-rational rows have been read.*
8. *H records componentwise* hsame *transport for the criterion, modulus, effective handoff, stream-window, dyadic, regular-rational, real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a Cauchy-criterion request through $Q, M, E, S, D, R, L, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusBridge}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, EffectiveCauchyCriterio StreamName$^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, M, E, S, D, R, L, H, C, P, N$. It has no coordinate for quotient streams, selected limits, host sequence equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusBridgeUp.CauchyModulusBridgeTasteGate single carrier alignment`

Theorem 4335.2 (Cauchy modulus bridge NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *carrier $B = (Q, M, E, S, D, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed criterion row Q, modulus schedule M, effective criterion handoff E, finite stream window S, dyadic tolerance ledger D, regular-rational readback R, terminal real seal L, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 5728.1. The analytic rows visible to a consumer are exactly the criterion request Q, modulus schedule M, effective handoff E, finite window S, dyadic tolerance ledger D, regular-rational readback R, and terminal real seal L.

The bridge obligation is the ordering of those rows. A Cauchy-criterion request first exposes Q and then reads the displayed threshold in M through the effective handoff E; only after that handoff are the stream window S and dyadic tolerance ledger D available for regular readback.

The downstream rows are forced by the same carrier projection. The row R is the $\mathsf{RegSeqRat}^{\uparrow}$ readback obtained from the displayed window and tolerance data, and L is the $\mathsf{Real}^{\uparrow}$ seal reached only through that readback.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4335.3 (Cauchy modulus bridge effective-criterion handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CauchyCriterion}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{EffectiveCauchyCriterion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Re}$$

The handoff exposes only the displayed criterion request, explicit modulus schedule, effective criterion row, finite stream window, dyadic tolerance ledger, regular rational readback, terminal real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. It exports no quotient stream equality, selected host limit, hidden modulus oracle, countable-choice schedule, trichotomy split, host sequence equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with Definition 5728.2. It places every consumer read behind the criterion row, the explicit modulus row, and the effective criterion handoff.

Next open the finite observation route. The stream-window row S and dyadic tolerance row D are downstream of Q, M, E, so the regular-rational row R is a displayed readback from the same request rather than a detached sequence or selected limit.

The terminal seal is last. The $\mathsf{Real}^{\uparrow}$ row L is consumed only after R has been displayed, while H, C, P, N preserve the same dependency order under transport, replay, provenance, and local naming.

Thus any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer sees exactly the route stated in the theorem and cannot bypass it through a hidden analytic object. □

Theorem 4335.4 (Cauchy modulus bridge choice-free schedule)**.** *Let*

$$B = (Q, M, E, S, D, R, L, H, C, P, N) \quad \textit{and} \quad B' = (Q', M', E', S', D', R', L', H', C', P', N')$$

be accepted $\mathsf{CauchyModulusBridge}^{\uparrow}$ *carriers. If they agree componentwise on the displayed rows* $Q, M, E, S, D, R, L, H, C, P, N$*, then they determine the same modulus schedule and the same* $\mathsf{Real}^{\uparrow}$ *seal. No consumer of either packet can insert a countable-choice schedule, hidden modulus oracle, selected host limit, or extra selector coordinate between the criterion request and the terminal seal.*

Proof. Project both carriers through Definition 5728.1. The hypothesis identifies every displayed coordinate of B and B', so the criterion requests, explicit modulus rows, effective handoff rows, stream windows, dyadic ledgers, regular readbacks, Real seals, transport, replay, provenance, and local names are the same.

Use Definition 5728.2 to read the NameCert surface. Its obligation list has no row outside $Q, M, E, S, D, R, L, H, C, P, N$, so there is no remaining coordinate in which a second schedule or selector could differ.

Apply Definition 5728.3. The consumer order is forced as Q then M then E then S then D then R then L, and the terminal $\mathsf{Real}^{\uparrow}$ seal is downstream from the same regular-rational readback.

Thus the two accepted packets determine the same choice-free schedule and the same Real seal. The excluded choice and selector objects cannot be inserted because the carrier and its NameCert obligations expose no such coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyModulusBridge}^{\uparrow}$ packet is generated from a CauchyCriterion request row, a CauchyModulus schedule, an effective Cauchy criterion handoff, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5728.1, Definition 5728.2, Definition 5728.3, and Definition 5728.4 seed the finite bridge from Cauchy-criterion requests to explicit modulus schedules before RegSeqRat and Real consumers read the route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyModulusBridgeUp.CauchyModulusBridgeTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, hidden modulus oracles, countable choice, trichotomy, host sequence equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion-to-modulus exactness, effective handoff ordering, StreamName and DyadicRatCore readback, RegSeqRat handoff, RealUp seal confinement, transport stability, continuation replay, and provenance nonescape for BEDC.Derived.CauchyModulusBridgeUp.

Chapter 4336

A Concrete Naming Certificate for $\mathsf{BoundedLinearFunctional}^{\uparrow}$

Following Banach and Bourbaki functional analysis, the $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet records the scalar-valued bounded-linear-operator row that duality and weak-star consumers inspect before any host dual space is available. It sits over the linear-map route of chapter 48, the bounded-linear-operator surface of chapter 1644, the scalar-bound neighbour chapter 3603, the Banach-dual row of chapter 2265, the finite weak-star window of chapter 3420, the scalar endpoint seal of chapter 38, and the normed source surface of chapter 1950. The chapter names only displayed scalar-functional data: source rows, linearity rows, scalar target readback, norm-bound evidence, transport, replay, provenance, and local naming.

Definition 4336.1 (Bounded linear functional carrier)**.** *For a displayed* $\mathsf{NormedSpace}^{\uparrow}$ *source row* E *over the scalar endpoint surface of* $\mathsf{Real}^{\uparrow}$*, a* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E)$ *carrier is a finite* BHist *packet*

$$\Lambda = (E, L, T, K, O, H, C, P, N)$$

with the following displayed rows:

1. *E is the source normed-space row, including its carrier endpoints, scalar action, additive row, norm row, and classifier.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row from E to the scalar* $\mathsf{Real}^{\uparrow}$ *target.*
3. *T is the scalar-valued* $\mathsf{BoundedLinearOperator}^{\uparrow}(E, \mathsf{Real}^{\uparrow})$ *row carrying the same endpoint action as L.*
4. *K is the* $\mathsf{Real}^{\uparrow}$ *nonnegative bound endpoint for the functional.*
5. *O is the* $\mathsf{OperatorNorm}^{\uparrow}$ *handoff row exposing where the bound K is used.*
6. *H records componentwise* hsame *transport for the source, linear-map row, bounded-operator row, scalar bound, operator-norm handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a scalar-functional request through E, L, T, K, O, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedLinearFunctional}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{BanachDual}^{\uparrow}$, $\mathsf{BanachAlaoglu}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed source classifier, scalar endpoint transport, bounded-operator transport, bound transport, norm-bound ledger transport, replay, provenance, and local naming rows. It has no coordinate for a host dual space, quotient equality of functions, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BoundedLinearFunctionalUp.BoundedLinearFunctionalTasteGate single carrier alignment`

Theorem 4336.2 (Bounded linear functional NameCert obligations)**.** *For every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *carrier* $\Lambda = (E, L, T, K, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *surface consists exactly of source normed-space admission, linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from host dual objects. A consumer may inspect* $E, L, T, K, O, H, C, P, N$*, but it receives no ambient function space, quotient operator equality, selected representative, Hahn–Banach witness, unrestricted weak-star compactness theorem, or bridge data.*

Proof. Project the carrier rows. The analytic coordinates are exactly the source normed-space row E, the linear-map row L, the scalar-valued bounded-operator row T, the RealUp bound endpoint K, and the operator-norm handoff O.

The linearity obligation is read through $\mathsf{LinMap}^{\uparrow}$, while boundedness is read through $\mathsf{BoundedLinearOperator}^{\uparrow}(E,$ The scalar target is already the displayed $\mathsf{Real}^{\uparrow}$ endpoint surface, so the functional row never becomes a host-level function.

The bound exactness is the shared route through K and O. The operator-norm handoff records where the scalar bound is used, and componentwise hsame transport moves the source, action, bound, ledger, replay, provenance, and local naming rows together.

No remaining coordinate can manufacture a dual-space quotient, selected representative, Hahn–Banach witness, unrestricted compactness theorem, or bridge check. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 4336.3 (Bounded linear functional operator-norm handoff)**.** *Every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E$ *packet exports the finite route*

$$\mathsf{LinMap}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{OperatorNorm}^{\uparrow} \longmapsto \mathsf{BoundedLinearFunctional}^{\uparrow}$$

to functional-analysis consumers. The route first exposes the carried scalar-valued linear action, then the bounded-operator row, then the RealUp bound endpoint and operator-norm ledger; it does not expose a host supremum, quotient equality of functionals, selected norm-attaining vector, or hidden Banach completeness.

Proof. Begin with an accepted packet $\Lambda = (E, L, T, K, O, H, C, P, N)$. The read of L supplies only the displayed linear-map action from the source row to the scalar target.

The read of T then packages the same action as a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row. Its target row is $\mathsf{Real}^{\uparrow}$, and its bound endpoint is the displayed scalar K.

Finally the operator-norm handoff O records the norm-bound ledger that downstream consumers may inspect. Because no host norm function, quotient functional equality, selected vector, or hidden completion row is present, the exported handoff is exactly the displayed scalar-bound route. □

Theorem 4336.4 (Bounded linear functional dual-row nonescape)**.** *Any read of a* $\mathsf{BanachDual}^{\uparrow}$ *or* $\mathsf{BanachAlaoglu}^{\uparrow}$ *consumer that uses a* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *row factors through the same source normed-space row, scalar-valued bounded-operator row, RealUp bound endpoint, operator-norm handoff, componentwise transport, replay, provenance, and local naming rows of Definition 5790.1. The duality consumer receives a finite scalar-functional row, not a host dual space, a quotient function class, an unrestricted weak-star compactness theorem, or a selected cluster point.*

Proof. Read the duality consumer first. A $\mathsf{BanachDual}^{\uparrow}$ request needs a scalar-functional row over a displayed source, while a $\mathsf{BanachAlaoglu}^{\uparrow}$ request needs a finite family of such scalar-functional observations.

In either case the only scalar-functional packet available here is Λ. Its source row, bounded-operator row, bound endpoint, operator-norm handoff, and structural rows are projected in the order displayed by Definition 5790.1.

The downstream dual chapters may reuse those rows, but they cannot add coordinates that are absent from the packet. Thus quotient dual objects, host function classes, unrestricted weak-star compactness, selected cluster points, and bridge checks remain outside the read. □

Falsifiable prediction: Every accepted $\mathsf{BoundedLinearFunctional}^{\uparrow}$ scalar-functional read factors through a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ action row, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, and the local hsame, Cont, Pkg, and NameCert rows.

Independence witness: linearmap, boundedlinearoperator, operatornorm, banachdual, banachalaoglu, real, and normedspace: no listed sibling is bijective to $\mathsf{BoundedLinearFunctional}^{\uparrow}$ because this packet stores the scalar target restriction, the dual-facing provenance row, the operator-norm handoff, transport, replay, and local naming together as one finite scalar-functional surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet is generated from a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ scalar action, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5790.1, Definition 5790.2, Definition 5790.3, and Definition 5790.4 seed the scalar-functional row consumed by BanachDualUp and BanachAlaogluUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host dual spaces, quotient equality of functionals, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, scalar linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm handoff exactness, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BoundedLinearFunctionalUp.

Chapter 4337

A Concrete Naming Certificate for $\mathsf{CompletionModulusCategory}^{\uparrow}$

Following Bishop and Bridges on constructive completion and the functorial treatment of completions, the $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet records the finite category surface whose arrows preserve displayed completion moduli. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the completion functor of chapter 426, and the Cauchy completion functor of chapter 423. The packet names modulus-preserving completion morphisms as BEDC rows; it does not export quotient completions, selected representatives, host continuous maps, countable choice, or ambient completeness.

Definition 4337.1 (CompletionModulusCategory carrier)**.** *A* $\mathsf{CompletionModulusCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, A, S, R, D, E, F, H, C, P, N)$$

with the following displayed rows:

1. *O is the object ledger. Each object row records a completion-facing source, its displayed Cauchy-modulus discipline, and the local completion target read through the surrounding completion chapters.*
2. *A is the arrow ledger. Each arrow row records a finite morphism request together with the modulus transformation that sends source tolerances to target tolerances.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source and target names of an arrow.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the stream windows have been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare source and target moduli.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row read only after S, R, D have supplied the displayed tolerance route.*
7. *F records identity and composition rows for the completion functoriality surface, with identity arrows preserving the same modulus and composite arrows composing the displayed modulus transformations.*
8. *H records componentwise* hsame *transport for object rows, arrow rows, stream windows, regular readback, dyadic tolerances, Real seals, functoriality rows, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an arrow request through $O, A, S, R, D, E, F, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CompletionModulusCategory}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite category packet for modulus-preserving completion morphisms. It has no coordinate for quotient completion points, selected representatives, host functions, global choice schedules, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryTasteGate single carrier alignment`

Theorem 4337.2 (CompletionModulusCategory NameCert obligations)**.** *For every accepted* CompletionModulusCa *carrier $M = (O, A, S, R, D, E, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed object ledger, arrow ledger, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, identity and composition rows, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface additionally requires each arrow row in A to expose its source modulus, target modulus, and modulus transformation before any $\mathsf{Real}^{\uparrow}$*-facing read is accepted; each identity row in F to preserve the displayed modulus without adding a choice coordinate; and each composition row in F to compose the two displayed modulus transformations before the downstream seal is visible.*

Proof. Project the accepted carrier. The packet contains only the rows $O, A, S, R, D, E, F, H, C, P, N$, so carrier admission and ledger exhaustion are componentwise.

An arrow-facing request first reads the object and arrow ledgers O, A. The source and target names are then inspected through the finite stream windows S, regular rational readback R, and dyadic tolerance ledger D.

The functoriality rows F are local to the same displayed moduli. Identity preserves the stored modulus transformation, and composition combines the two stored transformations before the terminal seal E can be read.

Finally H, C, P, N transport, replay, source, and name this same finite route. Since quotient completions, selected representatives, host functions, global choice schedules, and ambient completeness are not carrier coordinates, they cannot be exported by the local NameCert. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryNameCertObligations`

Theorem 4337.3 (CompletionModulusCategory modulus functoriality)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompletionModulusCategory}^{\uparrow}$ *packet reads a modulus-preserving morphism through the finite route*

$$O, A, S, R, D, F, E, H, C, P, N.$$

Thus identity and composition of completion morphisms preserve the displayed modulus data before any $\mathsf{Real}^{\uparrow}$ *seal or completion-functor read is exposed. The route factors through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, *and* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *rather than through quotient completion equality, selected representatives, host continuous maps, countable choice, or ambient completeness.*

Proof. Start with a completion-facing morphism request. The object ledger O fixes the source and target completion rows, and the arrow ledger A fixes the modulus transformation to be checked.

The readback rows S, R, D display the inspected stream windows, regular rational observations, and dyadic tolerance comparisons. These rows are the only route by which the requested modulus can face the terminal Real seal.

The functoriality row F then supplies the identity or composition clause. In the identity case the same displayed modulus is replayed. In the composition case the two displayed modulus transformations are composed as finite rows before the result is handed to E.

The structural rows H, C, P, N preserve and name the same route. Therefore every completion-functor consumer receives finite modulus preservation data and no excluded quotient, selection, host-map, choice, or ambient-completeness surface. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryModulusFunctoriality`

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}$.

Constructive story: A $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet is generated from completion object rows, modulus-preserving arrow rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, RealUp seals, identity and composition rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5791.1, Definition 5791.2, and Definition 5791.3 seed the finite category surface for modulus-preserving completion morphisms.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host continuous maps, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-preserving arrow exactness, identity and composition rows, tolerance readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionModulusCategoryUp.

Chapter 4338

A Concrete Naming Certificate for $\mathsf{MarkovTriggerDynamics}^{\uparrow}$

The $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet realizes the finite rank-trigger dynamics of Definition 9462.1541, Definition 9462.1542, and Definition 9462.1546 as BEDC NameCert data. It records the state, support-rank, transition-count, drift, trigger-time, classifier, continuation, provenance, and naming rows needed by a downstream finite-dynamics consumer. The packet is a finite BHist surface for trigger-time readback; it is not a stochastic process on an ambient probability space, not an infinite sample path, not a hidden field model, and not a host Markov-chain object.

Definition 4338.1 (MarkovTriggerDynamics carrier)**.** *A* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, K, A, D, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite state row. It records the consumed external-codon count m and the covered support rank r for the current trigger state.*
2. *K is the support-rank row. It records the finite support coordinates currently covered by the observed codon rows and the rank read from that support.*
3. *A is the transition-count row. It stores the finite count of rank-preserving and rank-increasing next draws available from the current state.*
4. *D is the drift row. It records the displayed one-step rank drift computed from the same transition counts.*
5. *G is the trigger-time row. It records the finite recursion for the time to reach full rank and the deterministic threshold row consumed by trigger-time readers.*
6. *H records componentwise* hsame *transport for state, support-rank, transition-count, drift, trigger-time, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a state read through S, K, A, D, G, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$, BHist, hsame, Cont, *finite rank-trigger rows, finite transition-count rows, finite trigger-time rows, and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient probability space, hidden generator field, infinite sample path, external random oracle, host Markov-chain semantics, or unstated independence assumption.

Lean4 ✓ `BEDC.Derived.MarkovTriggerDynamicsUp.MarkovTriggerDynamicsTasteGate single carrier alignment`

Theorem 4338.2 (MarkovTriggerDynamics NameCert obligations)**.** *For every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier* $T = (S, K, A, D, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed state row, support-rank row, transition-count row, drift row, trigger-time row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface requires the transition-count row A *to be computed from the finite support-rank row* K*, the drift row* D *to read only the transition counts in* A*, and the trigger-time row* G *to replay the finite recursion from the displayed state row* S *without adding an external probability carrier.*

Proof. Project the accepted carrier. The packet exposes only $S, K, A, D, G, H, C, P, N$, so every NameCert obligation is a componentwise obligation on those rows.

The state and support rows S, K determine the finite rank-trigger situation. The transition-count row A counts rank-preserving and rank-increasing next draws from that finite support surface.

The drift row D is downstream of A, and the trigger-time row G is downstream of the same state and transition-count data. Thus the trigger-time read is a finite recursion over displayed rows, not an imported Markov-chain object.

Transport, replay, provenance, and local naming preserve the same coordinates. Since the excluded ambient and hidden objects are not coordinates of T, no consumer can read them from the packet. □

Theorem 4338.3 (MarkovTriggerDynamics finite trigger readback)**.** *Every trigger-time consumer of an accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *packet reads the finite route*

$$S, K, A, D, G, H, C, P, N.$$

Consequently the transition law, drift, and trigger-time rows are all determined by finite BHist transition-count data. No trigger-time read exports an infinite sample path, host Markov process, hidden field, or unstated independence source.

Proof. Start with the state row S and support-rank row K. They display the finite input state and the rank information that determines which next-draw counts are available.

The transition-count row A is the only row from which the drift row D may be read. The trigger-time row G then replays the finite recursion from those same transition counts.

Finally H, C, P, N transport, replay, source, and name the finite trigger route. Because no other row exists in the carrier, the stated nonescape clauses follow. □

Falsifiable prediction: Every $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ trigger-time read factors through finite state, support-rank, transition-count, drift, trigger-time, hsame, Cont, Pkg, and NameCert rows.

Independence witness: dna-boundary-tile, rank-trigger, finite-markov-transition: $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries state rows, support-rank rows, transition-count rows, drift rows, trigger-time rows, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Theorem 4338.4 (MarkovTriggerDynamics sibling dependency route)**.** *Every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *trigger-time read routes its finite state and transition-count rows through chapter 189 or chapter 4074 when the carrier is read as a Markov surface, through chapter 195 when it is read as finite transition evolution, and through chapter 3508 for the DNA boundary-trigger consumer.*

Proof. Project the existing carrier rows $S, K, A, D, G, H, C, P, N$. The state row S, support-rank row K, and transition-count row A provide exactly the finite Markov read, so a Markov-surface consumer reaches this packet through the Markov-chain or finite Markov-partition certificates.

The same rows, together with drift row D and trigger-time row G, form the finite transition-evolution route consumed by the dynamical-system certificate. The structural rows H, C, P, N then transport, replay, source, and name that route for the DNA boundary-trigger consumer.

This is a dependency route only. It does not add an ambient probability space, infinite sample path, unstated independence source, or host Markov-chain object to the carrier. □

Nontrivial TasteGate and FieldFaithful instances remain required before this finite trigger surface can be read as a checked biological field-faithfulness claim.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet is generated from finite state rows, support-rank rows, transition-count rows, drift rows, trigger-time recursion rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5792.1, Definition 5792.2, and Definition 5792.3 seed the finite rank-trigger Markov readback surface for DNA boundary-tile dynamics.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient probability spaces, infinite sample paths, hidden field models, host Markov-chain semantics, biological field-faithfulness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-count exactness, drift readback, trigger-time recursion, nontrivial TasteGate coverage, FieldFaithful evidence, transport, replay, provenance, and local naming for BEDC.Derived.MarkovTriggerDynamicsUp.

Chapter 4339

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet records the finite constructive route from regular Cauchy rational names to located completion data and then to the terminal $\mathsf{Real}^{\uparrow}$ seal. It reads the dyadic arithmetic surface of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the completion service exposed by chapter 128, and the real-name boundary of chapter 38. The packet supplies a located completion neighbour for the regular-Cauchy real route without asserting quotient completion equality, selected representatives, host order completeness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4339.1 (Regular Cauchy located completion carrier)**.** *A* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, Q, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the Cauchy name is inspected at requested precision scales.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for tolerance comparison, shrinkage, and rational distance estimates.*
4. *Q is the located completion row, recording the displayed located-distance and approximation data extracted from S, R, D.*
5. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row used only as a finite completion handoff for the displayed located data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback and located completion rows have been displayed.*
7. *H records componentwise* hsame *transport for stream windows, regular rational readbacks, dyadic arithmetic, located completion data, completion service, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a located-completion request through $S, R, D, Q, K, E, H, P, N$.*

9. *P is the* Pkg *provenance over* RegularCauchyLocatedCompletion$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RegularCauchyLocatedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, K, E, H, C, P, N$. The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host order completeness, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedCompletionUp.RegularCauchyLocatedCompletionTasteGate single carrier alignment`

Theorem 4339.2 (Regular Cauchy located completion obligations)**.** *For every accepted* RegularCauchyLocatedCom *carrier*

$$L = (S, R, D, Q, K, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyLocatedCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream-window row, regular rational readback row, dyadic arithmetic ledger, located completion row, complete-metric handoff, real seal, transport, replay, provenance, and local name;*
2. *window-readback coherence, requiring S to expose the finite inspection windows before R may be consumed as a regular rational name;*
3. *dyadic locatedness, requiring D to supply the tolerance comparisons and distance estimates used by the located completion row Q;*
4. *completion handoff ordering, requiring Q to be displayed before the* CompleteMetric$^{\uparrow}$ *row K is exposed;*
5. *real-seal ordering, requiring E to be read only after S, R, D, Q, K have been displayed;*
6. *classifier stability, requiring componentwise* hsame *transport and displayed* Cont *replay to preserve all visible rows;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no quotient completion equality, selected representative, countable choice, host order completeness, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5793.1. Its rows list the finite stream windows, regular rational readback, dyadic arithmetic ledger, located completion data, complete-metric handoff, real seal, and the structural rows.

Window-readback coherence follows because R has no independent observation coordinate in this packet. The regular rational read must pass through S, and the tolerance computations used by that read are then checked against the dyadic row D.

The located completion row Q is the only row that records located-distance data. The completion handoff K consumes that displayed row, and the real seal E is exposed only after the handoff has been displayed.

Transport, replay, provenance, and local naming are exhausted by H, C, P, N. Since quotient completion equality, selected representatives, countable choice, host order completeness, and ambient Real$^{\uparrow}$ completeness are absent from the carrier, no NameCert obligation can export them. □

Theorem 4339.3 (Regular Cauchy located completion Real seal route)**.** *Let* $L = (S, R, D, Q, K, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the located completion read factors through the finite route*

$$S, R, D \longmapsto Q \longmapsto K \longmapsto E \longmapsto H, C, P, N.$$

Thus the packet reaches the real-name boundary only through displayed $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic, located completion data, and the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff. It does not export quotient completion equality, selected representatives, countable choice, host order completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing read of the packet. The only observable name data are the stream windows S and the regular rational readback R, so any request for a real seal must first inspect those rows.

The dyadic row D supplies the tolerance and distance comparisons used by the located completion data Q. The complete-metric handoff K is then read as a service row for that displayed located data, not as an ambient completeness theorem.

Finally the seal row E exposes the $\mathsf{Real}^{\uparrow}$ boundary, and H, C, P, N transport, replay, source, and name the same displayed route. No remaining carrier coordinate can provide quotient completion equality, selected representatives, choice data, host order completeness, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5793.1, Definition 5793.2, and Definition 5793.3 seed a finite route from regular Cauchy names through located completion data to the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host order completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback coherence, dyadic locatedness, completion handoff ordering, real-seal ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLocatedCompletionU

Constructive story: A $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore arithmetic, located completion data, a CompleteMetric handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4340

A Concrete Naming Certificate for $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$

Following Banach, Picard, and Bishop–Bridges constructive analysis, the $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet records the finite handoff from an explicit contraction estimate to the Cauchy threshold consumed by the regular-rational and real endpoint routes. It sits between the Banach fixed-point modulus packet of chapter 4188, the Picard iteration and error-estimate packets of chapter 2359 and chapter 2233, and the regular Cauchy completion boundary of chapter 5793. The packet gives the endpoint route a single displayed Cauchy-threshold surface without selecting a fixed point, quotienting completion names, or importing ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4340.1 (Picard threshold Cauchy handoff carrier)**.** *A* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, I, E, M, R, K, S, T, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BanachFixedPointModulus}^{\uparrow}$ *source row whose contraction-rate route has already exposed the rational Lipschitz and finite Picard ledgers.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *ledger of adjacent iterate windows and replay order.*
3. *E is the* $\mathsf{PicardErrorEstimate}^{\uparrow}$ *row, carrying the residual-and-ratio estimate used to bound the Picard tail.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row produced from B, I, E for each requested dyadic or rational tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row made available only after the threshold row M has been displayed.*
6. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row consumed at the handoff boundary, not an ambient completeness theorem.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, R, K have been read.*
8. *T stores componentwise* hsame *transports for the Banach-modulus, Picard-iteration, error-estimate, Cauchy-threshold, regular-rational, complete-metric, real-seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from the contraction-rate request through $B, I, E, M, R, K, S, T, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$, $\mathsf{BanachFixedPointModulus}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{PicardErrorEstimate}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, I, E, M, R, K, S, T, C, P, N$. It has no coordinate for a selected fixed point, host fixed-point equality, quotient completion equality, detached Cauchy selector, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.PicardThresholdCauchyHandoffUp.PicardThresholdCauchyHandoffTasteGate`
`single carrier alignment`

Theorem 4340.2 (Picard threshold Cauchy handoff NameCert obligations)**.** *For every accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier $H = (B, I, E, M, R, K, S, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyH}}$ *surface consists exactly of carrier admission for the displayed rows; Banach-modulus source visibility through B; Picard-iteration visibility through I; error-estimate visibility through E; Cauchy-threshold construction through M; regular-rational readback through R; complete-metric service access through K; real seal access through S; classifier stability through T and C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 5794.1. The accepted packet exposes exactly the Banach-modulus source row, the Picard-iteration ledger, the error-estimate row, the Cauchy-threshold row, the regular-rational readback, the complete-metric service, the real seal, and the structural rows.

The threshold rows are ordered. The rows B, I, E must be displayed before M can answer a tolerance request, since M is the only coordinate that records the finite Cauchy threshold.

The endpoint rows are downstream. The row R reads the threshold as regular rational data, K is the visible complete-metric service row, and S is exposed only after those rows have been displayed. Transport, replay, provenance, and local naming are exhausted by T, C, P, N, so no further NameCert obligation is present. □

Theorem 4340.3 (Picard threshold Cauchy handoff Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing endpoint read of an accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{BanachFixedPointModulus}^{\uparrow},\ \mathsf{PicardIteration}^{\uparrow},\ \mathsf{PicardErrorEstimate}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Complete}$$

Thus the real seal is reached only after the explicit Picard threshold has been displayed as a $\mathsf{CauchyModulus}^{\uparrow}$ *row and repacked through the regular-rational and complete-metric handoff rows. The route exports no selected fixed point, quotient completion equality, detached Cauchy selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing endpoint request. The only contraction-rate source row is B, and its Picard data are refined in the visible rows I and E, so the request first reads those rows.

The threshold stage is forced by M. Apply the Banach fixed-point modulus route of Definition 4188.3 together with the Picard iteration surface of chapter 2359 and the error-estimate surface of chapter 2233. These sources supply the displayed threshold row without adding a selected endpoint.

After M is fixed, the readback and completion rows R and K expose the regular-rational and complete-metric boundary used by chapter 301 and chapter 128. The seal row S is then the only $\mathsf{Real}^{\uparrow}$ coordinate, and the structural rows T, C, P, N preserve the same route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5794.1, Definition 5794.2, and Definition 5794.3 seed the finite Picard-threshold handoff from BanachFixedPointModulus, PicardIteration, and PicardErrorEstimate rows to CauchyModulus, RegSeqRat, CompleteMetric, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, host fixed-point equality, quotient completion equality, detached Cauchy selectors, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard-threshold construction, regular-rational readback, complete-metric service access, real-seal ordering, classifier stability, provenance, and local naming for BEDC.Derived.PicardThreshol

Constructive story: A $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet is generated from a BanachFixedPointModulus source row, PicardIteration ledger, PicardErrorEstimate row, CauchyModulus threshold, RegSeqRat readback, CompleteMetric service row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4341

A Concrete Naming Certificate for $\mathsf{DiniUniformLimitModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the classical Dini theorem, the $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet extracts the finite uniform-modulus ledger visible in compact-metric monotone convergence data. It sits over chapter 2196, chapter 1436, chapter 129, chapter 130, chapter 463, chapter 369, chapter 301, and chapter 38. The packet names the finite net, rational tolerance budget, and extracted modulus route; it does not import open-cover compactness, chosen limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4341.1 (Dini uniform-limit modulus carrier)**.** *A* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row naming the compact-metric finite-source observations consumed by the extraction.*
2. *F is the monotone* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, recording the displayed continuous approximants and their pointwise monotone order.*
3. *W is the pointwise window row supplied by the Dini-continuity and Dini-uniform-convergence routes.*
4. *E is the finite net row over K, naming the finite mesh on which pointwise windows are inspected.*
5. *Q is the rational tolerance-budget row, storing the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerances assigned to the finite net and to the later readback.*
6. *U is the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row, obtained from E, Q, W and the monotone continuous family row F.*
7. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row, exposing only the modulus-controlled limit route supplied by U.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance transport.*
9. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row, naming the real-valued read without adding ambient real completeness.*
10. *H records componentwise* hsame *transport for compact-metric source, monotone family, pointwise window, finite net, rational tolerance, extracted modulus, uniform-limit handoff, rational readback, real seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the compact-metric source and monotone family through the finite net, tolerance budget, extracted modulus, and uniform-limit handoff.*
12. *P is the* Pkg *provenance over* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$, $\mathsf{DiniContinuity}^{\uparrow}$, $\mathsf{DiniUniformConvergence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, W, E, Q, U, L, R, S, H, C, P, N$. It has no coordinate for open-cover compactness, selected limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiniUniformLimitModulusUp.TasteGate.DiniUniformLimitModulusTasteGate single carrier alignment`

Theorem 4341.2 (Dini uniform-limit modulus NameCert obligations)**.** *For every accepted* DiniUniformLimitModulu *carrier*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact-metric source, monotone continuous family, pointwise window, finite net, rational tolerance budget, extracted uniform modulus, UniformLimit handoff, RegSeqRat readback, Real seal, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires monotone-window visibility through F and W, finite-net extraction through E and Q, modulus handoff through U and L, Real-seal nonescape through S, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses open-cover compactness, selected limiting values, quotient function equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only computational rows are the compact-metric source K, monotone family F, pointwise windows W, finite net E, rational budget Q, extracted modulus U, uniform-limit handoff L, rational readback R, and real seal S.

The monotone-window step is local to F and W. The finite-net step is local to E and Q, so the modulus row U is extracted from displayed finite data rather than from an open cover or a choice of limiting values.

The handoff to $\mathsf{UniformLimit}^{\uparrow}$ passes only through U and L. The rational and real readback rows R and S name the downstream values without adding quotient function equality or ambient completeness.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded objects are not coordinates of D, no NameCert consumer can read them from this carrier. □

Falsifiable prediction: Every accepted $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ read must expose compact-metric source rows, monotone continuous-family rows, pointwise window rows, a finite net, a rational tolerance budget, an extracted uniform modulus, a UniformLimit handoff, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dini-continuity, diniuniformconvergence, compactmetric, continuousmap, uniformlimit, uniformmodulus, regseqrat, real: $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ is not bijective to any

listed sibling because it binds the finite net and rational tolerance budget to an extracted uniform-modulus handoff before UniformLimit and Real consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5795.1 and Definition 5795.2 seed the finite uniform-modulus ledger extracted from compact-metric monotone convergence data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limiting values, quotient function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window visibility, finite-net extraction, modulus handoff, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniUniformLimitModulusUp.

Constructive story: A $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet is generated from compact-metric source rows, monotone continuous-family rows, pointwise windows, finite net rows, rational tolerance-budget rows, extracted uniform-modulus rows, UniformLimit handoff rows, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4342

A Concrete Naming Certificate for $\mathsf{SummationByParts}^{\uparrow}$

Following Abel and Dirichlet, the $\mathsf{SummationByParts}^{\uparrow}$ packet records the finite identity surface by which displayed partial sums, coefficient windows, adjacent differences, and endpoint terms are bound into one NameCert row. It sits beside the Abel-summation route of chapter 1763, the Abel-test consumer of chapter 1496, and the Dirichlet-test consumer of chapter 1497. Its source rows use the finite series carrier of chapter 121; its regular readback, dyadic tolerance, and endpoint seal use chapter 301, chapter 291, and chapter 38. The packet names a finite algebraic identity for downstream convergence tests; it does not import infinite sums, quotient series equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4342.1 (Summation by parts carrier)**.** *A* $\mathsf{SummationByParts}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Series}^{\uparrow}$ *source row, exposing only the inspected finite term window and its displayed partial sums.*
2. *A is the coefficient-window row, naming the coefficient entries read over the same finite interval.*
3. *Δ is the adjacent-difference row, recording the displayed values $a_k - a_{k+1}$ used by the identity.*
4. *P is the partial-sum-window row, naming the cumulative sums paired with A and Δ.*
5. *B is the boundary-term row, displaying the endpoint products and the finite interior products determined by S, A, Δ, P.*
6. *T is the convergence-test handoff row consumed by* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$.
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed finite identity data.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the finite additions, subtractions, products, and endpoint comparisons used by B.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after $S, A, \Delta, P, B, T, R, D$ have been displayed.*
10. *H records componentwise* hsame *transport for the source, coefficient, difference, partial-sum, boundary, handoff, readback, dyadic, endpoint, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the route*

$$S, A, \Delta, P, B, T, R, D \longmapsto E.$$

12. *Q is the* Pkg *provenance over* $\mathsf{SummationByParts}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$. It has no coordinate for an infinite sum, quotient series equality, selected convergence witness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SummationByPartsUp.SummationByPartsTasteGate single carrier alignment`

Theorem 4342.2 (Summation by parts NameCert obligations)**.** *For every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *carrier*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet; source and partial-sum exposure through S and P; coefficient-window and adjacent-difference exposure through A and Δ; boundary-term exactness through B; convergence-test handoff through T; regular readback, dyadic accounting, and endpoint sealing through R, D, E; and transport, replay, provenance, and local naming through H, C, Q, N.*

Proof. Project the accepted carrier. The projection exposes exactly the rows $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$, so every naming obligation must be read from one of those displayed coordinates.

The identity rows are finite. The source row S and partial-sum row P display the inspected cumulative sums, the coefficient row A displays the paired coefficients, and Δ displays the adjacent differences used by the interior terms. The boundary row B records only the endpoint products and interior products determined by those rows.

The consumer handoff is downstream of the identity. A convergence-test consumer first reads T, and the regular and real-facing route then passes through R, D, E. These rows can transport the displayed finite calculation, but they do not introduce an independent summation principle.

Finally H, C, Q, N preserve, replay, source, and name the same route. Because the carrier has no coordinate for infinite sums, quotient series equality, selected convergence witnesses, countable choice, trichotomy, or ambient real completeness, the stated rows exhaust the local NameCert surface. □

Theorem 4342.3 (Summation by parts Cauchy-series handoff)**.** *Every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *packet that is consumed by an* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$ *route hands off only the finite identity chain*

$$\mathsf{Series}^{\uparrow} \longmapsto S, A, \Delta, P, B, T \longmapsto R, D, E, H, C, Q, N.$$

Thus a Cauchy-series or real-seal consumer may read the summation-by-parts row only after the series window, coefficient window, adjacent-difference ledger, partial-sum window, boundary ledger, and test handoff have been displayed. The handoff supplies no infinite sum, quotient series equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a convergence-test read. Carrier admission exposes the source row S and the finite identity rows A, Δ, P, B before the handoff row T is available.

The downstream chapters may add their own test-specific rows. The $\mathsf{AbelSummation}^{\uparrow}$ consumer reads the displayed finite identity as its transform row, the $\mathsf{AbelTest}^{\uparrow}$ consumer combines it with a monotone null coefficient ledger, and the $\mathsf{DirichletTest}^{\uparrow}$ consumer combines it with bounded partial sums and a null-tail schedule. In each case the summation-by-parts contribution remains the same displayed finite packet.

The Cauchy-facing route is therefore forced through R and D before E can seal the endpoint. Transport, replay, provenance, and local naming preserve that same route, so no excluded summation or completeness datum can be read from the packet. □

Falsifiable prediction: An accepted $\mathsf{SummationByParts}^{\uparrow}$ consumer that reaches an $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without reading the displayed source, coefficient, adjacent-difference, partial-sum, boundary-term, and handoff rows refutes the carrier surface.

Independence witness: abel-summation, abel-test, dirichlet-test, series, regseqrat, dyadicratcore, real: no listed sibling supplies the whole thirteen-row packet $K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$, because each sibling contributes only a transform consumer, convergence-test consumer, source series, regular readback, dyadic ledger, or endpoint seal while this chapter binds the finite identity itself.

Closure status for $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$.

Constructive story: A $\mathsf{SummationByParts}^{\uparrow}$ packet is generated from a SeriesUp finite source row, coefficient windows, adjacent-difference rows, partial-sum windows, boundary-term ledgers, AbelSummation/AbelTest/DirichletTest handoff rows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$, seed)

Scope closed: Definition 5796.1, Definition 5796.2, and Definition 5796.3 seed the finite summation-by-parts identity packet over $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite summation, quotient series equality, selected convergence witnesses, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite identity exactness, convergence-test handoff, Cauchy-series readback, dyadic accounting, endpoint sealing, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.SummationByPartsUp.

Chapter 4343

A Concrete Naming Certificate for $\mathsf{RealLineOrder}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealLineOrder}^{\uparrow}$ packet records the constructive real-line order and apartness boundary visible to finite BEDC NameCert consumers. It sits over the dyadic tolerance ledger of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the rational Cauchy completion route of chapter 3670, and the Bishop regular Cauchy limit seal of chapter 1821. The packet gives L10 consumers a located comparison interface before any real-order algebra can read it; it does not import trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4343.1 (Real line order carrier)**.** *A* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D, S, R, L, A, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the positive dyadic radius used by every finite comparison request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing only the finite stream observations inspected at that tolerance.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream windows into regular rational comparison data.*
4. *L is the located comparison row, recording the finite verdict surface for $x < y$ as a witnessed positive gap at the displayed tolerance, an unresolved window requiring a smaller displayed tolerance, or a symmetric failure of the current request.*
5. *A is the apartness row, recording positive-gap readback for $x \# y$ only through D, S, R, L.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same displayed stream and regular-rational data, not from host real equality.*
7. *H records componentwise* hsame *transport for dyadic tolerance, stream windows, regular-rational readback, located comparison, apartness, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite order request through $D, S, R, L, A, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, L, A, E, H, C, P, N$. It has no coordinate for trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderTasteGate single carrier alignment`

Theorem 4343.2 (Real line order NameCert obligations)**.** *For every accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier*

$$O = (D, S, R, L, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance row, stream-window row, regular-rational readback row, located comparison row, apartness row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise transport row, replay row, provenance row, and local naming row.*

The obligation surface requires finite tolerance visibility through D, window visibility through S, regular-rational comparison readback through R, located order exposure through L, apartness exposure through A, real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier of Definition 5797.1. The only analytic rows are the dyadic tolerance D, the finite stream windows S, the regular-rational readback R, the located comparison row L, the apartness row A, and the terminal real seal E.

The comparison step is located rather than trichotomic. A finite request may display a positive gap, request a smaller displayed tolerance, or fail symmetrically at the current window; none of these outcomes supplies a global three-way case split.

The equality-sensitive routes are absent. The readback row R is regular-rational data over the displayed windows, and the seal row E is reached only after D, S, R, L, A have been inspected. Thus the packet refuses quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded principles are not coordinates of O, no local NameCert obligation can demand them. □

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderNameCertObligations`

Theorem 4343.3 (Real line order apartness readback)**.** *Every apartness read exported by an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The apartness row A may expose only a positive-gap witness already visible through D, S, R, L. It exports no trichotomy datum, quotient equality, selected representative, host real equality, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Proof. Start with an apartness request. The request must first choose a displayed positive dyadic tolerance in D and inspect the finite windows in S.

The regular-rational readback R is then the only comparison source. The located comparison row L reads this finite data and either displays a positive gap at the requested tolerance or leaves the request unresolved for a smaller displayed tolerance.

The apartness row A can cite only the positive-gap branch already exposed by L. It refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$ because those objects are not carrier rows.

The terminal seal E preserves the same finite route into $\mathsf{Real}^{\uparrow}$. Transport and replay through H and C keep the route stable, while P and N only record provenance and local naming. □

Theorem 4343.4 (Real line order L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier must read the dyadic tolerance, stream-window, regular-rational readback, located comparison, apartness, and* $\mathsf{Real}^{\uparrow}$ *seal rows in the order*

$$D, S, R, L, A, E.$$

Consequently the handoff supplies a finite non-quotient comparison boundary for later real algebra and order packets, while refusing trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. An L10 order request begins with finite tolerance data. The row D fixes the displayed dyadic radius, and S opens only the stream windows inspected at that radius.

The row R repacks those windows as regular-rational readback. The located comparison row L can then answer only with the finite comparison surface generated from D, S, R.

Apartness is downstream of located comparison. The row A may expose a positive gap only when L has already displayed one, and E seals the same finite route as a $\mathsf{Real}^{\uparrow}$-facing endpoint.

Because no earlier or later row stores trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$, the L10 handoff cannot export those principles to later consumers. □

Falsifiable prediction: Every accepted $\mathsf{RealLineOrder}^{\uparrow}$ read must expose dyadic tolerance, StreamName windows, RegSeqRat readback, located comparison, apartness, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before an L10 order consumer can read a comparison boundary.

Independence witness: dyadicratcore, streamname, regseqrat, real, rational-cauchy-completion, bishop-regular-cauchy-limit-seal: $\mathsf{RealLineOrder}^{\uparrow}$ is not bijective to any listed sibling because it binds located comparison and apartness rows to the finite readback route before the RealUp seal is available.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5797.1, Definition 5797.2, Definition 5797.3, and Definition 5797.4 seed the finite non-quotient order and apartness boundary for displayed RealUp names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient equality, selected representatives, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite tolerance visibility, stream-window visibility, regular-rational readback, located comparison, apartness readback, RealUp seal handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.RealLineOrderUp.

Constructive story: A $\mathsf{RealLineOrder}^{\uparrow}$ packet is generated from a DyadicRatCoreUp tolerance row, StreamName finite windows, RegSeqRat readback, located comparison, apartness, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4344

A Concrete Naming Certificate for $\mathsf{SchwartzKernel}^{\uparrow}$

Following Schwartz and Gelfand–Shilov, the $\mathsf{SchwartzKernel}^{\uparrow}$ packet records the finite NameCert route by which a distribution kernel is read as a bilinear action between Schwartz test probes and tempered-distribution endpoints. It sits over the Schwartz-function carrier of chapter 3399, the tempered-distribution endpoint of chapter 2310, the nuclear factorization row of chapter 215, the projective tensor norm route of chapter 4088, the tensor-product source of chapter 87, and the real seal of chapter 38. The chapter exposes the kernel theorem as finite action, tensor, nuclearity, bound, transport, replay, provenance, and local naming rows; it does not import a host distribution space, quotient test-function equality, selected representatives, or an unrestricted topological-vector-space oracle.

Definition 4344.1 (Schwartz kernel carrier)**.** *A* $\mathsf{SchwartzKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, U, J, B, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SchwartzFunction}^{\uparrow}$ *test-probe row naming the finite seminorm windows inspected on the source side.*
2. *T is the* $\mathsf{TemperedDistribution}^{\uparrow}$ *endpoint row naming the distributional action read after the test windows are displayed.*
3. *U is the* $\mathsf{TensorProduct}^{\uparrow}$ *row naming the finite tensor source on which the two test-probe sides are paired.*
4. *J is the* ***??*** *row recording the projective-tensor bound used to compare the paired test windows.*
5. *B is the* $\mathsf{Nuclear}^{\uparrow}$ *factorization row, exposing the finite nuclear decomposition route by which the kernel action is read.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed scalar bounds and kernel-action readbacks.*
7. *H records componentwise* hsame *transport for test probes, tempered endpoint, tensor source, projective bound, nuclear factorization, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite kernel request through $S, T, U, J, B, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SchwartzKernel}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{Nuclear}^{\uparrow}$, ***??***, $\mathsf{TensorProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $S, T, U, J, B, R, H, C, P, N$. It has no coordinate for a host distribution space, quotient equality of test functions, selected representatives, ambient bornological completeness, or a topological-vector-space theorem outside the displayed rows.

Lean4 ✓ `BEDC.Derived.SchwartzKernelUp.SchwartzKernelTasteGate single carrier alignment`

Theorem 4344.2 (Schwartz kernel NameCert obligations)**.** *For every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *carrier*

$$K = (S, T, U, J, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *surface consists exactly of Schwartz test-probe admission through S, tempered-distribution endpoint admission through T, tensor-source admission through U, projective-bound exposure through J, nuclear-factorization exposure through B, scalar RealUp sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every kernel consumer must read the distributional action through these ten rows. No consumer may replace them by an ambient kernel theorem, quotient test-function equality, selected representative, hidden topological vector space, or host nuclear-space completion.

Proof. Project the accepted carrier of Definition 5798.1. The analytic rows are the Schwartz test row S, the tempered-distribution endpoint T, the tensor source U, the projective bound J, the nuclear factorization B, and the RealUp seal R.

The action route is finite. The tensor row U supplies the paired test-probe source, J records the displayed projective bound, and B records the nuclear factorization by which the kernel action becomes readable by a finite consumer.

Transport and replay do not create new analytic structure. The rows H and C preserve the displayed packet componentwise and replay only the same kernel request. The provenance and naming rows P, N package the route without adding host quotient equality or a hidden completion theorem.

Thus the listed rows are exactly the local NameCert obligations for $\mathsf{SchwartzKernel}^\uparrow$. □

Theorem 4344.3 (Schwartz kernel nuclear factorization boundary)**.** *Every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *read factors through the finite route*

$$\mathsf{SchwartzFunction}^\uparrow,\ \mathsf{TensorProduct}^\uparrow,\ ??,\ \mathsf{Nuclear}^\uparrow \longmapsto \mathsf{TemperedDistribution}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The nuclear row may expose only the displayed factorization and bound data already routed through S, U, J. It exports no host theorem identifying all kernels with all continuous bilinear forms, no quotient equality of test probes, no selected representative of a distribution, and no ambient completeness claim for the surrounding function spaces.

Proof. Start with a kernel read. The request first displays the finite Schwartz windows in S and the tensor source U on which the two test-probe sides are paired.

The projective tensor bound J is the only bound row available to the consumer. The nuclear factorization row B can cite only this displayed tensor-bound route, so its readback is a finite factorization certificate rather than an ambient nuclear-space theorem.

The tempered-distribution endpoint T then reads the resulting action, and R seals the scalar outputs as RealUp data. Transport through H and replay through C keep the same row order, while P and N record source and local naming.

Since no carrier coordinate stores host quotient equality, selected representatives, or ambient completeness, those principles cannot be exported by the factorization boundary. □

Falsifiable prediction: Every accepted $\mathsf{SchwartzKernel}^{\uparrow}$ packet must expose SchwartzFunctionUp test probes, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, TemperedDistributionUp endpoint action, RealUp scalar sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a kernel consumer can read the action.

Independence witness: schwartz-function, tempered-distribution, nuclear, projective-tensor-norm, tensorproduct, real: $\mathsf{SchwartzKernel}^{\uparrow}$ is not bijective to any listed sibling because it binds the test-probe tensor route, nuclear factorization boundary, distribution endpoint, and scalar seal as one finite kernel-action packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{SchwartzKernel}^{\uparrow}$ packet is generated from SchwartzFunctionUp test probes, a TemperedDistributionUp endpoint, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, RealUp scalar seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5798.1, Definition 5798.2, Definition 5798.3, the falsifiable prediction, and the independence witness seed the finite kernel-action route over Schwartz, tempered-distribution, tensor, nuclear, bound, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host distribution-space semantics, quotient equality of test functions, selected distribution representatives, ambient nuclear-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, test-probe visibility, tensor-source admission, projective-bound exactness, nuclear-factorization exposure, tempered-endpoint action, RealUp scalar sealing, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SchwartzKernelUp.

Chapter 4345

A Concrete Naming Certificate for $\mathsf{SynonymousTransition}^{\uparrow}$

The $\mathsf{SynonymousTransition}^{\uparrow}$ packet realizes the finite synonymous-transition geometry of Definition 9462.1186 as BEDC NameCert data. It sits beside the six-bit codon-window carrier of chapter 2234, the codon transition matrix of chapter 2245, the DNA boundary-tile packet of chapter 3393, the window-coverage trigger algebra of chapter 3478, and the DNA-window trigger threshold of chapter 4217. The packet names finite codon-window, class-adjacency, boundary-spectrum, threshold, transport, replay, provenance, and local naming rows; it is not a biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Definition 4345.1 (Synonymous transition carrier)**.** *A* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (W, M, A, B, T, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *row naming the finite Q_6 codon-window surface.*
2. *M is the* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *row naming one-bit codon transitions inspected by the packet.*
3. *A is the class-adjacency row recording the displayed synonymous and cross-class adjacency counts, including the largest weights of Definition 9462.1186.*
4. *B is the boundary-spectrum row recording internal edge counts, external boundary degrees, and the control-pair corner-contact data.*
5. *T is the* $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$ *row naming the finite threshold at which an adjacency or boundary-spectrum read may trigger a downstream tile consumer.*
6. *H records componentwise* hsame *transport for codon windows, transition matrix, class adjacency, boundary spectrum, trigger threshold, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite synonymous-transition request through W, M, A, B, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{SynonymousTransition}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{CodonTransitionMatrix}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, M, A, B, T, H, C, P, N$. It has no coordinate for biological mechanism, stochastic fitness, quotient codon equality, hidden enumeration, or an ambient graph-theory oracle outside the displayed finite rows.

Theorem 4345.2 (Synonymous transition NameCert obligations)**.** *For every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier*

$$G = (W, M, A, B, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *surface consists exactly of codon-window admission through W, transition-matrix admission through M, class-adjacency exposure through A, boundary-spectrum exposure through B, trigger-threshold exposure through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every downstream synonymous-transition consumer must read the graph through these nine rows. It cannot replace them by biological causation, stochastic selection, quotient codon semantics, an unrecorded enumeration, or a hidden graph oracle.

Proof. Project the accepted carrier of Definition 5799.1. The finite codon surface is W, the one-bit transition source is M, and the named graph data are the class-adjacency row A and boundary-spectrum row B.

The trigger row T records when the displayed adjacency or boundary-spectrum data may be read by a downstream tile or trigger consumer. It does not add a biological mechanism or a stochastic model; it only names the finite threshold over the same graph rows.

Transport and replay are componentwise. The rows H and C preserve and replay W, M, A, B, T with the same finite endpoints, while P and N record provenance and local naming.

Since the carrier has no coordinate for quotient codon equality, hidden enumeration, biological causation, or ambient graph semantics, the listed rows exhaust the local NameCert obligations. □

Theorem 4345.3 (Synonymous transition boundary-spectrum handoff)**.** *Every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *read factors through the finite route*

$$\mathsf{CodonSixBitWindow}^{\uparrow},\ \mathsf{CodonTransitionMatrix}^{\uparrow} \longmapsto \mathsf{SynonymousTransition}^{\uparrow} \longmapsto \mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{Wind}$$

The handoff exposes class-adjacency weights, internal-edge counts, external boundary degrees, and control-pair corner contacts only as finite packet rows. It exports no biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Proof. Start with the codon-window row W and the one-bit transition matrix row M. These rows supply the finite Q_6 source and the adjacency relation inspected by the packet.

The class-adjacency row A records the largest displayed weights, and B records the boundary-spectrum data. The downstream boundary-tile and trigger-algebra consumers therefore receive a finite graph packet rather than a biological or stochastic explanation.

The threshold row T names when the finite rows can be consumed by the trigger route. Transport through H and replay through C keep the same graph rows visible, while P and N only package their provenance and local name.

Thus every public read of the synonymous-transition geometry remains inside the finite codon-window, transition, adjacency, boundary-spectrum, threshold, transport, replay, provenance, and naming surface. □

Falsifiable prediction: Every accepted $\mathsf{SynonymousTransition}^{\uparrow}$ packet must expose CodonSixBitWindowUp, CodonTransitionMatrixUp, class-adjacency, boundary-spectrum, DNAWindowSixTriggerThresholdUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ rows before a downstream tile or trigger consumer can read the synonymous-transition graph.

Independence witness: codon-six-bit-window, codon-transition-matrix, dna-window-six-boundary-tile, window-coverage-trigger-algebra, dna-window-six-trigger-threshold: $\mathsf{SynonymousTransition}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries class-adjacency weights, boundary-spectrum rows, and trigger-threshold handoff over the finite codon-window graph.

Closure status for $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$.

Constructive story: A $\mathsf{SynonymousTransition}^{\uparrow}$ packet is generated from a CodonSixBitWindowUp source, a CodonTransitionMatrixUp one-bit transition row, class-adjacency counts, boundary-spectrum data, DNAWindowSixTriggerThresholdUp rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5799.1, Definition 5799.2, Definition 5799.3, the falsifiable prediction, and the independence witness seed the finite synonymous-transition packet over codon-window, transition, adjacency, boundary-spectrum, threshold, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic fitness, quotient codon semantics, hidden enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, codon-window visibility, transition-matrix exactness, class-adjacency exposure, boundary-spectrum exposure, trigger-threshold handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SynonymousTransitionUp.

Chapter 4346

A Concrete Naming Certificate for $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$

Following Feller and Billingsley on finite-sum normal approximation, the $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet records the finite BEDC surface by which an iid random-variable window is centered, scaled, read as a distribution row, and handed to a real-normal comparison seal. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the law readback of chapter 186, the regular rational window of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite central-limit-facing certificate; it is not an asymptotic central limit theorem, a characteristic-function convergence theorem, a host probability-limit operator, countable choice, quotient distribution equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4346.1 (Central-limit finite-window carrier)**.** *A* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, V, S, K, D, R, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row V is the displayed iid* $\mathsf{RandomVar}^{\uparrow}$ *window over P, including the finite index range and the shared law token read by the window. The row S is the finite partial-sum ledger naming the displayed sum, the sample count, and the centered numerator. The row K is the centering and scaling row, recording the finite mean token, variance or spread token, positive scale request, and normalized finite-sum expression. The row D is the* $\mathsf{Distribution}^{\uparrow}$ *readback for the normalized finite sum and its comparison request. The row R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *window that presents rational test intervals, tolerances, and finite comparison samples for the distribution read. The row E is the* $\mathsf{Real}^{\uparrow}$ *normal-window seal naming the terminal real comparison against the displayed normal row at the requested finite window. The row H records componentwise* hsame *transport for the probability source, iid window, partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat window, Real normal-window seal, continuation, provenance, and local naming rows. The row C records* Cont *replay from a normal-facing read through P, V, S, K, D, R, E and then through the structural rows. The row Q is the* Pkg *provenance over* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert. *The row N is the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these eleven rows.*

Lean4 ✓ `BEDC.Derived.CentralLimitFiniteWindowUp.TasteGate.CentralLimitFiniteWindowTasteGate single carrier alignment`

Theorem 4346.2 (Central-limit finite-window NameCert obligations)**.** *For every accepted* CentralLimitFiniteWindo *carrier* $(P, V, S, K, D, R, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 5800.1. Carrier admission displays the probability source, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, transport, replay, provenance, and local naming row. The certificate imports no host asymptotic central limit theorem, characteristic-function limit, Lindeberg replacement principle, countable-choice schedule, quotient distribution equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Project the carrier rows in order. The probability source P and iid random-variable window V are the only stochastic data exposed to the certificate, and the partial-sum ledger S fixes the finite sum before any normal-facing read is visible.

The centering and scaling row K then determines the normalized finite expression. The distribution row D and RegSeqRat window R provide the only comparison surface through which a finite law read can reach the terminal $\mathsf{Real}^{\uparrow}$ normal-window seal E.

Finally H, C, Q, N transport, replay, source, and name the same displayed route. Since the carrier has no coordinate for an asymptotic theorem, characteristic-function limit, quotient law equality, countable choice, or ambient completeness, the listed rows exhaust the local finite NameCert surface. □

Theorem 4346.3 (Central-limit finite-window normal handoff)**.** *Every normal-facing read of an accepted* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier factors through the finite route*

$$P \longmapsto V \longmapsto S \longmapsto K \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, Q, N$$

before any consumer receives a normal-window comparison. Thus the read is the displayed iid finite-sum, normalization, distribution, RegSeqRat, and RealUp handoff itself; it exports no host asymptotic CLT, countable choice, quotient distribution equality, characteristic-function convergence principle, or ambient real completeness.

Proof. Begin with a normal-facing request. The only probability data available are the source row P and the finite iid window V, so the request must first read the displayed sample range and shared law token.

The partial-sum row S and normalization row K are then forced. They provide the finite sum, centering token, scaling token, and normalized expression that the downstream distribution read consumes.

The request can reach a normal-window comparison only through D, R, E. The distribution row D names the finite law read, the RegSeqRat row R exposes rational windows and tolerances, and the RealUp row E seals the displayed normal comparison. The structural rows H, C, Q, N preserve that route without adding analytic content.

Therefore every accepted read factors through the finite iid-sum, normalization, distribution, RegSeqRat, and RealUp rows. The excluded asymptotic, choice, quotient, characteristic-function, and completeness principles cannot be inserted into the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet is generated from a probability source row, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5800.1, Definition 5800.2, and Definition 5800.3 seed the finite central-limit-facing handoff through ProbSpace, RandomVar, Distribution, RegSeqRat, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CentralLimitFiniteWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the asymptotic central limit theorem, characteristic-function convergence, Lindeberg replacement, countable-choice schedules, quotient distribution equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, iid-window routing, partial-sum ledger exactness, normalization stability, distribution-to-RegSeqRat handoff, RealUp normal-window nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.CentralLimitFiniteWindowUp.

Chapter 4347

A Concrete Naming Certificate for $\mathsf{LipschitzRealMap}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LipschitzRealMap}^{\uparrow}$ packet records a constructive real-map certificate whose continuity is controlled by a displayed dyadic Lipschitz constant and finite regular-rational windows. It sits after the dyadic tolerance ledger of chapter 291, the countable-name window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the located order and apartness neighbour of chapter 5797. The packet names the finite L10 route by which later continuous-map and metric-uniform-continuity consumers may read a real-valued map without importing host function extensionality, quotient representatives, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4347.1 (Lipschitz real-map carrier)**.** *A* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, K, W, R, M, H, C, P, N)$$

with the following rows:

1. *S is the source* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real input surface through displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
2. *T is the target* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real output surface through the same kind of finite readback.*
3. *K is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *Lipschitz constant row, including the positive dyadic bound and the displayed tolerance ledger used by every modulus request.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the source and target names inspected by the request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the displayed source and target windows into rational comparison data.*
6. *M is the modulus-inequality row, recording that every accepted finite pair of source reads with displayed apartness or distance bound is sent to a target read whose displayed difference is bounded by the dyadic constant in K times the source bound, up to the requested displayed tolerance.*
7. *H records componentwise* hsame *transport for source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a finite map request through $S, T, K, W, R, M, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LipschitzRealMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, T, K, W, R, M, H, C, P, N$. It has no coordinate for host function equality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LipschitzRealMapUp.LipschitzRealMapTasteGate single carrier alignment`

Theorem 4347.2 (Lipschitz real-map NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier*

$$F = (S, T, K, W, R, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* $\mathsf{Real}^{\uparrow}$ *seal, target* $\mathsf{Real}^{\uparrow}$ *seal, dyadic Lipschitz constant, finite StreamName windows, RegSeqRat readback, modulus inequality, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires finite source and target visibility through S and T, dyadic bound visibility through K, finite window visibility through W, rational readback through R, modulus-inequality exposure through M, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses host function extensionality, quotient equality of real presentations, selected representatives, global uniform-continuity principles, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5801.1. The source and target real seals are the only real-name endpoints, and both are read through finite StreamName and RegSeqRat windows rather than through host real equality.

The Lipschitz datum is the dyadic row K. A map request can inspect only the finite windows W and their rational readback R before the modulus row M exposes the displayed inequality for the requested tolerance.

The structural rows do not add analytic content. The transport row H preserves the already displayed source, target, constant, window, readback, and modulus rows componentwise, while C replays the same route and P, N record provenance and local naming.

Since no carrier coordinate stores host function equality, quotient real equality, selected representatives, global uniform continuity, or ambient completeness, no local NameCert obligation can require those objects. □

Theorem 4347.3 (Lipschitz real-map modulus stability)**.** *Let F_0 and F_1 be accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carriers whose source seals, target seals, dyadic Lipschitz constant rows, finite StreamName windows, and RegSeqRat readback rows are componentwise* hsame*-transported. Then every displayed modulus-inequality read exported by F_0 transports to the corresponding displayed modulus-inequality read exported by F_1.*

The stability claim is confined to the finite rows $S, T, K, W, R, M, H, C, P, N$. It does not identify host functions, quotient real presentations, selected Cauchy names, or ambient complete metric structures.

Proof. Start with a displayed modulus request for F_0. Its source and target real seals are read only through the finite StreamName windows and RegSeqRat readback rows named by S, T, W, R.

Use the componentwise hsame hypotheses. They transport the dyadic constant row K and the finite window/readback rows into the corresponding rows of F_1, so the same displayed source tolerance and target tolerance are available after transport.

The modulus row M is a row of the carrier rather than a host theorem about all representatives. Therefore the transported request reads the F_1 modulus row with the same displayed dyadic bound and the transported finite readback data.

Finally C, P, N replay, source, and name the transported route. No quotient equality, host function equality, selected representative, or ambient completeness principle is introduced by this transport. □

Theorem 4347.4 (Lipschitz real-map L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier must read the route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{LipschitzRealMap}^{\uparrow}$$

through the finite source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, transport, replay, provenance, and local NameCert rows. The handoff supplies a finite Lipschitz-control surface for later continuous-map and metric-uniform-continuity packets, while refusing host function extensionality, quotient equality, selected representatives, global uniform-continuity principles, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. An L10 map request begins with source and target real-name seals. By the carrier definition, these seals are visible only through the finite StreamName windows and RegSeqRat readback rows used by S, T, W, R.

The request then reads the dyadic constant row K and the located comparison surface supplied by the real-line order neighbour. These rows provide the displayed source difference and target tolerance against which the modulus inequality is checked.

The modulus row M is the only analytic output of the packet. It hands a consumer a finite inequality route, not a host-level function theorem.

The rows H, C, P, N transport, replay, source, and name the same route. Thus later continuous-map and metric-uniform-continuity packets can consume the finite Lipschitz surface without receiving quotient equality, selected representatives, host function extensionality, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzRealMap}^{\uparrow}$ packet is generated from source and target RealUp seal rows, a DyadicRatCore Lipschitz constant, finite StreamName windows, RegSeqRat readback, a displayed modulus-inequality row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, seed)

Scope closed: Definition 5801.1, Definition 5801.2, Definition 5801.3, and Definition 5801.4 seed the finite Lipschitz real-map surface over the current L10 real and completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and target RealUp sealing, dyadic constant visibility, finite window readback, modulus-inequality stability, transport, replay, provenance, and local naming for future BEDC.Derived.LipschitzRealMapUp.

Chapter 4348

A Concrete Naming Certificate for HyperbolicQuasiGeodesicShadow$^{\uparrow}$

The HyperbolicQuasiGeodesicShadow$^{\uparrow}$ packet realizes the observer-expansion shadow route of section 9463.4 as finite quasi-geodesic, boundary, visual-metric, Busemann, and lamination-compatible rows. It sits after disk readout through chapter 377, the metric surface of chapter 3474, the visual-metric packet of chapter 3866, the Busemann cocycle route of chapter 4134, the geodesic-lamination packet of chapter 4203, and the observer-expansion packet of chapter 4167. The packet names a finite shadow tied to a displayed quasi-geodesic route; it does not complete the boundary, choose a global geodesic representative, identify quotient ideal points, or import host hyperbolic geometry.

Definition 4348.1 (Hyperbolic quasi-geodesic shadow carrier)**.** *A* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, G, E, V, B, L, H, C, P, A, N)$$

with the following rows:

1. *D is the disk readout row, exposing only displayed* UnitDisk$^{\uparrow}$ *coordinates and the associated* HyperbolicMetric$^{\uparrow}$ *metric-read data.*
2. *G is the quasi-geodesic route row, recording the finite path samples, distortion budget, endpoint-facing direction, and local route ledger inspected by the shadow request.*
3. *E is the boundary endpoint row named by the displayed route, not by a completed ideal-boundary quotient.*
4. *V is the visual-metric shadow row, recording the finite shadow window read through* HyperbolicVisualMetric$^{\uparrow}$ *and the boundary endpoint E.*
5. *B is the Busemann cocycle tolerance row, recording the displayed additive tolerance used to compare the route and the shadow window.*
6. *L is the geodesic-lamination compatibility row, recording whether the displayed route is compatible with the finite noncrossing leaf data consumed by* HyperbolicGeodesicLamination$^{\uparrow}$.
7. *H records componentwise* hsame *transport for disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, replay, provenance, refusal, and local naming rows.*
8. *C records displayed* Cont *replay from an observer-expansion shadow request through $D, G, E, V, B, L, H, P, A, N$.*

9. *P is the* Pkg *provenance over* HyperbolicQuasiGeodesicShadow$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HyperbolicGeodesicLamination$^{\uparrow}$, HyperbolicObserverExpar BHist, hsame, Cont, *and* NameCert.
10. *A is the refusal row excluding completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, and host curvature semantics.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, G, E, V, B, L, H, C, P, A, N$.

Theorem 4348.2 (Hyperbolic quasi-geodesic shadow NameCert obligations)**.** *For every accepted* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier*

$$Q = (D, G, E, V, B, L, H, C, P, A, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *surface consists exactly of disk-readout visibility, quasi-geodesic route visibility, boundary endpoint exposure, visual-metric shadow-window exposure, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise transport, replay, provenance, refusal, and local naming rows.*

The packet exports no completed ideal boundary, quotient boundary equality, selected global geodesic, ambient hyperbolic compactification, physical observer trajectory, host curvature theorem, or global field semantics.

Proof. Project the carrier rows in order. The disk readout D supplies the only coordinate and metric source, while G supplies the displayed route samples and distortion budget inspected by the request.

The endpoint and shadow rows are downstream of that route. The endpoint row E names only the boundary read visible from G, and the visual row V records the finite shadow window tied to that endpoint.

The comparison rows B and L keep the shadow route finite. The Busemann tolerance is a displayed cocycle budget, and lamination compatibility is a finite noncrossing-leaf check, not a global geodesic-foliation theorem.

Finally H, C, P, A, N transport, replay, source, refuse, and name the same packet. Since the excluded host objects are not carrier rows, they cannot appear as NameCert obligations. □

Theorem 4348.3 (Hyperbolic quasi-geodesic shadow stability)**.** *Let Q_0 and Q_1 be accepted* HyperbolicQuasiGeodesi *carriers whose disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow window, Busemann tolerance, lamination compatibility, refusal, provenance, and local naming rows are componentwise* hsame*-transported. Then every observer-expansion consumer reads the same finite shadow surface through Q_0 and Q_1.*

The stability claim is confined to the finite rows $D, G, E, V, B, L, H, C, P, A, N$. It does not identify completed boundaries, quotient ideal points, selected geodesics, ambient compactifications, physical observer trajectories, host curvature data, or global fields.

Proof. Start with an observer-expansion shadow request for Q_0. The request must read disk coordinates and metric data through D and then the finite route samples and distortion budget through G.

Use the componentwise hsame transport. It carries the endpoint E, visual shadow window V, Busemann tolerance B, and lamination compatibility row L to the corresponding rows of Q_1.

The refusal row is transported with the same packet. Therefore the transported consumer sees the same excluded host objects and cannot insert completed boundary quotients, selected global geodesics, ambient compactifications, physical trajectories, curvature theorems, or global fields.

The replay row C and the provenance and naming rows P, N then present the transported shadow as the same finite observer-expansion surface. □

Theorem 4348.4 (Hyperbolic quasi-geodesic shadow vision handoff)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ *carrier must read the route*

$\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicGeodesicLaminatio}$

through disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, transport, replay, provenance, refusal, and local NameCert rows. The handoff realizes the vision-level shadow route as finite NameCert data without turning observer expansion into physical cosmology or a host hyperbolic-boundary theorem.

Proof. The vision handoff begins with disk and metric data. Rows D and G ensure that the consumer reads only displayed disk observations, metric readouts, finite route samples, and a distortion budget.

The endpoint and shadow window are then forced. Rows E and V bind the boundary endpoint and visual-metric shadow to the same route, while B records the Busemann tolerance needed to compare route and shadow.

Lamination compatibility is read through L. This makes the packet consumable by geodesic-lamination and observer-expansion rows without selecting a global geodesic representative or completing the boundary.

The rows H, C, P, A, N transport, replay, source, refuse, and name the handoff. Thus the vision-level quasi-geodesic shadow is realized as finite NameCert data and not as ambient hyperbolic geometry. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ read must expose a boundary endpoint, visual-metric shadow window, Busemann cocycle tolerance, quasi-geodesic route, transport row, provenance row, refusal row, and local NameCert before any observer-expansion consumer may read the shadow.

Independence witness: hyperbolic-visual-metric, hyperbolic-busemann-cocycle, hyperbolic-geodesic-lamination, hyperbolic-observer-expansion: $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ is not bijective to these siblings because it binds the quasi-geodesic route and shadow window together before the observer-expansion packet may consume the boundary read.

The Lean TasteGate for this packet must later provide Nontrivial $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ in `lean4/BEDC/Derived/HyperbolicQuasiGeodesicShadowUp/` Those instances must keep $D, G, E, V, B, L, H, C, P, A, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ packet is generated from disk readout rows, a quasi-geodesic route, a boundary endpoint, a visual-metric shadow window, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, refusal, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5802.1, Definition 5802.2, Definition 5802.3, and Definition 5802.4 seed the finite quasi-geodesic shadow route for observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, host curvature semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk readout, quasi-geodesic route admission, endpoint exposure, visual-metric shadow windows, Busemann tolerance, lamination compatibility, TasteGate nontriviality, field faithfulness, refusal exactness, transport, replay, provenance, and local naming for future BEDC.Derived.HyperbolicQuasiGeodesicShadowUp.

Chapter 4349

A Concrete Naming Certificate for $\mathsf{Dendrite}^{\uparrow}$

Following Nadler and Kuratowski on continuum theory, the $\mathsf{Dendrite}^{\uparrow}$ packet records the finite BEDC surface for a locally connected compact metric continuum whose tree-like form is read through unique arcs and cutpoint separation. It sits over the compact metric carrier of chapter 129, the locally connected surface of chapter 5809, the Peano continuum boundary of chapter 2160, and the tree certificate of chapter 119. The packet names displayed endpoint, unique-arc, and cutpoint-separation rows; it does not import host continua, arbitrary path spaces, open-cover compactness, or quotient equality of arcs.

Definition 4349.1 (Dendrite carrier)**.** *A* $\mathsf{Dendrite}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric distance rows, finite ProbeBundle-net rows, complete-limit witness rows, and rational tolerance comparisons already certified by the compact-metric chapter.*
2. *L is the* $\mathsf{LocallyConnected}^{\uparrow}$ *row, recording the displayed connected neighbourhood refinements through which local arc and cutpoint requests are inspected.*
3. *P is the* $\mathsf{PeanoContinuum}^{\uparrow}$ *row, binding the compact metric and locally connected continuum surfaces before any dendrite consumer reads an arc boundary.*
4. *T is the* $\mathsf{Tree}^{\uparrow}$ *row, recording the finite tree-like separation surface used to rule out cycle-shaped routes.*
5. *E is the endpoint ledger, listing endpoint rows and their neighbourhood-read witnesses.*
6. *A is the unique-arc ledger, recording for every displayed endpoint or carried point pair the finite arc row, its endpoint membership rows, and its non-branching comparison rows.*
7. *C is the cutpoint-separation ledger, recording the displayed separation rows used when removing a carried point disconnects the relevant finite tree-like boundary.*
8. *H records componentwise* hsame *transport for compact metric data, local connectedness data, Peano-continuum data, tree data, endpoint rows, unique-arc rows, cutpoint-separation rows, replay, provenance, and local naming.*

9. *R records displayed* Cont *replay from a dendrite request through* $K, L, P, T, E, A, C, H, G, Q, N$.
10. *G is the* Pkg *provenance over* Dendrite$^{\uparrow}$, CompactMetric$^{\uparrow}$, LocallyConnected$^{\uparrow}$, PeanoContinuum$^{\uparrow}$, Tree$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *Q records the local source and consumer provenance for endpoint, unique-arc, and cutpoint-separation reads.*
12. *N is the local* NameCert$_{\text{Dendrite}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host continuum, arbitrary path selection, open-cover compactness, cycle elimination by excluded middle, or quotient equality of arcs.

Lean4 ✓ `BEDC.Derived.DendriteUp.DendriteTasteGate single carrier alignment`

Theorem 4349.2 (Dendrite NameCert obligations)**.** *For every accepted* Dendrite$^{\uparrow}$ *carrier*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N),$$

the local NameCert$_{\text{Dendrite}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source, locally connected row, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming;*
2. *compact-continuum visibility, requiring every dendrite consumer to read compact metric and local connectedness data through K, L, P before reading endpoint or arc rows;*
3. *tree-like exactness, requiring the non-cycle and separation information to pass through T and the cutpoint-separation ledger C;*
4. *unique-arc exactness, requiring every arc-facing read to use the displayed ledger A with its endpoint membership and non-branching comparison rows;*
5. *endpoint exactness, requiring endpoint reads to use only the displayed endpoint ledger E and not a host boundary predicate;*
6. hsame, Cont, *and* Pkg *stability, requiring componentwise transport, displayed replay, and provenance to preserve precisely the listed rows;*
7. *non-escape, excluding host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, and quotient equality of arcs.*

No dendrite obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5803.1. The accepted tuple displays exactly the compact metric source, local connectedness, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming.

The compact-continuum route is K, L, P. The compact metric source supplies distance, finite-net, complete-limit, and tolerance-comparison rows; the locally connected row supplies connected neighbourhood refinements; and the Peano-continuum row binds those surfaces before endpoint or arc data are exposed.

The tree-like route is T, E, A, C. The tree row supplies the finite non-cycle surface, the endpoint ledger records boundary reads, the unique-arc ledger records the displayed arc row between

carried point pairs, and the cutpoint-separation ledger records the separation witnesses used by downstream consumers.

Finally, H, R, G, Q, N transport, replay, source, and name the same finite packet. Since the carrier has no row for a host continuum, arbitrary path space, open-cover compactness principle, selected arc representative, or quotient equality of arcs, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$ surface. □

Theorem 4349.3 (Dendrite unique-arc handoff)**.** *Every unique-arc or cutpoint-facing consumer of an accepted* $\mathsf{Dendrite}^\uparrow$ *carrier must read the finite route*

$$\mathsf{CompactMetric}^\uparrow,\ \mathsf{LocallyConnected}^\uparrow,\ \mathsf{PeanoContinuum}^\uparrow,\ \mathsf{Tree}^\uparrow \longmapsto E, A, C, H, R, G, Q, N.$$

The handoff exposes endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It does not expose arbitrary host paths, open-cover compactness, selected arc representatives, quotient equality of arcs, or a continuum object outside the displayed packet.*

Proof. Start with the compact-continuum source. The rows K, L, P force a consumer to read the compact metric, locally connected, and Peano-continuum surfaces before any arc-facing data can be inspected.

Next read the tree row T. This is the only row carrying the tree-like non-cycle surface, so a later cutpoint or arc argument cannot replace it by a host graph or a classical continuum theorem.

The endpoint and arc data are then E, A, C. Endpoint reads pass through E, unique-arc reads pass through A, and cutpoint-separation reads pass through C; the three ledgers remain tied to the same compact-continuum and tree source rows.

The structural rows H, R, G, Q, N preserve this route under transport, replay, provenance, and local naming. Because no excluded host-side row appears in the carrier, the consumer receives exactly the displayed unique-arc handoff and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{Dendrite}^\uparrow$ read must expose CompactMetric, LocallyConnected, PeanoContinuum, Tree, endpoint, unique-arc, cutpoint-separation, componentwise hsame, displayed Cont, Pkg, source provenance, and local NameCert rows before a continuum or arc consumer can inspect the dendrite boundary.

Independence witness: compactmetric, locally-connected, peano-continuum, tree: $\mathsf{Dendrite}^\uparrow$ is not bijective to any listed sibling because it binds endpoint, unique-arc, and cutpoint-separation ledgers over their common compact-continuum and tree-like source.

Closure status for $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$**.**

Constructive story: A $\mathsf{Dendrite}^\uparrow$ packet is generated from CompactMetricUp, LocallyConnectedUp, PeanoContinuumUp, TreeUp, endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, source provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, seed)

Scope closed: Definition 5803.1, Definition 5803.2, and Definition 5803.3 seed the finite dendrite certificate over compact metric, locally connected, Peano-continuum, tree, endpoint, unique-arc, cutpoint-separation, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, quotient equality of arcs, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-continuum visibility, tree-like exactness, endpoint exactness, unique-arc exactness, cutpoint-separation exactness, transport, replay, provenance, and local naming for BEDC.Derived.DendriteUp.

Chapter 4350

A Concrete Naming Certificate for $\mathsf{YoungIntegration}^{\uparrow}$

Following Young's integration theorem and Bishop–Bridges constructive analysis, the $\mathsf{YoungIntegration}^{\uparrow}$ packet records the finite dyadic route for integrating one Holder-controlled path against another. It sits beside the Holder-continuity surface of chapter 1766, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the tagged-mesh Riemann integral boundary of chapter 1526. The chapter names only a finite partition-and-error certificate; it does not import host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4350.1 (Young integration finite partition carrier)**.** *A* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the integrand path row, read through a* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
2. *G is the integrator path row, read through a second* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its own source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
3. *A and B are the two Holder exponent ledgers. They include the finite comparison row witnessing that the displayed exponents have a Young margin for the dyadic partition family.*
4. *W is the dyadic partition-window row. It lists the inspected endpoints, dyadic mesh refinements, cell order, adjacent-cell handoffs, and the finite cells on which the integration read is allowed to form sums.*
5. *V is the cross-variation tolerance ledger. It records the cellwise oscillation products, Holder-bound products, Young-margin comparisons, and finite sum-difference tolerances consumed by the route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for endpoint radii, mesh widths, exponent-comparison margins, oscillation products, and final error bounds.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational trace of dyadic Young sums.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the integral value, reached only after the two Holder rows, dyadic windows, cross-variation ledger, dyadic tolerances, and regular readback have been displayed.*
9. *H records componentwise* hsame *transport for the two Holder paths, exponent ledgers, partition windows, cross-variation ledger, dyadic ledger, readback, Real seal, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from a Young-integration request through Holder admission, dyadic partition windows, cross-variation tolerances, regular rational readback, and the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{YoungIntegration}^{\uparrow}$, $\mathsf{HolderContinuity}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, G, A, B, W, V, D, R, E, H, C, P, N$. It has no coordinate for an ambient path space, quotient equality of functions, a selected sequence of partitions, a hidden limiting argument, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.YoungIntegrationUp.YoungIntegrationTasteGate single carrier alignment`

Theorem 4350.2 (Young integration NameCert obligations)**.** *For every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier $Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *surface is exhausted by admission of two* $\mathsf{HolderContinuity}^{\uparrow}$ *path rows, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting,* $\mathsf{DyadicRatCore}^{\uparrow}$ *exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No accepted consumer may replace these rows by host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5804.1. The rows F and G expose the two Holder-controlled paths, and A, B expose only the finite exponent and Young-margin comparisons attached to those rows.

The partition and tolerance data are then forced. The row W lists the dyadic windows available to the route, while V records the cross-variation products and sum-difference tolerances over exactly those windows.

The terminal read is D, R, E. Dyadic exactness is read through D, the regular rational trace through R, and the Real integral seal through E only after the preceding rows have been consumed.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4350.3 (Young integration dyadic error budget)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *read that reaches the* $\mathsf{Real}^{\uparrow}$ *seal factors through the finite dyadic budget*

$$\mathsf{HolderContinuity}^{\uparrow}, \mathsf{HolderContinuity}^{\uparrow} \longmapsto \mathsf{DyadicPartition}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The row V must display the cross-variation tolerance consumed between the partition windows and the rational readback. Therefore the exported integral value is a finite dyadic Young-sum seal, not a Riemann-integral replacement, a measure-completion integral, a quotient path equality, a selected limiting partition, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the two Holder rows. Their displayed exponents and constants are read through F, G, A, B, so the route has only the finite power-law data needed to bound oscillations on dyadic cells.

Next read the dyadic partition windows. The row W fixes the cells, endpoints, mesh refinements, and adjacent-cell handoffs before any sum-difference comparison is requested.

The error budget is the pair V, D. The cross-variation ledger V records the oscillation products and Young-margin comparisons, and the dyadic ledger D records the exact rational tolerances used to compare any two displayed sums.

The readback and seal are downstream. The regular sequence row R is the only rational trace exported from the finite budgets, and E is the only Real seal. Thus the consumer cannot obtain any of the excluded host-level or choice-level objects from the packet. □

Theorem 4350.4 (Young integration Riemann boundary)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet reads it only as a finite tagged-mesh boundary: two Holder path rows, a dyadic partition-window row, a cross-variation tolerance ledger, dyadic exactness, regular rational readback, Real sealing, transport, replay, provenance, and local naming. The consumer receives no independent Riemann-integral certificate, no Darboux gap claim, no quotient equality of integrands, no measure-completion object, and no selected mesh-limit principle.*

Proof. The only Riemann-facing data in the carrier are the displayed dyadic windows and finite sum budgets. The two Holder path rows provide values to be sampled, while W supplies the finite tagged-mesh boundary.

The cross-variation ledger is not a Darboux or measure-theoretic claim. It records only the tolerance comparisons needed for the Young-sum route before the regular rational readback is sealed as a Real value.

The provenance row may name $\mathsf{RiemannIntegral}^{\uparrow}$ as a consumer boundary, but the local certificate remains $F, G, A, B, W, V, D, R, E, H, C, P, N$. Therefore a Riemann-integral consumer receives a finite boundary row rather than any independent integral theorem or hidden limiting principle. □

Theorem 4350.5 (Young integration Cauchy-modulus consumer)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet whose cross-variation ledger* V *requests a tail precision must consume the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route before* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *sealing. The route remains finite: it exports the displayed Young partition windows, dyadic error budget, explicit Cauchy-modulus handoff, regular rational readback, and terminal Real seal, but it exports no selected limiting partition, countable-choice schedule, hidden modulus oracle, or ambient completion theorem.*

Proof. Project the carrier of Definition 5804.1. The rows W, V, D, R, E expose the partition windows, cross-variation tolerance ledger, dyadic error budget, regular rational readback, and terminal Real seal.

Use Definition 5804.3. The row V is the place where sum-difference tolerances and tail precision demands are recorded, and D is the dyadic ledger that makes those demands finite.

When such a tail precision is requested, apply the effective handoff of Definition 5728.3 and the schedule determinacy of Definition 5728.4. They force the precision request through an explicit $\mathsf{CauchyModulusBridge}^{\uparrow}$ schedule before R can be read and before E can seal the result.

The remaining rows H, C, P, N transport, replay, source, and name the same finite route. Since neither the Young carrier nor the bridge carrier contains a selected limiting partition, countable-choice schedule, hidden oracle, or ambient completion coordinate, no such object is exported. □

Falsifiable prediction: An accepted $\mathsf{YoungIntegration}^{\uparrow}$ packet is refuted if a consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting either $\mathsf{HolderContinuity}^{\uparrow}$ path row, the dyadic partition-window row W, the cross-variation ledger V, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: HolderContinuity, DyadicPartition, DyadicRatCore, RegSeqRat, Real, RiemannIntegral: none is bijective with $\mathsf{YoungIntegration}^{\uparrow}$ because the packet jointly carries two Holder paths, Young-margin exponent rows, dyadic partition windows, cross-variation tolerances, dyadic exactness, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$.

Constructive story: A $\mathsf{YoungIntegration}^{\uparrow}$ packet is generated from two HolderContinuityUp path rows, exponent-margin ledgers, dyadic partition windows, cross-variation tolerance accounting, DyadicRatCore exactness, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5804.1, Definition 5804.2, Definition 5804.3, Definition 5804.4, and Definition 5804.5 seed the finite dyadic Young-integration route over HolderContinuityUp, DyadicPartitionUp, DyadicRatCoreUp, CauchyModulusBridgeUp, RegSeqRatUp, RealUp, and RiemannIntegralUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked two-path admission, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting, dyadic exactness, regular rational readback, Real-seal nonescape, and structural transport for BEDC.Derived.YoungIntegrationUp.

