Independence witness: Nearest siblings include $\mathsf{RegularCauchyTailBudget}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. None is bijective to $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$ because the budget packet stores observation service, the modulus packet stores a general tolerance schedule, the regular sequence packet stores the source reads, the stream packet stores names, the dyadic packet stores rational tolerances, and the real packet stores a seal rather than the finite tail-majorant threshold binding them.

Definition 5094.1 (Regular Cauchy tail majorant carrier)**.** *A* $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule naming the inspected regular-sequence tail requests.*
2. *M is the majorant-threshold row assigning to each displayed tolerance request a finite stage after which the tail estimate is accepted.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger whose dyadic entries are the error bounds tested by M.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that exposes the regular rational sequence only through the displayed schedule, threshold, and dyadic tolerance rows.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the scheduled tail-majorant readback has been replayed.*

6. *H records componentwise* hsame *transport for the schedule, majorant threshold, dyadic tolerance, regular readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from schedule requests through the majorant threshold, dyadic tolerance ledger, regular readback, and seal handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailMajorant}^{\uparrow}}$ *row.*

The carrier accepts only packets whose regular Cauchy tail estimates are read through a displayed finite majorant threshold for the requested dyadic tolerance before any $\mathsf{Real}^{\uparrow}$ *seal row is consumed.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailMajorantUp.RegularCauchyTailMajorantTasteGate single carrier alignment`

Theorem 5094.2 (Regular Cauchy tail majorant NameCert obligations)**.** *For the carrier of Definition 5900.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailMajorant}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$J = (S, M, D, R, E, H, C, P, N),$$

schedule exposure through S, majorant-threshold exposure through M, dyadic tolerance readability through D, regular rational readback through R, seal handoff through E, componentwise hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier. The displayed rows $S, M, D, R, E, H, C, P, N$ are the only coordinates of an accepted $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$ packet.

Read the analytic rows in order. The schedule row S names the inspected tail requests, the threshold row M supplies the finite majorant stage for each displayed request, and the dyadic row D supplies the tolerance being tested.

The readback and seal rows are downstream of that finite service. The $\mathsf{RegSeqRat}^{\uparrow}$ row R may be read only after S, M, D have been displayed, and the $\mathsf{Real}^{\uparrow}$ seal row E consumes that readback rather than creating an ambient limit.

Finally H, C, P, N transport, replay, package, and name the same finite route. Since no carrier coordinate stores quotient real equality, a selected limit, countable choice, or completeness, the local NameCert obligations are exactly the displayed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailMajorant}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailMajorant}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5900.1 and Definition 5900.2 bind the seed carrier and local NameCert surface for explicit regular Cauchy tail majorants.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailMajorant}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completeness of $\mathsf{Real}^{\uparrow}$, selected limits, quotient equality of real names, countable choice, or Lean verification.

Upgrade path: Formalization requires a Lean carrier for the schedule, dyadic tolerance, regular readback, seal handoff, and finite majorant-threshold rows.

Constructive story: A $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$ packet is generated from a finite stream schedule, displayed majorant thresholds, dyadic tolerance rows, regular readback, a seal handoff, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Chapter 5095

A Concrete Naming Certificate for $\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}$

Following Bishop and Bridges on nested interval principles, the $\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}$ packet records the finite Real-facing window by which nested located intervals are inspected before a real-name seal is read. It sits over the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the nested/Cantor neighbours chapter 320 and chapter 4359. The packet names a finite witness route for Real and Completion consumers; it does not claim open-cover compactness, countable choice, quotient reals, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5095.1 (RealCantorIntersectionFiniteWindow carrier)**.** *A* $\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (I, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the nested located-interval row, carrying the visible interval prefix, the containment witness, and the located endpoint tests read from the nested-interval surface.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter ledger, recording the dyadic width bounds and tolerance requests attached to the displayed prefix.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming exactly the interval and endpoint observations inspected by the consumer.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and the diameter ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after I, D, W, R have been displayed.*
6. *H records componentwise* hsame *transport for the nested interval, diameter, window, readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$I, D \longmapsto W \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{CantorIntersectionMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $I, D, W, R, E, H, C, P, N$ and the displayed replay order. It has no coordinate for an infinite intersection selector, quotient real equality, open-cover compactness, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealCantorIntersectionFiniteWindowUp.RealCantorIntersectionFiniteWindowTasteGate`
`single carrier alignment`

Theorem 5095.2 (RealCantorIntersectionFiniteWindow NameCert obligations)**.** *For every accepted* $\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}$ *carrier*

$$Q = (I, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}}$ *surface consists exactly of carrier admission, nested located-interval exposure, dyadic diameter accounting, finite StreamName window exposure, RegSeqRat readback, Real-seal routing, componentwise transport, displayed continuation replay, package provenance, and local naming. Every Real or Completion consumer read of the packet must pass through the finite nested-window route*

$$I, D \longmapsto W \longmapsto R \longmapsto E$$

before the terminal seal is public.

Proof. Project the carrier of Definition 5901.1. The accepted packet exposes exactly the nested interval row I, dyadic diameter ledger D, finite window row W, regular readback row R, Real seal E, and the structural rows H, C, P, N.

The analytic obligations are read by projection through those rows. The nested located-interval row supplies the visible containment prefix and endpoint locatedness, while the dyadic ledger supplies the diameter budget that makes the inspected prefix usable for a Real-facing read.

Next the window and readback rows fix the finite observation route. The StreamName row W names the inspected observations, and the RegSeqRat row R is the only regular rational readback coordinate generated from them.

Finally the seal and structural rows close the packet. The continuation row places E after I, D, W, R, the transport row preserves the same coordinates, and P, N source and name only this local certificate. Since no further coordinate occurs in the carrier, the listed rows exhaust the NameCert obligations and exclude open-cover compactness, countable choice, quotient reals, selected limits, and ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}}$, seed)

Scope closed: Definition 5901.1 and Definition 5901.2 seed the finite Cantor-intersection window route over nested located intervals, dyadic diameter ledgers, StreamName windows, RegSeqRat readback, and the terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, quotient reals, selected infinite intersections, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested located-interval exposure, diameter accounting, finite-window exposure, regular readback, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RealCantorIntersectionFiniteWindowUp.

Constructive story: A $\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}$ packet is generated from nested located intervals, a DyadicRatCore diameter ledger, StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ selector chapter is a structural consumer of chapter 381 and chapter 5899 through its finite selected-window route.

Chapter 5096

A Concrete Naming Certificate for $\mathsf{CauchySubsequenceSelector}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy sequences, the $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ packet records the finite selector schedule by which a regular rational Cauchy name may expose a monotone subsequence corridor before a Real or Completion consumer reads the terminal seal. It sits after the regular rational source of chapter 301, the finite window surface of chapter 126, the terminal real-name boundary of chapter 38, and the Cauchy hub of chapter 406. The packet gives diagonal, tail, and completion-facing chapters a named L10 selector object; it is not a quotient of streams, a selected host limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Any subsequence-selector read must display the $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ route of chapter 4080 and the $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ finite-window schedule of chapter 8091 before reaching $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers. The selector is therefore a visible diagonal-and-window corridor, not a detached subsequence choice. The fast selector route of chapter 1518 consumes this schedule when the cofinal subsequence corridor must be made fast enough for $\mathsf{Real}^{\uparrow}$ completion windows, while chapter 5899 consumes compatible selected windows when the subsequence corridor is glued back into a regular Cauchy route.

Definition 5096.1 (Cauchy subsequence selector carrier)**.** *A* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, W, M, G, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose rational reads are being sampled.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the source observations consumed by the selector.*
3. *M is the monotone selector row, recording a finite schedule of indices and the strict order checks between successive selected positions.*
4. *G is the Cauchy-gap ledger, recording the tail comparison requests that make the selected windows compatible with the source Cauchy evidence.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after R, W, M, G have been displayed.*
6. *H records componentwise* hsame *transport for the source, window, monotone selector, Cauchy-gap, seal, replay, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from a subsequence request through R, W, M, G, E, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, W, M, G, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 5096.2 (Cauchy subsequence selector NameCert obligations)**.** *For every accepted* CauchySubsequenceSel *carrier $S = (R, W, M, G, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelector}^{\uparrow}}$ *surface consists exactly of carrier admission, selector monotonicity,* $\mathsf{StreamName}^{\uparrow}$ *window coverage, Cauchy-gap compatibility,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise transport, displayed replay, package provenance, and local naming. Each obligation is read through the finite route*

$$R, W, M, G \longrightarrow E \longrightarrow H, C, P, N.$$

Proof. Carrier admission is projection from Definition 5902.1. The packet first exposes the regular rational source R, the finite observation windows W, the monotone selector schedule M, and the Cauchy-gap ledger G.

Selector monotonicity is local to M. The window coverage obligation then reads W at precisely the positions displayed by M, so every selected index has a finite $\mathsf{StreamName}^{\uparrow}$ observation before any handoff is consumed.

The $\mathsf{RegSeqRat}^{\uparrow}$ handoff is the source row R restricted along the displayed schedule and checked against the Cauchy-gap ledger G. The terminal seal E is downstream of those rows, and it is only a $\mathsf{Real}^{\uparrow}$ seal for the displayed subsequence corridor.

Transport through H, replay through C, provenance P, and local naming N preserve the same route. Since quotient stream equality, selected limits, host real equality, countable choice, trichotomy, and ambient Real completeness are absent from the carrier coordinates, no obligation can discharge outside the displayed finite packet. □

Theorem 5096.3 (Cauchy subsequence selector real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *packet must first read the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the monotone selector schedule, and the Cauchy-gap ledger. The handoff to E therefore supplies a finite subsequence corridor from regular rational data to Real-facing data, not a host subsequence theorem, not a selected limit, and not a quotient construction.*

Proof. Project an accepted carrier $S = (R, W, M, G, E, H, C, P, N)$. The source row R is the only regular rational input, and W is the only finite observation surface available to a consumer.

The selector row M records the monotone schedule. The Cauchy-gap ledger G records the finite tail comparisons that let the scheduled windows be read as a subsequence corridor of the same source.

Only after R, W, M, G are present may the consumer inspect E as a Real-facing seal. The transport, replay, provenance, and naming rows keep that order visible to downstream chapters.

The carrier contains no coordinate for quotient stream equality, a chosen host subsequence, a selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Thus every Real or Completion handoff factors through the displayed selector rows. □

Theorem 5096.4 (Cauchy subsequence selector sibling lattice route)**.** *Every* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *consumer must pass through* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *and* $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ *before the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows are consumed. The selector route therefore reads the diagonal-selection corridor, the regular Cauchy finite-window induction ledger, the source row R, finite windows W, monotone selector schedule M, Cauchy-gap ledger G, seal row E, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelector}^{\uparrow}}$ *row as one sibling lattice. Before any gluing-facing consumer reads* $\mathsf{RegularCauchyGluing}^{\uparrow}$, *the selected finite windows are certified as regular-Cauchy subsequence data through chapter 381; only then can the gluing route consume the selector rows R, W, M, G before the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

The route exports no detached subsequence choice, quotient stream equality, selected limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project an accepted carrier $S = (R, W, M, G, E, H, C, P, N)$ from Definition 5902.1. The source, window, monotone selector, Cauchy-gap, and seal rows are the only analytic rows available to a consumer, while H, C, P, N are the structural rows that transport, replay, source, and name them.

Apply Definition 5902.2. It forces carrier admission, selector monotonicity, window coverage, Cauchy-gap compatibility, regular-rational handoff, seal non-escape, transport, replay, provenance, and local naming before any consumer can read the selector.

Apply Definition 5902.3. The $\mathsf{Real}^{\uparrow}$ or Completion-facing read reaches E only after R, W, M, G have been displayed, so the diagonal-selection corridor and regular Cauchy window-induction ledger must be upstream of the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows named in the introduction; the same displayed windows are first certified by chapter 381 before $\mathsf{RegularCauchyGluing}^{\uparrow}$ can consume them.

Since the carrier has no coordinate for detached subsequence choice, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, the sibling lattice cannot export any of those principles. □

Theorem 5096.5 (Cauchy subsequence selector diagonal-window readiness)**.** *Every fast-selector or gluing-facing consumer of a* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *packet must expose the* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *route and the* $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ *finite schedule before it consumes the selector rows $R, W, M, G, E, H, C, P, N$. In particular, a* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *consumer cannot read the fast cofinal corridor, and a* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *consumer cannot read compatible selected windows, until the diagonal route and finite-window schedule have already displayed the source row, finite windows, monotone selector row, Cauchy-gap ledger, terminal seal, transport, replay, provenance, and local naming rows.*

Proof. Apply Definition 5902.2. It makes $R, W, M, G, E, H, C, P, N$ the full NameCert surface for an accepted selector packet, so a downstream consumer has no row outside that finite display from which to read subsequence data.

Apply Definition 5902.3. The Real or Completion-facing handoff reaches E only after the regular rational source, finite windows, selector schedule, and Cauchy-gap ledger have been displayed.

Now apply Definition 5902.4. It places the $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ corridor and the $\mathsf{RegularCauchyWindowIndu}$ schedule before the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, terminal $\mathsf{Real}^{\uparrow}$, and gluing-facing rows are consumed. Therefore both the fast-selector route and the gluing route must expose the diagonal-window readiness surface before reading $R, W, M, G, E, H, C, P, N$. □

Theorem 5096.6 (Cauchy subsequence selector regular-window handoff)**.** *Every* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *handoff that is later glued or sealed through* $\mathsf{Real}^{\uparrow}$ *first consumes* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *as the finite-window certificate that the selected rows remain regular-Cauchy subsequence data. Thus the selected windows* W *and monotone schedule* M *are certified through chapter 381 before any* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *or terminal* $\mathsf{Real}^{\uparrow}$ *consumer reads* R, W, M, G, E.

Proof. Project the accepted carrier $S = (R, W, M, G, E, H, C, P, N)$. The selected windows W and monotone schedule M are the only rows that can present subsequence data to a downstream consumer.

Use the sibling lattice route of Definition 5902.4. It places the diagonal-selection corridor and regular Cauchy window-induction ledger before the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are consumed.

The regular-window handoff is therefore a finite certification step: W and M are read as regular-Cauchy subsequence data before gluing or sealing can consume R, W, M, G, E. The route has no coordinate for a detached subsequence choice, selected host limit, or ambient completeness principle. □

Theorem 5096.7 (Cauchy subsequence selector forward density route)**.** *Every* $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ *or density-facing completion consumer that reads selected Cauchy subsequence windows from an accepted* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *packet must first pass through* $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal route displayed by the selector. The forward density read therefore consumes the selector rows* $R, W, M, G, E, H, C, P, N$ *as finite regular-Cauchy subsequence data, not as a separate host subsequence, a choice-selected limit, or an ambient completeness principle.*

Proof. Apply the Real handoff theorem, Definition 5902.3. It forces every Real or Completion-facing read through the regular rational source row R, finite windows W, monotone selector schedule M, Cauchy-gap ledger G, and terminal seal row E.

Use the sibling lattice route of Definition 5902.4 together with the regular-window handoff of Definition 5902.6. These place $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{RegularCauchySubsequence}^{\uparrow}$ before any downstream gluing, sealing, or density-facing consumer reads the selected windows.

Thus a $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ consumer receives only the displayed finite selector corridor. Since the carrier has no coordinate for a detached host subsequence, selected limit, quotient stream equality, or ambient completeness, the forward density route cannot bypass the existing selector handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ packet is generated from a RegSeqRat source row, finite StreamName windows, monotone selector schedule, Cauchy-gap ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelector}^{\uparrow}}$, seed)

Scope closed: Definition 5902.1, Definition 5902.2, and Definition 5902.3 seed the finite selector corridor from regular rational Cauchy data to a Real-facing seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelector}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, selector monotonicity, StreamName window coverage, Cauchy-gap compatibility, RegSeqRat handoff, Real seal non-escape, transport, replay, provenance, and local naming.