Chapter 4351

A Concrete Naming Certificate for $\mathsf{VariationDiminishing}^{\uparrow}$

Following Schoenberg and Karlin, the $\mathsf{VariationDiminishing}^{\uparrow}$ packet records a finite analysis row for transformations that do not increase displayed sign variation. It consumes the total-variation function surface of chapter 2257, the bounded-variation real-function carrier of chapter 3654, the regulated-function source of chapter 1554, and the tagged integration boundary of chapter 1526. The packet names the finite comparison by which a kernel or transformation row is read as variation-diminishing without importing a host operator algebra, total-positivity theorem, selected partitions, quotient functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4351.1 (Variation-diminishing carrier)**.** *A* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (B, T, R, I, K, M, H, C, P, N)$$

with the following rows:

1. *B is the* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *source row naming the accepted bounded-variation input surface.*
2. *T is the* $\mathsf{TotalVariationFunction}^{\uparrow}$ *row naming the displayed total-variation ledger used to count variation before and after the transformation.*
3. *R is the* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *row naming the regulated readback through which input and output functions are compared by finite step windows.*
4. *I is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *row naming the finite tagged-mesh integration boundary used when the transformation is read by kernel action or integral averaging.*
5. *K is the kernel or transformation row, including its displayed positivity-order or sign-regularity window.*
6. *M is the variation comparison row recording that each accepted finite sign-change ledger for the output is routed to a no-larger sign-change ledger for the input.*
7. *H records componentwise* hsame *transport for bounded-variation source, total-variation ledger, regulated readback, integral boundary, kernel row, comparison row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite transformation request through $B, T, R, I, K, M, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{VariationDiminishing}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RegulatedRealFunction}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and sibling* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, T, R, I, K, M, H, C, P, N$. It has no coordinate for host function equality, quotient representatives, selected limiting partitions, a global total-positivity theorem, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.VariationDiminishingUp.VariationDiminishingTasteGate single carrier alignment`

Theorem 4351.2 (Variation-diminishing NameCert obligations)**.** *For every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier*

$$V = (B, T, R, I, K, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded-variation source row B, total-variation ledger T, regulated-function readback R, Riemann-integral boundary I, kernel or transformation row K, variation comparison row M, componentwise transport H, displayed replay C, provenance P, and local naming N.*

The obligation surface requires every output variation read to pass through the displayed comparison row M after B, T, R, I, K have been projected. It refuses host operator equality, quotient equality of functions, selected partitions, unrestricted total positivity, measure-theoretic kernels, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5805.1. The source row B supplies the bounded-variation input, while T supplies the total-variation ledger on which finite sign-change comparisons can be read.

The rows R and I keep the analytic route finite. Regulated readback gives step-window access to input and output functions, and the Riemann-integral boundary records only the tagged-mesh action needed by a kernel or averaging read.

The row K names the transformation window, and M is the only row that compares variation before and after the transformation. Thus the NameCert consumer obtains a variation-diminishing assertion only through the displayed comparison row, not through a host theorem about all kernels.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores quotient functions, selected limiting partitions, unrestricted total positivity, measure completion, or ambient real completeness, no local obligation can require them. □

Theorem 4351.3 (Variation-diminishing total-variation route)**.** *Every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *consumer read factors through the route*

$$\mathsf{BoundedVariationRealFunction}^{\uparrow},\ \mathsf{TotalVariationFunction}^{\uparrow},\ \mathsf{RegulatedRealFunction}^{\uparrow},\ \mathsf{RiemannIntegral}^{\uparrow} \longmapsto \mathsf{VariationD}$$

The output variation ledger is accepted only after the bounded-variation input, cumulative total-variation ledger, regulated readback, tagged integration boundary, kernel row, and comparison row have been displayed. The route exports no selected limit, quotient function equality, global total-positivity principle, measure-completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. A variation-diminishing request first projects B and T. These rows bind the input function to the bounded-variation and total-variation sibling surfaces, so the requested comparison starts from finite variation data rather than from a host function space.

Next project R and I. The regulated row supplies finite step-window readback, while the integral boundary supplies the tagged-mesh route through which a kernel or averaging transformation can be inspected.

The transformation row K and comparison row M then give the only accepted variation comparison. They state that the displayed output sign-change ledger routes to a no-larger input ledger in the same finite packet.

Finally H, C, P, N preserve the route under transport, replay, provenance, and local naming. Hence every public read of $\mathsf{VariationDiminishing}^{\uparrow}$ passes through the four cited sibling anchors and does not acquire the excluded host-level principles. □

Falsifiable prediction: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet whose output variation read bypasses the displayed total-variation ledger or the regulated readback row is not accepted by the local NameCert.

Independence witness: total-variation-function, bounded-variation-real-function, regulatedrealfunction, riemannintegral: $\mathsf{VariationDiminishing}^{\uparrow}$ is not bijective to any listed sibling because it binds the source variation ledger, regulated readback, tagged integration boundary, transformation row, and no-increase comparison as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet is generated from bounded-variation source data, a total-variation ledger, regulated readback, Riemann tagged-mesh boundary, a kernel or transformation row, a variation comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5805.1, Definition 5805.2, Definition 5805.3, the falsifiable prediction, and the independence witness seed the finite variation-diminishing route over the current analysis rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host operator equality, quotient equality of functions, selected limiting partitions, unrestricted total positivity, measure completion, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation source visibility, total-variation ledger exactness, regulated readback, tagged integration boundary, transformation-row exposure, comparison-row stability, transport, replay, provenance, and local naming for future BEDC.Derived.VariationDiminishingUp.

$\mathsf{FrobeniusReciprocity}^{\uparrow}$ routes induction–restriction comparison through chapter 247, chapter 246, and chapter 245 before the child file states the local certificate.

Chapter 4352

A Concrete Naming Certificate for $\mathsf{FrobeniusReciprocity}^{\uparrow}$

Following Frobenius on induced characters, Serre's finite-group representation theory, and the induction–restriction formulation used by Fulton–Harris, the $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet records the finite comparison row between induction from a subgroup and restriction to that subgroup. It consumes the action rows of chapter 3662, the subgroup source of chapter 80, the representation-ring ledger of chapter 246, the induction–restriction packet of chapter 247, and the character-pairing surface of chapter 245. The packet names only finite source rows, adjunction ledgers, character-pairing boundaries, transport, replay, provenance, and downstream handoff rows; it does not assert a host category of representations, a functor equality, semisimplicity, Schur orthogonality, or a completed character table.

Theorem 4352.1 (FrobeniusReciprocityUp source obligations)**.** *For every accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet, the source surface is the displayed finite tuple*

$$\mathcal{F} = (G, H, R, I, Q, \Phi, \eta, \epsilon, \chi, \lambda, C, P, N),$$

where G is the consumed $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *action row, H is the consumed* $\mathsf{Subgroup}^{\uparrow}$ *row, R is the consumed* $\mathsf{RepresentationRing}^{\uparrow}$ *ledger, I is the consumed* $\mathsf{InducedRep}^{\uparrow}$ *induction–restriction row, Q is the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *pairing row, Φ is the Frobenius comparison row, η, ϵ are the displayed unit and counit rows, χ is the character-pairing boundary, λ is the finite ledger of visible source and endpoint reads, C is componentwise* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *row. No source obligation is imported from a host representation category, quotient carrier, functor category, or external adjunction object.*

Proof. Project the accepted packet. The source rows are precisely G, H, R, I, Q together with the local comparison rows $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

The consumed rows are already finite BEDC certificates. The finite-group representation row supplies the action display, the subgroup row supplies the inclusion boundary, the representation-ring row supplies the Grothendieck ledger, the induced-representation row supplies the induction–restriction endpoints, and the character-theory row supplies the pairing surface.

Since the tuple has no coordinate for a host representation category, quotient carrier, functor category, or external adjunction object, the listed rows exhaust the source obligations. □

Theorem 4352.2 (FrobeniusReciprocityUp adjunction ledger)**.** *The adjunction data of an accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet are exactly the finite rows $\Phi, \eta, \epsilon, \lambda$ over the consumed sources*

H, R, I. The row Φ compares the displayed induction endpoint with the displayed restriction endpoint, η and ϵ record the unit and counit witnesses as BHist *rows, and λ records the visible continuations among source, endpoint, and Frobenius reads. The ledger exports no host naturality square, functor equality, adjunction object, or semisimple decomposition.*

Proof. Begin with the induction–restriction source. The packet consumes the $\mathsf{InducedRep}^{\uparrow}$ row I, so the available endpoints are the displayed induction and restriction rows already carried by that certificate.

The Frobenius comparison is read through Φ. The unit and counit witnesses are read through η and ϵ, and every visible path among source and endpoint reads is recorded by the finite ledger λ.

Exactness is projection from the tuple. Any row outside $\Phi, \eta, \epsilon, \lambda$ is not part of the adjunction ledger, and no host naturality square or functor equality can be recovered from a coordinate that the packet does not carry. □

Theorem 4352.3 (FrobeniusReciprocityUp character-pairing boundary)**.** *Every character-pairing read of a* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet factors through the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *row Q, the representation-ring source R, the induction–restriction source I, and the displayed pairing boundary χ before it can inspect Φ, η, ϵ or λ. The boundary supplies only the finite character-pairing comparison needed for reciprocity and does not export Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra.*

Proof. Read the character side first. The only character-theory coordinate is Q, and the only representation-ring coordinate feeding it is R.

The induction and restriction endpoints enter through I. The displayed pairing boundary χ then names the finite comparison used by the Frobenius row before the ledger reads $\Phi, \eta, \epsilon, \lambda$.

Because the tuple has no coordinate for Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra, every character-pairing read remains inside the stated finite boundary. □

Theorem 4352.4 (FrobeniusReciprocityUp NameCert surface)**.** *The* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *obligation surface is the conjunction of the source obligations of Definition 5806.1, the adjunction ledger of Definition 5806.2, the character-pairing boundary of Definition 5806.3, componentwise* hsame *transport on all displayed source and ledger rows, finite* Cont *replay through C, and* Pkg *provenance through P. The surface exports no obligation outside the displayed tuple $\mathcal{F}$.*

Proof. First combine the source obligations with the adjunction ledger. The source theorem identifies the consumed BEDC certificates, and the ledger theorem identifies the only Frobenius comparison, unit, counit, and continuation rows.

Next add the character-pairing boundary. It places every character read behind Q, R, I, χ before the Frobenius ledger can be inspected.

Finally apply componentwise transport and replay. The rows C and P preserve exactly the displayed tuple, and the local row N names the resulting certificate. Since no obligation outside $\mathcal{F}$ is available, these clauses give the stated NameCert surface. □

Theorem 4352.5 (FrobeniusReciprocityUp consumer handoff)**.** *A downstream consumer of* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *may read exactly the consumed finite-group action row G, subgroup row H, representation-ring row R, induced-representation row I, character-theory row Q, Frobenius rows Φ, η, ϵ, character-pairing boundary χ, visible ledger λ, replay row C, provenance row P, and local name row N. Any consumer handoff to* $\mathsf{InducedRep}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, *or* $\mathsf{CharacterTheory}^{\uparrow}$ *factors through those*

rows and cannot bypass them through a host category, functor equality, semisimplicity theorem, or character-table computation.

Proof. Start with a downstream read. The only visible source coordinates are G, H, R, I, Q, and the only local Frobenius coordinates are $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

For an $\mathsf{InducedRep}^{\uparrow}$ consumer, the handoff is through I together with the Frobenius rows. For a $\mathsf{RepresentationRing}^{\uparrow}$ consumer, the handoff is through R and the source ledger. For a $\mathsf{CharacterTheory}^{\uparrow}$ consumer, the handoff is through Q and the pairing boundary χ.

The replay and provenance rows preserve the same finite route. Thus a consumer cannot bypass the displayed packet through a host category, functor equality, semisimplicity theorem, or character-table computation. □

Theorem 4352.6 (FrobeniusReciprocityUp sibling lattice)**.** *The* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet is a finite comparison consumer of the sibling carriers in chapter 3662, chapter 80, chapter 246, chapter 247, and chapter 245. Its local rows compare induction and restriction after those carriers are visible; they do not form an isolated kernel row and do not replace the representation, subgroup, ring, induced-representation, or character-theory certificates.*

Proof. Read the source tuple of Definition 5806.1. The rows G, H, R, I, Q are precisely the five sibling certificates named in the statement.

The consumer handoff of Definition 5806.5 permits downstream reads only through those rows together with the Frobenius comparison, unit, counit, pairing boundary, ledger, replay, provenance, and local name rows.

Therefore the packet sits inside the displayed representation-theory lattice. It is a comparison consumer over the sibling carriers, not a standalone kernel surface from which the sibling certificates can be reconstructed. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5806.1, Definition 5806.2, Definition 5806.3, Definition 5806.4, Definition 5806.5, and Definition 5806.6 seed the finite Frobenius reciprocity certificate over displayed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, semisimplicity, Schur orthogonality, irreducible decomposition, character-table computation, functor-category equality, or a host adjunction theorem.

Upgrade path: Obligation closure requires checked carrier admission, adjunction-ledger exactness, character-pairing boundary, NameCert surface, and downstream handoff for the same finite packet.

Constructive story: A $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet is generated from consumed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows, then records a finite Frobenius comparison, unit and counit rows, character-pairing boundary, visible continuation ledger, package provenance, and local NameCert evidence.

Chapter 4353

A Concrete Naming Certificate for $\mathsf{NormalOperator}^{\uparrow}$

Following Reed and Simon, the $\mathsf{NormalOperator}^{\uparrow}$ packet records the standard normal-operator surface as finite NameCert data over displayed Hilbert and inner-product candidates. It consumes the inner-product carrier of chapter 86, the Hilbert carrier of chapter 91, the linear-map rows of chapter 48, the operator-norm boundary of chapter 3603, and the downstream spectral-theorem consumer of chapter 214. The packet exposes only a bounded linear operator, its displayed adjoint-action row, the norm ledger, and the normality commutator row; it does not claim spectral measure existence, functional calculus, diagonalization, projection-valued measures, or a host operator algebra.

Definition 4353.1 (NormalOperator carrier)**.** *For a displayed* $\mathsf{Hilbert}^{\uparrow}$ *candidate* H *with* $\mathsf{InnerProduct}^{\uparrow}$ *row* I*, a* $\mathsf{NormalOperator}^{\uparrow}(H)$ *carrier is a finite* BHist *packet*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N)$$

with the following ten displayed fields:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *carrier row and I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row over the same point-history carrier.*
2. *T is a bounded* $\mathsf{LinMap}^{\uparrow}$ *endpoint action on the carried Hilbert endpoints.*
3. *T^* is the displayed adjoint-action row, certified by the finite inner-product comparison*

   $$\langle Tx, y\rangle_I \ \mathsf{hsame}\ \langle x, T^*y\rangle_I$$

   for the vector histories inspected by the packet.
4. *A is the adjoint-domain ledger, recording that the adjoint row is read over the same Hilbert, inner-product, linear-map, and boundedness surfaces as T.*
5. *K is the* $\mathsf{OperatorNorm}^{\uparrow}$ *bound row for T and for the displayed adjoint action T^*.*
6. *Q is the normality commutator row*

   $$T^*T \ \mathsf{hsame}\ TT^*$$

   read only on certified vector histories.
7. *L is the operator graph ledger: it stores inspected input histories, output histories, linearity rows, adjoint rows, norm-bound rows, and the commutator row.*

8. *H_T records componentwise* hsame *transport for the Hilbert source, inner-product row, endpoint actions, adjoint row, norm row, commutator row, and ledger.*
9. *C records displayed* Cont *replay for endpoint action requests, adjoint-action requests, norm-bound requests, and commutator inspections.*
10. *P, N are the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *naming rows.*

The classifier compares accepted carriers by action agreement on certified vector histories, adjoint-action agreement on the same inspected histories, transport of the operator-norm row, and transport of the graph, adjoint, normality, continuation, provenance, and local-name ledgers. It has no coordinate for host operator equality, quotient completion, spectral measures, eigenvector bases, or external functional calculus.

Lean4 ✓ `BEDC.Derived.NormalOperatorUp.NormalOperatorTasteGate single carrier alignment`

Theorem 4353.2 (NormalOperator NameCert obligations)**.** *For every accepted* $\mathsf{NormalOperator}^\uparrow$ *carrier*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the common* $\mathsf{Hilbert}^\uparrow$ *and* $\mathsf{InnerProduct}^\uparrow$ *rows;*
2. *bounded* $\mathsf{LinMap}^\uparrow$ *action for T on certified vector histories;*
3. *adjoint-action agreement for T^* against the displayed inner product;*
4. $\mathsf{OperatorNorm}^\uparrow$ *bound rows for the operator action and adjoint action;*
5. *normality commutator exactness through the displayed row Q;*
6. *graph-ledger exactness for input histories, output histories, linearity rows, adjoint rows, norm rows, and commutator rows;*
7. *classifier transport by action agreement, adjoint-action agreement, norm-row agreement, and componentwise ledger transport;*
8. Cont *replay,* Pkg *provenance, and local naming for exactly the displayed packet;*
9. *refusal of spectral measure existence, diagonalization, projection-valued measures, host operator quotients, and unrecorded functional calculus.*

Proof. Project the carrier of Definition 5807.1. The Hilbert and inner-product source rows, endpoint action, adjoint-action row, adjoint-domain ledger, norm row, commutator row, graph ledger, transport row, continuation row, provenance row, and local name are the full displayed inventory.

The adjoint and boundedness obligations are read before any spectral consumer appears. The adjoint row is the finite inner-product comparison for certified vector histories, and the norm row is the displayed $\mathsf{OperatorNorm}^\uparrow$ bound attached to both endpoint actions.

Normality is exactly the commutator row Q. Because Q compares T^*T and TT^* only through inspected vector histories and their graph ledger, the packet does not appeal to host equality of operators.

Finally H_T, C, P, N transport, replay, source, and name those rows. Since the carrier has no spectral-measure, diagonalization, projection-valued-measure, quotient, or functional-calculus coordinate, the listed rows exhaust the local normal-operator NameCert obligations. □

Theorem 4353.3 (NormalOperator InnerProduct spectral anchor)**.** *Every downstream spectral read of an accepted* $\mathsf{NormalOperator}^{\uparrow}$ *packet factors through the common Hilbert and inner-product rows, the bounded linear action, the displayed adjoint-action row, the operator-norm bound, and the normality commutator ledger before it can be consumed by the* $\mathsf{SpectralTheorem}^{\uparrow}$ *surface. The route is*

$$(H, I) \longmapsto (T, T^*, A, K, Q, L) \longmapsto (H_T, C, P, N),$$

and it exports no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality.

Proof. Expose the accepted packet by Definition 5807.1. The only analytic source rows are the Hilbert carrier, inner-product comparison row, endpoint action, displayed adjoint action, norm bound, and normality commutator.

Apply Definition 5807.2. The graph ledger forces the operator action, adjoint action, boundedness evidence, and commutator evidence to be read from one finite packet, and classifier transport keeps the operator and adjoint rows over the same certified vector histories.

It remains to hand the packet to spectral consumers. The $\mathsf{SpectralTheorem}^{\uparrow}$ chapter may consume the normality anchor only through the displayed rows already named here. Because no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality is a field of the carrier, the anchor supplies a pre-spectral normal-operator surface rather than a spectral theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5807.1, Definition 5807.2, and Definition 5807.3 seed the normal-operator surface over Hilbert, inner-product, bounded linear-map, adjoint-action, operator-norm, and commutator rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim spectral measures, spectral projections, diagonalization, eigenbasis construction, Borel functional calculus, host operator quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, adjoint-action agreement, norm-bound stability, normality commutator exactness, classifier transport, graph-ledger exactness, spectral-consumer nonescape, and bridge data for BEDC.Derived.NormalOperatorUp.

Constructive story: A $\mathsf{NormalOperator}^{\uparrow}$ packet is generated from a Hilbert source, an inner-product row, a bounded linear endpoint action, a displayed adjoint action, operator-norm bounds, a normality commutator row, graph and transport ledgers, continuation replay, provenance, and a local NameCert row.

Chapter 4354

A Concrete Naming Certificate for $\mathsf{HausdorffMeasure}^{\uparrow}$

Following Hausdorff and Federer's metric measure theory, the $\mathsf{HausdorffMeasure}^{\uparrow}$ packet records the finite dyadic-cover surface through which Hausdorff content and scale-stable measure reads become visible inside BEDC. It sits over the metric carrier of chapter 57, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the cover-valued outer-measure boundary of chapter 3385, and the finite scale-cover comparison surface of chapter 3877. The packet names only displayed dyadic cover packets, diameter budgets, weighted cover sums, scale comparison, transport, replay, provenance, and local naming; it is not a quotient cover family, not a selected infimum, not countable choice over covers, and not an ambient measure primitive.

Definition 4354.1 (Hausdorff measure dyadic-cover carrier)**.** *A* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (M, D, R, O, B, C, S, T, E, K, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the finite point classifier and distance comparisons used to bound cover diameters.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row, naming the dyadic radius budget and dyadic exponent used by the cover packet.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *value-seal row for diameter powers and finite cover sums.*
4. *O is the* $\mathsf{OuterMeasure}^{\uparrow}$ *handoff row, read only as a finite cover-valued boundary and not as a completed measure primitive.*
5. *B is the* $\mathsf{BoxDimension}^{\uparrow}$ *comparison row, exposing finite scale-cover counts against the same dyadic scale.*
6. *C is the finite dyadic cover packet, listing the displayed cover cells, their metric diameter witnesses, and their membership reads.*
7. *S is the cover-sum ledger, recording the finite Real-sealed sum of dyadic diameter weights.*
8. *T is the scale-stability ledger, recording that dyadic refinement reads the same metric source, outer-measure boundary, and box-dimension comparison rows.*
9. *E records componentwise* hsame *transport for metric, dyadic scale, Real seal, outer-measure handoff, box-dimension comparison, cover packet, cover sum, and stability rows.*

10. *K records displayed* Cont *replay from a metric source and dyadic scale through C, S, T, E, P, N.*
11. *P is the* Pkg *provenance over* $\mathsf{HausdorffMeasure}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{OuterMeasure}^{\uparrow}$, $\mathsf{BoxDimension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D, R, O, B, C, S, T, E, K, P, N$. It has no coordinate for quotient cover families, selected infima, countable-choice schedules over covers, host sigma-algebras, or ambient measure primitives.

Lean4 ✓ `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate single carrier alignment`

Theorem 4354.2 (Hausdorff measure NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier $H = (M, D, R, O, B, C, S, T, E, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *surface consists exactly of metric source admission, dyadic scale exposure, Real value sealing, finite outer-measure handoff, box-dimension scale comparison, finite dyadic cover admission, cover-sum exactness, scale-stability replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every measure-facing or dimension-facing consumer must read the displayed route*

$$\mathsf{Met}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto C, S, T \longmapsto \mathsf{OuterMeasure}^{\uparrow}, \mathsf{BoxDimension}^{\uparrow} \longmapsto E, K, P, N$$

before treating the packet as a Hausdorff-measure read.

Proof. Project the carrier of Definition 5808.1. The metric row M, dyadic row D, and Real seal row R are the only sources for distances, scales, and finite value readback.

The cover packet C and cover-sum ledger S are finite rows. They record displayed cover cells and dyadic diameter weights, so no step selects a minimizing cover family or takes an external infimum.

The outer-measure and box-dimension rows O, B are downstream comparison boundaries. They can read the same finite cover data, but they do not add a completed host measure, a quotient of covers, or countable choice over refinements.

Finally T, E, K, P, N transport, replay, source, and name the same finite route. Since every exported obligation is one of the listed rows, the local classifier cannot expose an ambient measure primitive or any detached cover selector. □

Theorem 4354.3 (Hausdorff measure dyadic-cover stability)**.** *Let $H = (M, D, R, O, B, C, S, T, E, K, P, N)$ be an accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier. For any displayed dyadic refinement of the scale row D, the scale-stability ledger T forces the refined read to reuse the same* $\mathsf{Met}^{\uparrow}$ *source, the same* $\mathsf{Real}^{\uparrow}$ *value-seal route, the same finite* $\mathsf{OuterMeasure}^{\uparrow}$ *cover boundary, and the same* $\mathsf{BoxDimension}^{\uparrow}$ *scale-count comparison before any consumer reads a Hausdorff-measure claim. The stable route is*

$$M, D, R, C, S, T \longmapsto O, B \longmapsto E, K, P, N.$$

It exports no quotient cover family, selected infimum, countable-choice cover schedule, host sigma-algebra closure, or ambient measure primitive.

Proof. Read the carrier of Definition 5808.1. A dyadic refinement changes only the displayed scale request inside D and the finite cover packet admitted by C.

Use the stability ledger T. It records that the refined cover is replayed against the same metric source and that its finite cover sum is sealed through the same Real row, so the refinement cannot introduce a detached minimizing cover or a host infimum.

The comparison rows O and B then read the refined packet as finite outer-measure and box-dimension boundary data. Componentwise transport and displayed replay through E, K, P, N preserve that route, while quotient covers, countable choice, host sigma-algebras, and ambient measure primitives remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HausdorffMeasure}^{\uparrow}$ consumer that reaches a Hausdorff-measure read without first exposing a MetricUp source row, a DyadicRatCore scale row, a RealUp value seal, a finite dyadic cover packet, a finite cover-sum ledger, an OuterMeasureUp handoff, a BoxDimensionUp comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row refutes the carrier surface.

Independence witness: metric, dyadicratcore, real, outermeasure, boxdimension: $\mathsf{HausdorffMeasure}^{\uparrow}$ is not bijective to any listed sibling because it binds metric diameter data, dyadic scales, Real-sealed finite cover sums, outer-measure cover boundaries, and box-dimension scale counts into one finite cover-stability NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffMeasure}^{\uparrow}$ packet is generated from a MetricUp source row, DyadicRatCore scale row, RealUp value-seal row, finite OuterMeasureUp handoff, BoxDimensionUp comparison row, finite dyadic cover packet, cover-sum ledger, scale-stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5808.1, Definition 5808.2, and Definition 5808.3 seed the finite dyadic-cover Hausdorff-measure interface over MetricUp, DyadicRatCoreUp, RealUp, OuterMeasureUp, and BoxDimensionUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient cover families, selected infima, countable choice over covers, host sigma-algebra completion, ambient measure primitives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic scale exposure, finite cover admission, cover-sum exactness, scale-stability replay, outer-measure handoff, box-dimension comparison, transport, provenance, and no-escape for BEDC.Derived.HausdorffMeasureUp.

Chapter 4355

A Concrete Naming Certificate for $\mathsf{LocallyConnected}^{\uparrow}$

Following Kelley and Bourbaki on local connectedness, the $\mathsf{LocallyConnected}^{\uparrow}$ packet records finite neighbourhood-component data rather than a selected basis of connected open sets. It sits beside the global connectedness carrier of chapter 2353, the compact metric source discipline of chapter 129, the metric ball rows of chapter 57, and the open-neighbourhood ledger of chapter 88. The packet exposes the local component route needed by compact-metric and connected-space consumers without importing path selection, arc connectedness, open-cover compactness, or a host topological basis.

Definition 4355.1 (Locally connected carrier)**.** *A* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, M, G, K, B, C, H, R, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-neighbourhood row whose entries name the ambient open requests.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *ball-observation row used when the local request is metric.*
3. *G is the* $\mathsf{ConnectedSpace}^{\uparrow}$ *global component row available to consumers that compare local and global connectedness.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-source row available to compact-metric consumers.*
5. *B is the finite neighbourhood-refinement row: each displayed point and open request has a named smaller neighbourhood row.*
6. *C is the local connected-component row attached to the refinement in B.*
7. *H records componentwise* hsame *transport for the topology, metric, connectedness, compact-metric, refinement, component, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from an ambient open request through metric ball observations when present, the finite refinement row, and the local component row.*
9. *P is the* Pkg *provenance over* $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConnectedSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, M, G, K, B, C, H, R, P, N$. It has no coordinate for selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, or a host basis of connected neighbourhoods.

Lean4 ✓ `BEDC.Derived.LocallyConnectedUp.TasteGate.LocallyConnectedTasteGate single carrier alignment`

Theorem 4355.2 (Locally connected NameCert obligations)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier* $L = (T, M, G, K, B, C, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *surface consists exactly of carrier admission for the topology, metric, connected-space, compact-metric, finite neighbourhood-refinement, local component, transport, replay, provenance, and naming rows; neighbourhood refinement from T through B; component exposure through C; metric compatibility through M when the request is ball-based; compact-metric compatibility through K for compact finite-source consumers; connected-space comparison through G; and non-escape from selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice.*

Proof. Project the carrier of Definition 5809.1. The projection exposes exactly the rows $T, M, G, K, B, C, H, R, P, N$ so every local naming obligation must be read from those coordinates.

The neighbourhood part is finite. An ambient open request is first read in T, then refined by the displayed row B, and only then receives the local component row C.

The metric and compact-metric rows are compatibility rows rather than extra selectors. A ball-based request may inspect M, and a compact-metric consumer may inspect K, but both routes still pass through the same B and C rows before local connectedness is exported.

Finally, H and R transport and replay the displayed route, while P and N source and name it. Since paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice are not rows of the carrier, the NameCert surface cannot export them. □

Theorem 4355.3 (Locally connected neighbourhood component route)**.** *Every connected-space or compact-metric consumer of an accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *packet reaches local connectedness through*

$$\mathsf{Topology}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{ConnectedSpace}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The finite route reads an ambient neighbourhood, optionally reads metric ball observations, refines to a displayed smaller neighbourhood, and then reads the named local connected component. It does not select a path, an arc, a subcover, a quotient component representative, or a host connected-neighbourhood basis.

Proof. Start with a consumer that asks for local connectedness around a displayed point. Carrier admission gives the consumer the topology row T, the metric row M when a ball observation is part of the request, the global connectedness row G, and the compact-metric row K.

The route then passes through B and C. The row B supplies the finite neighbourhood refinement, and C supplies the local component attached to that refinement.

The structural rows H, R, P, N do not add a hidden selector. They transport, replay, source, and name the same finite route, so no path, arc, arbitrary subcover, quotient representative, or host basis can replace the displayed neighbourhood-component data. □

Theorem 4355.4 (Locally connected obligation closure surface)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier* $L = (T, M, G, K, B, C, H, R, P, N)$*, the obligation-closure surface is exhausted by the displayed finite topology, metric, connected-space, compact-metric, neighbourhood-refinement, local-component, transport, replay, provenance, and naming rows. The row T supplies the open-neighbourhood*

source, M supplies metric-ball observations, G supplies connected-space comparison, K supplies compact-metric finite-source compatibility, B, C supply the local refinement and component rows, and H, R, P, N supply transport, replay, provenance, and local naming.

The local component route therefore consumes the connected-space carrier of chapter 2353, the compact-metric finite neighbourhood discipline of chapter 129, the metric-ball rows of chapter 57, and the topology neighbourhood ledger of chapter 88 before a local component can be named.

Proof. Apply Definition 5809.2 to the accepted carrier. It identifies the complete NameCert surface with the rows $T, M, G, K, B, C, H, R, P, N$.

Apply Definition 5809.3. The route from an open request to a local component passes through topology, optional metric-ball observations, connected-space comparison, compact-metric compatibility, finite refinement, and component rows before the structural rows transport and name the result.

The sibling lattice is read in that order: topology supplies the neighbourhood ledger, metric supplies ball observations, connected-space supplies the comparison carrier, and compact metric supplies the finite neighbourhood discipline. The local refinement and component rows then bind those sibling contributions into the $\mathsf{LocallyConnected}^{\uparrow}$ packet.

Thus the obligation surface is the stated finite route. Path or arc selection, open-cover compactness, quotient components, and a host basis are refused because none of them is a carrier coordinate or a row used by the two preceding theorems. □

Falsifiable prediction: Every accepted $\mathsf{LocallyConnected}^{\uparrow}$ read must expose a $\mathsf{Topology}^{\uparrow}$ open-neighbourhood row, optional $\mathsf{Met}^{\uparrow}$ ball observations, the $\mathsf{ConnectedSpace}^{\uparrow}$ comparison row when a global consumer is present, the $\mathsf{CompactMetric}^{\uparrow}$ finite-source row when a compact-metric consumer is present, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: topology, metric, connected-space, compactmetric: $\mathsf{LocallyConnected}^{\uparrow}$ is not bijective to any listed sibling because it binds a local neighbourhood-refinement row to a local component row before connected-space or compact-metric consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5809.1, Definition 5809.2, and Definition 5809.3 seed the finite local neighbourhood-component route over topology, metric, connected-space, and compact-metric rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close path connectedness, arc connectedness, arbitrary open-cover compactness, quotient component spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, neighbourhood refinement, local component exposure, connected-space comparison, compact-metric compatibility, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.LocallyConnectedUp.

Constructive story: A $\mathsf{LocallyConnected}^{\uparrow}$ packet is generated from an open-neighbourhood row, optional metric ball observations, connected-space and compact-metric compatibility rows, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

The $\mathsf{EquicontinuousSequence}^{\uparrow}$ hub reads the shared-modulus lattice of chapter 4287 before routing compact finite-net and Arzela–Ascoli consumers through its own child files.

Chapter 4356

A Concrete Naming Certificate for $\mathsf{EquicontinuousSequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{EquicontinuousSequence}^{\uparrow}$ packet records a sequence-indexed equicontinuity surface as finite NameCert data. It sits over the equicontinuity row of chapter 4076, the finite-net selector of chapter 3358, the finite Arzela–Ascoli modulus handoff of chapter 3568, the compact metric source of chapter 129, the displayed continuous-map row of chapter 130, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet gives compact-uniformity and Arzela–Ascoli consumers a finite sequence carrier instead of repeating family-level rows; it is not a host function-space compactness theorem, not countable choice, and not an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 4356.1 (Equicontinuous sequence carrier)**.** *An* $\mathsf{EquicontinuousSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, S, W, Q, R, A, T, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose finite cover and metric inspection data bound the common domain.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the displayed maps inspected by the sequence.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that records which sequence indices and domain windows are read.*
4. *W is the shared equicontinuity-window row, displayed as a finite request schedule over K, F, S.*
5. *Q is the* $\mathsf{Equicontinuity}^{\uparrow}$ *row asserting that the schedule W is common to the inspected sequence window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for endpoint and modulus values reached through the same finite windows.*
7. *A is the* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *handoff row, available only after K, F, S, W, Q, R have been displayed.*
8. *T is the* $\mathsf{EquicontinuityFiniteNetSelector}^{\uparrow}$ *selector row, recording the finite net queries permitted by K and W.*

9. *H records componentwise* hsame *transport for compact source, map row, stream windows, common modulus schedule, equicontinuity row, regular readback, Arzela–Ascoli handoff, finite-net selector, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a sequence-window request through $K, F, S, W, Q, R, A, T, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{EquicontinuousSequence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, $\mathsf{EquicontinuityFiniteNetSelector}^{\uparrow}$, $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{EquicontinuousSequence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, F, S, W, Q, R, A, T, H, C, P, N$. It has no coordinate for a host function sequence, quotient equality of maps, countable choice, open-cover compactness, selected subsequences, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 4356.2 (Equicontinuous sequence NameCert obligations)**.** *For every accepted* $\mathsf{EquicontinuousSequence}^{\uparrow}$ *carrier*

$$E = (K, F, S, W, Q, R, A, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EquicontinuousSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, displayed continuous-map row, finite stream windows, shared modulus schedule, equicontinuity row, regular rational readback, Arzela–Ascoli finite-modulus handoff, finite-net selector, componentwise transport, replay, provenance, and local naming rows. No obligation may replace these rows by a host function-space object, quotient map equality, a selected subsequence, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 4356.1. The analytic rows are exactly K, F, S, W, Q, R, A, T: compact source, displayed maps, finite sequence windows, the common schedule, the equicontinuity row, regular readback, the finite-modulus handoff, and the finite-net selector.

The common modulus is visible only as W and Q. Since the packet stores no host function sequence and no quotient equality of maps, every local obligation must read the displayed continuous-map and stream-window rows before it can compare sequence entries.

The compactness-facing rows are A and T. They are downstream of K, F, S, W, Q, R and therefore cannot supply an independent subsequence selection, countable-choice principle, open-cover compactness theorem, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. These rows preserve the displayed route but do not add any excluded object, so the listed rows exhaust the local NameCert surface. □

Theorem 4356.3 (Equicontinuous sequence finite window modulus)**.** *Every modulus read exported by an accepted* $\mathsf{EquicontinuousSequence}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{Equicontinuity}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

Thus a consumer may inspect only the displayed compact-metric windows, the continuous-map row, the finite sequence-window schedule, and the regular rational readback attached to that schedule. It gains no pointwise-only family, quotient function space, selected subsequence, countable-choice principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with a modulus request. The carrier first exposes the compact source K, the displayed map row F, and the stream-window row S, so the request is confined to finitely many sequence and domain windows.

The common schedule W is then certified by the equicontinuity row Q. Its values are read through the same finite windows by the regular rational row R, not by a host function-space metric or a quotient presentation of maps.

Because A and T are downstream consumers of the same schedule, they cannot create another modulus source. Transport and replay through H and C preserve the route, while P and N only record provenance and local naming. □

Theorem 4356.4 (Equicontinuous sequence Arzela–Ascoli handoff)**.** *Every Arzela–Ascoli or compact-uniformity consumer of an accepted* $\mathsf{EquicontinuousSequence}^{\uparrow}$ *carrier must read the finite route*

$$K, F, S, W, Q, R, T, A$$

before using a common modulus or finite net. The handoff supplies a sequence-indexed finite carrier for later compactness arguments, while refusing host subsequence selection, quotient equality of functions, countable choice, open-cover compactness, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. An Arzela–Ascoli consumer starts with the compact source K and displayed maps F. The finite sequence windows S determine which entries and domain windows are visible.

The common schedule W, equicontinuity row Q, and regular rational readback R provide the only shared modulus surface. The finite-net selector T can query only that visible schedule over the compact metric source.

The finite-modulus handoff A is therefore a repackaging of K, F, S, W, Q, R, T, not an independent compactness principle. Since no carrier row stores a selected subsequence, quotient function equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the handoff exports only the displayed finite route. □

Falsifiable prediction: Every accepted $\mathsf{EquicontinuousSequence}^{\uparrow}$ read must expose compact metric data, a ContinuousMap row, finite StreamName windows, a shared Equicontinuity schedule, RegSeqRat readback, EquicontinuityFiniteNetSelector data, ArzelaAscoliFiniteModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a compact-uniformity consumer may read a common modulus.

Independence witness: equicontinuity, equicontinuity-finite-net-selector, arzela-ascoli-finite-modulus, compactmetric, continuousmap, streamname, regseqrat, real: $\mathsf{EquicontinuousSequence}^{\uparrow}$ is not bijective to any listed sibling because it binds a sequence-window schedule to a common equicontinuity row and compact finite-net handoff before any Arzela–Ascoli consumer can read the modulus.

Closure status for $\mathsf{NameCert}_{\mathsf{EquicontinuousSequence}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EquicontinuousSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4356.1, Definition 4356.2, Definition 4356.3, and Definition 4356.4 seed the finite sequence-indexed equicontinuity carrier and its compact-uniformity handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EquicontinuousSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function-space compactness, quotient equality of maps, selected subsequences, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window visibility, common modulus exposure, regular rational readback, finite-net selector exactness, Arzela–Ascoli handoff nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.EquicontinuousSequenceUp.

Constructive story: An $\mathsf{EquicontinuousSequence}^{\uparrow}$ packet is generated from a CompactMetricUp source row, ContinuousMap row, finite StreamName windows, shared equicontinuity schedule, EquicontinuityUp row, RegSeqRat readback, EquicontinuityFiniteNetSelectorUp row, ArzelaAscoliFiniteModulusUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Every $\mathsf{EquicontinuousSequence}^{\uparrow}$ read consumes the family-level modulus discipline of chapter 413 and the sequence-level uniform route of chapter 4287 before any compactness or Ascoli-facing consumer may inspect it.

Theorem 4356.5 (Equicontinuous sequence uniform lattice route)**.** *Every compact-uniformity consumer of an accepted* $\mathsf{EquicontinuousSequence}^{\uparrow}$ *carrier reads the same displayed rows as the shared-modulus route of chapter 4287: the* $\mathsf{CompactMetric}^{\uparrow}$ *source row,* $\mathsf{ContinuousMap}^{\uparrow}$ *sequence-entry row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{Equicontinuity}^{\uparrow}$ *common schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal. The* $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ *sibling supplies the shared-modulus boundary, while chapter 129, chapter 301, and chapter 38 fix the compact, rational, and real-facing rows. Thus the route exports a finite compact-uniform sequence lattice, not a host function-space compactness theorem, quotient equality of maps, selected subsequence, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier of Definition 4356.1. Its compact-uniformity data are the compact metric row K, displayed map row F, finite stream-window row S, shared schedule W, equicontinuity row Q, regular readback row R, finite-net selector T, and Arzela–Ascoli handoff A.

The $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ route of chapter 4287 names the sibling boundary where a sequence of displayed maps shares one modulus row. The present packet reads that boundary through W, Q over the same K, F, S window, so a compact-uniformity consumer cannot detach the modulus from the compact source or from the inspected sequence entries.

Finally, the compact source, rational readback, and real seal remain anchored in chapter 129, chapter 301, and chapter 38. Transport, replay, provenance, and local naming preserve the same finite route, and none of those rows adds a host function space, quotient equality, selected subsequence, countable-choice schedule, or ambient completeness principle. □

Chapter 4357

A Concrete Naming Certificate for $\mathsf{DecimalIntervalReal}^{\uparrow}$

Bishop–Bridges constructive analysis uses rational and decimal brackets as finite evidence before a real name is treated as complete. The $\mathsf{DecimalIntervalReal}^{\uparrow}$ packet records this decimal-bracket carrier as BEDC NameCert data. It sits after the decimal prefix surface of chapter 1417, the finite decimal stream of chapter 4191, the dyadic tolerance ledger of chapter 291, the finite window schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located interval source of chapter 1709. The packet gives L10 Real and Completion consumers a finite decimal interval carrier without quotient reals, trichotomy, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4357.1 (Decimal interval real carrier)**.** *A* $\mathsf{DecimalIntervalReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (A, B, D, W, Q, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the lower finite decimal-prefix row, read through* $\mathsf{DecimalExpansion}^{\uparrow}$ *and the finite* $\mathsf{DecimalStream}^{\uparrow}$ *schedule.*
2. *B is the upper finite decimal-prefix row, read through the same decimal surfaces and carrying the advertised bracket side.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger translating decimal place values into dyadic comparison margins.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule opened for endpoint-prefix reads, bracket comparison, and downstream replay.*
5. *Q is the bracket-order row, recording that the lower decimal prefix and upper decimal prefix are compared only through the displayed tolerance ledger.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the endpoint windows, decimal prefix rows, dyadic ledger, and bracket-order row.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regular rational readback has been displayed.*
8. *L is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *handoff row that consumes the same endpoint, tolerance, readback, and seal rows as a located interval boundary.*

9. *H records componentwise* hsame *transport for endpoint prefixes, tolerance rows, windows, bracket order, regular readback, real seal, located interval handoff, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a decimal-bracket request through endpoint prefixes, dyadic comparison, finite windows, regular readback, real sealing, and located interval handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{DecimalIntervalReal}^{\uparrow}$, $\mathsf{DecimalExpansion}^{\uparrow}$, $\mathsf{DecimalStream}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, D, W, Q, R, E, L, H, C, P, N$. It has no coordinate for a quotient real, a trichotomy decision, a selected decimal representative, host endpoint equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.DecimalIntervalRealUp.DecimalIntervalRealCarrier`
Lean4 ✓ `BEDC.Derived.DecimalIntervalRealUp.DecimalIntervalRealTasteGate single carrier alignment`

Theorem 4357.2 (Decimal interval real NameCert obligations)**.** *For every accepted* $\mathsf{DecimalIntervalReal}^{\uparrow}$ *carrier $J = (A, B, D, W, Q, R, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the lower decimal prefix, upper decimal prefix, dyadic tolerance ledger, stream windows, bracket-order row, regular rational readback, real seal, located interval handoff, transport, replay, provenance, and local naming rows;*
2. *decimal-prefix visibility, requiring endpoint reads to enter through A and B before any bracket comparison is inspected;*
3. *tolerance discipline, requiring the place-value comparison to use the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D and no hidden real-order oracle;*
4. *window discipline, requiring each endpoint and comparison read to be scheduled by the finite* $\mathsf{StreamName}^{\uparrow}$ *row W;*
5. *regular-readback order, requiring R to consume A, B, D, W, Q before any* $\mathsf{Real}^{\uparrow}$ *seal is available;*
6. *located-interval handoff, requiring L to consume the same endpoint, tolerance, readback, and seal route rather than a host interval;*
7. *componentwise* hsame *transport and displayed* Cont *replay for exactly the rows carried by H and C;*
8. *ledger non-escape, excluding quotient reals, trichotomy, selected decimal representatives, host endpoint equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4357.1. The projection exposes exactly the two decimal endpoint-prefix rows, the dyadic tolerance ledger, the finite window schedule, the bracket-order row, the regular readback, the terminal real seal, the located interval handoff, transport, replay, provenance, and local naming.

The endpoint reads are visible before comparison. Rows A and B carry the finite decimal prefixes, while D supplies the dyadic margin used to compare their place-value readings. The row W schedules the inspected prefixes and comparison windows, so the bracket-order row Q has no access to a hidden real-order decision.

The real-facing route is downstream of the finite bracket data. Row R is read only after A, B, D, W, Q have been displayed, and row E seals the result only after that regular rational readback.

Finally, the located interval handoff L consumes the same displayed route, while H, C, P, N transport, replay, source, and name the packet. Since no remaining coordinate stores quotient equality, trichotomy, a selected decimal representative, host endpoint equality, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.DecimalIntervalRealUp.DecimalIntervalRealCarrier semantic name certificate`

Theorem 4357.3 (Decimal interval real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{LocatedRealInterval}^{\uparrow}$ *read exported by an accepted* $\mathsf{DecimalIntervalReal}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DecimalExpansion}^{\uparrow},\ \mathsf{DecimalStream}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{LocatedRealInterval}^{\uparrow}.$$

Equivalently, a downstream Real and Completion consumer receives the two decimal endpoint-prefix rows, the dyadic comparison ledger, the finite window row, the regular rational readback, the terminal real seal, the located interval handoff, transport, replay, provenance, and local naming before it can use the bracket.

Proof. Start with an accepted carrier $J = (A, B, D, W, Q, R, E, L, H, C, P, N)$. The only real-facing row is E, and the only located-interval row is L.

The definition places E after the endpoint-prefix rows A, B, the dyadic tolerance ledger D, the window schedule W, the bracket-order row Q, and the regular rational readback R. Thus a $\mathsf{Real}^{\uparrow}$ consumer must first inspect the decimal, dyadic, window, and readback rows.

The located interval handoff is not an alternate route. Row L consumes the same A, B, D, W, Q, R, E path, and componentwise transport through H preserves that path under hsame.

The replay, provenance, and local naming rows only record the displayed carrier. They do not add quotient reals, trichotomy, selected representatives, host endpoint equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so the displayed route is the whole exported handoff. □

Falsifiable prediction: Every accepted $\mathsf{DecimalIntervalReal}^{\uparrow}$ read displays two finite decimal-prefix rows, one dyadic comparison ledger, one finite StreamName window row, one RegSeqRat readback row, one RealUp seal row, one LocatedRealIntervalUp handoff row, and local transport, replay, provenance, and naming rows before it is consumed as a decimal bracket.

Independence witness: decimalexpansion, decimal-stream, dyadicratcore, streamname, regseqrat, real, located-real-interval: $\mathsf{DecimalIntervalReal}^{\uparrow}$ is not bijective to any listed sibling because it binds two ordered decimal endpoint-prefix rows, one dyadic comparison ledger, finite observation windows, regular rational readback, RealUp sealing, located interval handoff, componentwise hsame, displayed Cont, Pkg, and local $\mathsf{NameCert}$ into one accepted bracket packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}$.

Constructive story: A $\mathsf{DecimalIntervalReal}^{\uparrow}$ packet is generated from lower and upper decimal-prefix rows, DecimalStream windows, a DyadicRatCore comparison ledger, a StreamName schedule, a RegSeqRat readback, a RealUp seal, a LocatedRealIntervalUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4357.1, Definition 4357.2, and Definition 4357.3 seed the finite decimal-bracket route over DecimalExpansionUp, DecimalStreamUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, LocatedRealIntervalUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DecimalIntervalReal}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.DecimalIntervalRealUp`

Bridge status: none

Not claimed: This chapter does not claim quotient reals, trichotomy, selected decimal representatives, host endpoint equality, countable choice, Lean verification, bridge checking, or ambient $\mathrm{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, decimal-prefix visibility, dyadic tolerance discipline, finite-window discipline, regular-readback order, Real seal handoff, located interval handoff, transport, replay, provenance, and ledger non-escape for BEDC.Derived.DecimalIntervalRealUp.

Chapter 4358

A Concrete Naming Certificate for $\mathsf{AttouchWetsTopology}^{\uparrow}$

Following Attouch and Wets on variational convergence, the $\mathsf{AttouchWetsTopology}^{\uparrow}$ packet records local Hausdorff-window convergence for closed metric figures as finite BEDC NameCert data over the metric-completion and L10 real-name surface. It sits after the metric carrier of chapter 57, the Hausdorff-distance surface of chapter 3653, the terminal real seal of chapter 38, the regular rational readback of chapter 301, and the finite stream windows of chapter 126. The packet names the finite observation topology; it does not import host closed-set topology, arbitrary hyperspace compactness, quotient closed sets, selected nearest points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4358.1 (Attouch-Wets topology carrier)**.** *An* $\mathsf{AttouchWetsTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A_{\mathrm{aw}} = (M, H, D, W, R, E, Q, T, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose metric, point windows, and bounded-window radii are the only ambient metric data available to the packet.*
2. *H is the* $\mathsf{HausdorffDistance}^{\uparrow}$ *local-window row, read only on displayed bounded metric windows rather than on an ambient hyperspace.*
3. *D is the dyadic tolerance ledger for window radius, Hausdorff comparison margin, and late-window precision.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected centers, bounded windows, comparison stages, and requested precision cells.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational Hausdorff-window comparisons obtained from M, H, D, W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the regular rational readback has been displayed.*
7. *Q records componentwise* hsame *transport for metric source rows, Hausdorff-window rows, dyadic ledgers, stream windows, regular readbacks, real seals, replay rows, provenance, and local naming.*
8. *T records displayed* Cont *replay from an Attouch–Wets observation request through M, H, D, W, R, E.*

9. *C is the local bounded-window classifier row comparing packets only through the displayed metric source, Hausdorff-window, tolerance, stream, readback, seal, transport, replay, provenance, and naming coordinates.*

10. *P is the* Pkg *provenance over* $\mathsf{AttouchWetsTopology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{HausdorffDistance}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}$ *row.*

The classifier has no coordinate for global closed-set topology, open-cover compactness, selected nearest points, quotient hyperspace equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.AttouchWetsTopologyUp.AttouchWetsTopologyTasteGate single carrier alignment`

Theorem 4358.2 (Attouch-Wets topology NameCert obligation surface)**.** *For every accepted* $\mathsf{AttouchWetsTopology}^{\uparrow}$ *carrier*

$$A_{\mathrm{aw}} = (M, H, D, W, R, E, Q, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *expose the* $\mathsf{Met}^{\uparrow}$ *source row M before any local Hausdorff comparison is read;*

2. *display the* $\mathsf{HausdorffDistance}^{\uparrow}$ *window row H only on bounded metric windows named by the packet;*

3. *bind all numerical precision to the dyadic tolerance ledger D, the* $\mathsf{StreamName}^{\uparrow}$ *row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E;*

4. *preserve the same finite route by componentwise* hsame *transport Q and displayed* Cont *replay T;*

5. *source and name the same packet through the bounded-window classifier C,* Pkg *provenance P, and the local* NameCert *row N.*

No obligation row is stored for a host hyperspace topology, arbitrary closed-set compactness, selected representatives, quotient closed-set equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 4358.1. The metric row M is the only source of ambient distance data, and the Hausdorff row H is read only after the bounded window has been displayed.

The numerical part is downstream of that window. The tolerance ledger D, finite window row W, regular readback R, and real seal E are the only precision and value rows available to an observation request.

Transport and replay keep the same route. Rows Q and T preserve the displayed metric, Hausdorff, tolerance, window, readback, and seal data, while C, P, N classify, source, and name the finite packet.

Since the carrier contains none of the excluded topology, compactness, selection, quotient, choice, or ambient-completeness coordinates, the displayed obligations exhaust the local NameCert surface. □

Theorem 4358.3 (Attouch-Wets local Hausdorff window)**.** *Every topology-facing read exported by an accepted* $\mathsf{AttouchWetsTopology}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{HausdorffDistance}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}.$$

Thus a downstream metric-completion consumer receives the displayed metric source, bounded local Hausdorff window, finite observation schedule, regular rational readback, terminal real seal, componentwise transport, replay, provenance, and local naming before it can use Attouch–Wets convergence data.

Proof. Start with a topology-facing read of the accepted carrier. The only available metric source is M, and the only Hausdorff comparison row is the local-window row H.

The observation is then forced through D, W, R, E. The dyadic ledger fixes the requested tolerance, the stream row displays the inspected bounded windows, the regular rational row records the readback, and the real row seals the reported Hausdorff-window value.

Finally Q, T, C, P, N transport, replay, classify, source, and name that same finite route. Because no row supplies host closed-set topology, arbitrary hyperspace compactness, selected nearest points, quotient closed-set equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every exported topology-facing read factors through the displayed local Hausdorff window. □

Closure status for $\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}$.

Constructive story: An $\mathsf{AttouchWetsTopology}^{\uparrow}$ packet is generated from a MetricSpace source row, a HausdorffDistance bounded-window row, a dyadic tolerance ledger, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, a bounded-window classifier row, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4358.1, Definition 4358.2, and Definition 4358.3 seed the local Hausdorff-window topology route over MetricSpaceUp, HausdorffDistanceUp, StreamNameUp, RegSeqRatUp, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AttouchWetsTopology}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.AttouchWetsTopologyUp`

Bridge status: none

Not claimed: This chapter does not claim host closed-set topology, arbitrary hyperspace compactness, quotient closed sets, selected nearest points, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded Hausdorff-window exposure, finite-window scheduling, regular readback, Real sealing, transport, replay, classifier exactness, provenance, and local naming for BEDC.Derived.AttouchWetsTopologyUp.

Chapter 4359

A Concrete Naming Certificate for $\mathsf{CantorIntersectionMetric}^{\uparrow}$

Following Cantor's intersection theorem and Bishop–Bridges constructive metric completion, the $\mathsf{CantorIntersectionMetric}^{\uparrow}$ packet records the metric nested-closed-set intersection route as finite BEDC NameCert data over the L10 completion surface. It sits after the complete-metric source of chapter 128, the metric-completion route of chapter 1506, the nested closed-ball packet of chapter 3526, the Cantor complete metric route of chapter 2199, the Cauchy-filter interface of chapter 333, and the L10 real-name route through chapter 291, chapter 126, chapter 301, and chapter 38. The metric packet is the metric-completion specialization of the finite Cantor-intersection route in chapter 1421 and the theorem-facing intersection route in chapter 2318; it consumes their nested-window and diagonal-readback rows before exposing complete-metric service. The packet names a nested metric intersection handoff; it does not assert open-cover compactness, arbitrary closed-set compactness, quotient stream equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4359.1 (CantorIntersectionMetric carrier)**.** *A* $\mathsf{CantorIntersectionMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I_{\mathrm{cim}} = (M, E, B, K, F, D, S, R, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row whose metric and convergence service are the only complete-metric data available to the packet.*
2. *E is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row naming the surrounding completion request before any intersection point is read.*
3. *B is the* $\mathsf{NestedClosedBall}^{\uparrow}$ *row, recording the descending closed metric ball spine and its finite containment witnesses.*
4. *K is the* $\mathsf{CantorCompleteMetric}^{\uparrow}$ *row, used only as the displayed nested closed-ball completion handoff.*
5. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row generated by the nested metric spine and read only through the displayed filter route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter and tolerance ledger, storing the shrink schedule, late-radius comparisons, and requested precision bounds.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected centers, radii, and containment data.*

8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the regular rational readback of the displayed center schedule.*
9. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after B, K, F, D, S, R have been displayed.*
10. *H records componentwise* hsame *transport for the complete-metric source, completion route, nested-ball row, Cantor handoff, filter, dyadic ledger, stream windows, regular readback, real seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a nested metric intersection request through $M, E, B, K, F, D, S, R, L$.*
12. *P is the* Pkg *provenance over* $\mathsf{CantorIntersectionMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{NestedClosedBall}^{\uparrow}$, $\mathsf{CantorCompleteMetric}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, B, K, F, D, S, R, L, H, C, P, N$. It has no coordinate for open-cover compactness, arbitrary closed-set compactness, quotient completion equality, a selected limit, host trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorIntersectionMetricUp.CantorIntersectionMetricTasteGate single carrier alignment`

Theorem 4359.2 (CantorIntersectionMetric NameCert obligations)**.** *For every accepted* $\mathsf{CantorIntersectionMetric}^{\uparrow}$ *carrier*

$$I_{\mathrm{cim}} = (M, E, B, K, F, D, S, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *expose the complete-metric and metric-completion source rows M, E before any intersection witness is read;*
2. *display the nested metric route through B, K, F, namely the nested closed-ball spine, Cantor complete-metric handoff, and generated Cauchy-filter row;*
3. *bind all numerical readback to the L10 rows D, S, R, L, namely the dyadic tolerance ledger, finite stream windows, regular rational handoff, and terminal real seal;*
4. *preserve the route by componentwise* hsame *transport and displayed* Cont *replay through H, C;*
5. *source and name the same finite packet through* Pkg *provenance P and the local* NameCert *row N.*

No obligation row is stored for open-cover compactness, arbitrary closed-set compactness, quotient completions, selected limits, trichotomy, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 4359.1. The rows M, E expose the metric and completion sources before the packet can read an intersection point.

The nested metric content is then displayed through B, K, F. The nested closed-ball row supplies the descending closed metric spine, the Cantor complete-metric row supplies the existing handoff, and the Cauchy-filter row records the generated filter route.

The L10 readback is downstream. The dyadic ledger D, stream windows S, regular rational row R, and real seal L are the only numerical coordinates available before a completion-facing consumer receives a named output.

Finally H, C, P, N transport, replay, source, and name that same finite route. Since the carrier contains none of the excluded compactness, quotient, selected-limit, trichotomy, or ambient-completeness coordinates, the five displayed obligations exhaust the local NameCert surface. □

Theorem 4359.3 (CantorIntersectionMetric complete handoff)**.** *Every completion-facing read exported by an accepted* $\mathsf{CantorIntersectionMetric}^{\uparrow}$ *carrier factors through the displayed nested metric route*

$\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{NestedClosedBall}^{\uparrow}$, $\mathsf{CantorCompleteMetric}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, S

Thus a consumer receives the complete-metric service, completion request, nested closed-ball spine, Cantor complete-metric handoff, Cauchy-filter row, dyadic tolerance ledger, finite stream windows, regular rational readback, terminal real seal, componentwise transport, replay, provenance, and local naming rows before it may use the intersection output. The handoff exports no $\mathsf{Real}^{\uparrow}$ *completeness principle, open-cover compactness theorem, arbitrary closed-set compactness, quotient stream equality, or selected limit.*

Proof. Begin with a completion-facing read of the accepted carrier. The first available rows are M and E, so the read is grounded in the displayed complete-metric service and the surrounding metric-completion request.

Next pass through the nested route B, K, F. The descending closed-ball spine is read through the $\mathsf{NestedClosedBall}^{\uparrow}$ row, the existing Cantor complete-metric handoff is read through K, and the generated filter is read through F.

The numerical output is then forced through the L10 readback rows D, S, R, L. The dyadic ledger supplies tolerance control, the stream row supplies finite windows, the regular rational row supplies readback, and the terminal real seal is reached only after those rows are present.

The structural rows H, C, P, N preserve the same route for downstream consumers. Because no row supplies full real completeness, open-cover compactness, arbitrary closed-set compactness, quotient stream equality, or a selected limit, every completion-facing read factors through the displayed nested metric route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorIntersectionMetric}^{\uparrow}$ packet is generated from a CompleteMetric source row, a MetricCompletion request row, a NestedClosedBall spine, a CantorCompleteMetric handoff, a CauchyFilter row, a DyadicRatCore tolerance ledger, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$, seed)

Scope closed: Definition 4359.1, Definition 4359.2, and Definition 4359.3 seed the metric nested-closed-set intersection route over displayed completion, nested-ball, Cantor handoff, filter, dyadic, stream, regular readback, real seal, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CantorIntersectionMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, arbitrary closed-set compactness, quotient completions, selected limits, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested metric inclusion, Cantor handoff, Cauchy-filter generation, dyadic shrink exactness, finite-window readback, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CantorIntersectionMetricUp.

Chapter 4360

A Concrete Naming Certificate for $\mathsf{TightRealInterval}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{TightRealInterval}^{\uparrow}$ packet names a finite lower-upper real interval by displaying both endpoint names and every rational cell through which those endpoints are inspected. It sits downstream of the located endpoint surface of chapter 394 and the dyadic refinement surface of chapter 306: consumers may read a tight interval only after the lower endpoint, upper endpoint, rational cell ledger, dyadic refinement ledger, stream windows, regular rational readbacks, and Real seal rows have all been displayed.

Definition 4360.1 (TightRealInterval carrier)**.** *A* $\mathsf{TightRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (L, U, Q, D, S, R, E, H, C, P, N)$$

with the following visible rows:

1. *L is the lower* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint row and U is the upper* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint row.*
2. *Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger recording the finite rational windows that enclose the endpoint reads and witness lower-before-upper compatibility.*
3. *D is the* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement ledger attached to the rational cells in Q.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming exactly the endpoint observations and interval cells inspected by the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those endpoint windows and cell refinements.*
6. *E is the paired* $\mathsf{Real}^{\uparrow}$ *seal row reached from L, U, S, R, Q, D.*
7. *H records componentwise* hsame *transport for endpoints, rational cells, dyadic refinements, stream windows, readbacks, Real seals, replay, provenance, and the local name.*
8. *C records displayed* Cont *replay through $L, U, Q, D, S, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}$ *row.*

The carrier has no coordinate for host interval equality, chosen endpoint values, quotient real equality, trichotomy, countable choice, or ambient real completeness.

Lean4 (definition) `BEDC.Derived.TightRealIntervalUp.TightRealIntervalUp`
Lean4 ✓ `BEDC.Derived.TightRealIntervalUp.TasteGate.TightRealIntervalTasteGate single carrier alignment`

Theorem 4360.2 (TightRealInterval NameCert obligations)**.** *For an accepted* $\mathsf{TightRealInterval}^{\uparrow}$ *carrier* $T = (L, U, Q, D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the lower and upper* $\mathsf{LocatedReal}^{\uparrow}$ *endpoint rows, rational and dyadic interval ledgers, finite stream windows, regular rational readbacks, paired Real seal rows, componentwise transport, continuation replay, package provenance, and local naming; endpoint-order visibility through* Q*; dyadic refinement discipline through* D*; stream-readback exactness through* S, R*; and ledger non-escape from host intervals, selected endpoints, quotient real equality, choice, trichotomy, and ambient completeness.*

Proof. Project the carrier of Definition 4360.1. The lower and upper endpoint rows, the rational cell ledger, the dyadic refinement ledger, finite windows, regular readbacks, Real seals, transport rows, replay rows, provenance row, and local naming row are all visible before any interval consumer can read the packet.

Endpoint-order visibility is supplied by Q. Since each dyadic refinement in D is attached to a rational cell, the refinement discipline cannot detach from the endpoint ledger.

Stream-readback exactness is then read through S and R. The rows H, C, P, N transport, replay, source, and name the same finite route, while the excluded interval and completeness data have no carrier coordinate. □

Theorem 4360.3 (TightRealInterval Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{TightRealInterval}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{LocatedReal}^{\uparrow},\ \mathsf{RationalInterval}^{\uparrow},\ \mathsf{DyadicInterval}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Nam}$$

The read exposes lower and upper endpoint windows together with the rational and dyadic cell ledgers that bind them. It does not expose a host real interval, a selected endpoint value, quotient real equality, countable choice, trichotomy, or ambient real completeness.

Proof. Begin with the accepted carrier. The only seal-facing row is E, and it is displayed after L, U, Q, D, S, R in the finite packet.

Apply Definition 4360.2. Endpoint-order visibility forces the Real read to keep the rational cell ledger Q, dyadic refinement discipline forces any dyadic window through D, and stream-readback exactness forces finite observations through S, R.

Finally route through H, C, P, N. These rows preserve and name the same packet, so no host interval, endpoint selector, quotient equality, choice schedule, trichotomy row, or ambient completeness principle can enter the Real seal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TightRealInterval}^{\uparrow}$ packet is generated from lower and upper $\mathsf{LocatedReal}^{\uparrow}$ endpoint rows, a $\mathsf{RationalInterval}^{\uparrow}$ cell ledger, a $\mathsf{DyadicInterval}^{\uparrow}$ refinement ledger, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, paired $\mathsf{Real}^{\uparrow}$ seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4360.1, Definition 4360.2, and Definition 4360.3 seed the finite lower-upper Real interval packet over located endpoints, rational cells, dyadic refinements, stream windows, regular readbacks, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TightRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host interval equality, selected endpoint values, quotient real equality, trichotomy, countable choice, or ambient real completeness.

Upgrade path: Scoped closure requires a checked carrier-obligation package and a public consumer route for the same finite lower-upper interval packet.

Chapter 4361

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$

Following Bishop-style compact metric uniform continuity, the $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$ packet records the finite handoff that transfers compact finite-net and pointwise continuity data into a uniform modulus row. It consumes the finite compact source of chapter 60, the compact metric net surface of chapter 129, the continuity interface of chapter 391, the finite stream and regular readback rows of chapter 126 and chapter 301, and the dyadic tolerance ledger of chapter 291. The packet is a finite modulus-transfer NameCert surface, not an open-cover compactness proof or a host modulus selector.

Definition 4361.1 (Compact uniform modulus transfer carrier)**.** *A* $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, G, U, S, R, D, F, H, C, P, N)$$

with the following visible rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-net source row.*
2. *G is the* $\mathsf{CompactMetric}^{\uparrow}$ *metric coverage row for the same finite centers and source distance witnesses.*
3. *U is the* $\mathsf{UniformContinuity}^{\uparrow}$ *pointwise-to-uniform continuity row consumed by the transfer.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing the inspected finite centers, tolerance requests, and pointwise-radius reads.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for finite radius comparison and shrinkage.*
7. *F is the modulus-transfer ledger that records the finite lower-bound handoff into the downstream uniform-modulus consumer row.*
8. *H records componentwise* hsame *transport for compact, compact-metric, uniform-continuity, stream, readback, dyadic, transfer, replay, provenance, and local-name rows.*
9. *C records displayed* Cont *replay through $K, G, U, S, R, D, F, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusTransfer}^{\uparrow}}$ *row.*
The carrier has no coordinate for open-cover compactness, selected centers, selected Lebesgue numbers, host modulus functions, quotient point equality, countable choice, or ambient metric completeness.

Lean4 ✓ `BEDC.Derived.CompactUniformModulusTransferUp.CompactUniformModulusTransferTasteGate`
`single carrier alignment`

Theorem 4361.2 (Compact uniform modulus transfer obligations)**.** *For an accepted* CompactUniformModulusTrans *carrier $M = (K, G, U, S, R, D, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusTransfer}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact finite-net row, compact-metric coverage row, uniform-continuity row, stream windows, regular rational readbacks, dyadic tolerance ledger, modulus-transfer ledger, componentwise transport, continuation replay, package provenance, and local naming; source lock between K, G, U; finite-window exactness through S, R; dyadic tolerance exactness through D; and non-escape from open-cover compactness, selected centers, selected Lebesgue numbers, host modulus functions, quotient equality, choice, and ambient completeness.*

Proof. Project the carrier of Definition 4361.1. The compact row, compact-metric row, continuity row, stream windows, readbacks, dyadic tolerance ledger, transfer ledger, transport rows, replay rows, provenance row, and local name are displayed as one finite packet.

The source lock is the shared read of K, G, U. A transfer consumer cannot use the compact finite-net row without the compact-metric distance surface and the continuity row that supplies pointwise radius data.

Finite-window and dyadic exactness are read through S, R, D. The ledger F can therefore transfer only the displayed finite lower-bound data, and H, C, P, N preserve that route without adding any excluded compactness or choice principle. □

Theorem 4361.3 (Compact uniform modulus transfer handoff)**.** *Every accepted* $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$ *packet hands a downstream uniform-modulus consumer only the finite route*

$$\mathsf{Compact}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{UniformContinuity}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont}$$

The handoff records compact finite-net coverage, pointwise continuity radius reads, finite stream windows, regular rational readbacks, dyadic tolerance comparison, and the transfer ledger. It exports no open-cover compactness theorem, selected net center, selected Lebesgue number, host modulus function, quotient equality, countable choice, or ambient completeness.

Proof. Start from the transfer obligations of Definition 4361.2. They identify the compact, compact-metric, continuity, stream, readback, dyadic, and transfer rows as the only NameCert-readable data.

Route the downstream consumer through F. The ledger can be consumed only after K, G, U, S, R, D have supplied the finite-net, pointwise-radius, window, readback, and tolerance rows.

Finally use H, C, P, N to transport, replay, source, and name the same packet. Since the excluded compactness, selection, equality, choice, and completeness data have no coordinate in the carrier, the downstream handoff is exactly the displayed finite modulus-transfer route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusTransfer}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactUniformModulusTransfer}^{\uparrow}$ packet is generated from compact finite-net rows, compact-metric coverage rows, uniform-continuity rows, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, a modulus-transfer ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactUniformModulusTransfer}\uparrow}$, seed)

Scope closed: Definition 4361.1, Definition 4361.2, and Definition 4361.3 seed the finite compact-net modulus-transfer packet for uniform-continuity consumers.

Formal verification: FormalStatus(NameCert$_{\text{CompactUniformModulusTransfer}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.CompactUniformModulusTransferUp.CompactUniformModulusTransferTasteGate\_single\_carrier`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected centers, selected Lebesgue numbers, host modulus functions, quotient point equality, countable choice, or ambient metric completeness.

Upgrade path: Scoped closure requires a checked transfer-obligation package and a public uniform-modulus consumer route for the same finite packet.

Chapter 4362

A Concrete Naming Certificate for $\mathsf{RealIntervalApartness}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RealIntervalApartness}^{\uparrow}$ packet records located separation of two real intervals by a displayed positive dyadic gap rather than by a trichotomy decision on completed real endpoints. It sits after the terminal real-name seal of chapter 38, the located endpoint interval surface of chapter 1709, the dyadic tolerance ledger of chapter 291, the finite window discipline of chapter 126, the regular rational readback of chapter 301, and the separability boundary of chapter 1809. The packet names interval separation only through visible endpoint rows, gap rows, transport, replay, provenance, and local naming.

Definition 4362.1 (RealIntervalApartness carrier)**.** *A* $\mathsf{RealIntervalApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, J, L, U, L', U', G, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I and J are the two* $\mathsf{LocatedRealInterval}^{\uparrow}$ *endpoint packets whose lower and upper endpoint rows are exposed before any apartness read.*
2. *L, U are the lower and upper* $\mathsf{Real}^{\uparrow}$ *seal rows for I, and L', U' are the corresponding* $\mathsf{Real}^{\uparrow}$ *seal rows for J.*
3. *G is a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap witness, attached either to the displayed comparison $U + G \leq L'$ or to the displayed comparison $U' + G \leq L$.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming exactly the endpoint observations and gap inspections used by the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those endpoint windows and dyadic gap checks.*
6. *E records the* $\mathsf{RealSeparability}^{\uparrow}$ *boundary row witnessing that the two exposed endpoint intervals are separated by the displayed dyadic gap.*
7. *H records componentwise* hsame *transport for intervals, endpoint seals, dyadic gap rows, finite windows, readbacks, separability rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay through $I, J, L, U, L', U', G, S, R, E, H$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealIntervalApartness}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}$ *row.*

The carrier has no coordinate for real trichotomy, quotient real equality, a selected endpoint representative, a host interval order, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 4362.2 (RealIntervalApartness NameCert obligations)**.** *For every accepted* $\mathsf{RealIntervalApartness}^{\uparrow}$ *carrier*

$$A = (I, J, L, U, L', U', G, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *admit the two located real interval packets I, J and expose their lower and upper endpoint rows through L, U, L', U';*
2. *expose the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *gap witness G and the side on which the gap separates the displayed endpoint rows;*
3. *bind every endpoint and gap inspection to the finite* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows S, R;*
4. *preserve the interval, endpoint, gap, readback, and separability rows by componentwise* hsame *transport through H;*
5. *replay the same finite route through* Cont *row C, source it by* Pkg *provenance P, and name it by the local* NameCert *row N.*

No obligation row is stored for real trichotomy, quotient equality of completed real names, selected endpoint representatives, host interval order, or ambient real completeness.

Proof. Project the carrier of Definition 4362.1. The two located interval packets and their endpoint seals are the only interval data exposed to a consumer.

The separation datum is the row G. Positivity is read as a dyadic-row property, and the side of separation is part of the displayed ledger; no trichotomy comparison is consulted.

The numerical readback is forced through S and R, then through the separability row E. The structural rows H, C, P, N transport, replay, source, and name the same finite packet.

Since none of the excluded host-order, quotient-equality, representative-selection, trichotomy, or completeness data occurs as a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.RealIntervalApartnessUp.TasteGate.RealIntervalApartnessTasteGate single carrier alignment`

Theorem 4362.3 (RealIntervalApartness separability route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{RealIntervalApartness}^{\uparrow}$ *carrier factors through*

$\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, hsame, Cont, Pkg, Na

The route exports located interval separation only as a positive dyadic gap between displayed endpoint rows. It exports no real trichotomy, quotient real equality, host interval order, selected endpoint representative, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Begin with the NameCert obligations of Definition 4362.2. They force the two located interval packets and endpoint seals to be visible before a consumer may read an apartness claim.

Next read the dyadic gap row and its finite endpoint inspections through the stream and regular-rational rows. The separability row is therefore attached to the displayed positive gap, not to a host comparison of completed reals.

Finally route through transport, replay, provenance, and local naming. These rows preserve the same finite packet, so the consumer receives located interval apartness without importing any excluded trichotomy, quotient, selection, host-order, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}$.

Constructive story: A $\mathsf{RealIntervalApartness}^{\uparrow}$ packet is generated from two LocatedRealInterval endpoint packets, Real endpoint seal rows, a positive DyadicRatCore gap witness, finite StreamName windows, RegSeqRat readback, a RealSeparability boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4362.1, Definition 4362.2, and Definition 4362.3 seed the located interval separation packet over displayed endpoint, dyadic gap, finite-window, regular-readback, Real seal, separability, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealIntervalApartness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim real trichotomy, quotient real equality, selected endpoint representatives, host interval order, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exposure, positive-gap exposure, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.RealIntervalApartnessUp.

Chapter 4363

A Concrete Naming Certificate for $\mathsf{PartitionBasinPolynomial}^{\uparrow}$

Following finite enumerative combinatorics, the $\mathsf{PartitionBasinPolynomial}^{\uparrow}$ packet records the partition-basin product formula of Definition 9462.1736 as displayed NameCert data over block sizes, legal decorations, defect exponents, incidence totals, transport, replay, provenance, and local naming. It sits after the partition carrier of chapter 201, the defect-flow partition skeleton of chapter 4236, and the partition-core incidence certificate of chapter 4214. The packet names a finite polynomial enumeration surface; it is not a biological stochastic model, a host generating-function oracle, or a quotient-level semantic identification.

Definition 4363.1 (PartitionBasinPolynomial carrier)**.** *A* $\mathsf{PartitionBasinPolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, S, D, E, F, Q, I, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite block-count row for the partition core, and S is the finite block-size ledger $(s_1, \ldots, s_m)$.*
2. *D is the legal-decoration row, recording for each coordinate of block i the admissible subset of the other $m-1$ rows and the private-coordinate exclusion.*
3. *E is the defect-exponent ledger that assigns exponent weight q^r to a coordinate receiving r additional rows.*
4. *F is the product-formula row*
$$\prod_{i=1}^{m} \left[(1+q)^{(m-1)s_i} - \left((1+q)^{m-1} - 1 \right)^{s_i} \right].$$
5. *Q is the four-coordinate specialization row for the five partition types 4, $3+1$, $2+2$, $2+1+1$, and $1+1+1+1$.*
6. *I is the incidence-total row that reads the quotient-level and codon-level totals from the displayed specialization.*
7. *T records the downstream defect-flow handoff to the partition skeleton and incidence certificate.*
8. *H records componentwise* hsame *transport for block sizes, legal decorations, defect exponents, product rows, specialization rows, incidence rows, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay through $M, S, D, E, F, Q, I, T, H$.*
10. *P is the* Pkg *provenance over* PartitionBasinPolynomial$^{\uparrow}$, Partition$^{\uparrow}$, DefectFlowPartitionSkeleton$^{\uparrow}$, PartitionCoreIncidenceCertificate$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$ *row.*

The carrier has no coordinate for a stochastic biology model, a host polynomial oracle, a quotient-semantic equality, an unbounded partition enumeration, or a hidden recurrence outside the displayed finite rows.

Lean4 ✓ `BEDC.Derived.PartitionBasinPolynomialUp.PartitionBasinPolynomialTasteGate single carrier alignment`

Theorem 4363.2 (PartitionBasinPolynomial NameCert obligations)**.** *For every accepted* PartitionBasinPolynomial$^{\uparrow}$ *carrier*

$$B = (M, S, D, E, F, Q, I, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$ *surface consists exactly of block-count and block-size admission through M, S, legal-decoration admission through D, defect-exponent admission through E, product-formula exposure through F, four-coordinate specialization through Q, incidence-total readback through I, defect-flow handoff through T, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 4363.1. The block-count and block-size rows supply the finite partition core on which the enumeration is read.

The decoration and defect rows are then exposed coordinatewise. For block i, the all-decoration contribution is $(1+q)^{(m-1)s_i}$, and the excluded no-private-coordinate contribution is $\left((1+q)^{m-1}-1\right)^{s_i}$.

Multiplying the legal block rows gives the product row F. The specialization row Q evaluates the same finite formula on the five four-coordinate partition types, and the incidence row I sums the displayed rows with their finite multiplicities.

Finally T, H, C, P, N route the same polynomial surface to the defect-flow and incidence packets. Because no excluded stochastic, host-oracle, quotient-semantic, unbounded-enumeration, or hidden-recurrence coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 4363.3 (PartitionBasinPolynomial product specialization)**.** *Every defect-flow consumer of an accepted* PartitionBasinPolynomial$^{\uparrow}$ *carrier receives the product formula row for $\mathcal{B}_P(q)$ and the four-coordinate specialization row before reading quotient-level or codon-level incidence totals. The consumer sees only finite block-size, decoration, defect, product, specialization, incidence, transport, replay, provenance, and local NameCert rows.*

Proof. Start from the obligations of Definition 4363.2. They force the block-size ledger and legal-decoration rows to be displayed before the product formula can be consumed.

The four-coordinate row is a finite specialization of the same product row. Its incidence totals are read only after the partition types and finite multiplicities have been displayed.

The handoff through T, H, C, P, N preserves the same finite surface for the defect-flow skeleton and partition-core incidence certificate. Thus no stochastic model, host generating-function oracle, quotient-semantic equality, or hidden enumeration can be read from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$.

Constructive story: A PartitionBasinPolynomial$^{\uparrow}$ packet is generated from block-count rows, block-size ledgers, legal-decoration rows, defect-exponent ledgers, a product-formula row, a four-coordinate specialization row, incidence-total rows, a defect-flow handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$, seed)

Scope closed: Definition 4363.1, Definition 4363.2, and Definition 4363.3 seed the finite partition-basin polynomial packet over displayed block-size, decoration, defect, product, specialization, incidence, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{PartitionBasinPolynomial}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a stochastic biology model, host generating-function oracle, quotient-level semantic equality, unbounded partition enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, product-formula exposure, four-coordinate specialization, incidence readback, transport, replay, provenance, and local naming for BEDC.Derived.PartitionBasinPolynomialUp.

Chapter 4364

A Concrete Naming Certificate for $\mathsf{DistanceToSet}^{\uparrow}$

Following Bishop and Bridges on located subsets in metric spaces, the $\mathsf{DistanceToSet}^{\uparrow}$ packet records the finite route by which a point-to-set distance request is read through displayed located-radius rows and closed-ball witnesses. It sits after the metric source of chapter 57, the located-set surface of chapter 1541, the metric closed-ball boundary of chapter 1451, the located closed-ball handoff of chapter 4063, and the terminal real-name seal of chapter 38. The packet names distance-to-set as finite BEDC data; it is not a host infimum, not a selected nearest point, not quotient real equality, and not a countable-choice construction.

Definition 4364.1 (Distance-to-set carrier)**.** *A* $\mathsf{DistanceToSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, A, x, r, B, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row over which point and subset reads are interpreted.*
2. *A is the* $\mathsf{LocatedSet}^{\uparrow}$ *row naming the subset by finite located-radius observations.*
3. *x is the displayed point row in the metric source.*
4. *r is the dyadic radius ledger recording the inspected tolerance windows.*
5. *B is the* $\mathsf{MetricClosedBall}^{\uparrow}$ *witness row attached to the point and radius ledger.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the exported distance name, read only after the located-set and closed-ball rows are displayed.*
7. *H records componentwise* hsame *transport for the metric source, located set, point row, dyadic ledger, closed-ball witness, Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from the metric source through located-set exposure, point inspection, dyadic-radius accounting, closed-ball handoff, and the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{DistanceToSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{LocatedClosedBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DistanceToSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, A, x, r, B, R, H, C, P, N$. It has no coordinate for a host infimum over all points of A, a selected nearest point, quotient real equality, countable choice, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.DistanceToSetUp.DistanceToSetTasteGate single carrier alignment`

Theorem 4364.2 (Distance-to-set NameCert obligations)**.** *For every accepted* $\mathsf{DistanceToSet}^{\uparrow}$ *carrier*

$$D = (X, A, x, r, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DistanceToSet}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the metric source, located set, point row, dyadic radius ledger, closed-ball witness, Real seal, transport, replay, provenance, and local naming;*
2. *located-set exposure, requiring every subset read to pass through the* $\mathsf{LocatedSet}^{\uparrow}$ *row A before a distance row is exported;*
3. *dyadic-radius monotonicity, requiring the tolerance ledger r to preserve the displayed radius order used by the located-set and closed-ball rows;*
4. *closed-ball handoff, requiring each ball membership or exclusion read to pass through the* $\mathsf{MetricClosedBall}^{\uparrow}$ *witness B and the located closed-ball sibling surface before the Real seal is read;*
5. *Real seal non-escape, requiring R to seal only the displayed distance name and not a host infimum or quotient real;*
6. *componentwise transport, displayed replay, package provenance, and local* NameCert *naming for exactly the displayed packet.*

No DistanceToSet obligation is stored outside these rows.

Proof. Project the carrier of Definition 4364.1. The metric source is X, the located subset is A, the inspected point is x, and the finite tolerance information is held by r.

The closed-ball witness B is read only after those rows are displayed. Its radius requests are therefore attached to the same metric source, located-set row, point row, and dyadic ledger.

The Real seal R comes after the located-radius and closed-ball rows. Transport H and replay C preserve the same order, while P and N record provenance and local naming.

Since no coordinate stores a host infimum, a nearest-point selector, quotient real equality, countable choice, or ambient completeness, those objects cannot become local NameCert obligations. □

Theorem 4364.3 (Distance-to-set located-radius handoff)**.** *Every consumer of an accepted* $\mathsf{DistanceToSet}^{\uparrow}$ *packet reads distance-to-set data only through the displayed located-radius row A, the dyadic radius ledger r, the closed-ball witness B, and the Real seal R, transported by H and replayed by C. The consumer cannot bypass these rows by reading a host infimum, a selected nearest point, quotient real equality, countable choice, or an ambient completeness principle.*

Proof. Read the carrier of Definition 4364.1. The only subset coordinate is the located-set row A, and the only radius coordinate is the dyadic ledger r.

The closed-ball witness B supplies the displayed ball boundary before the Real seal R is exposed. Thus a distance consumer reaches the exported real name only through the located-radius and closed-ball rows.

Apply Definition 4364.2. The transport, replay, provenance, and local naming rows preserve the same finite packet and add no host infimum, nearest-point selector, quotient real equality, countable choice, or ambient completeness data. □

Closure status for $\mathsf{NameCert}_{\mathsf{DistanceToSet}\uparrow}$.

Constructive story: A $\mathsf{DistanceToSet}^{\uparrow}$ packet is generated from a metric source, located set row, point row, dyadic radius ledger, closed-ball witness, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DistanceToSet}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4364.1, Definition 4364.2, and Definition 4364.3 seed the finite located-radius and closed-ball interface for distance-to-set consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DistanceToSet}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host infimum construction, selected nearest points, quotient real equality, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, located-set exposure, dyadic-radius monotonicity, closed-ball handoff, Real seal non-escape, transport stability, replay stability, provenance, and local naming for BEDC.Derived.DistanceToSetUp.

Chapter 4365

A Concrete Naming Certificate for $\mathsf{JordanCurve}^{\uparrow}$

Following Jordan and constructive topology, the $\mathsf{JordanCurve}^{\uparrow}$ packet records the finite polygonal and winding-ledger route by which a displayed simple closed curve in the real plane may be consumed as a separation boundary. It sits after the terminal real-name seal of chapter 38, the circle carrier of chapter 58, the graph and modulus rows of chapter 130, the finite compact-metric source of chapter 129, and the simplex inventory of chapter 238. The packet names a constructive finite obligation surface; it does not import classical open-cover compactness, selected complementary components, quotient path equality, or a choice-dependent separation theorem.

Definition 4365.1 (Jordan curve carrier)**.** *A* $\mathsf{JordanCurve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, F, P, W, O, I, E, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{S}^{1\uparrow}$ *source row, recording the circle parameter ledger and its local classifier.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row into the displayed* $\mathsf{Real}^{\uparrow} \times \mathsf{Real}^{\uparrow}$ *plane, with graph and modulus observations visible.*
3. *P is the finite polygonal approximation row, read through a* $\mathsf{SimplicialComplex}^{\uparrow}$ *subdivision and its vertex-image ledger.*
4. *W is the winding ledger, recording the finite edge-crossing and sign-change data used to compare test points with the polygonal boundary.*
5. *O is the orientation row, recording the compatible cyclic order inherited from the* $\mathsf{S}^{1\uparrow}$ *row and the polygonal subdivision.*
6. *I is the injectivity-apartness row, stating that distinct inspected arcs carry displayed positive separation windows before they are used by the boundary read.*
7. *E is the exterior-interior ledger, recording only the finite side classification certified by the current polygonal and winding rows.*
8. *H records componentwise* hsame *transport for $S, F, P, W, O, I, E, C, Q, N$.*
9. *C records displayed* Cont *replay from circle, map, polygonal, winding, orientation, and apartness rows to the side-classification row.*

10. *Q is the* Pkg *provenance over* $\mathsf{JordanCurve}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{JordanCurve}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, F, P, W, O, I, E, H, C, Q, N$. It has no coordinate for a host Jordan curve theorem, selected complementary components, open-cover compactness, arbitrary path lifting, quotient path equality, or countable-choice separation.

Lean4 ✓ `BEDC.Derived.JordanCurveUp.JordanCurveTasteGate single carrier alignment`

Theorem 4365.2 (Jordan curve orientation ledger)**.** *For every accepted* $\mathsf{JordanCurve}^{\uparrow}$ *carrier*

$$J = (S, F, P, W, O, I, E, H, C, Q, N),$$

the orientation row O is determined by the finite $\mathsf{S}^{1\uparrow}$ *cyclic order, the* $\mathsf{SimplicialComplex}^{\uparrow}$ *subdivision in P, and the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *edge-image ledger in F. The winding ledger W can read orientation only through those rows, transported by H and replayed by C.*

Proof. Project the accepted carrier. The only circle-facing coordinate is S, and the only finite boundary skeleton is the polygonal row P together with the displayed edge images in F.

The orientation row O is therefore read by following the cyclic order of S across the subdivision cells of P. Each edge-image comparison is a finite real-plane observation supplied by F, not by an ambient topological orientation principle.

The winding ledger W consumes that ordered edge list. Componentwise transport H and replay C preserve the same ordered rows, while Q and N record provenance and local naming. Since the carrier contains no host orientation object or quotient path coordinate, the finite ledger is the entire orientation source. □

Theorem 4365.3 (Jordan curve winding separation boundary)**.** *Every side-classification read from an accepted* $\mathsf{JordanCurve}^{\uparrow}$ *packet factors through the finite route*

$$S, F, P, O, I, W \longmapsto E \longmapsto H, C, Q, N.$$

Thus the packet exposes polygonal approximation, injectivity-apartness, orientation, and winding ledgers before it names an interior or exterior row. It does not assert a blanket classical Jordan separation theorem, selected complementary components, open-cover compactness, quotient path equality, or choice-dependent planar separation.

Proof. Read the carrier of Definition 4365.1. The curve source is S, the displayed map is F, and the finite polygonal boundary is P.

Before a side row is exported, the packet requires the orientation ledger O, injectivity-apartness row I, and winding ledger W. These rows are finite BHist data: the winding read uses edge crossings and signs already attached to the polygonal boundary.

The exterior-interior row E is downstream of that route. Transport, replay, provenance, and naming through H, C, Q, N preserve the same finite packet. The excluded host theorem, selected components, open covers, quotient paths, and choice rows are not coordinates of the carrier, so they cannot be read from the local NameCert surface. □

Falsifiable prediction: A $\mathsf{JordanCurve}^{\uparrow}$ consumer that exports side separation without reading P, W, O, I refutes the carrier surface.

Independence witness: real, sone, continuousmap, compactmetric, simplicialcomplex: the sibling chapters supply real-plane coordinates, circle source data, continuous graph and modulus rows, compact-metric finite inspection, and subdivision cells separately, while $\mathsf{JordanCurve}^{\uparrow}$ binds them into the finite packet $J = (S, F, P, W, O, I, E, H, C, Q, N)$.

Closure status for $\mathsf{NameCert}_{\mathsf{JordanCurve}\uparrow}$.

Constructive story: A $\mathsf{JordanCurve}^{\uparrow}$ packet is generated from a circle source row, continuous real-plane map row, finite polygonal subdivision, winding ledger, orientation row, injectivity-apartness row, side-classification ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JordanCurve}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4365.1, Definition 4365.2, and Definition 4365.3 seed the finite polygonal, winding, orientation, apartness, side-classification, transport, replay, provenance, and local naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JordanCurve}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.JordanCurveUp.JordanCurveTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, the classical Jordan curve theorem, selected complementary components, open-cover compactness, arbitrary path lifting, quotient path equality, or choice-dependent separation.

Upgrade path: Obligation closure requires checked carrier admission, polygonal approximation exactness, winding-ledger stability, orientation transport, injectivity-apartness handoff, side-classification non-escape, replay, provenance, and local naming for BEDC.Derived.JordanCurveUp.

Chapter 4366

A Concrete Naming Certificate for MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$

The MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ packet realizes the normalization remaining question of chapter 9386 as finite NameCert data. It sits beside the candidate-set packet of chapter 2320 and the normalization router of chapter 1108: those siblings expose candidate evidence and route selection, while this packet records the boundary where empty-context closed typed terms may or may not enter the candidate interface. The packet names a closed-projection frontier only; it does not turn candidate-mediated normalization into an unconditional strong-normalization theorem for every closed MetaCIC term.

Definition 4366.1 (MetaCIC candidate closed-projection boundary carrier)**.** *A* MetaCICCandidateClosedProjection *carrier is a finite* BHist *packet*

$$B = (T, K, R, E, NF, O, H, C, P, L)$$

with the following displayed rows:

1. *T is the empty-context typed closed-term row whose projection into the candidate interface is being tested.*
2. *K is the candidate-set evidence row, read through* CandidateSetNormalization$^{\uparrow}$ *when the projection is admitted.*
3. *R is the router row, read through* MetaCICNormalizationCertificateRouter$^{\uparrow}$ *and recording which candidate, closed-candidate, or candidate-set route is exposed.*
4. *E is the bounded-normal endpoint seal row, recording the finite normal-output evidence available after candidate admission.*
5. *NF is the no-infinite-reduction row exported only downstream of K, R, E.*
6. *O is the obstruction row recording refusal when the closed term cannot be placed into the displayed candidate interface.*
7. *H records componentwise* hsame *transport for $T, K, R, E, NF, O, C, P, L$.*
8. *C records displayed* Cont *replay from the closed-term row through candidate admission, router selection, endpoint seal, no-infinite-reduction read, and obstruction retention.*

9. *P is the* Pkg *provenance over* MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$, CandidateSetNormalization$^{\uparrow}$, MetaCICNormalizationCertificateRouter$^{\uparrow}$, MetaCICOpenProblemLedger$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* NameCert$_{\text{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, K, R, E, NF, O, H, C, P, L$. It has no coordinate for evidence-free closed-term strong normalization, unrestricted subject reduction, host reduction equality, quotient conversion, or a global normalizer.

Lean4 ✓ `BEDC.Derived.MetaCICCandidateClosedProjectionBoundaryUp.MetaCICCandidateClosedProjectionBoundar`
`single carrier alignment`

Theorem 4366.2 (MetaCIC candidate-set closed projection frontier)**.** *For every accepted* MetaCICCandidateClosed *carrier*

$$B = (T, K, R, E, NF, O, H, C, P, L),$$

the closed-term row T reaches a strong-normalization-facing read only through candidate evidence K, router selection R, and bounded-normal endpoint seal E. If those rows do not place T inside the candidate interface, the obstruction row O is the only exported boundary datum.

Proof. Project the carrier. The closed-term row T is present as a finite syntactic and typing packet, but it is not itself a normalization theorem.

The positive route first reads K through chapter 2320. The router row R then records the candidate, closed-candidate, or candidate-set branch through chapter 1108. Only after those rows are displayed can the endpoint seal E and no-infinite-reduction row NF be consumed.

If candidate admission is absent, O records the refusal. Transport, replay, provenance, and local naming through H, C, P, L preserve that same finite boundary, so the packet exports no evidence-free closed-term strong-normalization claim. □

Theorem 4366.3 (MetaCIC candidate-set SN handoff boundary)**.** *Every strong-normalization handoff exported by an accepted* MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ *packet is a handoff for rows already inside the displayed candidate interface. It cannot be read as a blanket theorem that all empty-context typed closed MetaCIC terms are strongly normalizing.*

Proof. Start with the frontier theorem. It places the normalization-facing route behind K, R, E and keeps the obstruction row O visible when the candidate interface is not supplied.

For an admitted row, the handoff consumes candidate evidence from CandidateSetNormalization$^{\uparrow}$ and route evidence from MetaCICNormalizationCertificateRouter$^{\uparrow}$. The no-infinite-reduction row NF is therefore downstream of the admitted candidate branch rather than a second source of normalization evidence.

For a closed term outside that interface, the carrier has only T and the obstruction row O on the boundary. The structural rows H, C, P, L transport, replay, source, and name the boundary, but they do not add subject reduction, host conversion equality, quotient reduction equality, or a global normalizer. Hence the handoff is candidate-scoped. □

Theorem 4366.4 (MetaCIC candidate-set public boundary)**.** *Any public no-infinite-reduction or strong-normalization read from an accepted* MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ *packet must cite candidate-set membership or soundness, router selection, and bounded-normal endpoint rows. A bare empty-context typed closed-term row T is insufficient: the public boundary may expose NF only downstream of the candidate-set facts named by* closed_typed_term_sn_from_candidateSet, candidateSet_implies_sn, *and* canonicalCandidateSet_sound *together with the router row R and endpoint seal E.*

Proof. Start with Definition 4366.2. It places every normalization-facing read behind the candidate evidence row K, router row R, and endpoint seal E, and leaves the obstruction row O as the only datum when candidate admission is absent.

Next apply Definition 4366.3. That theorem identifies the handoff as a candidate-interface handoff rather than a theorem about all empty-context closed typed rows. Thus the public NF row cannot be projected from T alone.

Finally read the MetaCIC normalization audit map through the existing candidate-set facts closed_typed_term_sn_from_candidateSet, candidateSet_implies_sn, and canonicalCandidateSet_sound. Those facts supply the candidate membership and soundness side of the route, while R and E supply the public router and endpoint rows. The resulting boundary is therefore candidate-mediated and evidence-bearing, not an unconditional closed-term normalizer. □

Falsifiable prediction: A MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ consumer that exports strong normalization from T without reading K, R, E refutes the carrier surface.

Independence witness: candidate-set-normalization, metacicnormalizationcertificaterouter, metacicopenproblemledger: the candidate-set packet carries candidate evidence, the router selects the admissible normalization route, and the open-problem ledger records the frontier question; this packet binds those rows into a closed-projection boundary without adding an evidence-free normalization theorem.

Closure status for NameCert$_{\text{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}}$.

Constructive story: A MetaCICCandidateClosedProjectionBoundary$^{\uparrow}$ packet is generated from an empty-context typed closed-term row, candidate-set evidence, normalization-router selection, bounded-normal endpoint seal, no-infinite-reduction row, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 4366.1, Definition 4366.2, Definition 4366.3, and Definition 4366.4 seed the finite closed-projection, candidate-evidence, router-selection, endpoint-seal, obstruction, public-boundary, transport, replay, provenance, and local naming surface.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICCandidateClosedProjectionBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, unconditional strong normalization for all closed typed MetaCIC terms, unrestricted subject reduction, host reduction equality, quotient conversion, or a global normalizer.

Upgrade path: Obligation closure requires checked closed-term projection, candidate-evidence admission, router selection, bounded-normal endpoint sealing, no-infinite-reduction handoff, obstruction exactness, replay, provenance, and local naming for BEDC.Derived.MetaCICCandidateClosedProjectionBoundaryUp.

Chapter 4367

A Concrete Naming Certificate for $\mathsf{PointedMetricSpace}^{\uparrow}$

Following Bourbaki and Kelley on based metric spaces, the $\mathsf{PointedMetricSpace}^{\uparrow}$ packet records a metric carrier together with a named basepoint route before completion, loop-space, or embedding consumers are allowed to inspect point-level data. It sits over the $\mathsf{Met}^{\uparrow}$ carrier of chapter 57, reads names through the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, passes regular rational distance observations through chapter 301 and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and offers a based source for the distance-preserving consumer route of chapter 439. The certificate names only finite BEDC rows; it does not import host points, quotient metric equality, selected representatives, or ambient completeness.

Definition 4367.1 (Pointed metric space carrier)**.** *A* $\mathsf{PointedMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, b, D, S, R, E, H, C, P_0, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *metric carrier row.*
2. *b is the basepoint name row, stored as finite BEDC data attached to M rather than as a host-level point.*
3. *D is the basepoint distance ledger, recording the finite requests that compare b with inspected metric names.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which basepoint and metric names are inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed distance windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the basepoint-distance observations.*
7. *H records componentwise* hsame *transport for M, b, D, S, R, E and the local certificate rows.*
8. *C records displayed* Cont *replay from a based metric request through the stream windows, regular rational readback, and real-distance seal.*
9. *P_0 is the* Pkg *provenance over* $\mathsf{PointedMetricSpace}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only after transporting the metric carrier, basepoint name, distance ledger, stream windows, regular readback, real seal, replay, provenance, and local naming rows together.

Lean4 ✓ `BEDC.Derived.PointedMetricSpaceUp.PointedMetricSpaceTasteGate single carrier alignment`

Theorem 4367.2 (Pointed metric space NameCert obligations)**.** *For every accepted* $\mathsf{PointedMetricSpace}^{\uparrow}$ *carrier* $P = (M, b, D, S, R, E, H, C, P_0, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the metric row, basepoint name, basepoint distance ledger, stream windows, regular rational readback, real-distance seal, transport, replay, provenance, and local naming rows;*
2. *common-carrier classification, requiring every comparison of basepoint data to be read over the transported metric row* M*;*
3. *basepoint-distance exposure, requiring every basepoint comparison to pass through* D, S, R, E *before any completion-facing or embedding-facing consumer reads it;*
4. *package provenance and local naming for exactly the displayed finite packet.*

No NameCert obligation is stored in a host point, quotient metric equality, a selected representative, or an ambient completeness principle.

Proof. Project the carrier of Definition 4367.1. The projection exposes the metric row, basepoint name, distance ledger, stream windows, regular readback, real seal, transport, replay, provenance, and local name as the only available coordinates.

The classifier route is common-carrier. Componentwise transport in H moves M, b, D, S, R, E together, so a consumer cannot compare a basepoint name over one metric carrier with distance observations over another.

The distance ledger fixes the read order. A basepoint comparison is first a finite request in D, then a scheduled stream observation in S, then a regular rational readback in R, and only then a $\mathsf{Real}^{\uparrow}$ distance seal in E.

Finally replay C and attach P_0, N. Since the carrier has no coordinate for host points, quotient equality, selected representatives, or ambient completeness, the listed rows exhaust the local naming surface. □

Theorem 4367.3 (Pointed metric space basepoint nonescape)**.** *Let* $P = (M, b, D, S, R, E, H, C, P_0, N)$ *be an accepted* $\mathsf{PointedMetricSpace}^{\uparrow}$ *carrier. Every completion-facing, loop-space-facing, or isometric-embedding-facing consumer of the basepoint row* b *must read it through the displayed route*

$$M, b, D \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P_0, N.$$

Thus the basepoint is exported only as finite named metric data over M*, not as a host point, quotient representative, selected completion point, or ambient metric-equality witness.*

Proof. Begin with carrier admission. The only row naming the basepoint is b, and it is stored beside the metric carrier M and distance ledger D.

Read the inspection route next. The stream windows S and regular rational readback R display every observed distance from the basepoint before the $\mathsf{Real}^{\uparrow}$ seal E is available to downstream consumers.

Transport and replay preserve that same route. The rows H, C, P_0, N move, replay, source, and name the displayed packet; they do not add host points, quotient representatives, selected completion points, or ambient metric equality.

Therefore every based consumer receives exactly the finite route displayed in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{PointedMetricSpace}^{\uparrow}$ packet is generated from a $\mathsf{Met}^{\uparrow}$ carrier, a named basepoint row, a basepoint distance ledger, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ distance seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4367.1, Definition 4367.2, and Definition 4367.3 seed the based metric route over $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointedMetricSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.PointedMetricSpaceUp.PointedMetricSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host point equality, quotient metric equality, selected completion points, loop-space closure, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, basepoint-distance exposure, classifier transport, basepoint nonescape, and downstream completion and isometric-embedding consumer alignment for BEDC.Derived.PointedMetricSpaceUp.

Chapter 4368

A Concrete Naming Certificate for $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$

Following Bourbaki and Kelley on based complete metric spaces, the $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ packet records a based metric carrier together with a displayed completion service before completion, loop-space, or embedding consumers are allowed to read a point as complete. It sits over the $\mathsf{Met}^{\uparrow}$ carrier of chapter 57, the $\mathsf{CompleteMetric}^{\uparrow}$ limit-service boundary of chapter 128, the $\mathsf{PointedMetricSpace}^{\uparrow}$ basepoint route of chapter 4367, the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ rational readback of chapter 301, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The certificate names only finite BEDC rows; it does not import host points, quotient metric equality, selected completion representatives, countable choice, or ambient order completeness.

Definition 4368.1 (Pointed complete metric space carrier)**.** *A* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, B, Q, S, R, E, L, H, C, P_0, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *metric carrier row.*
2. *B is the basepoint row, stored as finite named metric data over M rather than as a host-level point.*
3. *Q is the Cauchy-window route, listing the finite tail requests through which regular Cauchy names based at B are inspected.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *readback row for the basepoint and Cauchy windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational distance and modulus observations.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed metric-distance and limit-distance observations.*
7. *L is the* $\mathsf{CompleteMetric}^{\uparrow}$ *completion seal, exposing only the displayed limit-service handoff for the Cauchy-window route Q.*
8. *H records componentwise* hsame *transport for M, B, Q, S, R, E, L and the local certificate rows.*
9. *C records displayed* Cont *replay from a based complete-metric request through the Cauchy windows, stream observations, regular rational readback, real seal, and completion seal.*

10. *P_0 is the* Pkg *provenance over* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PointedMetricSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only after transporting the metric carrier, basepoint, Cauchy-window route, stream windows, regular rational readback, real seal, completion seal, replay, provenance, and local naming rows together.

Lean4 ✓ `BEDC.Derived.PointedCompleteMetricSpaceUp.TasteGate.PointedCompleteMetricSpaceTasteGate single carrier alignment`

Theorem 4368.2 (Pointed complete metric space NameCert obligations)**.** *For every accepted* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *carrier* $P = (M, B, Q, S, R, E, L, H, C, P_0, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSp}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the metric row, basepoint row, Cauchy-window route, stream windows, regular rational readback, real seal, completion seal, transport, replay, provenance, and local naming rows;*
2. *common-carrier classification, requiring the basepoint row, Cauchy windows, and completion seal to be read over the transported metric row M;*
3. *Cauchy-window exposure, requiring every completion-facing read to pass through Q, S, R, E, L before any downstream consumer may inspect the limit handoff;*
4. *package provenance and local naming for exactly the displayed finite packet.*

No NameCert obligation is stored in a host point, quotient metric equality, selected completion representative, countable-choice selector, or ambient order-completeness principle.

Proof. Project the carrier of Definition 4368.1. The projection exposes the metric row, basepoint, Cauchy-window route, stream windows, regular readback, real seal, completion seal, transport, replay, provenance, and local name as the only available coordinates.

The classifier route is common-carrier. Componentwise transport in H moves M, B, Q, S, R, E, L together, so a consumer cannot compare a based Cauchy route over one metric carrier with a completion seal over another.

The completion-facing read order is fixed by the route rows. A completion request begins as a finite Cauchy-window request in Q, becomes a scheduled stream observation in S, is read back as regular rational data in R, is sealed as real-distance data in E, and only then reaches the $\mathsf{CompleteMetric}^{\uparrow}$ limit-service row L.

Finally replay C and attach P_0, N. Since the carrier has no coordinate for host points, quotient equality, selected completion representatives, countable-choice selectors, or ambient order completeness, the listed rows exhaust the local naming surface. □

Theorem 4368.3 (Pointed complete metric space Cauchy basepoint route)**.** *Let $P = (M, B, Q, S, R, E, L, H, C, P_0$ be an accepted* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *carrier. Every based regular Cauchy request whose initial window is anchored at B is read through the displayed route*

$$M, B, Q \longmapsto S \longmapsto R \longmapsto E \longmapsto L \longmapsto H, C, P_0, N.$$

Thus the basepoint participates in completion only as named metric and Cauchy-window data over M, not as a selected host point or completed-limit representative.

Lean4 ✓ `BEDC.Derived.PointedCompleteMetricSpaceUp.PointedCompleteMetricSpaceCauchyBasepointRoute`

Proof. Begin with carrier admission. The only row naming the basepoint is B, and it is stored beside the metric row M and the Cauchy-window route Q.

Read the window route next. The stream row S schedules the inspected windows, the regular rational row R reads the tail and distance ledgers, and the $\mathsf{Real}^{\uparrow}$ row E seals the observed distances before the complete-metric row L can expose any limit-service handoff.

Transport and replay preserve that same path. The rows H, C, P_0, N move, replay, source, and name the displayed packet; they do not add a host basepoint, a selected limit representative, quotient equality, or a separate completion object.

Therefore every based Cauchy consumer receives exactly the finite route displayed in the statement. □

Theorem 4368.4 (Pointed complete metric basepoint completion handoff)**.** *Let $P = (M, B, Q, S, R, E, L, H, C, P_0$ and $P' = (M', B', Q', S', R', E', L', H', C', P'_0, N')$ be accepted* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *carriers. If the two packets transport M, B, Q, S, R, E through the same componentwise H row, then every* $\mathsf{CompleteMetric}^{\uparrow}$ *service read of L is taken over that same named basepoint route before any loop-space or embedding consumer may inspect a completed point.*

Equivalently, a consumer may inspect

$$L \quad \text{or} \quad L'$$

only after the route

$$M, B, Q, S, R, E \longmapsto H, C, P_0, N$$

has been displayed; it cannot detach completion service from the transported basepoint row.

Proof. Project both carriers. In each packet the completion-service coordinate is L, and the only rows upstream of it are the metric row M, the basepoint row B, the Cauchy-window row Q, the stream row S, the regular rational row R, and the real-distance seal E.

Apply Definition 4368.3 to the first packet. The displayed route forces every based Cauchy request to pass through M, B, Q, S, R, E before the service row L is visible.

Use the assumed componentwise transport row H to move the same route to the second packet. The replay row C then reproduces the transported route for the completion-facing consumer, and the provenance and local name rows P_0, N record no independent completed point.

Thus a loop-space or embedding consumer can inspect a completed point only after the transported basepoint route has been displayed. There is no carrier coordinate from which the consumer could read L apart from B. □

Theorem 4368.5 (Pointed complete metric space completion nonescape)**.** *Every completion-facing, loop-space-facing, or embedding-facing consumer of an accepted* $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ *packet factors its completed-point read through*

$$M, B, Q, S, R, E, L, H, C, P_0, N.$$

Consequently the packet exports a based complete metric certificate only as finite BEDC NameCert data; it exports neither host points nor quotient completion equality.

Proof. Inspect the carrier coordinates. The only completion coordinate is L, and the definition makes L a completion seal for the already displayed Cauchy-window route Q over the metric row M and basepoint row B.

The readback rows precede the completion seal. Any consumer must first pass through S, R, E to display stream windows, regular rational ledgers, and real distance seals, so no completed point can be read before the finite analytic route is visible.

The remaining rows are administrative in the BEDC sense. Transport H, replay C, provenance P_0, and local name N preserve and source the packet but do not create host points, quotient completion equality, selected representatives, or ambient completeness.

Thus every downstream completed-point read factors through the displayed finite packet, which proves completion nonescape. □

Closure status for $\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{PointedCompleteMetricSpace}^{\uparrow}$ packet is generated from a MetricUp carrier, a named basepoint row, a Cauchy-window route, StreamName windows, RegSeqRat readback, a RealUp seal, a CompleteMetricUp completion seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4368.1, Definition 4368.2, Definition 4368.3, and Definition 4368.5 seed the based complete-metric route over $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PointedMetricSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointedCompleteMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient completion equality, selected host endpoints, loop-space closure, embedding closure, or ambient order completeness.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-window exposure, classifier transport, basepoint completion routing, completion nonescape, and downstream completion, loop-space, and embedding consumer alignment for BEDC.Derived.PointedCompleteMetricSpaceUp.

Chapter 4369

A Concrete Naming Certificate for $\mathsf{IntervalConnectedness}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{IntervalConnectedness}^{\uparrow}$ packet records the finite constructive route by which a located real interval is inspected as one connected interval surface before intermediate-value, zero-envelope, or completion-facing consumers use it. It sits after the endpoint seal of chapter 38, the located interval carrier of chapter 1709, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the sandwich consumer surface of chapter 2163. The packet names interval connectedness as displayed finite BEDC data; it does not import host topology, open-cover compactness, trichotomy, quotient real equality, selected roots, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4369.1 (Interval connectedness carrier)**.** *An* $\mathsf{IntervalConnectedness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (E, L, D, S, R, T, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint-pair row, storing the lower and upper endpoint names through their displayed real seals.*
2. *L is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *witness row, carrying the located interval budget, locator reads, and endpoint-radius checks attached to E.*
3. *D is the finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *subdivision-chain ledger, recording the dyadic cells, adjacent-cell overlaps, and tolerance requests inspected inside L.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which endpoint, cell, and witness observations are scheduled.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the scheduled endpoint and subdivision observations.*
6. *T records componentwise* hsame *transport for endpoint pairs, located interval witnesses, dyadic subdivision chains, stream windows, regular readbacks, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from endpoint pairs through located interval exposure, dyadic subdivision, stream-window inspection, regular readback, and the interval-connectedness handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{IntervalConnectedness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{SqueezeTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{IntervalConnectedness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, L, D, S, R, T, C, P, N$. It has no coordinate for host topological connectedness, open-cover compactness, trichotomy, quotient real equality, selected intermediate points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.IntervalConnectednessUp.IntervalConnectednessTasteGate single carrier alignment`

Theorem 4369.2 (Interval connectedness NameCert obligations)**.** *For every accepted* $\mathsf{IntervalConnectedness}^{\uparrow}$ *carrier*

$$I = (E, L, D, S, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{IntervalConnectedness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the endpoint pair, located interval witness, dyadic subdivision chain, stream windows, regular readbacks, transport, replay, provenance, and local naming rows;*
2. *classifier transport, requiring endpoint, locatedness, subdivision, window, readback, replay, provenance, and naming data to move componentwise through T;*
3. *dyadic chain exactness, requiring every inspected subinterval and adjacent-cell overlap to be recorded in D before a connectedness consumer reads the packet;*
4. *endpoint handoff nonescape, requiring every consumer of interval endpoints to pass through E, L, D, S, R before using any* $\mathsf{Real}^{\uparrow}$ *seal;*
5. *ledger exhaustion, requiring the packet to expose no host topological connectedness theorem, open-cover compactness, trichotomy, quotient real equality, selected intermediate point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

The sibling routes through $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{SqueezeTheorem}^{\uparrow}$ *are the only named consumers of this local certificate surface.*

Proof. Project the carrier of Definition 4369.1. The endpoint pair is visible only in E, and the located interval evidence is visible only in L.

The subdivision data are then forced through D. Each finite cell, overlap, and tolerance request is read as dyadic data before any stream-window or regular-readback consumer can inspect it.

Transport and replay preserve the same route. The rows T and C move endpoint, locatedness, subdivision, window, and readback data componentwise, while P and N source and name exactly that displayed packet.

Since the carrier has no coordinate for the excluded host principles, the local certificate cannot export them. □

Falsifiable prediction: Every accepted $\mathsf{IntervalConnectedness}^{\uparrow}$ consumer reads endpoint pairs, located interval witnesses, dyadic subdivision chains, StreamName windows, RegSeqRat readbacks, hsame transport, Cont replay, Pkg provenance, and local naming before any interval-connectedness handoff is visible.

Independence witness: real, locatedrealinterval, dyadicratcore, streamname, regseqrat, squeezetheorem: $\mathsf{IntervalConnectedness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint pairs, located interval witnesses, finite dyadic subdivision chains, scheduled stream windows, regular rational readbacks, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalConnectedness}^{\uparrow}}$.

Constructive story: An IntervalConnectedness$^{\uparrow}$ packet is generated from Real endpoint pairs, a LocatedRealInterval witness, a finite DyadicRatCore subdivision chain, StreamName windows, RegSeqRat readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\text{IntervalConnectedness}^{\uparrow}}$, seed)

Scope closed: Definition 4369.1 and Definition 4369.2 seed the finite located-interval connectedness route over Real$^{\uparrow}$, LocatedRealInterval$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and SqueezeTheorem$^{\uparrow}$ rows.

Formal verification: FormalStatus(NameCert$_{\text{IntervalConnectedness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host topology, open-cover compactness, trichotomy, quotient real equality, selected intermediate points, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, dyadic chain exactness, endpoint handoff nonescape, ledger exhaustion, and downstream intermediate-value consumer alignment for BEDC.Derived.IntervalConnectedness

Chapter 4370

A Concrete Naming Certificate for MetaCICResidualSubstitutionCompatibility$^{\uparrow}$

Following Tait–Martin-Lof and Barendregt on residuals, parallel reduction, and confluence discipline, the MetaCICResidualSubstitutionCompatibility$^{\uparrow}$ packet records the finite boundary where a beta-parallel branch and a substitution replay must meet before the MetaCIC confluence route may use the conditional diamond bridge. It sits over the audit map of chapter 9378 and names the residual-substitution input as packet data rather than as a global Church–Rosser theorem. The packet does not claim full closed Church–Rosser, arbitrary closed-source confluence, or an unrestricted substitution theorem.

The residual-substitution packet is consumed by chapter 765 as a guarded input to candidate-mediated SN/confluence scheduling. The dependency is the residual join row together with the closedness guard data: it tells the scheduler which finite substitution replay may enter a candidate branch and which source windows are closed enough for that handoff, not that the full Church–Rosser theorem has already been completed.

Definition 4370.1 (MetaCIC residual-substitution compatibility carrier)**.** *A* MetaCICResidualSubstitutionCompatil *carrier is a finite* BHist *packet*

$$M = (s, t, b, j, g, a, h, c, p, n)$$

with the following displayed rows:

1. *s is the source term row whose beta-parallel residual branch is inspected.*
2. *t is the substituted term row, storing the finite substitution request and the target occurrence window.*
3. *b is the parallel branch row, displaying the left and right beta-parallel steps before any join is named.*
4. *j is the residual join row, recording the candidate common reduct obtained after substitution replay and residual transport.*
5. *g is the closedness guard row, saying exactly which source and substitution windows are closed enough for the guarded handoff.*
6. *a is the atom-shape separation row, keeping atom, application, lambda, Pi, and beta-redex cases visibly disjoint.*
7. *h records componentwise* hsame *transport for source, substitution, branch, residual join, closedness guard, atom-shape separation, replay, provenance, and local naming rows.*

8. *c records displayed* Cont *replay from the source term through substitution, parallel branching, residual join construction, closedness guarding, and atom-shape separation.*
9. *p is the* Pkg *provenance over* MetaCICResidualSubstitutionCompatibility$^{\uparrow}$*, MetaCIC beta-parallel reduction, residual joins, closedness guards, atom-shape separation,* BHist*,* hsame*,* Cont*, and* NameCert*.*
10. *n is the local* NameCert$_{\text{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $s, t, b, j, g, a, h, c, p, n$. It has no coordinate for a completed parallel diamond, full closed Church–Rosser, arbitrary closed-source confluence, or an unguarded substitution principle.

Lean4 ✓ BEDC.Derived.MetaCICResidualSubstitutionCompatibilityUp.MetaCICResidualSubstitutionCompatibilit
single carrier alignment

Theorem 4370.2 (MetaCIC residual-substitution compatibility NameCert obligations)**.** *For every accepted* MetaCICResidualSubstitutionCompatibility$^{\uparrow}$ *carrier*

$$M = (s, t, b, j, g, a, h, c, p, n),$$

the local NameCert$_{\text{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source term, substituted term, parallel branch, residual join, closedness guard, atom-shape separation, transport, replay, provenance, and local naming rows;*
2. *branch-shape disjointness, requiring atom, application, lambda, Pi, and beta-redex branches to be separated by a before a residual join row is accepted;*
3. *substitution residual replay, requiring c to display how the substituted term row and beta-parallel branch row reach the same candidate join j;*
4. *closed-source guard, requiring g to expose the exact closedness assumptions consumed by the guarded compatibility packet;*
5. *non-claim of full closed Church–Rosser, requiring the packet to remain an input boundary for the conditional confluence bridge rather than a proof of arbitrary closed-source confluence.*

No obligation is stored outside $s, t, b, j, g, a, h, c, p, n$.

Proof. Project the carrier of Definition 4370.1. The source term, substituted term, branch, residual join, closedness guard, and atom-shape separation rows are the only computational coordinates.

The branch-shape row a fixes the case split before the join row is read. Thus a beta-redex residual branch cannot be silently identified with an atom, application, lambda, or Pi shape.

Replay then supplies the compatibility boundary. The row c records the finite route from substitution and beta-parallel branching to the candidate join j, while g states the closedness guard consumed by that route.

Finally h, p, n transport, source, and name exactly the displayed packet. Since full closed Church–Rosser and arbitrary closed-source confluence are not carrier coordinates, they are not exported by this NameCert surface. □

Theorem 4370.3 (MetaCIC residual-substitution candidate projection route)**.** *Every accepted* MetaCICResidualSubstitutionCompatibility$^{\uparrow}$ *carrier*

$$M = (s, t, b, j, g, a, h, c, p, n)$$

exports a candidate-closed projection route to chapter 4366 only after the source term row s, substituted term row t, beta-parallel branch row b, residual join row j, closedness guard row g, and atom-shape separation row a have all been displayed. The downstream candidate boundary receives a guarded compatibility packet, not full Church–Rosser and not arbitrary closed-source confluence.

Proof. Project the carrier of Definition 4370.1. The rows s, t, b, j, g, a are the only computational rows available before the structural transport, replay, provenance, and local naming rows are read.

Use Definition 4370.2. Branch-shape disjointness exposes a, substitution residual replay exposes the route from t and b to j, and the closed-source guard exposes exactly the assumptions in g.

The candidate boundary of chapter 4366 is therefore reached through a guarded compatibility packet. The route supplies source, substitution, beta-parallel, residual-join, closedness, and atom-shape data, while h, c, p, n only transport, replay, source, and name those rows.

Since completed Church–Rosser and arbitrary closed-source confluence are absent from the carrier, the candidate-closed projection route cannot export them. It hands off only the displayed residual-substitution compatibility boundary. □

Theorem 4370.4 (MetaCIC residual-substitution obligation closure surface)**.** *For every accepted* $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ *carrier*

$$M = (s, t, b, j, g, a, h, c, p, n),$$

the obligation surface is exactly the displayed source term, substituted term, parallel branch, residual join, closedness guard, atom-shape separation, transport, replay, provenance, and naming rows. The candidate-closed projection boundary receives only this guarded compatibility packet.

Proof. Apply Definition 4370.2. It identifies carrier admission, branch-shape disjointness, substitution residual replay, closed-source guarding, transport, replay, provenance, and naming as rows of $s, t, b, j, g, a, h, c, p, n$.

Apply Definition 4370.3. The candidate boundary receives the source, substitution, beta-parallel branch, residual-join, closedness, and atom-shape data only through that guarded projection route.

Therefore the obligation surface packages the candidate handoff without exporting full closed Church–Rosser, arbitrary closed-source confluence, or unguarded substitution compatibility. Those claims are not coordinates of the carrier and are not supplied by the candidate projection. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ read displays source term, substituted term, parallel branch, residual join, closedness guard, atom-shape separation, hsame transport, Cont replay, Pkg provenance, and local naming rows before the conditional MetaCIC confluence bridge can consume it.

Independence witness: metacic-confluence-audit: $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ is not a completed confluence theorem because it carries only the finite residual-substitution compatibility boundary consumed by the conditional parallel-diamond route.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ packet is generated from source term, substituted term, parallel branch, residual join, closedness guard, atom-shape separation, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4370.1, Definition 4370.2, and Definition 4370.3 seed the finite residual-substitution compatibility boundary consumed by the conditional MetaCIC confluence bridge and the candidate-closed projection route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full closed Church–Rosser, arbitrary closed-source confluence, unguarded substitution compatibility, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch-shape disjointness, substitution residual replay, closed-source guard, and conditional confluence handoff alignment for BEDC.MetaCIC.BetaParallelSubstitutionCompatibility.

Chapter 4371

A Concrete Naming Certificate for $\mathsf{ComputableCompactMetric}^{\uparrow}$

Following Weihrauch-style computable analysis and the Bishop–Bridges compact metric arguments, the $\mathsf{ComputableCompactMetric}^{\uparrow}$ packet records the effective compact-metric surface as finite BEDC NameCert data. It sits after the compact metric carrier of chapter 129, the effective Polish source of chapter 1706, the total-bounded finite-net route of chapter 127, the complete metric source of chapter 128, and the L10 readback route through chapter 126, chapter 301, and chapter 38. The packet names the finite-cover realizer surface consumed by effective compact analysis; it does not assert open-cover compactness, selected subcovers, quotient completion equality, or an ambient real-completeness principle.

Definition 4371.1 (Computable compact metric carrier)**.** *A* $\mathsf{ComputableCompactMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K_{\mathrm{ccm}} = (K, E, T, C, S, R, L, H, Q, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row carrying the compact metric packet whose finite-net behavior is being made effective.*
2. *E is the* $\mathsf{EffectivePolishSpace}^{\uparrow}$ *source row exposing the effective dense-name and semidecidable basic-ball interface.*
3. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *row naming the finite-net source for each displayed dyadic tolerance request.*
4. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row recording the convergence service available to Cauchy and compact consumers.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for inspected dense names, finite net centers, tolerance requests, and cover indices.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the regular rational readback of distances and tolerance comparisons.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite windows and regular rational comparisons have been displayed.*

8. *H records componentwise* hsame *transport for compact metric, effective Polish, total-bounded, complete-metric, stream-window, regular-readback, real-seal, finite-cover realizer, provenance, and local naming rows.*
9. *Q records displayed* Cont *replay from an effective compactness request through K, E, T, C, S, R, L, H.*
10. *P is the* Pkg *provenance over* $\mathsf{ComputableCompactMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{EffectivePolishSpace}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, E, T, C, S, R, L, H, Q, P, N$. It has no coordinate for an open-cover subcover, a choice-selected finite set, quotient completion equality, excluded-middle compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ComputableCompactMetricUp.ComputableCompactMetricTasteGate single carrier alignment`

Theorem 4371.2 (Computable compact metric NameCert obligations)**.** *For every accepted* ComputableCompactMe *carrier*

$$K_{\mathrm{ccm}} = (K, E, T, C, S, R, L, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}$ *surface consists exactly of the displayed rows in Definition 4371.1. Carrier admission must expose the compact metric source, effective Polish source, total-bounded finite-net source, complete-metric convergence service, finite stream windows, regular rational readback, terminal real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Classifier transport is componentwise through those same rows, and ledger exhaustion says that every finite-cover or compact-analysis consumer can inspect only $K, E, T, C, S, R, L, H, Q, P, N$.*

Proof. Project the carrier of Definition 4371.1. The rows K, E, T, C are the only structural compactness sources, so carrier admission exposes compact metric data, effective Polish naming data, total-bounded finite nets, and complete-metric convergence before any realizer can be read.

The readback rows S, R, L then bind numerical access to finite windows, regular rational comparisons, and the terminal real seal. This is the same L10 readback discipline used by the StreamName, RegSeqRat, and Real siblings named in the chapter introduction.

Transport and replay are visible rows rather than hidden meta-operations. The row H records componentwise hsame transport, Q records displayed Cont replay, and P, N source and name the same finite packet.

For ledger exhaustion, read any compact-analysis consumer from the accepted packet. The carrier exposes only $K, E, T, C, S, R, L, H, Q, P, N$, so no open-cover subcover, selected finite set, quotient completion equality, excluded-middle compactness, or ambient real-completeness principle can be obtained from this NameCert surface. □

Theorem 4371.3 (Computable compact metric finite-cover realizer)**.** *Every effective finite-cover read exported by an accepted* $\mathsf{ComputableCompactMetric}^{\uparrow}$ *packet factors through the route*

$\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{EffectivePolishSpace}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsa

Thus a consumer receives a compact metric source, effective dense-name interface, total-bounded finite-net source, complete-metric convergence service, finite stream windows, regular rational tolerance comparisons, terminal real seal, componentwise transport, replay, provenance, and local

naming rows before it uses the finite-cover realizer. The packet exports no selected subcover, open-cover compactness theorem, quotient completion representative, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with an accepted carrier $K_{\mathrm{ccm}} = (K, E, T, C, S, R, L, H, Q, P, N)$. The compact metric row K and effective Polish row E name the metric and effective dense-name surfaces, while T supplies the finite-net source used for the requested tolerance.

The convergence row C keeps the compact route compatible with complete-metric consumers. A finite-cover realizer cannot leave these displayed sources, because the later rows are read only after the compact, effective, total-bounded, and complete rows are present.

The numerical readback is finite. The stream row S exposes inspected names, center windows, cover indices, and tolerance requests; the regular rational row R compares the displayed distances; and the terminal seal L is reached only after those windows and comparisons have been read.

Finally H, Q, P, N preserve the route under transport, replay, provenance, and local naming. Since selected subcovers, open-cover compactness theorems, quotient representatives, choice selectors, and ambient completeness witnesses are not carrier coordinates, the exported realizer is exactly the displayed finite-cover surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{ComputableCompactMetric}^{\uparrow}$ packet is generated from CompactMetric, EffectivePolishSpace, TotallyBounded, CompleteMetric, StreamName, RegSeqRat, RealUp, componentwise hsame, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4371.1, Definition 4371.2, and Definition 4371.3 seed the effective finite-cover realizer route for computable compact metric consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ComputableCompactMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected subcovers, open-cover compactness, quotient completion equality, countable-choice selectors, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, effective dense-name exposure, total-bounded finite-net exposure, complete-metric convergence exposure, finite-window readback, regular rational comparison, real sealing, finite-cover realizer nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ComputableCompactMetricUp.

Chapter 4372

A Concrete Naming Certificate for $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ packet records the separated-completion reflection route for regular Cauchy rational names as finite BEDC NameCert data. It sits over the regular rational readback surface of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the uniqueness boundary of chapter 3390. The packet lets a Real-facing consumer treat two representative regular Cauchy names as the same separated reflection point only after the displayed finite windows, dyadic budgets, and uniqueness ledger have been exposed.

Definition 4372.1 (Regular-Cauchy Hausdorff-reflection carrier)**.** *A* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, Y, S, T, D, U, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the first* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name row.*
2. *Y is the second* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational Cauchy name row presented to the same separated-reflection request.*
3. *S and T are the paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows through which X and Y are observed.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows.*
5. *U is the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *row witnessing that the displayed tail comparisons force separated agreement.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after X, Y, S, T, D, U have been displayed.*
7. *H records componentwise* hsame *transport for the two regular names, stream windows, dyadic ledger, uniqueness row, Real seal, and local certificate rows.*
8. *C records the displayed* Cont *replay from a reflection request to the paired windows, dyadic tolerance ledger, uniqueness row, and terminal Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyUniqueness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, S, T, D, U, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionCarrier admission surface`

Theorem 4372.2 (Regular-Cauchy Hausdorff-reflection NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *carrier* $R = (X, Y, S, T, D, U, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}}$ *surface consists exactly of carrier admission for two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, paired* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *separated-agreement row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation may replace these rows by quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionTasteGate single carrier alignment`

Proof. Project the carrier of Definition 4372.1. The only displayed coordinates are $X, Y, S, T, D, U, E, H, C, P, N$.

The two regular rational names are compared through the paired stream windows S, T and the dyadic tolerance ledger D. The separated-agreement row U is therefore a displayed uniqueness boundary, not a quotient of streams or a host equality proof.

The terminal Real seal E is downstream of that boundary. Transport, replay, provenance, and local naming are supplied by H, C, P, N, and no excluded quotient, selector, host-equality, choice, trichotomy, or ambient-completeness coordinate can be projected from the carrier. □

Theorem 4372.3 (Regular-Cauchy Hausdorff-reflection representative independence)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read accepted by a* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *packet is independent of the chosen representative regular Cauchy name in the following BEDC sense: if the two presented* $\mathsf{RegSeqRat}^{\uparrow}$ *rows are compared through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, then the terminal seal can distinguish them only through the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *row. The packet exports no quotient stream equality, selected representative, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionRepresentativel`

Proof. Begin with an accepted carrier $R = (X, Y, S, T, D, U, E, H, C, P, N)$. The rows X and Y are not presented as completed real objects; they are presented as regular rational names observed through finite stream windows.

The dyadic ledger D binds the comparison budget for those windows, and the uniqueness row U is the only row that can turn the displayed tail comparison into separated agreement. Thus any Real-facing read of E must pass through the same finite comparison route.

The rows H, C, P, N transport, replay, source, and name this route without adding analytic content. Since the carrier contains no further equality coordinate, changing representatives cannot be detected except through the displayed uniqueness row. □

Theorem 4372.4 (Regular-Cauchy Hausdorff-reflection Real seal non-escape)**.** *No terminal* $\mathsf{Real}^{\uparrow}$ *seal consumer accepted by a* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *packet can bypass the displayed route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegularCauchyUniqueness}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In particular, the separated reflection supplies representative independence for the Real seal without quotient streams, host real equality, selected representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionCarrier real seal nonescape`

Proof. Read the carrier coordinates in order. The terminal row E appears only after the two regular rational names, paired stream windows, dyadic tolerance ledger, and uniqueness row have been displayed.

Apply Definition 4372.2. The local NameCert surface exposes exactly those rows, with H, C, P, N preserving the same route for downstream consumers.

The advertised route is therefore the only public path to the Real seal. Since no excluded equality or choice coordinate occurs in the carrier, the seal cannot escape through quotient streams, host equality, representatives selected outside the packet, countable choice, trichotomy, or ambient completeness. □

Theorem 4372.5 (Regular-Cauchy Hausdorff-reflection finite-window uniqueness route)**.** *Suppose two accepted* $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ *packets display the same paired* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the same* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *row, and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal. Then every separated-reflection consumer factors through the same finite-window route on the underlying* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The factorization does not use quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHausdorffReflectionUp.RegularCauchyHausdorffReflectionCarrier finite window uniqueness route`

Proof. Apply Definition 4372.3. Once the paired StreamName windows, dyadic tolerance ledger, and uniqueness row agree, the terminal Real seal cannot distinguish the two regular Cauchy representatives by any route other than the displayed uniqueness row.

Apply Definition 4372.4. The Real seal is downstream of the finite windows, dyadic ledger, and uniqueness row, so a separated-reflection consumer has no bypass around those displayed rows.

The remaining rows are structural. The hsame rows transport only the displayed components, the Cont rows replay the same finite-window request, and the Pkg and NameCert rows name that route inside BHist. Therefore the consumer factors through the same finite-window route. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ consumer that reaches the terminal RealUp seal without reading two RegSeqRat source rows, paired StreamName windows, a DyadicRatCore tolerance ledger, and a RegularCauchyUniqueness row refutes the carrier surface.

Independence witness: regseqrat, streamname, dyadicratcore, real, regularcauchyuniqueness: $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ is not bijective to any listed sibling because it binds two regular rational representatives to one separated uniqueness row and one downstream Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}$ packet is generated from two RegSeqRat source rows, paired StreamName finite windows, a DyadicRatCore tolerance ledger, a RegularCauchyUniqueness separated-agreement row, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4372.1, Definition 4372.2, Definition 4372.3, Definition 4372.4, and Definition 4372.5 seed the separated reflection route for regular Cauchy representatives and Real seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyHausdorffReflection}\uparrow}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove the finite NameCert obligation surface, representative-independence handoff, and Real seal non-escape theorem.

Chapter 4373

A Concrete Naming Certificate for $\mathsf{WeakLawLargeNumbers}^{\uparrow}$

Following Kolmogorov and Bishop–Bridges on finite averages and probability estimates, the WeakLawLargeNumbers packet names the displayed finite-average route behind the weak law of large numbers. It sits after the normalized probability surface of chapter 184, the measurable random-variable rows of chapter 185, the finite tail-bound carrier of chapter 6592, and the terminal real-name seal of chapter 38. The packet is a finite certificate for Chebyshev-controlled averages; it is not an almost-sure convergence theorem, a central limit theorem, a countable-choice subsequence selector, a host probability-limit principle, or an ambient $\mathsf{Real}^{\uparrow}$ completeness result.

Definition 4373.1 (Weak law finite-average carrier)**.** *A* $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, R, A, V, T, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the total-event normalization and event classifier. The row R is the finite family of* $\mathsf{RandomVar}^{\uparrow}$ *entries read over that same probability source. The row A records the displayed finite average of the entries in R, while V records the variance or uniform second-moment bound used by the estimate. The row T reads the Chebyshev tail row through* $\mathsf{ChebyshevInequality}^{\uparrow}$ *for the event where the finite average differs from its displayed center by more than the requested tolerance. The row E is the* $\mathsf{Real}^{\uparrow}$ *epsilon seal naming the positive tolerance and the final probability bound. The row H records componentwise* hsame *transport, C records* Cont *replay of the finite averaging route, Q records* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{ChebyshevInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert, *and N is the local* $\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these ten rows.*

Lean4 ✓ `BEDC.Derived.WeakLawLargeNumbersUp.WeakLawLargeNumbersTasteGate single carrier alignment`

Theorem 4373.2 (Weak law NameCert obligations)**.** *For every accepted* $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ *carrier $(P, R, A, V, T, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 4373.1. Carrier admission displays the probability source, the random-variable family, the finite-average row, the variance-bound row, the Chebyshev tail row, the epsilon seal, the transport and replay rows, the provenance row, and the local naming row. The packet imports no host law of large numbers, selected subsequence, external probability-limit operation, countable-choice principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Read the carrier rows in order. The probability source P supplies the measurable-event classifier and total-mass normalization, and the random-variable row R exposes only the finitely displayed variables over that source.

The average row A and variance row V are then internal finite data. They record the algebraic averaging expression and the bound used by the tail estimate before any limiting statement is visible.

Finally read T, E, H, C, Q, N. The Chebyshev tail row and epsilon seal name the probability estimate at the requested tolerance, while transport, replay, provenance, and local naming keep the same finite route under classifier replacement. Since no carrier coordinate stores an infinite limit or subsequence selector, the listed rows exhaust the local certificate surface. □

Theorem 4373.3 (Weak law Chebyshev handoff)**.** *Every accepted* $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ *Chebyshev read factors through the route*

$$P \longmapsto R \longmapsto A \longmapsto V \longmapsto T \longmapsto E \longmapsto H, C, Q, N$$

before any probability-bound consumer receives the finite-average estimate. Thus the Chebyshev step is handed to later probability and $\mathsf{Real}^{\uparrow}$ *formalization as a displayed finite source, finite random-variable row, average row, variance-bound row, tail-event row, epsilon seal, transport, replay, provenance, and local naming data.*

Proof. Start with a probability-bound request. The only probability source exposed by the packet is P, and the only random-variable data exposed over it are the finite rows in R.

The request must next read the average and variance-bound rows. The average row A fixes the finite expression being estimated, and V fixes the bound that the Chebyshev tail row may consume.

Only after these rows are displayed can T and E be read as a bound on the exceptional event. The structural rows H, C, Q, N then preserve that same route for downstream consumers, so the handoff is the finite Chebyshev estimate itself rather than a host-side convergence theorem. □

Theorem 4373.4 (Weak law finite-average nonescape)**.** *Every accepted* $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ *probability-limit-facing read remains inside the finite-average route of Definition 4373.1. In particular, a consumer can read a tail estimate only after displaying the source probability row, finite random-variable rows, average row, variance-bound row, Chebyshev tail row,* $\mathsf{Real}^{\uparrow}$ *epsilon seal, componentwise transport, replay, provenance, and local* $\mathsf{NameCert}$ *row. No accepted read may replace this route by almost-sure convergence, central limit normalization, countable-choice subsequence selection, a host probability-limit operator, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Let a consumer request the finite-average estimate from an accepted carrier. Projection of Definition 4373.1 shows that the request first meets P, R, A, V, T, E and has no independent coordinate for a limit object.

The displayed Chebyshev row T is downstream from the variance-bound row V and upstream from the epsilon seal E. Hence any probability bound read is already tied to the visible finite average and its tolerance.

The remaining rows H, C, Q, N do not add new analytic content. They transport equal displayed histories, replay the finite route, record the package provenance, and attach the local name. Therefore every accepted probability-limit-facing read stays inside the finite-average certificate surface and cannot escape to the excluded convergence or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{WeakLawLargeNumbers}^{\uparrow}$ packet is generated from a probability source row, finite random-variable rows, a finite-average row, a variance or second-moment bound row, a Chebyshev tail row, a RealUp epsilon seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4373.1, Definition 4373.2, Definition 4373.3, and Definition 4373.4 seed the finite-average probability route through ProbSpace, RandomVar, RealUp, Chebyshev tail, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeakLawLargeNumbers}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close almost-sure convergence, the central limit theorem, countable-choice subsequence selection, host probability limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-average routing, variance-bound stability, Chebyshev tail handoff, epsilon-seal nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.WeakLawLargeNumbe

Chapter 4374

A Concrete Naming Certificate for $\mathsf{LocatedSubset}^{\uparrow}$

Following Bishop and Bridges on located subsets of metric and real spaces, the $\mathsf{LocatedSubset}^{\uparrow}$ packet records a displayed subset together with finite distance-witness rows. It sits after the real-valued metric route of chapter 1638, the Hausdorff comparison boundary of chapter 2086, the real-separability window surface of chapter 1809, the dyadic tolerance core of chapter 291, and the regular rational readback surface of chapter 301. The packet gives Real and Completion consumers a finite located-subset interface without host set extensionality, selected nearest points, quotient subset equality, or ambient completeness.

The located-subset distance route consumes chapter 1809 as its finite search-window source and consumes chapter 2086 only after the real-distance seal has been displayed.

Definition 4374.1 (LocatedSubset carrier)**.** *A* $\mathsf{LocatedSubset}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, W, D, R, E, K, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{RealMetric}^{\uparrow}$ *source row, carrying the ambient metric distance through finite real-name observations.*
2. *S is the subset-admission row, naming the displayed members read by the carrier and exporting no host powerset equality.*
3. *W is the* $\mathsf{RealSeparability}^{\uparrow}$ *search-window row, recording the countable dense or finite-window probes available to a distance request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to each positive distance query.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, packaging the rational comparison data produced from W and D.*
6. *E is the real distance seal row, read only after the metric source, subset admission, search windows, dyadic tolerances, and regular rational readback have been displayed.*
7. *K is the optional* $\mathsf{HausdorffMetric}^{\uparrow}$ *comparison boundary for compact or hyperspace consumers; it records only the finite directed comparisons visible through the preceding rows.*
8. *H records componentwise* hsame *transport for the metric source, subset admission, search windows, dyadic ledger, regular readback, real seal, Hausdorff boundary, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from an ambient point and tolerance request through subset admission, separability windows, dyadic comparison, regular rational readback, real sealing, and any Hausdorff-facing comparison.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedSubset}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSubset}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, S, W, D, R, E, K, H, C, P, N$. It has no coordinate for a host subset object, extensional equality of subsets, a selected nearest point, quotient real equality, countable choice, or an ambient completion theorem.

Lean4 ✓ `BEDC.Derived.LocatedSubsetUp.LocatedSubsetTasteGate single carrier alignment`

Theorem 4374.2 (LocatedSubset NameCert obligations)**.** *For every accepted* $\mathsf{LocatedSubset}^{\uparrow}$ *carrier*

$$L = (M, S, W, D, R, E, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedSubset}^{\uparrow}}$ *surface consists exactly of carrier admission, ambient real-metric visibility, subset-admission stability, separability-window exposure, dyadic-tolerance compatibility, regular-rational readback, real-distance sealing, optional Hausdorff comparison routing, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 4374.1. The displayed packet lists exactly the rows used by an ambient point, subset-membership, tolerance, rational-readback, real-seal, or Hausdorff-facing request.

The metric and subset rows M, S are read first. A distance query can inspect the ambient space only through $\mathsf{RealMetric}^{\uparrow}$, and it can inspect membership only through the displayed admission row S.

The search, tolerance, and readback rows W, D, R then supply finite witnesses for the locatedness request. The real seal E is reached only after those rows have been displayed, while K is available only as a downstream comparison boundary.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no host subset, selected nearest point, quotient equality, countable-choice schedule, or ambient completion coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 4374.3 (LocatedSubset dyadic distance witness)**.** *Every distance read exported by an accepted* $\mathsf{LocatedSubset}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{RealMetric}^{\uparrow} \longmapsto \mathsf{RealSeparability}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto E.$$

The read may be handed to a $\mathsf{HausdorffMetric}^{\uparrow}$ *consumer only after the same route has produced the displayed real-distance seal, transported by H and replayed by C.*

Proof. Begin with a point-to-subset distance request. The ambient metric row M supplies the only metric observations, and the subset-admission row S supplies the only visible membership data.

The finite search window W names the inspected probes. The dyadic ledger D fixes the positive tolerance requests, and the regular rational row R records the resulting readback windows.

The real-distance seal E is therefore downstream of M, S, W, D, R. Any Hausdorff-facing row K can compare only the finite distance data already sealed by this route.

Transport and replay do not add another distance object. The componentwise hsame row H, the displayed Cont route C, the Pkg provenance P, and the local NameCert row N preserve the

same witness surface, so no nearest-point selector or host infimum can bypass the dyadic distance route. □

Falsifiable prediction: Every accepted LocatedSubsetUp distance read exposes RealMetricUp, subset admission, RealSeparabilityUp windows, DyadicRatCoreUp tolerance rows, RegSeqRatUp readback, and a real-distance seal before any HausdorffMetricUp or completion-facing consumer reads the packet.

Independence witness: realmetric, hausdorffmetric, realseparability, dyadicratcore, regseqrat: none of these siblings alone carries the full located-subset packet with subset admission, finite search windows, dyadic tolerance rows, regular rational readback, real-distance sealing, optional Hausdorff comparison, transport, replay, package provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSubset}\uparrow}$.

Constructive story: A $\mathsf{LocatedSubset}^{\uparrow}$ packet is generated from a RealMetricUp source, displayed subset admission, RealSeparabilityUp search windows, DyadicRatCoreUp tolerance rows, RegSeqRatUp readback, a real-distance seal, optional HausdorffMetricUp comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedSubset}\uparrow}, \mathsf{seed})$

Scope closed: Definition 4374.1, Definition 4374.2, and Definition 4374.3 seed the finite located-subset interface for real-metric and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedSubset}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LocatedSubsetUp.LocatedSubsetTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host subset extensionality, selected nearest points, quotient subset equality, countable choice, open-cover compactness, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, real-metric visibility, subset-admission stability, separability-window exposure, dyadic-tolerance compatibility, regular-rational readback, real-distance sealing, Hausdorff comparison routing, transport stability, replay stability, provenance, and local naming for BEDC.Derived.LocatedSubsetUp.

Chapter 4375

A Concrete Naming Certificate for $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$

Following Heine, Borel, and Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ packet records the explicit finite dyadic closed-interval net route for regular Cauchy real names. It sits over the dyadic arithmetic core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the finite-net Heine–Borel surface of chapter 3471. The chapter is a finite dyadic closed-interval net route over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; it is not general Heine–Borel for arbitrary subsets of $\mathsf{Real}^{\uparrow}$, does not import open-cover compactness, and does not select limits outside the displayed interval-net data.

Definition 4375.1 (Regular Cauchy Heine–Borel route carrier)**.** *A* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, D, S, Q, E, W, F, H, C, P, N)$$

with the following displayed rows:

1. *I is the closed bounded regular-Cauchy interval row, exposing two endpoint* $\mathsf{RegSeqRat}^{\uparrow}$ *names, their* $\mathsf{StreamName}^{\uparrow}$ *finite windows, and the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seals.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh row, recording the finite dyadic subdivision, endpoint comparisons, cell widths, and requested tolerance bound.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that lists the finite observations used to compare each regular-Cauchy endpoint and each inspected interval cell.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the endpoint names and the retained dyadic cell names.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, Q have been displayed.*
6. *W is the closed-interval witness row, pairing every retained dyadic cell with its lower and upper endpoint comparisons inside I.*
7. *F is the finite net row, containing only the finite bundle of dyadic cell centers and radius witnesses read by the interval-net route.*
8. *H records componentwise* hsame *transport for the interval, dyadic mesh, stream windows, regular readback, real seal, cell witnesses, finite net, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a closed-interval net request through* I, D, S, Q, E, W, F, H.
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, Q, E, W, F, H, C, P, N$. *It has no coordinate for an arbitrary subset of* $\mathsf{Real}^{\uparrow}$, *arbitrary open covers, selected finite subcovers, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyHeineBorelRouteUp.TasteGate.RegularCauchyHeineBorelRouteTasteGate single carrier alignment`

Theorem 4375.2 (Regular Cauchy Heine–Borel route obligations)**.** *For every accepted* RegularCauchyHeineBorelRo *carrier*

$$R = (I, D, S, Q, E, W, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *expose the closed bounded regular-Cauchy interval row I before any interval-net consumer reads a cell;*
2. *display the dyadic subdivision and tolerance ledger D as the only mesh source;*
3. *route endpoint and cell observations through the finite* $\mathsf{StreamName}^{\uparrow}$ *windows S and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q;*
4. *reach the terminal* $\mathsf{Real}^{\uparrow}$ *seal E only after the dyadic, stream, and regular-rational rows have been displayed;*
5. *bind each retained dyadic interval cell to the closed interval by the witness row W and export the finite net bundle F;*
6. *preserve the route by componentwise* hsame *transport and displayed* Cont *replay through H, C;*
7. *source and name the same finite packet through* Pkg *provenance P and the local* NameCert *row N.*

No obligation row states general Heine–Borel compactness for arbitrary subsets of $\mathsf{Real}^{\uparrow}$, *arbitrary open-cover compactness, a selected subcover functional, quotient real equality, countable choice, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 5715.1. The interval row I is the only source for the closed bounded regular-Cauchy endpoints, and the route cannot inspect an interval cell before those endpoint rows are present.

Next read the dyadic mesh and observation rows. The dyadic ledger D supplies the finite subdivision and the tolerance comparison, while S and Q supply the finite windows and regular-rational readbacks needed to compare endpoint and cell data.

The Real-facing boundary is downstream. The terminal row E is reached only after the dyadic, stream, and regular-rational rows have been displayed, so the route exports a named real seal rather than a host-selected real limit or quotient equality.

Finally the finite-net part is exhausted by W and F. The witness row W binds each retained dyadic cell to the closed interval, and F lists the finite cell centers and radii. The structural rows H, C, P, N transport, replay, source, and name this same packet, so no arbitrary subset, open cover, selected subcover, choice, selected-limit, or ambient-completeness coordinate remains. □

Theorem 4375.3 (Regular Cauchy Heine–Borel finite interval-net route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer of an accepted* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{HeineBorelFiniteNet}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{RegularCauchy}}$$

The route supplies an explicit finite dyadic closed-interval net for closed bounded regular-Cauchy interval data. It supplies no compactness theorem for arbitrary subsets of $\mathsf{Real}^{\uparrow}$*, no arbitrary open-cover subcover extraction, no quotient real equality, no countable choice, and no* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with a consumer read of the carrier. The only numerical mesh coordinate is D, and every inspected endpoint or cell must be read through the finite windows S and regular-rational row Q before the terminal seal E is available.

The closed-interval part is then bound by W. Each retained dyadic cell is paired with displayed lower and upper endpoint comparisons, so the interval-net route remains a finite dyadic route inside the presented closed bounded interval.

The finite net export is exactly F. It lists the dyadic centers and radius witnesses read by the Heine–Borel finite-net surface, while H, C, P, N preserve and name the same route. Since the carrier contains none of the excluded arbitrary-subset, open-cover, quotient, choice, selected-limit, or completeness coordinates, every such consumer remains on the displayed finite interval-net route. □

Theorem 4375.4 (Regular Cauchy Heine–Borel inductive subcover route)**.** *Every finite interval-net consumer of an accepted* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ *carrier may build subcover reads only by induction over the displayed dyadic cell list* F*. The base read over the empty cell list exports no cover row. The successor read appends one displayed dyadic cell, routes endpoint and cell comparisons through* D, S, Q, E, W*, and preserves the same* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. No read imports arbitrary open-cover compactness, selected finite subcovers, countable choice, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5715.1. The finite net row F is the only coordinate that lists dyadic cells, and the rows D, S, Q, E, W are the only coordinates available for mesh, window, readback, Real seal, and closed-interval comparisons.

The induction base is the empty displayed cell list. With no cell in F, the consumer can read the interval, dyadic mesh, stream windows, regular readback, and structural rows, but it has no cover row to export.

For the successor step, append one displayed dyadic cell from F. Its endpoint and cell comparisons are routed through the dyadic mesh D, finite windows S, regular readback Q, terminal seal E, and witness row W before the consumer extends the finite read.

The structural rows H, C, P, N are preserved componentwise. They transport, replay, source, and name the same finite induction route, so no arbitrary open cover, selected subcover, countable-choice schedule, quotient equality, or ambient completeness principle is introduced. □

Theorem 4375.5 (Regular Cauchy Heine–Borel route obligation scope)**.** *Every accepted* $\mathsf{RegularCauchyHeineBorelR}$ *carrier*

$$R = (I, D, S, Q, E, W, F, H, C, P, N)$$

scopes its obligation rows through finite BEDC primitives as follows:

1. *I is scoped by the* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint rows and the closed bounded regular-Cauchy interval data;*
2. *D is scoped by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh and tolerance rows;*
3. *S is scoped by finite* $\mathsf{StreamName}^{\uparrow}$ *windows;*
4. *Q is scoped by* $\mathsf{RegSeqRat}^{\uparrow}$ *readback;*
5. *E is scoped by the terminal* $\mathsf{Real}^{\uparrow}$ *seal;*
6. *W, F are scoped by the* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *finite closed-interval net route;*
7. *H, C, P, N are scoped respectively by componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row.*

The scoped surface exports no arbitrary subset compactness, open-cover subcover selector, quotient real equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5715.1. Its rows are exactly $I, D, S, Q, E, W, F, H, C, P, N$, so the obligation theorem can inspect no coordinate outside the displayed packet.

Apply Definition 5715.2. The interval row, dyadic mesh, finite stream windows, regular-rational readback, Real seal, closed-interval witnesses, finite net bundle, transport, replay, provenance, and local naming rows are precisely the finite obligations available to the local certificate.

Use Definition 5715.3. It identifies the consumer route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, with hsame, Cont, Pkg, and $\mathsf{NameCert}$ preserving the same displayed packet. The excluded compactness, quotient, selector, choice, selected-limit, and completeness readings therefore have no scoped row. □

Theorem 4375.6 (Regular Cauchy Heine–Borel closed-interval net scope)**.** *Every closed-interval net consumer of an accepted* $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ *carrier*

$$R = (I, D, S, Q, E, W, F, H, C, P, N)$$

must read the displayed rows in the order

$$I,\ D,\ S,\ Q,\ E,\ W,\ F,\ H,\ C,\ P,\ N.$$

Here I binds the closed bounded $\mathsf{RegSeqRat}^{\uparrow}$ *interval, D supplies the dyadic mesh, S and Q provide the finite* $\mathsf{StreamName}^{\uparrow}$ *observations and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and W, F are the finite closed-interval witness row and finite interval-net bundle. The remaining rows H, C, P, N transport, replay, source, and name the same route. Thus the consumer sees only the displayed closed-interval net data and imports no arbitrary open-cover compactness, selected subcover functional, quotient real equality, countable choice, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5715.1. Its row list is exactly $I, D, S, Q, E, W, F, H, C, P, N$, and there is no coordinate before I from which a consumer could infer a cell, mesh, cover, or selected limit.

Apply Definition 5715.2. The obligation surface forces the closed bounded interval row I to be exposed before any interval-net read, then forces the mesh D, finite windows S, regular-rational readback Q, and terminal Real seal E before the closed-interval witness and finite-net rows can be exported.

Use Definition 5715.3 and Definition 5715.4. They identify W, F as the finite closed-interval net surface and restrict subcover reads to induction over the displayed dyadic cell list, with endpoint and cell comparisons routed through D, S, Q, E, W.

Finally apply Definition 5715.5. It scopes H, C, P, N as componentwise transport, displayed replay, provenance, and local naming for the same packet. The composed read order is therefore the displayed order $I, D, S, Q, E, W, F, H, C, P, N$, and the excluded compactness, quotient, selector, choice, selected-limit, and completeness principles have no row to enter through. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}$ packet is generated from a closed bounded regular-Cauchy interval row, a DyadicRatCore mesh row, StreamName windows, RegSeqRat readback, a RealUp seal, closed-interval cell witnesses, a finite dyadic net row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 5715.1, Definition 5715.2, and Definition 5715.3 seed the explicit finite dyadic closed-interval net route over DyadicRatCore, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyHeineBorelRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim general Heine–Borel compactness for arbitrary subsets of $\mathsf{Real}^{\uparrow}$, arbitrary open-cover compactness, selected finite subcovers, quotient real equality, countable choice, selected limits, Lean verification, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, dyadic mesh exactness, finite stream-window readback, regular-rational endpoint routing, Real seal nonescape, finite interval-net exposure, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyHeineBorelRouteUp.

Chapter 4376

A Concrete Naming Certificate for $\mathsf{CauchyApproximationTree}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyApproximationTree}^{\uparrow}$ packet records a finite branching approximation surface over the L10 Cauchy spine: each active branch carries a displayed tolerance window, a dyadic approximation row, a regular-rational readback row, and a terminal Real seal. It sits between the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback surface of chapter 301, the real-name seal of chapter 38, and the Cauchy route of chapter 3413. The packet gives Real and Completion consumers a finite approximation tree without quotient streams, selected limits, countable choice, host real equality, trichotomy, or ambient completeness.

Definition 4376.1 (Cauchy approximation tree carrier)**.** *A* $\mathsf{CauchyApproximationTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (V, E, B, D, S, R, L, H, C, P, N)$$

with the following displayed rows:

1. *V is the finite tree-node row, listing the nodes presently opened by the approximation packet.*
2. *E is the finite edge and parenthood row, recording the branch relation among the nodes in V.*
3. *B is the branch-window row, assigning each active branch the finite tolerance window currently inspected.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic approximants, radius comparisons, and the error rows attached to each branch window.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by the branch windows and no hidden stream coordinates.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and dyadic tolerance rows.*
7. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the node, branch-window, dyadic, stream, and regular-readback rows have been exposed.*
8. *H records componentwise* hsame *transport for tree nodes, branch windows, dyadic rows, stream schedules, regular readbacks, Real seals, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a finite tree branch through B, D, S, R and into the terminal Real seal L.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyApproximationTree}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, E, B, D, S, R, L, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyApproximationTreeUp.CauchyApproximationTreeTasteGate single carrier alignment`

Theorem 4376.2 (Cauchy approximation tree NameCert obligations)**.** *For every accepted* CauchyApproximationTre *carrier $T = (V, E, B, D, S, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the tree-node row, edge row, branch windows, dyadic tolerance ledger, stream schedule, regular readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *tree finiteness, requiring every inspected branch to be generated by the finite node and edge rows V, E;*
3. *branch-window exactness, requiring each active branch to read its tolerance window from B before any dyadic approximation in D is accepted;*
4. *dyadic and stream exactness, requiring D and S to expose only the dyadic approximants and finite observations demanded by the displayed branch windows;*
5. *regular readback and Real-seal boundary, requiring R and L to remain downstream of V, E, B, D, S and never to serve as selected limits or host equality objects;*
6. *componentwise transport and replay, requiring H and C to preserve exactly the displayed finite branch route;*
7. *provenance and local naming, requiring P and N to export the route over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{Cauchy}^{\uparrow}$ *without adding quotient equality, choice, trichotomy, or ambient completeness.*

No approximation-tree obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5716.1. The accepted packet displays exactly the finite node row V, edge row E, branch windows B, dyadic ledger D, stream schedule S, regular readback R, Real seal L, and structural rows H, C, P, N.

Tree finiteness and branch-window exactness follow from the row order. A consumer first reads a node and its branch relation from V, E; only then may it inspect the branch tolerance window B and the dyadic approximation row D attached to that branch.

The stream and readback rows are downstream of the same branch window. The schedule S opens only the finite observations demanded by B, and R records the regular-rational data justified by D and S.

Finally, the Real seal row L is terminal for this finite branch route. The transport row H, replay row C, provenance row P, and local naming row N preserve and name the same displayed packet, so no quotient stream equality, selected limit, countable-choice selector, host real equality, trichotomy principle, or ambient completeness theorem can become a local obligation. □

Theorem 4376.3 (Cauchy approximation tree branch readback)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Cauchy}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyApproximationTree}^{\uparrow}$ *carrier reads a branch only through the displayed route*

$$V, E, B, D, S, R, L, H, C, P, N.$$

Consequently each consumed branch exposes finite tree nodes, branch windows, dyadic tolerance rows, StreamName observations, RegSeqRat readbacks, a Real seal, componentwise transport, displayed replay, provenance, and local naming data. It exposes no quotient stream equality, selected limit, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Let a Real-facing or Cauchy-facing consumer read an accepted packet $T = (V, E, B, D, S, R, L, H, C, P, N)$. Carrier projection gives access only to the rows named in Definition 5716.1.

The read begins with the finite tree rows V, E and then chooses a displayed branch window in B. The dyadic ledger D supplies the approximant and tolerance comparison for that branch, the stream schedule S opens the finite observation windows, and the regular readback row R exposes the rational data that the Real seal may consume.

The terminal row L is therefore reached only after the finite route through V, E, B, D, S, R has been displayed. The structural rows H, C, P, N transport, replay, source, and name the same route without adding any second equality or limit coordinate.

Since the packet has no carrier row for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, a Real-facing or Cauchy-facing consumer cannot read any of those objects from the local certificate. □

Falsifiable prediction: Every $\mathsf{CauchyApproximationTree}^{\uparrow}$ Real-facing or Cauchy-facing read factors through finite tree nodes, branch windows, a DyadicRatCore tolerance ledger, selected StreamName observations, RegSeqRat readbacks, a RealUp seal row, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy: $\mathsf{CauchyApproximationTree}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite tree nodes, branch windows, dyadic tolerance rows, finite stream schedules, regular-rational readback, a terminal Real seal, transport, replay, provenance, and local naming in one branch-indexed packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyApproximationTree}^{\uparrow}$ packet is generated from finite tree nodes, branch windows, a DyadicRatCore tolerance ledger, StreamName finite observations, RegSeqRat readback rows, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5716.1, Definition 5716.2, and Definition 5716.3 seed the finite branch-indexed route from L10 Cauchy approximation windows to RealUp endpoint consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyApproximationTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tree finiteness, branch-window exactness, dyadic ledger exactness, stream and readback exactness, Real seal boundary, componentwise transport, replay, provenance, and local naming for BEDC.Derived.CauchyApproximationTreeUp.

Chapter 4377

A Concrete Naming Certificate for $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$ packet records the finite comparison surface between Bishop-style Cauchy representations and the BEDC real-name ladder. It sits after the Cauchy-representation route of chapter 1680, the precision ledger of chapter 4141, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names the comparison route as finite NameCert data; it is not quotient stream equality, selected host limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4377.1 (Bishop Cauchy representation comparison carrier)**.** *A* $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, B, S, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{CauchyRepresentation}^{\uparrow}$ *row whose decoder route supplies the representation-facing observations.*
2. *B is the* $\mathsf{BishopRealPrecision}^{\uparrow}$ *row recording the requested constructive precision discipline for the comparison.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row shared by the representation and precision reads.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed stream windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the precision and regular-readback rows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after R, B, S, Q, D have been displayed.*
7. *H records componentwise* hsame *transport for the representation row, precision row, stream windows, regular readback, dyadic ledger, terminal seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a comparison request through $R, B, S, Q, D, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$, $\mathsf{CauchyRepresentation}^{\uparrow}$, $\mathsf{BishopRealPrecision}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite comparison packet. It has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopCauchyRepresentationComparisonUp.BishopCauchyRepresentationComparisonTasteGa`
`single carrier alignment`

Theorem 4377.2 (Bishop Cauchy representation comparison NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$ *carrier* $K = (R, B, S, Q, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, representation decoding through* R*, constructive precision exposure through* B*, shared finite-window access through* S*, regular rational readback through* Q*, dyadic tolerance accounting through* D*, terminal real-name sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The visible analytic data are the representation decoder R, precision row B, shared stream window S, regular rational readback Q, dyadic tolerance ledger D, and terminal real seal E.

The comparison obligations are componentwise. A representation-facing consumer first reads R, then the requested Bishop precision surface B, and then the common finite-window, regular-readback, and dyadic-tolerance route S, Q, D.

Only after these rows are displayed may the consumer inspect the terminal seal E. The support rows H, C, P, N transport, replay, source, and name the same finite route, so no further NameCert obligation remains outside the listed coordinates. □

Theorem 4377.3 (Bishop Cauchy representation comparison nonescape)**.** *No accepted* BishopCauchyRepresentatio*n carrier exports quotient streams, selected host limits, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every downstream Real or Completion consumer receives only the displayed representation row, Bishop precision row, stream-window row, regular readback row, dyadic tolerance ledger, terminal real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Proof. Inspect the carrier inventory. The tuple contains only $R, B, S, Q, D, E, H, C, P, N$.

The rows R, B, S, Q, D are the complete comparison route before the terminal Real seal can be consumed. Thus the seal E is not a selected host limit; it is the downstream endpoint of the displayed representation, precision, window, readback, and tolerance data.

Transport, replay, provenance, and local naming preserve the same boundary. Since no coordinate stores quotient stream equality, a choice schedule, a trichotomy branch, host real equality, or an ambient completeness principle, none can escape from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}$ packet is generated from a CauchyRepresentation decoder, a BishopRealPrecision row, a StreamName finite window, a RegSeqRat readback row, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$, seed)

Scope closed: Definition 5717.1, Definition 5717.2, and Definition 5717.3 seed the finite representation-comparison route from CauchyRepresentation and BishopRealPrecision data to StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCauchyRepresentationComparison}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, representation-decoder exactness, precision-row exposure, shared-window readback, dyadic tolerance accounting, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyRepresentationComparisonUp.

The SeparableSpace$^{\uparrow}$ hub routes its countable dense schedule through chapter 1809 for Real-facing L10 density consumers.

Chapter 4378

A Concrete Naming Certificate for $\mathsf{SeparableSpace}^{\uparrow}$

Following Bourbaki's countable-base presentation and Bishop and Bridges' constructive dense-sequence discipline, the $\mathsf{SeparableSpace}^{\uparrow}$ packet names a countable dense schedule as finite BEDC data. It sits over the metric carrier of chapter 57, the finite window surface of chapter 126, the regular rational readback route of chapter 301, the terminal real-name surface of chapter 38, and the complete-separable consumer of chapter 1490. Its Real-facing dense schedule is also consumed by the downstream sibling dependency chapter 1809. The packet exports a dense schedule visible to L10 completion consumers without host set equality, selected dense points, countable choice, or ambient completeness.

Definition 4378.1 (Separable-space carrier)**.** *A* $\mathsf{SeparableSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, S, R, D, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *row containing the admitted metric carrier, distance classifier, and metric local* $\mathsf{NameCert}$*.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row that schedules finite dense-name probes and radius requests.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row that reads the rational windows attached to those probes.*
4. *D is the countable-density ledger, recording that every displayed metric-radius request reaches an admitted stream probe with a regular rational distance bound.*
5. *W is the observation ledger joining stream positions, regular rational windows, metric-radius requests, and terminal* $\mathsf{Real}^{\uparrow}$ *seal reads.*
6. *H records componentwise* hsame *transport for M, S, R, D, W and the local certificate rows.*
7. *C records displayed* Cont *replay from a density request to the corresponding stream and regular-rational readback rows.*
8. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparableSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a host dense subset, selected nearest point, quotient point equality, or external enumeration.

Theorem 4378.2 (Separable-space NameCert obligations)**.** *For every accepted* $\mathsf{SeparableSpace}^{\uparrow}$ *carrier* $Q = (M, S, R, D, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SeparableSpace}^{\uparrow}}$ *surface consists exactly of six obligation rows: carrier admission for* $M, S, R, D, W, H, C, P, N$*; classifier transport to a common* $\mathsf{Met}^{\uparrow}$ *row before density is read; stability of the stream schedule and regular rational readback under* H*; exactness of* W *as the only route from a radius request to finite stream and rational-window data; displayed* Cont *replay from density requests through* S, R, D, W*; and* Pkg *provenance with local naming for precisely this packet. No additional obligation stores a selected dense point, countable-choice function, host set equality, or ambient completion datum.*

Proof. Project the carrier of Definition 5718.1. Carrier admission exposes the metric row, stream schedule, regular rational readback, density ledger, observation ledger, transport, replay, provenance, and local name.

The classifier route begins at M. Componentwise transport in H moves M, S, R, D, W together, so a dense schedule cannot be compared after changing the metric source.

The exactness row is W. Every radius request reaches a finite stream position in S, reads its rational window through R, and records the density witness in D before any terminal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Finally replay the request through C and source it through P, N. Since no row names a selected point, host dense subset, countable-choice selector, or ambient completion, the six listed rows exhaust the NameCert obligations. □

Theorem 4378.3 (Separable-space StreamName dense readback)**.** *Let* $Q = (M, S, R, D, W, H, C, P, N)$ *be an accepted* $\mathsf{SeparableSpace}^{\uparrow}$ *carrier. Every dense-readback consumer reads the countable schedule only through* $\mathsf{StreamName}^{\uparrow}$ *row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, observation ledger* W*, and density ledger* D *over the common* $\mathsf{Met}^{\uparrow}$ *row* M*. When the read is Real-facing it may consume only the terminal* $\mathsf{Real}^{\uparrow}$ *seal already displayed by* R, W*; when it is completion-facing, a* $\mathsf{PolishSpace}^{\uparrow}$ *or* $\mathsf{SeparableMetric}^{\uparrow}$ *consumer receives the same finite schedule route and no selected dense point, quotient point equality, host enumeration, or ambient completeness principle.*

Proof. Expose the accepted carrier. The only scheduling coordinate is S, and the only regular rational readback coordinate attached to the schedule is R.

Use Definition 5718.2. Observation exactness forces a dense-readback request through W before the density ledger D is available, while H keeps the route over the same metric row M.

The Real-facing boundary is downstream of the regular rational observations. Thus any $\mathsf{Real}^{\uparrow}$ seal is read after S, R, W, D, not as a separate host-real shortcut.

Finally pass the displayed route to the complete-separable consumers. The $\mathsf{PolishSpace}^{\uparrow}$ and $\mathsf{SeparableMetric}^{\uparrow}$ packets may inspect the same finite schedule rows, but the carrier contains no coordinate for selected dense points, quotient equality, host enumeration, or ambient completeness. □

Theorem 4378.4 (Separable-space finite dense-schedule induction)**.** *Let* $Q = (M, S, R, D, W, H, C, P, N)$ *be an accepted* $\mathsf{SeparableSpace}^{\uparrow}$ *carrier. Any finite list of dense-readback requests over* Q *is discharged by induction through the same* $\mathsf{StreamName}^{\uparrow}$ *schedule row* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, observation ledger* W*, density ledger* D*, and common* $\mathsf{Met}^{\uparrow}$ *row* M*. The induction exports only the displayed finite schedule route and no selected dense point, host enumeration, quotient equality, or countable-choice selector.*

Proof. Induct on the displayed finite list of dense-readback requests.

For the empty list, no dense point is selected and no host enumeration is opened. The carrier projection of Definition 5718.1 leaves only the common rows $M, S, R, D, W, H, C, P, N$, so the empty schedule is discharged by the displayed packet itself.

For a cons list, apply Definition 5718.3 to the head request. The head is routed through S, R, W, D over the fixed metric row M, and any Real-facing read remains behind the already displayed regular rational observations.

Apply the induction hypothesis to the tail list using the same accepted carrier. Componentwise transport through H and replay through C keep every tail request on the same S, R, W, D, M route. Since no step introduces a selected dense point, host enumeration, quotient equality, or countable-choice selector, the whole finite list is discharged inside the finite dense-schedule packet. □

Theorem 4378.5 (Separable-space RealSeparability forward route)**.** *Any* $\mathsf{RealSeparability}^{\uparrow}$ *consumer reading a* $\mathsf{SeparableSpace}^{\uparrow}$ *dense schedule must factor the read through the* $\mathsf{Met}^{\uparrow}$ *row* M*, the* $\mathsf{StreamName}^{\uparrow}$ *row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal displayed by* R, W*, and the countable-density ledger* D *before the* $\mathsf{RealSeparability}^{\uparrow}$ *row of chapter 1809 is consumed. The route exports a finite dense-readback dependency, not a selected dense point, quotient point equality, host enumeration, countable-choice selector, or ambient completeness principle.*

Proof. Start with the accepted carrier $Q = (M, S, R, D, W, H, C, P, N)$. The metric source is M, the finite schedule is S, and the regular rational readback is R.

Use Definition 5718.3. It forces every dense read through S, R, W, D over the same metric row M before any Real-facing seal is consumed.

Now route the downstream sibling dependency through chapter 1809. The $\mathsf{RealSeparability}^{\uparrow}$ row receives the displayed countable-density ledger only after the metric, stream, regular rational, and $\mathsf{Real}^{\uparrow}$ rows are visible.

Because the carrier has no coordinate for selected dense points, quotient point equality, host enumeration, countable choice, or ambient completeness, the forward route remains a finite dependency edge. □

Theorem 4378.6 (SeparableSpace real-metric dependency route)**.** *Every completion, compactness, or real-facing consumer of an accepted* $\mathsf{SeparableSpace}^{\uparrow}$ *dense schedule reads the metric carrier data of chapter 57 and the Real-density route of chapter 1809 before it may inspect the downstream separability surface. The route exposes countable dense data only through displayed* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{RealSeparability}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows; it exports no host enumeration, selected dense point, quotient point equality, countable-choice selector, or ambient completeness principle.*

Proof. Project the accepted dense schedule. Its metric source is the row that supplies distance observations, while the real-separability row supplies the Real-facing density readback.

The existing forward route through Definition 5718.5 places the Real-density consumer after the metric, stream, regular rational, terminal Real, and countable-density ledgers. Thus the child dependency route is not a separate carrier; it records the horizontal lattice edge through which completion and compactness consumers must enter the same finite packet.

Since the carrier has no coordinate for a host enumeration, selected dense point, quotient equality, countable-choice selector, or ambient completeness theorem, every such consumer remains inside the displayed metric and Real-separability dependency route. □

The $\mathsf{DedekindCutStream}^{\uparrow}$ route points its finite readback through chapter 301 and its terminal seal through chapter 38.

Chapter 4379

A Concrete Naming Certificate for $\mathsf{DedekindCutStream}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DedekindCutStream}^{\uparrow}$ packet records a located cut-observation stream over the L10 stream-name substrate, not the forbidden Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$. It sits after the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the rounded located cut interface of chapter 436. The packet names the finite stream route by which lower and upper cut observations can be sampled before any Real-facing consumer treats them as regular Cauchy data.

Definition 4379.1 (Dedekind-cut stream carrier)**.** *A* $\mathsf{DedekindCutStream}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S_{\mathrm{cut}} = (D, L, U, W, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row, recording the finite dyadic rational endpoints, radii, and comparison budgets used by the cut observation.*
2. *L is the located lower-cut observation row, carrying finite evidence that the displayed endpoints lie on the lower side of the cut.*
3. *U is the located upper-cut observation row, carrying finite evidence that the displayed endpoints lie on the upper side of the cut.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing exactly the finite observation windows through which L and U are sampled.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the stream windows and dyadic endpoint budgets have been displayed.*
6. *H records componentwise* hsame *transport for dyadic endpoints, lower observations, upper observations, stream windows, regular readbacks, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located cut-observation request through D, L, U, W, R.*
8. *P is the* Pkg *provenance over* $\mathsf{DedekindCutStream}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, L, U, W, R, H, C, P, N$. It has no coordinate for quotient cuts, quotient stream equality, trichotomy, selected suprema, selected real limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4379.2 (Dedekind-cut stream NameCert obligations)**.** *For every accepted* $\mathsf{DedekindCutStream}^{\uparrow}$ *carrier* $S_{\mathrm{cut}} = (D, L, U, W, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the dyadic endpoint ledger, located lower observations, located upper observations, stream windows, regular rational readback, transport, replay, provenance, and local naming rows;*
2. *endpoint exactness, requiring every lower or upper cut observation to name its rational endpoint and comparison budget through D;*
3. *located observation separation, requiring L and U to remain displayed lower and upper observations rather than a quotient cut object;*
4. *stream-window exactness, requiring every cut observation consumed downstream to pass through the finite* $\mathsf{StreamName}^{\uparrow}$ *row W;*
5. *regular-readback boundary, requiring R to be read only after D, L, U, W have been exposed;*
6. *componentwise transport and replay, requiring H and C to preserve the same endpoint, observation, stream, and readback route;*
7. *provenance and local naming, requiring P and N to source the packet through* $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *without adding quotient cuts, trichotomy, completeness, or host real equality.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5719.1. The accepted packet exposes only the dyadic endpoint row D, the lower and upper observation rows L, U, the stream window row W, the regular readback row R, and the structural rows H, C, P, N.

Endpoint exactness and located observation separation are read from the same projection. The rows L and U can mention a rational observation only through the dyadic endpoint and budget data in D, and they remain two displayed observation ledgers rather than a quotient cut.