The fast selector route of chapter 1518 consumes the $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ monotone schedule when the subsequence corridor must be made fast enough for $\mathsf{Real}^{\uparrow}$ completion windows. The $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ route is consumed by chapter 1518 when a cofinal fast subsequence schedule must be displayed before a completion-facing read, and by chapter 5899 when selected finite windows are glued back into a regular Cauchy route. Thus the selector sits in the L10 dependency lattice between finite StreamName windows, regular rational source rows, fast subsequence scheduling, and regular Cauchy gluing, rather than floating as a kernel-only carrier.

Theorem 5096.8 (CauchySubsequenceSelector regular Cauchy gluing forward route)**.** *Every* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *packet must first read the source regular-rational row R, the selected finite windows W, the monotone selector schedule M, and the Cauchy-gap ledger G before gluing compatible selected windows back into a regular Cauchy route. The handoff to chapter 5899 therefore remains a displayed finite-window route rather than a selected representative, quotient stream equality, countable-choice schedule, or ambient Real-completeness principle.*

Proof. Project the selector carrier described in chapter 5902. Its gluing-facing data are the source row R, finite selected windows W, monotone selector schedule M, and Cauchy-gap ledger G.

Only after those rows are visible can a gluing consumer inspect compatible windows. The $\mathsf{RegularCauchyGluing}^{\uparrow}$ route then supplies its own regular-Cauchy compatibility and terminal Real-seal boundary, so the selector packet is a forward dependency of gluing rather than a replacement for the gluing certificate.

Since neither the selector rows nor the gluing route contain quotient stream equality, selected representatives, countable choice, or ambient Real completeness, the composed route exports only the finite selected-window data and the downstream regular Cauchy gluing surface. □

Theorem 5096.9 (Cauchy subsequence selector finite-window forward link)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *read factors through the finite-window route*

$$\mathsf{FiniteStream}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{CauchyDiagonalSelection}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

before the terminal seal is available. The consumer therefore reads the selector carrier rows as displayed finite windows and diagonal-selection data, not as a quotient subsequence, selected limit, countable-choice schedule, host real equality, or ambient completeness principle.

Proof. Project the selector carrier from Definition 5902.1. Its source row, finite windows, monotone schedule, Cauchy-gap ledger, real seal, transport, replay, provenance, and local naming rows are the only coordinates available to a downstream read.

Use the real handoff of Definition 5902.3. It forces every seal consumer to pass through the regular rational source row, the $\mathsf{StreamName}^{\uparrow}$ finite windows, the selector schedule, and the Cauchy-gap ledger before reading the terminal $\mathsf{Real}^{\uparrow}$ row.

Now read the sibling lattice route of Definition 5902.4. The lattice places the selector between $\mathsf{CauchyDiagonalSelection}^{\uparrow}$, $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$, finite window data, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally identify the forward consumer rows: $\mathsf{FiniteStream}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ provide the finite observations, $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ supplies the displayed diagonal corridor, $\mathsf{RegSeqRat}^{\uparrow}$ reads the regular rational name, and $\mathsf{DyadicRatCore}^{\uparrow}$ records the tolerance row before the terminal seal. Since all of these rows are explicit carrier-local reads, no refused quotient, choice, selected-limit, host-equality, or ambient-completeness endpoint can enter the route. □

The selector packet also consumes the regular-Cauchy subsequence surface of chapter 381. Its monotone selector row, finite windows, and Cauchy-gap ledger are read as a route inside the same regular-Cauchy finite-window surface before the terminal $\mathsf{Real}^{\uparrow}$ seal is available. Thus a downstream completion consumer sees the selected subsequence as displayed regular-Cauchy data, not as a detached host subsequence or a separate choice principle. The selector dependency route is consumed by both the fast subsequence handoff of chapter 1518 and the regular-Cauchy gluing route of chapter 301. Thus a downstream Cauchy consumer reads the same displayed selector schedule, finite windows, and gap ledger before treating the selected route as fast enough for completion-facing readback.

Theorem 5096.10 (Cauchy subsequence selector orphan lattice route)**.** *Every selector read consumed by* $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ *must preserve the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ *witness row, and the* $\mathsf{Real}^{\uparrow}$ *terminal seal before any subsequence extraction is public. Thus the extractor-facing selector route is the finite lattice*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegularCauchyMinModulus}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

inside the accepted $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *packet, not a detached subsequence choice or quotient stream selection.*

Proof. Project the selector carrier of Definition 5902.1. The available selector rows are the source row R, finite windows W, monotone selector schedule M, Cauchy-gap ledger G, terminal seal E, transport, replay, provenance, and local naming.

Use the selector dependency route and the cofinal subsequence dependency route. They force every extractor-facing read to pass through the displayed selector schedule before the extraction row can be consumed as finite subsequence data.

Finally read the regular-Cauchy minimum-modulus forward link. It keeps the $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ witness visible alongside the $\mathsf{RegSeqRat}^{\uparrow}$ source row and $\mathsf{StreamName}^{\uparrow}$ finite windows before the terminal $\mathsf{Real}^{\uparrow}$ seal is public. Hence the selector exports only the stated finite lattice to the extractor and no separate host-side subsequence selection. □

Chapter 5097

A Concrete Naming Certificate for $\mathsf{ArtinianRing}^{\uparrow}$

Following Hopkins–Levitzki and the Atiyah–Macdonald Artinian ring tradition, the $\mathsf{ArtinianRing}^{\uparrow}$ packet records finite descending ideal-chain stabilization data over a ring, commutative-ring, and ideal source. In BEDC form it sits after $\mathsf{NameCert}_{\mathsf{Ring}^{\uparrow}}$ (chapter 43), $\mathsf{NameCert}_{\mathsf{CommRing}^{\uparrow}}$ (chapter 44), and $\mathsf{NameCert}_{\mathsf{Ideal}^{\uparrow}}$ (chapter 81), while complementing the ascending-chain sibling $\mathsf{NameCert}_{\mathsf{NoetherianRing}^{\uparrow}}$ of chapter 3637. The packet supplies a descending-chain source row for later algebra consumers; it does not assert module finite length, semisimplicity, quotient ideal spaces, maximal ideal choice, or the Hopkins–Levitzki theorem itself.

5097.1 Carrier Definition

Definition 5097.1 (Artinian ring carrier)**.** *An* $\mathsf{ArtinianRing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{ArtRing}(R, C, I, D, L, H, Q, P, N).$$

The row R is the ambient $\mathsf{Ring}^{\uparrow}$ *source surface. The row C is the* $\mathsf{CommRing}^{\uparrow}$ *source surface when the consumer reads the commutative specialization. The row I is the* $\mathsf{Ideal}^{\uparrow}$ *source surface over the same classifier. The row D is the descending-chain stabilization witness: every displayed descending chain of ideal rows over R, C, I carries a finite stage after which all later ideal endpoints classify with that stage. The row L is the finite-length ledger used by algebraic consumers that read descending stabilization together with the ascending-chain sibling of* $\mathsf{NoetherianRing}^{\uparrow}$*. The row H is componentwise* hsame *transport for the ring, commutative-ring, ideal, stabilization, and finite-length rows. The row Q is displayed* Cont *replay for the chain and length certificates. The row P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{ArtinianRing}^{\uparrow}}$ *naming row.*

Lean4 ✓ `BEDC.Derived.ArtinianRingUp.ArtinianRingTasteGate single carrier alignment`

Theorem 5097.2 (Artinian ring NameCert obligations)**.** *For an accepted* $\mathsf{ArtinianRing}^{\uparrow}$ *carrier* $\mathsf{ArtRing}(R, C, I, D, L, H, Q, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ArtinianRing}^{\uparrow}}$ *surface consists exactly of carrier admission for the nine displayed rows, source compatibility with* $\mathsf{Ring}^{\uparrow}$*,* $\mathsf{CommRing}^{\uparrow}$*, and* $\mathsf{Ideal}^{\uparrow}$*, descending-chain stabilization access through D, finite-length ledger access through L, componentwise classifier transport through H, displayed continuation replay through Q, provenance non-escape through P, and local naming through N.*

Proof. Project the rows of Definition 5097.1. The source rows R, C, I fix the ring, commutative-ring, and ideal classifiers before any chain is inspected.

The stabilization row D is then read over that shared source surface. The finite-length ledger L is available only as a displayed ledger attached to the same classifier, so it cannot replace the descending-chain witness by a host theorem.

Finally H, Q, P, N provide componentwise transport, continuation replay, provenance, and local naming. Since no quotient ideal space, maximal ideal selector, semisimplicity proof, or Hopkins–Levitzki theorem row is present, the listed coordinates exhaust the NameCert obligations. □

Theorem 5097.3 (Artinian descending-chain stability)**.** *Let* $\mathsf{ArtRing}(R, C, I, D, L, H, Q, P, N)$ *be an accepted* $\mathsf{ArtinianRing}^{\uparrow}$ *carrier. For every displayed descending chain of ideal rows over the shared* $\mathsf{Ring}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, *and* $\mathsf{Ideal}^{\uparrow}$ *classifier, the witness* D *supplies a finite stabilization stage, and* H *transports that stabilization along the same classifier. Any downstream algebra consumer may therefore use* $\mathsf{ArtinianRing}^{\uparrow}$ *as a finite descending ideal-chain certificate without re-proving stabilization inside its own packet.*

Proof. Begin with the source compatibility rows from Definition 5097.2. They force the descending ideal chain to be read over the ring, commutative-ring, and ideal classifiers already present in R, C, I.

Apply the stabilization witness D to obtain a finite stage for the displayed descending chain. If the accepted packet is transported through a classified replacement, use the componentwise transport row H to move both the chain entries and the stabilization witness through the shared classifier.

The transported stage remains a stage for the same finite chain surface because Q replays only the displayed continuation data and P prevents provenance escape. The conclusion is therefore a reusable finite descending ideal-chain certificate that can be paired with the ascending-chain surface of chapter 3637. □

Closure status for $\mathsf{NameCert}_{\mathsf{ArtinianRing}^{\uparrow}}$.

Constructive story: An $\mathsf{ArtinianRing}^{\uparrow}$ packet is generated from RingUp, CommRingUp, and IdealUp source rows, a descending-chain stabilization witness, a finite-length ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArtinianRing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5097.1, Definition 5097.2, and Definition 5097.3 seed the finite descending ideal-chain stabilization interface over RingUp, CommRingUp, IdealUp, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArtinianRing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close module finite length, semisimplicity, quotient ideal spaces, maximal ideal choice, the Hopkins–Levitzki theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, descending stabilization access, finite-length ledger access, componentwise transport, provenance non-escape, and local NameCert exactness for BEDC.Derived.ArtinianRingUp.

Chapter 5098

A Concrete Naming Certificate for $\mathsf{MooreSmithSubnet}^{\uparrow}$

Following Moore and Smith on nets and Kelley-style subnet reindexing, the $\mathsf{MooreSmithSubnet}^{\uparrow}$ packet records the standard subnet relation as finite BEDC naming data. It sits between the $\mathsf{DirectedSubnet}^{\uparrow}$ cofinal-tail surface of chapter 1600, the Cauchy-facing restriction route of $\mathsf{CauchySubnet}^{\uparrow}$ in chapter 1592, and the convergence interface of chapter 1667. Its Real-facing readback uses the finite windows of chapter 126, the dyadic tolerance row of chapter 291, the regular rational handoff of chapter 301, and the terminal seal of chapter 38. The packet names cofinal subnet evidence without selecting a host subnet representative, quotienting nets, invoking countable choice, or importing ambient completeness.

Definition 5098.1 (Moore–Smith subnet carrier)**.** *A* $\mathsf{MooreSmithSubnet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, J, \phi, A, T, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the directed source-index row for the original net.*
2. *J is the directed subnet-index row.*
3. *ϕ is the monotone cofinal map row from J into I, read through the* $\mathsf{DirectedSubnet}^{\uparrow}$ *interface.*
4. *A is the source net-value row, containing only the finite values inspected by the packet.*
5. *T is the cofinal tail ledger, recording for each displayed source tail a subnet tail whose image lies inside it.*
6. *W is the finite observation-window row over* $\mathsf{StreamName}^{\uparrow}$*.*
7. *D is the dyadic tolerance row over* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
8. *R is the regular rational readback row over* $\mathsf{RegSeqRat}^{\uparrow}$*.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, exposed only after $I, J, \phi, A, T, W, D, R$ have been displayed.*
10. *H records componentwise* hsame *transport for the directed, cofinal, observation, readback, seal, replay, provenance, and naming rows.*
11. *C records displayed* Cont *replay from subnet requests through the same finite route.*

12. *P is the* Pkg *provenance over* $\mathsf{MooreSmithSubnet}^{\uparrow}$, $\mathsf{DirectedSubnet}^{\uparrow}$, $\mathsf{CauchySubnet}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreSmithSubnet}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through the displayed rows $I, J, \phi, A, T, W, D, R, E, H, C, P, N$. It has no coordinate for a selected host subnet, quotient-net equality, a chosen limit point, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.MooreSmithSubnetUp.MooreSmithSubnetTasteGate single carrier alignment`

Theorem 5098.2 (Moore–Smith subnet NameCert obligations)**.** *For every accepted* $\mathsf{MooreSmithSubnet}^{\uparrow}$ *carrier $M = (I, J, \phi, A, T, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MooreSmithSubnet}^{\uparrow}}$ *surface consists exactly of directed source admission, directed subnet-index admission, monotone cofinal map admission, finite net-value observation, cofinal-tail exactness,* $\mathsf{StreamName}^{\uparrow}$ *window stability,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the finite carrier of Definition 5098.1.*

Proof. Project the accepted carrier of Definition 5098.1. The directed rows I, J and the map row ϕ supply the Moore–Smith reindexing surface, while A, T record the finite source values and the cofinal tail ledger.

The observation and Real-facing rows are read after that subnet route. The packet exposes W, D, R, E as the StreamName window, dyadic tolerance, regular rational readback, and terminal Real seal, with E unavailable before the finite observation and readback rows have been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since no row carries a selected host subnet, quotient-net equality, selected limit, countable choice, trichotomy, open-cover compactness, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 5098.3 (Moore–Smith subnet cofinality route)**.** *Every convergence-facing or completion-facing consumer of an accepted* $\mathsf{MooreSmithSubnet}^{\uparrow}$ *carrier must read the monotone cofinal map row and the cofinal-tail ledger before it can consume the* $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{CauchySubnet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *rows. The public route factors through*

$$I, J, \phi, T \longmapsto W, D, R \longmapsto E \longmapsto H, C, P, N.$$

Proof. Begin with $M = (I, J, \phi, A, T, W, D, R, E, H, C, P, N)$. The subnet data are not represented by an external object; the only available reindexing evidence is the displayed directed pair I, J together with the map row ϕ.

The cofinality condition is then read through T. For each finite source-tail request, T supplies the matching subnet-tail evidence that permits a downstream $\mathsf{NetConvergence}^{\uparrow}$ or $\mathsf{CauchySubnet}^{\uparrow}$ consumer to follow the same tail route.

Only after the cofinal route has been displayed may the packet expose W, D, R and then the terminal seal E. Transport, replay, provenance, and local naming preserve this order through H, C, P, N, so no consumer can bypass cofinality by reading a selected subnet representative or a host convergence predicate. □

Theorem 5098.4 (Moore–Smith subnet nonescape)**.** *An accepted* $\mathsf{MooreSmithSubnet}^{\uparrow}$ *packet exports no selected host subnet, quotient-net equality, selected limit, countable-choice coordinate, open-cover compactness principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim. Every public read remains*

inside the finite rows of Definition 5098.1 and the sibling surfaces $\mathsf{DirectedSubnet}^{\uparrow}$, $\mathsf{CauchySubnet}^{\uparrow}$, $\mathsf{NetConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$.

Proof. Apply Definition 5098.2. The obligations list every row of the accepted carrier and identifies the structural rows as componentwise transport, displayed replay, provenance, and local naming.

Apply Definition 5098.3. The downstream route keeps convergence and completion reads behind the displayed cofinal map, tail ledger, observation windows, tolerance row, regular readback, and terminal seal.

The carrier has no coordinate for the excluded host objects. Therefore no structural transport or replay step can synthesize a selected subnet, quotient equality, selected limit, choice coordinate, compactness principle, or ambient completeness claim from the finite Moore–Smith subnet rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{MooreSmithSubnet}^{\uparrow}}$.

Constructive story: A $\mathsf{MooreSmithSubnet}^{\uparrow}$ packet is generated from source and subnet directed-index rows, a monotone cofinal map, finite net-value observations, a cofinal-tail ledger, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MooreSmithSubnet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5098.1, Definition 5098.2, Definition 5098.3, and Definition 5098.4 seed the finite Moore–Smith subnet packet for topology and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MooreSmithSubnet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected host subnets, quotient-net equality, chosen limit points, countable choice, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal-map exactness, cofinal-tail coverage, finite observation stability, Real seal nonescape, transport stability, replay stability, provenance exhaustion, and Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.MooreSmithSubnetUp.

Chapter 5099

A Concrete Naming Certificate for FiniteObservationConfluenceBudget$^{\uparrow}$

The FiniteObservationConfluenceBudget$^{\uparrow}$ packet realizes the MetaCIC residual-confluence frontier as a finite observation surface. It sits beside the residual-substitution boundary of chapter 2181, the bounded residual frontier of chapter 3808, the residual checker of chapter 3827, and the bounded normal-conversion bridge of chapter 3439. The packet records a typed finite window, local join evidence, bounded checker status, obstruction retention, transport, replay, provenance, and local naming without claiming full residual substitution compatibility, subject reduction, or unconditional confluence.

Definition 5099.1 (Finite observation confluence-budget carrier)**.** *A* FiniteObservationConfluenceBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, R, L, B, O, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed finite-window row, recording the closed term, typed context fragment, and observation depth inspected by the packet.*
2. *R is the residual-frontier row, recording only the residual substitutions visible inside the displayed window.*
3. *L is the local-join row, naming the bounded join diagram accepted inside that window.*
4. *B is the bounded-checker row, recording the finite checker budget, checker result, and replay fuel.*
5. *O is the obstruction-retention row, preserving the subject-reduction and residual-substitution boundary that prevents the packet from becoming a full confluence theorem.*
6. *S is the transport row from bounded conversion and finished-normal endpoint evidence into the same finite observation budget.*
7. *H records componentwise* hsame *transport for typed windows, residual frontiers, local joins, bounded checks, obstruction rows, transport rows, replay, provenance, and naming.*
8. *C records displayed* Cont *replay from a candidate confluence request through $T, R, L, B, O, S, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteObservationConfluenceBudget}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICConfluenceRes}$ $\mathsf{BoundedResidualSubstitutionFrontier}^{\uparrow}$, $\mathsf{BoundedNormalConversionBridge}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationConfluenceBudget}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $T, R, L, B, O, S, H, C, P, N$. It has no coordinate for unrestricted residual substitution, global subject reduction, arbitrary closed star confluence, quotient conversion equality, or an unbounded normalizer.

Theorem 5099.2 (Finite observation confluence-budget NameCert obligations)**.** *For every accepted* $\mathsf{FiniteObservationConfluenceBudget}^{\uparrow}$ *carrier $F = (T, R, L, B, O, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteObservat}}$ *surface consists exactly of typed-window admission, residual-frontier admission, local-join recording, bounded-checker exactness, obstruction retention, bounded-conversion transport, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the finite carrier of Definition 5099.1.*

Proof. Project the accepted carrier. The rows T, R, L, B, O, S are the only mathematical data rows: typed observation window, residual frontier, local join, bounded checker, retained obstruction, and bounded-conversion transport.

The bounded-checker exactness is tied to the local join row, not to an unbounded confluence theorem. The obstruction row remains present in the same carrier, so the accepted packet can expose local candidate evidence while still retaining the subject-reduction and residual-substitution boundary.

Rows H, C, P, N preserve and name the same finite surface. Since the carrier contains no unrestricted residual-substitution, global subject-reduction, arbitrary confluence, quotient-conversion, or unbounded-normalization coordinate, the listed obligations are exact. □

Theorem 5099.3 (Finite observation confluence-budget obstruction retention)**.** *Every accepted* $\mathsf{FiniteObservationConfluenceBudget}^{\uparrow}$ *packet that exposes a local join row also exposes the bounded-checker row and the obstruction-retention row before any MetaCIC confluence consumer can read the packet as evidence. Thus a candidate confluence read factors through*

$$T, R \longmapsto L, B, O \longmapsto S \longmapsto H, C, P, N.$$

Proof. Start with the typed window and residual frontier. The rows T and R determine the finite observation budget in which any local join can be interpreted.

The join row L is accepted only with the bounded checker B. The obstruction row O remains adjacent to that checker, so the packet records the local join together with the precise residual-substitution and subject-reduction boundary still blocking full confluence.

The transport row S and structural rows H, C, P, N replay the same finite budget. They cannot remove the obstruction row or enlarge the bounded checker into a global confluence proof. □

Falsifiable prediction: If the bounded-checker row is removed, no accepted packet can expose both a local join row and a subject-reduction obstruction-retention row.

Independence witness: metacic-residual-substitution-boundary, bounded-residual-substitution-frontier, metacic-confluence-residual-checker, bounded-normal-conversion-bridge: the confluence-budget carrier includes a simultaneous finite observation budget and local-join row not bijective to any single residual or conversion endpoint packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteObservationConfluenceBudget}^{\uparrow}}$.

Constructive story: A FiniteObservationConfluenceBudget$^{\uparrow}$ packet is generated from typed finite-window rows, residual-frontier rows, local joins, bounded-checker rows, obstruction-retention rows, bounded-conversion transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteObservationConfluenceBudget}^{\uparrow}}$, seed)

Scope closed: Definition 5099.1, Definition 5099.2, and Definition 5099.3 seed the finite observation confluence-budget packet for MetaCIC residual-confluence consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteObservationConfluenceBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unrestricted residual substitution, global subject reduction, arbitrary closed star confluence, quotient conversion equality, unbounded normalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window coverage, residual-frontier exactness, local-join exposure, bounded-checker exactness, obstruction retention, bounded-conversion transport stability, replay stability, provenance exhaustion, and Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.FiniteObservationConfluenceBudgetU

Chapter 5100

A Concrete Naming Certificate for $\mathsf{FrobeniusNorm}^{\uparrow}$

Following Horn and Johnson on matrix analysis, the $\mathsf{FrobeniusNorm}^{\uparrow}$ packet records the finite square-sum matrix norm as BEDC NameCert data. It sits over the finite matrix carrier of chapter 49, the scalar endpoint discipline of chapter 38, the vector-space transport rows of chapter 47, the norm interface of chapter 89, the orthogonalization route of chapter 1875, and the scalar-bound surface of chapter 3603. The packet names the finite Hilbert–Schmidt ledger for displayed entries; it is not a host supremum, spectral theorem, singular-value theorem, quotient matrix equality, or selected basis construction.

Definition 5100.1 (FrobeniusNorm carrier)**.** *A* $\mathsf{FrobeniusNorm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, E, S, R, N_0, V, G, O, H, C, P, L)$$

with the following displayed rows:

1. *A is the input* $\mathsf{Mat}^{\uparrow}$ *row, exposing a finite row-column table together with its scalar-source and shape ledgers.*
2. *E is the finite entry-read row, listing exactly the displayed matrix entries to be squared and summed.*
3. *S is the square-sum ledger, recording the finite addition route for the displayed real squares of the entries in E.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row carrying the nonnegative square-sum endpoint and the square-root boundary used for the norm value.*
5. *N_0 is the* $\mathsf{Norm}^{\uparrow}$ *comparison row, asserting that the displayed norm coordinate is read from S and R rather than from an ambient operator supremum.*
6. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *scalar-transport row, recording compatibility of the entry table with scalar multiplication and finite matrix addition.*
7. *G is the* $\mathsf{GramSchmidt}^{\uparrow}$ *sibling row used by column-orthogonalization consumers that compare the square-sum ledger with displayed column data.*
8. *O is the* $\mathsf{OperatorNorm}^{\uparrow}$ *sibling row used by bounded-operator consumers that read the Frobenius ledger as a finite norm bound, not as the defining operator norm.*

9. *H records componentwise* hsame *transport for the matrix row, entry reads, square-sum ledger, real readback, norm comparison, vector-space scalar transport, sibling rows, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a matrix-norm request through $A, E, S, R, N_0, V, G, O, H$.*
11. *P is the* Pkg *provenance over* $\mathsf{FrobeniusNorm}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{GramSchmidt}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *L is the local* $\mathsf{NameCert}_{\mathsf{FrobeniusNorm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, E, S, R, N_0, V, G, O, H, C, P, L$. It has no coordinate for singular values, spectral decomposition, host supremum over unit vectors, quotient matrix equality, selected orthonormal bases, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FrobeniusNormUp.FrobeniusNormTasteGate single carrier alignment`

Theorem 5100.2 (FrobeniusNorm NameCert obligations)**.** *For every accepted* $\mathsf{FrobeniusNorm}^{\uparrow}$ *carrier*

$$F = (A, E, S, R, N_0, V, G, O, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{FrobeniusNorm}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *matrix admission for the displayed* $\mathsf{Mat}^{\uparrow}$ *row A and its finite entry table E;*
2. *square-sum readback through S and R, requiring every norm value to be read from the finite real square ledger of the displayed entries;*
3. *norm and scalar-transport compatibility through N_0 and V, preserving matrix addition and scalar multiplication at the carrier boundary;*
4. *sibling consumption through G and O, exposing only the Gram–Schmidt column route and the OperatorNorm bound route attached to the same finite ledger;*
5. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, L.*

No Frobenius-norm obligation is stored outside these rows.

Proof. Project the carrier of Definition 5100.1. The only matrix data available to the packet are the finite table A and the entry row E.

The square-sum obligation is the ledger S together with its $\mathsf{Real}^{\uparrow}$ endpoint R. Each entry is squared and folded by the displayed finite addition route, so the norm value is read from the square-sum row rather than selected from a host norm function.

The rows N_0 and V record compatibility with the norm interface and vector-space scalar transport. They preserve the finite entry ledger under the displayed matrix operations without adding quotient matrix equality.

Finally the sibling rows G and O expose exactly how Gram–Schmidt and operator-norm consumers may use the same square-sum packet. The structural rows H, C, P, L transport, replay, source, and name only this finite route, so the five listed rows exhaust the local certificate. □

Theorem 5100.3 (FrobeniusNorm square-sum route)**.** *Every* $\mathsf{FrobeniusNorm}^{\uparrow}$ *consumer that reads a matrix norm value must pass through the finite route*

$$A \longmapsto E \longmapsto S \longmapsto R \longmapsto N_0.$$

The route exposes the displayed matrix entries, their real square-sum ledger, and the norm comparison row before any vector-space transport, Gram–Schmidt handoff, or operator-norm bound row is consumed.

Proof. Start from an accepted carrier $F = (A, E, S, R, N_0, V, G, O, H, C, P, L)$. Carrier projection first exposes the matrix table and the finite entry row.

The square-sum ledger S is downstream of those entries, and the $\mathsf{Real}^{\uparrow}$ readback row R is downstream of the ledger. Hence a norm consumer cannot inspect the displayed norm comparison N_0 before the finite entry squares and their sum have been displayed.

The vector-space, Gram–Schmidt, and OperatorNorm rows are sibling-facing consumers of the same route. They may transport or compare the finite ledger, but they do not replace it by a host supremum, spectral calculation, or selected basis. □

Theorem 5100.4 (FrobeniusNorm sibling compatibility)**.** *The* $\mathsf{GramSchmidt}^{\uparrow}$ *row* G *and the* $\mathsf{OperatorNorm}^{\uparrow}$ *row* O *of an accepted* $\mathsf{FrobeniusNorm}^{\uparrow}$ *carrier consume the same displayed square-sum route* A, E, S, R, N_0*. A Gram–Schmidt consumer reads column data through* G *only after the finite entry ledger is fixed, and an OperatorNorm consumer reads* O *only as a finite bound-facing comparison row over that ledger.*

Proof. Apply Definition 5100.3. Both sibling rows occur after the matrix table, entry reads, square-sum ledger, real readback, and norm comparison row.

The Gram–Schmidt handoff therefore receives displayed column data already governed by the same entry ledger. It cannot choose a second basis or alter the square-sum route.

The OperatorNorm handoff receives a finite bound-facing comparison row. It does not convert the Frobenius packet into the host supremum definition of operator norm, because the only available scalar data are S, R, N_0 transported by H and replayed by C. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrobeniusNorm}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FrobeniusNorm}^{\uparrow}$ packet is generated from a displayed MatrixUp table, finite entry reads, real square-sum ledger, RealUp readback, NormUp comparison, VecSpaceUp scalar transport, GramSchmidtUp and OperatorNormUp sibling rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FrobeniusNorm}^{\uparrow}}$, seed)

Scope closed: Definition 5100.1, Definition 5100.2, Definition 5100.3, and Definition 5100.4 seed the finite matrix square-sum norm packet and its sibling consumption routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FrobeniusNorm}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close singular-value theory, spectral decomposition, host operator supremum, quotient matrix equality, selected orthonormal bases, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked matrix admission, square-sum readback, norm comparison, scalar transport, sibling compatibility, transport, replay, provenance, and local naming for BEDC.Derived.FrobeniusNormUp.

Chapter 5101

A Concrete Naming Certificate for $\mathsf{BoundedBilinearMap}^{\uparrow}$

Following Bourbaki's normed-module treatment and Ryan's account of tensor products, the $\mathsf{BoundedBilinearMap}^{\uparrow}$ packet records a two-input bounded map as finite NameCert data rather than as a disguised one-input operator. It is grounded in the algebraic tensor-product surface of chapter 87, the operator-norm rows of chapter 3603, the projective tensor norm route of chapter 4088, and the bounded-linear-operator interface of chapter 1644.