The stream and readback obligations are downstream. A consumer first opens the finite windows in W, then obtains the regular rational readback R justified by those windows and the endpoint budget.

Finally, H and C transport and replay that same finite route, while P and N source and name it. Since the carrier contains no row for quotient cuts, trichotomy, completeness, host real equality, or selected real limits, the listed rows exhaust the local NameCert surface. □

Theorem 4379.3 (Dedekind-cut stream regular-Cauchy handoff)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{DedekindCutStream}^{\uparrow}$ *carrier must pass through the* $\mathsf{StreamName}^{\uparrow}$ *window row W and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before the cut-observation stream can be consumed. Equivalently, the only Real-facing route exported by the packet is*

$$\mathsf{DedekindCut}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}.$$

The handoff supplies located cut observations as finite stream-name data; it supplies no Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$*, quotient cut, trichotomy branch, completeness theorem, selected supremum, selected limit, or host real equality.*

This handoff is a source route for chapter 4372 when a downstream Real-facing consumer compares two regular-Cauchy presentations through the shared $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows, because the comparison sees displayed stream windows and dyadic tolerance ledgers rather than a quotient cut or host real equality.

Proof. Let a downstream Real-facing consumer read an accepted carrier $S_{\mathrm{cut}} = (D, L, U, W, R, H, C, P, N)$. By carrier projection, the only cut-facing data available before readback are the endpoint ledger D and the displayed lower and upper observation rows L, U.

The consumer cannot reach a regular rational datum directly from L or U. The finite stream-name row W records the observation windows that are opened, and the readback row R records the regular rational data obtained from those windows and the dyadic endpoint budget.

Thus any Real-facing use of the cut-observation stream is downstream of W and R. The remaining rows H, C, P, N preserve, replay, source, and name the same route.

Because no carrier coordinate stores quotient cuts, a Dedekind construction of reals, trichotomy, completeness, selected suprema, selected limits, or host real equality, the handoff is exactly the displayed stream-name and regular-Cauchy boundary. □

Falsifiable prediction: Every accepted $\mathsf{DedekindCutStream}^{\uparrow}$ Real-facing read factors through DyadicRatCore endpoints, located lower and upper cut observations, StreamName windows, RegSeqRat readback, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: dedekindcut, dyadicratcore, streamname, regseqrat, real: $\mathsf{DedekindCutStream}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries located lower and upper cut observations, dyadic endpoint budgets, stream windows, regular rational readback, transport, replay, provenance, and local naming in one stream-observation packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}$.

Constructive story: A $\mathsf{DedekindCutStream}^{\uparrow}$ packet is generated from DyadicRatCore endpoint rows, located lower and upper cut observations, StreamName finite windows, RegSeqRat readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5719.1, Definition 5719.2, and Definition 5719.3 seed the located cut-observation stream route over DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, DedekindCutUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$, quotient cuts, trichotomy, completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, located observation separation, stream-window exactness, regular-readback boundary, transport, replay, provenance, and local naming for BEDC.Derived.DedekindCutStreamUp.

Theorem 4379.4 (Dedekind-cut stream RegSeqRat forward route)**.** *Every* $\mathsf{DedekindCutStream}^{\uparrow}$ *Real-facing consumer that exports a comparison must first display the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{Real}^{\uparrow}$ *seal row of the accepted packet. The forward route is*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

inside the same BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{DedekindCutStream}^{\uparrow}}$ *surface. It exports no quotient cut, quotient stream equality, trichotomy branch, selected supremum, selected limit, ambient real completeness, or host comparison outside the displayed route.*

Proof. Start with the carrier of Definition 5719.1. A Real-facing comparison can read endpoint budgets only through the $\mathsf{DyadicRatCore}^{\uparrow}$ row D, and it can inspect cut observations only through the finite $\mathsf{StreamName}^{\uparrow}$ window row W.

Apply the regular-Cauchy handoff of Definition 5719.3. It places the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R downstream of the displayed stream windows and dyadic endpoint budgets before any Real-facing read consumes the cut-observation stream.

Finally pass through the terminal $\mathsf{Real}^{\uparrow}$ seal while preserving the transport, replay, provenance, and local naming rows H, C, P, N. Since the packet has no coordinate for quotient cuts, selected suprema, selected limits, trichotomy, ambient completeness, or host comparison, the exported comparison route is exactly the displayed forward dependency chain. □

The $\mathsf{DedekindCutStream}^{\uparrow}$ dependency lattice consumes the finite-window $\mathsf{StreamName}^{\uparrow}$ spine of chapter 126 and the $\mathsf{RegSeqRat}^{\uparrow}$ readback route of chapter 301 before any $\mathsf{Real}^{\uparrow}$-facing cut stream is inspected through chapter 38. Thus the cut-observation packet remains a horizontal L10 route through displayed stream windows and regular rational readback, not a kernel-only pointer to a selected real limit or quotient cut.

Chapter 4380

A Concrete Naming Certificate for $\mathsf{StokesTheorem}^{\uparrow}$

Following Cartan and de Rham, the $\mathsf{StokesTheorem}^{\uparrow}$ packet names the finite BEDC surface on which exterior differentiation, oriented boundary, and integration over a carried chain can be consumed as one certificate. It reads differential forms from chapter 136, the cochain boundary route from chapter 137, the charted domain surface from chapter 96, and the scalar integral handoff from chapter 1526. The packet is only a naming certificate for the displayed Stokes boundary route; it does not supply a host smooth manifold, a selected triangulation, a quotient de Rham class, a measure completion, or an ambient real-completeness theorem.

Definition 4380.1 (Stokes theorem carrier)**.** *A* $\mathsf{StokesTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, F, B, E, I, H, C, P, N)$$

whose rows have the following BEDC-facing meaning.

- M *is the carried* $\mathsf{Manifold}^{\uparrow}$ *chart-and-orientation source row for the integration domain.*
- F *is the carried* $\mathsf{DiffForm}^{\uparrow}$ *form row together with the exterior-derivative row consumed by the Stokes boundary read.*
- B *is the oriented boundary-chain row whose source and target faces are read through the same displayed manifold surface.*
- E *is the* $\mathsf{DeRham}^{\uparrow}$ *boundary route identifying the exterior derivative and boundary pairing as one chain-complex comparison.*
- I *is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *scalar-integration handoff for the displayed domain, boundary, form, and derivative rows.*
- H *records componentwise* hsame *transport for* M, F, B, E, I *and the structural rows.*
- C *records displayed* Cont *replay of the route from manifold charts through form rows, boundary-chain rows, de Rham boundary data, and integration handoff.*
- P *is the* Pkg *provenance over* $\mathsf{Manifold}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{DeRham}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
- N *is the local* $\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.StokesTheoremUp.StokesTheoremTasteGate single carrier alignment`

Theorem 4380.2 (Stokes theorem NameCert obligations)**.** *For every accepted* $\mathsf{StokesTheorem}^{\uparrow}$ *carrier* $K = (M, F, B, E, I, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}$ *surface is exhausted by carrier admission for* M, F, B, E, I*, boundary-chain compatibility between* B *and* E*, integral-handoff compatibility between* E *and* I*, componentwise* hsame *transport in* H*, displayed* Cont *replay in* C*, provenance in* P*, and local naming in* N*. The certificate exports no host smooth map, no selected chain representative, no quotient de Rham class, no measure-completion object, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 5720.1. The analytic rows are exactly the manifold row M, differential-form row F, boundary-chain row B, de Rham boundary row E, and integration handoff row I.

The boundary compatibility is local: B supplies the displayed oriented boundary route, while E supplies the de Rham chain-complex comparison over the same form data. The integration compatibility is also local: I is read only after those rows have been displayed.

Finally attach H, C, P, N. These rows transport, replay, source, and name the same finite route. Since the carrier has no coordinate for the excluded host objects, the listed rows exhaust the local NameCert obligations. □

Theorem 4380.3 (Stokes boundary-chain route)**.** *Let* $K = (M, F, B, E, I, H, C, P, N)$ *be an accepted* $\mathsf{StokesTheorem}^{\uparrow}$ *carrier. Any consumer of the Stokes boundary comparison must first read the manifold row* M*, the differential-form row* F*, and the oriented boundary-chain row* B *before it can consume the de Rham boundary row* E *or the integration handoff* I*. The comparison is therefore a finite BEDC route through* $M, F, B, E, I, H, C, P, N$*, not an appeal to a host boundary operator or an unlogged smooth-chain equality.*

Proof. Read the carrier inventory. The row B is the only boundary-chain coordinate, and it is stated over the manifold and form rows M, F.

Apply Definition 5720.2. Boundary-chain compatibility places B before the de Rham row E, and integral-handoff compatibility places I downstream from the same displayed route.

The structural rows H, C, P, N preserve and name this route without adding a second boundary source. Hence no consumer can bypass M, F, B when reading the Stokes comparison. □

Theorem 4380.4 (Stokes closed-form nonescape)**.** *Let* $K = (M, F, B, E, I, H, C, P, N)$ *be an accepted* $\mathsf{StokesTheorem}^{\uparrow}$ *carrier whose displayed* $\mathsf{DiffForm}^{\uparrow}$ *row* F *is read as closed along the de Rham route* E*. Then every zero-boundary integral read exported by the packet remains inside* $M, F, B, E, I, H, C, P, N$*. It may use the carried closed-form row, the boundary-chain route, the de Rham boundary comparison, and the Riemann-integral handoff, but it cannot introduce a quotient cohomology representative, a host Stokes theorem, a measure-completion argument, selected charts outside* M*, or ambient real completeness.*

Proof. Begin with the closed-form read inside F and E. The form row supplies the exterior data, and the de Rham row supplies the boundary comparison over the same displayed form.

The zero-boundary integral is then read through B and I. The boundary row supplies the oriented chain surface, and the integral row supplies only the scalar handoff already tied to M, F, B, E.

Transport and replay are confined to H and C, while P and N attach provenance and local naming. None of these rows contains a quotient representative, host theorem, measure-completion carrier, external chart selector, or ambient completeness coordinate, so the closed-form read cannot escape the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{StokesTheorem}^{\uparrow}$ packet records a displayed manifold-and-orientation row, carried differential-form row, oriented boundary-chain row, de Rham boundary route, Riemann-integral handoff, componentwise transport, continuation replay, provenance, and local naming. The packet names the Stokes boundary comparison only through these finite rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed scope covers the displayed $\mathsf{Manifold}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{DeRham}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local NameCert rows of Definition 5720.1.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StokesTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close a public Stokes bridge, a host smooth-chain theorem, quotient cohomology, measure completion, selected triangulations, or ambient real completeness.

Upgrade path: Obligation closure requires checked carrier admission, boundary-chain compatibility, integral-handoff compatibility, transport, replay, provenance, and ledger non-escape for BEDC.Derived.StokesTheoremUp.

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ hub routes completion existence through the diagonal-window handoff of chapter 4080 and the pointwise stream metric boundary of chapter 4139 before its child files expose the completion seal.

Chapter 4381

A Concrete Naming Certificate for $\mathsf{MetricCompletionExistence}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{MetricCompletionExistence}^{\uparrow}$ packet records the finite BEDC surface by which a displayed metric source receives a completion-facing existence certificate without selecting quotient classes or host representatives. It sits between the metric carrier of chapter 4230, the Cauchy route of chapter 3413, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the real seal of chapter 38, the completion object surface of chapter 1506, and the complete-metric consumer row of chapter 128. The selected finite windows used by the completion-existence seal are compatible with the diagonal-selection route of chapter 4080 before any completion consumer treats the seal as public. The packet names existence as finite certificate data; it is not an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4381.1 (Metric completion existence carrier)**.** *A* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, S, D, W, R, Y, U, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row whose metric observations are to be completed.*
2. *S is the* $\mathsf{Cauchy}^{\uparrow}$ *schedule row naming the finite Cauchy requests admitted from M.*
3. *D is the dense-embedding row that presents source points inside the completion-facing surface without choosing representatives.*
4. *W is the selected* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the schedule is inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the inspected windows.*
6. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that bounds the readback by finite dyadic budgets.*
7. *U is the completion seal row, tying the preceding route to* $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{CompleteMetric}^{\uparrow}$ *consumers while preserving the displayed* $\mathsf{Real}^{\uparrow}$ *distance boundary.*
8. *H records componentwise* hsame *transport for the source metric, Cauchy schedule, dense embedding, windows, readback, dyadic ledger, completion seal, uniqueness ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$M, S, D \longmapsto W \longmapsto R \longmapsto Y \longmapsto U.$$

10. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionExistence}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows, their uniqueness ledger inside H, and the replay path C. It has no coordinate for quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4381.2 (Metric completion existence NameCert obligations)**.** *For every accepted* MetricCompletionExiste *carrier $E = (M, S, D, W, R, Y, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed source metric, Cauchy schedule, dense embedding, selected finite stream windows, regular rational readback, dyadic tolerance ledger, completion seal, uniqueness ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The certificate refuses quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5721.1. Its rows expose the source $\mathsf{Met}^{\uparrow}$ data, the $\mathsf{Cauchy}^{\uparrow}$ schedule, the dense embedding, selected $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, completion seal, transport, replay, provenance, and local name.

The NameCert obligations follow the displayed order. The schedule is read from M, the embedding row D is inspected before any window, W and R provide finite observations and regular rational readback, and Y bounds them by dyadic tolerances before the completion seal U is available.

Transport and replay supply the uniqueness ledger. The row H moves the same coordinates componentwise, and C repeats the same inspection route for each consumer request; neither row introduces a host equality test or a chosen quotient representative.

Finally, P and N source and name the packet. Since the carrier contains no quotient-completion coordinate, selected representative, choice schedule, host equality oracle, trichotomy row, open-cover compactness row, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 4381.3 (Metric completion existence completion-seal nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier $E = (M, S, D, W, R, Y, U, H, C, P, N)$ reaches the completion seal U only after reading M, S, D, W, R, Y through the displayed* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, hsame, Cont, Pkg, *and local* NameCert *route. The seal cannot be replaced by quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5721.1. The only route to U first exposes the source metric row M, the Cauchy schedule S, the dense embedding row D, selected finite windows W, regular rational readback R, and dyadic tolerance ledger Y.

Apply the NameCert obligations theorem, Definition 5721.2. It orders those rows before the completion seal and binds the same route through componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ row.

The refused objects are absent from the carrier. Quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no coordinate in E, so no completion-facing consumer can substitute them for the displayed seal row U. □

Theorem 4381.4 (Metric completion existence CompleteMetric consumer route)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier* $E = (M, S, D, W, R, Y, U, H, C, P, N)$ *may use the completion seal* U *only after the* $\mathsf{Met}^{\uparrow}$ *source row,* $\mathsf{Cauchy}^{\uparrow}$ *schedule, dense embedding row,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *boundary,* $\mathsf{MetricCompletion}^{\uparrow}$ *surface, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows have been displayed. The route exports no quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier $E = (M, S, D, W, R, Y, U, H, C, P, N)$. The rows M, S, D, W, R, Y display the source metric, Cauchy schedule, dense embedding, finite windows, regular rational readback, and dyadic tolerance ledger before the completion seal row can be read.

Invoke Definition 5721.2. It binds the same rows to the $\mathsf{Real}^{\uparrow}$ boundary, the $\mathsf{MetricCompletion}^{\uparrow}$ surface, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ row.

Invoke Definition 5721.3. It prevents any completion-facing consumer from replacing U by quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Finally read the consumer side through chapter 128. A $\mathsf{CompleteMetric}^{\uparrow}$ consumer receives only the displayed completion seal and the rows that precede it, so its use of U factors through $M, S, D, W, R, Y, U, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetricCompletionExistence}^{\uparrow}$ packet is generated from a MetricSpace source row, a Cauchy schedule, dense embedding data, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a completion seal, uniqueness transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$, seed)

Scope closed: Definition 5721.1, Definition 5721.2, Definition 5721.3, and Definition 5721.4 seed the finite completion-existence packet over MetricSpace, Cauchy, StreamName, RegSeqRat, DyadicRatCore, Real, MetricCompletion, CompleteMetric, hsame, Cont, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-embedding order, finite-window readback, dyadic tolerance nonescape, completion-seal routing, CompleteMetric consumer routing, uniqueness transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionExistenceUp.

Every $\mathsf{MetricCompletionExistence}^{\uparrow}$ existence seal is read after the separated uniqueness boundary of chapter 1796, the universal-mapping row of chapter 1456, and the reflective completion route of chapter 1793. The handoff is finite completion-existence data: a source metric row, completion-facing route rows, uniqueness transport, universal-mapping visibility, reflective visibility, replay, provenance, and local $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ naming. It is not quotient completion, selected representative equality, host limit choice, or an ambient completeness construction.

Theorem 4381.5 (Metric completion existence sibling handoff)**.** *For every accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *packet* $E = (M, S, D, W, R, Y, U, H, C, P, N)$*, a completion-existence consumer may use* U *only after the uniqueness route of chapter 1796, the universal-mapping route of chapter 1456, and the*

reflective-subcategory route of chapter 1793 have been displayed through the same finite packet. The consumer receives the completion seal, uniqueness transport, universal-mapping visibility, reflective visibility, replay, provenance, and local naming rows; it receives no quotient completion, choice-selected limit, or host completeness theorem.

Proof. Project the carrier of Definition 5721.1. The packet exposes $M, S, D, W, R, Y, U, H, C, P, N$ as the only completion-existence surface.

Use the local obligations of Definition 5721.2 to order every read of U through the source metric, Cauchy schedule, dense embedding, finite stream windows, rational readback, dyadic tolerance ledger, uniqueness ledger, transport, replay, provenance, and local naming rows.

The three sibling chapters supply the horizontal route: metric-completion uniqueness contributes the separated comparison boundary, Cauchy-completion adjunction contributes the universal-mapping row, and Cauchy-completion reflective subcategory contributes the reflective visibility boundary. The adjunction row forces completion-facing consumers and source finite-window consumers through the same dense embedding and uniqueness ledger before reflection is read.

Since all three are consumed as displayed rows inside the same finite handoff, no quotient completion or choice-selected limit construction can be substituted for the packet. □

Theorem 4381.6 (Metric completion existence Cauchy-filter basis route)**.** *Every accepted* MetricCompletionExisten *completion seal is read only after the Cauchy-filter basis row and the separated metric reflection boundary have been displayed with the same finite completion packet. In particular, a public completion seal must expose* $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{SeparatedMetricReflection}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before any completion consumer treats the seal as public. The route exports no quotient completion, selected representative, host limit choice, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 5721.1. Its finite route already displays the source metric, Cauchy schedule, dense embedding, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real-facing completion seal, transport, replay, provenance, and local naming rows.

Insert the Cauchy-filter basis boundary before the completion seal is consumed. The basis row refines the Cauchy schedule into finite filter requests, while the separated metric reflection row fixes the equality boundary through which the completion consumer may read the result.

The remaining rows are then forced in order: $\mathsf{MetricCompletion}^{\uparrow}$ supplies the completion target, $\mathsf{CompletionEmbedding}^{\uparrow}$ supplies the dense embedding boundary, and the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows supply the finite readback and tolerance seal. Since none of those rows contains a quotient object, selected representative, host limit selector, choice schedule, or ambient completeness principle, the public completion seal has exactly the stated dependency route. □

Theorem 4381.7 (Metric completion existence finite basis-read route)**.** *Every completion-facing read of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier first normalizes the Cauchy schedule into a finite* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *basis before exposing the public* $\mathsf{MetricCompletion}^{\uparrow}$ *seal. Only after that basis row is displayed may the consumer read the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *row attached to the same completion packet.*

The basis-read route exports no quotient completion, selected representative, host limit choice, countable-choice schedule, excluded ambient completeness row, or separated metric shortcut outside the displayed basis packet.

Proof. Project the carrier of Definition 5721.1. Its completion-facing coordinates already include the Cauchy schedule, finite readback rows, completion seal, embedding boundary, transport, replay, provenance, and local naming.

Apply Definition 5721.6. That route inserts the $\mathsf{CauchyFilterBasis}^{\uparrow}$ boundary before the completion seal is public, so the Cauchy schedule is read as finite basis data rather than as an ambient filter object.

Now expose the consumer rows in order. The $\mathsf{MetricCompletion}^{\uparrow}$ seal can be inspected only after the basis row, and the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are the finite observation, rational readback, tolerance, and terminal seal rows of that same packet.

The excluded rows have no coordinate in the carrier. There is no quotient completion row, selected representative row, host limit-choice row, countable-choice schedule row, or ambient completeness row from which the consumer could read additional data. □

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ completion-existence packet consumes the finite Cauchy-filter basis route of chapter 1501 and the completion-facing filter handoff of chapter 1569 before exporting its own seal to the complete-metric consumer surface of chapter 128. The dependency is horizontal: the basis rows choose the finite requests, the completion rows bind the public completion route, and the complete-metric rows receive only the displayed existence packet, not quotient completion, selected representatives, host limit choice, or ambient completeness.

Theorem 4381.8 (Metric completion existence separated forward route)**.** *Every* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *completion-seal row U is consumed by the separated-completion route of chapter 1612 only after the* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Cauchy}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, and* $\mathsf{CompleteMetric}^{\uparrow}$ *rows are visible. The forward link exports a displayed completion-existence seal into* $\mathsf{SeparatedCompletion}^{\uparrow}$ *as finite route evidence, not as quotient completion equality, selected representatives, host point equality, countable choice, or an ambient complete metric space.*

Proof. Project the accepted carrier of Definition 5721.1. Its completion-seal row is not isolated; it is read downstream of the metric-space source, Cauchy request, StreamName observation schedule, RegSeqRat readback, DyadicRatCore tolerance row, Real seal, MetricCompletion row, CompleteMetric row, transport, replay, provenance, and local naming rows.

Apply Definition 5721.2. The obligation surface forces the seal consumer to expose those prerequisite rows before the completion-existence claim can be replayed or named.

The separated-completion sibling then reads the displayed completion-existence seal as route evidence for chapter 1612. Since the carrier and obligation theorem have no coordinate for quotient completion equality, selected representatives, host point equality, countable choice, or an ambient complete metric space, the forward route exports none of those endpoints. □

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ seal is read only after the Cauchy-filter basis route of chapter 1501 and the separated-completion route of chapter 1612 have both been displayed for the same completion packet. Thus a completion-existence consumer first sees the finite Cauchy-basis rows, then the separated-completion boundary, and only then treats the $\mathsf{MetricCompletionExistence}^{\uparrow}$ row as a seal for a complete metric forward route.

Theorem 4381.9 (Metric completion existence uniqueness-reflective route)**.** *Every accepted* MetricCompletionExist *read factors first through the existence carrier of Definition 5721.1. Before any completion consumer receives the completion seal U, the read must display the separated comparison boundary of* $\mathsf{MetricCompletionUniqueness}^{\uparrow}$ *and the reflective visibility boundary of* $\mathsf{CauchyCompletionReflectiveSubcategory}^{\uparrow}$

over the same finite source, Cauchy schedule, dense embedding, window, readback, dyadic, transport, replay, provenance, and local naming rows. It exports no quotient completion, selected representative, host limit choice, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the existence carrier. Its rows $M, S, D, W, R, Y, U, H, C, P, N$ are the whole route by which the source metric and Cauchy schedule reach a completion seal.

Use Definition 5721.2 to keep the source metric, schedule, dense embedding, finite windows, regular rational readback, dyadic tolerance, completion seal, transport, replay, provenance, and local naming in the displayed order.

Now read the sibling surfaces named in the packet provenance. The separated comparison boundary of chapter 1796 supplies the uniqueness side, and the reflective visibility boundary of chapter 1793 supplies the reflective side.

Because both sibling reads are consumed through the same finite carrier route, the completion consumer receives a uniqueness-reflective handoff rather than a quotient object, selected representative, host limit choice, countable-choice schedule, or ambient completeness theorem. □

Theorem 4381.10 (Metric completion existence to Cauchy completion monad law forward link)**.** *Every* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *completion seal consumed by a completion-law reader must pass through the finite* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Cauchy}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*, and* $\mathsf{CompleteMetric}^{\uparrow}$ *rows before the* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *law surface of chapter 3834 is read. The forward link exports only this displayed completion-existence route, together with componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionExistence}^{\uparrow}}$ *row.*

Proof. Project the carrier of Definition 5721.1. The source metric row M, Cauchy schedule S, selected stream windows W, regular rational readback R, dyadic tolerance ledger Y, and completion seal U form the ordered finite route toward $\mathsf{MetricCompletion}^{\uparrow}$ and $\mathsf{CompleteMetric}^{\uparrow}$ consumers.

Apply Definition 5721.2. It states that the local certificate is exhausted by carrier admission, the displayed completion-existence rows, transport, replay, provenance, and local naming. Hence a completion-law reader cannot bypass those rows when reaching the law surface.

Finally read the structural rows H, C, P, N. They preserve and replay the same finite route for the consumer, so the $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ handoff is a forward sibling dependency through the completion-existence carrier rather than a quotient completion, selected representative, or ambient completeness principle. □

Theorem 4381.11 (Metric completion existence Real-consumer route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *carrier must read the* $\mathsf{Met}^{\uparrow}$ *source row,* $\mathsf{Cauchy}^{\uparrow}$ *schedule row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *distance seal,* $\mathsf{MetricCompletion}^{\uparrow}$ *completion row, and* $\mathsf{CompleteMetric}^{\uparrow}$ *consumer row before using the completion seal. The route is a finite L10 dependency route through the displayed completion-existence packet, not a quotient completion, selected representative, countable-choice schedule, host equality oracle, trichotomy row, open-cover compactness row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the carrier of Definition 5721.1. Its only completion seal is the row U, and the route to U first displays the metric source M, Cauchy schedule S, dense embedding D, finite windows W, regular rational readback R, and dyadic tolerance ledger Y.

Apply the NameCert obligation theorem Definition 5721.2. It keeps $\mathsf{Met}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CompleteMetric}^{\uparrow}$ as separate source and consumer rows before the completion seal is exposed.

The sibling routes then keep the same boundary for downstream consumers. The complete-metric forward route and the completion uniqueness reflective route preserve the completion seal as packet data, while the Cauchy completion monad-law forward link reads the same finite source rows before any algebraic consumer uses the seal.

Since none of these rows contains quotient completion, selected representatives, countable choice, host equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every Real/completion consumer remains on the displayed L10 route. □

Theorem 4381.12 (MetricCompletionExistence pointwise-stream lattice route)**.** *Any* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *read consumed by* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *or by a regular Cauchy completion consumer first exposes the finite lattice*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{PointwiseStreamMetric}^{\uparrow}$$

before it reaches the completion-existence boundary. Thus the read travels through displayed stream windows, regular rational readback, terminal real-name sealing, the metric carrier, and the pointwise stream metric row; it is not a quotient completion, a selected limit, an ambient completeness theorem, or a host equality of real streams.

Proof. Read the pointwise-stream metric consumer first. Its distance observations are stream-indexed, so the consumer must display the $\mathsf{StreamName}^{\uparrow}$ row and the $\mathsf{PointwiseStreamMetric}^{\uparrow}$ row before any completion-existence seal can be used.

For a regular Cauchy completion consumer, the same route exposes the $\mathsf{RegSeqRat}^{\uparrow}$ readback and the terminal $\mathsf{Real}^{\uparrow}$ seal on top of the ambient $\mathsf{Met}^{\uparrow}$ row. These rows are the finite completion-facing lattice visible to the consumer.

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ boundary is therefore reached only after the displayed lattice has been opened. Since none of those rows carries quotient completion, selected limits, ambient completeness, or host stream equality, the handoff cannot export those conclusions. □

Theorem 4381.13 (MetricCompletionExistence pointwise-stream factorization)**.** *Every completion-existence read consumed through* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *factors through the displayed order*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{PointwiseStreamMetric}^{\uparrow}$$

before it reaches the $\mathsf{MetricCompletionExistence}^{\uparrow}$ *boundary. The factorization exposes finite stream windows, regular rational readback, the terminal Real seal, metric-space carrier rows, and the pointwise-stream distance row in that order; it exports no quotient completion, selected limit, ambient completeness theorem, or host equality of streams.*

Proof. Project the lattice route of Definition 5721.12. It already displays the only rows available to a pointwise-stream metric consumer before the completion-existence boundary.

The first factor is the finite stream read. A consumer sees $\mathsf{StreamName}^{\uparrow}$ windows and then the $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to those windows before any Real or metric row can be used.

The second factor is the completion-facing metric read. The terminal $\mathsf{Real}^{\uparrow}$ seal is exposed before the ambient $\mathsf{Met}^{\uparrow}$ row, and the $\mathsf{PointwiseStreamMetric}^{\uparrow}$ distance row is downstream of both.

Since the route contains only these displayed rows, it has no coordinate for quotient completions, selected limits, ambient completeness, or host stream equality. The completion-existence handoff therefore consumes the pointwise-stream factorization rather than a hidden completion principle. □

The $\mathsf{MetricCompletionExistence}^{\uparrow}$ seal consumes $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ before exposing completion-facing rows: finite tail thresholds enter through chapter 1487, then travel along the existing metric-completion sibling handoff of Definition 5721.5. Thus a completion consumer sees the tail estimate as displayed threshold and readback data attached to the same $\mathsf{Met}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, and $\mathsf{CompleteMetric}^{\uparrow}$ route, not as a quotient completion or ambient completeness principle.

Theorem 4381.14 (Metric completion existence Cauchy-convergence dependency route)**.** *Every* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *completion-seal consumer that uses Cauchy-convergence data first reads the Cauchy filter basis of chapter 1501, the regular Cauchy tail row, the separated-completion boundary of chapter 1612, and the terminal real-name readback row before the completion seal is public. Thus the consumer receives finite basis, tail, separated-completion, and* $\mathsf{Real}^{\uparrow}$ *rows attached to the same displayed completion packet, not quotient completion, selected representatives, host limit choice, or ambient completeness.*

Proof. Project the accepted $\mathsf{MetricCompletionExistence}^{\uparrow}$ carrier. Its existing route displays the source metric, Cauchy schedule, dense embedding, finite stream windows, regular rational readback, dyadic tolerance ledger, completion seal, transport, replay, provenance, and local naming rows.

Insert the Cauchy-filter and separated-completion dependencies before the seal is read. The basis row fixes the finite Cauchy requests, the regular tail row supplies the readback thresholds, and the separated-completion boundary fixes the equality route that downstream consumers may inspect.

The final readback remains terminal. The $\mathsf{Real}^{\uparrow}$ row is reached only through the same displayed packet, so the completion-seal consumer cannot replace the dependency route by quotient completion, selected representatives, host limit choice, or ambient completeness. □

Theorem 4381.15 (MetricCompletionExistence to CauchyRealSpread route)**.** *Every* $\mathsf{CauchyRealSpread}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *packet receives the completion-facing seal only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *boundary, and* $\mathsf{MetricCompletion}^{\uparrow}$ *completion row of Definition 5721.1. The route supplies a finite completion-facing seal for chapter 4161; it does not add quotient completion, selected representatives, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, host equality, trichotomy, or a choice principle.*

Proof. Project the carrier of Definition 5721.1. The only completion-facing route is the displayed chain from the source metric and Cauchy schedule through selected stream windows, regular rational readback, dyadic tolerance data, and the completion seal.

Apply Definition 5721.2. It requires the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{MetricCompletion}^{\uparrow}$ rows to remain visible before the seal is consumed.

The $\mathsf{CauchyRealSpread}^{\uparrow}$ consumer reads exactly that seal as finite spread data. Since the carrier has no quotient-completion coordinate, selected representative, ambient completeness theorem, host equality oracle, trichotomy row, or choice schedule, the route cannot export any of the excluded objects. □

The $\mathsf{FiniteLimitSeal}^{\uparrow}$ route is consumed by the regular Cauchy gluing boundary of chapter 5899, so this hub records the finite seal as a sibling dependency before routing the child files.

Chapter 4382

A Concrete Naming Certificate for $\mathsf{FiniteLimitSeal}^{\uparrow}$

Following Bishop regular-Cauchy completion, the $\mathsf{FiniteLimitSeal}^{\uparrow}$ packet records the finite seal used by diagonal-limit arguments before any selected limit or quotient stream equality can be mentioned. It is anchored in the finite-window route through chapter 126, chapter 301, chapter 291, and chapter 38. The packet packages the local Real-completion limit service as displayed BEDC data; it is not a global completeness theorem for $\mathsf{Real}^{\uparrow}$.

Its downstream role is fixed by the sibling routes Definition 5722.4 and Definition 5722.5: CategoryUp finite-limit consumers must first pass through the same M, W, R, D, E seal rows, and RealUp limit-seal consumers receive only that finite modulus-window-readback-tolerance-seal route. The Cauchy-filter forward route of Definition 5722.9 is consumed through the same finite seal rows, so completion-facing filter reads do not acquire a selected limit or quotient stream equality outside the local packet.

Definition 4382.1 (Finite limit seal carrier)**.** *A* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus schedule row naming the finite tail and tolerance requests used by the diagonal-limit route.*
2. *W is the selected* $\mathsf{StreamName}^{\uparrow}$ *window row containing exactly the finite observations requested by M.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger against which the readback is checked.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after M, W, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the modulus schedule, selected windows, readback, tolerance ledger, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$M \longmapsto W \longmapsto R \longmapsto D \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{FiniteLimitSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by the displayed modulus schedule, window reads, rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local name. It has no coordinate for selected limits, quotient stream equality, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4382.2 (Finite limit seal route nonescape)**.** *Every accepted* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *carrier exports its diagonal-limit service only through the finite route*

$$M \longmapsto W \longmapsto R \longmapsto D \longmapsto E.$$

It exports no selected limit, quotient stream equality, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Inspect the carrier of Definition 5722.1. The only limit-facing row is the terminal $\mathsf{Real}^{\uparrow}$ seal E, and the definition places it after the modulus schedule, selected stream windows, regular rational readback, and dyadic tolerance ledger.

Thus any consumer of the seal must first read M, W, R, D. The transport row H and replay row C preserve this same route under componentwise renaming and repeated consumer requests.

The provenance row P and local name N source the packet without adding mathematical content. Since the tuple contains no selected-limit coordinate, quotient equality relation, choice schedule, host real equality oracle, trichotomy branch, or ambient completeness theorem, the displayed route is the whole exported surface. □

Theorem 4382.3 (Finite limit seal bounded regular Cauchy route)**.** *When the modulus schedule M and the selected* $\mathsf{StreamName}^{\uparrow}$ *windows W of an accepted* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *carrier*

$$L = (M, W, R, D, E, H, C, P, N)$$

are supplied by an accepted $\mathsf{BoundedRegularCauchy}^{\uparrow}$ *packet, the finite-limit seal route factors through the bounded tail envelope of chapter 1697 before reaching M, W, R, D, E. The handoff first reads the bounded regular Cauchy threshold and late-window rows, then repacks the displayed windows as the local* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the seal. It exports no selected limit, quotient stream equality, countable choice, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the accepted $\mathsf{FiniteLimitSeal}^{\uparrow}$ carrier and the supplying accepted $\mathsf{BoundedRegularCauchy}^{\uparrow}$ packet. The bounded regular Cauchy chapter provides the finite tail-envelope route before any Real-facing seal is consumed.

Read that envelope into the local coordinates M, W, R, D, E. The supplied threshold schedule becomes the modulus row M, the supplied late stream windows become W, and their regular rational and dyadic tolerance readbacks become the local rows R and D before the terminal seal E is exposed.

Finally apply Definition 5722.2. The structural rows H, C, P, N preserve the displayed route from M through E, and the local classifier has no coordinate for a selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^\uparrow}$.

Constructive story: A $\mathsf{FiniteLimitSeal}^\uparrow$ packet is generated from a modulus schedule, selected StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^\uparrow}$, seed)

Scope closed: Definition 5722.1, Definition 5722.2, and Definition 5722.3 seed the finite diagonal-limit seal over StreamName, RegSeqRat, DyadicRatCore, Real, hsame, Cont, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window selection, regular readback, dyadic tolerance nonescape, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteLimitSealUp.

Theorem 4382.4 (Finite limit seal categorical consumer route)**.** *Every categorical or completion-facing consumer of an accepted* $\mathsf{FiniteLimitSeal}^\uparrow$ *carrier reads the seal through the finite-window route*

$$M \longmapsto W \longmapsto R \longmapsto D \longmapsto E$$

of Definition 5722.2, then through downstream completion siblings such as chapter 1276 and chapter 3701 before it can use the terminal $\mathsf{Real}^\uparrow$ *seal. The consumer receives a finite categorical handoff over the displayed StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and local NameCert rows; it receives no selected limits, quotient stream equality, countable choice, host real equality, trichotomy, or ambient Real completeness.*

Proof. Start with the carrier of Definition 5722.1. Its only completion-facing route places the modulus schedule, finite stream windows, regular readback, dyadic tolerance ledger, and terminal Real seal in the ordered rows M, W, R, D, E.

Apply Definition 5722.2. This prevents a categorical consumer from bypassing the finite-window rows or reading a selected limit directly from the seal.

Use Definition 5722.3 to align bounded regular Cauchy data with the same route. The bounded threshold and late-window rows are repacked as M, W, R, D before the Real seal E is visible.

Finally pass through the downstream envelope and classifier-lock chapters. chapter 1276 records the finite envelope consumed by Real and Completion routes, while chapter 3701 keeps the diagonal limit classifier on a single displayed seal route. Since none of these rows adds a selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient completeness theorem, the categorical consumer remains on the finite-window lattice. □

Theorem 4382.5 (Finite limit seal real dependency route)**.** *Every public* $\mathsf{FiniteLimitSeal}^\uparrow$ *seal consumes its real-facing rows in the displayed dependency order*

$$\mathsf{Real}^\uparrow,\ \mathsf{RegSeqRat}^\uparrow,\ \mathsf{StreamName}^\uparrow,\ \mathsf{MetricCompletion}^\uparrow$$

only through the finite modulus, window, readback, tolerance, and completion-envelope rows of Definition 5722.1. A limit consumer must first read the $\mathsf{StreamName}^\uparrow$ *observation windows, then the* $\mathsf{RegSeqRat}^\uparrow$ *rational readback, then the* $\mathsf{Real}^\uparrow$ *seal and* $\mathsf{MetricCompletion}^\uparrow$ *envelope route before the local* $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^\uparrow}$ *row is public; it receives no selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient completeness theorem.*

Proof. Project the accepted carrier from Definition 5722.1. The only real-facing path is the finite route from the modulus schedule through stream windows, regular rational readback, dyadic tolerance, and terminal Real seal.

Apply Definition 5722.2 and Definition 5722.4. They force completion-facing consumers to remain behind the displayed M, W, R, D, E rows before any categorical or completion envelope can read the seal.

The added dependency order records the same lattice edge: $\mathsf{StreamName}^{\uparrow}$ supplies the finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the rational readback, $\mathsf{Real}^{\uparrow}$ supplies the terminal seal, and $\mathsf{MetricCompletion}^{\uparrow}$ consumes that seal only through the completion route. Since the local packet has no coordinate for a selected limit or ambient completeness theorem, the dependency route is exactly the finite readback route already named by the carrier. □

Theorem 4382.6 (FiniteLimitSeal MetricCompletionFinite forward link)**.** *Every finite-limit seal consumed by a completion-facing route must expose its* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows before entering* $\mathsf{MetricCompletionFinite}^{\uparrow}$*. The forward link into chapter 1559 is a finite readback route, not a selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient Real completeness theorem.*

Proof. Start with the real dependency route above. It already forces a public $\mathsf{FiniteLimitSeal}^{\uparrow}$ consumer to read finite stream windows, regular rational readback, terminal Real sealing, and the completion envelope before any local naming row is public.

Next project the structural rows of Definition 5722.1. The same route carries hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data, so a completion-facing consumer cannot bypass the finite seal packet.

Finally compose this route with chapter 1559. A $\mathsf{MetricCompletionFinite}^{\uparrow}$ consumer therefore receives the finite-limit seal only after the StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and naming rows are exposed, with no selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient Real completeness. □

Theorem 4382.7 (FiniteLimitSeal Real-completion route)**.** *Every accepted* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *completion-facing consumer factors through the route*

$$M, W, R, D, E, H, C, P, N.$$

Here W is supplied by $\mathsf{StreamName}^{\uparrow}$*, R by* $\mathsf{RegSeqRat}^{\uparrow}$*, D by* $\mathsf{DyadicRatCore}^{\uparrow}$*, E by* $\mathsf{Real}^{\uparrow}$*, and downstream completion is read only through* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{MetricCompletionFinite}^{\uparrow}$*. No selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient Real completeness enters the route.*

Proof. Project the carrier of Definition 5722.1. The completion-facing rows available to a consumer are the displayed modulus, window, readback, dyadic tolerance, Real seal, transport, replay, provenance, and local naming rows.

Use route nonescape, Definition 5722.2. It prevents a completion consumer from bypassing M, W, R, D, E or replacing them by a selected limit, quotient stream equality, host equality, trichotomy branch, or ambient completeness theorem.

Apply the real dependency route above. It identifies W as the $\mathsf{StreamName}^{\uparrow}$ window row, R as the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, D as the dyadic tolerance row, and E as the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally use the $\mathsf{MetricCompletionFinite}^{\uparrow}$ forward link, Definition 5722.6. It records the finite completion handoff and leaves downstream completion only through $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{MetricCompletionFinite}^{\uparrow}$, so the displayed route is exhausted by $M, W, R, D, E, H, C, P, N$. □

Theorem 4382.8 (FiniteLimitSeal PointwiseStreamMetric reverse route)**.** *Any* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *consumer entering* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *must expose* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{Met}^{\uparrow}$ *row,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *before the finite seal is read. The route from chapter 4139 is therefore the reverse completion-facing edge to the finite-limit seal routes above, not a selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient Real completeness theorem.*

Proof. Project the completion-facing route of Definition 5722.7. It requires the finite seal to expose $M, W, R, D, E, H, C, P, N$ before downstream completion data can be read.

Now read the $\mathsf{PointwiseStreamMetric}^{\uparrow}$ consumer through chapter 4139. Its stream metric input already carries a displayed $\mathsf{Met}^{\uparrow}$ row and pointwise StreamName observations, so entry into $\mathsf{FiniteLimitSeal}^{\uparrow}$ must align those observations with the seal rows W, R, D, E.

Finally apply the real dependency route and the $\mathsf{MetricCompletionFinite}^{\uparrow}$ forward link. They identify W as the $\mathsf{StreamName}^{\uparrow}$ window row, R as the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, D as the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and E as the $\mathsf{Real}^{\uparrow}$ seal, while H, C, P, N keep transport, replay, provenance, and naming visible. Thus the reverse route contributes only the displayed finite rows and no selected limit, quotient stream equality, choice schedule, host equality, trichotomy branch, or ambient Real completeness. □

Real-facing $\mathsf{FiniteLimitSeal}^{\uparrow}$ consumers of finite limits must read the $\mathsf{StreamName}^{\uparrow}$ observation windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ sealing boundary of chapter 38 before exporting finite-limit rows. This dependency route keeps the finite seal on displayed windows, regular rational readback, dyadic tolerance, and Real-name sealing; it does not supply selected limits, quotient stream equality, trichotomy, countable choice, or ambient Real completeness.

Theorem 4382.9 (FiniteLimitSeal CauchyFilterLimit forward route)**.** *Let*

$$L = (M, W, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{FiniteLimitSeal}^{\uparrow}$ *carrier. Every completion-facing read of* L *that is consumed as a* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *route first projects the displayed modulus schedule* M*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and only then enters the Cauchy-filter limit surface of chapter 1558. The handoff preserves the componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^{\uparrow}}$ *row* N*. It exports no selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy branch, or ambient completeness theorem.*

Proof. Project the carrier of Definition 5722.1. Its only completion-facing route is the finite sequence M, W, R, D, E together with H, C, P, N.

Apply Definition 5722.2. This keeps the seal read behind the displayed StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, and Real seal rather than behind a selected limit or quotient stream equality.

Now use the real dependency route of Definition 5722.5. It records the same L10 path from $\mathsf{StreamName}^{\uparrow}$ through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$, so a $\mathsf{CauchyFilterLimit}^{\uparrow}$ consumer can only receive the finite seal after those rows have been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since no excluded coordinate is present in L, the route into chapter 1558 is a substantive dependency of the finite seal and not an external citation. □

Theorem 4382.10 (FiniteLimitSeal regular Cauchy gluing route)**.** *Every* $\mathsf{FiniteLimitSeal}^{\uparrow}$ *consumer that reads a glued regular-Cauchy limit must expose the finite-limit seal rows* $M, W, R, D, E, H, C, P, N$*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the sibling* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *route before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is public. The route exports no selected representatives, quotient stream equality, countable choice, or ambient Real completeness.*

Proof. Project the finite-limit seal carrier of Definition 5722.1. Its public limit-facing route is the displayed sequence from the modulus schedule through stream windows, regular rational readback, dyadic tolerance, and terminal Real seal, together with transport, replay, provenance, and local naming rows.

Apply the real-limit dependency route and the Cauchy-filter forward route, Definition 5722.5 and Definition 5722.9. These require every completion-facing seal read to pass through the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before the local $\mathsf{NameCert}_{\mathsf{FiniteLimitSeal}^{\uparrow}}$ row is public.

For a glued regular-Cauchy limit, cite the substantive sibling dependency chapter 5899. The gluing packet supplies the compatible-window route, but the finite-limit seal still exposes its own $M, W, R, D, E, H, C, P, N$ rows before the terminal seal can be consumed.

The carrier and the cited sibling route contain no coordinate for selected representatives, quotient stream equality, countable choice, or ambient Real completeness. Thus a glued regular-Cauchy limit is read only through the finite seal route and the $\mathsf{RegularCauchyGluing}^{\uparrow}$ dependency. □

Chapter 4383

A Concrete Naming Certificate for $\mathsf{FormalBallDomain}^{\uparrow}$

Following Edalat and Heckmann on formal balls and domain-theoretic completion, the $\mathsf{FormalBallDomain}^{\uparrow}$ packet records the rounded, directed, radius-ordered domain surface used by constructive completion arguments. It sits over the formal-ball carrier of chapter 1510, the basis refinement route of chapter 3943, the radius-order ledger of chapter 3968, the completion route of chapter 2012, the metric completion boundary of chapter 1506, and the terminal real-name seal of chapter 38. The packet gives L10 completion consumers a finite domain-neighbour route without quotienting Cauchy names, selecting limits, invoking host point equality, using countable choice, or assuming ambient completeness.

Definition 4383.1 (FormalBallDomain carrier)**.** *A* $\mathsf{FormalBallDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, R, Q, I, C, E, H, T, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FormalBall}^{\uparrow}$ *observation row, carrying the visible centre-radius windows used by the domain packet.*
2. *R is the* $\mathsf{FormalBallRadiusOrder}^{\uparrow}$ *row, recording the finite radius refinement and order comparisons available before any rounded-domain read is exported.*
3. *Q is the* $\mathsf{FormalBallBasis}^{\uparrow}$ *row, exposing the basis elements and basis-refinement route inspected by the domain surface.*
4. *I is the directed-ideal row, listing the finite compatible formal-ball windows retained by the rounded domain read.*
5. *C is the* $\mathsf{FormalBallCompletion}^{\uparrow}$ *row, reached only after the formal-ball, radius-order, basis, and directed-ideal rows have been displayed.*
6. *E is the completion endpoint row, read through* $\mathsf{MetricCompletion}^{\uparrow}$ *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rather than through host point equality.*
7. *H records componentwise* hsame *transport for formal balls, radius orders, bases, directed ideals, completion rows, endpoint seals, replay, provenance, and local naming.*
8. *T records displayed* Cont *replay from a rounded-domain request through $B, R, Q, I, C, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{FormalBallDomain}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{FormalBallBasis}^{\uparrow}$, $\mathsf{FormalBallRadiusOrder}^{\uparrow}$, $\mathsf{FormalBallCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FormalBallDomain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, R, Q, I, C, E, H, T, P, N$. It has no coordinate for quotient completion, selected representatives, host point equality, countable choice, trichotomy, or ambient completeness.

Lean4 (definition) `BEDC.Derived.FormalBallDomainUp.FormalBallDomainUp`

Theorem 4383.2 (FormalBallDomain NameCert obligations)**.** *For every accepted* $\mathsf{FormalBallDomain}^{\uparrow}$ *carrier $D = (B, R, Q, I, C, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FormalBallDomain}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the formal-ball row, radius-order row, basis row, directed-ideal row, formal-ball-completion row, endpoint row, transport row, replay row, provenance row, and local naming row;*
2. *radius-order exactness, requiring every refinement or rounded containment used by the domain read to be recorded in R before any ideal or completion row is consumed;*
3. *basis coverage, requiring each retained formal-ball window to be inspected through Q and then recorded in the directed row I;*
4. *completion handoff, requiring C and E to remain downstream of B, R, Q, I and to expose only the displayed* $\mathsf{FormalBallCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *route;*
5. *structural stability, requiring H and T to preserve the same component rows under* hsame *transport and displayed* Cont *replay;*
6. *provenance and local naming through P and N, with no obligation row for quotient completion, selected representatives, host point equality, countable choice, trichotomy, or ambient completeness.*

No $\mathsf{FormalBallDomain}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5723.1. The accepted packet exposes exactly the formal-ball, radius-order, basis, directed-ideal, completion, endpoint, transport, replay, provenance, and naming rows.

Radius-order exactness and basis coverage are forced by the row order. A domain read must first inspect B through the finite comparisons in R, then use Q to identify the displayed basis route before the retained directed row I is available.

The completion handoff is downstream of those rows. The formal-ball-completion row C and endpoint row E can be read only after B, R, Q, I have been displayed, so they cannot supply a quotient-completion representative or host point equality on their own.

Finally H and T transport and replay the same finite packet, while P and N source and name it. Since the carrier has no coordinate for quotient completion, selected representatives, countable choice, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 4383.3 (FormalBallDomain Cauchy completion handoff)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, *or* $\mathsf{FormalBallCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{FormalBallDomain}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{FormalBall}^{\uparrow} \longmapsto \mathsf{FormalBallRadiusOrder}^{\uparrow} \longmapsto \mathsf{FormalBallBasis}^{\uparrow} \longmapsto I \longmapsto \mathsf{FormalBallCompletion}^{\uparrow} \longmapsto \mathsf{MetricComplet}$$

The handoff exports rounded formal-ball domain data, directed finite coverage, and completion-facing endpoint seals, but it exports no quotient completion, selected Cauchy representative, host point equality, countable-choice selector, trichotomy, or ambient completeness principle.

Proof. Start with an accepted carrier $D = (B, R, Q, I, C, E, H, T, P, N)$. A Cauchy-facing or completion-facing request can first read only the formal-ball row B and the displayed radius-order comparisons in R.

The basis and directed stages are then forced through Q and I. The basis row identifies the finite neighbourhood data retained by the packet, and the directed row records the compatible finite family used by the rounded-domain read.

The completion rows are terminal for this route. The row C supplies the formal-ball-completion handoff, while E records the metric-completion and Real-seal endpoint data that downstream consumers may inspect.

Componentwise transport and replay through H, T preserve the same route, and P, N record provenance and local naming. Since no excluded quotient, selected representative, host equality, choice, trichotomy, or ambient-completeness coordinate exists in the carrier, the handoff exposes only the displayed domain data. □

Theorem 4383.4 (FormalBallDomain Real seal boundary)**.** *For every accepted* $\mathsf{FormalBallDomain}^{\uparrow}$ *carrier* $D = (B, R, Q, I, C, E, H, T, P, N)$*, each* $\mathsf{Real}^{\uparrow}$*-facing read exported by* D *remains downstream of the formal-ball row* B*, radius-order row* R*, basis row* Q*, directed-ideal row* I*, and formal-ball-completion row* C*. The Real seal is therefore a terminal endpoint of the displayed completion route, not a detached real point, quotient-completion class, selected representative, host point equality, countable-choice selector, or ambient completeness witness.*

Proof. Read the endpoint row E from the carrier. By Definition 5723.1, E is exposed only after the formal-ball, radius-order, basis, directed-ideal, and formal-ball-completion rows have been displayed.

Apply the NameCert obligations of Definition 5723.2. Radius-order exactness keeps every refinement inside R, basis coverage keeps retained windows inside Q, I, and completion handoff keeps C, E downstream of that finite route.

The replay row T and transport row H preserve the same component order. The provenance row P and local naming row N name no second Real route, no representative selector, and no host point-equality witness.

Thus any $\mathsf{Real}^{\uparrow}$ read exported by the packet is terminal for $B, R, Q, I, C, E, H, T, P, N$. The excluded detached real point, quotient class, selected representative, choice schedule, and ambient completeness data have no carrier coordinate from which a consumer could read them. □

Falsifiable prediction: Every accepted $\mathsf{FormalBallDomain}^{\uparrow}$ completion-facing read factors through displayed FormalBallUp windows, FormalBallRadiusOrderUp comparisons, FormalBallBasisUp coverage, a directed finite row, FormalBallCompletionUp handoff, MetricCompletionUp endpoint data, RealUp sealing, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: formalball, formalballbasis, formalballradiusorder, formalballcompletion, metriccompletion, real: $\mathsf{FormalBallDomain}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries formal-ball windows, radius-order comparisons, basis coverage, directed finite domain data, completion handoff, endpoint sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FormalBallDomain}^{\uparrow}}$.

Constructive story: A FormalBallDomain$^{\uparrow}$ packet is generated from FormalBallUp windows, FormalBallRadiusOrderUp comparisons, FormalBallBasisUp coverage, directed finite domain rows, FormalBallCompletionUp handoff, MetricCompletionUp and RealUp endpoint rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FormalBallDomain}^{\uparrow}}$, seed)

Scope closed: Definition 5723.1, Definition 5723.2, Definition 5723.3, and Definition 5723.4 seed the finite formal-ball domain route from rounded neighbourhood data to completion and Real endpoint consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{FormalBallDomain}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, host point equality, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius-order exactness, basis coverage, directed-row stability, completion handoff, Real seal boundary, componentwise transport, replay, provenance, and local naming for BEDC.Derived.FormalBallDomainUp.

Chapter 4384

A Concrete Naming Certificate for CauchyCompletionReflectiveLocalization$^{\uparrow}$

Mac Lane reflective subcategories and Bishop–Bridges constructive completion present Cauchy completion as a reflector whose completed objects form a saturated boundary of the metric-name world. The CauchyCompletionReflectiveLocalization$^{\uparrow}$ packet isolates that boundary as finite BEDC NameCert data: it reads the reflective subcategory of chapter 1793, the reflector of chapter 1585, the functorial route of chapter 423, the universal property of chapter 397, the stream-name surface of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The chapter names the L10 localization boundary used by completion adjoint and universal-reflector consumers; it does not add a quotient completion carrier, selected limit representative, host equality on completed objects, countable-choice selector, ambient completeness theorem, or full Real$^{\uparrow}$ completeness principle.

Definition 4384.1 (CauchyCompletionReflectiveLocalization carrier)**.** *A* CauchyCompletionReflectiveLocalization$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, Q, I, U, F, K, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the source metric and source name-data row, including the displayed metric classifier, finite Cauchy observations,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *reads, and* DyadicRatCore$^{\uparrow}$ *tolerance ledger available before localization is read.*

2. *Q is the Cauchy completion reflector row, read through* CauchyCompletionReflector$^{\uparrow}$ *and* CauchyCompletionFunctc *naming the completed-object surface without exposing a quotient carrier or selected host limit.*

3. *I is the reflective subcategory inclusion row, read through* CauchyCompletionReflectiveSubcategory$^{\uparrow}$*, exposing completed objects as the public inclusion boundary.*

4. *U is the universal-property factorization row, read through* CompletionUniversalProperty$^{\uparrow}$ *after S, Q, I have all been displayed.*

5. *F is the saturated complete-object localization row, saying that a second completion-facing read returns to the same included complete-object surface rather than creating a second host completion.*

6. *K is the StreamName–RegSeqRat–DyadicRatCore–Real transport row, carrying finite windows, regular rational readback, dyadic tolerance accounting, and the terminal* Real$^{\uparrow}$ *seal used by S, Q, I, U, F.*

7. *T stores componentwise* hsame *transport for source metric/name data, the reflector, the inclusion, universal factorization, saturated localization, the local name route, continuation replay, provenance, and local naming.*

8. *H stores the displayed* Cont *replay from source observations through reflector admission, reflective inclusion, universal-property factorization, localization return, and the local StreamName–RegSeqRat–DyadicRatCore–Real route.*

9. *C stores the* Pkg *provenance over* $\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}$, $\mathsf{CauchyCompletionReflectiveSubcatego}$ $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *P is the local provenance ledger tying the source, reflector, inclusion, factorization, localization, transport, replay, and naming rows to the same finite history.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It contains no coordinate for quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectiveLocalizationUp.CauchyCompletionReflectiveLocalizationTas`
`single carrier alignment`

Theorem 4384.2 (CauchyCompletionReflectiveLocalization NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}$ *carrier* $L = (S, Q, I, U, F, K, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed source metric/name data, Cauchy completion reflector, reflective subcategory inclusion, universal-property factorization, saturated complete-object localization, StreamName–RegSeqRat–DyadicRatCore–Real transport,* hsame *transport,* Cont *replay,* Pkg *provenance, local provenance, and local naming rows;*

2. *reflector visibility, requiring every completion-facing read to pass through Q after the source row S has displayed the relevant finite windows and tolerance ledger;*

3. *inclusion exactness, requiring every completed-object consumer to pass through I as the reflective subcategory boundary;*

4. *universal factorization, requiring every finite-window continuous consumer to reach its extension route only through U after S, Q, I have been projected;*

5. *localization saturation, requiring repeated completion-facing reads or already-complete reads to return through F to the same included complete-object surface;*

6. *local name-route discipline, requiring* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *data to be consumed only through K;*

7. *transport and replay nonescape, requiring T, H, C, P, N to preserve the displayed dependency surface and to export no quotient completion, selected limit, host equality, countable choice, ambient completeness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside $S, Q, I, U, F, K, T, H, C, P, N$.

Proof. Project the carrier of Definition 5724.1. The displayed rows are the only data available to the local classifier: source metric/name data, reflector, reflective inclusion, universal factorization,

saturated localization, local name transport, structural transport, replay, provenance, and local naming.

The reflector and inclusion obligations are read in order. The row Q supplies the Cauchy completion reflector and functor route from the source data, while I exposes the completed objects only as the reflective-subcategory boundary.

The universal-property and saturation obligations are downstream from those rows. The row U is the sole factorization surface for finite-window continuous consumers, and F records that already-complete or repeated completion-facing reads remain on the same included complete-object surface.

Finally K, T, H, C, P, N preserve and name the route. Since the carrier has no coordinate for quotient completion equality, selected limits, host equality, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ completeness, the NameCert surface cannot export any of those objects. □

Theorem 4384.3 (CauchyCompletionReflectiveLocalization universal exhaustion)**.** *Let $L = (S, Q, I, U, F, K, T, H$ be an accepted* $\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}$ *carrier. Every L10 completion consumer that reads a reflector, completed-object inclusion, universal factorization, or repeated-completion return factors through the finite localization route*

$$S \longmapsto Q \longmapsto I \longmapsto U \longmapsto F \longmapsto K \longmapsto T, H, C, P, N.$$

Thus the completion route is exhausted by the source metric/name data, Cauchy completion reflector, reflective subcategory inclusion, universal-property factorization, saturated complete-object localization, StreamName–RegSeqRat–DyadicRatCore–Real transport, hsame *transport,* Cont *replay,* Pkg *provenance, and local NameCert rows of the carrier.*

Proof. Start with an L10 completion consumer and project the source row S. The finite source observations, stream windows, regular rational readbacks, and dyadic tolerances are visible before the consumer reaches any completed-object surface.

Next project the reflector and inclusion rows. The consumer enters completion data through Q and reads completed objects through I, so the reflective subcategory boundary is part of the same finite route rather than an external host collection.

The row U supplies universal-property factorization, and F supplies the saturated return to the same complete-object surface. Hence extension reads and repeated completion-facing reads have no second completion coordinate.

The local transport row K and structural rows T, H, C, P, N close the route. They carry StreamName, RegSeqRat, DyadicRatCore, and Real data together with transport, replay, provenance, and local naming, so the listed carrier rows exhaust every public completion read. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}$ packet is generated from source metric/name data, a Cauchy completion reflector, reflective subcategory inclusion, universal-property factorization, saturated complete-object localization, StreamName-RegSeqRat-DyadicRatCore-Real transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, local provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5724.1, Definition 5724.2, and Definition 5724.3 seed the finite reflective-localization boundary for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectiveLocalization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host equality on completed objects, countable choice, ambient completeness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reflector visibility, inclusion exactness, universal factorization, localization saturation, local name-route discipline, and transport-replay nonescape for BEDC.Derived.CauchyCompletionReflecti

$\mathsf{RieszThorinInterpolation}^{\uparrow}$ reads endpoint bounded-operator and strip-estimate rows through chapter 1644, chapter 3893, and chapter 38 before any interpolated norm-bound ledger is exposed.

Chapter 4385

A Concrete Naming Certificate for $\mathsf{RieszThorinInterpolation}^{\uparrow}$

Following Riesz, Thorin, and Stein-Weiss, the $\mathsf{RieszThorinInterpolation}^{\uparrow}$ packet records the finite interpolation certificate by which two endpoint bounded-operator rows and a Hadamard three-lines strip estimate expose one interpolated norm bound. It sits after the strip-bound packet of chapter 3893, the endpoint normed-space surface of chapter 1950, the bounded-operator row of chapter 1644, the interpolation carrier of chapter 224, and the terminal real-name seal of chapter 38. The chapter names the displayed certificate only; it does not import a host interpolation functor, quotient operator equality, selected extremal analytic family, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Every interpolated-bound consumer must read endpoint bounded-operator rows through chapter 1644 and the strip estimate through chapter 3893 before the $\mathsf{Real}^{\uparrow}$ norm-bound ledger is visible.

Definition 4385.1 (Riesz-Thorin interpolation carrier)**.** *A* $\mathsf{RieszThorinInterpolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B, H, C, P, N)$$

with the following displayed rows:

1. X_0, X_1, Y_0, Y_1 *are endpoint* $\mathsf{NormedSpace}^{\uparrow}$ *rows for the source and target normed spaces at the two endpoints.*
2. A_0, A_1 *are endpoint* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *rows, recording the same displayed operator action with endpoint norm bounds over the corresponding normed-space rows.*
3. E_0, E_1 *are endpoint exponent rows, storing the source and target exponent ledgers and their rational comparison data.*
4. S *is the* $\mathsf{HadamardThreeLines}^{\uparrow}$ *strip-estimate row used to compare the endpoint bounds along the displayed interpolation strip.*
5. Θ *is the interpolation-parameter row, storing the inspected parameter, its endpoint incidence, and the convex-weight ledger consumed by* S*.*
6. B *is the* $\mathsf{Real}^{\uparrow}$ *norm-bound ledger exporting the interpolated bound only after* $A_0, A_1, E_0, E_1, S, \Theta$ *have been displayed.*

7. *H records componentwise* hsame *transport for endpoint normed spaces, bounded operators, exponent rows, strip estimate, interpolation parameter, norm-bound ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an interpolated-bound request through $X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B$*
9. *P is the* Pkg *provenance over* $\mathsf{RieszThorinInterpolation}^{\uparrow}$, $\mathsf{HadamardThreeLines}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Interpolation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows. It has no coordinate for a host interpolation space, quotient equality of operators, selected extremal analytic family, non-displayed exponent completion, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4385.2 (Riesz-Thorin interpolation NameCert obligations)**.** *For every accepted* $\mathsf{RieszThorinInterpolation}^{\uparrow}$ *carrier*

$$T = (X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}$ *surface consists exactly of endpoint normed-space admission through X_0, X_1, Y_0, Y_1, bounded-operator endpoint admission through A_0, A_1, endpoint exponent admission through E_0, E_1, Hadamard three-lines strip-estimate compatibility through S, interpolation-parameter admission through Θ, interpolated* $\mathsf{Real}^{\uparrow}$ *norm-bound export through B, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5725.1. The rows X_0, X_1, Y_0, Y_1 provide the endpoint normed-space surfaces, and A_0, A_1 are the only bounded-operator coordinates available to the classifier.

The exponent and strip data are then forced by row order. The endpoint exponent rows E_0, E_1 and the interpolation parameter Θ determine the displayed convex weights, while the $\mathsf{HadamardThreeLines}^{\uparrow}$ row S is the sole strip-estimate route that can compare endpoint bounds.

The bound row B reads only after those endpoint and strip rows are displayed. It exports the interpolated $\mathsf{Real}^{\uparrow}$ norm-bound ledger, not a selected analytic family or a host interpolation space.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since every excluded host object lacks a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 4385.3 (Riesz-Thorin horizontal dependency route)**.** *Every accepted interpolated-bound read for a* $\mathsf{RieszThorinInterpolation}^{\uparrow}$ *packet exposes the Hadamard three-lines strip row, endpoint* $\mathsf{NormedSpace}^{\uparrow}$ *rows, endpoint* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *rows, interpolation-parameter row, and terminal* $\mathsf{Real}^{\uparrow}$ *bound row before the interpolated estimate is visible. Equivalently, every consumer route factors through the displayed dependency lattice*

$$X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B, H, C, P, N$$

and through the sibling certificate surfaces of chapter 3893, chapter 1950, chapter 1644, chapter 224, and chapter 38.

Proof. Project the carrier $T = (X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B, H, C, P, N)$ of Definition 5725.1. The rows X_0, X_1, Y_0, Y_1 are exactly the endpoint normed-space rows, and A_0, A_1 are exactly the endpoint bounded-operator rows over those spaces.

The rows E_0, E_1, Θ record the endpoint exponent and interpolation-parameter data consumed by the strip comparison. The only strip-estimate coordinate is S, so the interpolated estimate cannot be read before the Hadamard three-lines surface named in chapter 3893 is displayed.

The terminal bound row B is downstream of the endpoint, operator, exponent, strip, and interpolation-parameter rows. The structural rows H, C, P, N transport, replay, package, and name that same dependency lattice, and they introduce no bypass around the sibling NormedSpace, BoundedLinearOperator, Interpolation, HadamardThreeLines, or Real surfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}$.

Constructive story: A $\mathsf{RieszThorinInterpolation}^{\uparrow}$ packet is generated from endpoint NormedSpace rows, endpoint BoundedLinearOperator rows, endpoint exponent rows, a HadamardThreeLines strip-estimate row, an interpolation-parameter row, a RealUp norm-bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5725.1, Definition 5725.2, and Definition 5725.3 seed the finite Riesz-Thorin interpolation carrier over endpoint normed spaces, bounded operators, exponent rows, strip estimates, interpolation parameters, norm-bound ledgers, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host interpolation spaces, quotient operator equality, selected extremal analytic families, non-displayed exponent completion, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint normed-space admission, bounded-operator admission, endpoint exponent compatibility, HadamardThreeLines strip-estimate compatibility, interpolation-parameter admission, RealUp norm-bound export, transport, replay, provenance, and local naming for BEDC.Derived.RieszThorinInterpolationUp.

The top-level $\mathsf{RieszThorinInterpolation}^{\uparrow}$ route records the sibling lattice that every interpolated norm-bound read must traverse. The proof surface is anchored in the three-lines estimate of chapter 3893, the normed source and target rows of chapter 1950, the operator-action rows of chapter 1644, the interpolation-family carrier of chapter 224, and the scalar seal of chapter 38.

Lemma 4385.4 (Riesz–Thorin sibling lattice route)**.** *Every accepted* $\mathsf{RieszThorinInterpolation}^{\uparrow}$ *consumer reads its endpoint bounds, analytic-strip comparison, interpolation parameter, bounded-linear-operator action, norm rows, and terminal* $\mathsf{Real}^{\uparrow}$ *scalar estimate through the displayed sibling lattice before the interpolated bound is public. The route exports no host complex interpolation theorem, quotient operator equality, selected analytic family, or ambient completeness coordinate beyond those sibling rows.*

Chapter 4386

A Concrete Naming Certificate for $\mathsf{HoeffdingFiniteSum}^{\uparrow}$

Following Hoeffding's finite bounded-sum inequality, the $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ packet records the finite concentration route by which independent bounded random variables yield an exponential tail estimate. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the law and range summaries of chapter 186, the independence ledger of chapter 187, the dyadic exponential-bound arithmetic of chapter 291, the terminal seal of chapter 38, and the finite-average probability route of chapter 4373. The packet names a bounded finite-sum concentration certificate; it is not a martingale inequality, a Chernoff optimization principle, an almost-sure convergence theorem, a host measure-theoretic limit, or an ambient $\mathsf{Real}^{\uparrow}$ completeness result.

Definition 4386.1 (Hoeffding finite-sum carrier)**.** *A* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, V, I, B, S, D, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row V is the finite family of* $\mathsf{RandomVar}^{\uparrow}$ *entries read over P. The row I is the* $\mathsf{Independence}^{\uparrow}$ *ledger certifying that the displayed family is independent in the finite index range under inspection. The row B is the bounded-range ledger: for each displayed variable it records lower and upper* $\mathsf{Real}^{\uparrow}$ *seals and the corresponding* $\mathsf{Distribution}^{\uparrow}$ *range summary. The row S records the centered finite-sum expression and the positive deviation request. The row D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *exponential-bound row naming the finite dyadic numerator, denominator, square, range-width sum, and slack comparison used by the displayed Hoeffding bound. The row E is the terminal* $\mathsf{Real}^{\uparrow}$ *tail seal naming the probability estimate for the exceptional event. The row H records componentwise* hsame *transport, C records* Cont *replay of the finite concentration route, Q records* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Independence}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$, *and N is the local* $\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these eleven rows.*

Lean4 ✓ `BEDC.Derived.HoeffdingFiniteSumUp.HoeffdingFiniteSumTasteGate single carrier alignment`

Theorem 4386.2 (Hoeffding finite-sum NameCert obligations)**.** *For every accepted* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *carrier $(P, V, I, B, S, D, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 5726.1. Carrier admission displays the probability source, finite random-variable family, independence ledger, bounded-range ledger, finite-sum row, dyadic*

exponential-bound row, $\mathsf{Real}^{\uparrow}$ *tail seal, transport, replay, provenance, and local naming row. The certificate imports no host concentration theorem, martingale filtration, Chernoff variational optimizer, countable-choice schedule, external probability-limit operation, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Read the carrier rows in order. The source row P supplies the event classifier and normalization, while V exposes only a finite family of random variables over that same probability source.

The independence row I and bounded-range row B are then finite ledgers. They state exactly which variables are independent and which displayed lower and upper seals bound each variable before any exponential estimate is available.

The finite-sum row S fixes the centered sum and requested deviation. The dyadic row D records the arithmetic denominator, squared deviation, accumulated range-width budget, and slack comparison used by the exponential estimate, and the $\mathsf{Real}^{\uparrow}$ row E seals the resulting tail bound.

Finally H, C, Q, N transport, replay, source, and name the same route. Since the carrier has no coordinate for a host concentration theorem, variational optimizer, infinite limit, or completeness principle, these displayed rows exhaust the local certificate surface. □

Theorem 4386.3 (Hoeffding finite tail-bound route)**.** *Every accepted* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *tail-bound read factors through the route*

$$\mathsf{ProbSpace}^{\uparrow},\ \mathsf{RandomVar}^{\uparrow},\ \mathsf{Independence}^{\uparrow},\ \mathsf{Distribution}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by the carrier rows $P, V, I, B, S, D, E, H, C, Q, N$*. A probability-bound consumer can inspect the exceptional-event estimate only after the finite probability source, random-variable family, independence ledger, bounded-range ledger, centered-sum row, dyadic exponential-bound row, terminal real seal, transport, replay, provenance, and local naming row have been displayed.*

Proof. Start with an accepted carrier and project the source rows. The probability source P and finite random-variable family V provide the only measurable data available to the tail-bound request.

Next read I and B. The independence ledger is the only route by which the product-event step enters the packet, and the bounded-range ledger is the only route by which distributional lower and upper seals enter the range-width budget.

The centered-sum row S then determines the finite event being bounded. The dyadic row D supplies the exponential-bound arithmetic for that event, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream from the same displayed dyadic comparison.

The structural rows H, C, Q, N preserve that route under classifier replacement and local naming. Therefore every tail-bound read is the finite Hoeffding handoff itself, not a hidden appeal to an external concentration theorem or ambient real-completeness principle. □

Theorem 4386.4 (Hoeffding finite-sum nonescape)**.** *For every accepted* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *packet, every concentration-facing read remains inside the displayed rows* $P, V, I, B, S, D, E, H, C, Q, N$*. In particular, the packet exports no martingale filtration, Chernoff optimizer, almost-sure convergence claim, host probability-limit operator, countable-choice selection, quotient equality of real names, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. The carrier of Definition 5726.1 has no coordinate beyond the eleven displayed rows. Thus a concentration-facing request can only project the probability source, finite variables, independence

ledger, range ledger, sum row, dyadic estimate, real tail seal, transport, replay, provenance, and local name.

The analytic content of the request is concentrated in I, B, S, D, E. Independence, bounded ranges, the finite centered sum, dyadic exponential arithmetic, and the terminal tail seal appear as explicit rows, so no further theorem object can be read from the packet.

The remaining rows H, C, Q, N are structural. They preserve displayed histories, replay the finite route, record package provenance, and attach the local certificate. Hence the accepted packet cannot export any of the excluded limit, optimizer, quotient, choice, or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}$.

Constructive story: A $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ packet is generated from a probability source row, finite random-variable family, independence ledger, bounded-range ledger, centered finite-sum row, dyadic exponential-bound row, RealUp tail seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5726.1, Definition 5726.2, Definition 5726.3, and Definition 5726.4 seed the bounded finite-sum concentration route through ProbSpace, RandomVar, Independence, Distribution, DyadicRatCore, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close martingale inequalities, Chernoff optimization, almost-sure convergence, host probability limits, countable-choice selection, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite independence routing, bounded-range stability, dyadic exponential-bound handoff, tail-seal nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.HoeffdingFiniteSumUp.

Chapter 4387

A Concrete Naming Certificate for RegularCauchyLatticeOperations$^{\uparrow}$

Following Bishop and Bridges, the RegularCauchyLatticeOperations$^{\uparrow}$ packet records the finite constructive lattice-operation surface for regular Cauchy real names. It reads the regular rational route of chapter 301, the terminal real-name seal of chapter 38, the dyadic arithmetic surface of chapter 291, the lower-member packet of chapter 1832, and the upper-member packet of chapter 1833. The certificate gives downstream Real$^{\uparrow}$ consumers one finite min/max interface without importing trichotomy, quotient real equality, selected limits, countable choice, host order completeness, or ambient Real$^{\uparrow}$ completeness.

Definition 4387.1 (Regular Cauchy lattice operations carrier)**.** *A* RegularCauchyLatticeOperations$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, Y, T, D, M, A, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two accepted* Real$^{\uparrow}$ *rows presented by regular Cauchy names, exposing only their finite* RegSeqRat$^{\uparrow}$ *readbacks and terminal real seals.*
2. *T is the shared tolerance row used to align the lower-member and upper-member requests.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *ledger for the displayed comparison scale, branch budgets, and readback arithmetic consumed by both operation rows.*
4. *M is the* RegularCauchyMinimum$^{\uparrow}$ *lower-member row.*
5. *A is the* RegularCauchyMaximum$^{\uparrow}$ *upper-member row.*
6. *R is the paired regular rational readback row for the two operation outputs.*
7. *E is the paired* Real$^{\uparrow}$ *seal row, reached only after M, A, R have been displayed.*
8. *H records componentwise* hsame *transport for the two input names, tolerance, dyadic arithmetic, minimum row, maximum row, readback, seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from a lattice-operation request through $X, Y, T, D, M, A, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* RegularCauchyLatticeOperations$^{\uparrow}$*,* RegularCauchyMinimum$^{\uparrow}$*,* RegularCauchyMaximu RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, T, D, M, A, R, E, H, C, P, N$. The carrier has no coordinate for trichotomy, quotient real equality, host order completeness, selected limits, countable choice, a host lattice structure, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularCauchyLatticeOperationsUp.RegularCauchyLatticeOperationsTasteGate`
`single carrier alignment`

Theorem 4387.2 (Regular Cauchy lattice operations NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ *carrier*

$$L = (X, Y, T, D, M, A, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two regular Cauchy real rows, shared tolerance row, dyadic arithmetic ledger, minimum row, maximum row, paired readback, paired seal, transport, replay, provenance, and local name;*
2. *shared-scale exposure, requiring T and D to be displayed before either M or A may be consumed;*
3. *lower-member routing, requiring the minimum output to be read through the* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *row M;*
4. *upper-member routing, requiring the maximum output to be read through the* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *row A;*
5. *readback and seal ordering, requiring R to expose the paired regular rational outputs before E exposes the paired* $\mathsf{Real}^{\uparrow}$ *seals;*
6. *classifier stability, requiring componentwise* hsame *transport of $X, Y, T, D, M, A, R, E, C, P, N$ to preserve the accepted operation route;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no trichotomy, quotient real equality, host order completeness, selected limit, countable choice, host lattice structure, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5727.1. Its displayed rows are exactly the two regular Cauchy real inputs, the shared tolerance row, the dyadic ledger, the two operation rows, the paired readback and seal rows, and the structural rows.

Shared-scale exposure follows because M and A have no independent tolerance coordinate inside this packet. Both operation rows read the same T, D surface before any output row can be consumed.

The lower-member and upper-member obligations are inherited as named rows, not as host operations. The packet can read the lower member only through M and the upper member only through A.

Readback and seal ordering is forced by R, E. The real-facing consumer first receives the paired regular rational readback and only then the paired $\mathsf{Real}^{\uparrow}$ seal. Transport, replay, provenance, and local naming are exhausted by H, C, P, N, so no excluded host or quotient object is available. □

Theorem 4387.3 (Regular Cauchy lattice operations min-max readback)**.** *Let* $L = (X, Y, T, D, M, A, R, E, H, C, P$ *be an accepted* $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the lattice-operation output factors through the finite route*

$$X, Y, T, D \longmapsto M, A \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the packet exports the lower and upper regular Cauchy operation outputs only as paired $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *and* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *readbacks over the same dyadic scale. It exports no trichotomy, quotient real equality, host order completeness, selected limit, countable choice, or host lattice operation.*

Proof. Start with a real-facing read of the carrier. The only input rows are X, Y, and the only scale rows are T, D, so the consumer must read those coordinates before either operation row is available.

The operation rows are M and A. By Definition 5727.1, M names the lower-member route and A names the upper-member route; neither row carries a separate host order principle.

After the operation rows are displayed, the readback row R exposes the paired regular rational outputs and the seal row E exposes the paired $\mathsf{Real}^{\uparrow}$ boundary. The structural rows H, C, P, N preserve and name this route without adding any coordinate beyond it. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5727.1, Definition 5727.2, and Definition 5727.3 seed a finite min/max operation route for two regular Cauchy real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, host order completeness, selected limits, countable choice, host lattice operations, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-scale exposure, lower-member routing, upper-member routing, readback ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLatticeOperationsUp.

Constructive story: A $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ packet is generated from two regular Cauchy Real rows, a shared dyadic tolerance surface, RegularCauchyMinimum and RegularCauchyMaximum rows, paired regular rational readback, a paired RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4388

A Concrete Naming Certificate for $\mathsf{CauchyModulusBridge}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyModulusBridge}^{\uparrow}$ packet records the finite handoff by which a displayed Cauchy-criterion request becomes an explicit modulus schedule before any regular-rational readback or real-name seal is consumed. It sits after the effective criterion packet of chapter 3695, the modulus schedule surface of chapter 292, the regular rational readback of chapter 301, the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the L10 bridge from criterion-facing reads to explicit schedules as finite NameCert data; it is not quotient stream equality, a selected host limit, countable choice, trichotomy, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4388.1 (Cauchy modulus bridge carrier)**.** *A* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, M, E, S, D, R, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyCriterion}^{\uparrow}$ *request row naming the late-pair comparison surface to be served by the bridge.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row assigning the displayed precision request to a finite tail threshold.*
3. *E is the* $\mathsf{EffectiveCauchyCriterion}^{\uparrow}$ *row tying the same criterion request and modulus schedule to a finite effective handoff.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the criterion request and scheduled by the modulus row.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the radius, tail comparison, and endpoint budget used by the request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row available only after Q, M, E, S, D have been displayed.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the criterion, modulus, effective handoff, window, tolerance, and regular-rational rows have been read.*
8. *H records componentwise* hsame *transport for the criterion, modulus, effective handoff, stream-window, dyadic, regular-rational, real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a Cauchy-criterion request through $Q, M, E, S, D, R, L, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusBridge}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, EffectiveCauchyCriterio StreamName$^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, M, E, S, D, R, L, H, C, P, N$. It has no coordinate for quotient streams, selected limits, host sequence equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusBridgeUp.CauchyModulusBridgeTasteGate single carrier alignment`

Theorem 4388.2 (Cauchy modulus bridge NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *carrier $B = (Q, M, E, S, D, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed criterion row Q, modulus schedule M, effective criterion handoff E, finite stream window S, dyadic tolerance ledger D, regular-rational readback R, terminal real seal L, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 5728.1. The analytic rows visible to a consumer are exactly the criterion request Q, modulus schedule M, effective handoff E, finite window S, dyadic tolerance ledger D, regular-rational readback R, and terminal real seal L.

The bridge obligation is the ordering of those rows. A Cauchy-criterion request first exposes Q and then reads the displayed threshold in M through the effective handoff E; only after that handoff are the stream window S and dyadic tolerance ledger D available for regular readback.

The downstream rows are forced by the same carrier projection. The row R is the $\mathsf{RegSeqRat}^{\uparrow}$ readback obtained from the displayed window and tolerance data, and L is the $\mathsf{Real}^{\uparrow}$ seal reached only through that readback.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4388.3 (Cauchy modulus bridge effective-criterion handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CauchyCriterion}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{EffectiveCauchyCriterion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Re}$$

The handoff exposes only the displayed criterion request, explicit modulus schedule, effective criterion row, finite stream window, dyadic tolerance ledger, regular rational readback, terminal real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. It exports no quotient stream equality, selected host limit, hidden modulus oracle, countable-choice schedule, trichotomy split, host sequence equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with Definition 5728.2. It places every consumer read behind the criterion row, the explicit modulus row, and the effective criterion handoff.

Next open the finite observation route. The stream-window row S and dyadic tolerance row D are downstream of Q, M, E, so the regular-rational row R is a displayed readback from the same request rather than a detached sequence or selected limit.

The terminal seal is last. The $\mathsf{Real}^{\uparrow}$ row L is consumed only after R has been displayed, while H, C, P, N preserve the same dependency order under transport, replay, provenance, and local naming.

Thus any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer sees exactly the route stated in the theorem and cannot bypass it through a hidden analytic object. □

Theorem 4388.4 (Cauchy modulus bridge choice-free schedule)**.** *Let*

$$B = (Q, M, E, S, D, R, L, H, C, P, N) \quad \textit{and} \quad B' = (Q', M', E', S', D', R', L', H', C', P', N')$$

be accepted $\mathsf{CauchyModulusBridge}^{\uparrow}$ *carriers. If they agree componentwise on the displayed rows* $Q, M, E, S, D, R, L, H, C, P, N$*, then they determine the same modulus schedule and the same* $\mathsf{Real}^{\uparrow}$ *seal. No consumer of either packet can insert a countable-choice schedule, hidden modulus oracle, selected host limit, or extra selector coordinate between the criterion request and the terminal seal.*

Proof. Project both carriers through Definition 5728.1. The hypothesis identifies every displayed coordinate of B and B', so the criterion requests, explicit modulus rows, effective handoff rows, stream windows, dyadic ledgers, regular readbacks, Real seals, transport, replay, provenance, and local names are the same.

Use Definition 5728.2 to read the NameCert surface. Its obligation list has no row outside $Q, M, E, S, D, R, L, H, C, P, N$, so there is no remaining coordinate in which a second schedule or selector could differ.

Apply Definition 5728.3. The consumer order is forced as Q then M then E then S then D then R then L, and the terminal $\mathsf{Real}^{\uparrow}$ seal is downstream from the same regular-rational readback.

Thus the two accepted packets determine the same choice-free schedule and the same Real seal. The excluded choice and selector objects cannot be inserted because the carrier and its NameCert obligations expose no such coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyModulusBridge}^{\uparrow}$ packet is generated from a CauchyCriterion request row, a CauchyModulus schedule, an effective Cauchy criterion handoff, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5728.1, Definition 5728.2, Definition 5728.3, and Definition 5728.4 seed the finite bridge from Cauchy-criterion requests to explicit modulus schedules before RegSeqRat and Real consumers read the route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyModulusBridgeUp.CauchyModulusBridgeTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, hidden modulus oracles, countable choice, trichotomy, host sequence equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion-to-modulus exactness, effective handoff ordering, StreamName and DyadicRatCore readback, RegSeqRat handoff, RealUp seal confinement, transport stability, continuation replay, and provenance nonescape for BEDC.Derived.CauchyModulusBridgeUp.

Chapter 4389

A Concrete Naming Certificate for $\mathsf{MyhillNerode}^{\uparrow}$

Following Myhill and Nerode, the $\mathsf{MyhillNerode}^{\uparrow}$ packet records the finite right-congruence classifier behind regular languages and minimal finite automata as displayed BEDC data. It consumes accepted-word rows from chapter 351, presentation rows from chapter 2364, finite carrier rows from chapter 112, and word-spine rows from chapter 36. The packet does not import an external quotient of all languages; it names the finite distinguishability ledger that a minimization consumer can audit.

Definition 4389.1 (Myhill–Nerode carrier)**.** *A* $\mathsf{MyhillNerode}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (\Sigma, W, L, E, C, D, Q, \delta, q_0, F, \mu, H, R, P, N)$$

with the following displayed rows:

1. Σ *is the finite alphabet row, read through* $\mathsf{FinSet}^{\uparrow}$*.*
2. W *is the finite word-window row, read through* $\mathsf{List}^{\uparrow}$ *over* Σ*.*
3. L *is the accepted-word observation ledger supplied by a* $\mathsf{RegularLanguage}^{\uparrow}$ *packet.*
4. E *is the finite right-congruence table on the displayed word window.*
5. C *is the context-extension row recording that suffix extension by displayed words preserves the table.*
6. D *is the distinguishability row naming a displayed suffix witness whenever two table rows are separated.*
7. Q *is the finite state row whose states are the displayed equivalence classes of* E*.*
8. δ *is the transition row induced by appending one alphabet symbol to a class representative.*
9. q_0 *is the start class of the empty word.*
10. F *is the accepting-class row, determined by membership in the accepted-word ledger.*
11. μ *is the minimization handoff row from the right-congruence table to the finite automaton presentation.*
12. H *stores componentwise* hsame *transport for alphabet, word-window, language, congruence, suffix, state, transition, accepting, and minimization rows.*

13. *R stores* Cont *replay from a regular-language query through the displayed right-congruence table.*
14. *P stores* Pkg *provenance over* $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{FiniteAutomaton}^{\uparrow}$, $\mathsf{FinSet}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
15. *N is the local* $\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Sigma, W, L, E, C, D, Q, \delta, q_0, F, \mu, H, R, P, N$. It has no coordinate for an infinite language quotient, a nondeterministic presentation, a regular-expression conversion, or a proof that an arbitrary external automaton has already been minimized.