Definition 5101.1 (Bounded bilinear map carrier)**.** *For displayed normed or Banach source rows E, F and a displayed target row G, a* $\mathsf{BoundedBilinearMap}^{\uparrow}(E, F; G)$ *carrier is a finite* BHist *packet*

$$\mathcal{B} = (E, F, G, B, K, L, R, T, P, N)$$

with the following rows:

1. *B is a displayed two-input endpoint action on carried endpoints of E and F with target endpoints in G.*
2. *K is a RealUp bound endpoint and L is the finite ledger asserting additivity and scalar compatibility in each input separately.*
3. *R records the boundedness row: every accepted endpoint pair reads through the source norm rows and the estimate named by K before a target norm claim is public.*
4. *T records the tensor handoff row from the two-input action to the displayed* $\mathsf{TensorProduct}^{\uparrow}$ *and* ***??*** *routes.*
5. *P is the* Pkg *provenance over* $\mathsf{BoundedBilinearMap}^{\uparrow}$, $\mathsf{TensorProduct}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, ***??***, BoundedLinearOperator BHist, hsame, Cont, *and* NameCert.
6. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedBilinearMap}^{\uparrow}}$ *row.*

The classifier compares accepted representatives only through componentwise hsame *transport of the two source endpoint rows, the target endpoint row, the bound endpoint, the bilinearity ledger, the boundedness ledger, the tensor handoff row, provenance, and local naming. It has no coordinate for currying into a host function space, quotienting by extensional equality, selecting a completed tensor representative, or importing a bridge.*

Lean4 ✓ `BEDC.Derived.BoundedBilinearMapUp.BoundedBilinearMapTasteGate single carrier alignment`

Theorem 5101.2 (Bounded bilinear map NameCert obligations)**.** *For every accepted* $\mathsf{BoundedBilinearMap}^{\uparrow}$ *carrier* $\mathcal{B} = (E, F, G, B, K, L, R, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedBilinearMap}^{\uparrow}}$ *surface consists of carrier admission, separate additivity and homogeneity in both input coordinates, classifier stability under the two source rows and the target row, norm-bound exactness through* K *and* R*, tensor-handoff exactness through* T*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and refusal of hidden currying, host function extensionality, tensor quotient completion, selected decompositions, and bridge data.*

Proof. Project the finite carrier of Definition 5101.1. The endpoint action B, bound endpoint K, bilinearity ledger L, boundedness ledger R, tensor handoff row T, provenance row P, and local name row N are all displayed before any public read is accepted.

The bilinearity obligations are the four rows in L: additivity in the first input, additivity in the second input, scalar compatibility in the first input, and scalar compatibility in the second input. Each row is stated over carried source endpoints and carried target endpoints, so the proof uses only the packet coordinates and their componentwise transports.

The boundedness obligation is read from R. It exposes the source norm rows and the RealUp bound endpoint K before the target norm estimate is exported. The classifier stability row follows by transporting B, K, L, R, T, P, N along the displayed hsame data for E, F, G.

Finally T gives the tensor handoff and P, N give provenance and local naming. Since the carrier has no row for host currying, host function extensionality, quotient completion, selected tensor decompositions, or bridge checking, those objects cannot appear in the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.BoundedBilinearMapUp.BoundedBilinearMapCarrier namecert obligations`

Theorem 5101.3 (Bounded bilinear map operator-norm handoff)**.** *Every operator-norm consumer of an accepted* $\mathsf{BoundedBilinearMap}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{OperatorNorm}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

It may read the bound endpoint K *and the finite boundedness ledger* R *as an operator-norm witness for the bilinear action, but it receives no curried host operator, no host supremum over unit balls, no quotient equality of maps, and no selected norm-attaining pair.*

Proof. Begin with a public operator-norm read. By Definition 5101.1, the only norm-facing coordinates are K and R, together with the endpoint action B and the bilinearity ledger L.

The row R supplies the finite estimate before the consumer reaches $\mathsf{OperatorNorm}^{\uparrow}$. The bounded-linear-operator sibling can consume this data only as a displayed boundedness witness: it sees the two-input action and its ledger, not a host-level curried function.

The non-attainment and quotient exclusions follow from the same projection. No carrier coordinate stores a unit-ball supremum, a selected pair attaining the bound, an extensional quotient of maps, or a bridge row, so the handoff cannot export those objects. □

Theorem 5101.4 (Bounded bilinear map projective tensor route)**.** *Every projective-tensor consumer of an accepted* $\mathsf{BoundedBilinearMap}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{TensorProduct}^{\uparrow}, ??, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

The handoff row T *sends elementary tensor reads to the two-input action* B *and sends finite decomposition reads to the finite bound ledger* R*. It does not create a completed projective tensor product, an ambient universal property, a selected minimizing decomposition, or an equality principle beyond the displayed tensor-product classifier.*

Proof. Read the tensor handoff row T from the carrier. For an elementary tensor, T names the route from the displayed tensor-product row to the endpoint action B on the two carried source endpoints.

For a finite projective decomposition, the route repeats this elementary read across the displayed finite list and then invokes the boundedness ledger R for the finite scalar estimate. The construction therefore uses the same finite rows consumed by chapter 4088.

Nothing in the route adds completion data. The tensor-product classifier, finite decomposition ledger, bound row, transport row, replay row, provenance row, and local naming row are the only sources of public information, so completed tensor products, universal host properties, selected minimizing decompositions, and stronger equality principles remain outside the packet. □

Theorem 5101.5 (Bounded bilinear map nonescape boundary)**.** *Every accepted* $\mathsf{BoundedBilinearMap}^{\uparrow}$ *consumer factors through*

$$\mathsf{TensorProduct}^{\uparrow}, \mathsf{OperatorNorm}^{\uparrow}, ??, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

In particular, the packet cannot export host currying, host function extensionality, quotient equality of bilinear maps, completed tensor products, selected decompositions, norm-attaining pairs, ambient Banach completion, or bridge checking data.

Proof. Let a consumer read an accepted carrier. The carrier projection exposes only $E, F, G, B, K, L, R, T, P, N$ and the componentwise transport and replay data attached to those rows.

The operator-norm path uses K and R as in Definition 5101.3. The projective-tensor path uses T and then returns to B and R as in Definition 5101.4. Both paths are finite BEDC routes through displayed histories and local naming.

The excluded objects are absent from every coordinate. Since no row stores host currying, extensional equality, quotient equality, a completed tensor product, a selected decomposition, a norm-attaining pair, ambient completion data, or a bridge, no public consumer can read them from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedBilinearMap}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedBilinearMap}^{\uparrow}$ packet is generated from two displayed source rows, one displayed target row, a two-input endpoint action, a RealUp bound endpoint, separate bilinearity rows, a boundedness ledger, a tensor handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedBilinearMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5101.1, Definition 5101.2, Definition 5101.3, Definition 5101.4, and Definition 5101.5 seed the finite two-input bounded-map surface over tensor-product, operator-norm, projective-tensor-norm, and bounded-linear-operator rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedBilinearMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host currying, host function extensionality, quotient equality of bilinear maps, completed tensor products, selected decompositions, norm-attaining pairs, or ambient Banach completion.

Upgrade path: Obligation closure requires checked carrier admission, separate bilinearity, classifier stability, norm-bound exactness, tensor handoff, operator-norm handoff, projective-tensor route, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BoundedBilinearMapUp.

Chapter 5102

A Concrete Naming Certificate for $\mathsf{KalmanFilter}^{\uparrow}$

Following Kalman and Bucy, the $\mathsf{KalmanFilter}^{\uparrow}$ interface records the finite prediction-and-update packet of a discrete linear estimator. Its BEDC surface consumes $\mathsf{NameCert}_{\mathsf{DynSystem}^{\uparrow}}$ for transition rows, $\mathsf{NameCert}_{\mathsf{ControlObservability}^{\uparrow}}$ for observation rows, $\mathsf{NameCert}_{\mathsf{Mat}^{\uparrow}}$ for covariance and gain updates, $\mathsf{NameCert}_{\mathsf{VecSpace}^{\uparrow}}$ for state and measurement rows, and $\mathsf{NameCert}_{\mathsf{LinMap}^{\uparrow}}$ for the displayed linear maps. Standard references are Kailath, Sayed, and Hassibi, *Linear Estimation* (2000), and Anderson and Moore, *Optimal Filtering* (1979).

The dependency surface is displayed through existing concrete siblings: chapter 329 supplies the state-transition packet, chapter 307 supplies the Riccati covariance ledger, chapter 294 supplies the observability row, chapter 49 and chapter 48 supply the linear algebra rows, chapter 184 and chapter 185 mark the non-exported stochastic boundary, chapter 230 supplies the estimator comparison surface, and chapter 38 supplies the scalar real rows. The deterministic observer-correction sibling chapter 5909 supplies the adjacent state-space, observability, output-error, and gain rows at the non-stochastic boundary of the prediction-update packet. $\mathsf{KalmanFilter}^{\uparrow}$ consumes those rows as finite BHist coordinates before exposing its prediction-update $\mathsf{NameCert}$ surface.

5102.1 Finite carrier

Definition 5102.1 (KalmanFilterUp BHist carrier)**.** *A* $\mathsf{KalmanFilter}^{\uparrow}$ *carrier is a finite* BHist *packet whose visible rows are:*

1. *a state-estimate row* $\widehat{x}$ *and predicted-state row* $\widehat{x}^{-}$ *over* $\mathsf{VecSpace}^{\uparrow}$*;*
2. *an error and covariance ledger row* P^{-}, P, K, P^{+} *over* $\mathsf{Mat}^{\uparrow}$*;*
3. *a transition row* A *and optional input row read from* $\mathsf{DynSystem}^{\uparrow}$*;*
4. *an observation row* C *and finite observation ledger read from* $\mathsf{ControlObservability}^{\uparrow}$*;*
5. *linear-map rows for prediction, observation, innovation, gain application, and estimate transport read from* $\mathsf{LinMap}^{\uparrow}$*;*
6. *matrix update rows for the displayed Riccati-style covariance, gain, and posterior covariance ledgers read from* $\mathsf{Mat}^{\uparrow}$*;*
7. Cont *and* Pkg *provenance rows naming the consumed* $\mathsf{DynSystem}^{\uparrow}$*,* $\mathsf{ControlObservability}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*, and* $\mathsf{LinMap}^{\uparrow}$ *certificates.*

No host stochastic process, probability measure, analytic convergence theorem, infinite trajectory, or external estimator object is part of the carrier.

Lean4 (definition) `BEDC.Derived.KalmanFilterUp.KalmanFilterCarrier`
Lean4 ✓ `BEDC.Derived.KalmanFilterUp.KalmanFilterTasteGate single carrier alignment`

Theorem 5102.2 (KalmanFilterUp prediction and update obligation)**.** *Every accepted* KalmanFilter$^{\uparrow}$ *packet exposes a finite prediction row, innovation row, gain row, and posterior-update row. The prediction row reads the transition and prior estimate through* DynSystem$^{\uparrow}$, VecSpace$^{\uparrow}$, *and* LinMap$^{\uparrow}$*; the update row reads the observation, innovation, gain, and posterior estimate through* ControlObservability$^{\uparrow}$, Mat$^{\uparrow}$, VecSpace$^{\uparrow}$, *and* LinMap$^{\uparrow}$*. Each row remains a* BHist *row with its displayed* Cont/Pkg *provenance.*

Lean4 ✓ `BEDC.Derived.KalmanFilterUp.KalmanFilterCarrier prediction update obligation`

Proof. Inspect the carrier of Definition 5102.1. The prediction rows are exactly the transition, state-estimate, and linear-map rows, while the update rows are exactly the observation, innovation, gain, and posterior-estimate rows.

The matrix rows supply the covariance and gain ledgers, the vector rows supply the state and observation endpoints, and the provenance rows name the certificates consumed by each read. Since the packet has only finite BHist rows, every exported prediction or update entry remains inside the displayed carrier. □

Theorem 5102.3 (KalmanFilterUp observation innovation ledger)**.** *For an accepted* KalmanFilter$^{\uparrow}$ *packet, the observation residual and innovation covariance are read from the displayed observation row of* ControlObservability$^{\uparrow}$*, the predicted estimate row of* VecSpace$^{\uparrow}$*, and the covariance and observation-matrix rows of* Mat$^{\uparrow}$*. The innovation ledger is exact: no unrecorded measurement stream, hidden residual object, or host probabilistic equality contributes to the consumer-visible innovation row.*

Lean4 ✓ `BEDC.Derived.KalmanFilterUp.KalmanFilterCarrier observation innovation ledger`

Proof. Read the observation row first. By Definition 5102.1, it is a finite ControlObservability$^{\uparrow}$ row paired with vector, matrix, and linear-map rows.

The residual is the displayed comparison between the observation endpoint and the predicted observation endpoint. The innovation covariance is the displayed matrix update over the covariance and observation rows. Because the carrier excludes host stochastic and trajectory objects, exactness is only the projection from these finite rows. □

Theorem 5102.4 (KalmanFilterUp prediction-update ledger exactness)**.** *For every accepted* KalmanFilter$^{\uparrow}$ *packet, each prediction, innovation, gain, posterior-estimate, and posterior-covariance read factors through the displayed finite* BHist *packet. The packet rows are exactly the* DynSystem$^{\uparrow}$ *transition rows,* ControlObservability$^{\uparrow}$ *observation rows,* Mat$^{\uparrow}$ *covariance and gain rows,* VecSpace$^{\uparrow}$ *state rows,* LinMap$^{\uparrow}$ *linear-map rows, the* Cont *and* hsame *comparison rows, and the* Pkg *provenance rows named by the carrier. No consumer-visible prediction-update read uses a stochastic process, probability space, unrecorded random variable, or external estimator semantics.*

Proof. Project the accepted carrier of Definition 5102.1. Its prediction face consists of the prior estimate, transition, predicted estimate, and predicted covariance rows, together with the LinMap$^{\uparrow}$, Cont, hsame, and Pkg rows that name the finite calculation.

Split the update face into observation, innovation, gain, posterior-estimate, and posterior-covariance reads. The observation and innovation reads are exact by Definition 5102.3, while the gain and posterior rows are the displayed $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{LinMap}^{\uparrow}$ entries transported by the same packet.

Estimate transport stability is supplied by Definition 5102.5. Thus any representative change remains inside the same finite ledger, and the excluded stochastic and probability-space objects cannot be recovered from the certificate surface. □

Lean4 ✓ `BEDC.Derived.KalmanFilterUp.KalmanFilterCarrier prediction update endpoint transport`

Theorem 5102.5 (KalmanFilterUp estimate transport stability)**.** *If two accepted* $\mathsf{KalmanFilter}^{\uparrow}$ *packets have* hsame*-matched state-estimate, covariance, transition, observation, linear-map,* Cont*, and* Pkg *rows, then prediction, innovation, gain, posterior-estimate, and posterior-covariance reads transport to accepted* $\mathsf{KalmanFilter}^{\uparrow}$ *rows. The classifier is therefore stable under componentwise* hsame *transport of the displayed carrier.*

Lean4 ✓ `BEDC.Derived.KalmanFilterUp.KalmanFilterCarrier estimate transport stability`

Proof. Transport each dependency row componentwise along the displayed hsame witnesses. The transition and observation rows remain accepted by their consumed certificates, while the vector, matrix, and linear-map rows remain inside their carrier surfaces.

Apply the same componentwise transport to the prediction, innovation, gain, and posterior rows. The Cont and Pkg entries transport the provenance, so the resulting packet again satisfies the finite carrier inventory of Definition 5102.1. □

Lean4 ✓ `BEDC.Derived.KalmanFilterUp.KalmanFilterCarrier estimate transport`

Theorem 5102.6 (KalmanFilterUp NameCert obligation surface)**.** *The local* $\mathsf{NameCert}_{\mathsf{KalmanFilter}^{\uparrow}}$ *obligation surface consists of five finite rows:*

1. *prediction carrier: prior estimate, transition, predicted estimate, and predicted covariance rows;*
2. *update carrier: observation, residual, gain, posterior estimate, and posterior covariance rows;*
3. *innovation ledger exactness: the residual and innovation covariance are exactly the displayed observation, prediction, covariance, and matrix-update reads;*
4. *classifier transport under* hsame*: componentwise transport preserves accepted prediction and update packets;*
5. *downstream read boundary: consumers may read only the prediction, update, innovation, covariance, classifier,* Cont*, and* Pkg *rows displayed by the carrier.*

Proof. The prediction carrier and update carrier are the two action faces of Definition 5102.1. Their rows are finite because each consumed dependency certificate exports finite BHist data.

The innovation row is exact by Definition 5102.3, and classifier stability is the componentwise transport of Definition 5102.5. The consumer boundary is the remaining projection from the same finite inventory. □

Lean4 ✓ `BEDC.Derived.KalmanFilterUp.KalmanFilterCarrier namecert obligation surface`

Theorem 5102.7 (KalmanFilterUp downstream consumer boundary)**.** *Any algebraic or control-theory consumer of* $\mathsf{NameCert}_{\mathsf{KalmanFilter}^\uparrow}$ *may read only the finite state-estimate, covariance, transition, observation, innovation, gain, posterior-update,* hsame, Cont, *and* Pkg *rows of the carrier. It cannot infer a host probability space, optimality theorem, convergence rate, controllability decomposition, or external trajectory semantics from the* $\mathsf{KalmanFilter}^\uparrow$ *certificate alone.*

Lean4 ✓ `BEDC.Derived.KalmanFilterUp.KalmanFilterCarrier endpoint closed generation`
Lean4 ✓ `BEDC.Derived.KalmanFilterUp.KalmanFilterCarrier downstream consumer boundary`

Proof. Project the exported rows from Definition 5102.1. These are precisely the finite rows named by the prediction-update obligation and the NameCert obligation surface.

All excluded objects are absent from the carrier inventory. Since consumer reads are projections from accepted BHist rows and their provenance, no consumer can recover a host stochastic or analytic object without an additional certificate. □

Theorem 5102.8 (KalmanFilterUp standard prediction-update bridge)**.** *The public* $\mathsf{KalmanFilter}^\uparrow$ *carrier and consumer boundary interpret exactly as the standard finite discrete prediction-update schema over displayed* $\mathsf{DynSystem}^\uparrow$ *transition rows,* $\mathsf{ControlObservability}^\uparrow$ *observation rows,* $\mathsf{Mat}^\uparrow$ *covariance and gain rows,* $\mathsf{VecSpace}^\uparrow$ *state rows,* $\mathsf{LinMap}^\uparrow$ *linear-map rows, and visible* hsame/Cont/Pkg *provenance. No stochastic process, probability-space semantics, convergence theorem, or external estimator object is exported.*

Lean4 ✓ `BEDC.Derived.KalmanFilterUp.KalmanFilterUp StdBridge`

Proof. Start from the carrier of Definition 5102.1. Its rows are the finite state-estimate, covariance, transition, observation, innovation, gain, posterior-update, linear-map, transport, continuation, and package rows.

The prediction-update face is exactly Definition 5102.2. The observation and innovation reads are controlled by Definition 5102.3, and the full ledger is exact by Definition 5102.4.

Representative changes remain inside the same finite packet by Definition 5102.5. The $\mathsf{NameCert}_{\mathsf{KalmanFilter}^\uparrow}$ surface is the finite obligation surface of Definition 5102.6, and downstream consumers are bounded by Definition 5102.7.

Repack those finite rows as the standard prediction-update schema. Since every schema field is one of the displayed BEDC rows and the consumer boundary has no coordinate for stochastic, probabilistic, convergence, or external-estimator data, the interpretation exports exactly the finite prediction-update packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{KalmanFilter}^\uparrow}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KalmanFilter}^\uparrow}$, maturePackageClosed)

Scope closed: Definition 5102.8 binds the public finite Kalman prediction-update packet to $\mathsf{DynSystem}^\uparrow$, $\mathsf{ControlObservability}^\uparrow$, $\mathsf{Mat}^\uparrow$, $\mathsf{VecSpace}^\uparrow$, $\mathsf{LinMap}^\uparrow$, BHist, hsame, Cont, and Pkg rows.

Constructive story: The construction starts from the finite observation packet and dynamic-system transition row, adds matrix and vector rows for prediction, covariance propagation, innovation, gain, and posterior estimate transport, and records the whole calculation as BHist rows with Cont and Pkg provenance.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KalmanFilter}^\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.KalmanFilterUp.KalmanFilterCarrier\_downstream\_consumer\_boundary`

Bridge status: bridgeChecked

Origin: human

Not claimed: This chapter does not close stochastic optimality, analytic convergence, probability-space semantics, or controllability decomposition.

Upgrade path: No further formal-axis upgrade remains for the finite Kalman packet.

Theorem 5102.9 (KalmanFilterUp zero-gain posterior estimate collapse)**.** *Let $\mathcal{K}$ be an accepted* $\mathsf{KalmanFilter}^{\uparrow}$ *packet in the sense of Definition 5102.1. Write*

$$\widehat{x}^{-}$$

for its predicted-estimate row, K for its gain row, ν for its innovation row, $K\nu$ for the displayed gain-application row, and $\widehat{x}^{+}$ for its posterior-estimate row. Assume that the update face is the displayed affine Kalman estimate row

$$\widehat{x}^{+} \sim_{\mathsf{VecSpace}^{\uparrow}} \widehat{x}^{-} +_{\mathsf{VecSpace}^{\uparrow}} K\nu,$$

with the gain application $K\nu$ read through the $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, *and* $\mathsf{LinMap}^{\uparrow}$ *rows exposed by Definition 5102.2. If the gain row is classified with the zero matrix row,*

$$K \sim_{\mathsf{Mat}^{\uparrow}} Z,$$

where Z is the zero matrix datum of Definition 49.113, then the posterior-estimate row is classified with the predicted-estimate row:

$$\widehat{x}^{+} \sim_{\mathsf{VecSpace}^{\uparrow}} \widehat{x}^{-}.$$

Lean4 ✓ `BEDC.Derived.KalmanFilterUp.KalmanFilterCarrier zero gain posterior estimate collapse`

Proof. Project the accepted packet by Definition 5102.2. The projection supplies the finite prediction row, innovation row, gain row, posterior-estimate row, and the provenance rows saying that the gain application is read only through the displayed $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{LinMap}^{\uparrow}$ certificates. By Definition 5102.1, no hidden estimator object or stochastic equality is available; every comparison must be assembled from those rows.

The gain hypothesis identifies the carried gain endpoint with the zero matrix datum Z. Matrix classifier stability transports the gain-application row along this comparison, so the displayed product $K\nu$ is classified with the zero-gain product $Z\nu$. The finite-fold zero matrix multiplication law, Definition 49.114, classifies $Z\nu$ with the zero vector endpoint in the codomain vector carrier. Thus the gain-application contribution satisfies

$$K\nu \sim_{\mathsf{VecSpace}^{\uparrow}} 0.$$

The use of Definition 49.114 is entrywise: each scalar summand has a zero matrix factor, the scalar zero-product row reduces it to the scalar zero, and the finite additive fold reduces the whole displayed product to the zero endpoint.

Now apply vector-space addition congruence to the posterior affine row. The comparison $K\nu \sim_{\mathsf{VecSpace}^{\uparrow}} 0$ transports

$$\widehat{x}^{-} +_{\mathsf{VecSpace}^{\uparrow}} K\nu$$

to

$$\widehat{x}^{-} +_{\mathsf{VecSpace}^{\uparrow}} 0.$$

The vector additive right-unit row in the $\mathsf{VecSpace}^{\uparrow}$ certificate identifies this endpoint with $\widehat{x}^{-}$. Transitivity in the $\mathsf{VecSpace}^{\uparrow}$ classifier composes the displayed affine update comparison, the transported zero-gain comparison, and the additive right-unit comparison. Hence

$$\widehat{x}^{+} \sim_{\mathsf{VecSpace}^{\uparrow}} \widehat{x}^{-}.$$

All rows used in the argument are among the finite prediction, innovation, gain, posterior-estimate, matrix, vector-space, linear-map, Cont, hsame, and Pkg rows named by Definition 5102.1; the consumer boundary of Definition 5102.7 excludes any additional analytic or probabilistic premise. □

$\mathsf{ControlRiccati}^{\uparrow}$ routes its finite Riccati value, gain-readback, and regulator rows through chapter 307, chapter 296, and chapter 49 before the child file opens the local NameCert surface.

Chapter 5103

A Concrete Naming Certificate for $\mathsf{ControlRiccati}^{\uparrow}$

Following Kalman and Anderson–Moore, the $\mathsf{ControlRiccati}^{\uparrow}$ packet records the control-facing Riccati certificate surface that sits between finite Riccati ledgers and regulator or estimator consumers. It reads the displayed Riccati recursion of chapter 307, the finite regulator packet of chapter 296, the estimator packet of chapter 5102, the observability and controllability rows of chapter 294 and chapter 297, the finite matrix rows of chapter 49, and the normed-state boundary of chapter 1950. The packet names a finite stabilizing residual and gain-readback route; it is not an ambient algebraic Riccati solver.

Definition 5103.1 (ControlRiccati carrier)**.** *A* $\mathsf{ControlRiccati}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (R, A, B, Q, S, G, L, O, K, H, T, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{Riccati}^{\uparrow}$ *value-ledger row.*
2. *A, B are the displayed state-transition and control-input matrix rows read through* $\mathsf{Mat}^{\uparrow}$ *and the finite state/control carrier.*
3. *Q, S are the displayed state-cost and control-cost matrix rows, including the symmetry and positivity ledgers needed by the control read.*
4. *G is the finite gain-readback row naming the feedback matrix computed from the displayed Riccati ledger.*
5. *L is the* $\mathsf{LQR}^{\uparrow}$ *handoff row saying the regulator consumer reads the same Riccati value and gain rows.*
6. *O is the* $\mathsf{ControlObservability}^{\uparrow}$ *row and K is the* $\mathsf{ControlControllability}^{\uparrow}$ *row used to keep the residual and gain checks inside the displayed control surface.*
7. *H is the residual-stability row: under the displayed normed-state and matrix rows, the Riccati residual remains inside the finite tolerance ledger exported by* $\mathsf{NormedSpace}^{\uparrow}$ *and* $\mathsf{Mat}^{\uparrow}$*.*
8. *T is componentwise* hsame *transport for the Riccati value, matrix, cost, gain, observability, controllability, and residual rows.*
9. *P is* Pkg *provenance over* $\mathsf{Riccati}^{\uparrow}$*,* $\mathsf{LQR}^{\uparrow}$*,* $\mathsf{KalmanFilter}^{\uparrow}$*,* $\mathsf{ControlObservability}^{\uparrow}$*,* $\mathsf{ControlControllability}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*, and* $\mathsf{NormedSpace}^{\uparrow}$*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ControlRiccati}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host matrix equation, a selected stabilizing solution, an infinite-horizon limit, a spectral separation oracle, or an unlogged controller.

Theorem 5103.2 (ControlRiccati NameCert obligations)**.** *For the carrier of Definition 5103.1, the local* $\mathsf{NameCert}_{\mathsf{ControlRiccati}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the finite packet $C = (R, A, B, Q, S, G, L, O, K, H, T, P, N)$;*
2. *Riccati residual stability through the displayed* $\mathsf{Mat}^{\uparrow}$ *and* $\mathsf{NormedSpace}^{\uparrow}$ *rows;*
3. *gain-readback exactness, saying the feedback row G is read only from the displayed Riccati, transition, input, and cost rows;*
4. *LQR handoff, saying the* $\mathsf{LQR}^{\uparrow}$ *consumer receives the same value and gain rows through L;*
5. *no-host-matrix nonescape, saying no accepted consumer can project an algebraic Riccati equation, selected stabilizing solution, spectral oracle, or unbounded controller from the packet.*

Proof. Project the carrier of Definition 5103.1. The rows $R, A, B, Q, S, G, L, O, K, H, T, P, N$ are the only visible Riccati value, matrix, cost, gain, regulator, observability, controllability, residual, transport, provenance, and local naming rows.

The residual-stability obligation reads the finite residual row H together with the matrix and normed-state rows. Since the residual is compared inside the displayed $\mathsf{Mat}^{\uparrow}$ and $\mathsf{NormedSpace}^{\uparrow}$ ledgers, the check cannot call on a host spectral or convergence theorem.

The gain-readback obligation then reads G from the same Riccati value, transition, input, and cost rows. The $\mathsf{LQR}^{\uparrow}$ handoff row L exports exactly this finite value-and-gain surface to the regulator packet, while the $\mathsf{KalmanFilter}^{\uparrow}$ dependency is only the neighboring estimator use of Riccati-style covariance ledgers.

Finally inspect the excluded coordinates. A host matrix equation, selected stabilizing solution, infinite-horizon limit, spectral separation oracle, and unlogged controller would require rows not present in C. Therefore every accepted $\mathsf{ControlRiccati}^{\uparrow}$ read remains inside the displayed NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ControlRiccati}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ControlRiccati}^{\uparrow}$ packet is generated from a Riccati value ledger, displayed transition and input matrices, cost matrices, gain readback, LQR handoff, observability and controllability rows, residual stability, componentwise transport, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ControlRiccati}^{\uparrow}}$, seed)

Scope closed: Definition 5103.1 and Definition 5103.2 seed the finite control-Riccati carrier and its five NameCert obligation rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ControlRiccati}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close algebraic Riccati existence, stabilizing uniqueness, infinite-horizon convergence, spectral separation, host matrix equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual stability, gain-readback exactness, LQR handoff, and no-host-matrix nonescape for BEDC.Derived.ControlRiccatiUp.

The $\mathsf{RoucheTheorem}^{\uparrow}$ hub routes contour-zero stability through the residue, Cauchy-integral, contour-socket, complex-differentiability, and real-comparison siblings recorded in chapter 125, chapter 4136, chapter 583, chapter 67, and chapter 38.

Chapter 5104

A Concrete Naming Certificate for $\mathsf{RoucheTheorem}^{\uparrow}$

Following Ahlfors and Conway, the $\mathsf{RoucheTheorem}^{\uparrow}$ packet names the finite contour-zero stability surface that lets a holomorphic perturbation be compared with a base holomorphic function along a displayed boundary. It sits beside the residue ledger of chapter 125, the point-evaluation route of chapter 4136, the contour socket of chapter 583, and the complex differentiability and real-comparison infrastructure already exposed by their neighbouring chapters. Its zero-count read is explicitly routed through the argument-principle and Riemann zero-count ledger siblings before the Rouche boundary-dominance row exports stability. The chapter records only certificate-bound contour admissibility, boundary dominance, and finite zero-count ledger handoffs; it does not claim global analytic continuation, host winding-number completeness, or an unrestricted homotopy theorem.

Definition 5104.1 (Rouche theorem carrier)**.** *A* $\mathsf{RoucheTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (C, F, G, B, Z, I, L, H, P, N)$$

with the following displayed rows:

1. *C is the contour-admissibility row, naming the finite boundary contour and the containment witness for the analytic region being inspected.*
2. *F is the base holomorphic row for f, including the local complex differentiability and contour-avoidance data used by the zero-count ledger.*
3. *G is the perturbation holomorphic row for g, displayed over the same contour window and the same complex arithmetic surface.*
4. *B is the boundary-dominance row, recording the finite comparison $|g| < |f|$ on the displayed contour boundary through the real-order rows available to the packet.*
5. *Z is the zero-count ledger row, listing the finite interior zero accounting read for f and for $f+g$.*
6. *I is the residue and Cauchy-integral handoff row, routing the zero-count comparison through the residue chapter and the Cauchy integral formula chapter without adding a second analytic oracle.*
7. *L is the stability ledger row, recording that the two displayed zero-count ledgers agree inside the accepted contour window.*

8. *H records componentwise* hsame *transport for contour, holomorphic, boundary-dominance, zero-count, integral-handoff, stability, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* $\mathsf{RoucheTheorem}^{\uparrow}$, $\mathsf{ContourIntegralSocket}^{\uparrow}$, $\mathsf{Residue}^{\uparrow}$, $\mathsf{CauchyIntegralFormula}^{\uparrow}$, $\mathsf{ComplexDifferentiability}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RoucheTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $C, F, G, B, Z, I, L, H, P, N$. It has no coordinate for a host analytic-continuation theorem, unbounded root isolation, quotient path equality, or classical compactness oracle outside the displayed packet.