Lean4 ✓ `BEDC.Derived.MyhillNerodeUp.MyhillNerodeTasteGate single carrier alignment`

Theorem 4389.2 (Myhill–Nerode NameCert obligations)**.** *For every accepted* $\mathsf{MyhillNerode}^{\uparrow}$ *carrier*

$$M = (\Sigma, W, L, E, C, D, Q, \delta, q_0, F, \mu, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}$ *surface consists exactly of finite alphabet exposure, word-window exposure, accepted-word observation, right-congruence tabulation, suffix-stability replay, distinguishability witnesses, quotient-state construction, induced transition replay, start-class selection, accepting-class selection, minimization handoff, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5729.1. The rows Σ, W, L, E, C, D expose the finite observation table and the suffix-stability checks used to read right congruence.

The rows Q, δ, q_0, F then repackage the table as a deterministic finite automaton presentation. Since Q is built from the displayed classes of E, the transition row is read by extending a representative by one displayed alphabet symbol and returning to the corresponding class.

The rows μ, H, R, P, N keep the minimization handoff, transport, replay, provenance, and local name attached to the same packet. No omitted coordinate can supply an external quotient, nondeterministic branch, or regular-expression conversion, so the listed rows exhaust the NameCert obligations. □

Theorem 4389.3 (Myhill–Nerode DFA minimization handoff)**.** *Every* $\mathsf{RegularLanguage}^{\uparrow}$ *consumer that claims a minimal deterministic finite automaton through a* $\mathsf{MyhillNerode}^{\uparrow}$ *packet must expose the finite right-congruence row E, the suffix-stability row C, the distinguishability row D, the quotient-state row Q, the induced transition row δ, the accepting-class row F, and the minimization handoff row μ. The handoff may feed a* $\mathsf{FiniteAutomaton}^{\uparrow}$ *presentation with those rows, but it does not identify arbitrary automaton presentations, choose a nondeterministic branch, or translate the packet into a regular-expression proof.*

Proof. Begin with the obligation theorem Definition 5729.2. It forces every minimization read through the displayed right-congruence table, suffix-stability replay, and distinguishability witnesses before any quotient-state row is consumed.

The quotient construction then uses the finite rows Q, δ, q_0, F to build a deterministic presentation. This presentation is compatible with the finite automaton carrier of chapter 2364 because it exposes finite states, a finite alphabet, a transition table, a start state, accepting states, and replay rows.

The minimization handoff remains bounded by the displayed table. It proves only the certificate route from regular-language observations to the minimal finite presentation named by the packet; stronger equivalence claims are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}$.

Constructive story: A $\mathsf{MyhillNerode}^{\uparrow}$ packet is generated from a finite alphabet row, word-window row, accepted-word observation ledger, right-congruence table, suffix-stability row, distinguishability witnesses, quotient-state row, induced transition row, start class, accepting classes, minimization handoff, componentwise transport, continuation replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5729.1, Definition 5729.2, and Definition 5729.3 seed the finite right-congruence certificate and its deterministic-minimization handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary automaton equivalence, nondeterministic minimization, regular-expression conversion, host-language quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, right-congruence stability, distinguishability coverage, quotient-state exactness, induced-transition replay, minimization handoff, TasteGate coverage, transport, replay, provenance, and local naming for BEDC.Derived.MyhillNerodeUp.

Chapter 4390

A Concrete Naming Certificate for $\mathsf{VariationSeminorm}^{\uparrow}$

Following Bishop–Bridges bounded-variation analysis and the Bourbaki treatment of seminormed structures, the $\mathsf{VariationSeminorm}^{\uparrow}$ packet records the finite seminorm-budget surface attached to displayed partition variation data. It sits between the bounded-variation carrier of chapter 398, the bounded-variation real-function row of chapter 3654, the variation-norm consumer of chapter 3804, the Jordan route of chapter 2069, the total-variation function surface of chapter 2257, the regular rational readback of chapter 301, and the terminal real endpoint seal of chapter 38. The packet names displayed partition-variation budgets and seminorm comparison rows without selecting a host supremum over all partitions, a quotient class of functions, or a completed bounded-variation space.

Definition 4390.1 (VariationSeminorm carrier)**.** *A* $\mathsf{VariationSeminorm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, F, J, T, R, Q, A, L, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{BoundedVariation}^{\uparrow}$ *packet, including its displayed partition ledger, endpoint rows, adjacent-edge observations, finite variation sum, and common-refinement data.*
2. *F is the* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *read tying the partition ledger to a displayed real-valued function row over the inspected interval.*
3. *J is the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *handoff row, exposing only the finite positive- and negative-variation ledgers available from the same partition data.*
4. *T is the* $\mathsf{TotalVariationFunction}^{\uparrow}$ *observation row for the displayed partition windows inspected by the packet.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal for all scalar values and variation budgets that the packet compares.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used when scalar budgets and endpoint values are inspected through regular rational names.*
7. *A is the displayed variation-seminorm row. It records the null-row witness for constant differences, finite additivity over displayed concatenations, scalar budget transport, and monotone comparison of partition refinements.*

8. *L is the seminorm ledger, listing the partition windows, budget rows, finite variation sums, constant-row witnesses, and refinement comparisons used by A.*
9. *H records componentwise* hsame *transport for the bounded-variation source, real-function row, Jordan route, total-variation observation, Real seal, regular-name readback, seminorm row, ledger, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a seminorm-budget request through $B, F, J, T, R, Q, A, L, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{VariationSeminorm}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{VariationNorm}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed source packet, real-function row, Jordan route, total-variation observation, Real and RegSeqRat scalar reads, seminorm ledger, componentwise transport, replay, provenance, and local name. It has no coordinate for a host supremum, quotient equality of functions, a completed seminormed space, a measure-theoretic variation object, or bridge checking.

Lean4 ✓ `BEDC.Derived.VariationSeminormUp.VariationSeminormTasteGate single carrier alignment`

Theorem 4390.2 (VariationSeminorm NameCert obligations)**.** *For every accepted* $\mathsf{VariationSeminorm}^{\uparrow}$ *carrier $S = (B, F, J, T, R, Q, A, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}$ *surface consists exactly of bounded-variation source admission, bounded-variation real-function readback, Jordan-route availability, total-variation observation, Real endpoint sealing, RegSeqRat scalar readback, displayed seminorm-row formation, ledger exactness, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming through the displayed rows.*

Proof. Project the finite carrier of Definition 5730.1. The analytic data available to the packet are the bounded-variation source B, the real-function row F, the Jordan handoff J, the total-variation observation T, the Real seal R, and the regular-name readback Q.

The seminorm row A is then formed from the displayed budget comparisons in those rows. Its null-row, finite-additivity, scalar-transport, and refinement-monotonicity clauses are recorded in the ledger L, so each seminorm request is tied to inspected partition windows rather than to a hidden family of all partitions.

Finally H, C, P, N transport, replay, source, and name exactly the same finite surface. Since the carrier has no host-supremum, quotient-function, completed-space, variation-measure, or bridge coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 4390.3 (VariationSeminorm refinement budget route)**.** *Every accepted* $\mathsf{VariationSeminorm}^{\uparrow}$ *packet exports the finite route*

$$\mathsf{BoundedVariation}^{\uparrow}, \mathsf{BoundedVariationRealFunction}^{\uparrow} \longrightarrow \mathsf{JordanVariationDecomposition}^{\uparrow}, \mathsf{TotalVariationFunction}^{\uparrow} \longrightarrow$$

to bounded-variation completion and regulated-integration consumers. The route transports displayed partition-variation budgets and seminorm comparison rows, but it exports no host supremum over all partitions, quotient equality of functions, selected Jordan decomposition, completed bounded-variation Banach space, or bridge data.

Proof. Begin with an accepted packet $S = (B, F, J, T, R, Q, A, L, H, C, P, N)$. A consumer first reads the bounded-variation source and real-function rows, so every endpoint value and edge variation remains tied to the finite partition windows in B and F.

The Jordan and total-variation rows are then read only as displayed handoffs. They expose finite positive- and negative-variation ledgers and total-variation observations attached to the same partition windows.

The scalar budget route is sealed by Q and R. The seminorm ledger L records the null, additivity, scalar-transport, and refinement-comparison rows used by A, while H, C, P, N transport, replay, source, and name the packet. No remaining coordinate can supply the excluded host objects, so the exported route is exactly the displayed finite seminorm-budget route. □

Falsifiable prediction: Every accepted $\mathsf{VariationSeminorm}^{\uparrow}$ read factors through a displayed $\mathsf{BoundedVariation}^{\uparrow}$ source, a $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ row, $\mathsf{JordanVariationDecomposition}^{\uparrow}$ and $\mathsf{TotalVariationFunction}^{\uparrow}$ handoff rows, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ scalar reads, and the local seminorm ledger, transport, replay, provenance, and naming rows.

Independence witness: boundedvariation, bounded-variation-real-function, variation-norm, jordan-variation-decomposition, total-variation-function, regseqrat, and real: no listed sibling is bijective to $\mathsf{VariationSeminorm}^{\uparrow}$ because this packet stores the seminorm-specific null, finite-additivity, scalar-transport, refinement-budget, ledger, replay, provenance, and local naming rows together as one finite surface.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationSeminorm}^{\uparrow}$ packet is generated from a BoundedVariation source, a BoundedVariationRealFunction read, JordanVariationDecomposition and TotalVariationFunction handoff rows, RegSeqRat and Real scalar reads, a displayed seminorm row, a finite budget ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5730.1, Definition 5730.2, and Definition 5730.3 seed the finite variation-seminorm carrier, obligation surface, and refinement-budget route over displayed bounded-variation and scalar-readback rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.VariationSeminormUp.VariationSeminormTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host suprema over all partitions, quotient equality of functions, selected Jordan decompositions, completed bounded-variation Banach spaces, variation measures, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, real-function readback, Jordan and total-variation handoff availability, Real and RegSeqRat scalar exactness, seminorm ledger exactness, classifier transport, replay, provenance, local naming, and nonescape for BEDC.Derived.VariationSeminormUp.

Chapter 4391

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet records the separated completion boundary needed by the L10 Real and Completion route as finite BEDC data. It sits after the separation predicate of chapter 1925, the separated-completion carrier of chapter 1612, the metric completion route of chapter 1506, the finite stream interface of chapter 126, the dyadic tolerance core of chapter 291, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the envelope through displayed rows only; it does not quotient filters, select representatives, identify host equalities, invoke countable choice, or import ambient completeness.

Definition 4391.1 (Hausdorff completion envelope carrier)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (H, S, M, W, D, R, L, T, K, P, N)$$

where H *is the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$ *separation row,* S *is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* L *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal,* T *is componentwise* $\mathsf{BHist}/\mathsf{hsame}$ *transport,* K *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *row. A consumer of* E *receives a separated completion boundary only through these coordinates.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeTasteGate single carrier alignment`

Theorem 4391.2 (Hausdorff completion envelope obligations)**.** *Every accepted* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *read must expose the carrier of Definition 5789.1 in the order*

$$H, S, M, W, D, R, L, T, K, P, N.$$

The separation row H *and separated-completion row* S *are available before metric completion, stream observation, dyadic tolerance, regular readback, and real-seal rows are consumed; the transport, replay, provenance, and naming rows preserve the same displayed packet.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeNameCertObligations`

Proof. Project the carrier of Definition 5789.1. The packet has no completion-facing coordinates except $H, S, M, W, D, R, L, T, K, P, N$.

The Hausdorff and separated-completion rows are the first boundary data in the packet. Thus a consumer cannot inspect the metric completion route, finite stream windows, dyadic tolerances, regular readback, or terminal real seal without first reading the displayed separation surface.

Finally, the structural rows T, K, P, N only transport, replay, source, and name the same finite packet. They do not create quotient filters, selected representatives, host equality, choice-selected routes, or ambient completeness. □

Theorem 4391.3 (Hausdorff completion separated metric route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier factors through the separated route*

$$H, S \longmapsto M \longmapsto W, D, R, L.$$

The route records a separated metric-completion boundary for the L10 Real and Completion interface, not a quotient completion, a host equality theorem, a choice-selected representative, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier separated metric route`

Proof. Start from Definition 5789.2. It places the Hausdorff row H and separated-completion row S before the metric completion row M and before the stream, dyadic, regular-rational, and real-seal rows.

Read the metric completion route through M. Since M is downstream of H, S, every completion-facing use of M carries the displayed separated boundary with it.

The final Real-facing read is the finite route W, D, R, L. Because these rows are still coordinates of the same carrier, the route cannot be replaced by quotient representatives, host equality, countable choice, or ambient completeness. □

Theorem 4391.4 (Hausdorff completion envelope sibling route)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *consumer may hand its separated boundary to* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *only through the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$*,* $\mathsf{SeparatedCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows of*

$$E = (H, S, M, W, D, R, L, T, K, P, N).$$

The handoff contains no quotient-filter coordinate, representative-selection coordinate, host-equality coordinate, or ambient-completeness coordinate.

Proof. Apply Definition 5789.2. It places the Hausdorff row H, separated-completion row S, metric-completion row M, stream row W, dyadic row D, regular-rational row R, and terminal Real row L inside one displayed packet.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

The sibling $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ consumer therefore reads the same separated boundary as its input surface rather than receiving a separate primitive. Since the carrier only has the displayed rows and the structural rows T, K, P, N, quotient filters, selected representatives, host equality, and ambient completeness remain outside the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier sibling route`

Theorem 4391.5 (Hausdorff completion envelope Cauchy-net consumer link)**.** *Every* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier must read the same* $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before its directed-net completion route is consumed. The downstream sibling is chapter 3794, and the handoff is the displayed route*

$$H, S, M, W, D, R, L \longmapsto \mathsf{CauchyNetCompletion}^{\uparrow}.$$

It exports no quotient net, selected representative, host equality, countable-choice schedule, or ambient completeness coordinate.

Proof. Project the carrier $E = (H, S, M, W, D, R, L, T, K, P, N)$ of Definition 5789.1. The only completion-facing rows available to a consumer are the Hausdorff row H, separated-completion row S, metric-completion route M, finite stream row W, dyadic tolerance row D, regular readback row R, and terminal Real row L.

Apply Definition 5789.2. It places H, S, M, W, D, R, L inside one displayed packet before the structural rows T, K, P, N are used for transport, replay, provenance, and local naming.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

Therefore a downstream $\mathsf{CauchyNetCompletion}^{\uparrow}$ read can only consume the envelope through the same separated metric route before its directed-net completion surface is inspected. Since the packet has no quotient-net, selected-representative, host-equality, countable-choice, or ambient-completeness row, none of those objects can enter the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeForwardLink`

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5789.1, Definition 5789.2, and Definition 5789.3 name the separated completion envelope surface for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, host equality, choice-selected representatives, or ambient completeness.

Upgrade path: Obligation closure requires the carrier route to be tied to the sibling completion obligation theorems and then exposed as a public chapter surface.

Constructive story: A $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet is generated from Hausdorff separation, separated-completion boundary, metric-completion route, finite stream windows, dyadic tolerance, regular-rational readback, Real seal, transport, replay, provenance, and local NameCert rows.

Chapter 4392

A Concrete Naming Certificate for $\mathsf{BoundedLinearFunctional}^{\uparrow}$

Following Banach and Bourbaki functional analysis, the $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet records the scalar-valued bounded-linear-operator row that duality and weak-star consumers inspect before any host dual space is available. It sits over the linear-map route of chapter 48, the bounded-linear-operator surface of chapter 1644, the scalar-bound neighbour chapter 3603, the Banach-dual row of chapter 2265, the finite weak-star window of chapter 3420, the scalar endpoint seal of chapter 38, and the normed source surface of chapter 1950. The chapter names only displayed scalar-functional data: source rows, linearity rows, scalar target readback, norm-bound evidence, transport, replay, provenance, and local naming.

Definition 4392.1 (Bounded linear functional carrier)**.** *For a displayed* $\mathsf{NormedSpace}^{\uparrow}$ *source row* E *over the scalar endpoint surface of* $\mathsf{Real}^{\uparrow}$*, a* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E)$ *carrier is a finite* BHist *packet*

$$\Lambda = (E, L, T, K, O, H, C, P, N)$$

with the following displayed rows:

1. *E is the source normed-space row, including its carrier endpoints, scalar action, additive row, norm row, and classifier.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row from E to the scalar* $\mathsf{Real}^{\uparrow}$ *target.*
3. *T is the scalar-valued* $\mathsf{BoundedLinearOperator}^{\uparrow}(E, \mathsf{Real}^{\uparrow})$ *row carrying the same endpoint action as L.*
4. *K is the* $\mathsf{Real}^{\uparrow}$ *nonnegative bound endpoint for the functional.*
5. *O is the* $\mathsf{OperatorNorm}^{\uparrow}$ *handoff row exposing where the bound K is used.*
6. *H records componentwise* hsame *transport for the source, linear-map row, bounded-operator row, scalar bound, operator-norm handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a scalar-functional request through E, L, T, K, O, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedLinearFunctional}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{BanachDual}^{\uparrow}$, $\mathsf{BanachAlaoglu}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed source classifier, scalar endpoint transport, bounded-operator transport, bound transport, norm-bound ledger transport, replay, provenance, and local naming rows. It has no coordinate for a host dual space, quotient equality of functions, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BoundedLinearFunctionalUp.BoundedLinearFunctionalTasteGate single carrier alignment`

Theorem 4392.2 (Bounded linear functional NameCert obligations)**.** *For every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *carrier* $\Lambda = (E, L, T, K, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *surface consists exactly of source normed-space admission, linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from host dual objects. A consumer may inspect* $E, L, T, K, O, H, C, P, N$*, but it receives no ambient function space, quotient operator equality, selected representative, Hahn–Banach witness, unrestricted weak-star compactness theorem, or bridge data.*

Proof. Project the carrier rows. The analytic coordinates are exactly the source normed-space row E, the linear-map row L, the scalar-valued bounded-operator row T, the RealUp bound endpoint K, and the operator-norm handoff O.

The linearity obligation is read through $\mathsf{LinMap}^{\uparrow}$, while boundedness is read through $\mathsf{BoundedLinearOperator}^{\uparrow}(E,$ The scalar target is already the displayed $\mathsf{Real}^{\uparrow}$ endpoint surface, so the functional row never becomes a host-level function.

The bound exactness is the shared route through K and O. The operator-norm handoff records where the scalar bound is used, and componentwise hsame transport moves the source, action, bound, ledger, replay, provenance, and local naming rows together.

No remaining coordinate can manufacture a dual-space quotient, selected representative, Hahn–Banach witness, unrestricted compactness theorem, or bridge check. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 4392.3 (Bounded linear functional operator-norm handoff)**.** *Every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E$ *packet exports the finite route*

$$\mathsf{LinMap}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{OperatorNorm}^{\uparrow} \longmapsto \mathsf{BoundedLinearFunctional}^{\uparrow}$$

to functional-analysis consumers. The route first exposes the carried scalar-valued linear action, then the bounded-operator row, then the RealUp bound endpoint and operator-norm ledger; it does not expose a host supremum, quotient equality of functionals, selected norm-attaining vector, or hidden Banach completeness.

Proof. Begin with an accepted packet $\Lambda = (E, L, T, K, O, H, C, P, N)$. The read of L supplies only the displayed linear-map action from the source row to the scalar target.

The read of T then packages the same action as a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row. Its target row is $\mathsf{Real}^{\uparrow}$, and its bound endpoint is the displayed scalar K.

Finally the operator-norm handoff O records the norm-bound ledger that downstream consumers may inspect. Because no host norm function, quotient functional equality, selected vector, or hidden completion row is present, the exported handoff is exactly the displayed scalar-bound route. □

Theorem 4392.4 (Bounded linear functional dual-row nonescape)**.** *Any read of a* $\mathsf{BanachDual}^{\uparrow}$ *or* $\mathsf{BanachAlaoglu}^{\uparrow}$ *consumer that uses a* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *row factors through the same source normed-space row, scalar-valued bounded-operator row, RealUp bound endpoint, operator-norm handoff, componentwise transport, replay, provenance, and local naming rows of Definition 5790.1. The duality consumer receives a finite scalar-functional row, not a host dual space, a quotient function class, an unrestricted weak-star compactness theorem, or a selected cluster point.*

Proof. Read the duality consumer first. A $\mathsf{BanachDual}^{\uparrow}$ request needs a scalar-functional row over a displayed source, while a $\mathsf{BanachAlaoglu}^{\uparrow}$ request needs a finite family of such scalar-functional observations.

In either case the only scalar-functional packet available here is Λ. Its source row, bounded-operator row, bound endpoint, operator-norm handoff, and structural rows are projected in the order displayed by Definition 5790.1.

The downstream dual chapters may reuse those rows, but they cannot add coordinates that are absent from the packet. Thus quotient dual objects, host function classes, unrestricted weak-star compactness, selected cluster points, and bridge checks remain outside the read. □

Falsifiable prediction: Every accepted $\mathsf{BoundedLinearFunctional}^{\uparrow}$ scalar-functional read factors through a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ action row, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, and the local hsame, Cont, Pkg, and NameCert rows.

Independence witness: linearmap, boundedlinearoperator, operatornorm, banachdual, banachalaoglu, real, and normedspace: no listed sibling is bijective to $\mathsf{BoundedLinearFunctional}^{\uparrow}$ because this packet stores the scalar target restriction, the dual-facing provenance row, the operator-norm handoff, transport, replay, and local naming together as one finite scalar-functional surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet is generated from a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ scalar action, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5790.1, Definition 5790.2, Definition 5790.3, and Definition 5790.4 seed the scalar-functional row consumed by BanachDualUp and BanachAlaogluUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host dual spaces, quotient equality of functionals, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, scalar linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm handoff exactness, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BoundedLinearFunctionalUp.

Chapter 4393

A Concrete Naming Certificate for $\mathsf{CompletionModulusCategory}^{\uparrow}$

Following Bishop and Bridges on constructive completion and the functorial treatment of completions, the $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet records the finite category surface whose arrows preserve displayed completion moduli. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the completion functor of chapter 426, and the Cauchy completion functor of chapter 423. The packet names modulus-preserving completion morphisms as BEDC rows; it does not export quotient completions, selected representatives, host continuous maps, countable choice, or ambient completeness.

Definition 4393.1 (CompletionModulusCategory carrier)**.** *A* $\mathsf{CompletionModulusCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, A, S, R, D, E, F, H, C, P, N)$$

with the following displayed rows:

1. *O is the object ledger. Each object row records a completion-facing source, its displayed Cauchy-modulus discipline, and the local completion target read through the surrounding completion chapters.*
2. *A is the arrow ledger. Each arrow row records a finite morphism request together with the modulus transformation that sends source tolerances to target tolerances.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source and target names of an arrow.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the stream windows have been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare source and target moduli.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row read only after S, R, D have supplied the displayed tolerance route.*
7. *F records identity and composition rows for the completion functoriality surface, with identity arrows preserving the same modulus and composite arrows composing the displayed modulus transformations.*
8. *H records componentwise* hsame *transport for object rows, arrow rows, stream windows, regular readback, dyadic tolerances, Real seals, functoriality rows, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an arrow request through $O, A, S, R, D, E, F, H, P, N$.*
10. *P is the* Pkg *provenance over* CompletionModulusCategory$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, CauchyCompletionFunctor$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{CompletionModulusCategory}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite category packet for modulus-preserving completion morphisms. It has no coordinate for quotient completion points, selected representatives, host functions, global choice schedules, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryTasteGate single carrier alignment`

Theorem 4393.2 (CompletionModulusCategory NameCert obligations)**.** *For every accepted* CompletionModulusCa *carrier $M = (O, A, S, R, D, E, F, H, C, P, N)$, the local* NameCert$_{\text{CompletionModulusCategory}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed object ledger, arrow ledger, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, identity and composition rows, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface additionally requires each arrow row in A to expose its source modulus, target modulus, and modulus transformation before any Real$^{\uparrow}$*-facing read is accepted; each identity row in F to preserve the displayed modulus without adding a choice coordinate; and each composition row in F to compose the two displayed modulus transformations before the downstream seal is visible.*

Proof. Project the accepted carrier. The packet contains only the rows $O, A, S, R, D, E, F, H, C, P, N$, so carrier admission and ledger exhaustion are componentwise.

An arrow-facing request first reads the object and arrow ledgers O, A. The source and target names are then inspected through the finite stream windows S, regular rational readback R, and dyadic tolerance ledger D.

The functoriality rows F are local to the same displayed moduli. Identity preserves the stored modulus transformation, and composition combines the two stored transformations before the terminal seal E can be read.

Finally H, C, P, N transport, replay, source, and name this same finite route. Since quotient completions, selected representatives, host functions, global choice schedules, and ambient completeness are not carrier coordinates, they cannot be exported by the local NameCert. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryNameCertObligations`

Theorem 4393.3 (CompletionModulusCategory modulus functoriality)**.** *Every completion-facing consumer of an accepted* CompletionModulusCategory$^{\uparrow}$ *packet reads a modulus-preserving morphism through the finite route*

$$O, A, S, R, D, F, E, H, C, P, N.$$

Thus identity and composition of completion morphisms preserve the displayed modulus data before any Real$^{\uparrow}$ *seal or completion-functor read is exposed. The route factors through* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, *and* CauchyCompletionFunctor$^{\uparrow}$ *rather than through quotient completion equality, selected representatives, host continuous maps, countable choice, or ambient completeness.*

Proof. Start with a completion-facing morphism request. The object ledger O fixes the source and target completion rows, and the arrow ledger A fixes the modulus transformation to be checked.

The readback rows S, R, D display the inspected stream windows, regular rational observations, and dyadic tolerance comparisons. These rows are the only route by which the requested modulus can face the terminal Real seal.

The functoriality row F then supplies the identity or composition clause. In the identity case the same displayed modulus is replayed. In the composition case the two displayed modulus transformations are composed as finite rows before the result is handed to E.

The structural rows H, C, P, N preserve and name the same route. Therefore every completion-functor consumer receives finite modulus preservation data and no excluded quotient, selection, host-map, choice, or ambient-completeness surface. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryModulusFunctoriality`

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}$.

Constructive story: A $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet is generated from completion object rows, modulus-preserving arrow rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, RealUp seals, identity and composition rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5791.1, Definition 5791.2, and Definition 5791.3 seed the finite category surface for modulus-preserving completion morphisms.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host continuous maps, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-preserving arrow exactness, identity and composition rows, tolerance readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionModulusCategoryUp.

Chapter 4394

A Concrete Naming Certificate for $\mathsf{MarkovTriggerDynamics}^{\uparrow}$

The $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet realizes the finite rank-trigger dynamics of Definition 9462.1541, Definition 9462.1542, and Definition 9462.1546 as BEDC NameCert data. It records the state, support-rank, transition-count, drift, trigger-time, classifier, continuation, provenance, and naming rows needed by a downstream finite-dynamics consumer. The packet is a finite BHist surface for trigger-time readback; it is not a stochastic process on an ambient probability space, not an infinite sample path, not a hidden field model, and not a host Markov-chain object.

Definition 4394.1 (MarkovTriggerDynamics carrier)**.** *A* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, K, A, D, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite state row. It records the consumed external-codon count m and the covered support rank r for the current trigger state.*
2. *K is the support-rank row. It records the finite support coordinates currently covered by the observed codon rows and the rank read from that support.*
3. *A is the transition-count row. It stores the finite count of rank-preserving and rank-increasing next draws available from the current state.*
4. *D is the drift row. It records the displayed one-step rank drift computed from the same transition counts.*
5. *G is the trigger-time row. It records the finite recursion for the time to reach full rank and the deterministic threshold row consumed by trigger-time readers.*
6. *H records componentwise* hsame *transport for state, support-rank, transition-count, drift, trigger-time, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a state read through S, K, A, D, G, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$, BHist, hsame, Cont, *finite rank-trigger rows, finite transition-count rows, finite trigger-time rows, and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient probability space, hidden generator field, infinite sample path, external random oracle, host Markov-chain semantics, or unstated independence assumption.

Lean4 ✓ `BEDC.Derived.MarkovTriggerDynamicsUp.MarkovTriggerDynamicsTasteGate single carrier alignment`

Theorem 4394.2 (MarkovTriggerDynamics NameCert obligations)**.** *For every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier* $T = (S, K, A, D, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed state row, support-rank row, transition-count row, drift row, trigger-time row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface requires the transition-count row A *to be computed from the finite support-rank row* K*, the drift row* D *to read only the transition counts in* A*, and the trigger-time row* G *to replay the finite recursion from the displayed state row* S *without adding an external probability carrier.*

Proof. Project the accepted carrier. The packet exposes only $S, K, A, D, G, H, C, P, N$, so every NameCert obligation is a componentwise obligation on those rows.

The state and support rows S, K determine the finite rank-trigger situation. The transition-count row A counts rank-preserving and rank-increasing next draws from that finite support surface.

The drift row D is downstream of A, and the trigger-time row G is downstream of the same state and transition-count data. Thus the trigger-time read is a finite recursion over displayed rows, not an imported Markov-chain object.

Transport, replay, provenance, and local naming preserve the same coordinates. Since the excluded ambient and hidden objects are not coordinates of T, no consumer can read them from the packet. □

Theorem 4394.3 (MarkovTriggerDynamics finite trigger readback)**.** *Every trigger-time consumer of an accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *packet reads the finite route*

$$S, K, A, D, G, H, C, P, N.$$

Consequently the transition law, drift, and trigger-time rows are all determined by finite BHist transition-count data. No trigger-time read exports an infinite sample path, host Markov process, hidden field, or unstated independence source.

Proof. Start with the state row S and support-rank row K. They display the finite input state and the rank information that determines which next-draw counts are available.

The transition-count row A is the only row from which the drift row D may be read. The trigger-time row G then replays the finite recursion from those same transition counts.

Finally H, C, P, N transport, replay, source, and name the finite trigger route. Because no other row exists in the carrier, the stated nonescape clauses follow. □

Falsifiable prediction: Every $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ trigger-time read factors through finite state, support-rank, transition-count, drift, trigger-time, hsame, Cont, Pkg, and NameCert rows.

Independence witness: dna-boundary-tile, rank-trigger, finite-markov-transition: $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries state rows, support-rank rows, transition-count rows, drift rows, trigger-time rows, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Theorem 4394.4 (MarkovTriggerDynamics sibling dependency route)**.** *Every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *trigger-time read routes its finite state and transition-count rows through chapter 189 or chapter 4074 when the carrier is read as a Markov surface, through chapter 195 when it is read as finite transition evolution, and through chapter 3508 for the DNA boundary-trigger consumer.*

Proof. Project the existing carrier rows $S, K, A, D, G, H, C, P, N$. The state row S, support-rank row K, and transition-count row A provide exactly the finite Markov read, so a Markov-surface consumer reaches this packet through the Markov-chain or finite Markov-partition certificates.

The same rows, together with drift row D and trigger-time row G, form the finite transition-evolution route consumed by the dynamical-system certificate. The structural rows H, C, P, N then transport, replay, source, and name that route for the DNA boundary-trigger consumer.

This is a dependency route only. It does not add an ambient probability space, infinite sample path, unstated independence source, or host Markov-chain object to the carrier. □

Nontrivial TasteGate and FieldFaithful instances remain required before this finite trigger surface can be read as a checked biological field-faithfulness claim.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet is generated from finite state rows, support-rank rows, transition-count rows, drift rows, trigger-time recursion rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5792.1, Definition 5792.2, and Definition 5792.3 seed the finite rank-trigger Markov readback surface for DNA boundary-tile dynamics.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient probability spaces, infinite sample paths, hidden field models, host Markov-chain semantics, biological field-faithfulness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-count exactness, drift readback, trigger-time recursion, nontrivial TasteGate coverage, FieldFaithful evidence, transport, replay, provenance, and local naming for BEDC.Derived.MarkovTriggerDynamicsUp.

Chapter 4395

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet records the finite constructive route from regular Cauchy rational names to located completion data and then to the terminal $\mathsf{Real}^{\uparrow}$ seal. It reads the dyadic arithmetic surface of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the completion service exposed by chapter 128, and the real-name boundary of chapter 38. The packet supplies a located completion neighbour for the regular-Cauchy real route without asserting quotient completion equality, selected representatives, host order completeness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4395.1 (Regular Cauchy located completion carrier)**.** *A* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, Q, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the Cauchy name is inspected at requested precision scales.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for tolerance comparison, shrinkage, and rational distance estimates.*
4. *Q is the located completion row, recording the displayed located-distance and approximation data extracted from S, R, D.*
5. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row used only as a finite completion handoff for the displayed located data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback and located completion rows have been displayed.*
7. *H records componentwise* hsame *transport for stream windows, regular rational readbacks, dyadic arithmetic, located completion data, completion service, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a located-completion request through $S, R, D, Q, K, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, K, E, H, C, P, N$. The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host order completeness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedCompletionUp.RegularCauchyLocatedCompletionTasteGate single carrier alignment`

Theorem 4395.2 (Regular Cauchy located completion obligations)**.** *For every accepted* RegularCauchyLocatedCom *carrier*

$$L = (S, R, D, Q, K, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream-window row, regular rational readback row, dyadic arithmetic ledger, located completion row, complete-metric handoff, real seal, transport, replay, provenance, and local name;*
2. *window-readback coherence, requiring S to expose the finite inspection windows before R may be consumed as a regular rational name;*
3. *dyadic locatedness, requiring D to supply the tolerance comparisons and distance estimates used by the located completion row Q;*
4. *completion handoff ordering, requiring Q to be displayed before the* $\mathsf{CompleteMetric}^{\uparrow}$ *row K is exposed;*
5. *real-seal ordering, requiring E to be read only after S, R, D, Q, K have been displayed;*
6. *classifier stability, requiring componentwise* hsame *transport and displayed* Cont *replay to preserve all visible rows;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no quotient completion equality, selected representative, countable choice, host order completeness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5793.1. Its rows list the finite stream windows, regular rational readback, dyadic arithmetic ledger, located completion data, complete-metric handoff, real seal, and the structural rows.

Window-readback coherence follows because R has no independent observation coordinate in this packet. The regular rational read must pass through S, and the tolerance computations used by that read are then checked against the dyadic row D.

The located completion row Q is the only row that records located-distance data. The completion handoff K consumes that displayed row, and the real seal E is exposed only after the handoff has been displayed.

Transport, replay, provenance, and local naming are exhausted by H, C, P, N. Since quotient completion equality, selected representatives, countable choice, host order completeness, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier, no NameCert obligation can export them. □

Theorem 4395.3 (Regular Cauchy located completion Real seal route)**.** *Let* $L = (S, R, D, Q, K, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the located completion read factors through the finite route*

$$S, R, D \longmapsto Q \longmapsto K \longmapsto E \longmapsto H, C, P, N.$$

Thus the packet reaches the real-name boundary only through displayed $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic, located completion data, and the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff. It does not export quotient completion equality, selected representatives, countable choice, host order completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing read of the packet. The only observable name data are the stream windows S and the regular rational readback R, so any request for a real seal must first inspect those rows.

The dyadic row D supplies the tolerance and distance comparisons used by the located completion data Q. The complete-metric handoff K is then read as a service row for that displayed located data, not as an ambient completeness theorem.

Finally the seal row E exposes the $\mathsf{Real}^{\uparrow}$ boundary, and H, C, P, N transport, replay, source, and name the same displayed route. No remaining carrier coordinate can provide quotient completion equality, selected representatives, choice data, host order completeness, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5793.1, Definition 5793.2, and Definition 5793.3 seed a finite route from regular Cauchy names through located completion data to the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host order completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback coherence, dyadic locatedness, completion handoff ordering, real-seal ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLocatedCompletionU

Constructive story: A $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore arithmetic, located completion data, a CompleteMetric handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4396

A Concrete Naming Certificate for $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$

Following Banach, Picard, and Bishop–Bridges constructive analysis, the $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet records the finite handoff from an explicit contraction estimate to the Cauchy threshold consumed by the regular-rational and real endpoint routes. It sits between the Banach fixed-point modulus packet of chapter 4188, the Picard iteration and error-estimate packets of chapter 2359 and chapter 2233, and the regular Cauchy completion boundary of chapter 5793. The packet gives the endpoint route a single displayed Cauchy-threshold surface without selecting a fixed point, quotienting completion names, or importing ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4396.1 (Picard threshold Cauchy handoff carrier)**.** *A* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, I, E, M, R, K, S, T, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BanachFixedPointModulus}^{\uparrow}$ *source row whose contraction-rate route has already exposed the rational Lipschitz and finite Picard ledgers.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *ledger of adjacent iterate windows and replay order.*
3. *E is the* $\mathsf{PicardErrorEstimate}^{\uparrow}$ *row, carrying the residual-and-ratio estimate used to bound the Picard tail.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row produced from B, I, E for each requested dyadic or rational tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row made available only after the threshold row M has been displayed.*
6. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row consumed at the handoff boundary, not an ambient completeness theorem.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, R, K have been read.*
8. *T stores componentwise* hsame *transports for the Banach-modulus, Picard-iteration, error-estimate, Cauchy-threshold, regular-rational, complete-metric, real-seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from the contraction-rate request through $B, I, E, M, R, K, S, T, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$, $\mathsf{BanachFixedPointModulus}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{PicardErrorEstimate}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, I, E, M, R, K, S, T, C, P, N$. It has no coordinate for a selected fixed point, host fixed-point equality, quotient completion equality, detached Cauchy selector, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.PicardThresholdCauchyHandoffUp.PicardThresholdCauchyHandoffTasteGate`
`single carrier alignment`

Theorem 4396.2 (Picard threshold Cauchy handoff NameCert obligations)**.** *For every accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier $H = (B, I, E, M, R, K, S, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyH}}$ *surface consists exactly of carrier admission for the displayed rows; Banach-modulus source visibility through B; Picard-iteration visibility through I; error-estimate visibility through E; Cauchy-threshold construction through M; regular-rational readback through R; complete-metric service access through K; real seal access through S; classifier stability through T and C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 5794.1. The accepted packet exposes exactly the Banach-modulus source row, the Picard-iteration ledger, the error-estimate row, the Cauchy-threshold row, the regular-rational readback, the complete-metric service, the real seal, and the structural rows.

The threshold rows are ordered. The rows B, I, E must be displayed before M can answer a tolerance request, since M is the only coordinate that records the finite Cauchy threshold.

The endpoint rows are downstream. The row R reads the threshold as regular rational data, K is the visible complete-metric service row, and S is exposed only after those rows have been displayed. Transport, replay, provenance, and local naming are exhausted by T, C, P, N, so no further NameCert obligation is present. □

Theorem 4396.3 (Picard threshold Cauchy handoff Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing endpoint read of an accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{BanachFixedPointModulus}^{\uparrow},\ \mathsf{PicardIteration}^{\uparrow},\ \mathsf{PicardErrorEstimate}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Complete}$$

Thus the real seal is reached only after the explicit Picard threshold has been displayed as a $\mathsf{CauchyModulus}^{\uparrow}$ *row and repacked through the regular-rational and complete-metric handoff rows. The route exports no selected fixed point, quotient completion equality, detached Cauchy selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing endpoint request. The only contraction-rate source row is B, and its Picard data are refined in the visible rows I and E, so the request first reads those rows.

The threshold stage is forced by M. Apply the Banach fixed-point modulus route of Definition 4188.3 together with the Picard iteration surface of chapter 2359 and the error-estimate surface of chapter 2233. These sources supply the displayed threshold row without adding a selected endpoint.

After M is fixed, the readback and completion rows R and K expose the regular-rational and complete-metric boundary used by chapter 301 and chapter 128. The seal row S is then the only $\mathsf{Real}^{\uparrow}$ coordinate, and the structural rows T, C, P, N preserve the same route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5794.1, Definition 5794.2, and Definition 5794.3 seed the finite Picard-threshold handoff from BanachFixedPointModulus, PicardIteration, and PicardErrorEstimate rows to CauchyModulus, RegSeqRat, CompleteMetric, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, host fixed-point equality, quotient completion equality, detached Cauchy selectors, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard-threshold construction, regular-rational readback, complete-metric service access, real-seal ordering, classifier stability, provenance, and local naming for BEDC.Derived.PicardThreshol

Constructive story: A $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet is generated from a BanachFixedPointModulus source row, PicardIteration ledger, PicardErrorEstimate row, CauchyModulus threshold, RegSeqRat readback, CompleteMetric service row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4397

A Concrete Naming Certificate for $\mathsf{DiniUniformLimitModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the classical Dini theorem, the $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet extracts the finite uniform-modulus ledger visible in compact-metric monotone convergence data. It sits over chapter 2196, chapter 1436, chapter 129, chapter 130, chapter 463, chapter 369, chapter 301, and chapter 38. The packet names the finite net, rational tolerance budget, and extracted modulus route; it does not import open-cover compactness, chosen limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4397.1 (Dini uniform-limit modulus carrier)**.** *A* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row naming the compact-metric finite-source observations consumed by the extraction.*
2. *F is the monotone* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, recording the displayed continuous approximants and their pointwise monotone order.*
3. *W is the pointwise window row supplied by the Dini-continuity and Dini-uniform-convergence routes.*
4. *E is the finite net row over K, naming the finite mesh on which pointwise windows are inspected.*
5. *Q is the rational tolerance-budget row, storing the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerances assigned to the finite net and to the later readback.*
6. *U is the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row, obtained from E, Q, W and the monotone continuous family row F.*
7. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row, exposing only the modulus-controlled limit route supplied by U.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance transport.*
9. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row, naming the real-valued read without adding ambient real completeness.*
10. *H records componentwise* hsame *transport for compact-metric source, monotone family, pointwise window, finite net, rational tolerance, extracted modulus, uniform-limit handoff, rational readback, real seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the compact-metric source and monotone family through the finite net, tolerance budget, extracted modulus, and uniform-limit handoff.*
12. *P is the* Pkg *provenance over* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$, $\mathsf{DiniContinuity}^{\uparrow}$, $\mathsf{DiniUniformConvergence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, W, E, Q, U, L, R, S, H, C, P, N$. It has no coordinate for open-cover compactness, selected limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiniUniformLimitModulusUp.TasteGate.DiniUniformLimitModulusTasteGate`
`single carrier alignment`

Theorem 4397.2 (Dini uniform-limit modulus NameCert obligations)**.** *For every accepted* DiniUniformLimitModulu *carrier*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact-metric source, monotone continuous family, pointwise window, finite net, rational tolerance budget, extracted uniform modulus, UniformLimit handoff, RegSeqRat readback, Real seal, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires monotone-window visibility through F and W, finite-net extraction through E and Q, modulus handoff through U and L, Real-seal nonescape through S, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses open-cover compactness, selected limiting values, quotient function equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only computational rows are the compact-metric source K, monotone family F, pointwise windows W, finite net E, rational budget Q, extracted modulus U, uniform-limit handoff L, rational readback R, and real seal S.

The monotone-window step is local to F and W. The finite-net step is local to E and Q, so the modulus row U is extracted from displayed finite data rather than from an open cover or a choice of limiting values.

The handoff to $\mathsf{UniformLimit}^{\uparrow}$ passes only through U and L. The rational and real readback rows R and S name the downstream values without adding quotient function equality or ambient completeness.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded objects are not coordinates of D, no NameCert consumer can read them from this carrier. □

Falsifiable prediction: Every accepted $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ read must expose compact-metric source rows, monotone continuous-family rows, pointwise window rows, a finite net, a rational tolerance budget, an extracted uniform modulus, a UniformLimit handoff, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dini-continuity, diniuniformconvergence, compactmetric, continuousmap, uniformlimit, uniformmodulus, regseqrat, real: $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ is not bijective to any

listed sibling because it binds the finite net and rational tolerance budget to an extracted uniform-modulus handoff before UniformLimit and Real consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5795.1 and Definition 5795.2 seed the finite uniform-modulus ledger extracted from compact-metric monotone convergence data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limiting values, quotient function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window visibility, finite-net extraction, modulus handoff, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniUniformLimitModulusUp.

Constructive story: A $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet is generated from compact-metric source rows, monotone continuous-family rows, pointwise windows, finite net rows, rational tolerance-budget rows, extracted uniform-modulus rows, UniformLimit handoff rows, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4398

A Concrete Naming Certificate for $\mathsf{SummationByParts}^{\uparrow}$

Following Abel and Dirichlet, the $\mathsf{SummationByParts}^{\uparrow}$ packet records the finite identity surface by which displayed partial sums, coefficient windows, adjacent differences, and endpoint terms are bound into one NameCert row. It sits beside the Abel-summation route of chapter 1763, the Abel-test consumer of chapter 1496, and the Dirichlet-test consumer of chapter 1497. Its source rows use the finite series carrier of chapter 121; its regular readback, dyadic tolerance, and endpoint seal use chapter 301, chapter 291, and chapter 38. The packet names a finite algebraic identity for downstream convergence tests; it does not import infinite sums, quotient series equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4398.1 (Summation by parts carrier)**.** *A* $\mathsf{SummationByParts}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Series}^{\uparrow}$ *source row, exposing only the inspected finite term window and its displayed partial sums.*
2. *A is the coefficient-window row, naming the coefficient entries read over the same finite interval.*
3. *Δ is the adjacent-difference row, recording the displayed values $a_k - a_{k+1}$ used by the identity.*
4. *P is the partial-sum-window row, naming the cumulative sums paired with A and Δ.*
5. *B is the boundary-term row, displaying the endpoint products and the finite interior products determined by S, A, Δ, P.*
6. *T is the convergence-test handoff row consumed by* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$.
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed finite identity data.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the finite additions, subtractions, products, and endpoint comparisons used by B.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after $S, A, \Delta, P, B, T, R, D$ have been displayed.*
10. *H records componentwise* hsame *transport for the source, coefficient, difference, partial-sum, boundary, handoff, readback, dyadic, endpoint, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the route*

$$S, A, \Delta, P, B, T, R, D \longmapsto E.$$

12. *Q is the* Pkg *provenance over* $\mathsf{SummationByParts}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$. It has no coordinate for an infinite sum, quotient series equality, selected convergence witness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SummationByPartsUp.SummationByPartsTasteGate single carrier alignment`

Theorem 4398.2 (Summation by parts NameCert obligations)**.** *For every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *carrier*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet; source and partial-sum exposure through S and P; coefficient-window and adjacent-difference exposure through A and Δ; boundary-term exactness through B; convergence-test handoff through T; regular readback, dyadic accounting, and endpoint sealing through R, D, E; and transport, replay, provenance, and local naming through H, C, Q, N.*

Proof. Project the accepted carrier. The projection exposes exactly the rows $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$, so every naming obligation must be read from one of those displayed coordinates.

The identity rows are finite. The source row S and partial-sum row P display the inspected cumulative sums, the coefficient row A displays the paired coefficients, and Δ displays the adjacent differences used by the interior terms. The boundary row B records only the endpoint products and interior products determined by those rows.

The consumer handoff is downstream of the identity. A convergence-test consumer first reads T, and the regular and real-facing route then passes through R, D, E. These rows can transport the displayed finite calculation, but they do not introduce an independent summation principle.

Finally H, C, Q, N preserve, replay, source, and name the same route. Because the carrier has no coordinate for infinite sums, quotient series equality, selected convergence witnesses, countable choice, trichotomy, or ambient real completeness, the stated rows exhaust the local NameCert surface. □

Theorem 4398.3 (Summation by parts Cauchy-series handoff)**.** *Every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *packet that is consumed by an* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$ *route hands off only the finite identity chain*

$$\mathsf{Series}^{\uparrow} \longmapsto S, A, \Delta, P, B, T \longmapsto R, D, E, H, C, Q, N.$$

Thus a Cauchy-series or real-seal consumer may read the summation-by-parts row only after the series window, coefficient window, adjacent-difference ledger, partial-sum window, boundary ledger, and test handoff have been displayed. The handoff supplies no infinite sum, quotient series equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a convergence-test read. Carrier admission exposes the source row S and the finite identity rows A, Δ, P, B before the handoff row T is available.

The downstream chapters may add their own test-specific rows. The $\mathsf{AbelSummation}^{\uparrow}$ consumer reads the displayed finite identity as its transform row, the $\mathsf{AbelTest}^{\uparrow}$ consumer combines it with a monotone null coefficient ledger, and the $\mathsf{DirichletTest}^{\uparrow}$ consumer combines it with bounded partial sums and a null-tail schedule. In each case the summation-by-parts contribution remains the same displayed finite packet.

The Cauchy-facing route is therefore forced through R and D before E can seal the endpoint. Transport, replay, provenance, and local naming preserve that same route, so no excluded summation or completeness datum can be read from the packet. □

Falsifiable prediction: An accepted $\mathsf{SummationByParts}^{\uparrow}$ consumer that reaches an $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without reading the displayed source, coefficient, adjacent-difference, partial-sum, boundary-term, and handoff rows refutes the carrier surface.

Independence witness: abel-summation, abel-test, dirichlet-test, series, regseqrat, dyadicratcore, real: no listed sibling supplies the whole thirteen-row packet $K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$, because each sibling contributes only a transform consumer, convergence-test consumer, source series, regular readback, dyadic ledger, or endpoint seal while this chapter binds the finite identity itself.

Closure status for $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$.

Constructive story: A $\mathsf{SummationByParts}^{\uparrow}$ packet is generated from a SeriesUp finite source row, coefficient windows, adjacent-difference rows, partial-sum windows, boundary-term ledgers, AbelSummation/AbelTest/DirichletTest handoff rows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$, seed)

Scope closed: Definition 5796.1, Definition 5796.2, and Definition 5796.3 seed the finite summation-by-parts identity packet over $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite summation, quotient series equality, selected convergence witnesses, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite identity exactness, convergence-test handoff, Cauchy-series readback, dyadic accounting, endpoint sealing, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.SummationByPartsUp.

Chapter 4399

A Concrete Naming Certificate for $\mathsf{RealLineOrder}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealLineOrder}^{\uparrow}$ packet records the constructive real-line order and apartness boundary visible to finite BEDC NameCert consumers. It sits over the dyadic tolerance ledger of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the rational Cauchy completion route of chapter 3670, and the Bishop regular Cauchy limit seal of chapter 1821. The packet gives L10 consumers a located comparison interface before any real-order algebra can read it; it does not import trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4399.1 (Real line order carrier)**.** *A* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D, S, R, L, A, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the positive dyadic radius used by every finite comparison request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing only the finite stream observations inspected at that tolerance.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream windows into regular rational comparison data.*
4. *L is the located comparison row, recording the finite verdict surface for $x < y$ as a witnessed positive gap at the displayed tolerance, an unresolved window requiring a smaller displayed tolerance, or a symmetric failure of the current request.*
5. *A is the apartness row, recording positive-gap readback for $x \# y$ only through D, S, R, L.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same displayed stream and regular-rational data, not from host real equality.*
7. *H records componentwise* hsame *transport for dyadic tolerance, stream windows, regular-rational readback, located comparison, apartness, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite order request through $D, S, R, L, A, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, L, A, E, H, C, P, N$. It has no coordinate for trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderTasteGate single carrier alignment`

Theorem 4399.2 (Real line order NameCert obligations)**.** *For every accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier*

$$O = (D, S, R, L, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance row, stream-window row, regular-rational readback row, located comparison row, apartness row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise transport row, replay row, provenance row, and local naming row.*

The obligation surface requires finite tolerance visibility through D, window visibility through S, regular-rational comparison readback through R, located order exposure through L, apartness exposure through A, real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier of Definition 5797.1. The only analytic rows are the dyadic tolerance D, the finite stream windows S, the regular-rational readback R, the located comparison row L, the apartness row A, and the terminal real seal E.

The comparison step is located rather than trichotomic. A finite request may display a positive gap, request a smaller displayed tolerance, or fail symmetrically at the current window; none of these outcomes supplies a global three-way case split.

The equality-sensitive routes are absent. The readback row R is regular-rational data over the displayed windows, and the seal row E is reached only after D, S, R, L, A have been inspected. Thus the packet refuses quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded principles are not coordinates of O, no local NameCert obligation can demand them. □

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderNameCertObligations`

Theorem 4399.3 (Real line order apartness readback)**.** *Every apartness read exported by an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The apartness row A may expose only a positive-gap witness already visible through D, S, R, L. It exports no trichotomy datum, quotient equality, selected representative, host real equality, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Proof. Start with an apartness request. The request must first choose a displayed positive dyadic tolerance in D and inspect the finite windows in S.

The regular-rational readback R is then the only comparison source. The located comparison row L reads this finite data and either displays a positive gap at the requested tolerance or leaves the request unresolved for a smaller displayed tolerance.

The apartness row A can cite only the positive-gap branch already exposed by L. It refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$ because those objects are not carrier rows.

The terminal seal E preserves the same finite route into $\mathsf{Real}^{\uparrow}$. Transport and replay through H and C keep the route stable, while P and N only record provenance and local naming. □

Theorem 4399.4 (Real line order L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier must read the dyadic tolerance, stream-window, regular-rational readback, located comparison, apartness, and* $\mathsf{Real}^{\uparrow}$ *seal rows in the order*

$$D, S, R, L, A, E.$$

Consequently the handoff supplies a finite non-quotient comparison boundary for later real algebra and order packets, while refusing trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. An L10 order request begins with finite tolerance data. The row D fixes the displayed dyadic radius, and S opens only the stream windows inspected at that radius.

The row R repacks those windows as regular-rational readback. The located comparison row L can then answer only with the finite comparison surface generated from D, S, R.

Apartness is downstream of located comparison. The row A may expose a positive gap only when L has already displayed one, and E seals the same finite route as a $\mathsf{Real}^{\uparrow}$-facing endpoint.

Because no earlier or later row stores trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$, the L10 handoff cannot export those principles to later consumers. □

Falsifiable prediction: Every accepted $\mathsf{RealLineOrder}^{\uparrow}$ read must expose dyadic tolerance, StreamName windows, RegSeqRat readback, located comparison, apartness, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before an L10 order consumer can read a comparison boundary.

Independence witness: dyadicratcore, streamname, regseqrat, real, rational-cauchy-completion, bishop-regular-cauchy-limit-seal: $\mathsf{RealLineOrder}^{\uparrow}$ is not bijective to any listed sibling because it binds located comparison and apartness rows to the finite readback route before the RealUp seal is available.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5797.1, Definition 5797.2, Definition 5797.3, and Definition 5797.4 seed the finite non-quotient order and apartness boundary for displayed RealUp names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient equality, selected representatives, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite tolerance visibility, stream-window visibility, regular-rational readback, located comparison, apartness readback, RealUp seal handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.RealLineOrderUp.

Constructive story: A $\mathsf{RealLineOrder}^{\uparrow}$ packet is generated from a DyadicRatCoreUp tolerance row, StreamName finite windows, RegSeqRat readback, located comparison, apartness, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4400

A Concrete Naming Certificate for $\mathsf{SchwartzKernel}^{\uparrow}$

Following Schwartz and Gelfand–Shilov, the $\mathsf{SchwartzKernel}^{\uparrow}$ packet records the finite NameCert route by which a distribution kernel is read as a bilinear action between Schwartz test probes and tempered-distribution endpoints. It sits over the Schwartz-function carrier of chapter 3399, the tempered-distribution endpoint of chapter 2310, the nuclear factorization row of chapter 215, the projective tensor norm route of chapter 4088, the tensor-product source of chapter 87, and the real seal of chapter 38. The chapter exposes the kernel theorem as finite action, tensor, nuclearity, bound, transport, replay, provenance, and local naming rows; it does not import a host distribution space, quotient test-function equality, selected representatives, or an unrestricted topological-vector-space oracle.

Definition 4400.1 (Schwartz kernel carrier)**.** *A* $\mathsf{SchwartzKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, U, J, B, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SchwartzFunction}^{\uparrow}$ *test-probe row naming the finite seminorm windows inspected on the source side.*
2. *T is the* $\mathsf{TemperedDistribution}^{\uparrow}$ *endpoint row naming the distributional action read after the test windows are displayed.*
3. *U is the* $\mathsf{TensorProduct}^{\uparrow}$ *row naming the finite tensor source on which the two test-probe sides are paired.*
4. *J is the* ***??*** *row recording the projective-tensor bound used to compare the paired test windows.*
5. *B is the* $\mathsf{Nuclear}^{\uparrow}$ *factorization row, exposing the finite nuclear decomposition route by which the kernel action is read.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed scalar bounds and kernel-action readbacks.*
7. *H records componentwise* hsame *transport for test probes, tempered endpoint, tensor source, projective bound, nuclear factorization, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite kernel request through $S, T, U, J, B, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SchwartzKernel}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{Nuclear}^{\uparrow}$, ***??***, $\mathsf{TensorProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $S, T, U, J, B, R, H, C, P, N$. It has no coordinate for a host distribution space, quotient equality of test functions, selected representatives, ambient bornological completeness, or a topological-vector-space theorem outside the displayed rows.

Lean4 ✓ `BEDC.Derived.SchwartzKernelUp.SchwartzKernelTasteGate single carrier alignment`

Theorem 4400.2 (Schwartz kernel NameCert obligations)**.** *For every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *carrier*

$$K = (S, T, U, J, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *surface consists exactly of Schwartz test-probe admission through S, tempered-distribution endpoint admission through T, tensor-source admission through U, projective-bound exposure through J, nuclear-factorization exposure through B, scalar RealUp sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every kernel consumer must read the distributional action through these ten rows. No consumer may replace them by an ambient kernel theorem, quotient test-function equality, selected representative, hidden topological vector space, or host nuclear-space completion.

Proof. Project the accepted carrier of Definition 5798.1. The analytic rows are the Schwartz test row S, the tempered-distribution endpoint T, the tensor source U, the projective bound J, the nuclear factorization B, and the RealUp seal R.

The action route is finite. The tensor row U supplies the paired test-probe source, J records the displayed projective bound, and B records the nuclear factorization by which the kernel action becomes readable by a finite consumer.

Transport and replay do not create new analytic structure. The rows H and C preserve the displayed packet componentwise and replay only the same kernel request. The provenance and naming rows P, N package the route without adding host quotient equality or a hidden completion theorem.

Thus the listed rows are exactly the local NameCert obligations for $\mathsf{SchwartzKernel}^\uparrow$. □

Theorem 4400.3 (Schwartz kernel nuclear factorization boundary)**.** *Every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *read factors through the finite route*

$$\mathsf{SchwartzFunction}^\uparrow,\ \mathsf{TensorProduct}^\uparrow,\ ??,\ \mathsf{Nuclear}^\uparrow \longmapsto \mathsf{TemperedDistribution}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The nuclear row may expose only the displayed factorization and bound data already routed through S, U, J. It exports no host theorem identifying all kernels with all continuous bilinear forms, no quotient equality of test probes, no selected representative of a distribution, and no ambient completeness claim for the surrounding function spaces.

Proof. Start with a kernel read. The request first displays the finite Schwartz windows in S and the tensor source U on which the two test-probe sides are paired.

The projective tensor bound J is the only bound row available to the consumer. The nuclear factorization row B can cite only this displayed tensor-bound route, so its readback is a finite factorization certificate rather than an ambient nuclear-space theorem.

The tempered-distribution endpoint T then reads the resulting action, and R seals the scalar outputs as RealUp data. Transport through H and replay through C keep the same row order, while P and N record source and local naming.

Since no carrier coordinate stores host quotient equality, selected representatives, or ambient completeness, those principles cannot be exported by the factorization boundary. □

Falsifiable prediction: Every accepted $\mathsf{SchwartzKernel}^{\uparrow}$ packet must expose SchwartzFunctionUp test probes, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, TemperedDistributionUp endpoint action, RealUp scalar sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a kernel consumer can read the action.

Independence witness: schwartz-function, tempered-distribution, nuclear, projective-tensor-norm, tensorproduct, real: $\mathsf{SchwartzKernel}^{\uparrow}$ is not bijective to any listed sibling because it binds the test-probe tensor route, nuclear factorization boundary, distribution endpoint, and scalar seal as one finite kernel-action packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{SchwartzKernel}^{\uparrow}$ packet is generated from SchwartzFunctionUp test probes, a TemperedDistributionUp endpoint, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, RealUp scalar seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5798.1, Definition 5798.2, Definition 5798.3, the falsifiable prediction, and the independence witness seed the finite kernel-action route over Schwartz, tempered-distribution, tensor, nuclear, bound, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host distribution-space semantics, quotient equality of test functions, selected distribution representatives, ambient nuclear-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, test-probe visibility, tensor-source admission, projective-bound exactness, nuclear-factorization exposure, tempered-endpoint action, RealUp scalar sealing, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SchwartzKernelUp.

Chapter 4401

A Concrete Naming Certificate for $\mathsf{SynonymousTransition}^{\uparrow}$

The $\mathsf{SynonymousTransition}^{\uparrow}$ packet realizes the finite synonymous-transition geometry of Definition 9462.1186 as BEDC NameCert data. It sits beside the six-bit codon-window carrier of chapter 2234, the codon transition matrix of chapter 2245, the DNA boundary-tile packet of chapter 3393, the window-coverage trigger algebra of chapter 3478, and the DNA-window trigger threshold of chapter 4217. The packet names finite codon-window, class-adjacency, boundary-spectrum, threshold, transport, replay, provenance, and local naming rows; it is not a biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Definition 4401.1 (Synonymous transition carrier)**.** *A* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (W, M, A, B, T, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *row naming the finite Q_6 codon-window surface.*
2. *M is the* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *row naming one-bit codon transitions inspected by the packet.*
3. *A is the class-adjacency row recording the displayed synonymous and cross-class adjacency counts, including the largest weights of Definition 9462.1186.*
4. *B is the boundary-spectrum row recording internal edge counts, external boundary degrees, and the control-pair corner-contact data.*
5. *T is the* $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$ *row naming the finite threshold at which an adjacency or boundary-spectrum read may trigger a downstream tile consumer.*
6. *H records componentwise* hsame *transport for codon windows, transition matrix, class adjacency, boundary spectrum, trigger threshold, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite synonymous-transition request through W, M, A, B, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{SynonymousTransition}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{CodonTransitionMatrix}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, M, A, B, T, H, C, P, N$. It has no coordinate for biological mechanism, stochastic fitness, quotient codon equality, hidden enumeration, or an ambient graph-theory oracle outside the displayed finite rows.

Theorem 4401.2 (Synonymous transition NameCert obligations)**.** *For every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier*

$$G = (W, M, A, B, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *surface consists exactly of codon-window admission through W, transition-matrix admission through M, class-adjacency exposure through A, boundary-spectrum exposure through B, trigger-threshold exposure through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every downstream synonymous-transition consumer must read the graph through these nine rows. It cannot replace them by biological causation, stochastic selection, quotient codon semantics, an unrecorded enumeration, or a hidden graph oracle.

Proof. Project the accepted carrier of Definition 5799.1. The finite codon surface is W, the one-bit transition source is M, and the named graph data are the class-adjacency row A and boundary-spectrum row B.

The trigger row T records when the displayed adjacency or boundary-spectrum data may be read by a downstream tile or trigger consumer. It does not add a biological mechanism or a stochastic model; it only names the finite threshold over the same graph rows.

Transport and replay are componentwise. The rows H and C preserve and replay W, M, A, B, T with the same finite endpoints, while P and N record provenance and local naming.

Since the carrier has no coordinate for quotient codon equality, hidden enumeration, biological causation, or ambient graph semantics, the listed rows exhaust the local NameCert obligations. □

Theorem 4401.3 (Synonymous transition boundary-spectrum handoff)**.** *Every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *read factors through the finite route*

$$\mathsf{CodonSixBitWindow}^{\uparrow},\ \mathsf{CodonTransitionMatrix}^{\uparrow} \longmapsto \mathsf{SynonymousTransition}^{\uparrow} \longmapsto \mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{Wind}$$

The handoff exposes class-adjacency weights, internal-edge counts, external boundary degrees, and control-pair corner contacts only as finite packet rows. It exports no biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Proof. Start with the codon-window row W and the one-bit transition matrix row M. These rows supply the finite Q_6 source and the adjacency relation inspected by the packet.

The class-adjacency row A records the largest displayed weights, and B records the boundary-spectrum data. The downstream boundary-tile and trigger-algebra consumers therefore receive a finite graph packet rather than a biological or stochastic explanation.

The threshold row T names when the finite rows can be consumed by the trigger route. Transport through H and replay through C keep the same graph rows visible, while P and N only package their provenance and local name.

Thus every public read of the synonymous-transition geometry remains inside the finite codon-window, transition, adjacency, boundary-spectrum, threshold, transport, replay, provenance, and naming surface. □

Falsifiable prediction: Every accepted $\mathsf{SynonymousTransition}^{\uparrow}$ packet must expose CodonSixBitWindowUp, CodonTransitionMatrixUp, class-adjacency, boundary-spectrum, DNAWindowSixTriggerThresholdUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a downstream tile or trigger consumer can read the synonymous-transition graph.

Independence witness: codon-six-bit-window, codon-transition-matrix, dna-window-six-boundary-tile, window-coverage-trigger-algebra, dna-window-six-trigger-threshold: $\mathsf{SynonymousTransition}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries class-adjacency weights, boundary-spectrum rows, and trigger-threshold handoff over the finite codon-window graph.

Closure status for $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$.

Constructive story: A $\mathsf{SynonymousTransition}^{\uparrow}$ packet is generated from a CodonSixBitWindowUp source, a CodonTransitionMatrixUp one-bit transition row, class-adjacency counts, boundary-spectrum data, DNAWindowSixTriggerThresholdUp rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5799.1, Definition 5799.2, Definition 5799.3, the falsifiable prediction, and the independence witness seed the finite synonymous-transition packet over codon-window, transition, adjacency, boundary-spectrum, threshold, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic fitness, quotient codon semantics, hidden enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, codon-window visibility, transition-matrix exactness, class-adjacency exposure, boundary-spectrum exposure, trigger-threshold handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SynonymousTransitionUp.

Chapter 4402

A Concrete Naming Certificate for $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$

Following Feller and Billingsley on finite-sum normal approximation, the $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet records the finite BEDC surface by which an iid random-variable window is centered, scaled, read as a distribution row, and handed to a real-normal comparison seal. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the law readback of chapter 186, the regular rational window of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite central-limit-facing certificate; it is not an asymptotic central limit theorem, a characteristic-function convergence theorem, a host probability-limit operator, countable choice, quotient distribution equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4402.1 (Central-limit finite-window carrier)**.** *A* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, V, S, K, D, R, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row V is the displayed iid* $\mathsf{RandomVar}^{\uparrow}$ *window over P, including the finite index range and the shared law token read by the window. The row S is the finite partial-sum ledger naming the displayed sum, the sample count, and the centered numerator. The row K is the centering and scaling row, recording the finite mean token, variance or spread token, positive scale request, and normalized finite-sum expression. The row D is the* $\mathsf{Distribution}^{\uparrow}$ *readback for the normalized finite sum and its comparison request. The row R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *window that presents rational test intervals, tolerances, and finite comparison samples for the distribution read. The row E is the* $\mathsf{Real}^{\uparrow}$ *normal-window seal naming the terminal real comparison against the displayed normal row at the requested finite window. The row H records componentwise* hsame *transport for the probability source, iid window, partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat window, Real normal-window seal, continuation, provenance, and local naming rows. The row C records* Cont *replay from a normal-facing read through P, V, S, K, D, R, E and then through the structural rows. The row Q is the* Pkg *provenance over* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert. *The row N is the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these eleven rows.*

Lean4 ✓ `BEDC.Derived.CentralLimitFiniteWindowUp.TasteGate.CentralLimitFiniteWindowTasteGate`
`single carrier alignment`

Theorem 4402.2 (Central-limit finite-window NameCert obligations)**.** *For every accepted* CentralLimitFiniteWindo *carrier* $(P, V, S, K, D, R, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 5800.1. Carrier admission displays the probability source, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, transport, replay, provenance, and local naming row. The certificate imports no host asymptotic central limit theorem, characteristic-function limit, Lindeberg replacement principle, countable-choice schedule, quotient distribution equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Project the carrier rows in order. The probability source P and iid random-variable window V are the only stochastic data exposed to the certificate, and the partial-sum ledger S fixes the finite sum before any normal-facing read is visible.

The centering and scaling row K then determines the normalized finite expression. The distribution row D and RegSeqRat window R provide the only comparison surface through which a finite law read can reach the terminal $\mathsf{Real}^{\uparrow}$ normal-window seal E.

Finally H, C, Q, N transport, replay, source, and name the same displayed route. Since the carrier has no coordinate for an asymptotic theorem, characteristic-function limit, quotient law equality, countable choice, or ambient completeness, the listed rows exhaust the local finite NameCert surface. □

Theorem 4402.3 (Central-limit finite-window normal handoff)**.** *Every normal-facing read of an accepted* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier factors through the finite route*

$$P \longmapsto V \longmapsto S \longmapsto K \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, Q, N$$

before any consumer receives a normal-window comparison. Thus the read is the displayed iid finite-sum, normalization, distribution, RegSeqRat, and RealUp handoff itself; it exports no host asymptotic CLT, countable choice, quotient distribution equality, characteristic-function convergence principle, or ambient real completeness.

Proof. Begin with a normal-facing request. The only probability data available are the source row P and the finite iid window V, so the request must first read the displayed sample range and shared law token.

The partial-sum row S and normalization row K are then forced. They provide the finite sum, centering token, scaling token, and normalized expression that the downstream distribution read consumes.

The request can reach a normal-window comparison only through D, R, E. The distribution row D names the finite law read, the RegSeqRat row R exposes rational windows and tolerances, and the RealUp row E seals the displayed normal comparison. The structural rows H, C, Q, N preserve that route without adding analytic content.

Therefore every accepted read factors through the finite iid-sum, normalization, distribution, RegSeqRat, and RealUp rows. The excluded asymptotic, choice, quotient, characteristic-function, and completeness principles cannot be inserted into the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet is generated from a probability source row, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5800.1, Definition 5800.2, and Definition 5800.3 seed the finite central-limit-facing handoff through ProbSpace, RandomVar, Distribution, RegSeqRat, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CentralLimitFiniteWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the asymptotic central limit theorem, characteristic-function convergence, Lindeberg replacement, countable-choice schedules, quotient distribution equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, iid-window routing, partial-sum ledger exactness, normalization stability, distribution-to-RegSeqRat handoff, RealUp normal-window nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.CentralLimitFiniteWindowUp.

Chapter 4403

A Concrete Naming Certificate for $\mathsf{LipschitzRealMap}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LipschitzRealMap}^{\uparrow}$ packet records a constructive real-map certificate whose continuity is controlled by a displayed dyadic Lipschitz constant and finite regular-rational windows. It sits after the dyadic tolerance ledger of chapter 291, the countable-name window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the located order and apartness neighbour of chapter 5797. The packet names the finite L10 route by which later continuous-map and metric-uniform-continuity consumers may read a real-valued map without importing host function extensionality, quotient representatives, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4403.1 (Lipschitz real-map carrier)**.** *A* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, K, W, R, M, H, C, P, N)$$

with the following rows:

1. *S is the source* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real input surface through displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
2. *T is the target* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real output surface through the same kind of finite readback.*
3. *K is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *Lipschitz constant row, including the positive dyadic bound and the displayed tolerance ledger used by every modulus request.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the source and target names inspected by the request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the displayed source and target windows into rational comparison data.*
6. *M is the modulus-inequality row, recording that every accepted finite pair of source reads with displayed apartness or distance bound is sent to a target read whose displayed difference is bounded by the dyadic constant in K times the source bound, up to the requested displayed tolerance.*
7. *H records componentwise* hsame *transport for source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a finite map request through $S, T, K, W, R, M, H, P, N$.*
9. *P is the* Pkg *provenance over* LipschitzRealMap$^{\uparrow}$, Real$^{\uparrow}$, RealLineOrder$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{LipschitzRealMap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, T, K, W, R, M, H, C, P, N$. It has no coordinate for host function equality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, or ambient completeness of Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LipschitzRealMapUp.LipschitzRealMapTasteGate single carrier alignment`

Theorem 4403.2 (Lipschitz real-map NameCert obligations)**.** *For every accepted* LipschitzRealMap$^{\uparrow}$ *carrier*

$$F = (S, T, K, W, R, M, H, C, P, N),$$

the local NameCert$_{\text{LipschitzRealMap}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* Real$^{\uparrow}$ *seal, target* Real$^{\uparrow}$ *seal, dyadic Lipschitz constant, finite StreamName windows, RegSeqRat readback, modulus inequality, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires finite source and target visibility through S and T, dyadic bound visibility through K, finite window visibility through W, rational readback through R, modulus-inequality exposure through M, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses host function extensionality, quotient equality of real presentations, selected representatives, global uniform-continuity principles, and ambient completeness of Real$^{\uparrow}$.

Proof. Project the carrier of Definition 5801.1. The source and target real seals are the only real-name endpoints, and both are read through finite StreamName and RegSeqRat windows rather than through host real equality.

The Lipschitz datum is the dyadic row K. A map request can inspect only the finite windows W and their rational readback R before the modulus row M exposes the displayed inequality for the requested tolerance.

The structural rows do not add analytic content. The transport row H preserves the already displayed source, target, constant, window, readback, and modulus rows componentwise, while C replays the same route and P, N record provenance and local naming.

Since no carrier coordinate stores host function equality, quotient real equality, selected representatives, global uniform continuity, or ambient completeness, no local NameCert obligation can require those objects. □

Theorem 4403.3 (Lipschitz real-map modulus stability)**.** *Let F_0 and F_1 be accepted* LipschitzRealMap$^{\uparrow}$ *carriers whose source seals, target seals, dyadic Lipschitz constant rows, finite StreamName windows, and RegSeqRat readback rows are componentwise* hsame*-transported. Then every displayed modulus-inequality read exported by F_0 transports to the corresponding displayed modulus-inequality read exported by F_1.*

The stability claim is confined to the finite rows $S, T, K, W, R, M, H, C, P, N$. It does not identify host functions, quotient real presentations, selected Cauchy names, or ambient complete metric structures.

Proof. Start with a displayed modulus request for F_0. Its source and target real seals are read only through the finite StreamName windows and RegSeqRat readback rows named by S, T, W, R.

Use the componentwise hsame hypotheses. They transport the dyadic constant row K and the finite window/readback rows into the corresponding rows of F_1, so the same displayed source tolerance and target tolerance are available after transport.

The modulus row M is a row of the carrier rather than a host theorem about all representatives. Therefore the transported request reads the F_1 modulus row with the same displayed dyadic bound and the transported finite readback data.

Finally C, P, N replay, source, and name the transported route. No quotient equality, host function equality, selected representative, or ambient completeness principle is introduced by this transport. □

Theorem 4403.4 (Lipschitz real-map L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier must read the route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{LipschitzRealMap}^{\uparrow}$$

through the finite source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, transport, replay, provenance, and local NameCert rows. The handoff supplies a finite Lipschitz-control surface for later continuous-map and metric-uniform-continuity packets, while refusing host function extensionality, quotient equality, selected representatives, global uniform-continuity principles, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. An L10 map request begins with source and target real-name seals. By the carrier definition, these seals are visible only through the finite StreamName windows and RegSeqRat readback rows used by S, T, W, R.

The request then reads the dyadic constant row K and the located comparison surface supplied by the real-line order neighbour. These rows provide the displayed source difference and target tolerance against which the modulus inequality is checked.

The modulus row M is the only analytic output of the packet. It hands a consumer a finite inequality route, not a host-level function theorem.

The rows H, C, P, N transport, replay, source, and name the same route. Thus later continuous-map and metric-uniform-continuity packets can consume the finite Lipschitz surface without receiving quotient equality, selected representatives, host function extensionality, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzRealMap}^{\uparrow}$ packet is generated from source and target RealUp seal rows, a DyadicRatCore Lipschitz constant, finite StreamName windows, RegSeqRat readback, a displayed modulus-inequality row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, seed)

Scope closed: Definition 5801.1, Definition 5801.2, Definition 5801.3, and Definition 5801.4 seed the finite Lipschitz real-map surface over the current L10 real and completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and target RealUp sealing, dyadic constant visibility, finite window readback, modulus-inequality stability, transport, replay, provenance, and local naming for future BEDC.Derived.LipschitzRealMapUp.

Chapter 4404

A Concrete Naming Certificate for $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$

The $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ packet realizes the observer-expansion shadow route of section 9463.4 as finite quasi-geodesic, boundary, visual-metric, Busemann, and lamination-compatible rows. It sits after disk readout through chapter 377, the metric surface of chapter 3474, the visual-metric packet of chapter 3866, the Busemann cocycle route of chapter 4134, the geodesic-lamination packet of chapter 4203, and the observer-expansion packet of chapter 4167. The packet names a finite shadow tied to a displayed quasi-geodesic route; it does not complete the boundary, choose a global geodesic representative, identify quotient ideal points, or import host hyperbolic geometry.

Definition 4404.1 (Hyperbolic quasi-geodesic shadow carrier)**.** *A* $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, G, E, V, B, L, H, C, P, A, N)$$

with the following rows:

1. *D is the disk readout row, exposing only displayed* $\mathsf{UnitDisk}^{\uparrow}$ *coordinates and the associated* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read data.*
2. *G is the quasi-geodesic route row, recording the finite path samples, distortion budget, endpoint-facing direction, and local route ledger inspected by the shadow request.*
3. *E is the boundary endpoint row named by the displayed route, not by a completed ideal-boundary quotient.*
4. *V is the visual-metric shadow row, recording the finite shadow window read through* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *and the boundary endpoint E.*
5. *B is the Busemann cocycle tolerance row, recording the displayed additive tolerance used to compare the route and the shadow window.*
6. *L is the geodesic-lamination compatibility row, recording whether the displayed route is compatible with the finite noncrossing leaf data consumed by* $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$*.*
7. *H records componentwise* hsame *transport for disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, replay, provenance, refusal, and local naming rows.*
8. *C records displayed* Cont *replay from an observer-expansion shadow request through $D, G, E, V, B, L, H, P, A, N$.*

9. *P is the* Pkg *provenance over* HyperbolicQuasiGeodesicShadow$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HyperbolicGeodesicLamination$^{\uparrow}$, HyperbolicObserverExpar BHist, hsame, Cont, *and* NameCert.
10. *A is the refusal row excluding completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, and host curvature semantics.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, G, E, V, B, L, H, C, P, A, N$.

Theorem 4404.2 (Hyperbolic quasi-geodesic shadow NameCert obligations)**.** *For every accepted* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier*

$$Q = (D, G, E, V, B, L, H, C, P, A, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *surface consists exactly of disk-readout visibility, quasi-geodesic route visibility, boundary endpoint exposure, visual-metric shadow-window exposure, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise transport, replay, provenance, refusal, and local naming rows.*

The packet exports no completed ideal boundary, quotient boundary equality, selected global geodesic, ambient hyperbolic compactification, physical observer trajectory, host curvature theorem, or global field semantics.

Proof. Project the carrier rows in order. The disk readout D supplies the only coordinate and metric source, while G supplies the displayed route samples and distortion budget inspected by the request.

The endpoint and shadow rows are downstream of that route. The endpoint row E names only the boundary read visible from G, and the visual row V records the finite shadow window tied to that endpoint.

The comparison rows B and L keep the shadow route finite. The Busemann tolerance is a displayed cocycle budget, and lamination compatibility is a finite noncrossing-leaf check, not a global geodesic-foliation theorem.

Finally H, C, P, A, N transport, replay, source, refuse, and name the same packet. Since the excluded host objects are not carrier rows, they cannot appear as NameCert obligations. □

Theorem 4404.3 (Hyperbolic quasi-geodesic shadow stability)**.** *Let Q_0 and Q_1 be accepted* HyperbolicQuasiGeodesi *carriers whose disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow window, Busemann tolerance, lamination compatibility, refusal, provenance, and local naming rows are componentwise* hsame*-transported. Then every observer-expansion consumer reads the same finite shadow surface through Q_0 and Q_1.*

The stability claim is confined to the finite rows $D, G, E, V, B, L, H, C, P, A, N$. It does not identify completed boundaries, quotient ideal points, selected geodesics, ambient compactifications, physical observer trajectories, host curvature data, or global fields.

Proof. Start with an observer-expansion shadow request for Q_0. The request must read disk coordinates and metric data through D and then the finite route samples and distortion budget through G.

Use the componentwise hsame transport. It carries the endpoint E, visual shadow window V, Busemann tolerance B, and lamination compatibility row L to the corresponding rows of Q_1.

The refusal row is transported with the same packet. Therefore the transported consumer sees the same excluded host objects and cannot insert completed boundary quotients, selected global geodesics, ambient compactifications, physical trajectories, curvature theorems, or global fields.

The replay row C and the provenance and naming rows P, N then present the transported shadow as the same finite observer-expansion surface. □

Theorem 4404.4 (Hyperbolic quasi-geodesic shadow vision handoff)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ *carrier must read the route*

$\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicGeodesicLaminatio}$

through disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, transport, replay, provenance, refusal, and local NameCert rows. The handoff realizes the vision-level shadow route as finite NameCert data without turning observer expansion into physical cosmology or a host hyperbolic-boundary theorem.

Proof. The vision handoff begins with disk and metric data. Rows D and G ensure that the consumer reads only displayed disk observations, metric readouts, finite route samples, and a distortion budget.

The endpoint and shadow window are then forced. Rows E and V bind the boundary endpoint and visual-metric shadow to the same route, while B records the Busemann tolerance needed to compare route and shadow.

Lamination compatibility is read through L. This makes the packet consumable by geodesic-lamination and observer-expansion rows without selecting a global geodesic representative or completing the boundary.

The rows H, C, P, A, N transport, replay, source, refuse, and name the handoff. Thus the vision-level quasi-geodesic shadow is realized as finite NameCert data and not as ambient hyperbolic geometry. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ read must expose a boundary endpoint, visual-metric shadow window, Busemann cocycle tolerance, quasi-geodesic route, transport row, provenance row, refusal row, and local NameCert before any observer-expansion consumer may read the shadow.

Independence witness: hyperbolic-visual-metric, hyperbolic-busemann-cocycle, hyperbolic-geodesic-lamination, hyperbolic-observer-expansion: $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ is not bijective to these siblings because it binds the quasi-geodesic route and shadow window together before the observer-expansion packet may consume the boundary read.

The Lean TasteGate for this packet must later provide $\mathsf{Nontrivial}\ \mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ in `lean4/BEDC/Derived/HyperbolicQuasiGeodesicShadowUp/` Those instances must keep $D, G, E, V, B, L, H, C, P, A, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ packet is generated from disk readout rows, a quasi-geodesic route, a boundary endpoint, a visual-metric shadow window, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, refusal, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5802.1, Definition 5802.2, Definition 5802.3, and Definition 5802.4 seed the finite quasi-geodesic shadow route for observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, host curvature semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk readout, quasi-geodesic route admission, endpoint exposure, visual-metric shadow windows, Busemann tolerance, lamination compatibility, TasteGate nontriviality, field faithfulness, refusal exactness, transport, replay, provenance, and local naming for future BEDC.Derived.HyperbolicQuasiGeodesicShadowUp.

Chapter 4405

A Concrete Naming Certificate for $\mathsf{Dendrite}^{\uparrow}$

Following Nadler and Kuratowski on continuum theory, the $\mathsf{Dendrite}^{\uparrow}$ packet records the finite BEDC surface for a locally connected compact metric continuum whose tree-like form is read through unique arcs and cutpoint separation. It sits over the compact metric carrier of chapter 129, the locally connected surface of chapter 5809, the Peano continuum boundary of chapter 2160, and the tree certificate of chapter 119. The packet names displayed endpoint, unique-arc, and cutpoint-separation rows; it does not import host continua, arbitrary path spaces, open-cover compactness, or quotient equality of arcs.

Definition 4405.1 (Dendrite carrier)**.** *A* $\mathsf{Dendrite}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric distance rows, finite ProbeBundle-net rows, complete-limit witness rows, and rational tolerance comparisons already certified by the compact-metric chapter.*
2. *L is the* $\mathsf{LocallyConnected}^{\uparrow}$ *row, recording the displayed connected neighbourhood refinements through which local arc and cutpoint requests are inspected.*
3. *P is the* $\mathsf{PeanoContinuum}^{\uparrow}$ *row, binding the compact metric and locally connected continuum surfaces before any dendrite consumer reads an arc boundary.*
4. *T is the* $\mathsf{Tree}^{\uparrow}$ *row, recording the finite tree-like separation surface used to rule out cycle-shaped routes.*
5. *E is the endpoint ledger, listing endpoint rows and their neighbourhood-read witnesses.*
6. *A is the unique-arc ledger, recording for every displayed endpoint or carried point pair the finite arc row, its endpoint membership rows, and its non-branching comparison rows.*
7. *C is the cutpoint-separation ledger, recording the displayed separation rows used when removing a carried point disconnects the relevant finite tree-like boundary.*
8. *H records componentwise* hsame *transport for compact metric data, local connectedness data, Peano-continuum data, tree data, endpoint rows, unique-arc rows, cutpoint-separation rows, replay, provenance, and local naming.*

9. *R records displayed* Cont *replay from a dendrite request through* $K, L, P, T, E, A, C, H, G, Q, N$.
10. *G is the* Pkg *provenance over* $\mathsf{Dendrite}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{PeanoContinuum}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *Q records the local source and consumer provenance for endpoint, unique-arc, and cutpoint-separation reads.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host continuum, arbitrary path selection, open-cover compactness, cycle elimination by excluded middle, or quotient equality of arcs.

Lean4 ✓ `BEDC.Derived.DendriteUp.DendriteTasteGate single carrier alignment`

Theorem 4405.2 (Dendrite NameCert obligations)**.** *For every accepted* $\mathsf{Dendrite}^{\uparrow}$ *carrier*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source, locally connected row, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming;*
2. *compact-continuum visibility, requiring every dendrite consumer to read compact metric and local connectedness data through K, L, P before reading endpoint or arc rows;*
3. *tree-like exactness, requiring the non-cycle and separation information to pass through T and the cutpoint-separation ledger C;*
4. *unique-arc exactness, requiring every arc-facing read to use the displayed ledger A with its endpoint membership and non-branching comparison rows;*
5. *endpoint exactness, requiring endpoint reads to use only the displayed endpoint ledger E and not a host boundary predicate;*
6. hsame, Cont, *and* Pkg *stability, requiring componentwise transport, displayed replay, and provenance to preserve precisely the listed rows;*
7. *non-escape, excluding host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, and quotient equality of arcs.*

No dendrite obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5803.1. The accepted tuple displays exactly the compact metric source, local connectedness, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming.

The compact-continuum route is K, L, P. The compact metric source supplies distance, finite-net, complete-limit, and tolerance-comparison rows; the locally connected row supplies connected neighbourhood refinements; and the Peano-continuum row binds those surfaces before endpoint or arc data are exposed.

The tree-like route is T, E, A, C. The tree row supplies the finite non-cycle surface, the endpoint ledger records boundary reads, the unique-arc ledger records the displayed arc row between

carried point pairs, and the cutpoint-separation ledger records the separation witnesses used by downstream consumers.

Finally, H, R, G, Q, N transport, replay, source, and name the same finite packet. Since the carrier has no row for a host continuum, arbitrary path space, open-cover compactness principle, selected arc representative, or quotient equality of arcs, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$ surface. □

Theorem 4405.3 (Dendrite unique-arc handoff)**.** *Every unique-arc or cutpoint-facing consumer of an accepted* $\mathsf{Dendrite}^\uparrow$ *carrier must read the finite route*

$$\mathsf{CompactMetric}^\uparrow,\ \mathsf{LocallyConnected}^\uparrow,\ \mathsf{PeanoContinuum}^\uparrow,\ \mathsf{Tree}^\uparrow \longmapsto E, A, C, H, R, G, Q, N.$$

The handoff exposes endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It does not expose arbitrary host paths, open-cover compactness, selected arc representatives, quotient equality of arcs, or a continuum object outside the displayed packet.*

Proof. Start with the compact-continuum source. The rows K, L, P force a consumer to read the compact metric, locally connected, and Peano-continuum surfaces before any arc-facing data can be inspected.

Next read the tree row T. This is the only row carrying the tree-like non-cycle surface, so a later cutpoint or arc argument cannot replace it by a host graph or a classical continuum theorem.

The endpoint and arc data are then E, A, C. Endpoint reads pass through E, unique-arc reads pass through A, and cutpoint-separation reads pass through C; the three ledgers remain tied to the same compact-continuum and tree source rows.

The structural rows H, R, G, Q, N preserve this route under transport, replay, provenance, and local naming. Because no excluded host-side row appears in the carrier, the consumer receives exactly the displayed unique-arc handoff and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{Dendrite}^\uparrow$ read must expose CompactMetric, LocallyConnected, PeanoContinuum, Tree, endpoint, unique-arc, cutpoint-separation, componentwise hsame, displayed Cont, Pkg, source provenance, and local NameCert rows before a continuum or arc consumer can inspect the dendrite boundary.

Independence witness: compactmetric, locally-connected, peano-continuum, tree: $\mathsf{Dendrite}^\uparrow$ is not bijective to any listed sibling because it binds endpoint, unique-arc, and cutpoint-separation ledgers over their common compact-continuum and tree-like source.

Closure status for $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$**.**

Constructive story: A $\mathsf{Dendrite}^\uparrow$ packet is generated from CompactMetricUp, LocallyConnectedUp, PeanoContinuumUp, TreeUp, endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, source provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, seed)

Scope closed: Definition 5803.1, Definition 5803.2, and Definition 5803.3 seed the finite dendrite certificate over compact metric, locally connected, Peano-continuum, tree, endpoint, unique-arc, cutpoint-separation, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, quotient equality of arcs, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-continuum visibility, tree-like exactness, endpoint exactness, unique-arc exactness, cutpoint-separation exactness, transport, replay, provenance, and local naming for BEDC.Derived.DendriteUp.

Chapter 4406

A Concrete Naming Certificate for $\mathsf{YoungIntegration}^{\uparrow}$

Following Young's integration theorem and Bishop–Bridges constructive analysis, the $\mathsf{YoungIntegration}^{\uparrow}$ packet records the finite dyadic route for integrating one Holder-controlled path against another. It sits beside the Holder-continuity surface of chapter 1766, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the tagged-mesh Riemann integral boundary of chapter 1526. The chapter names only a finite partition-and-error certificate; it does not import host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4406.1 (Young integration finite partition carrier)**.** *A* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the integrand path row, read through a* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
2. *G is the integrator path row, read through a second* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its own source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
3. *A and B are the two Holder exponent ledgers. They include the finite comparison row witnessing that the displayed exponents have a Young margin for the dyadic partition family.*
4. *W is the dyadic partition-window row. It lists the inspected endpoints, dyadic mesh refinements, cell order, adjacent-cell handoffs, and the finite cells on which the integration read is allowed to form sums.*
5. *V is the cross-variation tolerance ledger. It records the cellwise oscillation products, Holder-bound products, Young-margin comparisons, and finite sum-difference tolerances consumed by the route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for endpoint radii, mesh widths, exponent-comparison margins, oscillation products, and final error bounds.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational trace of dyadic Young sums.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the integral value, reached only after the two Holder rows, dyadic windows, cross-variation ledger, dyadic tolerances, and regular readback have been displayed.*
9. *H records componentwise* hsame *transport for the two Holder paths, exponent ledgers, partition windows, cross-variation ledger, dyadic ledger, readback, Real seal, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from a Young-integration request through Holder admission, dyadic partition windows, cross-variation tolerances, regular rational readback, and the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{YoungIntegration}^{\uparrow}$, $\mathsf{HolderContinuity}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, G, A, B, W, V, D, R, E, H, C, P, N$. It has no coordinate for an ambient path space, quotient equality of functions, a selected sequence of partitions, a hidden limiting argument, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.YoungIntegrationUp.YoungIntegrationTasteGate single carrier alignment`

Theorem 4406.2 (Young integration NameCert obligations)**.** *For every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier $Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *surface is exhausted by admission of two* $\mathsf{HolderContinuity}^{\uparrow}$ *path rows, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting,* $\mathsf{DyadicRatCore}^{\uparrow}$ *exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No accepted consumer may replace these rows by host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5804.1. The rows F and G expose the two Holder-controlled paths, and A, B expose only the finite exponent and Young-margin comparisons attached to those rows.

The partition and tolerance data are then forced. The row W lists the dyadic windows available to the route, while V records the cross-variation products and sum-difference tolerances over exactly those windows.

The terminal read is D, R, E. Dyadic exactness is read through D, the regular rational trace through R, and the Real integral seal through E only after the preceding rows have been consumed.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4406.3 (Young integration dyadic error budget)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *read that reaches the* $\mathsf{Real}^{\uparrow}$ *seal factors through the finite dyadic budget*

$$\mathsf{HolderContinuity}^{\uparrow}, \mathsf{HolderContinuity}^{\uparrow} \longmapsto \mathsf{DyadicPartition}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The row V must display the cross-variation tolerance consumed between the partition windows and the rational readback. Therefore the exported integral value is a finite dyadic Young-sum seal, not a Riemann-integral replacement, a measure-completion integral, a quotient path equality, a selected limiting partition, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the two Holder rows. Their displayed exponents and constants are read through F, G, A, B, so the route has only the finite power-law data needed to bound oscillations on dyadic cells.

Next read the dyadic partition windows. The row W fixes the cells, endpoints, mesh refinements, and adjacent-cell handoffs before any sum-difference comparison is requested.

The error budget is the pair V, D. The cross-variation ledger V records the oscillation products and Young-margin comparisons, and the dyadic ledger D records the exact rational tolerances used to compare any two displayed sums.

The readback and seal are downstream. The regular sequence row R is the only rational trace exported from the finite budgets, and E is the only Real seal. Thus the consumer cannot obtain any of the excluded host-level or choice-level objects from the packet. □

Theorem 4406.4 (Young integration Riemann boundary)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet reads it only as a finite tagged-mesh boundary: two Holder path rows, a dyadic partition-window row, a cross-variation tolerance ledger, dyadic exactness, regular rational readback, Real sealing, transport, replay, provenance, and local naming. The consumer receives no independent Riemann-integral certificate, no Darboux gap claim, no quotient equality of integrands, no measure-completion object, and no selected mesh-limit principle.*

Proof. The only Riemann-facing data in the carrier are the displayed dyadic windows and finite sum budgets. The two Holder path rows provide values to be sampled, while W supplies the finite tagged-mesh boundary.

The cross-variation ledger is not a Darboux or measure-theoretic claim. It records only the tolerance comparisons needed for the Young-sum route before the regular rational readback is sealed as a Real value.

The provenance row may name $\mathsf{RiemannIntegral}^{\uparrow}$ as a consumer boundary, but the local certificate remains $F, G, A, B, W, V, D, R, E, H, C, P, N$. Therefore a Riemann-integral consumer receives a finite boundary row rather than any independent integral theorem or hidden limiting principle. □

Theorem 4406.5 (Young integration Cauchy-modulus consumer)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet whose cross-variation ledger* V *requests a tail precision must consume the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route before* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *sealing. The route remains finite: it exports the displayed Young partition windows, dyadic error budget, explicit Cauchy-modulus handoff, regular rational readback, and terminal Real seal, but it exports no selected limiting partition, countable-choice schedule, hidden modulus oracle, or ambient completion theorem.*

Proof. Project the carrier of Definition 5804.1. The rows W, V, D, R, E expose the partition windows, cross-variation tolerance ledger, dyadic error budget, regular rational readback, and terminal Real seal.

Use Definition 5804.3. The row V is the place where sum-difference tolerances and tail precision demands are recorded, and D is the dyadic ledger that makes those demands finite.

When such a tail precision is requested, apply the effective handoff of Definition 5728.3 and the schedule determinacy of Definition 5728.4. They force the precision request through an explicit $\mathsf{CauchyModulusBridge}^{\uparrow}$ schedule before R can be read and before E can seal the result.

The remaining rows H, C, P, N transport, replay, source, and name the same finite route. Since neither the Young carrier nor the bridge carrier contains a selected limiting partition, countable-choice schedule, hidden oracle, or ambient completion coordinate, no such object is exported. □

Falsifiable prediction: An accepted $\mathsf{YoungIntegration}^{\uparrow}$ packet is refuted if a consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting either $\mathsf{HolderContinuity}^{\uparrow}$ path row, the dyadic partition-window row W, the cross-variation ledger V, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: HolderContinuity, DyadicPartition, DyadicRatCore, RegSeqRat, Real, RiemannIntegral: none is bijective with $\mathsf{YoungIntegration}^{\uparrow}$ because the packet jointly carries two Holder paths, Young-margin exponent rows, dyadic partition windows, cross-variation tolerances, dyadic exactness, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$.

Constructive story: A $\mathsf{YoungIntegration}^{\uparrow}$ packet is generated from two HolderContinuityUp path rows, exponent-margin ledgers, dyadic partition windows, cross-variation tolerance accounting, DyadicRatCore exactness, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5804.1, Definition 5804.2, Definition 5804.3, Definition 5804.4, and Definition 5804.5 seed the finite dyadic Young-integration route over HolderContinuityUp, DyadicPartitionUp, DyadicRatCoreUp, CauchyModulusBridgeUp, RegSeqRatUp, RealUp, and RiemannIntegralUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked two-path admission, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting, dyadic exactness, regular rational readback, Real-seal nonescape, and structural transport for BEDC.Derived.YoungIntegrationUp.

Chapter 4407

A Concrete Naming Certificate for $\mathsf{VariationDiminishing}^{\uparrow}$

Following Schoenberg and Karlin, the $\mathsf{VariationDiminishing}^{\uparrow}$ packet records a finite analysis row for transformations that do not increase displayed sign variation. It consumes the total-variation function surface of chapter 2257, the bounded-variation real-function carrier of chapter 3654, the regulated-function source of chapter 1554, and the tagged integration boundary of chapter 1526. The packet names the finite comparison by which a kernel or transformation row is read as variation-diminishing without importing a host operator algebra, total-positivity theorem, selected partitions, quotient functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4407.1 (Variation-diminishing carrier)**.** *A* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (B, T, R, I, K, M, H, C, P, N)$$

with the following rows:

1. *B is the* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *source row naming the accepted bounded-variation input surface.*
2. *T is the* $\mathsf{TotalVariationFunction}^{\uparrow}$ *row naming the displayed total-variation ledger used to count variation before and after the transformation.*
3. *R is the* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *row naming the regulated readback through which input and output functions are compared by finite step windows.*
4. *I is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *row naming the finite tagged-mesh integration boundary used when the transformation is read by kernel action or integral averaging.*
5. *K is the kernel or transformation row, including its displayed positivity-order or sign-regularity window.*
6. *M is the variation comparison row recording that each accepted finite sign-change ledger for the output is routed to a no-larger sign-change ledger for the input.*
7. *H records componentwise* hsame *transport for bounded-variation source, total-variation ledger, regulated readback, integral boundary, kernel row, comparison row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite transformation request through $B, T, R, I, K, M, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{VariationDiminishing}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RegulatedRealFunction}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and sibling* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, T, R, I, K, M, H, C, P, N$. It has no coordinate for host function equality, quotient representatives, selected limiting partitions, a global total-positivity theorem, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.VariationDiminishingUp.VariationDiminishingTasteGate single carrier alignment`

Theorem 4407.2 (Variation-diminishing NameCert obligations)**.** *For every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier*

$$V = (B, T, R, I, K, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded-variation source row B, total-variation ledger T, regulated-function readback R, Riemann-integral boundary I, kernel or transformation row K, variation comparison row M, componentwise transport H, displayed replay C, provenance P, and local naming N.*

The obligation surface requires every output variation read to pass through the displayed comparison row M after B, T, R, I, K have been projected. It refuses host operator equality, quotient equality of functions, selected partitions, unrestricted total positivity, measure-theoretic kernels, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5805.1. The source row B supplies the bounded-variation input, while T supplies the total-variation ledger on which finite sign-change comparisons can be read.

The rows R and I keep the analytic route finite. Regulated readback gives step-window access to input and output functions, and the Riemann-integral boundary records only the tagged-mesh action needed by a kernel or averaging read.

The row K names the transformation window, and M is the only row that compares variation before and after the transformation. Thus the NameCert consumer obtains a variation-diminishing assertion only through the displayed comparison row, not through a host theorem about all kernels.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores quotient functions, selected limiting partitions, unrestricted total positivity, measure completion, or ambient real completeness, no local obligation can require them. □

Theorem 4407.3 (Variation-diminishing total-variation route)**.** *Every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *consumer read factors through the route*

$$\mathsf{BoundedVariationRealFunction}^{\uparrow},\ \mathsf{TotalVariationFunction}^{\uparrow},\ \mathsf{RegulatedRealFunction}^{\uparrow},\ \mathsf{RiemannIntegral}^{\uparrow} \longmapsto \mathsf{VariationD}$$

The output variation ledger is accepted only after the bounded-variation input, cumulative total-variation ledger, regulated readback, tagged integration boundary, kernel row, and comparison row have been displayed. The route exports no selected limit, quotient function equality, global total-positivity principle, measure-completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. A variation-diminishing request first projects B and T. These rows bind the input function to the bounded-variation and total-variation sibling surfaces, so the requested comparison starts from finite variation data rather than from a host function space.

Next project R and I. The regulated row supplies finite step-window readback, while the integral boundary supplies the tagged-mesh route through which a kernel or averaging transformation can be inspected.

The transformation row K and comparison row M then give the only accepted variation comparison. They state that the displayed output sign-change ledger routes to a no-larger input ledger in the same finite packet.

Finally H, C, P, N preserve the route under transport, replay, provenance, and local naming. Hence every public read of $\mathsf{VariationDiminishing}^{\uparrow}$ passes through the four cited sibling anchors and does not acquire the excluded host-level principles. □

Falsifiable prediction: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet whose output variation read bypasses the displayed total-variation ledger or the regulated readback row is not accepted by the local NameCert.

Independence witness: total-variation-function, bounded-variation-real-function, regulatedrealfunction, riemannintegral: $\mathsf{VariationDiminishing}^{\uparrow}$ is not bijective to any listed sibling because it binds the source variation ledger, regulated readback, tagged integration boundary, transformation row, and no-increase comparison as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet is generated from bounded-variation source data, a total-variation ledger, regulated readback, Riemann tagged-mesh boundary, a kernel or transformation row, a variation comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5805.1, Definition 5805.2, Definition 5805.3, the falsifiable prediction, and the independence witness seed the finite variation-diminishing route over the current analysis rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host operator equality, quotient equality of functions, selected limiting partitions, unrestricted total positivity, measure completion, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation source visibility, total-variation ledger exactness, regulated readback, tagged integration boundary, transformation-row exposure, comparison-row stability, transport, replay, provenance, and local naming for future BEDC.Derived.VariationDiminishingUp.

$\mathsf{FrobeniusReciprocity}^{\uparrow}$ routes induction–restriction comparison through chapter 247, chapter 246, and chapter 245 before the child file states the local certificate.

Chapter 4408

A Concrete Naming Certificate for $\mathsf{FrobeniusReciprocity}^{\uparrow}$

Following Frobenius on induced characters, Serre's finite-group representation theory, and the induction–restriction formulation used by Fulton–Harris, the $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet records the finite comparison row between induction from a subgroup and restriction to that subgroup. It consumes the action rows of chapter 3662, the subgroup source of chapter 80, the representation-ring ledger of chapter 246, the induction–restriction packet of chapter 247, and the character-pairing surface of chapter 245. The packet names only finite source rows, adjunction ledgers, character-pairing boundaries, transport, replay, provenance, and downstream handoff rows; it does not assert a host category of representations, a functor equality, semisimplicity, Schur orthogonality, or a completed character table.

Theorem 4408.1 (FrobeniusReciprocityUp source obligations)**.** *For every accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet, the source surface is the displayed finite tuple*

$$\mathcal{F} = (G, H, R, I, Q, \Phi, \eta, \epsilon, \chi, \lambda, C, P, N),$$

where G is the consumed $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *action row, H is the consumed* $\mathsf{Subgroup}^{\uparrow}$ *row, R is the consumed* $\mathsf{RepresentationRing}^{\uparrow}$ *ledger, I is the consumed* $\mathsf{InducedRep}^{\uparrow}$ *induction–restriction row, Q is the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *pairing row, Φ is the Frobenius comparison row, η, ϵ are the displayed unit and counit rows, χ is the character-pairing boundary, λ is the finite ledger of visible source and endpoint reads, C is componentwise* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *row. No source obligation is imported from a host representation category, quotient carrier, functor category, or external adjunction object.*

Proof. Project the accepted packet. The source rows are precisely G, H, R, I, Q together with the local comparison rows $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

The consumed rows are already finite BEDC certificates. The finite-group representation row supplies the action display, the subgroup row supplies the inclusion boundary, the representation-ring row supplies the Grothendieck ledger, the induced-representation row supplies the induction–restriction endpoints, and the character-theory row supplies the pairing surface.

Since the tuple has no coordinate for a host representation category, quotient carrier, functor category, or external adjunction object, the listed rows exhaust the source obligations. □

Theorem 4408.2 (FrobeniusReciprocityUp adjunction ledger)**.** *The adjunction data of an accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet are exactly the finite rows $\Phi, \eta, \epsilon, \lambda$ over the consumed sources*

H, R, I. The row Φ compares the displayed induction endpoint with the displayed restriction endpoint, η and ϵ record the unit and counit witnesses as BHist *rows, and λ records the visible continuations among source, endpoint, and Frobenius reads. The ledger exports no host naturality square, functor equality, adjunction object, or semisimple decomposition.*

Proof. Begin with the induction–restriction source. The packet consumes the $\mathsf{InducedRep}^{\uparrow}$ row I, so the available endpoints are the displayed induction and restriction rows already carried by that certificate.

The Frobenius comparison is read through Φ. The unit and counit witnesses are read through η and ϵ, and every visible path among source and endpoint reads is recorded by the finite ledger λ.

Exactness is projection from the tuple. Any row outside $\Phi, \eta, \epsilon, \lambda$ is not part of the adjunction ledger, and no host naturality square or functor equality can be recovered from a coordinate that the packet does not carry. □

Theorem 4408.3 (FrobeniusReciprocityUp character-pairing boundary)**.** *Every character-pairing read of a* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet factors through the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *row Q, the representation-ring source R, the induction–restriction source I, and the displayed pairing boundary χ before it can inspect Φ, η, ϵ or λ. The boundary supplies only the finite character-pairing comparison needed for reciprocity and does not export Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra.*

Proof. Read the character side first. The only character-theory coordinate is Q, and the only representation-ring coordinate feeding it is R.

The induction and restriction endpoints enter through I. The displayed pairing boundary χ then names the finite comparison used by the Frobenius row before the ledger reads $\Phi, \eta, \epsilon, \lambda$.

Because the tuple has no coordinate for Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra, every character-pairing read remains inside the stated finite boundary. □

Theorem 4408.4 (FrobeniusReciprocityUp NameCert surface)**.** *The* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *obligation surface is the conjunction of the source obligations of Definition 5806.1, the adjunction ledger of Definition 5806.2, the character-pairing boundary of Definition 5806.3, componentwise* hsame *transport on all displayed source and ledger rows, finite* Cont *replay through C, and* Pkg *provenance through P. The surface exports no obligation outside the displayed tuple $\mathcal{F}$.*

Proof. First combine the source obligations with the adjunction ledger. The source theorem identifies the consumed BEDC certificates, and the ledger theorem identifies the only Frobenius comparison, unit, counit, and continuation rows.

Next add the character-pairing boundary. It places every character read behind Q, R, I, χ before the Frobenius ledger can be inspected.

Finally apply componentwise transport and replay. The rows C and P preserve exactly the displayed tuple, and the local row N names the resulting certificate. Since no obligation outside $\mathcal{F}$ is available, these clauses give the stated NameCert surface. □

Theorem 4408.5 (FrobeniusReciprocityUp consumer handoff)**.** *A downstream consumer of* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *may read exactly the consumed finite-group action row G, subgroup row H, representation-ring row R, induced-representation row I, character-theory row Q, Frobenius rows Φ, η, ϵ, character-pairing boundary χ, visible ledger λ, replay row C, provenance row P, and local name row N. Any consumer handoff to* $\mathsf{InducedRep}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, *or* $\mathsf{CharacterTheory}^{\uparrow}$ *factors through those*

rows and cannot bypass them through a host category, functor equality, semisimplicity theorem, or character-table computation.

Proof. Start with a downstream read. The only visible source coordinates are G, H, R, I, Q, and the only local Frobenius coordinates are $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

For an $\mathsf{InducedRep}^{\uparrow}$ consumer, the handoff is through I together with the Frobenius rows. For a $\mathsf{RepresentationRing}^{\uparrow}$ consumer, the handoff is through R and the source ledger. For a $\mathsf{CharacterTheory}^{\uparrow}$ consumer, the handoff is through Q and the pairing boundary χ.

The replay and provenance rows preserve the same finite route. Thus a consumer cannot bypass the displayed packet through a host category, functor equality, semisimplicity theorem, or character-table computation. □

Theorem 4408.6 (FrobeniusReciprocityUp sibling lattice)**.** *The* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet is a finite comparison consumer of the sibling carriers in chapter 3662, chapter 80, chapter 246, chapter 247, and chapter 245. Its local rows compare induction and restriction after those carriers are visible; they do not form an isolated kernel row and do not replace the representation, subgroup, ring, induced-representation, or character-theory certificates.*

Proof. Read the source tuple of Definition 5806.1. The rows G, H, R, I, Q are precisely the five sibling certificates named in the statement.

The consumer handoff of Definition 5806.5 permits downstream reads only through those rows together with the Frobenius comparison, unit, counit, pairing boundary, ledger, replay, provenance, and local name rows.

Therefore the packet sits inside the displayed representation-theory lattice. It is a comparison consumer over the sibling carriers, not a standalone kernel surface from which the sibling certificates can be reconstructed. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5806.1, Definition 5806.2, Definition 5806.3, Definition 5806.4, Definition 5806.5, and Definition 5806.6 seed the finite Frobenius reciprocity certificate over displayed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, semisimplicity, Schur orthogonality, irreducible decomposition, character-table computation, functor-category equality, or a host adjunction theorem.

Upgrade path: Obligation closure requires checked carrier admission, adjunction-ledger exactness, character-pairing boundary, NameCert surface, and downstream handoff for the same finite packet.

Constructive story: A $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet is generated from consumed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows, then records a finite Frobenius comparison, unit and counit rows, character-pairing boundary, visible continuation ledger, package provenance, and local NameCert evidence.

Chapter 4409

A Concrete Naming Certificate for $\mathsf{NormalOperator}^{\uparrow}$

Following Reed and Simon, the $\mathsf{NormalOperator}^{\uparrow}$ packet records the standard normal-operator surface as finite NameCert data over displayed Hilbert and inner-product candidates. It consumes the inner-product carrier of chapter 86, the Hilbert carrier of chapter 91, the linear-map rows of chapter 48, the operator-norm boundary of chapter 3603, and the downstream spectral-theorem consumer of chapter 214. The packet exposes only a bounded linear operator, its displayed adjoint-action row, the norm ledger, and the normality commutator row; it does not claim spectral measure existence, functional calculus, diagonalization, projection-valued measures, or a host operator algebra.

Definition 4409.1 (NormalOperator carrier)**.** *For a displayed* $\mathsf{Hilbert}^{\uparrow}$ *candidate* H *with* $\mathsf{InnerProduct}^{\uparrow}$ *row* I*, a* $\mathsf{NormalOperator}^{\uparrow}(H)$ *carrier is a finite* BHist *packet*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N)$$

with the following ten displayed fields:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *carrier row and I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row over the same point-history carrier.*
2. *T is a bounded* $\mathsf{LinMap}^{\uparrow}$ *endpoint action on the carried Hilbert endpoints.*
3. *T^* is the displayed adjoint-action row, certified by the finite inner-product comparison*

   $$\langle Tx, y\rangle_I \ \mathsf{hsame}\ \langle x, T^*y\rangle_I$$

   for the vector histories inspected by the packet.
4. *A is the adjoint-domain ledger, recording that the adjoint row is read over the same Hilbert, inner-product, linear-map, and boundedness surfaces as T.*
5. *K is the* $\mathsf{OperatorNorm}^{\uparrow}$ *bound row for T and for the displayed adjoint action T^*.*
6. *Q is the normality commutator row*

   $$T^*T \ \mathsf{hsame}\ TT^*$$

   read only on certified vector histories.
7. *L is the operator graph ledger: it stores inspected input histories, output histories, linearity rows, adjoint rows, norm-bound rows, and the commutator row.*

8. *H_T records componentwise* hsame *transport for the Hilbert source, inner-product row, endpoint actions, adjoint row, norm row, commutator row, and ledger.*
9. *C records displayed* Cont *replay for endpoint action requests, adjoint-action requests, norm-bound requests, and commutator inspections.*
10. *P, N are the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *naming rows.*

The classifier compares accepted carriers by action agreement on certified vector histories, adjoint-action agreement on the same inspected histories, transport of the operator-norm row, and transport of the graph, adjoint, normality, continuation, provenance, and local-name ledgers. It has no coordinate for host operator equality, quotient completion, spectral measures, eigenvector bases, or external functional calculus.

Lean4 ✓ `BEDC.Derived.NormalOperatorUp.NormalOperatorTasteGate single carrier alignment`

Theorem 4409.2 (NormalOperator NameCert obligations)**.** *For every accepted* $\mathsf{NormalOperator}^\uparrow$ *carrier*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the common* $\mathsf{Hilbert}^\uparrow$ *and* $\mathsf{InnerProduct}^\uparrow$ *rows;*
2. *bounded* $\mathsf{LinMap}^\uparrow$ *action for T on certified vector histories;*
3. *adjoint-action agreement for T^* against the displayed inner product;*
4. $\mathsf{OperatorNorm}^\uparrow$ *bound rows for the operator action and adjoint action;*
5. *normality commutator exactness through the displayed row Q;*
6. *graph-ledger exactness for input histories, output histories, linearity rows, adjoint rows, norm rows, and commutator rows;*
7. *classifier transport by action agreement, adjoint-action agreement, norm-row agreement, and componentwise ledger transport;*
8. Cont *replay,* Pkg *provenance, and local naming for exactly the displayed packet;*
9. *refusal of spectral measure existence, diagonalization, projection-valued measures, host operator quotients, and unrecorded functional calculus.*

Proof. Project the carrier of Definition 5807.1. The Hilbert and inner-product source rows, endpoint action, adjoint-action row, adjoint-domain ledger, norm row, commutator row, graph ledger, transport row, continuation row, provenance row, and local name are the full displayed inventory.

The adjoint and boundedness obligations are read before any spectral consumer appears. The adjoint row is the finite inner-product comparison for certified vector histories, and the norm row is the displayed $\mathsf{OperatorNorm}^\uparrow$ bound attached to both endpoint actions.

Normality is exactly the commutator row Q. Because Q compares T^*T and TT^* only through inspected vector histories and their graph ledger, the packet does not appeal to host equality of operators.

Finally H_T, C, P, N transport, replay, source, and name those rows. Since the carrier has no spectral-measure, diagonalization, projection-valued-measure, quotient, or functional-calculus coordinate, the listed rows exhaust the local normal-operator NameCert obligations. □

Theorem 4409.3 (NormalOperator InnerProduct spectral anchor)**.** *Every downstream spectral read of an accepted* $\mathsf{NormalOperator}^{\uparrow}$ *packet factors through the common Hilbert and inner-product rows, the bounded linear action, the displayed adjoint-action row, the operator-norm bound, and the normality commutator ledger before it can be consumed by the* $\mathsf{SpectralTheorem}^{\uparrow}$ *surface. The route is*

$$(H, I) \longmapsto (T, T^*, A, K, Q, L) \longmapsto (H_T, C, P, N),$$

and it exports no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality.

Proof. Expose the accepted packet by Definition 5807.1. The only analytic source rows are the Hilbert carrier, inner-product comparison row, endpoint action, displayed adjoint action, norm bound, and normality commutator.

Apply Definition 5807.2. The graph ledger forces the operator action, adjoint action, boundedness evidence, and commutator evidence to be read from one finite packet, and classifier transport keeps the operator and adjoint rows over the same certified vector histories.

It remains to hand the packet to spectral consumers. The $\mathsf{SpectralTheorem}^{\uparrow}$ chapter may consume the normality anchor only through the displayed rows already named here. Because no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality is a field of the carrier, the anchor supplies a pre-spectral normal-operator surface rather than a spectral theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5807.1, Definition 5807.2, and Definition 5807.3 seed the normal-operator surface over Hilbert, inner-product, bounded linear-map, adjoint-action, operator-norm, and commutator rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim spectral measures, spectral projections, diagonalization, eigenbasis construction, Borel functional calculus, host operator quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, adjoint-action agreement, norm-bound stability, normality commutator exactness, classifier transport, graph-ledger exactness, spectral-consumer nonescape, and bridge data for BEDC.Derived.NormalOperatorUp.

Constructive story: A $\mathsf{NormalOperator}^{\uparrow}$ packet is generated from a Hilbert source, an inner-product row, a bounded linear endpoint action, a displayed adjoint action, operator-norm bounds, a normality commutator row, graph and transport ledgers, continuation replay, provenance, and a local NameCert row.

Chapter 4410

A Concrete Naming Certificate for $\mathsf{HausdorffMeasure}^{\uparrow}$

Following Hausdorff and Federer's metric measure theory, the $\mathsf{HausdorffMeasure}^{\uparrow}$ packet records the finite dyadic-cover surface through which Hausdorff content and scale-stable measure reads become visible inside BEDC. It sits over the metric carrier of chapter 57, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the cover-valued outer-measure boundary of chapter 3385, and the finite scale-cover comparison surface of chapter 3877. The packet names only displayed dyadic cover packets, diameter budgets, weighted cover sums, scale comparison, transport, replay, provenance, and local naming; it is not a quotient cover family, not a selected infimum, not countable choice over covers, and not an ambient measure primitive.

Definition 4410.1 (Hausdorff measure dyadic-cover carrier)**.** *A* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (M, D, R, O, B, C, S, T, E, K, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the finite point classifier and distance comparisons used to bound cover diameters.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row, naming the dyadic radius budget and dyadic exponent used by the cover packet.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *value-seal row for diameter powers and finite cover sums.*
4. *O is the* $\mathsf{OuterMeasure}^{\uparrow}$ *handoff row, read only as a finite cover-valued boundary and not as a completed measure primitive.*
5. *B is the* $\mathsf{BoxDimension}^{\uparrow}$ *comparison row, exposing finite scale-cover counts against the same dyadic scale.*
6. *C is the finite dyadic cover packet, listing the displayed cover cells, their metric diameter witnesses, and their membership reads.*
7. *S is the cover-sum ledger, recording the finite Real-sealed sum of dyadic diameter weights.*
8. *T is the scale-stability ledger, recording that dyadic refinement reads the same metric source, outer-measure boundary, and box-dimension comparison rows.*
9. *E records componentwise* hsame *transport for metric, dyadic scale, Real seal, outer-measure handoff, box-dimension comparison, cover packet, cover sum, and stability rows.*

10. *K records displayed* Cont *replay from a metric source and dyadic scale through C, S, T, E, P, N.*
11. *P is the* Pkg *provenance over* $\mathsf{HausdorffMeasure}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{OuterMeasure}^{\uparrow}$, $\mathsf{BoxDimension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D, R, O, B, C, S, T, E, K, P, N$. It has no coordinate for quotient cover families, selected infima, countable-choice schedules over covers, host sigma-algebras, or ambient measure primitives.

Lean4 ✓ `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate single carrier alignment`

Theorem 4410.2 (Hausdorff measure NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier $H = (M, D, R, O, B, C, S, T, E, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *surface consists exactly of metric source admission, dyadic scale exposure, Real value sealing, finite outer-measure handoff, box-dimension scale comparison, finite dyadic cover admission, cover-sum exactness, scale-stability replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every measure-facing or dimension-facing consumer must read the displayed route*

$$\mathsf{Met}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto C, S, T \longmapsto \mathsf{OuterMeasure}^{\uparrow}, \mathsf{BoxDimension}^{\uparrow} \longmapsto E, K, P, N$$

before treating the packet as a Hausdorff-measure read.

Proof. Project the carrier of Definition 5808.1. The metric row M, dyadic row D, and Real seal row R are the only sources for distances, scales, and finite value readback.

The cover packet C and cover-sum ledger S are finite rows. They record displayed cover cells and dyadic diameter weights, so no step selects a minimizing cover family or takes an external infimum.

The outer-measure and box-dimension rows O, B are downstream comparison boundaries. They can read the same finite cover data, but they do not add a completed host measure, a quotient of covers, or countable choice over refinements.

Finally T, E, K, P, N transport, replay, source, and name the same finite route. Since every exported obligation is one of the listed rows, the local classifier cannot expose an ambient measure primitive or any detached cover selector. □

Theorem 4410.3 (Hausdorff measure dyadic-cover stability)**.** *Let $H = (M, D, R, O, B, C, S, T, E, K, P, N)$ be an accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier. For any displayed dyadic refinement of the scale row D, the scale-stability ledger T forces the refined read to reuse the same* $\mathsf{Met}^{\uparrow}$ *source, the same* $\mathsf{Real}^{\uparrow}$ *value-seal route, the same finite* $\mathsf{OuterMeasure}^{\uparrow}$ *cover boundary, and the same* $\mathsf{BoxDimension}^{\uparrow}$ *scale-count comparison before any consumer reads a Hausdorff-measure claim. The stable route is*

$$M, D, R, C, S, T \longmapsto O, B \longmapsto E, K, P, N.$$

It exports no quotient cover family, selected infimum, countable-choice cover schedule, host sigma-algebra closure, or ambient measure primitive.

Proof. Read the carrier of Definition 5808.1. A dyadic refinement changes only the displayed scale request inside D and the finite cover packet admitted by C.

Use the stability ledger T. It records that the refined cover is replayed against the same metric source and that its finite cover sum is sealed through the same Real row, so the refinement cannot introduce a detached minimizing cover or a host infimum.

The comparison rows O and B then read the refined packet as finite outer-measure and box-dimension boundary data. Componentwise transport and displayed replay through E, K, P, N preserve that route, while quotient covers, countable choice, host sigma-algebras, and ambient measure primitives remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HausdorffMeasure}^{\uparrow}$ consumer that reaches a Hausdorff-measure read without first exposing a MetricUp source row, a DyadicRatCore scale row, a RealUp value seal, a finite dyadic cover packet, a finite cover-sum ledger, an OuterMeasureUp handoff, a BoxDimensionUp comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row refutes the carrier surface.

Independence witness: metric, dyadicratcore, real, outermeasure, boxdimension: $\mathsf{HausdorffMeasure}^{\uparrow}$ is not bijective to any listed sibling because it binds metric diameter data, dyadic scales, Real-sealed finite cover sums, outer-measure cover boundaries, and box-dimension scale counts into one finite cover-stability NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffMeasure}^{\uparrow}$ packet is generated from a MetricUp source row, DyadicRatCore scale row, RealUp value-seal row, finite OuterMeasureUp handoff, BoxDimensionUp comparison row, finite dyadic cover packet, cover-sum ledger, scale-stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5808.1, Definition 5808.2, and Definition 5808.3 seed the finite dyadic-cover Hausdorff-measure interface over MetricUp, DyadicRatCoreUp, RealUp, OuterMeasureUp, and BoxDimensionUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient cover families, selected infima, countable choice over covers, host sigma-algebra completion, ambient measure primitives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic scale exposure, finite cover admission, cover-sum exactness, scale-stability replay, outer-measure handoff, box-dimension comparison, transport, provenance, and no-escape for BEDC.Derived.HausdorffMeasureUp.

Chapter 4411

A Concrete Naming Certificate for $\mathsf{LocallyConnected}^{\uparrow}$

Following Kelley and Bourbaki on local connectedness, the $\mathsf{LocallyConnected}^{\uparrow}$ packet records finite neighbourhood-component data rather than a selected basis of connected open sets. It sits beside the global connectedness carrier of chapter 2353, the compact metric source discipline of chapter 129, the metric ball rows of chapter 57, and the open-neighbourhood ledger of chapter 88. The packet exposes the local component route needed by compact-metric and connected-space consumers without importing path selection, arc connectedness, open-cover compactness, or a host topological basis.

Definition 4411.1 (Locally connected carrier)**.** *A* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, M, G, K, B, C, H, R, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-neighbourhood row whose entries name the ambient open requests.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *ball-observation row used when the local request is metric.*
3. *G is the* $\mathsf{ConnectedSpace}^{\uparrow}$ *global component row available to consumers that compare local and global connectedness.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-source row available to compact-metric consumers.*
5. *B is the finite neighbourhood-refinement row: each displayed point and open request has a named smaller neighbourhood row.*
6. *C is the local connected-component row attached to the refinement in B.*
7. *H records componentwise* hsame *transport for the topology, metric, connectedness, compact-metric, refinement, component, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from an ambient open request through metric ball observations when present, the finite refinement row, and the local component row.*
9. *P is the* Pkg *provenance over* $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConnectedSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, M, G, K, B, C, H, R, P, N$. It has no coordinate for selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, or a host basis of connected neighbourhoods.

Lean4 ✓ `BEDC.Derived.LocallyConnectedUp.TasteGate.LocallyConnectedTasteGate single carrier alignment`

Theorem 4411.2 (Locally connected NameCert obligations)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier $L = (T, M, G, K, B, C, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *surface consists exactly of carrier admission for the topology, metric, connected-space, compact-metric, finite neighbourhood-refinement, local component, transport, replay, provenance, and naming rows; neighbourhood refinement from T through B; component exposure through C; metric compatibility through M when the request is ball-based; compact-metric compatibility through K for compact finite-source consumers; connected-space comparison through G; and non-escape from selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice.*

Proof. Project the carrier of Definition 5809.1. The projection exposes exactly the rows $T, M, G, K, B, C, H, R, P, N$ so every local naming obligation must be read from those coordinates.

The neighbourhood part is finite. An ambient open request is first read in T, then refined by the displayed row B, and only then receives the local component row C.

The metric and compact-metric rows are compatibility rows rather than extra selectors. A ball-based request may inspect M, and a compact-metric consumer may inspect K, but both routes still pass through the same B and C rows before local connectedness is exported.

Finally, H and R transport and replay the displayed route, while P and N source and name it. Since paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice are not rows of the carrier, the NameCert surface cannot export them. □

Theorem 4411.3 (Locally connected neighbourhood component route)**.** *Every connected-space or compact-metric consumer of an accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *packet reaches local connectedness through*

$$\mathsf{Topology}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{ConnectedSpace}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The finite route reads an ambient neighbourhood, optionally reads metric ball observations, refines to a displayed smaller neighbourhood, and then reads the named local connected component. It does not select a path, an arc, a subcover, a quotient component representative, or a host connected-neighbourhood basis.

Proof. Start with a consumer that asks for local connectedness around a displayed point. Carrier admission gives the consumer the topology row T, the metric row M when a ball observation is part of the request, the global connectedness row G, and the compact-metric row K.

The route then passes through B and C. The row B supplies the finite neighbourhood refinement, and C supplies the local component attached to that refinement.

The structural rows H, R, P, N do not add a hidden selector. They transport, replay, source, and name the same finite route, so no path, arc, arbitrary subcover, quotient representative, or host basis can replace the displayed neighbourhood-component data. □

Theorem 4411.4 (Locally connected obligation closure surface)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier $L = (T, M, G, K, B, C, H, R, P, N)$, the obligation-closure surface is exhausted by the displayed finite topology, metric, connected-space, compact-metric, neighbourhood-refinement, local-component, transport, replay, provenance, and naming rows. The row T supplies the open-neighbourhood*

source, M supplies metric-ball observations, G supplies connected-space comparison, K supplies compact-metric finite-source compatibility, B, C supply the local refinement and component rows, and H, R, P, N supply transport, replay, provenance, and local naming.

The local component route therefore consumes the connected-space carrier of chapter 2353, the compact-metric finite neighbourhood discipline of chapter 129, the metric-ball rows of chapter 57, and the topology neighbourhood ledger of chapter 88 before a local component can be named.

Proof. Apply Definition 5809.2 to the accepted carrier. It identifies the complete NameCert surface with the rows $T, M, G, K, B, C, H, R, P, N$.

Apply Definition 5809.3. The route from an open request to a local component passes through topology, optional metric-ball observations, connected-space comparison, compact-metric compatibility, finite refinement, and component rows before the structural rows transport and name the result.

The sibling lattice is read in that order: topology supplies the neighbourhood ledger, metric supplies ball observations, connected-space supplies the comparison carrier, and compact metric supplies the finite neighbourhood discipline. The local refinement and component rows then bind those sibling contributions into the $\mathsf{LocallyConnected}^{\uparrow}$ packet.

Thus the obligation surface is the stated finite route. Path or arc selection, open-cover compactness, quotient components, and a host basis are refused because none of them is a carrier coordinate or a row used by the two preceding theorems. □

Falsifiable prediction: Every accepted $\mathsf{LocallyConnected}^{\uparrow}$ read must expose a $\mathsf{Topology}^{\uparrow}$ open-neighbourhood row, optional $\mathsf{Met}^{\uparrow}$ ball observations, the $\mathsf{ConnectedSpace}^{\uparrow}$ comparison row when a global consumer is present, the $\mathsf{CompactMetric}^{\uparrow}$ finite-source row when a compact-metric consumer is present, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: topology, metric, connected-space, compactmetric: $\mathsf{LocallyConnected}^{\uparrow}$ is not bijective to any listed sibling because it binds a local neighbourhood-refinement row to a local component row before connected-space or compact-metric consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5809.1, Definition 5809.2, and Definition 5809.3 seed the finite local neighbourhood-component route over topology, metric, connected-space, and compact-metric rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close path connectedness, arc connectedness, arbitrary open-cover compactness, quotient component spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, neighbourhood refinement, local component exposure, connected-space comparison, compact-metric compatibility, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.LocallyConnectedUp.

Constructive story: A $\mathsf{LocallyConnected}^{\uparrow}$ packet is generated from an open-neighbourhood row, optional metric ball observations, connected-space and compact-metric compatibility rows, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4412

A Concrete Naming Certificate for $\mathsf{BishopCauchyMean}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{BishopCauchyMean}^{\uparrow}$ packet records the finite averaging step used when a Cauchy source is read through displayed rational windows and sealed as a Real-facing name. It sits after the $\mathsf{Cauchy}^{\uparrow}$ source route of chapter 3413, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names finite averages of observed Cauchy data; it does not assert a selected limit, quotient stream equality, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4412.1 (Bishop Cauchy mean carrier)**.** *A* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Cauchy}^{\uparrow}$ *source row naming the Cauchy data whose finite observations are being averaged.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested dyadic radius, denominator budget, and comparison scale for the average.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the source entries inspected at tolerance D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream window into regular rational data.*
5. *A is the finite averaging ledger: it lists the inspected rational entries, their displayed weights, the denominator row, the partial-sum row, and the final mean row consumed by the certificate.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, W, R, A have been displayed.*
7. *H records componentwise* hsame *transport for the source, tolerance, window, readback, averaging ledger, Real seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a finite mean request through $S, D, W, R, A, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyMean}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, D, W, R, A, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness of $\mathsf{Real}^{\uparrow}$*, or an infinite averaging oracle.*

Lean4 ✓ `BEDC.Derived.BishopCauchyMeanUp.BishopCauchyMeanTasteGate single carrier alignment`

Theorem 4412.2 (Bishop Cauchy mean NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier*

$$M = (S, D, W, R, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cauchy source row, dyadic tolerance row, finite stream window, regular rational readback, finite averaging ledger, terminal Real seal, componentwise transport row, displayed continuation replay, package provenance, and local naming row.*

The obligation surface requires Cauchy-source visibility through S, tolerance accounting through D, finite-window visibility through W, regular rational readback through R, average-ledger exactness through A, Real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It refuses selected limits, quotient stream equality, host real equality, countable choice, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the accepted carrier of Definition 5810.1. The only analytic rows are the Cauchy source S, the dyadic tolerance D, the finite window W, the regular rational readback R, the averaging ledger A, and the terminal Real seal E.

The averaging step is finite. The ledger A displays the inspected rational entries, their weights, the denominator row, the partial sums, and the final mean; no later consumer can ask for an average outside this listed window.

The terminal seal is downstream of the displayed route. Since the carrier has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness, or an infinite averaging oracle, those objects cannot enter the local NameCert surface.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. They preserve the displayed rows and do not add analytic content. □

Theorem 4412.3 (Bishop Cauchy mean finite-average stability)**.** *Let*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

be an accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier. Every accepted consumer read of the mean row factors through the finite route*

$$\mathsf{Cauchy}^{\uparrow}(S),\ \mathsf{DyadicRatCore}^{\uparrow}(D),\ \mathsf{StreamName}^{\uparrow}(W),\ \mathsf{RegSeqRat}^{\uparrow}(R),\ A,\ \mathsf{Real}^{\uparrow}(E).$$

If the source row, tolerance row, finite window, readback row, and averaging ledger are transported componentwise by the displayed hsame *rows in H and replayed through C, then the consumer-visible mean row is unchanged as a* $\mathsf{BishopCauchyMean}^{\uparrow}$ *read. No quotient stream equality, selected limit, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row participates in the stability claim.*

Proof. Start with the consumer route. By the carrier definition, a mean read must first inspect the Cauchy source S, choose the displayed dyadic tolerance D, open the finite window W, and read the regular rational row R.

The average itself is then the ledger row A. Its entries, weights, denominator, partial sums, and final mean are finite displayed data, so componentwise hsame transport preserves exactly the rows that the consumer can inspect.

Replay through C exposes the transported packet with the same provenance and local naming rows P, N. The terminal Real seal E is reached from that transported finite route, not from a quotient stream or selected limit.

Thus any consumer-visible equality of mean reads is exhausted by $S, D, W, R, A, E, H, C, P, N$. The excluded rows are absent from the carrier and cannot affect the stability conclusion. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ read must expose a Cauchy source, dyadic tolerance, StreamName window, RegSeqRat readback, finite averaging ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a Real or Completion consumer can read the mean boundary.

Independence witness: cauchy, dyadicratcore, streamname, regseqrat, real: $\mathsf{BishopCauchyMean}^{\uparrow}$ is not bijective to any listed sibling because it binds a finite averaging ledger between regular rational readback and the Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyMean}^{\uparrow}$ packet is generated from a Cauchy source row, DyadicRatCore tolerance row, StreamName finite window, RegSeqRat readback, finite averaging ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5810.1, Definition 5810.2, and Definition 5810.3 seed the finite Cauchy-mean certificate over Cauchy, DyadicRatCore, StreamName, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite average ledger exactness, tolerance-window readback, regular rational handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyMeanUp.

Chapter 4413

A Concrete Naming Certificate for $\mathsf{BishopFixedPointInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet records the constructive interval fixed-point route as finite NameCert data. It sits after the located interval source of chapter 394, the bisection discipline of chapter 1465, the finite Cauchy-modulus rows used by chapter 292, the regular rational readback of chapter 301, the finite name windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the fixed-point certificate for a displayed interval self-map; it does not import a host compactness theorem, quotient real equality, choice-selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4413.1 (Bishop fixed-point interval carrier)**.** *A* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, T, M, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the closed located interval, its endpoint reads, and its dyadic radius ledger.*
2. *T is the contraction self-map row over I, recording that every admitted interval point is sent back into the same located interval.*
3. *M is an explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *or Lipschitz modulus row that turns each tolerance request into a finite contraction budget.*
4. *B is the* $\mathsf{IntervalBisection}^{\uparrow}$ *or nested located interval row that records the displayed shrinking interval chain.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the rational midpoint, endpoint, and radius observations.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *fixed-point seal reached only after the interval, contraction, modulus, bisection, and readback rows have been exposed.*
7. *H records componentwise* hsame *transport for I, T, M, B, R, E and for the structural rows.*
8. *C records displayed* Cont *replay for interval requests, contraction reads, modulus reads, nested interval reads, rational readback, and real-seal requests.*

9. *P is the* Pkg *provenance over* BishopFixedPointInterval$^{\uparrow}$, LocatedInterval$^{\uparrow}$, IntervalBisection$^{\uparrow}$, CauchyModulus$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{BishopFixedPointInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, T, M, B, R, E, H, C, P, N$. It has no coordinate for a host fixed-point theorem, quotient completion, selected limit, trichotomy, countable choice, or ambient compactness principle.

Lean4 ✓ `BEDC.Derived.BishopFixedPointIntervalUp.BishopFixedPointIntervalTasteGate single carrier alignment`

Theorem 4413.2 (Bishop fixed-point interval NameCert obligations)**.** *For every accepted* BishopFixedPointInterval$^{\uparrow}$ *carrier*

$$F = (I, T, M, B, R, E, H, C, P, N),$$

the local NameCert$_{\text{BishopFixedPointInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the located interval row I, contraction self-map row T, explicit modulus row M, nested bisection row B, regular rational readback row R, terminal real seal E, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N. Every fixed-point consumer must read these rows in the displayed order and cannot replace them by host interval compactness, quotient real equality, a selected limit, or an unrecorded convergence principle.*

Proof. Carrier admission is the finite packet of Definition 5811.1. The rows $I, T, M, B, R, E, H, C, P, N$ are the only coordinates available to the local certificate.

The positive interval route is then forced. The interval source is I, the self-map evidence is T, the contraction budget is M, and the nested interval chain is B; each row is compared only through the componentwise transport row H and replayed only through C.

The readback and seal are downstream. Rational observations pass through R and the dyadic and stream-name data named in P before the terminal Real$^{\uparrow}$ row E is exposed. Since no host compactness, quotient equality, selected limit, or external convergence coordinate occurs in the carrier, the listed rows exhaust the NameCert surface. □

Theorem 4413.3 (Bishop fixed-point interval Cauchy-modulus route)**.** *Let $F = (I, T, M, B, R, E, H, C, P, N)$ be an accepted* BishopFixedPointInterval$^{\uparrow}$ *packet. Each tolerance request for the fixed-point name is answered by first reading the* LocatedInterval$^{\uparrow}$ *row I, then the contraction self-map row T, then the explicit* CauchyModulus$^{\uparrow}$ *or Lipschitz row M, and only then the* IntervalBisection$^{\uparrow}$ *or nested located interval row B. The resulting finite observations are read through* StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* RegSeqRat$^{\uparrow}$ *as recorded by P, so no consumer can infer convergence from an unbounded host iteration or a choice-selected subsequence.*

Proof. Start with a tolerance request. The packet has no direct convergence row, so the request must project I to know the interval source and T to know that the displayed map remains inside the interval.

Next read the modulus row M. This row converts the tolerance into a finite contraction or Lipschitz budget. The nested row B can then expose only the finite bisection or located-interval observations licensed by that budget.

Finally use the readback rows listed in P. Stream windows, dyadic tolerances, and regular rational observations feed R, and H, C, N transport and name the same route. Thus the Cauchy route is explicit and finite, with no unbounded host iteration or selected subsequence. □

Theorem 4413.4 (Bishop fixed-point interval real-seal nonescape)**.** *For every accepted* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *packet, the terminal row* E *is exposed only as the* $\mathsf{Real}^{\uparrow}$ *seal of the displayed nested interval and Cauchy-modulus route*

$$I, T, M, B, R \longmapsto E \longmapsto H, C, P, N.$$

The seal may be consumed as the named fixed-point endpoint of the packet, but it cannot escape as quotient real equality, a proof of ambient $\mathsf{Real}^{\uparrow}$ *completeness, a host fixed-point theorem, an unrestricted interval compactness principle, or a selected representative outside the displayed rows.*

Proof. Read E from the carrier. It is terminal in the packet: the interval, self-map, modulus, nested interval, and rational readback rows precede it, and the structural rows only transport, replay, source, and name the resulting read.

Apply Definition 5811.3. Every tolerance request reaching E has already passed through the finite interval, contraction, modulus, bisection, stream, dyadic, and regular rational observations recorded by I, T, M, B, R, P.

It remains to rule out escape. The carrier has no coordinate for quotient real equality, ambient completeness, a host fixed-point theorem, unrestricted compactness, or selected representatives. Therefore E seals only the displayed fixed-point name of this packet. □

Falsifiable prediction: An accepted $\mathsf{BishopFixedPointInterval}^{\uparrow}$ consumer that reaches the terminal $\mathsf{Real}^{\uparrow}$ row E without first reading $I, T, M, B, R, H, C, P, N$ refutes the carrier surface.

Independence witness: locatedinterval, intervalbisection, cauchymodulus, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the full interval self-map packet $F = (I, T, M, B, R, E, H, C, P, N$ because each sibling contributes only a located interval source, a bisection route, a modulus row, a readback row, a finite name window, a dyadic ledger, or a terminal real seal while this chapter binds them into one fixed-point NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet is generated from a located interval row, contraction self-map row, explicit Cauchy or Lipschitz modulus row, nested bisection row, regular rational readback row, terminal Real seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5811.1, Definition 5811.2, Definition 5811.3, and Definition 5811.4 seed the finite constructive interval fixed-point route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point compactness, quotient real equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction self-map admission, explicit modulus routing, nested interval readback, terminal Real seal nonescape, and a Lean carrier/obligation formalization for BEDC.Derived.BishopFixedPointIntervalUp.

Chapter 4414

A Concrete Naming Certificate for $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$

The $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet realizes the private-coordinate minimal-cover theorem of Definition 9462.1678 as finite NameCert data. It records a trigger-coordinate carrier, a support-family cover ledger, and one private-coordinate witness row for each displayed support before any minimal-trigger criterion may be consumed. The packet keeps the enumeration theorem auditable without identifying it with a generic finite set, word list, Boolean classifier, regular-language recognizer, or finite automaton presentation.

Falsifiable prediction: Every accepted $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ consumer must display a cover row and one private-coordinate witness row for each support before using the minimal-trigger criterion.

Independence witness: finset, list, bool, regularlanguage, finite-automaton: $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ is not bijective to these siblings because it carries a support-family cover ledger plus a private-coordinate witness for every support row.

Definition 4414.1 (Private-coordinate trigger carrier)**.** *A* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the finite trigger-coordinate row.*
2. A *is the finite support-family row whose entries are displayed subsets of* Ω*.*
3. U *is the cover ledger asserting that the displayed supports cover every coordinate of* Ω*.*
4. V *is the private-coordinate witness ledger, with one row for each support in* A*.*
5. π *maps each support row to its selected private coordinate and records membership in that support.*
6. E *records exclusion from every other support row for the selected private coordinate.*
7. K *is the minimal-cover criterion row, readable only after* U, V, π, E *have been displayed.*
8. H *stores componentwise* hsame *transport for coordinate, support, cover, witness, exclusion, and criterion rows.*

9. *C stores* Cont *replay from a trigger query through the cover ledger and the private-coordinate witness rows.*
10. *P stores* Pkg *provenance over* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Omega, A, U, V, \pi, E, K, H, C, P, N$. It has no coordinate for a bare finite set, unordered list, Boolean truth table, regular-language recognizer, finite automaton run, or support family without displayed private witnesses.

Theorem 4414.2 (Private-coordinate trigger NameCert obligations)**.** *For every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *surface consists exactly of coordinate exposure, support-family exposure, cover-ledger replay, one private-coordinate witness row for each support, membership and exclusion checks for the selected witnesses, minimal-cover criterion exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5812.1. The rows Ω, A, U display the finite coordinate space, the support family, and the fact that the supports cover the full coordinate row.

The rows V, π, E attach a private coordinate to each support. Membership is recorded by π, and exclusion from every other support is recorded by E, so deleting the support removes at least one displayed coordinate from the cover.

The criterion row K is therefore readable only after the cover and private-witness rows have been exposed. The remaining rows H, C, P, N preserve transport, replay, provenance, and local naming for the same finite packet, and no omitted sibling surface supplies the private-coordinate ledger. □

Theorem 4414.3 (Private-coordinate minimal-cover criterion)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier exposes a minimal full trigger exactly through the displayed cover row U together with the private-coordinate witness rows V, π, E. A consumer may use the criterion row K only after reading a cover of Ω and one witness coordinate for every support row in A that belongs to that support and belongs to no other displayed support. The packet does not turn the support family into a regular language, finite automaton, Boolean table, or list quotient.*

Proof. The forward read uses the cover ledger U and the private-coordinate witness rows. If a support row is removed, its selected witness coordinate remains outside all other displayed supports by E, so the remaining family no longer covers Ω.

For the reverse read, the cover row already gives full coverage. The witness rows ensure that every support has a coordinate lost by deleting that support, so no displayed support is redundant.

Thus the criterion row K is exactly the finite private-coordinate minimal-cover test. The transport, replay, provenance, and local naming rows carry this test without converting it into any sibling classifier. □

Theorem 4414.4 (Private-coordinate trigger finite-set cover route)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *packet reads its support-family row as a finite-set-indexed cover through chapter 112. The exclusions from regular-language and automaton presentations are bounded by chapter 351 and chapter 2364: the private-coordinate carrier may display finite support rows, recognizer-like acceptance tests, or transition-like exclusion checks, but it exports the minimal-cover criterion only through the rows $\Omega, A, U, V, \pi, E, K, H, C, P, N$.*

Proof. Project the accepted carrier

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N).$$

The row Ω is the displayed coordinate object, and A is read as a finite family of supports indexed by the finite-set surface. The cover ledger U then witnesses coverage of every coordinate in Ω by those displayed supports.

The rows V, π, E are the extra private-coordinate ledger. They attach one witness coordinate to each support, record membership in that support, and record exclusion from every other displayed support. These rows are not supplied by the finite-set sibling, nor by the regular-language or finite-automaton presentations.

Consequently K is a private-coordinate minimal-cover read rather than a bare finite-set cover, a regular-language recognizer, or an automaton acceptance predicate. The structural rows H, C, P, N transport and replay only this displayed packet, so the sibling route records the finite-combinatorial surface without replacing the private-coordinate data. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$.

Constructive story: A $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet is generated from a finite trigger-coordinate row, support-family row, cover ledger, per-support private-coordinate witness ledger, membership and exclusion rows, minimal-cover criterion row, componentwise transport, continuation replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5812.1, Definition 5812.2, Definition 5812.3, and Definition 5812.4 seed the finite NameCert packet for private-coordinate minimal-cover witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, regular-language recognition, finite-automaton minimization, Boolean classifier completeness, or enumeration beyond the displayed private-coordinate criterion.

Upgrade path: Obligation closure requires checked carrier admission, cover-ledger replay, private-coordinate witness coverage, exclusion exactness, minimal-cover criterion replay, TasteGate nontriviality, FieldFaithful projection, transport, replay, provenance, and local naming for BEDC.Derived.PrivateCoordinateTriggerUp.

Chapter 4415

A Concrete Naming Certificate for $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet records the finite modulus by which a located real comparison request is read through displayed apartness or equality evidence, dyadic tolerances, explicit Cauchy-modulus schedules, regular rational readback, and the terminal real-name seal. It sits after the comparison surface of chapter 1730, the tail envelope of chapter 1769, the Cauchy-modulus bridge of chapter 5728, the rational readback of chapter 301, and the public real route of chapter 38. The packet names a finite comparison-schedule carrier; it is not trichotomy, quotient real equality, a selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4415.1 (Located real comparison modulus carrier)**.** *A* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, A, D, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{LocatedRealComparison}^{\uparrow}$ *request row for the two located real endpoints and the comparison direction being inspected.*
2. *A is the located evidence row. It records the displayed positive apartness witness when the request separates the endpoints, or the displayed equality-facing refusal row when the request reaches only an overlap tolerance.*
3. *D is the dyadic tolerance schedule. It lists the requested precision, comparison slack, endpoint radii, and finite tolerance refinements consumed by the comparison read.*
4. *B is the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route connecting the comparison request to an explicit Cauchy-modulus schedule before regular rational readback is allowed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected rational tails exposed by B and bounded by D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the comparison-facing read, available only after Q, A, D, B, R have been displayed.*
7. *H records componentwise* hsame *transport for the comparison request, evidence row, dyadic tolerance schedule, bridge route, readback, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from the comparison request through located evidence, dyadic scheduling, Cauchy-modulus bridging, regular rational readback, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, LocatedRealTailEnvelop $\mathsf{CauchyModulusBridge}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, A, D, B, R, E, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, a hidden selector, countable choice, a host comparison oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedRealComparisonModulusUp.LocatedRealComparisonModulusTasteGate`
`single carrier alignment`

Theorem 4415.2 (Located real comparison modulus obligations)**.** *For every accepted* LocatedRealComparisonModu *carrier*

$$M = (Q, A, D, B, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *surface consists exactly of comparison-request admission, located apartness-or-equality evidence, dyadic tolerance scheduling,* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *routing,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer of the comparison schedule must read those rows in the displayed order and receives no trichotomy split, quotient real equality, hidden selector, countable-choice schedule, host comparison oracle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 5813.1. The comparison request is Q, and the only evidence row attached to it is A.

The schedule is then forced through D and B. The dyadic row D records the finite tolerances to be inspected, while the $\mathsf{CauchyModulusBridge}^{\uparrow}$ row B turns those tolerance requests into explicit tail thresholds before any rational readback is exposed.

The terminal read is downstream. The regular rational row R reads only the displayed tails opened by B, and the $\mathsf{Real}^{\uparrow}$ seal E is available only after that readback.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for the excluded host-level or choice-level objects, the listed rows exhaust the local NameCert surface. □

Theorem 4415.3 (Located real comparison modulus nontrichotomy boundary)**.** *Every accepted* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *packet exports a positive schedule for comparison reads without exporting trichotomy. If the evidence row A records positive apartness, a downstream consumer may read that apartness only through Q, D, B, R, E; if A records only an equality-facing overlap tolerance, the consumer receives the displayed tolerance route and no forced left-or-right order verdict.*

Proof. Read the evidence row A together with the comparison request Q. The carrier does not contain a three-way order coordinate, so the two possible reads are positive displayed apartness or finite overlap tolerance.

For the positive branch, the dyadic tolerance row D and bridge row B determine which tails are inspected before R and E can be consumed. The apartness read is therefore a finite schedule read, not a global order split.

For the overlap branch, the same schedule exposes only the inspected tolerance data. Since no trichotomy coordinate or hidden selector appears in $M = (Q, A, D, B, R, E, H, C, P, N)$, the packet refuses any forced left-or-right verdict not displayed by the rows. □

Falsifiable prediction: An accepted $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is refuted if a comparison consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting the $\mathsf{LocatedRealComparison}^{\uparrow}$ request row Q, the evidence row A, the dyadic tolerance schedule D, the $\mathsf{CauchyModulusBridge}^{\uparrow}$ route B, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: LocatedRealComparison, LocatedRealTailEnvelope, CauchyModulusBridge, RegSeqRat, Real: none is bijective with $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ because the packet jointly carries a comparison request, apartness-or-equality evidence, dyadic tolerance scheduling, explicit Cauchy-modulus bridging, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is generated from a LocatedRealComparison request row, located apartness-or-equality evidence, a dyadic tolerance schedule, a CauchyModulusBridge route, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5813.1, Definition 5813.2, and Definition 5813.3 seed the finite comparison-modulus route over LocatedRealComparisonUp, LocatedRealTailEnvelopeUp, CauchyModulusBridgeUp, RegSeqRatUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, host comparison oracles, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, evidence-row exactness, dyadic schedule determinacy, Cauchy-modulus bridge routing, regular rational readback, Real-seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealComparisonModulusUp.

Chapter 4416

A Concrete Naming Certificate for $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$

The $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet realizes the boundary-shadow and observer-expansion route of chapter 9463 as finite cocycle-level NameCert data. It sits after the boundary-shadow route of chapter 3813, the observer-shadow metric of chapter 4154, the Busemann cocycle of chapter 4134, the horosphere-flow ledger of chapter 4051, and the observer-expansion packet of chapter 4167. The chapter names a finite expansion cocycle over displayed boundary and horosphere rows; it is not a completed hyperbolic boundary, quotient geodesic ray space, physical observer dynamics, selected ideal point, or ambient manifold theorem.

Definition 4416.1 (Boundary-shadow expansion cocycle carrier)**.** *A* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, O, B, F, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row recording the visible boundary shadow through which the cocycle is read.*
2. *O is the* $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ *row recording the observer-facing shadow metric comparison for the same boundary read.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row recording the additive Busemann comparison consumed by the expansion read.*
4. *F is the* $\mathsf{HorosphereFlowLedger}^{\uparrow}$ *row recording the horosphere-flow level through which boundary and Busemann rows are replayed.*
5. *E is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *row recording the displayed observer-expansion magnitude or direction attached to S, O, B, F.*
6. *H records componentwise* hsame *transport for boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow ledger, observer expansion, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, and observer-expansion read.*

8. *P is the* Pkg *provenance over* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HorosphereFlowLedger}^{\uparrow}$, HyperbolicObserverExp BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, O, B, F, E, H, C, P, N$. It has no coordinate for completed boundary points, quotient geodesic rays, a hidden expansion selector, physical observer dynamics, selected ideal endpoints, or ambient hyperbolic manifold data.

Theorem 4416.2 (Boundary-shadow expansion cocycle NameCert obligations)**.** *For every accepted* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ *carrier*

$$X = (S, O, B, F, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *surface consists exactly of boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, observer-expansion read, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any accepted expansion read that omits either the boundary-shadow row S or the Busemann cocycle row B is outside the packet.*

Proof. Project the carrier of Definition 5814.1. The boundary-facing rows are S and O, while the cocycle and horosphere-flow rows are B and F.

The expansion row E is downstream from those four rows. It can be read only after the visible boundary shadow, observer-shadow metric, Busemann cocycle, and horosphere-flow ledger have all been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for completed boundary data, quotient geodesic rays, hidden selectors, physical observer dynamics, selected endpoints, or ambient manifold structure, the listed rows exhaust the local NameCert surface. □

Theorem 4416.3 (Boundary-shadow expansion cocycle dependency route)**.** *Every accepted* BoundaryShadowExpan *read factors through*

$\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, HorosphereFlowLed

before a consumer may inspect the expansion cocycle as a local NameCert row. The route is finite and preserves the boundary-shadow row and Busemann cocycle row as separate coordinates.

Proof. Use Definition 5814.2. It places the boundary-shadow row, observer-shadow metric row, Busemann cocycle row, and horosphere-flow ledger before the expansion row.

The cocycle dependency is not reducible to one sibling. The boundary-shadow row supplies the boundary face, the observer-shadow metric supplies the observer-facing comparison, the Busemann row supplies the additive cocycle read, and the horosphere-flow row supplies the level ledger.

Only after those rows are present can E, H, C, P, N expose the expansion cocycle as a local packet. Therefore a consumer cannot collapse the route to a single hyperbolic object or bypass the separate boundary-shadow and Busemann coordinates. □

Falsifiable prediction: Any accepted $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet is refuted if the expansion read omits either the boundary-shadow row S or the Busemann cocycle row B.

Independence witness: hyperbolic_boundary_shadow, hyperbolic_observer_shadow_metric, hyperbolic_busemann_cocycle, horosphere_flow_ledger, hyperbolic_observer_expansion: none

is bijective with $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ because the packet jointly carries boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow level, observer expansion, transport, replay, provenance, and local naming.

The Lean TasteGate route for this packet must provide `Nontrivial BoundaryShadowExpansionCocycleUp` and `FieldFaithful BoundaryShadowExpansionCocycleUp` instances in `lean4/BEDC/Derived/BoundaryShadowE` Those instances must preserve $S, O, B, F, E, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet is generated from HyperbolicBoundaryShadow rows, HyperbolicObserverShadowMetric rows, HyperbolicBusemannCocycle rows, HorosphereFlowLedger rows, HyperbolicObserverExpansion rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5814.1, Definition 5814.2, and Definition 5814.3 seed the finite boundary-shadow expansion cocycle route over boundary, observer-shadow, Busemann, horosphere-flow, expansion, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic boundaries, quotient geodesic ray spaces, physical observer dynamics, selected ideal endpoints, ambient manifold theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow exactness, observer-shadow metric readback, Busemann cocycle separation, horosphere-flow routing, observer-expansion exposure, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.BoundaryShadowExpansionCocycleUp.

The $\mathsf{HellyBraySelection}^{\uparrow}$ hub routes bounded-variation selection through chapter 398, chapter 2069, chapter 301, chapter 126, and chapter 38 before the child files expose the finite selection packet.

Chapter 4417

A Concrete Naming Certificate for $\mathsf{HellyBraySelection}^{\uparrow}$

Following Helly and Bray, the $\mathsf{HellyBraySelection}^{\uparrow}$ packet records the finite selection surface by which bounded-variation source data are read through Jordan signed-variation rows, finite stream windows, regular rational readback, and terminal real seals before a downstream selection consumer may use the packet. It sits after the bounded-variation carrier of chapter 398, the Jordan variation decomposition rows of chapter 2069, the regular rational readback route of chapter 301, the finite observation windows of chapter 126, and the terminal real-name boundary of chapter 38. Helly–Bray selection also feeds distribution-facing compactness through chapter 186, chapter 92, and chapter 4008 when the bounded-variation read is consumed as a tight probability-family route. The chapter names a finite BEDC selection packet, not host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4417.1 (Helly–Bray selection carrier)**.** *A* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, J, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, carrying the bounded-variation object, finite variation ledger, and endpoint budget exposed to the selection request.*
2. *J is the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *row, displaying the signed-variation split and the positive and negative variation rows read from B.*
3. *S is the family of* $\mathsf{StreamName}^{\uparrow}$ *finite windows opened by the inspected variation rows and by the downstream Real-facing request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, recording the rational comparisons used before any Real seal is visible.*
5. *E is the finite family of* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after B, J, S, R have been displayed.*
6. *T records componentwise* hsame *transport for the bounded-variation source, Jordan rows, finite windows, readbacks, Real seals, continuation, provenance, and local naming.*
7. *C records displayed* Cont *replay from bounded-variation data through Jordan signed-variation rows, finite windows, regular rational readback, Real seals, transport, provenance, and local naming.*

8. *P is the* Pkg *provenance over* $\mathsf{HellyBraySelection}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, J, S, R, E, T, C, P, N$. The carrier has no coordinate for host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4417.2 (Helly–Bray selection NameCert obligations)**.** *For every accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier*

$$H = (B, J, S, R, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded-variation source row, Jordan signed-variation decomposition row, StreamName finite windows, RegSeqRat readback row, Real seal rows, transport, replay, provenance, and local naming;*
2. *variation-source exposure, requiring every selection-facing read to begin with B and then pass through the signed-variation rows J rather than through a host weak-convergence theorem;*
3. *finite-window locality, requiring S to list the exact stream windows opened by the variation rows and the Real-facing request;*
4. *readback ordering, requiring R to consume the displayed windows in S before any row of E is exposed;*
5. *componentwise transport, displayed replay, provenance, and local naming for the same rows through T, C, P, N;*
6. *nonescape, excluding host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Helly–Bray selection obligation is stored outside these rows.

Proof. Project the accepted carrier. The only source coordinate is the bounded-variation row B, and the only signed-variation coordinate is the Jordan row J.

The finite observation surface is then forced by row order. The StreamName windows S are opened from the displayed variation rows, the RegSeqRat readback R reads only those windows, and the Real seals E appear only after that readback has been displayed.

Transport and replay preserve the same route componentwise through T and C. Provenance P and local naming N record that route as the local certificate surface.

Since none of the excluded objects occurs as a carrier coordinate, a consumer cannot add weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient Real completeness to the local NameCert obligations. □

Theorem 4417.3 (Helly–Bray selection finite-window route)**.** *Every Real-facing or variation-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier factors its read through*

$$\mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{JordanVariationDecomposition}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto T, C, P, N$$

Thus the consumer receives bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise transport, continuation replay, provenance, and local naming. The route supplies no host weak convergence, measure completion, quotient function equality, selected subsequence, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier $H = (B, J, S, R, E, T, C, P, N)$. The first projection gives the bounded-variation source row B, and the next projection gives the Jordan signed-variation row J over that source.

The finite-window part is local. The windows S are the only observation rows available to the packet, and R is the only regular rational readback attached to those windows.

The Real-facing boundary is reached only at E. The remaining rows T, C, P, N transport, replay, source, and name the same finite route; they do not add a new selection principle.

Because the carrier omits host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient Real completeness, every accepted consumer read is exhausted by the displayed finite-window route. □

Theorem 4417.4 (Helly–Bray distribution forward link)**.** *Every* $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, *or* $\mathsf{ProkhorovTightProbabi}$ *consumer that cites an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier must first read the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *signed-variation row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows of Definition 5815.1. The downstream route to chapter 186, chapter 92, and chapter 4008 therefore receives only bounded-variation source data, Jordan variation data, displayed windows, rational readback, Real seals, componentwise transport, replay, provenance, and local naming. It receives no host weak convergence theorem, measure completion, quotient equality, selected subsequence, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $H = (B, J, S, R, E, T, C, P, N)$. The only distribution-facing source row is B, and the only signed-measure decomposition row available to the packet is J.

Use the finite-window route of Definition 5815.3. It forces every Real-facing and variation-facing read through S, R, E before the transport, replay, provenance, and local naming rows can be consumed.

Now attach a downstream distribution, measure, or tight-probability request. Since those consumers cite the Helly–Bray packet only through the displayed route, the request reaches chapter 186, chapter 92, or chapter 4008 after $B, J, S, R, E, T, C, P, N$ have already been displayed.

The excluded objects are not carrier coordinates. Thus the forward link cannot export host weak convergence, measure completion, quotient equality, selected subsequences, countable choice, or ambient Real completeness to any distribution-facing consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5815.1, Definition 5815.2, Definition 5815.3, and Definition 5815.4 seed the finite Helly–Bray selection route over bounded-variation data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, transport, replay, provenance, local naming, and distribution-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, variation-source exposure, finite-window locality, readback ordering, transport, replay, provenance, local naming, and finite-window routing for BEDC.Derived.HellyBraySelectionUp.

Constructive story: A $\mathsf{HellyBraySelection}^{\uparrow}$ packet is generated from bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

The Helly–Bray route is a distribution-facing read of the finite selection surface already named by chapter 1732; its bounded real sequence and compactness rows are supplied through chapter 1415 before the distribution consumer is allowed to inspect the signed-variation packet.

Theorem 4417.5 (Helly–Bray Helly-selection dependency route)**.** *Every* $\mathsf{Distribution}^{\uparrow}$ *or compactness-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *packet must first expose the finite* $\mathsf{HellySelection}^{\uparrow}$ *selection surface of chapter 1732 together with the bounded real sequence route of chapter 1415. In carrier notation, the read passes through the bounded-variation source row, Jordan signed-variation row, finite window rows, regular rational readback, terminal Real seals, componentwise transport, replay, provenance, and local naming rows before the distribution-facing route of Definition 5815.4 is public. It is therefore not a free weak-convergence theorem, measure-completion theorem, quotient-function equality, choice-selected subsequence, or ambient compactness principle.*

Proof. Start with the carrier of Definition 5815.1. Its only sequence-facing data are the bounded-variation row, Jordan signed-variation row, finite windows, regular rational readback, and terminal Real seals.

Read those rows through the finite-window route of Definition 5815.3. The same bounded source discipline is the one exported by the $\mathsf{HellySelection}^{\uparrow}$ packet, and the bounded real sequence route supplies the finite window and bound rows before any compactness-facing consumer can inspect them.

Finally attach the distribution forward link. Since Definition 5815.4 exposes distribution consumers only after the Helly–Bray carrier rows have been displayed, the downstream route receives the Helly-selection and bounded-sequence surfaces as dependencies rather than as hidden host compactness or choice principles. □

Chapter 4418

A Concrete Naming Certificate for DiniFiniteMinimumBudget$^{\uparrow}$

Following Dini's theorem and Bishop–Bridges constructive compactness, the DiniFiniteMinimumBudget$^{\uparrow}$ packet records the finite extraction row that turns a monotone compact-window Dini certificate into one displayed tolerance budget. It consumes the CompactMetric$^{\uparrow}$ source, monotone ContinuousMap$^{\uparrow}$ family rows, the DiniTheorem$^{\uparrow}$ compact-window route, UniformModulus$^{\uparrow}$ handoff data, DyadicRatCore$^{\uparrow}$ tolerance cells, the terminal Real$^{\uparrow}$ seal, BHist history rows, hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data. The packet names only the finite minimum-budget route; it is not host supremum selection, a selected minimum outside the carrier, open-cover compactness, quotient equality, or ambient Real$^{\uparrow}$ completeness.

The dependency surface is horizontal: chapter 1387 supplies the compact-window Dini route, chapter 129 supplies the inspected compact carrier, chapter 130 supplies the monotone continuous-family rows, and chapter 369 receives the extracted budget. Thus the minimum-budget row is a downstream finite extraction from those sibling carriers, not an isolated tolerance selector.

Definition 4418.1 (Dini finite-minimum budget carrier)**.** *A* DiniFiniteMinimumBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, D, U, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row naming the finite compact-metric windows inspected by the extraction.*
2. *F is the monotone* ContinuousMap$^{\uparrow}$ *family row, including the displayed pointwise comparison ledger used by the Dini route.*
3. *D is the* DiniTheorem$^{\uparrow}$ *row that supplies the monotone uniform-window certificate over K and F.*
4. *U is the* UniformModulus$^{\uparrow}$ *handoff row consumed by uniform-limit and compact-uniform-modulus readers.*
5. *Q is the* DyadicRatCore$^{\uparrow}$ *tolerance row, listing the candidate dyadic budgets and their finite comparison cells.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row reached by every displayed tolerance and value comparison.*
7. *H records componentwise* hsame *transport for $K, F, D, U, Q, E, C, P, N$.*

8. *C records displayed* Cont *replay from compact windows and monotone family rows through the Dini row, the finite dyadic budget comparisons, the uniform-modulus handoff, and the Real seal.*
9. *P is the* Pkg *provenance over* DiniFiniteMinimumBudget$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DiniTheorem$^{\uparrow}$, UniformModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for an ambient supremum, an externally selected minimum, open-cover compactness, quotient equality of real names, countable choice, or host Real completeness.

Lean4 ✓ `BEDC.Derived.DiniFiniteMinimumBudgetUp.DiniFiniteMinimumBudgetTasteGate single carrier alignment`

Theorem 4418.2 (Dini compact finite-minimum budget)**.** *For every accepted* DiniFiniteMinimumBudget$^{\uparrow}$ *carrier*

$$B = (K, F, D, U, Q, E, H, C, P, N),$$

the finite probe cover displayed by K, F, D and the dyadic tolerance cells displayed by Q determine one displayed minimum tolerance budget before the uniform-modulus handoff U is exported. The extraction route is

$$K, F, D, Q, E, H, C, P, N \longrightarrow U.$$

Thus a UniformLimit$^{\uparrow}$ *or compact-uniform-modulus consumer receives a finite* DyadicRatCore$^{\uparrow}$ *budget sealed by* Real$^{\uparrow}$ *and transported by* hsame *and* Cont*, without host supremum, selected minimum outside the carrier, open-cover compactness, quotient equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the accepted packet. The compact source row K, monotone family row F, and Dini row D are the only rows that can name the finite probe cover for the tolerance request.

The dyadic row Q lists the candidate tolerance cells. Since the carrier is finite, the budget comparison is a displayed finite comparison among the cells in Q, with every real-valued read sealed through E before the handoff row is exposed.

The route to U is then replayed by C and transported componentwise by H. The provenance and naming rows P, N record the same finite route as the local certificate surface.

No excluded object is a coordinate of B. Consequently the exported budget is the displayed finite minimum-budget row inside the carrier, not an ambient supremum, external selector, open-cover argument, quotient equality, choice schedule, or completeness argument. □

Falsifiable prediction: Every accepted DiniFiniteMinimumBudget$^{\uparrow}$ consumer that exports a UniformModulus$^{\uparrow}$ handoff must first expose the compact-metric windows, monotone continuous-family rows, DiniTheorem route, finite DyadicRatCore$^{\uparrow}$ budget cells, Real$^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: dini-theorem, compactmetric, continuousmap, uniformmodulus, dyadicratcore, real: DiniFiniteMinimumBudget$^{\uparrow}$ is not bijective to any listed sibling because it binds the finite Dini probe cover to one displayed dyadic minimum-budget handoff before uniform-limit or compact-uniform-modulus consumers may read the result.

Closure status for NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, seed)

Scope closed: Definition 5816.1 and Definition 5816.2 seed the finite minimum-budget extraction route from compact Dini data to a uniform-modulus-facing handoff.

Formal verification: FormalStatus(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host supremum selection, selected minima outside the carrier, open-cover compactness, quotient equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite probe-cover exposure, dyadic minimum-budget extraction, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniFiniteMinimumBudgetUp.

Constructive story: A DiniFiniteMinimumBudget$^{\uparrow}$ packet is generated from compact-metric source rows, monotone ContinuousMap family rows, a DiniTheorem compact-window route, UniformModulus handoff rows, DyadicRatCore tolerance cells, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4419

A Concrete Naming Certificate for $\mathsf{FiniteCauchyFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet records the finite directed-tail surface used when a completion consumer asks for Cauchy-filter evidence before reading a regular rational name or a terminal real-name seal. It sits beside the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite filter basis for tail requests; it is not a quotient filter, a selected limit, countable choice, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4419.1 (Finite Cauchy filter carrier)**.** *A* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (W, T, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the filter request.*
2. T *is the directed-tail request row, naming the finite family of later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii and comparison budgets used by the directed tails.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and tolerance ledger.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, T, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the stream windows, tail requests, dyadic ledgers, regular readback, and real seal.*
7. C *records displayed* Cont *replay of the same finite filter route.*
8. P *records* Pkg *provenance over* $\mathsf{FiniteCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, T, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.FiniteCauchyFilterUp.FiniteCauchyFilterTasteGate single carrier alignment`

Theorem 4419.2 (Finite Cauchy filter NameCert obligations)**.** *For the carrier of Definition 5817.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail request visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-ledger preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal access, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $F = (W, T, D, R, E, H, C, P, N)$. The rows W, T, D expose the finite source windows, directed tail requests, and dyadic tolerance budgets before any regular-rational or real-facing read is admitted.

The readback row R is then determined by the displayed windows and tolerance ledger. Since the carrier stores no second regular-rational coordinate, every $\mathsf{RegSeqRat}^{\uparrow}$ consumer reads the same finite route.

The seal row E is downstream of W, T, D, R. The transport row H, continuation row C, package provenance row P, and local naming row N preserve exactly that route and provide no coordinate for quotient filters, selected limits, countable choice, host stream equality, host real equality, or ambient completeness. □

Theorem 4419.3 (Finite Cauchy filter Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier factors through the finite route*

$$W, T, D, R, E, H, C, P, N.$$

In particular, the consumer must first read $\mathsf{StreamName}^{\uparrow}$ *windows, directed tail requests,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Start with the carrier definition. The only real-facing row is E, and it is displayed after the stream windows, directed-tail row, dyadic ledger, and regular readback row.

Apply Definition 5817.2. The local NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Thus any Real-facing consumer receives the finite packet $W, T, D, R, E, H, C, P, N$ and no quotient-filter, selected-limit, countable-choice, host-equality, or ambient-completeness substitute. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet is generated from finite StreamName windows, directed tail requests, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 5817.1, Definition 5817.2, and Definition 5817.3 specify the finite directed-tail filter carrier and its Real-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filter construction, selected limits, countable choice, host stream equality, host real equality, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for directed-tail visibility, tolerance-ledger preservation, readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 4420

A Concrete Naming Certificate for DNAWindowSixTranslationBoundary$^{\uparrow}$

The DNAWindowSixTranslationBoundary$^{\uparrow}$ packet realizes the local translation-boundary branch of subsection 9462.28.21 as finite NameCert data. It consumes the codon-window and stop-tile boundary analysis in the source vision, the curated code-boundary ledger of **??**, and the trigger-threshold surface of chapter 4217. The packet names only a finite window-six translation-boundary carrier; biological translation realization, universality, protein function, and evolutionary mechanism remain outside the BEDC kernel packet.

Definition 4420.1 (DNA window-six translation-boundary carrier)**.** *A* DNAWindowSixTranslationBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, S, T, L, R, V, H, C, P, N)$$

with the following displayed rows:

1. *Q is the codon Q_6 window row recording the six-bit coordinate readback for the inspected codon window.*
2. *S is the stop-tile boundary row recording the local halt boundary and continuation-corner split from the source vision.*
3. *T is the translation-classifier row supplied by external biological bridge data.*
4. *L is the curated code-boundary ledger row inherited from* BioRealityQSixLeaveOneCodeBoundaryLedger$^{\uparrow}$*.*
5. *R is the release-factor or release-mechanism row that records which external recognition boundary is being tested.*
6. *V is the finite validation row recording which observed table, organismal code row, or assay class is used for the test.*
7. *H records componentwise* hsame *transport for the window, tile, classifier, ledger, release, and validation rows.*
8. *C records displayed* Cont *replay of the boundary read through those rows.*
9. *P records* Pkg *provenance over the source vision, the bio-reality ledger sibling,* DNAWindowSixTriggerThreshold$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and local naming rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for biological necessity, global identification of the genetic code with the window-six fold, protein-folding realization, universal stop assignment, hidden BEDC channel tokens, or untested mechanism.

Theorem 4420.2 (DNA window-six translation-boundary obligations)**.** *For the carrier of Definition 5818.1, the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *surface consists exactly of codon-window exposure, stop-tile boundary visibility, external translation-classifier disclosure, curated code-ledger preservation, release-boundary test exposure, finite validation-row visibility, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $B = (Q, S, T, L, R, V, H, C, P, N)$. The rows Q, S, T expose the finite codon window, the local translation boundary, and the external classifier before any biological reading is admitted.

The ledger and release rows L, R keep the packet anchored to the bio-reality boundary sibling and to a displayed recognition test. The validation row V records the observed table or assay class being tested, so the packet has a falsifiable contact surface rather than a kernel claim of biological necessity.

The structural rows H, C, P, N transport, replay, source, and name exactly the displayed boundary route. Since no further coordinate is present, the carrier cannot export global window-six identity, universal stop assignment, protein-folding realization, hidden channel tokens, or untested mechanism. □

Theorem 4420.3 (DNA window-six translation-boundary sibling handoff)**.** *Every accepted* DNAWindowSixTranslat *read that reaches a translation-boundary consumer must first expose the source-vision stop-tile row of subsection 9462.28.21, the curated code-boundary ledger row of* **??**, *and the finite trigger-threshold row of chapter 4217. The handoff is therefore a concrete finite boundary-tile NameCert route, not a narrative-only direction.*

Proof. Use Definition 5818.1. The source-vision row is carried by S, the code-boundary ledger is carried by L, and the trigger-facing finite boundary read is recorded in the same package provenance P.

Now apply Definition 5818.2. The local NameCert requires those rows before the translation-boundary consumer can read N. Hence the consumer sees the source vision, the bio-reality ledger sibling, and the trigger-threshold sibling as displayed packet data rather than as detached prose. □

Falsifiable prediction: An accepted $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet must expose a finite validation row naming the observed code table, organismal code row, or release-factor assay class before it can export a translation-boundary reading.

Independence witness: bioreality-q-six-leave-one-code-boundary-ledger, dna-window-six-trigger-threshold, synonymous-transition: the $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is not bijective to any listed sibling because it jointly carries codon-window, stop-tile, external translation-classifier, curated code-ledger, release-boundary, validation, transport, replay, provenance, and local naming rows.

The Lean follow-up must provide $\mathsf{Nontrivial}\ \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{DNAWindowSi}$ TasteGate instances before this packet can move beyond seed closure.

Closure status for $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is generated from codon Q-six window rows, stop-tile boundary rows, external translation-classifier rows, curated code-boundary ledgers, release-boundary tests, finite validation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, seed)

Scope closed: Definition 5818.1, Definition 5818.2, and Definition 5818.3 specify the finite translation-boundary carrier and sibling route.