The local NameCert obligation sketch has five grouped rows:

1. contour admission through C;
2. paired holomorphic source admission through F, G;
3. boundary dominance through B;
4. finite zero-count and residue/Cauchy-integral handoff through Z, I;
5. stability, transport, provenance, and local naming through L, H, P, N.

Theorem 5104.2 (Rouche theorem NameCert obligations)**.** *For every accepted* $\mathsf{RoucheTheorem}^{\uparrow}$ *carrier $R = (C, F, G, B, Z, I, L, H, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RoucheTheorem}^{\uparrow}}$ *surface consists exactly of contour admissibility through C, holomorphic source rows for f and g through F, G, boundary dominance through B, finite zero-count ledger exposure through Z, residue and Cauchy-integral handoffs through I, stability-ledger exactness through L, componentwise* hsame *transport through H,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier. The accepted rows are exactly $C, F, G, B, Z, I, L, H, P, N$, so the NameCert surface is finite and componentwise visible.

The contour row C supplies the only boundary window. The holomorphic rows F and G are read on that same window, and the dominance row B is attached to the displayed boundary comparison $|g| < |f|$ rather than to an ambient analytic theorem.

The zero-count ledger Z and handoff row I route the comparison through the residue and Cauchy-integral neighbours. The stability row L records the resulting equality of displayed ledgers, while H, P, N transport, source, and name the same data. Since no carrier coordinate stores global analytic continuation or unbounded root isolation, the listed rows exhaust the obligations. □

Theorem 5104.3 (Rouche theorem contour zero stability)**.** *If an accepted* $\mathsf{RoucheTheorem}^{\uparrow}$ *packet displays contour admissibility C, holomorphic rows F, G for f and g, boundary dominance B with $|g| < |f|$ on the displayed contour boundary, residue and Cauchy-integral handoffs I, and a finite zero-count ledger Z, then the stability ledger L preserves the zero-count read for f and $f + g$ inside that contour window. The claim is only the certificate-bound equality of displayed ledgers; it is not a claim of global analytic continuation, unrestricted homotopy invariance, or host completeness for all contours.*

Proof. Start with the contour row C. It fixes the finite boundary and interior window in which the two holomorphic rows F and G can be compared.

The boundary-dominance row B is read next. Because B is part of the packet, the comparison $|g| < |f|$ is visible at the same contour boundary rather than imported as an external maximum principle.

Use the handoff row I to pass through the residue and Cauchy-integral routes named in chapter 125 and chapter 4136. These handoffs identify the finite zero-count reads recorded in Z.

Finally L records equality of the two displayed zero-count ledger entries, and H, P, N preserve that equality under transport, provenance, and local naming. No row supplies global analytic continuation or unrestricted contour completeness, so the result remains the stated certificate-bound stability claim. □

Theorem 5104.4 (Rouche theorem holomorphic source route)**.** *Every zero-count stability read of an accepted* $\mathsf{RoucheTheorem}^{\uparrow}$ *carrier* $R = (C, F, G, B, Z, I, L, H, P, N)$ *must expose the* $\mathsf{Holomorphic}^{\uparrow}$ *and* $\mathsf{CplxDiff}^{\uparrow}$ *source rows* F, G*, the zero-count route through* $\mathsf{ArgumentPrinciple}^{\uparrow}$ *or* $\mathsf{RiemannZeroCountLedger}^{\uparrow}$*, the residue handoff, the Cauchy-integral formula handoff, and the same contour admissibility row* C *before the stability ledger* L *is public. The route is therefore a horizontal analytic dependency ledger over the displayed rows, not a hidden analytic-continuation oracle or an unrestricted contour homotopy principle.*

Proof. Begin with the contour and holomorphic rows. The row C fixes the admissible contour, while F and G expose the paired $\mathsf{Holomorphic}^{\uparrow}$ sources together with their $\mathsf{CplxDiff}^{\uparrow}$ pointwise data on the same displayed window.

Next read the zero-count route. The ledger Z may be consumed through the argument-principle sibling of chapter 7193 or through the Riemann zero-count ledger of chapter 573, but in either case the route remains attached to the same contour row and boundary-dominance row B.

Finally apply the analytic handoffs and structural rows. The row I records the residue and Cauchy-integral formula handoffs of chapter 125 and chapter 4136; then L, H, P, N publish, transport, source, and name the resulting stability ledger. No displayed coordinate supplies an ambient analytic-continuation oracle or unrestricted homotopy theorem. □

Theorem 5104.5 (Rouche theorem holomorphic winding dependency)**.** *Any accepted* $\mathsf{RoucheTheorem}^{\uparrow}$ *zero-count consumer must read the* $\mathsf{Holomorphic}^{\uparrow}$ *or complex-differentiability source rows* F, G*, the contour integral socket, and the* $\mathsf{ArgumentPrinciple}^{\uparrow}$ *or* $\mathsf{RiemannZeroCountLedger}^{\uparrow}$ *ledger before the boundary-dominance row* B *can export zero-count stability through* L*. The Rouche packet therefore publishes zero-count stability only as a route through the named holomorphic and winding-number boundaries, not as a detached contour-zero oracle.*

Proof. Start with the holomorphic route of Definition 5104.4. It exposes the paired holomorphic and complex-differentiability rows, the argument-principle or Riemann zero-count ledger route, and the contour row before the stability ledger is public.

Apply contour zero stability from Definition 5104.3. The row B can compare f and g only on the displayed contour boundary, and the stability row L records equality of the displayed zero-count ledgers after the residue and Cauchy-integral handoffs are visible.

The contour socket and ledger route are therefore prerequisites for the Rouche export. Since no carrier coordinate stores ambient analytic continuation, host winding-number completeness, or unrestricted homotopy invariance, the zero-count consumer receives only the named holomorphic and winding-boundary dependency. □

Falsifiable prediction: A packet that omits contour admissibility C, either holomorphic row F, G, the boundary-dominance row B, or the residue and Cauchy-integral handoff row I cannot be accepted as a $\mathsf{RoucheTheorem}^{\uparrow}$ packet, even if it records a candidate zero-count equality.

Independence witness: residue, cauchy-integral-formula, contourintegralsocket, complex-differentiability, real: $\mathsf{RoucheTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds contour admissibility, paired holomorphic rows, boundary dominance, zero-count ledgers, residue and Cauchy-integral handoffs, stability, transport, provenance, and local naming into one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RoucheTheorem}\uparrow}$.

Constructive story: A $\mathsf{RoucheTheorem}^{\uparrow}$ packet is generated from contour-admissibility rows, paired holomorphic rows, boundary-dominance rows, finite zero-count ledgers, residue and Cauchy-integral handoffs, stability ledgers, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RoucheTheorem}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5104.1, Definition 5104.2, Definition 5104.3, and Definition 5104.4 seed the finite contour-zero stability certificate over existing holomorphic, complex-differentiability, contour, zero-count, residue, Cauchy-integral, real-comparison, transport, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RoucheTheorem}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global analytic continuation, unrestricted homotopy invariance, host winding-number completeness, unbounded root isolation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked contour admissibility, paired holomorphic rows, boundary-dominance comparison, residue and Cauchy-integral handoffs, zero-count ledger exactness, stability transport, and non-escape for BEDC.Derived.RoucheTheoremUp.

Chapter 5105

A Concrete Naming Certificate for $\mathsf{FiniteIntervalCover}^{\uparrow}$

Following Bishop and Bridges, finite interval covers are read here as displayed finite data rather than as open-cover prose. The $\mathsf{FiniteIntervalCover}^{\uparrow}$ packet realizes the finite-cover branch of chapter 9237 beside the located interval surface of chapter 394, the dyadic interval ledger of chapter 306, the closed bounded interval packet of chapter 1591, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. A consumer sees a finite list of interval rows, endpoint and overlap ledgers, coverage witnesses, transport, replay, provenance, and local naming; it does not see a selected subcover, quotient real cover, endpoint convention selector, trichotomy oracle, or ambient real-completeness principle.

Definition 5105.1 (FiniteIntervalCover carrier)**.** *A* $\mathsf{FiniteIntervalCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, D, B, W, C, R, E, H, K, P, N)$$

with the following visible rows:

1. *I is the finite interval-index row, recording the displayed cover members.*
2. *D is the* $\mathsf{DyadicInterval}^{\uparrow}$ *endpoint row for the cover windows.*
3. *B is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row being covered.*
4. *W is the* $\mathsf{LocatedInterval}^{\uparrow}$ *witness row for membership and overlap inspections.*
5. *C is the finite coverage ledger, recording that every accepted source-window read is captured by one displayed interval row.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational endpoint comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for real-facing endpoint reads.*
8. *H records componentwise* hsame *transport for I, D, B, W, C, R, E.*
9. *K records displayed* Cont *replay for index lookup, endpoint comparison, coverage inspection, and Real-seal handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteIntervalCover}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteIntervalCover}^{\uparrow}}$ *row.*

The carrier has no coordinate for a choice-selected refinement, quotient real interval, ambient compactness theorem, trichotomy decision, or hidden endpoint convention.

Lean4 ✓ `BEDC.Derived.FiniteIntervalCoverUp.FiniteIntervalCoverTasteGate single carrier alignment`

Theorem 5105.2 (FiniteIntervalCover NameCert obligations)**.** *For every accepted* $\mathsf{FiniteIntervalCover}^{\uparrow}$ *packet* $F = (I, D, B, W, C, R, E, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteIntervalCover}^{\uparrow}}$ *surface consists exactly of finite index admission, dyadic endpoint exposure, closed-bounded source admission, located interval inspection, finite coverage, regular rational readback, terminal Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every cover consumer must read the sibling routes named in chapter 394, chapter 306, chapter 1591, chapter 126, chapter 301, and chapter 38 before it treats the cover as a real-facing interval cover.*

Proof. Project the carrier of Definition 5105.1. The rows I, D, B, W, C are the finite cover data: they display the interval indices, the dyadic endpoints, the closed bounded source, located membership and overlap checks, and coverage witnesses.

Read the comparison and seal rows next. The route from D and W to a real-facing endpoint passes through R and then E, so a consumer cannot replace finite endpoint comparisons by quotient real equality, a selected representative, or trichotomy.

Finally transport the same rows through H, K, P, N. Since the carrier contains no additional coordinate, the listed rows exhaust the local NameCert obligations and force every accepted cover read through the displayed sibling lattice. □

Theorem 5105.3 (FiniteIntervalCover Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{FiniteIntervalCover}^{\uparrow}$ *packet first consumes the finite interval-index row* I*, dyadic endpoint row* D*, closed-bounded source row* B*, located interval row* W*, coverage row* C*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison row* R*. Only after those rows have been transported through* H*, replayed through* K*, packaged by* P*, and named by* N *may the terminal Real seal* E *be exposed to a downstream compactness or uniform-modulus consumer.*

Proof. Start with Definition 5105.2. It makes the finite index, endpoint, source, locatedness, coverage, regular-rational, and Real-seal rows part of one local NameCert surface.

The real-facing handoff is therefore not a direct map from closed intervals to real endpoints. It must inspect the finite cover member, compare its displayed dyadic endpoints through R, and retain the closed-bounded source row B and located interval row W before E is available.

The structural rows then preserve the route. Transport by H, replay by K, provenance by P, and local naming by N keep the same packet visible to compactness and uniform-modulus consumers, while the absence of selected refinements, quotient intervals, trichotomy, and ambient completeness prevents any detached Real read. □

Falsifiable prediction: An accepted $\mathsf{FiniteIntervalCover}^{\uparrow}$ read is refuted if a RealUp endpoint seal is exposed without the finite index row, dyadic endpoint row, closed-bounded source row, located interval row, coverage row, RegSeqRat readback, transport, replay, provenance, and local naming rows.

Independence witness: locatedinterval, dyadicinterval, closedboundedinterval, streamname, regseqrat, and real: none is bijective to the finite interval-cover packet because only $\mathsf{FiniteIntervalCover}^{\uparrow}$ records finite interval indices, coverage witnesses, endpoint comparisons, and the Real handoff in one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteIntervalCover}^{\uparrow}}$**.**

Constructive story: A FiniteIntervalCover$^{\uparrow}$ packet is generated from finite interval indices, dyadic endpoint rows, a closed-bounded source row, located interval inspection, finite coverage witnesses, RegSeqRat comparison readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteIntervalCover}\uparrow}$, seed)

Scope closed: Definition 5105.1, Definition 5105.2, and Definition 5105.3 seed the finite interval-cover object consumed by compactness and uniform-modulus routes.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteIntervalCover}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected subcovers, endpoint-convention selectors, trichotomy, quotient real intervals, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite coverage, dyadic endpoint comparison, located interval inspection, RegSeqRat readback, RealUp handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteIntervalCoverUp.

Chapter 5106

A Concrete Naming Certificate for $\mathsf{ConstructiveHeineBorel}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ConstructiveHeineBorel}^{\uparrow}$ packet records the finite-subcover route for a closed real interval using only displayed interval endpoints, a dyadic mesh, finite cover requests, selected finite subcover rows, and Real readback. It consumes the real carrier of chapter 38, the dyadic arithmetic discipline of chapter 291, the StreamName window surface of chapter 126, the regular rational sequence readback of chapter 301, and the interval variant in chapter 1379. It is a finite NameCert packet for an interval-cover search, not a claim of arbitrary open-cover compactness.

Definition 5106.1 (Constructive Heine–Borel finite-subcover carrier)**.** *A* $\mathsf{ConstructiveHeineBorel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, D, G, F, S, W, Q, R, H, C, P, N)$$

with the following visible rows:

1. *A and B are the closed interval endpoint rows, read through* $\mathsf{Real}^{\uparrow}$ *seals and regular rational names;*
2. *D is the dyadic mesh row, recording a finite dyadic partition and its endpoint refinement data through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
3. *G is the finite cover-request row, recording finitely many interval-cover tests against the displayed mesh windows;*
4. *F is the finite-subcover selection row, storing the displayed finite list of cover indices that answer the tested mesh;*
5. *S is the StreamName window row, exposing the finite windows used to read the endpoints and test membership;*
6. *W is the RegSeqRat readback row, transporting the endpoint and mesh reads through regular rational sequence data;*
7. *Q is the Real seal row, recording the interval and cover reads as* $\mathsf{Real}^{\uparrow}$ *data without quotient real equality;*
8. *R records refusal of arbitrary open-cover compactness, choice-selected subcovers, quotient real equality, and ambient Real completeness;*

9. *H stores componentwise* hsame *transport for endpoint, mesh, cover-request, finite-subcover, stream-window, regular-sequence, Real-seal, refusal, replay, provenance, and local naming rows;*
10. *C stores displayed* Cont *replay for the same finite route;*
11. *P is the* Pkg *provenance over* $\mathsf{ConstructiveHeineBorel}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{HeineBorelInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveHeineBorel}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an arbitrary open cover, a non-finite subcover, a choice-selected subcover, quotient equality of reals, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.ConstructiveHeineBorelUp.ConstructiveHeineBorelTasteGate single carrier alignment`

Theorem 5106.2 (Constructive Heine–Borel NameCert obligations)**.** *For the carrier of Definition 5106.1, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveHeineBorel}^{\uparrow}}$ *surface consists exactly of endpoint admission, dyadic mesh admission, finite cover-request coverage, finite-subcover selection, StreamName window readback, RegSeqRat readback, Real seal preservation, refusal accountability, transport, replay, provenance, and local naming.*

Proof. Project the carrier $K = (A, B, D, G, F, S, W, Q, R, H, C, P, N)$. The endpoint rows A, B, dyadic mesh row D, cover-request row G, and finite-subcover row F are the only analytic coordinates of the packet.

The readback rows then bind the finite search to the real substrate. StreamName windows in S expose the finite interval reads, RegSeqRat rows in W replay the rational approximations, and the Real seal Q keeps the endpoint and cover tests inside displayed $\mathsf{Real}^{\uparrow}$ data.

Finally the refusal row R blocks the classical readings, while H, C, P, N transport, replay, source, and name the same rows. Since no further coordinate is present, the listed rows exhaust the local NameCert surface. □

Theorem 5106.3 (Constructive Heine–Borel finite-subcover route)**.** *Every accepted* $\mathsf{ConstructiveHeineBorel}^{\uparrow}$ *packet exports a finite-subcover reading only through the route*

$$A, B, D, G, F, S, W, Q, R, H, C, P, N.$$

The selected finite subcover row F must be read after the endpoint rows, dyadic mesh row, and finite cover-request row, and before the transport, replay, provenance, and local naming rows. The packet does not export an arbitrary open-cover compactness theorem or a choice-selected subcover.

Proof. Begin with the endpoint and mesh data. The rows A, B, D display the closed interval endpoints and the dyadic partition on which the finite search is performed.

Next read the cover request. The row G records only finitely many tested cover windows, so the subcover row F selects from a finite displayed list rather than from an ambient open cover.

The readback and structural rows preserve this route. Rows S, W, Q attach the StreamName, RegSeqRat, and Real seal data, while H, C, P, N keep the route stable under transport, replay, provenance, and naming. The refusal row R excludes the classical readings named in the statement. □

Theorem 5106.4 (Constructive Heine–Borel Real-seal nonescape)**.** *Let $K = (A, B, D, G, F, S, W, Q, R, H, C, P, N)$ be an accepted* $\mathsf{ConstructiveHeineBorel}^{\uparrow}$ *packet. Any Real-facing consumer of the finite-subcover route must read the StreamName windows S, RegSeqRat readback W, and Real seal Q together with the endpoint, mesh, cover, finite-subcover, refusal, transport, replay, provenance, and naming rows. It cannot replace this route by quotient real equality, ambient Real completeness, or an unlogged compactness principle.*

Proof. Use Definition 5106.2. It places the finite endpoint, mesh, cover-request, finite-subcover, StreamName, RegSeqRat, and Real-seal rows in one packet.

The Real-facing route is therefore not an ambient equality route. The seal Q is read only after S and W expose the finite windows and regular rational readbacks that generated the endpoint and mesh tests.

Apply Definition 5106.3 to close the nonescape boundary. A consumer that bypasses S, W, Q or imports ambient completeness no longer reads the accepted $\mathsf{ConstructiveHeineBorel}^{\uparrow}$ carrier. □

Theorem 5106.5 (Constructive Heine–Borel finite-net extraction)**.** *Every admitted finite-subcover read of an accepted* $\mathsf{ConstructiveHeineBorel}^{\uparrow}$ *packet*

$$K = (A, B, D, G, F, S, W, Q, R, H, C, P, N)$$

factors through the endpoint rows A, B, the dyadic mesh row D, the finite cover-request row G, the finite-subcover row F, the $\mathsf{StreamName}^{\uparrow}$ *window row S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback W, and the* $\mathsf{Real}^{\uparrow}$ *seal Q before transport, replay, provenance, or local naming is consumed. The extraction exports a finite-net replacement for the tested interval cover and exports no arbitrary open-cover compactness theorem, choice-selected subcover, quotient real equality, or ambient Real completeness row.*

Proof. Project the carrier of Definition 5106.1. The analytic rows are exactly the endpoint rows, dyadic mesh, finite cover request, finite subcover, StreamName window, RegSeqRat readback, Real seal, and refusal row.

Use the NameCert obligations of Definition 5106.2. They bind endpoint admission, mesh admission, finite cover-request coverage, finite-subcover selection, StreamName readback, RegSeqRat readback, Real sealing, and refusal accountability into one local surface.

Apply the finite-subcover route theorem Definition 5106.3. It forces F to be read only after the endpoint, dyadic mesh, and finite cover-request rows, so the extracted net is finite and displayed rather than selected from an arbitrary open cover.

Finally apply the Real-seal nonescape theorem Definition 5106.4. The rows S, W, Q keep the endpoint and cover tests inside the displayed StreamName, RegSeqRat, and Real-seal route, while R, H, C, P, N block the excluded classical readings and preserve the same packet. □

Falsifiable prediction: A finite-subcover consumer that exports a subcover without reading D, G, F, S, W, Q refutes the $\mathsf{ConstructiveHeineBorel}^{\uparrow}$ carrier.

Independence witness: real, dyadicratcore, streamname, regseqrat, heineborelinterval: the real carrier supplies sealed values without a finite cover search, the dyadic core supplies mesh arithmetic without interval coverage, StreamName and RegSeqRat supply readback without subcover selection, and the interval variant supplies interval-facing constraints without this finite endpoint-mesh-cover packet. None is bijective to $\mathsf{ConstructiveHeineBorel}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveHeineBorel}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveHeineBorel}^{\uparrow}$ packet is generated from endpoint, dyadic mesh, finite cover-request, finite-subcover, StreamName, RegSeqRat, Real-seal, refusal, transport, replay, provenance, and local naming rows.

Theory closure: TheoryGate(NameCert$_{\mathsf{ConstructiveHeineBorel}\uparrow}$, seed)

Scope closed: Definition 5106.1, Definition 5106.2, Definition 5106.3, and Definition 5106.4 seed the finite-subcover NameCert route for a closed interval.

Formal verification: FormalStatus(NameCert$_{\mathsf{ConstructiveHeineBorel}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, choice-selected subcovers, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint, dyadic mesh, finite cover-request, finite-subcover, StreamName, RegSeqRat, Real-seal, and refusal rows for BEDC.Derived.ConstructiveHeineBorelUp.

Chapter 5107

A Concrete Naming Certificate for $\mathsf{HyperbolicFixedPointObstruction}^{\uparrow}$

The $\mathsf{HyperbolicFixedPointObstruction}^{\uparrow}$ packet realizes the boundary fixed-point reading of section 9463.6 as finite NameCert data. Its obstruction row consumes disk coordinates from chapter 377, metric comparison from chapter 3474, observer-expansion rows from chapter 4167, and Busemann-boundary readback from chapter 3732 before refusing an interior fixed-point reading of the apophatic far end.

Definition 5107.1 (Hyperbolic fixed-point obstruction carrier)**.** *A* $\mathsf{HyperbolicFixedPointObstruction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D, M, B, E, U, G, R, H, C, P, N)$$

with the following visible rows:

1. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *coordinate row for the displayed disk surface;*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row for disk-distance and boundary comparison reads;*
3. *B is the Denjoy–Wolff boundary-dynamics row, recording the boundary route rather than an interior fixed point;*
4. *E is the hyperbolic observer-expansion row, recording the expansion ledger whose far-end reading is being inspected;*
5. *U is the Busemann-boundary row, exposing boundary-level readback for the far end;*
6. *G is the obstruction row, refusing an interior fixed-point reading of the apophatic far end;*
7. *R records refusal of a global disk center, a value fixed point for* T*, a hidden observer point, and a completed hyperbolic universe;*
8. *H stores componentwise* hsame *transport for disk, metric, boundary dynamics, observer expansion, Busemann boundary, obstruction, refusal, replay, provenance, and local naming rows;*
9. *C stores displayed* Cont *replay for the same route;*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicFixedPointObstruction}^{\uparrow}$*,* $\mathsf{UnitDisk}^{\uparrow}$*,* $\mathsf{HyperbolicMetric}^{\uparrow}$*, Denjoy–Wolff boundary dynamics, hyperbolic observer expansion, hyperbolic Busemann boundary,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows;*

11. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicFixedPointObstruction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an interior value of T*, a global disk center, a hidden Hilbert-space fixed point, or a completed ambient hyperbolic geometry.*

Theorem 5107.2 (Hyperbolic fixed-point obstruction NameCert obligations)**.** *For the carrier of Definition 5107.1, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicFixedPointObstruction}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission, hyperbolic-metric admission, boundary-dynamics coverage, observer-expansion coverage, Busemann-boundary readback, obstruction refusal, transport, replay, provenance, and local naming.*

Proof. Project the carrier $O = (D, M, B, E, U, G, R, H, C, P, N)$. The rows D, M, B, E, U display the disk, metric, boundary-dynamics, observer-expansion, and boundary-readback data that can be inspected.

The obstruction row G is then the only row that states the fixed-point refusal. It may compare the displayed boundary route with the disk and metric rows, but it cannot introduce an interior coordinate for the far end.

Finally R, H, C, P, N record the forbidden readings, transport the route, replay it, source it, and name it. Since the carrier has no further coordinate, these rows exhaust the local NameCert obligations. □

Theorem 5107.3 (Hyperbolic fixed-point boundary-route obstruction)**.** *Every accepted* HyperbolicFixedPointObstr *packet forces the apophatic far-end reading through the boundary route*

$$D, M, B, E, U, G, R, H, C, P, N.$$

A consumer may read boundary dynamics, observer expansion, and Busemann-level boundary data, but it cannot convert those rows into an interior disk fixed point, a global center, or a value of T*.*

Proof. Start with the disk and metric rows. The packet displays D and M only as coordinates and comparisons for the visible disk surface.

Next read the boundary rows. The Denjoy–Wolff-style row B, observer-expansion row E, and Busemann-boundary row U place the fixedness language at the boundary route, not at an interior point.

The obstruction row G and refusal row R block the forbidden conversions. Transport, replay, provenance, and naming through H, C, P, N preserve the same finite route, so the accepted packet exports a boundary-route obstruction and nothing stronger. □

Falsifiable prediction: A hyperbolic observer-expansion consumer that obtains an interior disk point for T without reading the boundary rows B, E, U, G refutes the $\mathsf{HyperbolicFixedPointObstruction}^{\uparrow}$ packet.

Independence witness: unitdisk, hyperbolic-metric, denjoy-wolff-boundary-dynamics, hyperbolic-observer-expansion, hyperbolic-busemann-boundary: the UnitDisk packet supplies disk coordinates without fixed-point refusal, the HyperbolicMetric packet supplies metric comparison without apophatic boundary routing, the Denjoy–Wolff boundary-dynamics packet supplies boundary dynamics without observer-expansion obstruction, the observer-expansion packet supplies expansion rows without Busemann boundary readback, and the Busemann-boundary packet supplies boundary-level readback without the full obstruction carrier. None is bijective to $\mathsf{HyperbolicFixedPointObstruction}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicFixedPointObstruction}^{\uparrow}}$**.**

Constructive story: A HyperbolicFixedPointObstruction$^{\uparrow}$ packet is generated from disk, hyperbolic metric, boundary-dynamics, observer-expansion, Busemann-boundary, obstruction, refusal, transport, replay, provenance, and local naming rows.

Theory closure: TheoryGate(NameCert$_{\text{HyperbolicFixedPointObstruction}^{\uparrow}}$, seed)

Scope closed: Definition 5107.1, Definition 5107.2, and Definition 5107.3 seed the finite boundary-route obstruction to interior fixed-point readings.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicFixedPointObstruction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a global disk center, an interior value for T, host hyperbolic dynamics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk, metric, boundary-dynamics, observer-expansion, Busemann-boundary, obstruction, and refusal rows for BEDC.Derived.HyperbolicFixedPointObstructionUp.

Chapter 5108

A Concrete Naming Certificate for $\mathsf{HardySpace}^{\uparrow}$

Following Hardy on boundary values of analytic functions and the classical Hardy-space tradition, the $\mathsf{HardySpace}^{\uparrow}$ packet records the finite boundary-read surface needed by constructive real-name analysis. It sits after the Hardy inequality route of chapter 3435, the real-series summation surface of chapter 1581, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names Hardy-space boundary analysis as finite L10 rows; it does not import host holomorphic function spaces, almost-everywhere boundary representatives, measure-class quotients, Banach-space completeness, or nonconstructive maximal theorems.

Definition 5108.1 (Hardy space carrier)**.** *A* $\mathsf{HardySpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (C, B, A, S, R, D, E, T, J, K, P, N)$$

with the following displayed rows:

1. *C is the coefficient row naming the finite analytic polynomial or power-series prefix under inspection.*
2. *B is the boundary-window row. It records the finitely many radial or angular boundary probes opened by the packet.*
3. *A is the* $\mathsf{HardyInequality}^{\uparrow}$ *control row used to compare displayed averages with the coefficient prefix.*
4. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *summation row attached to the inspected coefficient and boundary data.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed boundary values and partial averages.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by every boundary-value comparison.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after C, B, A, S, R, D have been displayed.*
8. *T records componentwise* hsame *transport for C, B, A, S, R, D, E.*
9. *J records displayed* Cont *replay from a boundary probe through coefficient prefix, Hardy control, real-series summation, rational readback, dyadic tolerance, and real seal.*
10. *K is the* Pkg *provenance over* $\mathsf{HardySpace}^{\uparrow}$, $\mathsf{HardyInequality}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *P records the finite boundary predicate saying that each exported boundary read uses only the displayed prefix, window, tolerance, and readback rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{HardySpace}^\uparrow}$ *row.*

The carrier contains no coordinate for a host Hardy space, an almost-everywhere boundary representative, a measure quotient, a selected nontangential limit, Banach completeness, or countable choice.

Lean4 ✓ `BEDC.Derived.HardySpaceUp.HardySpaceTasteGate single carrier alignment`

Theorem 5108.2 (Hardy space NameCert obligations)**.** *For every accepted* $\mathsf{HardySpace}^\uparrow$ *carrier* $H = (C, B, A, S, R, D, E, T, J, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HardySpace}^\uparrow}$ *surface consists exactly of carrier admission, coefficient-prefix exposure through C, finite boundary-window exposure through B, Hardy-control exposure through A, real-series exposure through S, regular rational readback through R, dyadic tolerance exposure through D, terminal real sealing through E, componentwise transport through T, displayed replay through J, package provenance through K, boundary-predicate exposure through P, and local naming through N.*

These obligations bind the finite Hardy-space route

$$\mathsf{HardyInequality}^\uparrow \longmapsto \mathsf{RealSeries}^\uparrow \longmapsto \mathsf{StreamName}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{DyadicRatCore}^\uparrow \longmapsto \mathsf{Real}^\uparrow$$

without adding a host analytic function space, quotient boundary class, selected limit, completeness theorem, or nonconstructive maximal principle.

Proof. Project the carrier of Definition 5108.1. The coefficient row and boundary-window row expose only finite analytic data and finitely many boundary probes.

The Hardy control and real-series rows are read next. Row A supplies the Hardy inequality packet used for finite average control, while S records the displayed real-series summation surface attached to the same prefix.

Readback and tolerance then pass through R and D. The regular rational row supplies the finite approximants for the boundary probes, and the dyadic ledger supplies the tolerance data used by each comparison.

Finally E, T, J, K, P, N seal, transport, replay, source, bound, and name the same route. Since no excluded analytic or quotient object appears among the carrier coordinates, the local NameCert surface exports exactly the listed finite obligations. □

Theorem 5108.3 (Hardy space real-boundary route)**.** *Let $H = (C, B, A, S, R, D, E, T, J, K, P, N)$ be an accepted* $\mathsf{HardySpace}^\uparrow$ *packet. Every Real-facing boundary-value consumer of H factors through a displayed coefficient prefix C, a finite boundary window B, the Hardy-control row A, the real-series row S, the regular rational readback R, and the dyadic tolerance ledger D before the* $\mathsf{Real}^\uparrow$ *seal E is available.*

Thus the packet records constructive boundary-value analysis as finite NameCert data over existing L10 real-name rows. It does not assert host holomorphy, almost-everywhere boundary equivalence, selected radial limits, quotient representative equality, or ambient completeness.