Formal verification: FormalStatus(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim biological-code necessity, global window-six identity, universal stop assignment, protein-folding realization, hidden BEDC channel tokens, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding, TasteGate nontriviality, field faithfulness, validation-row exactness, sibling-route preservation, transport, replay, provenance, and local naming.

Chapter 4421

A Concrete Naming Certificate for $\mathsf{RegulatedConvergence}^{\uparrow}$

Following Bishop and Bridges on regulated functions and uniform convergence, the $\mathsf{RegulatedConvergence}^{\uparrow}$ packet records the finite route by which a displayed sequence of regulated real functions converges uniformly to a regulated endpoint. It sits after the regulated-function carrier of chapter 1906, the regulated-integral consumer boundary of chapter 1557, the uniform-convergence ledger of chapter 3417, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite convergence-and-handoff surface; it does not import measure completion, quotient equality of functions, selected host limits, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4421.1 (Regulated convergence carrier)**.** *A* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

with the following displayed rows:

1. *F is the source row naming the regulated-function family through* $\mathsf{RegulatedFunction}^{\uparrow}$ *data, including the displayed interval, step-window, endpoint, and oscillation ledgers available to each inspected member.*
2. *U is the* $\mathsf{UniformConvergence}^{\uparrow}$ *tail row, recording one shared tolerance schedule for the whole regulated family rather than pointwise schedules chosen separately at each argument.*
3. *W is the finite window row exposing exactly the function indices, domain windows, and endpoint reads used by the shared tail schedule.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the real-valued observations in those windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after F, U, W, R have been displayed.*
6. *I is the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *handoff row; it records that integral-facing consumers may read the regulated endpoint only through the same finite regulated-function, uniform-tail, window, readback, and Real-seal route.*
7. *H records componentwise* hsame *transport for F, U, W, R, E, I and for the structural rows.*
8. *C records displayed* Cont *replay for regulated-function reads, uniform-tail requests, finite window reads, regular rational readback, Real-seal requests, and integral handoff requests.*

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedConvergence}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, U, W, R, E, I, H, C, P, N$. It has no coordinate for a host function quotient, selected limiting function, measure completion, pointwise-only convergence, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceTasteGate single carrier alignment`

Theorem 4421.2 (Regulated convergence NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier*

$$G = (F, U, W, R, E, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the regulated-function family row F, uniform-convergence tail row U, finite window row W, regular rational readback row R, terminal Real seal E, regulated-integral handoff row I, componentwise transport row H, displayed replay row C, package provenance row P, and local naming row N. Every endpoint-facing or integral-facing consumer must read these rows in the displayed route and cannot replace them by pointwise convergence, a selected host limit, quotient equality of functions, measure completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 5819.1. The only analytic rows are the regulated-function family F, the shared uniform tail ledger U, the finite window row W, the regular rational readback R, the terminal Real seal E, and the integral handoff I.

The convergence route is uniform. A consumer must read the single tail schedule U before it can inspect the windows W and the regular readback R, so pointwise-only schedules and externally selected host limits are not part of the packet.

The endpoint and integral rows are downstream. The seal E is exposed only after F, U, W, R, and the integral-facing row I reads that same route rather than a separate measure-completion or function-quotient object.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded row occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 4421.3 (Regulated convergence integral handoff)**.** *Let*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

be an accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier. Every* $\mathsf{RegulatedIntegral}^{\uparrow}$ *consumer read of the limiting regulated function factors through the finite route*

$$\mathsf{RegulatedFunction}^{\uparrow}(F),\ \mathsf{UniformConvergence}^{\uparrow}(U),\ W,\ \mathsf{RegSeqRat}^{\uparrow}(R),\ \mathsf{Real}^{\uparrow}(E),\ \mathsf{RegulatedIntegral}^{\uparrow}(I).$$

Thus the handoff to integration uses the same regulated-family rows, shared uniform-tail ledger, finite windows, regular rational readback, and Real seal as the convergence certificate. It supplies no measure completion, quotient function equality, selected limiting function, open-cover compactness, or ambient real-completeness principle.

Proof. Start with an integral-facing request. By the carrier definition, the only integral row is I, and its replay route in C passes through the same regulated-family and convergence rows used by endpoint-facing consumers.

Read the regulated source through F and the uniform tail through U. The finite windows W then expose the inspected function indices and domain reads, and the regular rational row R records the real-valued observations visible at those windows.

Only after this route is displayed can the terminal seal E be consumed and handed to I. Componentwise transport in H and replay in C preserve the same rows, while P and N record their provenance and local naming.

The carrier has no coordinate for measure completion, quotient function equality, selected limits, open-cover compactness, or ambient real completeness. Therefore every regulated-integral handoff is confined to the finite route displayed in the statement. □

Falsifiable prediction: An accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ consumer that reaches a $\mathsf{RegulatedIntegral}^{\uparrow}$ handoff without first reading $F, U, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: regulated-function, regulated-integral, uniform-convergence, regseqrat, real: none is bijective to $\mathsf{RegulatedConvergence}^{\uparrow}$ because this packet jointly binds a regulated-function family, a shared uniform tail ledger, finite windows, regular rational readback, terminal Real seal, integral handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedConvergence}^{\uparrow}$ packet is generated from a regulated-function family row, UniformConvergence tail row, finite window row, RegSeqRat readback, terminal Real seal, RegulatedIntegral handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5819.1, Definition 5819.2, and Definition 5819.3 seed the finite regulated-convergence route over regulated functions, uniform convergence, regular rational readback, Real seals, and regulated-integral consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, quotient function equality, selected host limits, pointwise-only convergence, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated-family visibility, uniform-tail exactness, finite window readback, Real-seal nonescape, regulated-integral handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedConvergenceUp.

Chapter 4422

A Concrete Naming Certificate for $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$

Following Cantor and Bishop–Bridges, the $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet records the finite located nested-interval route by which displayed interval windows become a regular rational Cauchy name and then a terminal real seal. It refines the nested dyadic Cauchy route of chapter 1811, reads endpoint and radius rows through chapter 291, schedules finite observations through chapter 126, hands the scheduled rows to chapter 301, and reaches only the seal boundary of chapter 38. The chapter isolates the located interval-to-name handoff; it does not claim a host intersection point, quotient stream equality, selected limit, countable choice, or ambient completeness.

Definition 4422.1 (Located nested-interval limit carrier)**.** *A* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite nested located-interval window. It records the inspected interval chain, endpoint rows, located containment witnesses, and the finite separation reads available at each displayed stage.*
2. *D is the dyadic shrink ledger. It records the dyadic endpoint comparisons, width bounds, and tolerance requests read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It names exactly the finite endpoint, midpoint, and shrink-ledger observations that may be queried before regular rational readback.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the scheduled located-interval observations and the dyadic shrink ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after I, D, S, R have been displayed.*
6. *H records componentwise* hsame *transport for interval windows, shrink ledgers, stream schedules, regular rational handoffs, real seals, replay rows, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located nested-interval request through I, D, S, R, E and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$*,* $\mathsf{NestedDyadicCauchy}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, R, E, H, C, P, N$. It has no coordinate for completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.LocatedNestedIntervalLimitUp.LocatedNestedIntervalLimitTasteGate single carrier alignment`

Theorem 4422.2 (Located nested-interval limit NameCert obligations)**.** *For every accepted* LocatedNestedIntervalL *carrier*

$$L = (I, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite located interval window, dyadic shrink ledger, StreamName schedule, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming row;*
2. *located nesting exposure, requiring every interval read to be one of the displayed rows of I together with its displayed containment and located separation witnesses;*
3. *dyadic shrink exactness, requiring every tolerance request to be discharged by a visible width or endpoint comparison stored in D and read through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
4. *schedule compatibility, requiring S to expose only the finite interval, endpoint, midpoint, and ledger observations used by D and R;*
5. *RegSeqRat handoff exactness, requiring R to be formed only after the interval window, shrink ledger, and schedule rows have been projected;*
6. *Real-seal nonescape, requiring E to be consumed only after I, D, S, R and the structural rows H, C, P, N have been displayed.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5820.1. The projection exposes one finite located nested-interval window, one dyadic shrink ledger, one StreamName schedule, one RegSeqRat handoff, one Real seal, and the transport, replay, provenance, and naming rows.

Located nesting exposure is forced by I. A consumer may inspect only interval rows already present in the finite window, and each such row carries its displayed containment and located separation witnesses.

Dyadic shrink exactness is forced by D. Each tolerance request is answered by a displayed dyadic width or endpoint comparison, so no host intersection or selected limit is needed to choose a tail.

The schedule and handoff rows are downstream. The row S records the finite observations that may be opened, and R repacks exactly those observations under the shrink ledger as a regular rational Cauchy surface.

Finally E, H, C, P, N close the route. The Real seal is reachable only after the regular handoff has been displayed, while the structural rows only transport, replay, source, and name the same finite data. Therefore no completed intersection, quotient stream equality, host real equality, countable choice, ambient completeness, Lean verification, or bridge-checking coordinate is present. □

Theorem 4422.3 (Located nested-interval RegSeqRat handoff)**.** *Let* $L = (I, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read exported by* L *factors through the displayed route*

$$I \longmapsto D \longmapsto S \longmapsto R \longmapsto H, C, P, N.$$

The route reads a finite located nested-interval window, a dyadic shrink ledger, and the scheduled endpoint observations before it exports the regular rational Cauchy row. The terminal $\mathsf{Real}^{\uparrow}$ *seal* E *is available only after this handoff has been displayed.*

Proof. Start with the displayed located interval window I. Its rows give the only endpoint, midpoint, containment, and located separation data available to a regular rational consumer.

Use the dyadic shrink ledger D to answer the displayed tolerance request. The chosen comparison is part of the same finite packet and is read through $\mathsf{DyadicRatCore}^{\uparrow}$, so there is no external modulus, choice-selected tail, or host interval intersection.

The schedule row S then fixes which interval observations are opened. The handoff row R is obtained by reading those scheduled observations under the shrink discipline and repacking them as the $\mathsf{RegSeqRat}^{\uparrow}$ surface.

The rows H, C, P, N transport, replay, source, and name that handoff, and the seal row E remains downstream of it. Since the carrier has no quotient-stream, host-real, selected-limit, choice, or completeness coordinate, every regular rational read factors through the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5820.1, Definition 5820.2, and Definition 5820.3 seed the finite located nested-interval route from displayed interval windows and dyadic shrink ledgers to a RegSeqRat handoff and terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located nesting exposure, dyadic shrink exactness, schedule compatibility, RegSeqRat handoff exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedNestedIntervalLimitUp.

Constructive story: A $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet is generated from a finite nested located-interval window, a dyadic shrink ledger, a StreamName schedule, a RegSeqRat handoff row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4423

A Concrete Naming Certificate for $\mathsf{CauchyTailRequest}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailRequest}^{\uparrow}$ packet isolates the finite directed-tail request that a Cauchy or completion consumer must expose before it can read a regular rational name or a terminal real-name seal. It sits beside the finite window carrier of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal seal of chapter 38, and the finite filter surface of chapter 5817. The packet names the request row consumed by those sibling routes; it is not a quotient filter, a selected limit, a countable-choice schedule, host stream equality, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4423.1 (Cauchy tail request carrier)**.** *A* $\mathsf{CauchyTailRequest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, Q, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the request.*
2. Q *is the directed tail request row, naming the finite later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the directed tail request.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and tolerances.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, Q, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the window, request, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay of the same finite directed-tail route.*
8. P *records* Pkg *provenance over* $\mathsf{CauchyTailRequest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteCauchyFilter}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, Q, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 (definition) `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestUp`

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestTasteGate single carrier alignment`

Theorem 4423.2 (Cauchy tail request NameCert obligations)**.** *For the carrier of Definition 5821.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *consumer that reads a directed-tail row receives it through this displayed request surface.*

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestCarrier namecert obligations`

Proof. Project the accepted packet $T = (W, Q, D, R, E, H, C, P, N)$. The rows W, Q, D expose the finite windows, directed tail request, and dyadic tolerance ledger before any regular-rational or real-facing read is admitted.

The readback row R is downstream of those displayed rows. It therefore records only the $\mathsf{RegSeqRat}^{\uparrow}$ observation generated from the named windows and tolerance ledger, not an external sequence or choice schedule.

The seal row E is terminal for the request route. Transport through H and replay through C preserve exactly the displayed route, while P and N record provenance and local naming.

Finally compare the route with Definition 5817.2. The finite filter packet consumes its directed-tail row as a request coordinate, and the rows above are precisely the admitted request surface available to that consumer. Since no remaining coordinate exists, quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, and bridge checking are outside the chapter claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyTailRequest}^{\uparrow}$ packet is generated from finite StreamName windows, a directed tail request row, DyadicRatCore tolerance data, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, seed)

Scope closed: Definition 5821.1 and Definition 5821.2 specify the finite directed-tail request carrier and its filter-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for tail visibility, tolerance preservation, readback, seal routing, transport, replay, provenance, and local naming.

Chapter 4424

A Concrete Naming Certificate for $\mathsf{QuotientLeakageMarkov}^{\uparrow}$

The $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet realizes the quotient leakage transition matrix of Definition 9462.1376 as finite NameCert data. It consumes the DNA window-six boundary-tile source of subsection 9462.28.21, the codon-window carrier of chapter 2234, the boundary-tile packet of chapter 3393, the six-boundary coverage route of chapter 3470, and the translation-boundary packet of chapter 5818. The packet names a finite six-state Markov ledger only; it is not a biological stochastic model, empirical evolutionary claim, host quotient-codon semantics, or unrestricted state-space enumeration.

Definition 4424.1 (QuotientLeakageMarkov carrier)**.** *A* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, T, O, E, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the six-state orbit row listing* AGR*,* Anchor_6*,* $\mathrm{StopStart}_6$*,* UUR*,* CUR*, and* CUY*.*
2. *T is the transient transition-matrix row of Definition 9462.1376, with entries read as exact rational finite counts.*
3. *O is the outside-probability row recording* $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ *for the six displayed states.*
4. *E is the expected-exit ledger row recording the rational exit values of Definition 9462.1380.*
5. *W is the finite window-six source row tying the orbit states to the codon-window and boundary-tile siblings.*
6. *H records componentwise* hsame *transport for the state, transition, outside-probability, exit-ledger, source, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite Markov read through* S, T, O, E, W, H, P, N*.*
8. *P is the* Pkg *provenance over* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$*,* $\mathsf{CodonSixBitWindow}^{\uparrow}$*,* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$*, the source vision of subsection 9462.28.21,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, O, E, W, H, C, P, N$*. It has no coordinate for biological transition realization, hidden codon quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process.*

Theorem 4424.2 (QuotientLeakageMarkov NameCert obligations)**.** *For the carrier of Definition 5822.1, the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *surface consists exactly of six-state exposure, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, window-six sibling routing, componentwise transport, displayed replay, provenance, and local naming. Every accepted read preserves the outside probabilities displayed in Definition 9462.1378.*

Proof. Project the accepted carrier $Q = (S, T, O, E, W, H, C, P, N)$. The state row S fixes the six orbit states, and the transition row T is the only source of one-bit flip probabilities.

The outside-probability row O is read from the outside column of T and matches the finite rational list in Definition 9462.1378. Thus an accepted packet cannot alter leakage rates without changing a displayed row.

The expected-exit row E is downstream of the same finite matrix and records the rational ledger of Definition 9462.1380. The source row W ties these finite state rows back to the codon-window, boundary-tile, coverage, and translation-boundary siblings.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since no other coordinate is present, the NameCert surface cannot export biological mechanism, hidden quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process. □

Theorem 4424.3 (QuotientLeakageMarkov sibling dependency route)**.** *Every accepted* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *consumer first reads the finite codon-window source, boundary-tile classifier, six-boundary coverage route, and translation-boundary packet before it consumes the transition row* T*, outside row* O*, or expected-exit row* E*. The dependency route is*

$$\mathsf{CodonSixBitWindow}^{\uparrow}, \mathsf{DnaWindowSixBoundaryTile}^{\uparrow}, \mathsf{SixBoundaryTileCoverage}^{\uparrow}, \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$$

Proof. Use the provenance row P and source row W of Definition 5822.1. These rows name the finite codon-window and boundary-tile sources before the Markov matrix is admitted.

The transition row T then reads the six-state quotient matrix of Definition 9462.1376. The outside-probability row O and expected-exit row E are downstream ledger rows, so they cannot be consumed before the sibling source route has been displayed.

Transport and replay by H and C preserve this order, while N names it locally. Hence the consumer receives a concrete dependency route rather than a detached numerical table. □

Falsifiable prediction: Every accepted $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ read preserves the displayed outside probabilities $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ for AGR, Anchor_6, StopStart_6, UUR, CUR, and CUY.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, six-boundary-tile-coverage, dna-window-six-translation-boundary: $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries six orbit states, a rational transition matrix, outside probabilities, expected-exit ledgers, window-source routing, transport, replay, provenance, and local naming.

The Lean follow-up must provide explicit $\mathsf{Nontrivial}\ \mathsf{QuotientLeakageMarkov}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{QuotientLeakageM}$ TasteGate instances preserving $S, T, O, E, W, H, C, P, N$ as distinct displayed rows.

Closure status for $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$**.**

Constructive story: A $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet is generated from six orbit states, a rational transition matrix, outside-probability rows, expected-exit ledgers, a finite window-six source row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5822.1, Definition 5822.2, and Definition 5822.3 specify the finite quotient-leakage Markov carrier and sibling dependency route.

Formal verification: FormalStatus(NameCert$_{\text{QuotientLeakageMarkov}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological transition realization, empirical evolutionary mechanism, hidden codon quotient semantics, unbounded simulation, completed stochastic processes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, sibling routing, transport, replay, provenance, and local naming for BEDC.Derived.QuotientLeakage

Chapter 4425

A Concrete Naming Certificate for $\mathsf{CauchyCriterionUniform}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet records the uniform Cauchy criterion route used when a Real and Completion consumer asks for one displayed threshold discipline across a finite family of stream windows. It sits beside the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Cauchy hub of chapter 3413. The packet names a uniform criterion surface; it is not a quotient Cauchy class, selected limit, host equality theorem, countable-choice schedule, trichotomy principle, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4425.1 (Cauchy criterion uniform carrier)**.** *A* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *S records the* $\mathsf{StreamName}^{\uparrow}$ *window family inspected by the uniform criterion request.*
2. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the dyadic radii and comparison budgets shared by the family.*
3. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and dyadic tolerances.*
4. *E records the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, available only after S, D, R, M have been exposed.*
5. *M records the uniform modulus row, naming the common threshold discipline for all displayed windows in the family.*
6. *H records componentwise* hsame *transport for the stream windows, dyadic tolerances, regular readback, Real seal, uniform modulus, replay route, provenance, and local name.*
7. *C records displayed* Cont *replay of the same finite route.*
8. *P records* Pkg *provenance over* $\mathsf{CauchyCriterionUniform}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N records the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, R, E, M, H, C, P, N$. It has no coordinate for a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUniformUp.CauchyCriterionUniformTasteGate single carrier alignment`

Theorem 4425.2 (Cauchy criterion uniform NameCert obligations)**.** *For the carrier of Definition 5823.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the finite packet* $U = (S, D, R, E, M, H, C, P, N)$*;*
2. *uniform window exposure through the* $\mathsf{StreamName}^{\uparrow}$ *row* S *and the common modulus row* M*;*
3. *dyadic tolerance exactness through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*;*
4. *regular readback through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*;*
5. *ledger non-escape through* H, C, P, N*.*

Proof. Project the accepted packet $U = (S, D, R, E, M, H, C, P, N)$. Carrier admission is exactly the admission of this finite tuple, so a consumer can inspect only the displayed coordinates.

The uniform window obligation reads S together with the common threshold discipline M. The dyadic tolerance obligation reads D, and the regular readback obligation reads R before any terminal seal row E is available.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since the carrier has no remaining coordinate, the ledger cannot export a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient completeness claim. □

Theorem 4425.3 (Cauchy criterion uniform Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier factors through the finite route*

$$S, D, R, M \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer must read stream windows, dyadic tolerances, regular readback, and the uniform modulus before the terminal real seal is exposed. The route exports no quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 5823.1. The only terminal real-facing coordinate is E, and the definition places it downstream of the finite stream-window, dyadic-tolerance, regular-readback, and uniform-modulus rows.

Apply Definition 5823.2. The NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Therefore any Real-facing consumer receives exactly the finite packet route displayed above. No quotient Cauchy class, selected limit, host equality, countable-choice schedule, trichotomy row, or ambient-completeness coordinate supplies another path to the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet is generated from finite StreamName windows, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, a uniform modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, seed)

Scope closed: Definition 5823.1, Definition 5823.2, and Definition 5823.3 specify the finite uniform Cauchy criterion carrier and its Real-facing seal route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy classes, selected limits, host equality, countable choice, trichotomy, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for uniform window exposure, dyadic tolerance exactness, regular readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 4426

A Concrete Naming Certificate for CauchyProductCompletionProjection$^{\uparrow}$

Following Bishop and Bridges on constructive products of Cauchy completions and Kelley on product uniformities, the CauchyProductCompletionProjection$^{\uparrow}$ packet records the coordinate projection surface for an accepted product-completion read. It sits downstream of the product packet of chapter 3797 and the completion-product route of chapter 1540, while every coordinate read still passes through the StreamName$^{\uparrow}$ windows of chapter 126, the RegSeqRat$^{\uparrow}$ readbacks of chapter 301, the DyadicRatCore$^{\uparrow}$ budgets of chapter 291, and the terminal Real$^{\uparrow}$ seal of chapter 38.

Definition 4426.1 (CauchyProductCompletionProjection carrier)**.** *A* CauchyProductCompletionProjection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* CauchyProductCompletion$^{\uparrow}$ *product-completion packet whose coordinate route is being inspected.*
2. *π_0, π_1 are the left and right projection selector rows, each naming which displayed coordinate window is exposed.*
3. *S_0, S_1 are the coordinate* StreamName$^{\uparrow}$ *windows opened by the two projection selectors.*
4. *D_0, D_1 are the* DyadicRatCore$^{\uparrow}$ *budget rows attached to the finite coordinate observations read from those windows.*
5. *R_0, R_1 are the* RegSeqRat$^{\uparrow}$ *readback rows obtained from the same coordinate windows and dyadic budgets.*
6. *L_0, L_1 are the coordinate completion-seal rows witnessing that each projected read remains inside the product-completion packet.*
7. *H records componentwise* hsame *transport for the product packet, selectors, stream windows, dyadic budgets, regular readbacks, and coordinate completion seals.*
8. *C records the* Cont *replay from the product-completion packet through the selected coordinate window, dyadic budget, regular readback, and completion seal.*
9. *P is the* Pkg *provenance over* CauchyProductCompletionProjection$^{\uparrow}$, CauchyProductCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *row.*
The carrier compares accepted projections only through $Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, host product equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CauchyProductCompletionProjectionUp.CauchyProductCompletionProjectionTasteGate`
`single carrier alignment`

Theorem 4426.2 (CauchyProductCompletionProjection NameCert obligations)**.** *For an accepted packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *surface consists exactly of product-packet admission, selector exposure, coordinate stream-window exposure, dyadic-budget accounting, regular readback, coordinate completion-seal nonescape, componentwise transport, replay, provenance, and local naming for the displayed rows.*

Proof. Project the carrier of Definition 5824.1. The row Q supplies the already displayed product-completion packet, while π_0, π_1 determine which coordinate route is being opened.

For each selector, the corresponding stream window is read before any dyadic budget or regular readback is available. Thus S_0, S_1 precede D_0, D_1, and the regular rows R_0, R_1 are exposed only through those windows and budgets.

The completion-seal rows L_0, L_1 bind the coordinate read back to Q. The transport table H and replay table C preserve the same product packet, selector, window, budget, readback, and seal rows, while P and N record provenance and local naming.

Since these are the only carrier coordinates, the NameCert surface has no route to quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 4426.3 (CauchyProductCompletionProjection route)**.** *Every coordinate read exported by an accepted* $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ *carrier factors through*

$\mathsf{CauchyProductCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameC

The left and right selectors expose only the displayed coordinate windows and their completion seals; they do not turn the product-completion packet into a host tuple, a quotient-completion equality, or a chosen representative.

Proof. Start with an accepted carrier J. The selector rows π_0, π_1 are not host projections; they are displayed BEDC rows attached to the product-completion packet Q.

Reading either selector first opens the matching $\mathsf{StreamName}^{\uparrow}$ window. The dyadic budget row is then inspected, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback is obtained from the same finite coordinate window.

The coordinate completion seal is the last coordinate-facing row before export. It keeps the read inside the product-completion packet named by Q, and the structural rows H, C, P, N attach transport, replay, provenance, and local naming to the same route.

Thus every projection read remains a finite NameCert route through the displayed rows. No coordinate of J supplies quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ packet is generated from an accepted CauchyProductCompletion packet, left and right projection selector rows, coordinate StreamName windows, DyadicRatCore budgets, RegSeqRat readbacks, coordinate completion seals, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5824.1, Definition 5824.2, and Definition 5824.3 seed the finite coordinate-projection route for product completions.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host product equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, selector exposure, coordinate window accounting, regular readback, completion-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductCompletionPro

Chapter 4427

A Concrete Naming Certificate for $\mathsf{CauchyModulusSubsequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet records the finite route by which a bounded regular Cauchy source exposes a modulus-indexed subsequence schedule without exporting an infinite selector. It sits between the bounded subsequence envelope of chapter 1698, the regular subsequence route of chapter 381, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a constructive completion-facing certificate: it supplies a monotone cofinal schedule, finite windows, tolerance accounting, and a Real seal, but not countable choice, quotient stream equality, a selected infinite subsequence, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4427.1 (Cauchy modulus subsequence carrier)**.** *A* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, M, T, W, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$ *source row whose bounded regular Cauchy data are available before any subsequence-modulus request is read.*
2. *M is the modulus row. It records the requested Cauchy tolerance discipline and the finite comparison budget used by the subsequence schedule.*
3. *T is the monotone cofinal schedule row. It records the finite evidence that requested indices are sent to later source windows and that the schedule is cofinal in the displayed source.*
4. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows selected by the schedule row T at the requested modulus levels.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed windows and dyadic tolerances.*
7. *R is the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff row reached from B, M, T, W, D, Q.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the bounded source, modulus, schedule, windows, tolerance ledger, regular readback, and regular subsequence handoff have been displayed.*

9. *H records componentwise* hsame *transport for the bounded source, modulus, cofinal schedule, windows, dyadic ledger, regular readback, regular subsequence handoff, terminal seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a subsequence-modulus request through $B, M, T, W, D, Q, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$, $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, M, T, W, D, Q, R, E, H, C, P, N$. It has no coordinate for a selected infinite subsequence, quotient stream equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusSubsequenceUp.CauchyModulusSubsequenceTasteGate single carrier alignment`

Theorem 4427.2 (Cauchy modulus subsequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier $S = (B, M, T, W, D, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequ}}$ *surface consists exactly of carrier admission, bounded-source admission through B, modulus monotonicity through M, monotone cofinal schedule admission through T, finite-window determinacy through W, dyadic tolerance accounting through D, regular rational readback through Q,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff through R, Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5825.1. Its analytic coordinates are exactly the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular readback Q, regular subsequence handoff R, and terminal Real seal E.

The modulus and schedule obligations are displayed before any support row is inspected. The row M supplies the tolerance discipline, while T records monotonicity and cofinality for the finite requested indices. The window row W and tolerance row D then determine which $\mathsf{StreamName}^{\uparrow}$ windows and dyadic bounds are visible at those requests.

The readback and seal obligations remain downstream. The row Q reads the visible windows as $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the $\mathsf{RegularCauchySubsequence}^{\uparrow}$ handoff, and E is reachable only after the preceding rows have been displayed. Rows H, C, P, N transport, replay, source, and name that same finite route, so no further NameCert obligation remains outside the listed coordinates. □

Theorem 4427.3 (Cauchy modulus subsequence window determinacy)**.** *Every consumer admitted by an accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier must read the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular rational readback Q, regular subsequence handoff R, and terminal Real seal E before reading the transport, replay, provenance, or local naming rows. The packet exports no selected infinite subsequence, quotient stream equality, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer read. By Definition 5825.1, the only consumer-facing route before the support rows is the ordered list B, M, T, W, D, Q, R, E.

The rows B, M, T fix the source, tolerance request, and monotone cofinal schedule. The row W then supplies only the finite windows named by that schedule, and D supplies the dyadic tolerance ledger attached to those windows. Thus the visible subsequence data are determined by displayed finite requests, not by an externally selected infinite object.

The remaining analytic rows are also fixed by the displayed windows. The readback row Q converts those windows into $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the regular subsequence handoff, and E is the terminal Real seal for that route. Since the carrier contains no coordinate for quotient stream equality, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the support rows H, C, P, N can only preserve the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet is generated from a bounded regular Cauchy source, a modulus row, a monotone cofinal schedule, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RegularCauchySubsequence handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5825.1, Definition 5825.2, and Definition 5825.3 seed the constructive subsequence-modulus route over bounded regular Cauchy data, finite windows, dyadic tolerances, regular readback, regular subsequence handoff, Real sealing, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, quotient stream equality, countable choice, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Lean verification requires carrier admission, modulus monotonicity, cofinal schedule admission, finite-window determinacy, dyadic tolerance accounting, RegSeqRat readback, RegularCauchySubsequence handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusSubsequenceUp.

Chapter 4428

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$

Following Mac Lane on monads and Eilenberg–Moore comparison, together with Bishop–Bridges constructive completion, the $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet records the finite BEDC surface where the L10 completion monad, its algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared as one NameCert boundary. The packet reads chapter 378, chapter 1845, chapter 1981, chapter 397, chapter 3351, chapter 126, chapter 301, chapter 291, and chapter 38. It names the comparison surface only; it does not assert quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4428.1 (CauchyCompletionMonadicity carrier)**.** *A* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion-monad row, displaying the unit and bind schedule before any algebra or comparison read is consumed.*
2. *A is the* $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ *action row, recording the Eilenberg–Moore algebra action over the displayed completion route.*
3. *K is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *row, exposing the unit, bind, and reassociated-bind consumer route.*
4. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row, carrying the extension and uniqueness ledger used by comparison consumers.*
5. *D is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *unit route, displaying the dense source-to-completion image before the algebra or universal-property read is exported.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row used by the monad, algebra, Kleisli, universal-property, and dense-embedding rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the same finite windows.*
8. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare completion-facing reads at the same finite precision.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *readback seal reached only after W, R, Q have all been displayed.*
10. *H records componentwise* hsame *transport for the monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from comparison requests through $T, A, K, U, D, W, R, Q, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, CauchyCompletionAlgebr $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, A, K, U, D, W, R, Q, E, H, C, P, N$. The carrier has no coordinate for quotient completion classes, selected limit representatives, host equality of completed objects, countable-choice schedules, ambient completeness, full $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadicityUp.TasteGate.CauchyCompletionMonadicityTasteGate`
`single carrier alignment`

Theorem 4428.2 (CauchyCompletionMonadicity NameCert obligations)**.** *For every accepted* CauchyCompletionM *carrier*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$ *surface consists exactly of carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, StreamName–RegSeqRat–DyadicRatCore–Real readback discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No local obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5827.1. The displayed tuple lists every row available to the classifier, so local comparison can inspect only the completion monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, transport, replay, provenance, and local naming.

The monadicity-facing rows are read in order. The monad row T displays the unit and bind schedule, the algebra row A records the Eilenberg–Moore action over that schedule, and the Kleisli row K keeps unit, bind, and reassociated-bind consumers on the same finite route.

The universal and dense rows then bind the comparison surface. The row U supplies extension and uniqueness data, while D supplies the dense source-to-completion unit route used before the comparison is exported.

Finally the readback and structural rows close the NameCert surface. The rows W, R, Q, E give finite windows, regular rational readback, dyadic tolerances, and the terminal Real seal; the rows H, C, P, N transport, replay, source, and name exactly that packet. Since no excluded coordinate occurs, no additional local obligation is available. □

Theorem 4428.3 (CauchyCompletionMonadicity comparison surface)**.** *Every comparison consumer of an accepted* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier factors through the finite route*

$$T, A, K, U, D \longmapsto W \longmapsto R \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the completion-monad route, the algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared only after the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$,

$\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback surface has been displayed. The comparison exports no quotient completion equality, selected limit, host equality of completed objects, countable choice, ambient completeness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the monad and algebra rows. The row T supplies the displayed completion transformer, and A reads its algebra action only as a row over that transformer.

Next attach the Kleisli and universal-property rows. The row K exposes the unit, bind, and reassociated-bind route, while U records the extension and uniqueness ledger for completion-facing consumers.

Now read the dense-embedding unit route D. It displays the source-to-completion image before the comparison reaches any terminal seal, so the route is a visible unit comparison rather than a selected representative.

Finally consume the readback and structural rows. The finite window W, regular readback R, dyadic tolerance ledger Q, and Real seal E precede transport, replay, provenance, and naming through H, C, P, N. Since the carrier contains no coordinate for the excluded objects, the comparison surface cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet is generated from a CauchyCompletionMonad route, CauchyCompletionAlgebra action row, CauchyCompletionKleisli route, CompletionUniversalProperty row, MetricCompletionDenseEmbedding unit route, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5827.1, Definition 5827.2, and Definition 5827.3 seed the finite monadicity comparison boundary for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, readback discipline, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionMonadicityUp.

Chapter 4429

A Concrete Naming Certificate for $\mathsf{BorsukUlam}^{\uparrow}$

Following Borsuk and Ulam, the $\mathsf{BorsukUlam}^{\uparrow}$ packet records the antipodal obstruction theorem as finite BEDC NameCert data rather than as a host topological principle. It sits after the degree surface of chapter 3745, the continuous-map rows of chapter 130, the real-name seal of chapter 38, the compact metric source of chapter 129, and the circle boundary model of chapter 58. The packet names the displayed antipodal route consumed by obstruction and degree-facing chapters; it does not select antipodal points, import unrestricted classical degree theory, identify quotient spheres, choose representatives, or appeal to ambient completeness.

Definition 4429.1 (Borsuk-Ulam carrier)**.** *A* $\mathsf{BorsukUlam}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, A, F, D, C, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the compact metric sphere row read through the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *surface and the* $\mathsf{S}^{1\uparrow}$ *boundary model.*
2. *A is the antipodal-pair ledger, exposing only named paired source rows and the finite equality-refusal data attached to them.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the map whose antipodal comparison is being inspected.*
4. *D is the* $\mathsf{BrouwerDegree}^{\uparrow}$ *obstruction row, read only through the displayed degree certificate and never through unrestricted host degree theory.*
5. *C is the* $\mathsf{Real}^{\uparrow}$ *comparison-seal row for the coordinate difference or collapsed real-valued comparison consumed by the obstruction route.*
6. *R is the refusal row excluding selected antipodal points, quotient equality of sphere points, choice, unrestricted classical degree theory, and ambient completeness.*
7. *H records componentwise* hsame *transport for the compact source, antipodal ledger, continuous-map row, degree row, real comparison seal, refusal row, provenance, and local naming.*
8. *K records displayed* Cont *replay from the compact metric source through the antipodal ledger, continuous-map row, degree obstruction, real comparison seal, and refusal row.*
9. *P is the* Pkg *provenance over* $\mathsf{BorsukUlam}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{BrouwerDegree}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *row.*

The classifier compares accepted packets only through $S, A, F, D, C, R, H, K, P, N$. It has no coordinate for a chosen antipodal pair, quotient equality on the sphere, unrestricted classical degree theory, countable choice, or ambient Real completeness.

Lean4 (definition) `BEDC.Derived.BorsukUlamUp.BorsukUlamUp`
Lean4 ✓ `BEDC.Derived.BorsukUlamUp.BorsukUlamTasteGate single carrier alignment`

Theorem 4429.2 (Borsuk-Ulam NameCert obligations)**.** *For every accepted* $\mathsf{BorsukUlam}^\uparrow$ *carrier* $U = (S, A, F, D, C, R, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *surface consists exactly of compact metric sphere admission, antipodal-pair ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, refusal of host and quotient shortcuts, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obstruction-facing consumer must read*

$$S, A, F \longmapsto D, C \longmapsto R, H, K, P, N$$

before treating the packet as a Borsuk-Ulam certificate.

Proof. Project the carrier of Definition 5828.1. The compact source row S, antipodal ledger A, and continuous-map row F are the only rows available before the obstruction is read.

The degree and real-comparison rows D, C are downstream of that source route. The degree row is the displayed $\mathsf{BrouwerDegree}^\uparrow$ certificate, and the real row is the displayed $\mathsf{Real}^\uparrow$ seal for the comparison consumed by the obstruction.

Finally R, H, K, P, N refuse shortcuts, transport the same rows, replay the finite route, source it, and name it locally. Since the carrier has no coordinate for selected antipodal points, quotient equality, unrestricted host degree theory, countable choice, or ambient Real completeness, no consumer can export those objects from the certificate. □

Theorem 4429.3 (Borsuk-Ulam antipodal route)**.** *Every accepted* $\mathsf{BorsukUlam}^\uparrow$ *antipodal-obstruction read factors through the displayed compact metric sphere row, the* $\mathsf{S}^{1\uparrow}$ *boundary model, the antipodal-pair ledger, the* $\mathsf{ContinuousMap}^\uparrow$ *row, the* $\mathsf{BrouwerDegree}^\uparrow$ *obstruction row, the terminal* $\mathsf{Real}^\uparrow$ *comparison seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert*. The route exports no selected antipodal point, unrestricted classical degree theorem, quotient equality of sphere points, choice principle, ambient completeness, Lean verification, or bridge-checked surface.*

Proof. Start with an accepted carrier $U = (S, A, F, D, C, R, H, K, P, N)$. The source read begins at S and A, so the antipodal data is visible only as a finite paired ledger over the displayed compact metric and circle rows.

Read the map through F and then the obstruction through D, C. The $\mathsf{ContinuousMap}^\uparrow$ row supplies the function-facing data, the $\mathsf{BrouwerDegree}^\uparrow$ row supplies the obstruction route, and the $\mathsf{Real}^\uparrow$ row supplies only the comparison seal reached from those displayed rows.

The refusal and structural rows close the route. The row R blocks selected points, quotient equality, unrestricted degree theory, choice, and ambient completeness, while H, K, P, N preserve the same finite certificate under transport, replay, provenance, and local naming. □

Falsifiable prediction: Every accepted $\mathsf{BorsukUlam}^\uparrow$ consumer reads compact metric sphere data, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a Real

comparison seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before it treats the packet as an antipodal obstruction certificate.

Independence witness: brouwer-degree, continuousmap, real, compactmetric, s1: $\mathsf{BorsukUlam}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact sphere data, antipodal pairing, continuous-map readback, degree obstruction, real comparison sealing, refusal, transport, replay, provenance, and local naming into one obstruction-facing certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}$.

Constructive story: A $\mathsf{BorsukUlam}^{\uparrow}$ packet is generated from a compact metric sphere row, an S1 boundary model, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a RealUp comparison seal, shortcut refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}$, seed)

Scope closed: Definition 5828.1, Definition 5828.2, and Definition 5828.3 seed the finite antipodal obstruction route over compact metric, circle, continuous-map, degree, real-seal, transport, replay, provenance, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected antipodal points, unrestricted classical degree theory, quotient equality, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, antipodal ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, transport, replay, provenance, and local naming for BEDC.Derived.BorsukUlamUp.

Chapter 4430

A Concrete Naming Certificate for $\mathsf{DenjoyYoungSaks}^{\uparrow}$

Following Saks and Bishop–Bridges constructive real analysis, the $\mathsf{DenjoyYoungSaks}^{\uparrow}$ packet records the finite boundary at which a real-valued interval map can expose upper and lower Dini-derivative rows without importing the classical almost-everywhere Denjoy–Young–Saks theorem. It sits next to the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation window of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet is a finite classification boundary for displayed Dini rows, oscillation windows, regular-rational readback, and terminal Real seals; it is not a measure theorem, an almost-everywhere classifier, or a host-real differentiability principle.

Definition 4430.1 (Denjoy–Young–Saks finite Dini carrier)**.** *A* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the inspected interval row, listing the finitely presented source intervals and endpoint cells on which the local boundary is read.*
2. *F is the function-observation row, recording the finite source and target windows used to compare difference quotients.*
3. *U is the upper Dini row, storing the displayed upper right, upper left, and two-sided upper derivative bounds visible at the inspected windows.*
4. *L is the lower Dini row, storing the corresponding lower right, lower left, and two-sided lower derivative bounds.*
5. *O is the oscillation-window row, recording the finite alternation and stabilization tests used to classify a displayed window as one of the Dini-boundary cases.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by I, F, O and no hidden stream coordinates.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data extracted from the finite stream windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger supporting the difference-quotient comparisons and oscillation bounds.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the interval, function-observation, Dini, oscillation, stream, readback, and dyadic rows have been exposed.*

10. *H records componentwise* hsame *transport for intervals, function observations, Dini rows, oscillation windows, stream schedules, regular readbacks, dyadic ledgers, Real seals, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the inspected interval and function rows through U, L, O, S, R, D and into the Real seal E.*

12. *P is the* Pkg *provenance over* $\mathsf{DenjoyYoungSaks}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, U, L, O, S, R, D, E, H, C, P, N$. It has no coordinate for measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, host real order trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.DenjoyYoungSaksUp.DenjoyYoungSaksTasteGate single carrier alignment`

Theorem 4430.2 (Denjoy–Young–Saks finite boundary obligations)**.** *For every accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier $Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the inspected interval, function-observation, upper Dini, lower Dini, oscillation-window, stream-schedule, regular-readback, dyadic-ledger, Real-seal, transport, replay, provenance, and local naming rows;*

2. *interval and observation exactness, requiring every Dini comparison to read its source cell from I and its finite function window from F before any derivative row is accepted;*

3. *upper and lower Dini-row exactness, requiring U and L to store only the finite upper and lower derivative bounds justified by the displayed difference-quotient windows;*

4. *oscillation-window classification, requiring O to record the finite alternation, stabilization, and gap tests that separate the visible Dini-boundary cases;*

5. *stream, readback, and dyadic exactness, requiring S, R, D to expose only the finite observations, regular rational readbacks, and dyadic tolerance rows demanded by I, F, U, L, O;*

6. *Real seal nonescape, requiring E to remain downstream of I, F, U, L, O, S, R, D and never to serve as a selected derivative, a host real equality witness, or an almost-everywhere theorem;*

7. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve exactly the displayed finite route.*

No $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *obligation is stored outside these rows, and the packet makes no claim that the classical Denjoy–Young–Saks alternatives hold almost everywhere.*

Proof. Carrier admission is projection from Definition 5829.1. The accepted packet displays exactly the inspected interval row I, function-observation row F, upper and lower Dini rows U, L, oscillation row O, stream schedule S, regular readback R, dyadic ledger D, Real seal E, and structural rows H, C, P, N.

Interval and observation exactness follow from the row order. A Dini comparison first reads the source cell in I and the finite function-observation window in F; only then may it inspect the upper row U, lower row L, or oscillation row O attached to that window.

The stream, regular-readback, and dyadic rows are downstream of the same finite windows. The schedule S opens only the observations demanded by I, F, O, the row R records the resulting regular rational readback, and D stores the tolerance comparisons needed for the displayed difference-quotient bounds.

Finally, the Real seal E is terminal for this finite boundary route. The transport row H, replay row C, provenance row P, and local naming row N preserve the same packet, so measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness cannot become local obligations. □

Theorem 4430.3 (Denjoy–Young–Saks Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{StreamName}^{\uparrow}$ *consumer of an accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier reads the displayed route*

$$I, F, U, L, O, S, R, D, E, H, C, P, N.$$

Consequently the consumer may inspect finite interval cells, function observations, upper and lower Dini rows, oscillation windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal Real seal, componentwise transport, replay, provenance, and local naming. It cannot read a measure structure, an almost-everywhere assertion, a selected derivative, quotient real equality, host real trichotomy, countable choice, or ambient completeness from the packet.

Proof. Project the accepted carrier through Definition 5829.1. Its Real-facing and readback-facing rows are exactly S, R, D, E together with the preceding interval, function, Dini, and oscillation rows I, F, U, L, O and the structural rows H, C, P, N.

The route reaches E only after the finite Dini and oscillation boundary has been displayed. Thus any consumer that asks for a Real seal or regular rational readback must already have passed through the interval cells, function observations, upper and lower Dini rows, oscillation windows, stream schedule, and dyadic tolerance ledger.

Since the carrier has no row for measure, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, or ambient completeness, none of those objects can be read by a downstream consumer. □

Theorem 4430.4 (Denjoy–Young–Saks oscillation-window induction)**.** *For an accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier* $Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$*, induction over the finite oscillation-window row* O *preserves the separation between the upper Dini row* U *and the lower Dini row* L*. At every displayed stage the packet remains a finite boundary classifier over the rows of Definition 5829.1; the induction cannot promote the packet to an almost-everywhere measure theorem, cannot select a derivative, and cannot export a host-real differentiability principle.*

Proof. Induct over the displayed list of oscillation windows in O. The empty row has no Dini comparison to transport, so the upper and lower rows remain separated by the carrier projection.

For the step, assume the previously displayed windows preserve the separation of U and L. The next window is admitted only through the oscillation-window classification row in Definition 5829.2, so it may inspect the finite alternation, stabilization, and gap tests attached to that window but cannot rewrite the carrier outside $I, F, U, L, O, S, R, D, E, H, C, P, N$.

The Real-seal nonescape theorem Definition 5829.3 keeps every downstream read behind the same finite route. Thus adjoining the next oscillation window preserves the visible upper/lower Dini separation and leaves measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness outside the packet. □

Falsifiable prediction: Every $\mathsf{DenjoyYoungSaks}^{\uparrow}$ Real-facing or readback-facing read factors through finite interval cells, function-observation windows, upper and lower Dini rows, oscillation windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{DenjoyYoungSaks}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries upper and lower Dini rows, oscillation-window classification, regular-rational readback, dyadic tolerance data, and a terminal Real seal in one finite boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$.

Constructive story: A $\mathsf{DenjoyYoungSaks}^{\uparrow}$ packet is generated from inspected interval cells, function-observation windows, upper and lower Dini rows, oscillation-window classifications, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5829.1, Definition 5829.2, and Definition 5829.3 seed the finite Denjoy–Young–Saks boundary route over Dini rows, oscillation windows, regular-rational readback, dyadic tolerance rows, and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DenjoyYoungSaksUp.DenjoyYoungSaksTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close the classical almost-everywhere Denjoy–Young–Saks theorem, measure-null exceptional sets, selected derivatives, quotient real equality, trichotomy, countable choice, ambient completeness, or bridge checking beyond the carrier-alignment Lean target.

Upgrade path: Obligation closure requires checked carrier admission, Dini-row exactness, oscillation-window classification, stream-readback-dyadic exactness, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.DenjoyYoungSaksUp.

Chapter 4431

A Concrete Naming Certificate for $\mathsf{UniformlyConvexSpace}^{\uparrow}$

Following Clarkson's uniformly convex Banach-space reading and Bishop–Bridges constructive normed-space practice, the $\mathsf{UniformlyConvexSpace}^{\uparrow}$ packet records a finite modulus-of-convexity surface over the normed-space carrier of chapter 1950. It consumes the $\mathsf{NormedSpace}^{\uparrow}$ row, the real-valued norm and midpoint reads through chapter 38, the metric handoff of chapter 57, and the completion-facing route of chapter 95 and chapter 3413. The packet gives Banach, Hilbert, fixed-point, and convexity consumers a named uniform-convexity certificate without importing host Banach-space equality, selected minimizers, quotient completions, or choice.

Definition 4431.1 (UniformlyConvexSpace carrier)**.** *A* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (N, R, A, M, \Delta, Q, H, T, P, C)$$

with the following displayed rows:

1. *N is the* $\mathsf{NormedSpace}^{\uparrow}$ *row, exposing vector operations, the norm read, and the induced metric only through the normed-space NameCert surface.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by norm values, radius comparisons, midpoint estimates, and positive modulus outputs.*
3. *A is the midpoint row, reading $(x + y)/2$ through the vector addition, scalar action, and real scalar rows already visible in N and R.*
4. *M is the metric handoff row, routing distance and unit-ball comparisons through the* $\mathsf{Met}^{\uparrow}$ *read induced by N.*
5. *Δ is the convexity-modulus row: for each displayed positive separation request it supplies a positive real margin forcing the midpoint norm below the unit bound whenever the two admitted unit vectors are separated by that request.*
6. *Q is the completion-facing row, allowing Cauchy and completion consumers to read the same norm, metric, midpoint, and modulus data without selecting a completed point.*
7. *H records componentwise* hsame *transport for N, R, A, M, Δ, Q and for the local structural rows.*
8. *T records displayed* Cont *replay from a uniform-convexity request through $N, R, A, M, \Delta, Q, H, P, C$.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformlyConvexSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. C is the local $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for host Banach-space equality, strict-convexity as a pointwise substitute, quotient completion, selected closest points, compactness, reflexivity, or a choice principle.

Theorem 4431.2 (UniformlyConvexSpace NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *carrier* $U = (N, R, A, M, \Delta, Q, H, T, P, C)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, normed-space visibility, real-valued norm and midpoint readback, metric separation handoff, positive modulus admission, midpoint contraction under the displayed separation request, completion-facing nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside* $N, R, A, M, \Delta, Q, H, T, P, C$*.*

Lean4 ✓ `BEDC.Derived.UniformlyConvexSpaceUp.UniformlyConvexSpaceTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 5831.1. The rows $N, R, A, M, \Delta, Q, H, T, P, C$ are the whole accepted packet.

The normed-space, Real, midpoint, and metric obligations are read first. The row N supplies the normed vector carrier, R supplies real-valued comparisons, A supplies midpoint formation, and M supplies the induced metric separation route.

The uniform-convexity content is isolated in Δ. For a displayed positive separation request, Δ supplies a positive margin and forces the midpoint norm read through A, N, R below the unit bound. Since Q, H, T, P, C only hand off, transport, replay, source, and name the same route, no host Banach-space equality, quotient completion, selected point, compactness, reflexivity, or choice coordinate can enter. □

Theorem 4431.3 (UniformlyConvexSpace modulus convexity route)**.** *Every accepted* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *consumer that asks for uniform convexity factors through*

$$\mathsf{NormedSpace}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{Completion}^{\uparrow}, \mathsf{Cauchy}^{\uparrow} \longmapsto H, T, P, C.$$

The modulus row Δ may be read only after the normed-space carrier, real norm values, midpoint operation, and metric separation row have been displayed. The route exports a finite modulus-of-convexity NameCert surface, not host strict convexity, a selected minimizer, quotient completion equality, compactness, reflexivity, or countable choice.

Proof. Begin with a uniform-convexity request. The normed-space row N supplies the only vector and norm data, while R supplies the real-valued unit-ball and positivity comparisons.

Read midpoint and separation next. The midpoint row A is formed from the displayed operations of N and R, and the metric handoff M reads separation through the induced metric of the same normed-space packet.

Only then can the modulus row Δ answer the request. Its output is tied to the displayed positive separation and midpoint norm route, and the completion-facing row Q sends Cauchy or completion consumers through the same route rather than through a selected completed point.

Finally H, T, P, C transport, replay, source, and name the packet. The excluded host strict-convexity, selected-minimizer, quotient-completion, compactness, reflexivity, and choice objects are absent from the carrier, so the finite modulus route is the whole exported surface. □

Falsifiable prediction: An accepted $\mathsf{UniformlyConvexSpace}^{\uparrow}$ read is refuted if a consumer obtains a uniform-convexity margin without first displaying the $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, midpoint, $\mathsf{Met}^{\uparrow}$, completion-facing, transport, replay, provenance, and local NameCert rows.

Independence witness: normedspace, real, metric, completion, cauchy: no listed sibling is bijective to $\mathsf{UniformlyConvexSpace}^{\uparrow}$ because the packet jointly carries normed-space data, real norm comparisons, midpoint formation, metric separation, a positive convexity modulus, completion-facing handoff, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformlyConvexSpace}^{\uparrow}$ packet is generated from a NormedSpace row, Real norm-comparison rows, a midpoint row, an induced Metric separation row, a convexity-modulus row, a Completion and Cauchy handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5831.1, Definition 5831.2, and Definition 5831.3 seed the finite modulus-of-convexity route over normed-space, real, metric, completion, and Cauchy rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.UniformlyConvexSpaceUp.UniformlyConvexSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host Banach-space equality, strict-convexity substitution, selected minimizers, quotient completions, compactness, reflexivity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, midpoint formation, metric separation, positive modulus exactness, completion-facing nonescape, and local naming for BEDC.Derived.UniformlyConvexSpaceUp.

Chapter 4432

A Concrete Naming Certificate for $\mathsf{HyperbolicTranslationLength}^{\uparrow}$

Following the classical translation length of a hyperbolic isometry, the $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ packet records the finite invariant-length route visible to the hyperbolic phase geometry of chapter 9463. It consumes the metric-read surface of chapter 3474, the routed geodesic-flow surface of chapter 3856, the additive Busemann cocycle route of chapter 4134, the four-boundary-point comparison of chapter 3948, and the terminal real seal of chapter 38. The packet names stable displacement growth as finite BEDC data; it does not import a host hyperbolic manifold, quotient ideal boundary, selected axis, spectral radius, or global curvature theorem.

Definition 4432.1 (HyperbolicTranslationLength carrier)**.** *A* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, F, B, X, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row, exposing displacement reads for the source and its iterated image.*
2. *F is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row, recording the finite routed-flow data used to compare iterates along the same visible geodesic route.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row, supplying additive boundary-cocycle comparisons for the same displayed endpoints.*
4. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *row, recording the four-boundary-point invariant used to stabilize the length read.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by displacement values, additive cocycle values, cross-ratio reads, and the final nonnegative length seal.*
6. *D is the displacement-growth row, comparing the displayed iterate window through M, F, B, X, R without selecting an infinite orbit or an axis.*
7. *E is the endpoint-stability row, stating that the same boundary data are replayed by the metric, flow, Busemann, and cross-ratio rows.*
8. *H records componentwise* hsame *transport for M, F, B, X, R, D, E and for the local structural rows.*

9. *C records displayed* Cont *replay from a translation-length request through $M, F, B, X, R, D, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host isometry group, selected invariant axis, quotient boundary equality, spectral radius, completed hyperbolic manifold, or physical expansion law.

Lean4 ✓ `BEDC.Derived.HyperbolicTranslationLengthUp.HyperbolicTranslationLengthTasteGate single carrier alignment`

Theorem 4432.2 (HyperbolicTranslationLength NameCert obligations)**.** *For every accepted* HyperbolicTranslation *carrier $L = (M, F, B, X, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$ *surface consists exactly of metric displacement visibility, geodesic-flow routing, Busemann additivity, cross-ratio stabilization, real-valued length sealing, displacement-growth comparison, endpoint stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside $M, F, B, X, R, D, E, H, C, P, N$.*

Proof. Project the carrier of Definition 5832.1. The rows $M, F, B, X, R, D, E, H, C, P, N$ are the whole visible packet.

The geometric route is read first. Metric displacement comes from M, routed iteration from F, additive boundary comparison from B, and four-boundary-point stabilization from X.

The Real and displacement rows then seal the length read. The row R supplies the real-valued comparison surface, while D and E ensure that the same endpoint data are used by the metric, flow, Busemann, and cross-ratio reads.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate names a host isometry group, selected invariant axis, quotient boundary equality, spectral radius, completed manifold, or physical expansion law, the listed obligations exhaust the local surface. □

Theorem 4432.3 (HyperbolicTranslationLength invariant route)**.** *Every accepted* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *read factors through*

$$\mathsf{HyperbolicMetric}^{\uparrow}, \mathsf{HyperbolicGeodesicFlow}^{\uparrow}, \mathsf{HyperbolicBusemannCocycle}^{\uparrow}, \mathsf{HyperbolicCrossRatio}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto H, C, P$$

The finite route records displacement growth and boundary stabilization as a real-sealed invariant length, and it exports no host hyperbolic isometry, selected axis, quotient ideal-boundary equality, spectral radius, completed hyperbolic manifold, or cosmological expansion claim.

Proof. Begin with the displacement request. The metric row M supplies finite distance reads, and the geodesic-flow row F keeps the iterated comparison on the same displayed route.

Read boundary stabilization next. The Busemann cocycle row B supplies additive endpoint comparison, while the cross-ratio row X records the four-boundary-point invariant. The endpoint-stability row E requires these boundary reads to describe the same displayed data.

The Real row R and displacement-growth row D seal the invariant length as a finite real-valued read. The structural rows H, C, P, N preserve, replay, source, and name that route, while the excluded host and quotient objects remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ consumer is refuted if it obtains an invariant length without displaying the $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}$ $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, displacement-growth, endpoint-stability, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: hyperbolicmetric, hyperbolic-geodesic-flow, hyperbolic-busemann-cocycle, hyperbolic-cross-ratio, real: no listed sibling is bijective to $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ because the packet jointly carries metric displacement, routed flow, additive boundary cocycle, cross-ratio stabilization, Real sealing, displacement-growth comparison, endpoint stability, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ packet is generated from HyperbolicMetric displacement rows, HyperbolicGeodesicFlow routing rows, HyperbolicBusemannCocycle additive boundary rows, HyperbolicCrossRatio stabilization rows, Real sealing rows, displacement-growth and endpoint-stability rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5832.1, Definition 5832.2, and Definition 5832.3 seed the finite invariant-length packet over metric, flow, Busemann, cross-ratio, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host hyperbolic isometries, selected axes, quotient ideal-boundary equality, spectral radii, completed hyperbolic manifolds, physical expansion laws, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, displacement visibility, flow routing, Busemann additivity, cross-ratio stabilization, Real length sealing, endpoint stability, and local naming for BEDC.Derived.HyperbolicTranslationLengthUp.

Chapter 4433

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ packet records the finite envelope that carries a regular Cauchy rational readback into the terminal Real naming seal. It sits after the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational sequence interface of chapter 301, the terminal real-name packet of chapter 38, and the completion route of chapter 1506. The packet is a finite NameCert envelope for the handoff itself; it does not assert that the host real line is complete.

Definition 4433.1 (Regular Cauchy completion envelope carrier)**.** *A* $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (W, D, R, E_R, M, T, C, P, N)$$

where W *is the displayed* $\mathsf{StreamName}^{\uparrow}$ *window row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row,* E_R *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* T *records componentwise* $\mathsf{BHist}/\mathsf{hsame}$ *transport,* C *records displayed* Cont *replay,* P *is* Pkg *provenance over the displayed rows, and* N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}$ *row. A consumer of the carrier receives the completion handoff only through these nine coordinates.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionEnvelopeUp.RegularCauchyCompletionEnvelopeTasteGate`
`single carrier alignment`

Theorem 4433.2 (Regular Cauchy completion envelope obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletion}$ *carrier*

$$E = (W, D, R, E_R, M, T, C, P, N),$$

the local NameCert surface consists exactly of window admission, tolerance admission, regular readback admission, terminal Real-seal admission, metric-completion route admission, transport stability, continuation replay, provenance preservation, and local naming preservation for the displayed packet. No quotient stream equality, selected representative, countable choice schedule, host completeness principle, or $\mathsf{Real}^{\uparrow}$ *completeness theorem is a coordinate of this surface.*

Proof. Project the carrier of Definition 5833.1. Its only data rows are $W, D, R, E_R, M, T, C, P, N$, so the local NameCert can inspect exactly those displayed coordinates.

The first four rows bind the finite observation, dyadic tolerance, regular rational readback, and terminal Real seal. The metric-completion row M is therefore read as a route row over those data, not as an ambient completeness object.

The structural rows T, C, P, N preserve the same packet under componentwise transport, continuation replay, provenance, and local naming. Since the carrier has no slot for quotient stream equality, selected representatives, countable choice, host completeness, or Real completeness, none of those objects can be exported by the obligation surface. □

Theorem 4433.3 (Regular Cauchy completion envelope Real handoff)**.** *Every Real-facing completion consumer of an accepted* $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ *carrier reads the terminal handoff through the ordered finite route*

$$W, D, R, E_R, M, T, C, P, N.$$

In particular, the consumer reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal only after the* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed inside the same envelope.*

Proof. Start from Definition 5833.2. It makes $W, D, R, E_R, M, T, C, P, N$ the entire accepted surface of the envelope.

Read the Real-facing route through W, D, R, E_R. The StreamName windows expose the finite observations, the dyadic ledger records the tolerance budget, the regular-rational row gives the readback, and the terminal row gives the Real seal inside the same packet.

The completion route M and the structural rows T, C, P, N only replay and name that displayed handoff. Thus the consumer cannot replace the handoff by quotient stream equality, a chosen representative, countable choice, host completeness, or a completeness theorem for $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5833.1, Definition 5833.2, and Definition 5833.3 seed the finite regular-Cauchy-to-Real completion envelope.

Lean target: `BEDC.Derived.RegularCauchyCompletionEnvelopeUp.RegularCauchyCompletionEnvelopeTasteGate\_single\_car`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host completeness, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, row order, Real handoff, transport stability, replay stability, provenance preservation, and local NameCert preservation for BEDC.Derived.RegularCauchyCompletionEnvelopeUp.

Constructive story: A $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore tolerance, RegSeqRat readback, terminal Real seal, metric-completion routing, transport, replay, provenance, and local NameCert rows.

Chapter 4434

A Concrete Naming Certificate for $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$

Following Bishop–Bridges constructive locatedness, the $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ packet records the finite interval-selection surface that can be read by Cauchy and Real interval consumers without selecting an endpoint or importing compactness. It sits over the located interval carrier of chapter 394, the rational cell ledger of chapter 354, the optional dyadic refinement rows of chapter 306, the endpoint observation windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal Real seal of chapter 38. The packet names a finite route through displayed interval data; it does not assert endpoint choice, Heine–Borel compactness, trichotomy, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4434.1 (WeaklyLocatedIntervalSelection carrier)**.** *A* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, Q, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the source interval and its locatedness probes.*
2. *Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger listing the rational subinterval cells visible to the selection route.*
3. *D is an optional* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row; when present, it refines cells already displayed by Q and adds no independent selector.*
4. *W is the paired* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window row through which finite endpoint observations are read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same endpoint windows and rational cells.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by any Real-facing endpoint or interval consumer.*
7. *H records componentwise* hsame *transport for $L, Q, D, W, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from located interval probes through rational cells, optional dyadic refinements, endpoint windows, regular readbacks, and the Real seal.*
9. *P is* Pkg *provenance over* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$*,* $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets componentwise through these ten rows. There is no coordinate for an endpoint selector, an open-cover compactness argument, a trichotomy oracle, quotient equality of Real names, or host Real completeness.

Lean4 ✓ `BEDC.Derived.WeaklyLocatedIntervalSelectionUp.WeaklyLocatedIntervalSelectionTasteGate single carrier alignment`

Theorem 4434.2 (WeaklyLocatedIntervalSelection NameCert obligations)**.** *For every accepted* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *carrier*

$$S = (L, Q, D, W, R, E, H, C, P, N),$$

the local NameCert surface consists exactly of the following obligations:

1. *carrier admission for the finite* BHist *packet S and its displayed rows;*
2. *located-cell visibility from the* $\mathsf{LocatedInterval}^{\uparrow}$ *row L into the* $\mathsf{RationalInterval}^{\uparrow}$ *ledger Q;*
3. *finite selection-route exactness through the visible rational cells and any displayed* $\mathsf{DyadicInterval}^{\uparrow}$ *refinements D;*
4. *endpoint-window transport from Q, D into the* $\mathsf{StreamName}^{\uparrow}$ *windows W and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R;*
5. *Real-seal nonescape, requiring every Real-facing read to pass through the displayed* $\mathsf{Real}^{\uparrow}$ *row E;*
6. *componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance preservation, and local* NameCert *preservation through H, C, P, N.*

No endpoint choice principle, Heine–Borel theorem, trichotomy principle, quotient equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem is an obligation or an output of this surface.*

Theorem 4434.3 (Weakly located interval selection route exhaustion)**.** *For every accepted* WeaklyLocatedIntervalSe *carrier*

$$S = (L, Q, D, W, R, E, H, C, P, N),$$

every endpoint, interval, or Real-facing consumer factors through the displayed rows $L, Q, D, W, R, E, H, C, P, N$. Such a consumer cannot read endpoint choice, Heine–Borel compactness, trichotomy, quotient equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows of Definition 5834.1. The located interval source is L, the rational cell ledger is Q, and the optional dyadic refinement row is D.

Located-cell visibility therefore passes through L, Q, D. Endpoint or interval reads have no route around these rows because the packet stores no detached endpoint selector or host interval object.

The endpoint windows and regular rational readbacks are then W and R. A Real-facing consumer reaches the seal row E only after those finite windows and readbacks are visible.

Finally H, C, P, N transport, replay, source, and name the same route. Since endpoint choice, Heine–Borel compactness, trichotomy, quotient equality, and ambient completeness are absent from the tuple, the displayed rows exhaust every admitted consumer read. □

Formal verification: FormalStatus(NameCert$_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close endpoint choice, Heine–Borel compactness, trichotomy, quotient real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-cell visibility, finite selection-route exactness, endpoint-window transport, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.WeaklyLocatedIntervalSelectionUp.

Constructive story: A WeaklyLocatedIntervalSelection$^{\uparrow}$ packet is generated from LocatedInterval rows, RationalInterval cell ledgers, optional DyadicInterval refinements, StreamName endpoint windows, RegSeqRat readbacks, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4435

A Concrete Naming Certificate for $\mathsf{UniformInverseModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UniformInverseModulus}^{\uparrow}$ packet records compact inverse-modulus extraction from uniform homeomorphism data as finite NameCert data. It reads the homeomorphism and inverse-graph surface of chapter 1815, the compact finite-net rows of chapter 129, the graph and pointwise continuity rows of chapter 130, the exported modulus interface of chapter 369, the metric-source and metric-target rows of chapter 4230, and the terminal real-name seal of chapter 38. The chapter names the finite compact route that turns displayed inverse radii into a uniform inverse modulus; it is not a selected inverse function, host function equality, quotient real equality, open-cover compactness, or ambient completeness principle.

Definition 4435.1 (Uniform inverse modulus carrier)**.** *A* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A)$$

with the following displayed rows:

1. *X is the compact source row, exposing the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net data used to cover the compact domain of the homeomorphism.*
2. *Y is the target metric row, including the distance ledger into which the inverse-modulus estimate is reported.*
3. *F is the* $\mathsf{UniformHomeomorphism}^{\uparrow}$ *graph row from X to Y, carrying the forward graph and the homeomorphism naming data.*
4. *G is the inverse graph row displayed by the same homeomorphism packet.*
5. *E is the positive precision row, read through* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint histories when the consumer presents a real tolerance.*
6. *N is the finite net row of the compact source at the scale needed for the inverse-modulus extraction.*
7. *R lists the pointwise inverse radius rows attached to the centers named by N.*
8. *M is the finite radius-fold row, obtained only by folding the finite family R over the index list of N.*
9. *T is the target estimate row, combining inverse-graph exactness, finite-net coverage, the folded radius row, and the target metric triangle ledger.*

10. *H records componentwise* hsame *transport for the compact source, target metric, homeomorphism graph, inverse graph, precision, finite-net, inverse-radius, radius-fold, and estimate rows.*
11. *C records the displayed* Cont *replay route from compact homeomorphism data and pointwise inverse radii to the* $\mathsf{UniformModulus}^{\uparrow}$ *export.*
12. *P records* Pkg *provenance over* $\mathsf{UniformInverseModulus}^{\uparrow}$, $\mathsf{UniformHomeomorphism}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, RegSeqRat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *A is the local* $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$ *row.*

The carrier exposes only displayed compact finite nets, graph rows, inverse-graph rows, endpoint readbacks, finite radius rows, componentwise transport, replay, provenance, and local naming. It has no coordinate for a host inverse function, selected inverse choice, host function equality, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformInverseModulusUp.UniformInverseModulusTasteGate single carrier alignment`

Theorem 4435.2 (Uniform inverse modulus obligations)**.** *For every accepted* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the compact source, target metric, homeomorphism graph, inverse graph, precision, finite-net, inverse-radius, radius-fold, target-estimate, transport, replay, provenance, and local naming rows;*
2. *inverse-graph exactness, requiring every inverse read to pass through the displayed row G attached to the homeomorphism row F;*
3. *compact finite-net handoff, requiring the compact source row X and precision row E to determine the finite row N before any inverse radius is folded;*
4. *finite radius fold, requiring M to be obtained only by folding the pointwise inverse radius rows R over the finite indices of N;*
5. *target estimate, requiring T to combine compact-net coverage, inverse-graph exactness, folded-radius data, and the target metric ledger;*
6. *transport, replay, and provenance, requiring H, C, P, A to source the same displayed route componentwise;*
7. *nonescape, requiring the packet to export no host inverse function, selected inverse choice, host function equality, quotient real equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 5835.1. The projection exposes exactly the rows $X, Y, F, G, E, N, R, M, T, H$ so carrier admission and row inventory are finite.

The inverse read is confined to G. Since G is listed as a row of the same homeomorphism packet that supplies F, inverse-graph exactness is consumed as displayed graph data rather than as host function equality or selected inverse choice.

The compact handoff reads X and E before radius data. These rows determine the finite net N, and the pointwise inverse radii in R are indexed only by the centers listed by N.

Fold R over that finite index list to obtain M. The target estimate row T then combines the compact-net coverage, inverse-graph exactness, folded radius, and target metric triangle route. Finally H, C, P, A transport, replay, source, and name the same route, so no excluded equality, choice, open-cover, trichotomy, or completeness coordinate is introduced. □

Theorem 4435.3 (Uniform inverse modulus compact handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *export from an accepted* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A)$$

factors through the displayed finite route

$$X, F, G, E \longmapsto N, R \longmapsto M, T \longmapsto H, C, P, A.$$

Thus the inverse-modulus export is a compact finite-net and radius-fold handoff. It exports no host function equality, selected inverse choice, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from a $\mathsf{UniformModulus}^{\uparrow}$ consumer of I. By Definition 5835.2, the consumer must read the compact source, homeomorphism graph, inverse graph, and precision rows before the finite-net row is available.

The only finite-net row is N, and the only pointwise inverse-radius inventory is R. Hence the consumer reaches the exported modulus row M only after the finite fold over R indexed by N.

The target estimate T is downstream of that fold. It cannot be read as a host inverse function or as quotient equality of inverse values, because the carrier contains only displayed graph and metric-ledger rows.

Finally the structural rows H, C, P, A transport, replay, source, and name the same compact route. Since the carrier contains no coordinate for selected inverse choice, trichotomy, open-cover compactness, or ambient completeness, the export factors through exactly the displayed finite-net and radius-fold handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformInverseModulus}^{\uparrow}$ packet is generated from UniformHomeomorphism graph and inverse-graph rows, CompactMetric finite-net rows, ContinuousMap pointwise inverse-radius rows, UniformModulus export rows, MetricSpace distance ledgers, RealUp and RegSeqRat endpoint readbacks, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$, seed)

Scope closed: Definition 5835.1, Definition 5835.2, and Definition 5835.3 seed the finite compact route from displayed inverse radii to a UniformModulus consumer.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient completeness, host inverse functions, selected inverse choice, quotient real equality, trichotomy, open-cover compactness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inverse-graph exactness, compact finite-net handoff, finite radius fold, target estimate, transport, replay, provenance, and local naming for BEDC.Derived.UniformInverseModulusUp.

Chapter 4436

A Concrete Naming Certificate for $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$

Following Bishop and Bridges on constructive real intervals, the $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ packet records a bounded interval together with the finite nested-window route used by Real and completion consumers. It sits over the dyadic rational arithmetic of chapter 291, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names a bounded interval principle for displayed nested windows; it does not assert open-cover compactness, a global supremum operator, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4436.1 (BoundedCompleteRealInterval carrier)**.** *A* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded interval row. It records the inspected lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, the boundedness witness visible to the packet, and the local containment predicate for interval windows.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger. It records the dyadic rational cuts used to compare successive windows and to certify the displayed diameter bound.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It lists exactly the finite endpoint and interval observations that may be inspected by the nested-window route.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same dyadic cuts and stream windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by every Real-facing extraction from B, D, W, R.*
6. *H records componentwise* hsame *transport for bounded interval rows, dyadic ledgers, stream windows, regular rational readbacks, Real seals, replay, provenance, and the local name.*
7. *C records displayed* Cont *replay from a nested-window request through B, D, W, R, E.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, D, W, R, E, H, C, P, N$. There is no coordinate for open-cover compactness, a selected supremum, host interval equality, quotient equality of Real names, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedCompleteRealIntervalUp.TasteGate.BoundedCompleteRealIntervalTasteGate single carrier alignment`

Theorem 4436.2 (BoundedCompleteRealInterval NameCert obligations)**.** *For every accepted* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier*

$$I = (B, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded interval row, dyadic endpoint ledger, stream windows, regular rational readback, Real seal, componentwise transport, continuation replay, package provenance, and local naming row;*
2. *bounded-window visibility, requiring every interval read to pass through the displayed lower-upper row B and its local containment predicate;*
3. *dyadic diameter discipline, requiring D to witness the inspected endpoint comparisons and the shrinking-width estimates used by the extraction route;*
4. *stream-readback exactness, requiring W and R to reuse the same finite endpoint observations and dyadic cuts rather than selecting a second Real representative;*
5. *Real-seal nonescape, requiring every Real-facing output to pass through E after B, D, W, R have all been projected;*
6. *structural preservation through H, C, P, N, with no exported row for open-cover compactness, selected suprema, host interval equality, quotient Real equality, countable choice, trichotomy, or ambient Real completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5836.1. The accepted packet displays exactly the bounded interval row, dyadic endpoint ledger, stream windows, regular rational readback, Real seal, and the structural rows.

Bounded-window visibility is forced by B. A consumer can inspect only the finite lower-upper interval data and the local containment predicate already present in the carrier.

Dyadic diameter discipline is forced by D. The endpoint comparisons and shrinking-width estimates used by the packet are the only numerical rows available to the later stream and readback rows.

The rows W and R are downstream of the same dyadic ledger. They schedule finite observations and repack them as regular rational readback without replacing the bounded interval by a second Real representative.

Finally, E, H, C, P, N close the route. The Real seal is reached only after B, D, W, R, while transport, replay, provenance, and naming preserve the same displayed data. Since no excluded coordinate occurs in the carrier, the local NameCert surface has exactly the listed obligations. □

Theorem 4436.3 (BoundedCompleteRealInterval nested-interval extraction)**.** *Let $I = (B, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier. Every nested-window extraction exported by I factors through the finite route*

$$B \longmapsto D \longmapsto W \longmapsto R \longmapsto E$$

before it can inspect transport, replay, provenance, or local naming rows. The extracted Real-facing read is therefore determined by the bounded interval row, the dyadic diameter ledger, the stream windows, and the regular rational readback visible in the packet.

Proof. Begin with a nested-window extraction from I. The carrier gives no source row before the bounded interval row B, so the lower-upper interval data and local containment predicate are inspected first.

The extraction then projects the dyadic ledger D. This fixes the endpoint comparisons and diameter estimates available to the finite window schedule.

Next the extraction passes through W and R. The stream row exposes only the finite endpoint observations allowed by B, D, and the regular rational row repacks those same observations as the readback consumed by the Real seal.

Only after this route has been displayed can the extraction reach E. The remaining rows H, C, P, N preserve, replay, source, and name the same route, so the exported extraction is exhausted by the displayed bounded-window data. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5836.1, Definition 5836.2, and Definition 5836.3 seed the bounded real interval packet over dyadic endpoint ledgers, StreamName windows, RegSeqRat readbacks, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, a global supremum operator, host interval equality, quotient real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-window visibility, dyadic diameter discipline, stream-readback exactness, Real-seal nonescape, structural preservation, and nested-window extraction for BEDC.Derived.BoundedCompleteRealIntervalUp.

Constructive story: A $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ packet is generated from a bounded Real interval row, a DyadicRatCore endpoint ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4437

A Concrete Naming Certificate for $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Mac Lane on functoriality, the $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ packet records the finite BEDC surface where a displayed real-completion request is read functorially through bounded windows rather than through a quotient completion object. It sits over the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the completion-map discipline of chapter 1937. The packet gives downstream completion consumers one named window-functor route before any quotient stream, selected limit, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle is available.

Definition 4437.1 (RealCompletionWindowFunctor carrier)**.** *A* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (W, D, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row naming the source and target observation windows used by the completion request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the source and target windows at the requested precision.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and tolerances.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, D, R have all been displayed.*
5. *F is the functorial map row, read through* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$*, recording how the displayed source window is transported to the displayed target window.*
6. *H records componentwise* hsame *transport for W, D, R, E, F, C, P, N.*
7. *C records displayed* Cont *replay from a completion-window request through W, D, R, E, F, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the nine displayed rows. It has no coordinate for quotient completion classes, selected representatives, host real equality, countable-choice schedules, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealCompletionWindowFunctorUp.RealCompletionWindowFunctorTasteGate single carrier alignment`

Theorem 4437.2 (RealCompletionWindowFunctor NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *carrier*

$$Q = (W, D, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed finite packet* Q*;*
2. *analytic readback order* $W \longmapsto D \longmapsto R \longmapsto E$*;*
3. *functorial map exposure through the row* F *over the same windows and tolerances;*
4. *structural stability through* hsame *transport and displayed* Cont *replay;*
5. *provenance and local naming through* P *and* N*.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5777.1. The accepted packet displays exactly $W, D, R, E, F, H, C, P, N$, so every local NameCert read must be a read of one of those coordinates.

The analytic route is ordered by the displayed rows. The finite StreamName windows W are inspected before the dyadic tolerance ledger D, the regular rational readback R, and the terminal Real seal E.

The functorial row F is attached to the same window and tolerance ledger through $\mathsf{CauchyCompletionFunctoriality}$ Thus a completion consumer receives only the displayed map action on the finite route, not a quotient completion map or a selected representative.

Finally the rows H, C, P, N transport, replay, source, and name the same packet. Since no excluded object occurs as a carrier coordinate, no additional local obligation is available. □

Theorem 4437.3 (RealCompletionWindowFunctor finite route)**.** *Every completion-facing read exported by an accepted* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *carrier factors through the finite route*

$$W \longmapsto D \longmapsto R \longmapsto E \longmapsto F \longmapsto H, C, P, N.$$

Consequently the functorial completion-map row is consumed only after the StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, and Real seal boundary have been displayed inside the same packet.

Proof. Apply Definition 5777.2. Its obligation surface exposes exactly carrier admission, analytic readback order, functorial map exposure, structural stability, provenance, and local naming.

Read the analytic side first. The rows W, D, R, E display the finite observation windows, dyadic tolerance ledger, regular rational readback, and terminal Real seal.

Then read the functorial side through F and the structural rows. The rows H, C, P, N keep that map action attached to the same finite packet. Therefore the completion consumer cannot detach the functorial map from the displayed window route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5777.1, Definition 5777.2, and Definition 5777.3 seed the finite completion-window functor route over StreamName, DyadicRatCore, RegSeqRat, Real, CauchyCompletionFunctoriality, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, full functor laws for all completion objects, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window order, tolerance readback, Real-seal routing, functorial-map exposure, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionWindowFunctorUp.

Constructive story: A $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a terminal Real seal, a CauchyCompletionFunctoriality map row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4438

A Concrete Naming Certificate for $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$

The $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ packet realizes the Real and Completion route of chapter 9238 as finite window-functor data before any completion consumer reads a limit-facing object. It binds the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the displayed completion functor row of chapter 5777. The packet names a finite completion-window functor surface for the Real completeness spine; it does not assert quotient completion equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4438.1 (RealCompletenessWindowFunctor carrier)**.** *A* $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (V, W, D, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *V is the originating Real-completeness request row read from chapter 9238.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row exposed before any regular-rational or Real-seal read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same window request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that consumes W and D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, D, R have been displayed.*
6. *F is the* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *row that packages the finite functorial completion handoff.*
7. *H records componentwise* hsame *transport for $V, W, D, R, E, F, C, P, N$.*
8. *C records displayed* Cont *replay from a Real-completeness request through $V, W, D, R, E, F, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$, $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten rows. It has no coordinate for quotient completion classes, selected representatives, countable-choice schedules, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 4438.2 (RealCompletenessWindowFunctor NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ *carrier*

$$Q = (V, W, D, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission, originating Real-completeness request exposure, StreamName window exposure, DyadicRatCore tolerance exposure, RegSeqRat readback exposure, Real seal exposure, finite completion-window functor exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Carrier admission is projection from Definition 5778.1. The tuple displays exactly $V, W, D, R, E, F, H, C, P, N$ so the local NameCert can inspect only those rows.

The Real-completeness request row V is read before the finite analytic route. The rows W, D, R, E then display StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and the terminal Real seal.

The functorial row F is the only completion-window handoff. It packages the Real-completion functorial read after the displayed analytic route rather than replacing it by a quotient completion object.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded coordinate occurs, no additional local obligation is available. □

Falsifiable prediction: Every accepted $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ read displays $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ seal rows before any completion consumer reads the packet.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchycompletionfunctoriality: $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ is not bijective to any listed sibling because it jointly retains the originating Real-completeness request, finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, Real seal, completion-window functor row, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5778.1 and Definition 5778.2 seed the finite Real-completeness completion-window functor route over StreamName, DyadicRatCore, RegSeqRat, Real, RealCompletionWindowFunctor, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, full Real-completeness proof, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request exposure, finite-window exposure, tolerance exposure, regular readback, Real-seal exposure, completion-window functor exposure, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletenessWindowFunctorUp.

Constructive story: A $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ packet is generated from a Real-completeness request row, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, a RealCompletionWindowFunctor row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4439

A Concrete Naming Certificate for $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ packet records the explicit modulus route by which a bounded compact-real sequence yields inspected subsequence windows before any downstream consumer reads a real cluster seal. It sits over the constructive subsequence packet of chapter 5830, the sibling Bolzano–Weierstrass route of chapter 1254, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite subsequence-modulus carrier for compact-real consumers; it is not an open-cover compactness theorem, not an arbitrary-choice selector, not quotient real equality, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4439.1 (Compact real subsequence modulus carrier)**.** *A* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, S, B, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact real source row, exposing the bounded* $\mathsf{Real}^{\uparrow}$ *sequence request and the compact-metric inspection data visible to the packet.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing exactly the finite source windows inspected by the modulus.*
3. *B is the* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ *and* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *route row, carrying the interval-refinement and subsequence scheduling surface without adding a host compactness principle.*
4. *W is the subsequence-modulus row, recording selected indices, monotonicity, cofinal scheduling, and the finite window assignment for each requested precision.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording radius requests, split budgets, comparison windows, and common-scale data used by the selected windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same selected windows and tolerance ledger.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *cluster seal, visible only after K, S, B, W, D, R have been displayed.*
8. *H records componentwise* hsame *transport for the source, stream windows, route, modulus, tolerance, readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a compact-real subsequence request through source inspection, stream windows, route selection, modulus scheduling, dyadic tolerance accounting, regular rational readback, and the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$, $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, S, B, W, D, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, arbitrary choice, quotient real equality, selected least cluster points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactRealSubsequenceModulusUp.TasteGate.CompactRealSubsequenceModulusTasteGate single carrier alignment`

Theorem 4439.2 (Compact real subsequence modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ *carrier*

$$M = (K, S, B, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}$ *surface consists exactly of compact real source exposure through K, finite stream-window exposure through S, constructive Bolzano–Weierstrass route exposure through B, subsequence-modulus scheduling through W, dyadic tolerance accounting through D, regular rational readback through R, terminal real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5779.1. Its analytic rows are the compact real source K, stream windows S, constructive route B, subsequence modulus W, tolerance ledger D, regular readback R, and real seal E.

The modulus obligation is finite because W records selected indices, monotonicity, cofinal scheduling, and selected windows as packet data. The route row B imports the displayed ConstructiveBolzanoWeierst and $\mathsf{BolzanoWeierstrass}^{\uparrow}$ subsequence construction rather than an ambient compactness theorem.

The readback obligation then passes through D and R. The same selected windows receive the dyadic tolerance budget before they can be read as a $\mathsf{RegSeqRat}^{\uparrow}$ sequence.

Finally E, H, C, P, N seal, transport, replay, source, and name only those rows. Since the carrier contains no open-cover, arbitrary-choice, quotient-equality, selected-least-cluster, or ambient-completeness coordinate, the listed rows exhaust the local certificate surface. □

Theorem 4439.3 (Constructive Bolzano–Weierstrass modulus route)**.** *Every* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ *consumer that reads a compact real subsequence route from an accepted carrier must factor through*

$$\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow},\quad \mathsf{BolzanoWeierstrass}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

The factorization exposes finite source windows, a displayed subsequence-modulus row, dyadic tolerance accounting, regular rational readback, and a terminal real seal; it exports no open-cover compactness, arbitrary-choice selector, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Apply Definition 5779.2. It places the constructive and sibling Bolzano–Weierstrass route row before the modulus row and before any regular rational readback.

The finite windows are exactly the row S, and the selected windows are exactly the row W. Thus any consumer that changes the source window or selected window must leave the displayed carrier.

The dyadic tolerance ledger D is read before R, and R is read before the terminal real seal E. This orders the packet through the stated route and prevents the excluded host principles from entering the subsequence-modulus handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5779.1, Definition 5779.2, and Definition 5779.3 seed the explicit compact-real subsequence-modulus route through finite windows, dyadic tolerances, regular readback, and real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, arbitrary choice, quotient real equality, selected least cluster points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exactness, constructive Bolzano–Weierstrass route exposure, subsequence-modulus scheduling, dyadic tolerance accounting, RegSeqRat readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactRealSubsequenceModulusUp.

Constructive story: A $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ packet is generated from compact real source data, finite StreamName windows, ConstructiveBolzanoWeierstrass and BolzanoWeierstrass route data, subsequence-modulus scheduling, DyadicRatCore tolerance accounting, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Chapter 4440

A Concrete Naming Certificate for MetaCICNormalEndpointComparator$^{\uparrow}$

The MetaCICNormalEndpointComparator$^{\uparrow}$ packet realizes the bounded-conversion endpoint bridge named by the MetaCIC decidability audit map of chapter 9379. It sits between the bounded normal conversion bridge of chapter 3439, the decidable conversion frontier of chapter 4097, the normalization frontier of chapter 892, the normal-form consistency seal of chapter 740, and the critical-path packet of chapter 765. The packet is a finite comparator for finished bounded normal endpoints; it is not a global beta-conversion decider, not a strong-normalization theorem, and not a host equality oracle.

Definition 4440.1 (MetaCIC normal endpoint comparator carrier)**.** *A* MetaCICNormalEndpointComparator$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, L, R, B, F, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed closed-term pair row supplied by the decidable conversion frontier.*
2. *L and R are the left and right bounded-normal computation traces, each carrying fuel, output syntax, and finished-endpoint evidence.*
3. *B is the* BoundedNormalConversionBridge$^{\uparrow}$ *row, exposing the bounded comparison result and its soundness route.*
4. *F is the* MetaCICNormalizationFrontier$^{\uparrow}$ *row, recording that both bounded traces have reached named normal endpoints at the comparator fuel.*
5. *S is the* NormalFormConsistencySeal$^{\uparrow}$ *row, checking that the two endpoint witnesses are read through the same normal-form consistency surface.*
6. *Q is the* MetaCICCriticalPath$^{\uparrow}$ *row that keeps the comparator tied to the decidability and normalization critical path rather than to an unrestricted conversion oracle.*
7. *H records componentwise* hsame *transport for the term pair, endpoint traces, bridge, frontier, seal, critical-path, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a bounded conversion request through endpoint computation, finished-normal evidence, endpoint comparison, consistency sealing, and critical-path accounting.*

9. *P is the* Pkg *provenance over* MetaCICNormalEndpointComparator$^{\uparrow}$, MetaCICDecidableConversionFrontier$^{\uparrow}$, BoundedNormalConversionBridge$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, NormalFormConsistencySeal$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, L, R, B, F, S, Q, H, C, P, N$. It has no coordinate for unrestricted conversion decidability, fuel-erased normalization, strong normalization, proof irrelevance, quotienting of syntax, or host equality.

Theorem 4440.2 (MetaCIC normal endpoint comparator NameCert obligations)**.** *For every accepted* MetaCICNormalEndpointComparator$^{\uparrow}$ *carrier*

$$E = (T, L, R, B, F, S, Q, H, C, P, N),$$

the local NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$ *surface consists exactly of typed closed-term pair admission through T, left and right bounded endpoint traces through L, R, bounded conversion bridge exposure through B, normalization-frontier endpoint evidence through F, normal-form consistency sealing through S, critical-path accounting through Q, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5780.1. The computational rows are exactly the term pair T, the endpoint traces L, R, the bounded conversion bridge B, the normalization frontier F, the consistency seal S, and the critical-path row Q.

The endpoint evidence is finite because L and R carry bounded traces at a displayed fuel. The row F records that those traces have reached finished normal endpoints before the comparator is consumed.

The comparison then passes through B and S. The bridge supplies the bounded conversion handoff, and the seal checks that the endpoint witnesses are compared through the same normal-form consistency surface.

Finally Q, H, C, P, N keep the packet on the MetaCIC critical path, transport it componentwise, replay it, source it, and name it. Since the carrier contains no unrestricted conversion, fuel-erased normalization, strong-normalization, proof-irrelevance, syntax-quotient, or host-equality coordinate, the listed rows exhaust the local certificate surface. □

Theorem 4440.3 (Bounded conversion endpoint handoff)**.** *Every* MetaCICNormalEndpointComparator$^{\uparrow}$ *consumer that promotes bounded conversion evidence to a finished endpoint comparison must factor through*

MetaCICDecidableConversionFrontier$^{\uparrow}$, BoundedNormalConversionBridge$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, No

The handoff supplies only typed closed-term pair data, bounded traces, finished endpoint evidence, endpoint consistency, critical-path accounting, transport, replay, provenance, and local naming.

Proof. Use Definition 5780.2. The typed closed-term pair is read first through T, while L and R record the bounded normal computations to be compared.

The row F is the endpoint boundary: it must be displayed before a bounded comparison can be read as a finished normal-form comparison. The bridge row B and seal row S then compare those endpoints through the bounded-conversion and normal-form consistency surfaces.

The critical-path row Q prevents the handoff from being read as a global conversion theorem. The structural rows H, C, P, N preserve and name only this finite route, so the consumer receives no unrestricted conversion decider or host equality oracle. □

Theorem 4440.4 (Closed-normal comparator vision obligations)**.** *The* MetaCICNormalEndpointComparator$^{\uparrow}$ *packet exposes exactly the finite comparator surface consumed by chapter 9376: closed normal endpoint rows, false-endpoint exclusion rows, and comparator determinacy rows are read through the displayed term pair T, bounded traces L, R, bounded conversion bridge B, normalization frontier F, normal-form consistency seal S, critical-path row Q, componentwise transport H, replay C, provenance P, and local naming N. No consumer of this surface receives unrestricted conversion decidability, fuel-erased normalization, proof irrelevance, syntax quotient equality, or host equality.*

Proof. Project the carrier of Definition 5780.1. The closed normal endpoint rows are precisely the finished bounded traces L, R read together with the normalization-frontier evidence F.

The false-endpoint exclusion row is read through the normal-form consistency seal S and the critical-path row Q. Those rows are the only coordinates tying the finished endpoint comparison to the closed-normal consistency boundary of chapter 9376.

Comparator determinacy is then read through the bounded conversion bridge B over the same typed pair T. The structural rows H, C, P, N transport, replay, source, and name this finite route.

Since the carrier contains no unrestricted conversion decider, fuel-erased normalizer, proof-irrelevance coordinate, syntax quotient, or host equality oracle, the listed rows are the complete comparator obligation surface consumed by the closed-normal consistency route. □

Falsifiable prediction: A MetaCIC conversion consumer that reads a finished endpoint comparison while omitting either bounded endpoint trace, the bounded-normal-conversion bridge, the normalization-frontier endpoint evidence, the normal-form consistency seal, the critical-path row, transport, replay, provenance, or local naming refutes MetaCICNormalEndpointComparator$^{\uparrow}$.

Independence witness: metacic-decidable-conversion-frontier, bounded-normal-conversion-bridge, metacicnormalizationfrontier, normal-form-consistency-seal, metaciccriticalpath: MetaCICNormalEndpointCompara is not bijective to any listed sibling because it jointly carries typed closed-term pair data, two bounded endpoint traces, bounded conversion bridge data, finished-normal endpoint evidence, consistency sealing, critical-path accounting, transport, replay, provenance, and local NameCert rows in one comparator packet.

The Lean follow-up must provide explicit Nontrivial MetaCICNormalEndpointComparator$^{\uparrow}$ and FieldFaithful MetaCICNormalEndpointComparator$^{\uparrow}$ instances in TasteGate.lean for the same finite carrier.

Closure status for NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$, seed)

Scope closed: Definition 5780.1, Definition 5780.2, and Definition 5780.3 seed the finite comparator that hands bounded conversion evidence to finished normal endpoints.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim unrestricted conversion decidability, fuel-erased normalization, strong normalization, proof irrelevance, quotient syntax equality, host equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint trace exactness, bounded bridge exposure, normalization-frontier endpoint evidence, normal-form consistency sealing, critical-path accounting, transport, replay, provenance, local naming, and TasteGate nontriviality with field faithfulness for BEDC.Derived.MetaCICNormalEndpointComparatorUp.

Constructive story: A MetaCICNormalEndpointComparator$^{\uparrow}$ packet is generated from typed closed-term pair data, two bounded endpoint traces, BoundedNormalConversionBridge data, MetaCICNormalizationFrontier endpoint evidence, NormalFormConsistencySeal data, MetaCICCriticalPath accounting, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Chapter 4441

A Concrete Naming Certificate for ContinuousRiemannIntegrability$^{\uparrow}$

Following Riemann and Bishop–Bridges constructive integration, the ContinuousRiemannIntegrability$^{\uparrow}$ packet records the finite route by which a continuous function on a located closed real interval receives a Darboux/Riemann integrability certificate. It consumes the pointwise-modulus surface of chapter 59, the tag-bearing finite interval route of chapter 4296, the Darboux upper/lower boundary of chapter 1880, the integrability carrier of chapter 1960, the weak located interval selector of chapter 5834, and the real-name seal of chapter 38. The packet gives integration consumers a finite NameCert surface for continuous functions without importing measure integration, open-cover compactness, quotient equality of real names, selected limiting values, or ambient Real$^{\uparrow}$ completeness.

Definition 4441.1 (Continuous Riemann integrability carrier)**.** *A* ContinuousRiemannIntegrability$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, T, D, J, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* Continuous$^{\uparrow}$ *row exposing the pointwise modulus and graph-stability data of the integrand over the displayed interval source.*
2. *T is the* TaggedRealPartition$^{\uparrow}$ *row naming the finite partition cells, tag containment, window reads, regular readbacks, and terminal real seals used for integration.*
3. *D is the* DarbouxSum$^{\uparrow}$ *row carrying lower and upper finite sums over the same displayed partition route.*
4. *J is the* RiemannIntegrable$^{\uparrow}$ *handoff row, read only after the Darboux gap row has been displayed.*
5. *W is the* WeaklyLocatedIntervalSelection$^{\uparrow}$ *row that exposes located cells and endpoint windows for the closed interval source.*
6. *S is the* StreamName$^{\uparrow}$ *finite-window family opened for interval endpoints, partition tags, and pointwise modulus reads.*
7. *R is the* RegSeqRat$^{\uparrow}$ *readback family attached to the same finite windows.*
8. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after F, T, D, J, W, S, R have been displayed.*

9. *H records componentwise* hsame *transport for the continuous row, tagged partition, Darboux rows, integrability handoff, weak interval selector, window and readback rows, real seal, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from pointwise modulus requests through located cells, finite tagged partitions, Darboux lower/upper rows, the integrability handoff, and the terminal real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, T, D, J, W, S, R, E, H, C, P, N$. It has no coordinate for full integration theory, measure integration, open-cover compactness, quotient equality, selected limits, or ambient real completeness.

Theorem 4441.2 (Continuous Riemann integrability NameCert obligations)**.** *For every accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier*

$$I = (F, T, D, J, W, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the finite* BHist *packet and the displayed rows $F, T, D, J, W, S, R, E, H, C, P, N$;*

2. *interval-source visibility through the weakly located interval row W and its located cell, endpoint-window, and regular-readback route;*

3. *pointwise modulus exposure through the continuous-function row F, with every modulus read tied to displayed interval cells and finite windows;*

4. *finite tagged partition coverage through T, including cell containment, tag containment, and the same* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows;*

5. *Darboux gap control through D, read as finite lower and upper sums over the displayed tagged partition route;*

6. *integrability handoff through J, allowed only after the Darboux gap row and partition coverage rows are visible;*

7. *Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No full integration theory, measure integration, open-cover compactness, quotient equality of real names, selected limiting value, Lean verification, or bridge checking is an obligation or output of this packet.

Proof. Carrier admission is the projection of Definition 5838.1. The accepted packet displays the continuous row, tagged partition, Darboux row, integrability handoff, weak interval selector, window family, regular readback, real seal, transport, replay, provenance, and local name.

The interval and modulus rows are read first. The row W supplies located cells and endpoint windows, while F supplies pointwise modulus data only over those displayed cells and windows.

The finite partition route is then exposed by T. Tags and endpoints are read through S and R, so the integration-facing partition is a finite BEDC object rather than a host partition or a selected representative family.

The Darboux and integrability rows are downstream. The row D computes lower and upper finite sums over the displayed partition route, and J exports integrability evidence only after that gap control is visible.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no coordinate for the excluded analytic objects, the listed rows exhaust the local NameCert surface. □

Theorem 4441.3 (Continuous Riemann integrability Darboux handoff)**.** *Every integration-facing consumer of an accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier factors through the finite partition and Darboux rows*

$$W, F \longmapsto T, S, R \longmapsto D \longmapsto J \longmapsto E, H, C, P, N.$$

Consequently the consumer receives a finite located-cell, pointwise-modulus, tagged-partition, lower/upper Darboux, integrability-handoff, and Real-seal route rather than quotient reals, host equality, choice-selected witnesses, or ambient Real completeness.

Proof. Begin with an integration-facing read. The weak interval selector W and continuous row F force the request through located cells, endpoint windows, and pointwise modulus rows before any partition or sum row can be inspected.

Next read the tagged partition route T, S, R. The finite cells and tags are displayed together with their StreamName windows and RegSeqRat readbacks, so later rows cannot detach the partition from the interval source.

The Darboux row D is then read as lower and upper finite sums over those displayed cells and tags. The integrability row J is therefore a handoff from finite Darboux gap control, not from a quotient real or host equality judgment.

The terminal seal and structural rows E, H, C, P, N preserve that route. No excluded object is stored in the carrier, so every consumer factors through the displayed finite partition and Darboux rows. □

Theorem 4441.4 (Continuous Riemann integrability uniform-modulus handoff)**.** *Every accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier whose continuous row factors through a displayed uniform-modulus or composed-modulus route passes the Darboux gap and* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff through the finite chain*

$$\mathsf{Continuous}^{\uparrow},\ \mathsf{UniformContinuityComposition}^{\uparrow},\ \mathsf{TaggedRealPartition}^{\uparrow},\ \mathsf{DarbouxSum}^{\uparrow},\ \mathsf{RiemannIntegrable}^{\uparrow},\ \mathsf{StreamNar}$$

The handoff therefore reads composed modulus data before the Darboux row and exports no host integral selector, quotient function equality, open-cover compactness argument, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5838.1. The displayed rows are the continuous row F, tagged partition row T, Darboux row D, Riemann-integrable handoff J, weak interval selector W, StreamName windows S, RegSeqRat readbacks R, Real seal E, transport, replay, provenance, and local naming rows.

Use Definition 5838.2 for row exhaustion. When the continuous row is supplied by a uniform-modulus or composed-modulus route, the only admitted modulus source is the displayed $\mathsf{Continuous}^{\uparrow}$ row together with the $\mathsf{UniformContinuityComposition}^{\uparrow}$ composed-modulus handoff of chapter 3891.

Now apply Definition 5838.3. The tagged partition, Darboux lower and upper sums, and integrability row must be read after the same StreamName windows, RegSeqRat readbacks, and terminal Real seal, so the composed-modulus source cannot bypass the finite Darboux route.

Since the carrier stores no host integral selector, quotient function equality, open-cover compactness proof, or ambient completeness object, the listed finite rows are the whole uniform-modulus handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$.

Constructive story: A $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ packet is generated from a Continuous row, TaggedRealPartition row, DarbouxSum row, RiemannIntegrable handoff row, WeaklyLocatedIntervalSelection row, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5838.1, Definition 5838.2, Definition 5838.3, and Definition 5838.4 seed the finite Darboux/Riemann integrability route for continuous functions on located closed real intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full integration theory, measure integration, open-cover compactness, quotient equality, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source visibility, pointwise modulus exposure, finite tagged partition coverage, Darboux gap control, integrability handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ContinuousRiemannIntegrabilityUp.

Chapter 4442

A Concrete Naming Certificate for $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy approximations, the $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ packet binds Cauchy mesh refinement, cofinal dyadic mesh selection, and diagonal Real mesh budgets into one finite common-refinement route. It sits over the two-request refinement carrier of chapter 3832, the cofinal dyadic selector of chapter 2254, the diagonal mesh-budget surface of chapter 618, and the terminal real-name seal of chapter 38. The packet gives Real-completeness consumers a finite cofinal mesh handoff without quotient streams, selected limits, countable choice, host real equality, or ambient completeness as an extra row.

Definition 4442.1 (Regular Cauchy mesh cofinality carrier)**.** *A* $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, R, D, B, S, A, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyMeshRefinement}^{\uparrow}$ *row exposing source Cauchy requests, two displayed dyadic meshes, and their common finite refinement.*
2. *R is the* $\mathsf{CofinalDyadicMesh}^{\uparrow}$ *row refining the incoming observation request to a dyadic mesh window.*
3. *D is the* $\mathsf{RealDiagonalMeshBudget}^{\uparrow}$ *row listing the inspected diagonal indices, selected windows, dyadic tolerances, and aggregation ledger.*
4. *B is the shared budget row aligning the request precision of Q, the cofinal selector depth of R, and the diagonal finite mesh budget of D.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened by the shared budget.*
6. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family over the same windows, with all dyadic tolerances read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, R, D, B, S, A have been displayed.*
8. *H records componentwise* hsame *transport for the refinement row, cofinal selector row, diagonal budget row, shared budget, window and readback rows, seal row, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from an observation request through*

$$Q, R, D \longmapsto B \longmapsto S \longmapsto A \longmapsto E.$$

10. *P is the* Pkg *provenance over* RegularCauchyMeshCofinality$^{\uparrow}$, CauchyMeshRefinement$^{\uparrow}$, CofinalDyadicMesh$^{\uparrow}$, RealDiagonalMeshBudget$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{RegularCauchyMeshCofinality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, R, D, B, S, A, E, H, C, P, N$. It has no coordinate for quotient streams, hidden subnets, selected limits, countable-choice schedules, host real equality, trichotomy, or ambient Real completeness.

Theorem 4442.2 (Regular Cauchy mesh cofinality NameCert obligations)**.** *For every accepted* RegularCauchyMeshCofinality$^{\uparrow}$ *carrier*

$$K = (Q, R, D, B, S, A, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyMeshCofinality}^{\uparrow}}$ *surface consists exactly of carrier admission, Cauchy mesh-refinement exposure through Q, cofinal dyadic mesh exposure through R, Real diagonal mesh-budget exposure through D, shared precision and mesh-budget alignment through B, finite* StreamName$^{\uparrow}$ *window exposure through S,* RegSeqRat$^{\uparrow}$ *readback and* DyadicRatCore$^{\uparrow}$ *tolerance visibility through A, terminal* Real$^{\uparrow}$ *seal admission through E, componentwise transport through H, route replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 5839.1. The accepted packet displays exactly the Cauchy refinement, cofinal selector, diagonal budget, shared budget, windows, readbacks, seal, transports, replay, provenance, and local name.

The three mesh sources are read before any Real-facing seal. The row Q displays the common refinement of source Cauchy meshes, R displays the cofinal dyadic selector for the observation request, and D displays the finite diagonal mesh budget.

The shared row B aligns these sources. It is the only place where the precision request, cofinal selector depth, and diagonal inspected indices meet, so the window row S and regular readback row A inherit one finite route.

The seal and structural rows E, H, C, P, N preserve that route. Since the carrier has no coordinate for the excluded completion objects, the listed rows exhaust the local certificate surface. □

Theorem 4442.3 (Regular Cauchy mesh cofinality Real-completeness handoff)**.** *Every Real-completeness or diagonal-limit consumer of an accepted* RegularCauchyMeshCofinality$^{\uparrow}$ *carrier receives its seal-facing data only through the cofinal finite route*

$$Q, R, D \longmapsto B \longmapsto S \longmapsto A \longmapsto E, H, C, P, N.$$

Thus the consumer factors through Cauchy mesh refinement, cofinal dyadic mesh selection, Real diagonal mesh budgeting, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, and the RealUp seal before any completion-facing conclusion is exported.

Proof. Start from a Real-completeness consumer request. The packet first exposes Q, so the two source Cauchy requests and their common refinement are finite displayed data.

The request then passes through R and D. The cofinal dyadic selector supplies a finite mesh window, while the diagonal mesh-budget row supplies the finite inspected indices and dyadic tolerance ledger.

The budget row B is the common meeting point. It forces the StreamName windows S and RegSeqRat readbacks A to use the same finite refinement and the same dyadic tolerance rows.

Only after this route is displayed may the Real seal E be read. Transport, replay, provenance, and local naming preserve the route, and the excluded quotient or choice-based completion objects are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ packet is generated from CauchyMeshRefinement, CofinalDyadicMesh, RealDiagonalMeshBudget, a shared precision and mesh-budget row, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5839.1, Definition 5839.2, and Definition 5839.3 seed the finite cofinal common-refinement mesh route used by Real-completeness and diagonal-limit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, hidden subnets, selected limits, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy mesh-refinement exposure, cofinal dyadic mesh exposure, Real diagonal mesh-budget exposure, shared-budget alignment, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance visibility, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMeshCofinalityUp.

Chapter 4443

A Concrete Naming Certificate for $\mathsf{OneSidedLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{OneSidedLimit}^{\uparrow}$ packet records the left- and right-hand real-limit interface as finite BEDC data. It sits next to the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation schedule of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet names only displayed side-tagged approach windows, regular rational reads, dyadic tolerance rows, transport, replay, provenance, and a terminal Real seal; it does not import two-sided completeness, host real equality, quotient streams, trichotomy, or a selected limiting point.

Definition 4443.1 (One-sided limit carrier)**.** *A* $\mathsf{OneSidedLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, L, W, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the approach-anchor row, naming the source point or endpoint cell at which the one-sided read is taken.*
2. *L is the side classifier row, with each visible approach window tagged as left-hand or right-hand before any limiting seal is inspected.*
3. *W is the finite approach-window row, listing only windows compatible with the tag in L and the anchor in A.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by the side-tagged windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data observed on S.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the displayed one-sided comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from A, L, W, S, R, D.*
8. *H records componentwise* hsame *transport for the anchor, side classifier, windows, stream schedule, regular readback, dyadic ledger, Real seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from the side-tagged approach windows through the stream, readback, dyadic, and Real-seal rows.*
10. *P is the* Pkg *provenance over* $\mathsf{OneSidedLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $A, L, W, S, R, D, E, H, C, P, N$. It has no coordinate for a two-sided completion theorem, quotient real equality, host order trichotomy, countable choice, or a selected limit outside the named side-tagged windows.

Lean4 ✓ `BEDC.Derived.OneSidedLimitUp.OneSidedLimitTasteGate single carrier alignment`

Theorem 4443.2 (One-sided limit NameCert obligations)**.** *For every accepted* $\mathsf{OneSidedLimit}^{\uparrow}$ *carrier $K = (A, L, W, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the approach anchor, side classifier, approach windows, stream schedule, regular readback, dyadic ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *side classifier stability, requiring each transported window to retain its left-hand or right-hand tag before a readback row is consumed;*
3. *dyadic tolerance ledger exactness, requiring D to expose only the tolerance rows demanded by the side-tagged windows in W;*
4. $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring S and R to read only the finite observations selected by A, L, W;*
5. *Real seal nonescape, requiring E to remain downstream of A, L, W, S, R, D and never to serve as a two-sided completeness witness or host real equality row;*
6. *componentwise transport, replay, provenance, and local naming through H, C, P, N.*

No $\mathsf{OneSidedLimit}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5841.1. The accepted packet displays the approach anchor A, side classifier L, finite approach windows W, stream schedule S, regular readback R, dyadic ledger D, Real seal E, and structural rows H, C, P, N.

Side classifier stability is componentwise. A transported window may be read only with the left-hand or right-hand tag already recorded in L, and the replay row C keeps the same tag attached while the stream and regular-rational rows are inspected.

The tolerance and readback rows are downstream of the same finite windows. The ledger D records the dyadic comparisons demanded by W, the schedule S opens only those observations, and R records the regular rational readback.

Finally, the Real seal E is terminal for the route. Since the carrier contains no row for two-sided completeness, quotient real equality, host order trichotomy, countable choice, or a selected limit outside the displayed windows, those objects cannot become local obligations. □

Theorem 4443.3 (One-sided limit Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{OneSidedLimit}^{\uparrow}$ *packet reads the proposed one-sided limit only through the displayed finite route*

$$A, L, W, S, R, D, E, H, C, P, N.$$

Consequently the handoff to $\mathsf{Real}^{\uparrow}$ *is available only after the approach anchor, side classifier, finite approach windows, StreamName schedule, RegSeqRat readback, and DyadicRatCore tolerance ledger have been exposed. The handoff exports no two-sided completeness theorem, quotient stream equality, host real equality, order trichotomy, countable choice principle, or selected limiting point.*

Proof. Project the accepted carrier through Definition 5841.1. Its Real-facing row is the single terminal coordinate E, and the only route to E passes through A, L, W, S, R, D and the structural rows H, C, P, N.

The finite approach windows determine the side of approach before readback begins. Thus a consumer that asks for a Real seal must already have read the side classifier, the compatible windows, the stream schedule, the regular rational row, and the dyadic tolerance ledger.

The remaining coordinates transport and name the same route. Because no carrier row stores a two-sided completion principle, quotient equality, host equality, trichotomy, choice, or an independent selected limit, the Real-seal handoff cannot export any of those objects. □

Falsifiable prediction: Every $\mathsf{OneSidedLimit}^{\uparrow}$ Real-facing read factors through an approach anchor, a left/right side classifier, finite approach windows, a StreamName schedule, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{OneSidedLimit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a side classifier, finite approach windows, scheduled regular-rational readback, dyadic tolerance data, and a terminal Real seal in one one-sided packet.

Closure status for $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{OneSidedLimit}^{\uparrow}$ packet is generated from an approach anchor, a left/right side classifier, finite approach windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5841.1, Definition 5841.2, and Definition 5841.3 seed the finite one-sided real-limit route through side-tagged approach windows and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.OneSidedLimitUp.OneSidedLimitTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close two-sided real completeness, quotient stream equality, host real equality, trichotomy, countable choice, selected limits outside the displayed windows, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, side classifier stability, dyadic tolerance exactness, StreamName and RegSeqRat readback, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.OneSidedLimitUp.

Chapter 4444

A Concrete Naming Certificate for $\mathsf{BertrandSeriesTest}^{\uparrow}$

Following Bertrand's logarithmic refinement of ratio-type convergence tests and Bishop–Bridges constructive real-series practice, the $\mathsf{BertrandSeriesTest}^{\uparrow}$ packet records the finite second-order quotient-defect route that turns displayed positive-series tail data into a regular Cauchy comparison handoff. It sits beside the neighboring quotient-defect surfaces of chapter 1719, chapter 2113, and chapter 2130, refines the ratio and comparison routes of chapter 1461 and chapter 1459, and exports endpoints only through the dyadic, stream, regular-rational, and Real seals of chapter 291, chapter 126, chapter 301, and chapter 38. The packet names finite Bertrand-test evidence only through inspected source windows, adjacent quotient windows, a logarithmic defect ledger, dyadic domination, comparison-test routing, regular rational readback, and terminal Real sealing; it is not host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 4444.1 (Bertrand series test carrier)**.** *A* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Q, L, D, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source real-series row, exposing only positive-term windows, partial-sum windows, and tail-threshold requests used by the current convergence test.*
2. *Q is the adjacent quotient-window row, recording the inspected neighboring-term quotients on the same displayed tail window.*
3. *L is the logarithmic defect ledger, storing the finite index, logarithmic scale, rational margin, and second-order defect rows used by the Bertrand comparison.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *domination ledger, converting the displayed logarithmic defect and margin rows into a finite majorant or minorant comparison.*
5. *T is the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff row that consumes S, Q, L, D before any convergence conclusion is exposed.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the source, quotient, logarithmic defect, domination, and comparison rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after the comparison handoff and stream windows have been displayed.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint-facing consumers.*
9. *H stores componentwise* hsame *transport for the source, quotient, logarithmic defect, domination, comparison, window, readback, seal, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay from each tail request through Q, L, D, T, W, R, E.*
11. *P is the* Pkg *provenance over* $\mathsf{BertrandSeriesTest}^{\uparrow}$, $\mathsf{RaabeDuhamelTest}^{\uparrow}$, $\mathsf{KummerTest}^{\uparrow}$, $\mathsf{GaussTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, L, D, T, W, R, E, H, C, P, N$. It has no coordinate for host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BertrandSeriesTestUp.BertrandSeriesTestTasteGate single carrier alignment`

Theorem 4444.2 (Bertrand series test NameCert obligations)**.** *For every accepted* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier*

$$B = (S, Q, L, D, T, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source real-series windows, adjacent quotient windows, logarithmic defect ledger, dyadic domination ledger, comparison-test handoff, stream windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming row;*
2. *quotient-window exactness, requiring every quotient read used by the Bertrand defect to be read from the displayed neighboring positive-term windows in S and Q;*
3. *logarithmic-defect stability, requiring the finite index, logarithmic scale, rational margin, and second-order defect rows in L to remain attached to the accepted tail request;*
4. *dyadic domination routing, requiring D and W to convert the displayed logarithmic defect data into the same finite comparison windows consumed by T;*
5. *regular and Real handoff, requiring endpoint-facing data to pass through T, W, R, E in that order before a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives data;*
6. *ledger non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed rows and to exclude host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 5842.1. Carrier admission is exactly the inventory $S, Q, L, D, T, W, R, E, H, C$ so the local certificate has no detached row for an infinite sum, quotient series equality, selected sum, or ambient completeness theorem.

The quotient and logarithmic-defect clauses are read before the comparison handoff. The row S exposes only inspected positive-term and partial-sum windows, the row Q exposes only neighboring-term quotient windows, and L records the finite index, logarithmic scale, rational margin, and second-order defect attached to the current tail request.

The domination route is then forced through D, W, T. The dyadic ledger D converts the displayed logarithmic defect data into comparison evidence, the window row W fixes the finite stream windows, and the comparison-test row T is the only route that may export a regular Cauchy conclusion.

Finally, R and E supply the regular rational and Real-facing endpoint route. The structural rows H, C, P, N preserve, replay, source, and name the same route, so none of them can introduce host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge data. □

Theorem 4444.3 (Bertrand series test tail route)**.** *Every endpoint-facing read of an accepted* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier factors through*

$$\mathsf{RaabeDuhamelTest}^{\uparrow},\ \mathsf{KummerTest}^{\uparrow},\ \mathsf{GaussTest}^{\uparrow},\ \mathsf{RegularCauchyRatioTest}^{\uparrow},\ \mathsf{RegularCauchyComparisonTest}^{\uparrow},\ \mathsf{Dyadic}$$

Concretely, the read consumes source real-series windows and adjacent quotient rows, reads the logarithmic second-order defect ledger, converts that ledger into dyadic domination and stream-window evidence, enters the $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff, and reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *only through the displayed readback and seal rows.*

Proof. Begin with an endpoint-facing read of an accepted carrier. By Definition 5842.1, the only source data available before the defect estimate are the source windows in S and the adjacent quotient windows in Q.

The Bertrand-specific data are then read from L and D. The logarithmic ledger supplies the finite index, logarithmic scale, rational margin, and second-order defect, while the dyadic ledger turns those rows into the domination evidence needed for comparison.

The neighboring quotient-defect tests are reference faces in the same lattice. The Raabe–Duhamel, Kummer, and Gauss packets identify the adjacent first-order and auxiliary defect surfaces, while the ratio route supplies the shared adjacent-quotient discipline. The accepted $\mathsf{BertrandSeriesTest}^{\uparrow}$ endpoint route still has to enter the comparison handoff T.

After T is displayed, the route proceeds through the finite $\mathsf{StreamName}^{\uparrow}$ windows in W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E. The transport, replay, provenance, and naming rows keep the same route, so no host summability, quotient series equality, selected sums, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness can enter. □

Falsifiable prediction: Every accepted $\mathsf{BertrandSeriesTest}^{\uparrow}$ endpoint-facing read factors through source real-series windows, adjacent quotient rows, a logarithmic defect ledger, dyadic domination, a RegularCauchyComparisonTest handoff, StreamName windows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: raabeduhameltest, kummertest, gausstest, regularcauchyratiotest, regularcauchycomparisontest, dyadicratcore, streamname, regseqrat, real: $\mathsf{BertrandSeriesTest}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source series windows, adjacent quotient windows, a logarithmic second-order defect ledger, dyadic domination, comparison-test routing, regular rational readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BertrandSeriesTest}^{\uparrow}$ packet is generated from source real-series windows, adjacent quotient windows, a logarithmic second-order defect ledger, dyadic domination, a RegularCauchyComparisonTest handoff, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5842.1, Definition 5842.2, and Definition 5842.3 seed the finite Bertrand convergence-test boundary over displayed source series, quotient, logarithmic defect, comparison, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier admission, quotient-window exactness, logarithmic-defect stability, dyadic domination routing, regular and Real handoff, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.BertrandSeriesTestUp.

Chapter 4445

A Concrete Naming Certificate for $\mathsf{RationalCanonicalForm}^{\uparrow}$

Following Frobenius and standard linear algebra treatments of finite-dimensional operators, the $\mathsf{RationalCanonicalForm}^{\uparrow}$ packet records the rational canonical form of a displayed finite linear operator as BEDC NameCert data. It consumes the finite matrix rows of chapter 49, the linear-map surface of chapter 48, the polynomial source of chapter 50, the module and vector-space carriers of chapter 46 and chapter 47, and the invariant-factor route supplied by chapter 2262. The packet names only a finite certificate surface for companion-block assembly; it does not assert a host Jordan form theorem, algebraic closure, eigenvalue selection, basis choice outside the displayed rows, or a global classification oracle.

Definition 4445.1 (Rational canonical form carrier)**.** *A* $\mathsf{RationalCanonicalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (V, L, M, S, I, B, A, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *or* $\mathsf{Module}^{\uparrow}$ *source row naming the finite underlying carrier and its scalar action.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row naming the endomorphism whose canonical form is being read.*
3. *M is the* $\mathsf{Mat}^{\uparrow}$ *presentation row for the same endomorphism over the displayed finite basis data already carried by V and L.*
4. *S is the consumed* $\mathsf{SmithNormalForm}^{\uparrow}$ *dependency row applied to the polynomial matrix route attached to M.*
5. *I is the invariant-factor* $\mathsf{Poly}^{\uparrow}$ *row, listing monic polynomial factors with the divisibility ledger exposed by S.*
6. *B is the companion-block row, assembling one finite block for each invariant factor in I and recording the row and column positions used by the assembly.*
7. *A is the block-assembly exactness row, stating that the displayed* $\mathsf{Mat}^{\uparrow}$ *presentation is transported to the companion-block matrix through the same* $\mathsf{LinMap}^{\uparrow}$ *and* $\mathsf{Poly}^{\uparrow}$ *rows.*
8. *H stores componentwise* hsame *transport for the vector or module source, linear map, matrix presentation, Smith-normal dependency, invariant factors, companion blocks, assembly row, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from a canonical-form request through V, L, M, S, I, B, A and back to the same finite operator surface.*
10. *P is the* Pkg *provenance over* $\mathsf{RationalCanonicalForm}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{SmithNormalForm}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$ *row.*

The carrier has no coordinate for selected eigenvalues, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, or a detached canonical-form oracle.

Lean4 ✓ `BEDC.Derived.RationalCanonicalFormUp.TasteGate.RationalCanonicalFormTasteGate single carrier alignment`

Theorem 4445.2 (Rational canonical form NameCert obligations)**.** *For every accepted* $\mathsf{RationalCanonicalForm}^{\uparrow}$ *carrier*

$$F = (V, L, M, S, I, B, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$ *surface consists exactly of finite source admission for V, L, M, Smith-normal dependency routing through S, invariant-factor exposure through I, companion-block assembly through B, block-assembly exactness through A, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5843.1. The algebraic source rows are exactly the vector or module carrier V, the endomorphism row L, the finite matrix presentation M, the Smith-normal dependency row S, the invariant-factor row I, and the companion-block assembly rows B, A.

The invariant factors are not read from a host classification theorem. They are exposed as $\mathsf{Poly}^{\uparrow}$ rows whose divisibility and matrix-reduction dependency is routed through $\mathsf{SmithNormalForm}^{\uparrow}$ before any companion block is assembled.

The companion-block row B is finite because it is indexed by the displayed invariant-factor list I. The exactness row A then compares the assembled block matrix with the original $\mathsf{Mat}^{\uparrow}$ presentation through the same $\mathsf{LinMap}^{\uparrow}$ endpoint and componentwise hsame transport.

Finally H, C, P, N transport, replay, source, and name only this finite route. Since the carrier contains no coordinate for eigenvalue selection, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, or a detached canonical-form oracle, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: A $\mathsf{RationalCanonicalForm}^{\uparrow}$ consumer that exports a canonical-form matrix while omitting the Smith-normal dependency row, invariant-factor polynomial row, companion-block assembly row, componentwise hsame, displayed Cont, Pkg, or local NameCert rows refutes the carrier of Definition 5843.1.

Independence witness: matrix, linearmap, polynomial, module, vecspace, smith-normal-form: $\mathsf{RationalCanonicalForm}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite operator source, matrix presentation, invariant-factor polynomial ledger, Smith-normal dependency, companion-block assembly, exactness row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RationalCanonicalForm}^{\uparrow}$ packet is generated from VecSpaceUp or ModuleUp source data, a LinearMapUp endomorphism row, a MatrixUp presentation, a SmithNormalFormUp dependency route, invariant-factor PolynomialUp rows, companion-block assembly rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RationalCanonicalForm}\uparrow}$, seed)

Scope closed: Definition 5843.1 and Definition 5843.2 seed the finite rational-canonical-form packet over matrix, linear-map, polynomial, module, vector-space, and Smith-normal rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RationalCanonicalForm}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim eigenvalue selection, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, invariant-factor exposure, Smith-normal dependency routing, companion-block assembly, exactness, transport, replay, provenance, and local naming for BEDC.Derived.RationalCanonicalForn

Chapter 4446

A Concrete Naming Certificate for $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$

The $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ packet realizes the Rule 110 pattern-classifier branch of chapter 9390 as finite BEDC NameCert data. It consumes the cellular automaton carrier of chapter 934, the row-classifier surface of chapter 941, the pattern catalog of chapter 995, the local-stencil observation route of chapter 1036, and the Rule 110 glider catalog of chapter 1045. The packet names finite row windows, transition-table reads, orbit prefixes, pattern tags, transport, replay, provenance, and a local NameCert row; it is not a universality theorem, an infinite-orbit classifier, an undecidable continuation oracle, or a hidden substrate semantics.

Definition 4446.1 (Rule 110 pattern classifier carrier)**.** *A* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (W, T, O, G, K, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite row-window row, naming the inspected Rule 110 space-time rectangle and its boundary cells.*
2. *T is the transition-table row, exposing the eight local update cases used to advance the window.*
3. *O is the orbit-prefix row, recording the finite sequence of rows replayed from the initial window by T.*
4. *G is the glider and ether catalog row consumed from* $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$ *and* $\mathsf{CellularPatternCatalog}^{\uparrow}$*.*
5. *K is the classifier-tag row, assigning each inspected subwindow to a displayed ether, glider, collision, boundary, or unknown tag.*
6. *H stores componentwise* hsame *transport for windows, transition-table rows, orbit prefixes, tags, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a classifier request through W, T, O, G, K.*
8. *P is the* Pkg *provenance over* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$*,* $\mathsf{CellularAutomaton}^{\uparrow}$*,* $\mathsf{CellularRowClassifier}^{\uparrow}$*,* $\mathsf{CellularPatternCatalog}^{\uparrow}$*,* $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$*,* $\mathsf{LocalStencilObservation}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$ *row.*

The carrier has no coordinate for infinite continuation, termination of all continuations, host universality, unbounded pattern search, quotient orbit equality, or a substrate semantics outside the displayed rows.

Theorem 4446.2 (Rule 110 pattern classifier NameCert obligations)**.** *For every accepted* RuleOneTenPatternClassif *carrier*

$$R = (W, T, O, G, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$ *surface consists exactly of row-window admission through* W*, transition-table exposure through* T*, orbit-prefix replay through* O*, catalog lookup through* G*, classifier-tag exactness through* K*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier of Definition 5844.1. The finite cellular rows are exactly the inspected window W, transition table T, orbit prefix O, catalog row G, classifier row K, and the structural rows H, C, P, N.

The transition-table row is read before the orbit prefix, so every displayed successor row is justified by the same eight local Rule 110 cases. The classifier tag is then attached to a finite subwindow already present in O and compared against the catalog row G.

The transport and replay rows preserve that order. Since the carrier contains no infinite continuation coordinate, no all-continuations termination field, no unbounded pattern search, no quotient orbit equality, and no host universality proof, the local NameCert obligations are exhausted by the listed finite rows. □

Falsifiable prediction: A $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ classifier read that assigns a glider, ether, collision, boundary, or unknown tag without exposing the finite row window, transition-table row, orbit-prefix row, catalog row, componentwise hsame, displayed Cont, Pkg, and local NameCert rows refutes the carrier of Definition 5844.1.

Independence witness: continuationautomaton, finiteprefixautomaton, continuationtermination, typecheckingmembershiptrace, classifiermorphism: $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Rule 110 row windows, the transition table, orbit prefixes, catalog tags, classifier transport, replay, provenance, and local NameCert rows.

The Lean TasteGate file for this packet must provide Nontrivial $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ and FieldFaithful $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ instances for the displayed rows $W, T, O, G, K, H, C, P, N$ before the classifier can serve as a verified taste-gate consumer.

Closure status for $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ packet is generated from a finite Rule 110 row window, transition table, orbit prefix, pattern catalog, classifier tags, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$, seed)

Scope closed: Definition 5844.1 and Definition 5844.2 seed the finite Rule 110 pattern-classifier packet over row-window, transition-table, orbit-prefix, catalog, tag, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a universality theorem, infinite-orbit classification, continuation termination, unbounded pattern search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked row-window admission, transition-table exposure, orbit-prefix replay, catalog lookup, classifier-tag exactness, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.RuleOneTenPatternClassifierUp.

Chapter 4447

A Concrete Naming Certificate for $\mathsf{ObservabilityGramian}^{\uparrow}$

The $\mathsf{ObservabilityGramian}^{\uparrow}$ interface records the finite observability Gramian packet of a finite-dimensional linear control system. Its textbook source is the finite-horizon observability Gramian in Kalman's control-theoretic duality and the matrix-ledger presentation used by Kailath, Sayed, and Hassibi for linear estimation. The BEDC packet is the finite dual certificate read beside $\mathsf{ReachabilityGramian}^{\uparrow}$ in chapter 455; it is not an ambient analytic observability theorem.

The dependency anchors are the finite observation surface of chapter 294, the reachability dual surface of chapter 297, the matrix rows of chapter 49, the vector-space rows of chapter 47, and the linear-map rows of chapter 48. These anchors force the Gramian to be read as displayed $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{LinMap}^{\uparrow}$ data before a control consumer can compare it with the reachability Gramian.

4447.1 Carrier definition

Definition 4447.1 (ObservabilityGramianUp finite carrier)**.** *An* $\mathsf{ObservabilityGramian}^{\uparrow}$ *carrier is a finite* BHist *packet with rows*

$$(A, C, n, W, L, R, P, N).$$

Here A is the displayed transition-matrix row, C is the displayed output-matrix row, n is a unary finite-horizon row, W is the displayed finite Gramian-sum ledger with summand rows

$$C^{\mathsf{T}}C, \quad A^{\mathsf{T}}C^{\mathsf{T}}CA, \quad (A^{\mathsf{T}})^2C^{\mathsf{T}}CA^2, \quad \ldots, \quad (A^{\mathsf{T}})^{n-1}C^{\mathsf{T}}CA^{n-1},$$

L is the componentwise hsame *transport ledger for the transition, output, horizon, summand, and Gramian endpoint rows, R is the finite dual-readback row comparing W with the observation-matrix rows $C, CA, \ldots, CA^{n-1}$ of* $\mathsf{ControlObservability}^{\uparrow}$*, P is the* Pkg *provenance over* $\mathsf{ObservabilityGramian}^{\uparrow}$*,* $\mathsf{ControlObservability}^{\uparrow}$*,* $\mathsf{ControlControllability}^{\uparrow}$*,* $\mathsf{ReachabilityGramian}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*, and N is the local* $\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by componentwise hsame *transport of the A, C, n, W, L, R, P, N rows. It does not quotient by a host unobservable subspace, analytic trajectory family, Riccati equation, spectral factorization, infinite-horizon Gramian, or external estimator object.*

Lean4 ✓ `BEDC.Derived.ObservabilityGramianUp.ObservabilityGramianTasteGate single carrier alignment`

4447.2 Certificate surface

Theorem 4447.2 (ObservabilityGramianUp NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}$ *obligation surface has exactly five finite rows:*

1. *carrier admission for the displayed* A, C, n, W, L, R, P, N *packet of Definition 5787.1;*
2. *classifier transport under componentwise* hsame *of the transition, output, horizon, Gramian, summand-ledger, dual-readback, package, and local certificate rows;*
3. *finite sum ledger exactness, saying that the Gramian endpoint inside* W *is read only as the finite sum of the displayed adjoint-output summands inside* W*;*
4. *observability handoff, saying that the observation-matrix surface of* $\mathsf{ControlObservability}^{\uparrow}$ *can consume* A*,* C*,* n*,* W*,* L*, and* R *only through the displayed* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* Cont*, and* Pkg *rows;*
5. *dual non-escape, saying that no accepted route exports a host unobservable subspace, analytic output trajectory, Riccati solution, spectral factorization, infinite-horizon Gramian, covariance process, or external estimator.*

Proof. The carrier row is Definition 5787.1. It displays the transition row, output row, unary horizon, Gramian endpoint, summand ledger, transport ledger, dual-readback row, package provenance, and local naming row as finite BHist coordinates.

Classifier transport is componentwise. Replacing each displayed coordinate by an hsame-matched coordinate leaves the same finite packet shape, so the transported packet is again admitted by the carrier.

For finite sum exactness, inspect W. Each summand is a displayed matrix product formed from A, C, and transposes, and the Gramian endpoint is the finite fold of precisely those rows. The readback row R ties that ledger to the observation rows without introducing a host observability theorem.

The observability handoff is a projection to the shared A, C, and n rows, to the finite observation rows of $\mathsf{ControlObservability}^{\uparrow}$, and to the Gramian sum named by W. Because those rows are already packaged with $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{LinMap}^{\uparrow}$ provenance, a downstream observability certificate can read them without importing analytic control-system semantics.

Dual non-escape follows from constructor inspection of the carrier. The packet has no coordinate for a host unobservable subspace, analytic output trajectory, Riccati solution, spectral factorization, infinite-horizon Gramian, covariance process, or external estimator, so none of those objects can be projected by a consumer route. □

Theorem 4447.3 (ObservabilityGramianUp finite dual handoff)**.** *Every* $\mathsf{ControlObservability}^{\uparrow}$*,* $\mathsf{ControlControllability}^{\uparrow}$*, or* $\mathsf{ReachabilityGramian}^{\uparrow}$ *consumer of an accepted* $\mathsf{ObservabilityGramian}^{\uparrow}$ *packet can read only the displayed* A *row,* C *row, unary horizon row* n*, finite Gramian-summand and endpoint row* W*,* hsame *transport ledger* L*, dual-readback row* R*,* Pkg *provenance, and local* NameCert *row of Definition 5787.1. The handoff supplies the finite dual route from observation rows to the reachability-side Gramian ledger, but it supplies no host Kalman decomposition, no analytic trajectory semantics, and no infinite-horizon duality theorem.*

Proof. Project the accepted packet to the rows A, C, n, W, L, R, P, N. The first three rows are the finite control-system coordinates shared with $\mathsf{ControlObservability}^{\uparrow}$, while W records the finite adjoint-output Gramian ledger and L records componentwise transport over those same coordinates.

The dual-readback row R ties the summands in W to the observation rows $C, CA, \ldots, CA^{n-1}$. Thus a $\mathsf{ControlObservability}^{\uparrow}$ consumer reads the packet through the observation matrix surface, and a $\mathsf{ControlControllability}^{\uparrow}$ or $\mathsf{ReachabilityGramian}^{\uparrow}$ consumer reads only the dual comparison route named by the shared package provenance.

The carrier contains no row for a host Kalman decomposition, analytic trajectory semantics, or infinite-horizon duality theorem. Therefore the handoff is exactly the finite BEDC packet projection and does not add a control-theory semantic bridge. □

Theorem 4447.4 (ObservabilityGramianUp ledger non-escape)**.** *Every exported route from an accepted* $\mathsf{ObservabilityGramian}^{\uparrow}$ *packet factors through the finite rows* A, C, n, W, L, R, P, N *of Definition 5787.1. In particular, the packet exports no ambient unobservable subspace, no analytic output trajectory family, no Riccati solution, no spectral factorization, no stochastic covariance process, no infinite-horizon Gramian, and no external numerical estimator.*

Proof. Take an exported consumer route and project the carrier. The available coordinates are exactly the transition row, output row, horizon row, finite Gramian-summand and endpoint row, transport ledger, dual-readback row, package provenance, and local certificate row.

The NameCert obligations account for carrier admission, classifier transport, finite sum exactness, observability handoff, and dual non-escape. Each obligation is stated over those displayed coordinates and is preserved by the stored hsame, Cont, and Pkg rows.

Thus every export factors through the listed finite coordinates. Since the carrier contains no ambient unobservable subspace, analytic output trajectory family, Riccati solution, spectral factorization, stochastic covariance process, infinite-horizon Gramian, or external numerical estimator, no accepted route can supply one downstream. □

Closure status for $\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}$.

Constructive story: An $\mathsf{ObservabilityGramian}^{\uparrow}$ packet is generated from displayed transition and output matrix rows, a unary finite horizon, the finite adjoint-output Gramian summand and endpoint row, componentwise hsame transport ledger, a dual-readback row to the observation-matrix surface, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5787.1, Definition 5787.2, Definition 5787.3, and Definition 5787.4 bind the finite carrier, five-row NameCert surface, dual handoff, and non-escape boundary for observability Gramian packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host unobservable-subspace semantics, analytic output trajectories, Riccati theory, spectral factorization, stochastic covariance, infinite-horizon Gramians, numerical estimators, or a checked Lean certificate.

Upgrade path: Obligation closure requires a Lean carrier encoding and checked finite-ledger theorems for finite sum exactness, dual handoff, and non-escape.

Chapter 4448

A Concrete Naming Certificate for $\mathsf{HelmholtzDecomposition}^{\uparrow}$

Following Helmholtz and Hodge-style decomposition theory, the $\mathsf{HelmholtzDecomposition}^{\uparrow}$ packet records the finite BEDC surface by which a displayed vector-field row is read as the sum of a gradient-potential row and a divergence-free row over a Hilbert source. It consumes the Hilbert carrier of chapter 91, the vector-space operations of chapter 47, the linear-map rows of chapter 48, and the projection-theorem surface of chapter 2374. The packet names only the displayed analytic decomposition route; it does not assert PDE solvability, global boundary regularity, unique gauges, Sobolev completeness, or a host Hodge theorem.

Definition 4448.1 (Helmholtz decomposition carrier)**.** *A* $\mathsf{HelmholtzDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (H, V, G, D, O, B, T, C, P, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row. It supplies the ambient inner-product and norm-facing carrier on which the vector field and both components are read.*
2. *V is the vector-field row. It records the admitted field endpoint together with the* $\mathsf{VecSpace}^{\uparrow}$ *addition, subtraction, and scalar rows used to state the splitting.*
3. *G is the gradient-potential row. It names a potential window and the displayed* $\mathsf{LinMap}^{\uparrow}$ *route that reads its gradient as a vector-field component.*
4. *D is the divergence-free row. It records the classifier saying that the second component lies in the displayed kernel row selected by the divergence operator.*
5. *O is the orthogonal-projection row. It reads the gradient component and the divergence-free component through the projection-theorem surface of chapter 2374.*
6. *B is the boundary ledger. It records exactly which boundary observations are available before a projection or divergence-free read is exposed.*
7. *T records componentwise* hsame *transport for the Hilbert source, vector field, gradient-potential row, divergence-free row, projection row, boundary ledger, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a Helmholtz-decomposition request through $H, V, G, D, O, B, T, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{HelmholtzDecomposition}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, OrthogonalProjectionThec BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $H, V, G, D, O, B, T, C, P, N$. It has no coordinate for a host PDE solution operator, selected gauge, ambient Sobolev space, hidden boundary regularity theorem, quotient vector-field equality, or unrestricted Hodge decomposition.

Lean4 ✓ `BEDC.Derived.HelmholtzDecompositionUp.HelmholtzDecompositionTasteGate single carrier alignment`

Theorem 4448.2 (Helmholtz decomposition NameCert obligations)**.** *For every accepted* $\mathsf{HelmholtzDecomposition}^{\uparrow}$ *carrier $K = (H, V, G, D, O, B, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}^{\uparrow}}$ *surface consists exactly of the following finite obligation families:*

1. *Hilbert-source admission for the displayed* $\mathsf{Hilbert}^{\uparrow}$ *row H;*
2. *vector-field admission for the field endpoint and* $\mathsf{VecSpace}^{\uparrow}$ *operations stored in V;*
3. *gradient-potential admission for the potential window and* $\mathsf{LinMap}^{\uparrow}$ *gradient route stored in G;*
4. *divergence-free admission for the kernel classifier stored in D;*
5. *orthogonal-projection admission for the projection row O over the gradient and divergence-free components;*
6. *boundary-ledger admission for the displayed boundary observations stored in B;*
7. *componentwise transport, displayed replay, provenance, and local naming through T, C, P, N.*

Consequently a downstream PDE, variational, or Hodge-facing consumer may read Helmholtz data only through the displayed Hilbert, vector-space, linear-map, projection, boundary, transport, replay, provenance, and local naming rows. The packet exports no host PDE solver, gauge selector, Sobolev-completion theorem, quotient vector-field equality, or unrestricted Hodge decomposition.

Proof. Project the carrier of Definition 5788.1. The visible analytic rows are the Hilbert source H, the vector-field row V, the gradient-potential row G, the divergence-free row D, the orthogonal-projection row O, and the boundary ledger B.

The source and algebraic rows are read first. The Hilbert row comes from chapter 91, while V supplies the vector operations inherited from chapter 47. Thus the decomposition statement is formed only inside a displayed carrier.

Next the two component rows are exposed. The gradient-potential row G factors its gradient read through the linear-map surface of chapter 48, and the divergence-free row D supplies the displayed kernel classifier before any splitting conclusion is available.

The projection and boundary rows then bind the route. The row O reads the orthogonal splitting discipline through chapter 2374, while B restricts the boundary observations available to that read.

Finally T, C, P, N transport, replay, source, and name the same displayed rows. Since no excluded analytic object is a coordinate of K, the listed obligation families exhaust the local NameCert surface. □

Theorem 4448.3 (Helmholtz decomposition orthogonal splitting route)**.** *Every splitting read accepted from a* $\mathsf{HelmholtzDecomposition}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Hilbert}^{\uparrow} \longmapsto \mathsf{VecSpace}^{\uparrow} \longmapsto \mathsf{LinMap}^{\uparrow} \longmapsto \mathsf{OrthogonalProjectionTheorem}^{\uparrow} \longmapsto \mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}^{\uparrow}}.$$

The exported surface is a displayed field row together with a gradient-potential component, a divergence-free component, an orthogonal projection ledger, and a boundary ledger. It does not provide a global PDE solution operator, a selected gauge, Sobolev regularity, quotient equality of vector fields, or the full Hodge decomposition theorem.

Proof. Start from an accepted packet $K = (H, V, G, D, O, B, T, C, P, N)$. A consumer first opens the Hilbert row H, so every norm, orthogonality, and projection read remains attached to the same displayed source.

The vector-space row V then supplies the algebra needed to read the field as the sum of two displayed components. This step uses only the finite operations exposed by chapter 47.

The gradient-potential component is read through G and the linear-map surface of chapter 48. The divergence-free component is read through D, whose kernel classifier is already part of the packet.

The orthogonal splitting claim is finally routed through O and the projection-theorem packet of chapter 2374. The boundary ledger B records the available boundary observations before the local name N is exposed.

Transport and replay through T and C preserve this order, while P records the provenance of the same finite route. No host solver, gauge selector, Sobolev regularity theorem, quotient equality, or unrestricted Hodge theorem is introduced. □

Closure status for $\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5788.1, Definition 5788.2, and Definition 5788.3 seed the finite Helmholtz decomposition packet over Hilbert, vector-space, linear-map, projection, boundary, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HelmholtzDecompositionUp.HelmholtzDecompositionTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim PDE solvability, global gauges, Sobolev regularity, quotient vector-field equality, unrestricted Hodge decomposition, or bridge checking.

Upgrade path: Obligation closure asks for checked Hilbert-source admission, vector-field admission, gradient-potential admission, divergence-free admission, orthogonal-projection admission, boundary-ledger admission, transport, replay, provenance, and local naming for BEDC.Derived.HelmholtzDecompositionUp.

Constructive story: A $\mathsf{HelmholtzDecomposition}^{\uparrow}$ packet is generated from a displayed Hilbert source, a vector-field row, a gradient-potential row read through LinearMapUp, a divergence-free kernel row, an orthogonal-projection row, a boundary ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4449

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet records the separated completion boundary needed by the L10 Real and Completion route as finite BEDC data. It sits after the separation predicate of chapter 1925, the separated-completion carrier of chapter 1612, the metric completion route of chapter 1506, the finite stream interface of chapter 126, the dyadic tolerance core of chapter 291, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the envelope through displayed rows only; it does not quotient filters, select representatives, identify host equalities, invoke countable choice, or import ambient completeness.

Definition 4449.1 (Hausdorff completion envelope carrier)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (H, S, M, W, D, R, L, T, K, P, N)$$

where H *is the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$ *separation row,* S *is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* L *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal,* T *is componentwise* $\mathsf{BHist/hsame}$ *transport,* K *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *row. A consumer of* E *receives a separated completion boundary only through these coordinates.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeTasteGate single carrier alignment`

Theorem 4449.2 (Hausdorff completion envelope obligations)**.** *Every accepted* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *read must expose the carrier of Definition 5789.1 in the order*

$$H, S, M, W, D, R, L, T, K, P, N.$$

The separation row H *and separated-completion row* S *are available before metric completion, stream observation, dyadic tolerance, regular readback, and real-seal rows are consumed; the transport, replay, provenance, and naming rows preserve the same displayed packet.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeNameCertObligations`

Proof. Project the carrier of Definition 5789.1. The packet has no completion-facing coordinates except $H, S, M, W, D, R, L, T, K, P, N$.

The Hausdorff and separated-completion rows are the first boundary data in the packet. Thus a consumer cannot inspect the metric completion route, finite stream windows, dyadic tolerances, regular readback, or terminal real seal without first reading the displayed separation surface.

Finally, the structural rows T, K, P, N only transport, replay, source, and name the same finite packet. They do not create quotient filters, selected representatives, host equality, choice-selected routes, or ambient completeness. □

Theorem 4449.3 (Hausdorff completion separated metric route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier factors through the separated route*

$$H, S \longmapsto M \longmapsto W, D, R, L.$$

The route records a separated metric-completion boundary for the L10 Real and Completion interface, not a quotient completion, a host equality theorem, a choice-selected representative, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier separated metric route`

Proof. Start from Definition 5789.2. It places the Hausdorff row H and separated-completion row S before the metric completion row M and before the stream, dyadic, regular-rational, and real-seal rows.

Read the metric completion route through M. Since M is downstream of H, S, every completion-facing use of M carries the displayed separated boundary with it.

The final Real-facing read is the finite route W, D, R, L. Because these rows are still coordinates of the same carrier, the route cannot be replaced by quotient representatives, host equality, countable choice, or ambient completeness. □

Theorem 4449.4 (Hausdorff completion envelope sibling route)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *consumer may hand its separated boundary to* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *only through the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$*,* $\mathsf{SeparatedCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows of*

$$E = (H, S, M, W, D, R, L, T, K, P, N).$$

The handoff contains no quotient-filter coordinate, representative-selection coordinate, host-equality coordinate, or ambient-completeness coordinate.

Proof. Apply Definition 5789.2. It places the Hausdorff row H, separated-completion row S, metric-completion row M, stream row W, dyadic row D, regular-rational row R, and terminal Real row L inside one displayed packet.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

The sibling $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ consumer therefore reads the same separated boundary as its input surface rather than receiving a separate primitive. Since the carrier only has the displayed rows and the structural rows T, K, P, N, quotient filters, selected representatives, host equality, and ambient completeness remain outside the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier sibling route`

Theorem 4449.5 (Hausdorff completion envelope Cauchy-net consumer link)**.** *Every* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier must read the same* $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before its directed-net completion route is consumed. The downstream sibling is chapter 3794, and the handoff is the displayed route*

$$H, S, M, W, D, R, L \longmapsto \mathsf{CauchyNetCompletion}^{\uparrow}.$$

It exports no quotient net, selected representative, host equality, countable-choice schedule, or ambient completeness coordinate.

Proof. Project the carrier $E = (H, S, M, W, D, R, L, T, K, P, N)$ of Definition 5789.1. The only completion-facing rows available to a consumer are the Hausdorff row H, separated-completion row S, metric-completion route M, finite stream row W, dyadic tolerance row D, regular readback row R, and terminal Real row L.

Apply Definition 5789.2. It places H, S, M, W, D, R, L inside one displayed packet before the structural rows T, K, P, N are used for transport, replay, provenance, and local naming.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

Therefore a downstream $\mathsf{CauchyNetCompletion}^{\uparrow}$ read can only consume the envelope through the same separated metric route before its directed-net completion surface is inspected. Since the packet has no quotient-net, selected-representative, host-equality, countable-choice, or ambient-completeness row, none of those objects can enter the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeForwardLink`

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5789.1, Definition 5789.2, and Definition 5789.3 name the separated completion envelope surface for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, host equality, choice-selected representatives, or ambient completeness.

Upgrade path: Obligation closure requires the carrier route to be tied to the sibling completion obligation theorems and then exposed as a public chapter surface.

Constructive story: A $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet is generated from Hausdorff separation, separated-completion boundary, metric-completion route, finite stream windows, dyadic tolerance, regular-rational readback, Real seal, transport, replay, provenance, and local NameCert rows.

Chapter 4450

A Concrete Naming Certificate for $\mathsf{BoundedLinearFunctional}^{\uparrow}$

Following Banach and Bourbaki functional analysis, the $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet records the scalar-valued bounded-linear-operator row that duality and weak-star consumers inspect before any host dual space is available. It sits over the linear-map route of chapter 48, the bounded-linear-operator surface of chapter 1644, the scalar-bound neighbour chapter 3603, the Banach-dual row of chapter 2265, the finite weak-star window of chapter 3420, the scalar endpoint seal of chapter 38, and the normed source surface of chapter 1950. The chapter names only displayed scalar-functional data: source rows, linearity rows, scalar target readback, norm-bound evidence, transport, replay, provenance, and local naming.

Definition 4450.1 (Bounded linear functional carrier)**.** *For a displayed* $\mathsf{NormedSpace}^{\uparrow}$ *source row* E *over the scalar endpoint surface of* $\mathsf{Real}^{\uparrow}$*, a* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E)$ *carrier is a finite* BHist *packet*

$$\Lambda = (E, L, T, K, O, H, C, P, N)$$

with the following displayed rows:

1. *E is the source normed-space row, including its carrier endpoints, scalar action, additive row, norm row, and classifier.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row from E to the scalar* $\mathsf{Real}^{\uparrow}$ *target.*
3. *T is the scalar-valued* $\mathsf{BoundedLinearOperator}^{\uparrow}(E, \mathsf{Real}^{\uparrow})$ *row carrying the same endpoint action as L.*
4. *K is the* $\mathsf{Real}^{\uparrow}$ *nonnegative bound endpoint for the functional.*
5. *O is the* $\mathsf{OperatorNorm}^{\uparrow}$ *handoff row exposing where the bound K is used.*
6. *H records componentwise* hsame *transport for the source, linear-map row, bounded-operator row, scalar bound, operator-norm handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a scalar-functional request through E, L, T, K, O, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedLinearFunctional}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{BanachDual}^{\uparrow}$, $\mathsf{BanachAlaoglu}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed source classifier, scalar endpoint transport, bounded-operator transport, bound transport, norm-bound ledger transport, replay, provenance, and local naming rows. It has no coordinate for a host dual space, quotient equality of functions, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BoundedLinearFunctionalUp.BoundedLinearFunctionalTasteGate single carrier alignment`

Theorem 4450.2 (Bounded linear functional NameCert obligations)**.** *For every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *carrier* $\Lambda = (E, L, T, K, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *surface consists exactly of source normed-space admission, linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from host dual objects. A consumer may inspect* $E, L, T, K, O, H, C, P, N$*, but it receives no ambient function space, quotient operator equality, selected representative, Hahn–Banach witness, unrestricted weak-star compactness theorem, or bridge data.*

Proof. Project the carrier rows. The analytic coordinates are exactly the source normed-space row E, the linear-map row L, the scalar-valued bounded-operator row T, the RealUp bound endpoint K, and the operator-norm handoff O.

The linearity obligation is read through $\mathsf{LinMap}^{\uparrow}$, while boundedness is read through $\mathsf{BoundedLinearOperator}^{\uparrow}(E,$ The scalar target is already the displayed $\mathsf{Real}^{\uparrow}$ endpoint surface, so the functional row never becomes a host-level function.

The bound exactness is the shared route through K and O. The operator-norm handoff records where the scalar bound is used, and componentwise hsame transport moves the source, action, bound, ledger, replay, provenance, and local naming rows together.

No remaining coordinate can manufacture a dual-space quotient, selected representative, Hahn–Banach witness, unrestricted compactness theorem, or bridge check. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 4450.3 (Bounded linear functional operator-norm handoff)**.** *Every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E$ *packet exports the finite route*

$$\mathsf{LinMap}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{OperatorNorm}^{\uparrow} \longmapsto \mathsf{BoundedLinearFunctional}^{\uparrow}$$

to functional-analysis consumers. The route first exposes the carried scalar-valued linear action, then the bounded-operator row, then the RealUp bound endpoint and operator-norm ledger; it does not expose a host supremum, quotient equality of functionals, selected norm-attaining vector, or hidden Banach completeness.

Proof. Begin with an accepted packet $\Lambda = (E, L, T, K, O, H, C, P, N)$. The read of L supplies only the displayed linear-map action from the source row to the scalar target.

The read of T then packages the same action as a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row. Its target row is $\mathsf{Real}^{\uparrow}$, and its bound endpoint is the displayed scalar K.

Finally the operator-norm handoff O records the norm-bound ledger that downstream consumers may inspect. Because no host norm function, quotient functional equality, selected vector, or hidden completion row is present, the exported handoff is exactly the displayed scalar-bound route. □

Theorem 4450.4 (Bounded linear functional dual-row nonescape)**.** *Any read of a* $\mathsf{BanachDual}^{\uparrow}$ *or* $\mathsf{BanachAlaoglu}^{\uparrow}$ *consumer that uses a* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *row factors through the same source normed-space row, scalar-valued bounded-operator row, RealUp bound endpoint, operator-norm handoff, componentwise transport, replay, provenance, and local naming rows of Definition 5790.1. The duality consumer receives a finite scalar-functional row, not a host dual space, a quotient function class, an unrestricted weak-star compactness theorem, or a selected cluster point.*

Proof. Read the duality consumer first. A $\mathsf{BanachDual}^{\uparrow}$ request needs a scalar-functional row over a displayed source, while a $\mathsf{BanachAlaoglu}^{\uparrow}$ request needs a finite family of such scalar-functional observations.

In either case the only scalar-functional packet available here is Λ. Its source row, bounded-operator row, bound endpoint, operator-norm handoff, and structural rows are projected in the order displayed by Definition 5790.1.

The downstream dual chapters may reuse those rows, but they cannot add coordinates that are absent from the packet. Thus quotient dual objects, host function classes, unrestricted weak-star compactness, selected cluster points, and bridge checks remain outside the read. □

Falsifiable prediction: Every accepted $\mathsf{BoundedLinearFunctional}^{\uparrow}$ scalar-functional read factors through a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ action row, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, and the local hsame, Cont, Pkg, and NameCert rows.

Independence witness: linearmap, boundedlinearoperator, operatornorm, banachdual, banachalaoglu, real, and normedspace: no listed sibling is bijective to $\mathsf{BoundedLinearFunctional}^{\uparrow}$ because this packet stores the scalar target restriction, the dual-facing provenance row, the operator-norm handoff, transport, replay, and local naming together as one finite scalar-functional surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet is generated from a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ scalar action, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5790.1, Definition 5790.2, Definition 5790.3, and Definition 5790.4 seed the scalar-functional row consumed by BanachDualUp and BanachAlaogluUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host dual spaces, quotient equality of functionals, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, scalar linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm handoff exactness, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BoundedLinearFunctionalUp.

Chapter 4451

A Concrete Naming Certificate for $\mathsf{CompletionModulusCategory}^{\uparrow}$

Following Bishop and Bridges on constructive completion and the functorial treatment of completions, the $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet records the finite category surface whose arrows preserve displayed completion moduli. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the completion functor of chapter 426, and the Cauchy completion functor of chapter 423. The packet names modulus-preserving completion morphisms as BEDC rows; it does not export quotient completions, selected representatives, host continuous maps, countable choice, or ambient completeness.

Definition 4451.1 (CompletionModulusCategory carrier)**.** *A* $\mathsf{CompletionModulusCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, A, S, R, D, E, F, H, C, P, N)$$

with the following displayed rows:

1. *O is the object ledger. Each object row records a completion-facing source, its displayed Cauchy-modulus discipline, and the local completion target read through the surrounding completion chapters.*
2. *A is the arrow ledger. Each arrow row records a finite morphism request together with the modulus transformation that sends source tolerances to target tolerances.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source and target names of an arrow.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the stream windows have been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare source and target moduli.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row read only after S, R, D have supplied the displayed tolerance route.*
7. *F records identity and composition rows for the completion functoriality surface, with identity arrows preserving the same modulus and composite arrows composing the displayed modulus transformations.*
8. *H records componentwise* hsame *transport for object rows, arrow rows, stream windows, regular readback, dyadic tolerances, Real seals, functoriality rows, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an arrow request through $O, A, S, R, D, E, F, H, P, N$.*
10. *P is the* Pkg *provenance over* CompletionModulusCategory$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, CauchyCompletionFunctor$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{CompletionModulusCategory}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite category packet for modulus-preserving completion morphisms. It has no coordinate for quotient completion points, selected representatives, host functions, global choice schedules, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryTasteGate single carrier alignment`

Theorem 4451.2 (CompletionModulusCategory NameCert obligations)**.** *For every accepted* CompletionModulusCa *carrier $M = (O, A, S, R, D, E, F, H, C, P, N)$, the local* NameCert$_{\text{CompletionModulusCategory}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed object ledger, arrow ledger, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, identity and composition rows, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface additionally requires each arrow row in A to expose its source modulus, target modulus, and modulus transformation before any Real$^{\uparrow}$*-facing read is accepted; each identity row in F to preserve the displayed modulus without adding a choice coordinate; and each composition row in F to compose the two displayed modulus transformations before the downstream seal is visible.*

Proof. Project the accepted carrier. The packet contains only the rows $O, A, S, R, D, E, F, H, C, P, N$, so carrier admission and ledger exhaustion are componentwise.

An arrow-facing request first reads the object and arrow ledgers O, A. The source and target names are then inspected through the finite stream windows S, regular rational readback R, and dyadic tolerance ledger D.

The functoriality rows F are local to the same displayed moduli. Identity preserves the stored modulus transformation, and composition combines the two stored transformations before the terminal seal E can be read.

Finally H, C, P, N transport, replay, source, and name this same finite route. Since quotient completions, selected representatives, host functions, global choice schedules, and ambient completeness are not carrier coordinates, they cannot be exported by the local NameCert. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryNameCertObligations`

Theorem 4451.3 (CompletionModulusCategory modulus functoriality)**.** *Every completion-facing consumer of an accepted* CompletionModulusCategory$^{\uparrow}$ *packet reads a modulus-preserving morphism through the finite route*

$$O, A, S, R, D, F, E, H, C, P, N.$$

Thus identity and composition of completion morphisms preserve the displayed modulus data before any Real$^{\uparrow}$ *seal or completion-functor read is exposed. The route factors through* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, *and* CauchyCompletionFunctor$^{\uparrow}$ *rather than through quotient completion equality, selected representatives, host continuous maps, countable choice, or ambient completeness.*

Proof. Start with a completion-facing morphism request. The object ledger O fixes the source and target completion rows, and the arrow ledger A fixes the modulus transformation to be checked.

The readback rows S, R, D display the inspected stream windows, regular rational observations, and dyadic tolerance comparisons. These rows are the only route by which the requested modulus can face the terminal Real seal.

The functoriality row F then supplies the identity or composition clause. In the identity case the same displayed modulus is replayed. In the composition case the two displayed modulus transformations are composed as finite rows before the result is handed to E.

The structural rows H, C, P, N preserve and name the same route. Therefore every completion-functor consumer receives finite modulus preservation data and no excluded quotient, selection, host-map, choice, or ambient-completeness surface. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryModulusFunctoriality`

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}$.

Constructive story: A $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet is generated from completion object rows, modulus-preserving arrow rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, RealUp seals, identity and composition rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5791.1, Definition 5791.2, and Definition 5791.3 seed the finite category surface for modulus-preserving completion morphisms.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host continuous maps, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-preserving arrow exactness, identity and composition rows, tolerance readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionModulusCategoryUp.

Chapter 4452

A Concrete Naming Certificate for $\mathsf{MarkovTriggerDynamics}^{\uparrow}$

The $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet realizes the finite rank-trigger dynamics of Definition 9462.1541, Definition 9462.1542, and Definition 9462.1546 as BEDC NameCert data. It records the state, support-rank, transition-count, drift, trigger-time, classifier, continuation, provenance, and naming rows needed by a downstream finite-dynamics consumer. The packet is a finite BHist surface for trigger-time readback; it is not a stochastic process on an ambient probability space, not an infinite sample path, not a hidden field model, and not a host Markov-chain object.

Definition 4452.1 (MarkovTriggerDynamics carrier)**.** *A* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, K, A, D, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite state row. It records the consumed external-codon count m and the covered support rank r for the current trigger state.*
2. *K is the support-rank row. It records the finite support coordinates currently covered by the observed codon rows and the rank read from that support.*
3. *A is the transition-count row. It stores the finite count of rank-preserving and rank-increasing next draws available from the current state.*
4. *D is the drift row. It records the displayed one-step rank drift computed from the same transition counts.*
5. *G is the trigger-time row. It records the finite recursion for the time to reach full rank and the deterministic threshold row consumed by trigger-time readers.*
6. *H records componentwise* hsame *transport for state, support-rank, transition-count, drift, trigger-time, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a state read through S, K, A, D, G, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$, BHist, hsame, Cont, *finite rank-trigger rows, finite transition-count rows, finite trigger-time rows, and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient probability space, hidden generator field, infinite sample path, external random oracle, host Markov-chain semantics, or unstated independence assumption.

Lean4 ✓ `BEDC.Derived.MarkovTriggerDynamicsUp.MarkovTriggerDynamicsTasteGate single carrier alignment`

Theorem 4452.2 (MarkovTriggerDynamics NameCert obligations)**.** *For every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier* $T = (S, K, A, D, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed state row, support-rank row, transition-count row, drift row, trigger-time row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface requires the transition-count row A *to be computed from the finite support-rank row* K*, the drift row* D *to read only the transition counts in* A*, and the trigger-time row* G *to replay the finite recursion from the displayed state row* S *without adding an external probability carrier.*

Proof. Project the accepted carrier. The packet exposes only $S, K, A, D, G, H, C, P, N$, so every NameCert obligation is a componentwise obligation on those rows.

The state and support rows S, K determine the finite rank-trigger situation. The transition-count row A counts rank-preserving and rank-increasing next draws from that finite support surface.

The drift row D is downstream of A, and the trigger-time row G is downstream of the same state and transition-count data. Thus the trigger-time read is a finite recursion over displayed rows, not an imported Markov-chain object.

Transport, replay, provenance, and local naming preserve the same coordinates. Since the excluded ambient and hidden objects are not coordinates of T, no consumer can read them from the packet. □

Theorem 4452.3 (MarkovTriggerDynamics finite trigger readback)**.** *Every trigger-time consumer of an accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *packet reads the finite route*

$$S, K, A, D, G, H, C, P, N.$$

Consequently the transition law, drift, and trigger-time rows are all determined by finite BHist transition-count data. No trigger-time read exports an infinite sample path, host Markov process, hidden field, or unstated independence source.

Proof. Start with the state row S and support-rank row K. They display the finite input state and the rank information that determines which next-draw counts are available.

The transition-count row A is the only row from which the drift row D may be read. The trigger-time row G then replays the finite recursion from those same transition counts.

Finally H, C, P, N transport, replay, source, and name the finite trigger route. Because no other row exists in the carrier, the stated nonescape clauses follow. □

Falsifiable prediction: Every $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ trigger-time read factors through finite state, support-rank, transition-count, drift, trigger-time, hsame, Cont, Pkg, and NameCert rows.

Independence witness: dna-boundary-tile, rank-trigger, finite-markov-transition: $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries state rows, support-rank rows, transition-count rows, drift rows, trigger-time rows, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Theorem 4452.4 (MarkovTriggerDynamics sibling dependency route)**.** *Every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *trigger-time read routes its finite state and transition-count rows through chapter 189 or chapter 4074 when the carrier is read as a Markov surface, through chapter 195 when it is read as finite transition evolution, and through chapter 3508 for the DNA boundary-trigger consumer.*

Proof. Project the existing carrier rows $S, K, A, D, G, H, C, P, N$. The state row S, support-rank row K, and transition-count row A provide exactly the finite Markov read, so a Markov-surface consumer reaches this packet through the Markov-chain or finite Markov-partition certificates.

The same rows, together with drift row D and trigger-time row G, form the finite transition-evolution route consumed by the dynamical-system certificate. The structural rows H, C, P, N then transport, replay, source, and name that route for the DNA boundary-trigger consumer.

This is a dependency route only. It does not add an ambient probability space, infinite sample path, unstated independence source, or host Markov-chain object to the carrier. □

Nontrivial TasteGate and FieldFaithful instances remain required before this finite trigger surface can be read as a checked biological field-faithfulness claim.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet is generated from finite state rows, support-rank rows, transition-count rows, drift rows, trigger-time recursion rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5792.1, Definition 5792.2, and Definition 5792.3 seed the finite rank-trigger Markov readback surface for DNA boundary-tile dynamics.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient probability spaces, infinite sample paths, hidden field models, host Markov-chain semantics, biological field-faithfulness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-count exactness, drift readback, trigger-time recursion, nontrivial TasteGate coverage, FieldFaithful evidence, transport, replay, provenance, and local naming for BEDC.Derived.MarkovTriggerDynamicsUp.

Chapter 4453

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet records the finite constructive route from regular Cauchy rational names to located completion data and then to the terminal $\mathsf{Real}^{\uparrow}$ seal. It reads the dyadic arithmetic surface of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the completion service exposed by chapter 128, and the real-name boundary of chapter 38. The packet supplies a located completion neighbour for the regular-Cauchy real route without asserting quotient completion equality, selected representatives, host order completeness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4453.1 (Regular Cauchy located completion carrier)**.** *A* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, Q, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the Cauchy name is inspected at requested precision scales.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for tolerance comparison, shrinkage, and rational distance estimates.*
4. *Q is the located completion row, recording the displayed located-distance and approximation data extracted from S, R, D.*
5. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row used only as a finite completion handoff for the displayed located data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback and located completion rows have been displayed.*
7. *H records componentwise* hsame *transport for stream windows, regular rational readbacks, dyadic arithmetic, located completion data, completion service, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a located-completion request through $S, R, D, Q, K, E, H, P, N$.*

9. *P is the* Pkg *provenance over* RegularCauchyLocatedCompletion$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RegularCauchyLocatedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, K, E, H, C, P, N$. The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host order completeness, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedCompletionUp.RegularCauchyLocatedCompletionTasteGate single carrier alignment`

Theorem 4453.2 (Regular Cauchy located completion obligations)**.** *For every accepted* RegularCauchyLocatedCom *carrier*

$$L = (S, R, D, Q, K, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyLocatedCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream-window row, regular rational readback row, dyadic arithmetic ledger, located completion row, complete-metric handoff, real seal, transport, replay, provenance, and local name;*
2. *window-readback coherence, requiring S to expose the finite inspection windows before R may be consumed as a regular rational name;*
3. *dyadic locatedness, requiring D to supply the tolerance comparisons and distance estimates used by the located completion row Q;*
4. *completion handoff ordering, requiring Q to be displayed before the* CompleteMetric$^{\uparrow}$ *row K is exposed;*
5. *real-seal ordering, requiring E to be read only after S, R, D, Q, K have been displayed;*
6. *classifier stability, requiring componentwise* hsame *transport and displayed* Cont *replay to preserve all visible rows;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no quotient completion equality, selected representative, countable choice, host order completeness, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5793.1. Its rows list the finite stream windows, regular rational readback, dyadic arithmetic ledger, located completion data, complete-metric handoff, real seal, and the structural rows.

Window-readback coherence follows because R has no independent observation coordinate in this packet. The regular rational read must pass through S, and the tolerance computations used by that read are then checked against the dyadic row D.

The located completion row Q is the only row that records located-distance data. The completion handoff K consumes that displayed row, and the real seal E is exposed only after the handoff has been displayed.

Transport, replay, provenance, and local naming are exhausted by H, C, P, N. Since quotient completion equality, selected representatives, countable choice, host order completeness, and ambient Real$^{\uparrow}$ completeness are absent from the carrier, no NameCert obligation can export them. □

Theorem 4453.3 (Regular Cauchy located completion Real seal route)**.** *Let* $L = (S, R, D, Q, K, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the located completion read factors through the finite route*

$$S, R, D \longmapsto Q \longmapsto K \longmapsto E \longmapsto H, C, P, N.$$

Thus the packet reaches the real-name boundary only through displayed $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic, located completion data, and the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff. It does not export quotient completion equality, selected representatives, countable choice, host order completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing read of the packet. The only observable name data are the stream windows S and the regular rational readback R, so any request for a real seal must first inspect those rows.

The dyadic row D supplies the tolerance and distance comparisons used by the located completion data Q. The complete-metric handoff K is then read as a service row for that displayed located data, not as an ambient completeness theorem.

Finally the seal row E exposes the $\mathsf{Real}^{\uparrow}$ boundary, and H, C, P, N transport, replay, source, and name the same displayed route. No remaining carrier coordinate can provide quotient completion equality, selected representatives, choice data, host order completeness, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5793.1, Definition 5793.2, and Definition 5793.3 seed a finite route from regular Cauchy names through located completion data to the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host order completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback coherence, dyadic locatedness, completion handoff ordering, real-seal ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLocatedCompletionU

Constructive story: A $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore arithmetic, located completion data, a CompleteMetric handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4454

A Concrete Naming Certificate for $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$

Following Banach, Picard, and Bishop–Bridges constructive analysis, the $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet records the finite handoff from an explicit contraction estimate to the Cauchy threshold consumed by the regular-rational and real endpoint routes. It sits between the Banach fixed-point modulus packet of chapter 4188, the Picard iteration and error-estimate packets of chapter 2359 and chapter 2233, and the regular Cauchy completion boundary of chapter 5793. The packet gives the endpoint route a single displayed Cauchy-threshold surface without selecting a fixed point, quotienting completion names, or importing ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4454.1 (Picard threshold Cauchy handoff carrier)**.** *A* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, I, E, M, R, K, S, T, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BanachFixedPointModulus}^{\uparrow}$ *source row whose contraction-rate route has already exposed the rational Lipschitz and finite Picard ledgers.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *ledger of adjacent iterate windows and replay order.*
3. *E is the* $\mathsf{PicardErrorEstimate}^{\uparrow}$ *row, carrying the residual-and-ratio estimate used to bound the Picard tail.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row produced from B, I, E for each requested dyadic or rational tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row made available only after the threshold row M has been displayed.*
6. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row consumed at the handoff boundary, not an ambient completeness theorem.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, R, K have been read.*
8. *T stores componentwise* hsame *transports for the Banach-modulus, Picard-iteration, error-estimate, Cauchy-threshold, regular-rational, complete-metric, real-seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from the contraction-rate request through $B, I, E, M, R, K, S, T, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$, $\mathsf{BanachFixedPointModulus}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{PicardErrorEstimate}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, I, E, M, R, K, S, T, C, P, N$. It has no coordinate for a selected fixed point, host fixed-point equality, quotient completion equality, detached Cauchy selector, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.PicardThresholdCauchyHandoffUp.PicardThresholdCauchyHandoffTasteGate`
`single carrier alignment`

Theorem 4454.2 (Picard threshold Cauchy handoff NameCert obligations)**.** *For every accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier $H = (B, I, E, M, R, K, S, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyH}}$ *surface consists exactly of carrier admission for the displayed rows; Banach-modulus source visibility through B; Picard-iteration visibility through I; error-estimate visibility through E; Cauchy-threshold construction through M; regular-rational readback through R; complete-metric service access through K; real seal access through S; classifier stability through T and C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 5794.1. The accepted packet exposes exactly the Banach-modulus source row, the Picard-iteration ledger, the error-estimate row, the Cauchy-threshold row, the regular-rational readback, the complete-metric service, the real seal, and the structural rows.

The threshold rows are ordered. The rows B, I, E must be displayed before M can answer a tolerance request, since M is the only coordinate that records the finite Cauchy threshold.

The endpoint rows are downstream. The row R reads the threshold as regular rational data, K is the visible complete-metric service row, and S is exposed only after those rows have been displayed. Transport, replay, provenance, and local naming are exhausted by T, C, P, N, so no further NameCert obligation is present. □

Theorem 4454.3 (Picard threshold Cauchy handoff Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing endpoint read of an accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{BanachFixedPointModulus}^{\uparrow},\ \mathsf{PicardIteration}^{\uparrow},\ \mathsf{PicardErrorEstimate}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Complete}$$

Thus the real seal is reached only after the explicit Picard threshold has been displayed as a $\mathsf{CauchyModulus}^{\uparrow}$ *row and repacked through the regular-rational and complete-metric handoff rows. The route exports no selected fixed point, quotient completion equality, detached Cauchy selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing endpoint request. The only contraction-rate source row is B, and its Picard data are refined in the visible rows I and E, so the request first reads those rows.

The threshold stage is forced by M. Apply the Banach fixed-point modulus route of Definition 4188.3 together with the Picard iteration surface of chapter 2359 and the error-estimate surface of chapter 2233. These sources supply the displayed threshold row without adding a selected endpoint.

After M is fixed, the readback and completion rows R and K expose the regular-rational and complete-metric boundary used by chapter 301 and chapter 128. The seal row S is then the only $\mathsf{Real}^{\uparrow}$ coordinate, and the structural rows T, C, P, N preserve the same route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5794.1, Definition 5794.2, and Definition 5794.3 seed the finite Picard-threshold handoff from BanachFixedPointModulus, PicardIteration, and PicardErrorEstimate rows to CauchyModulus, RegSeqRat, CompleteMetric, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, host fixed-point equality, quotient completion equality, detached Cauchy selectors, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard-threshold construction, regular-rational readback, complete-metric service access, real-seal ordering, classifier stability, provenance, and local naming for BEDC.Derived.PicardThreshol

Constructive story: A $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet is generated from a BanachFixedPointModulus source row, PicardIteration ledger, PicardErrorEstimate row, CauchyModulus threshold, RegSeqRat readback, CompleteMetric service row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4455

A Concrete Naming Certificate for $\mathsf{DiniUniformLimitModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the classical Dini theorem, the $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet extracts the finite uniform-modulus ledger visible in compact-metric monotone convergence data. It sits over chapter 2196, chapter 1436, chapter 129, chapter 130, chapter 463, chapter 369, chapter 301, and chapter 38. The packet names the finite net, rational tolerance budget, and extracted modulus route; it does not import open-cover compactness, chosen limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4455.1 (Dini uniform-limit modulus carrier)**.** *A* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row naming the compact-metric finite-source observations consumed by the extraction.*
2. *F is the monotone* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, recording the displayed continuous approximants and their pointwise monotone order.*
3. *W is the pointwise window row supplied by the Dini-continuity and Dini-uniform-convergence routes.*
4. *E is the finite net row over K, naming the finite mesh on which pointwise windows are inspected.*
5. *Q is the rational tolerance-budget row, storing the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerances assigned to the finite net and to the later readback.*
6. *U is the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row, obtained from E, Q, W and the monotone continuous family row F.*
7. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row, exposing only the modulus-controlled limit route supplied by U.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance transport.*
9. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row, naming the real-valued read without adding ambient real completeness.*
10. *H records componentwise* hsame *transport for compact-metric source, monotone family, pointwise window, finite net, rational tolerance, extracted modulus, uniform-limit handoff, rational readback, real seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the compact-metric source and monotone family through the finite net, tolerance budget, extracted modulus, and uniform-limit handoff.*
12. *P is the* Pkg *provenance over* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$, $\mathsf{DiniContinuity}^{\uparrow}$, $\mathsf{DiniUniformConvergence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, W, E, Q, U, L, R, S, H, C, P, N$. It has no coordinate for open-cover compactness, selected limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiniUniformLimitModulusUp.TasteGate.DiniUniformLimitModulusTasteGate single carrier alignment`

Theorem 4455.2 (Dini uniform-limit modulus NameCert obligations)**.** *For every accepted* DiniUniformLimitModulu *carrier*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact-metric source, monotone continuous family, pointwise window, finite net, rational tolerance budget, extracted uniform modulus, UniformLimit handoff, RegSeqRat readback, Real seal, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires monotone-window visibility through F and W, finite-net extraction through E and Q, modulus handoff through U and L, Real-seal nonescape through S, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses open-cover compactness, selected limiting values, quotient function equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*