Proof. Start with the finite boundary window B. A boundary-value request is accepted only after it names the finite probes being inspected, so no consumer can read an unbounded boundary trace from the packet.

The coefficient prefix C, Hardy-control row A, and real-series row S provide the finite analytic data for those probes. Their order prevents a Real-facing consumer from replacing the displayed prefix by a host Hardy-space element.

Rows R and D then expose the rational readback and dyadic tolerance ledger. The terminal seal E is downstream from these rows, while T, J, K, P, N only transport, replay, source, bound, and name the same finite route.

Therefore every Real-facing boundary read factors through the displayed L10 rows, and the excluded analytic, quotient, choice, and completeness principles remain outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{HardySpace}^{\uparrow}$ read exposes a coefficient prefix, finite boundary window, HardyInequalityUp control row, RealSeriesUp summation row, RegSeqRatUp readback, DyadicRatCoreUp tolerance ledger, RealUp seal, transport, replay, provenance, boundary predicate, and local NameCert before any boundary-value claim is exported.

Independence witness: hardyinequality, realseries, streamname, regseqrat, dyadicratcore, real: $\mathsf{HardySpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries coefficient-prefix, finite boundary-window, Hardy-control, summation, readback, tolerance, and Real-seal rows for boundary-value analysis.

Closure status for $\mathsf{NameCert}_{\mathsf{HardySpace}^{\uparrow}}$.

Constructive story: A $\mathsf{HardySpace}^{\uparrow}$ packet is generated from a coefficient prefix, finite boundary window, Hardy control, RealSeries summation, RegSeqRat readback, DyadicRatCore tolerance, RealUp seal, componentwise transport, Cont replay, Pkg provenance, boundary predicate, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HardySpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5108.1, Definition 5108.2, and Definition 5108.3 seed the finite Hardy-space boundary route over displayed real-name rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HardySpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Hardy-space theory, almost-everywhere boundary representatives, measure quotients, selected radial limits, Banach completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, boundary-window exposure, Hardy-control handoff, real-series handoff, readback and tolerance nonescape, Real seal handoff, and transport stability for BEDC.Derived.HardySpaceUp.

Chapter 5109

A Concrete Naming Certificate for $\mathsf{FiniteObservationReflection}^{\uparrow}$

The $\mathsf{FiniteObservationReflection}^{\uparrow}$ packet realizes the finite observation trace and open prediction horizon of section 9414.38 as one NameCert surface. It sits beside $\mathsf{ObservationReflectionPacket}^{\uparrow}$ of chapter 1126, the finite window interface of chapter 1007, the reflective inquiry carrier of chapter 1151, and the open reflection boundary of chapter 1161. Those siblings expose observation roles, windows, paired inquiry, or gap boundaries separately; this packet binds source, finite observation trace, signature, classifier, package, ledger, and open-continuation rows as one finite observation-reflection certificate.

Definition 5109.1 (Finite observation-reflection carrier)**.** *A* $\mathsf{FiniteObservationReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, O, G, C, P, L, E, T, R, N)$$

with the following displayed rows:

1. *S is the source row naming the reality-facing or formal-reflection source under inspection.*
2. *O is the finite observation-trace row, read through a displayed* $\mathsf{FiniteObservationInterface}^{\uparrow}$ *window.*
3. *G is the observed-signature row extracted from the finite trace.*
4. *C is the classifier row comparing the source claim with the observed signature.*
5. *P is the package row recording the model, law, or inquiry certificate that is being tested against the trace.*
6. *L is the ledger row for approximation budgets, rejected fits, and unresolved residue.*
7. *E is the open-continuation row preserving the prediction horizon beyond the displayed trace.*
8. *T records componentwise* hsame *transport for S, O, G, C, P, L, E.*
9. *R records displayed* Cont *replay from source and trace through signature, classifier, package, ledger, and open continuation.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationReflection}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a final physical oracle, a closed prediction horizon, source-domain identity, host validation, quotient trace equality, or an unbounded observation schedule.

Theorem 5109.2 (Finite observation-reflection NameCert obligations)**.** *For every accepted* $\mathsf{FiniteObservationReflec}$ *carrier* $F = (S, O, G, C, P, L, E, T, R, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationReflection}^{\uparrow}}$ *surface consists exactly of carrier admission, source exposure through* S*, finite observation-trace exposure through* O*, observed-signature exposure through* G*, classifier exposure through* C*, package exposure through* P*, ledger exposure through* L*, open-continuation exposure through* E*, componentwise transport through* T*, displayed replay through* R*, and local naming through* N*.*

These obligations bind the observation-reflection route

$$\mathsf{ObservationReflectionPacket}^{\uparrow} \longmapsto \mathsf{FiniteObservationInterface}^{\uparrow} \longmapsto \mathsf{ReflectiveInquiry}^{\uparrow} \longmapsto \mathsf{ReflectionGapBoundary}^{\uparrow}$$

without adding final truth, closed prediction, source identity, host validation, quotient trace equality, or an unbounded schedule.

Proof. Project the carrier of Definition 5109.1. The source and observation rows S, O are displayed separately, so the packet can relate source claims to traces without identifying them.

The signature, classifier, and package rows G, C, P supply the finite comparison surface. They read the observed trace and the tested certificate as rows of the packet rather than as external host judgments.

The ledger and open-continuation rows then preserve non-finality. Row L records budgets, rejected fits, and unresolved residue, while E keeps the prediction horizon open beyond the finite trace.

Finally T, R, N transport, replay, and name exactly the same rows. Since no final oracle, closed horizon, source identity, quotient trace, or unbounded schedule is present, the local NameCert surface has precisely the listed obligations. □

Theorem 5109.3 (Finite observation-reflection open horizon)**.** *Let* $F = (S, O, G, C, P, L, E, T, R, N)$ *be an accepted* $\mathsf{FiniteObservationReflection}^{\uparrow}$ *packet. Every consumer that reads an observation-reflection judgment from* F *must pass through the source row* S*, the finite observation trace* O*, the signature row* G*, the classifier row* C*, the package row* P*, the ledger row* L*, and the open-continuation row* E*.*

In particular, the packet can certify a finite source–trace–signature fit while refusing to close the prediction horizon or identify the source with its observations.

Proof. Begin with the trace route. The source row S and finite observation row O are distinct coordinates, and the signature row G is extracted only from the displayed finite trace.

The classifier and package rows C, P then record the tested fit. This fit is ledgered by L, which keeps approximation budgets, rejected alternatives, and unresolved residue visible to downstream readers.

The open-continuation row E is read before the local name is exported. Componentwise transport and replay through T, R preserve that order, so a consumer cannot turn a finite observation-reflection packet into a final truth oracle or a closed prediction horizon. □

Falsifiable prediction: Every accepted $\mathsf{FiniteObservationReflection}^{\uparrow}$ read exposes source, finite observation trace, signature, classifier, package, ledger, open continuation, transport, replay, and local NameCert rows before exporting an observation-reflection judgment.

Independence witness: observationreflectionpacket, finiteobservationinterface, reflectiveinquiry, reflectiongapboundary: $\mathsf{FiniteObservationReflection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source, finite trace, signature, classifier, package, ledger, and open-continuation rows in one NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteObservationReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteObservationReflection}^{\uparrow}$ packet is generated from source, finite observation trace, observed signature, classifier, package, ledger, open continuation, componentwise transport, displayed replay, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteObservationReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5109.1, Definition 5109.2, and Definition 5109.3 seed the finite observation-reflection route and its open prediction horizon.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteObservationReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close final physical truth, final formal truth, source-domain identity, host validation, quotient trace equality, unbounded observation schedules, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source, observation-trace, signature, classifier, package, ledger, open-continuation, transport, and replay rows for BEDC.Derived.FiniteObservationReflectionUp.

Chapter 5110

A Concrete Naming Certificate for $\mathsf{MobiusTransform}^{\uparrow}$

Following Ahlfors on fractional linear transformations, the $\mathsf{MobiusTransform}^{\uparrow}$ packet records the finite coefficient and action rows by which a transformation $z \mapsto (Az + B)/(Cz + D)$ may be read before complex, projective, holomorphic, or hyperbolic cross-ratio consumers inspect it. It sits over the complex arithmetic carrier of chapter 39, the homogeneous-line action surface of chapter 207, the disk-local analytic surface of chapter 68, and the four-boundary comparison packet of chapter 3948. The packet names the fractional-linear carrier as BEDC data; it does not import a host Riemann sphere, quotient projective equality, selected inverse matrix, global automorphism group, or unrecorded cross-ratio theorem.

Definition 5110.1 (Mobius transform carrier)**.** *A* $\mathsf{MobiusTransform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, C, D, G, PJ, HD, XR, H, K, Q, N)$$

with the following displayed rows:

1. A, B, C, D *are* $\mathsf{Complex}^{\uparrow}$ *coefficient rows for the fractional-linear numerator and denominator.*
2. G *is the determinant guard row, recording that the displayed complex determinant* $AD - BC$ *is apart from zero in the accepted complex-history reading.*
3. PJ *is the* $\mathsf{ProjectiveSpace}^{\uparrow}$ *action row, exposing the homogeneous coordinate transformation* $[z : w] \mapsto [Az + Bw : Cz + Dw]$ *only through the displayed projective carrier.*
4. HD *is the* $\mathsf{Holomorphic}^{\uparrow}$ *disk-action row, recording the local disk source, denominator-apartness ledger, and holomorphic readback for every admitted disk on which the denominator guard is available.*
5. XR *is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *preservation row, requiring any four-boundary comparison to enter through the disk row, metric row, four boundary rows, boundary-fixed transport row, cross-ratio row, refusal row, Schwarz–Pick provenance, and structural rows of chapter 3948.*
6. H *records componentwise* hsame *transport for the four coefficient rows, determinant guard, projective action, holomorphic disk action, cross-ratio preservation, package provenance, classifier replay, and local naming.*
7. K *records displayed* Cont *replay from coefficient reads through determinant guard, projective action, holomorphic disk action, and cross-ratio preservation.*

8. *Q is the* Pkg *provenance over* MobiusTransform$^{\uparrow}$, Complex$^{\uparrow}$, ProjectiveSpace$^{\uparrow}$, Holomorphic$^{\uparrow}$, HyperbolicCrossRatio$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{MobiusTransform}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, C, D, G, PJ, HD, XR, H, K, Q, N$. It has no coordinate for host matrix equality, quotient projective equality, a selected inverse, an ambient automorphism group, or a cross-ratio statement not routed through the displayed four-boundary packet.

Lean4 ✓ `BEDC.Derived.MobiusTransformUp.TasteGate.MobiusTransformTasteGate single carrier alignment`

Theorem 5110.2 (Mobius transform NameCert obligations)**.** *For every accepted* MobiusTransform$^{\uparrow}$ *carrier $M = (A, B, C, D, G, PJ, HD, XR, H, K, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{MobiusTransform}^{\uparrow}}$ *surface consists exactly of complex coefficient rows, the determinant guard, projective action, holomorphic disk action, hyperbolic cross-ratio preservation routed through* HyperbolicCrossRatio$^{\uparrow}$, *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted consumer must inspect those rows before treating the packet as a fractional-linear transformation.*

Proof. Project the carrier of Definition 5110.1. The four coefficient rows A, B, C, D are the only complex entries of the packet, and the determinant guard G is the only accepted witness that the displayed matrix is usable.

The action rows PJ and HD then expose the same coefficient data through two controlled surfaces. The projective action is read through ProjectiveSpace$^{\uparrow}$, while the holomorphic disk action is read through Holomorphic$^{\uparrow}$ with the denominator-apartness ledger in scope.

The cross-ratio row XR is not a free theorem about a host sphere. It is admitted only as a consumer of the HyperbolicCrossRatio$^{\uparrow}$ four-boundary packet, so preservation claims inherit the disk, metric, boundary, refusal, Schwarz–Pick, transport, replay, provenance, and local naming rows of that packet.

Finally H, K, Q, N transport, replay, source, and name the same finite carrier. Since no other row is present, a consumer cannot replace the determinant guard by host invertibility, replace projective action by quotient equality, or bypass the displayed cross-ratio route. □

Theorem 5110.3 (Mobius transform cross-ratio preservation route)**.** *Every accepted* MobiusTransform$^{\uparrow}$ *cross-ratio consumer factors through the finite route*

$$\mathsf{Complex}^{\uparrow},\ \mathsf{ProjectiveSpace}^{\uparrow},\ \mathsf{Holomorphic}^{\uparrow},\ \mathsf{HyperbolicCrossRatio}^{\uparrow}.$$

The route first reads the complex coefficient rows and determinant guard, then the projective action row, then the holomorphic disk-action row, and finally the HyperbolicCrossRatio$^{\uparrow}$ *preservation row with its disk, metric, four boundary rows, boundary-fixed transport, cross-ratio comparison, refusal, Schwarz–Pick provenance, transport, replay, package provenance, and local naming. It exports no host Riemann sphere, quotient projective equality, selected inverse matrix, global automorphism group, or unrecorded boundary invariant.*

Proof. Let $M = (A, B, C, D, G, PJ, HD, XR, H, K, Q, N)$ be accepted. The coefficient rows and determinant guard are read first, so the fractional-linear numerator, denominator, and apartness condition are fixed as finite Complex$^{\uparrow}$ histories.

The projective row PJ packages the same coefficients as a homogeneous action through ProjectiveSpace$^{\uparrow}$. The holomorphic row HD packages the same coefficients as a disk-local map through Holomorphic$^{\uparrow}$, with denominator-apartness retained before any analytic readback is exposed.

The row XR is the only coordinate where cross-ratio preservation can be claimed. By construction it points to the $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ four-boundary packet, so it must read the disk, metric, boundary, transport, comparison, refusal, Schwarz–Pick, and structural rows before preservation is visible.

The structural rows H, K, Q, N keep the same carrier under transport, replay, provenance, and naming. Thus the preservation route remains finite and local to the displayed NameCert data. □

Falsifiable prediction: Any accepted $\mathsf{MobiusTransform}^{\uparrow}$ consumer omitting one of the four $\mathsf{Complex}^{\uparrow}$ coefficient rows, the determinant guard, the $\mathsf{ProjectiveSpace}^{\uparrow}$ action row, the $\mathsf{Holomorphic}^{\uparrow}$ disk-action row, the $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ preservation row, Pkg provenance, or the local $\mathsf{NameCert}$ row refutes Definition 5110.2.

Independence witness: complex, projectivespace, holomorphic, hyperbolic-cross-ratio: $\mathsf{MobiusTransform}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries coefficient rows, determinant guard, projective action, holomorphic disk action, cross-ratio preservation, transport, replay, package provenance, and local naming for a fractional-linear transformation.

Closure status for $\mathsf{NameCert}_{\mathsf{MobiusTransform}^{\uparrow}}$.

Constructive story: A $\mathsf{MobiusTransform}^{\uparrow}$ packet is generated from four $\mathsf{Complex}^{\uparrow}$ coefficient rows, a determinant guard, a $\mathsf{ProjectiveSpace}^{\uparrow}$ homogeneous action row, a $\mathsf{Holomorphic}^{\uparrow}$ disk-action row, a $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ preservation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MobiusTransform}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5110.1, Definition 5110.2, and Definition 5110.3 seed the finite fractional-linear carrier over complex coefficients, determinant guard, projective action, holomorphic disk action, cross-ratio preservation, and structural rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MobiusTransform}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host Riemann-sphere equality, quotient projective equality, selected inverse matrices, global automorphism groups, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, determinant guard transport, projective action replay, holomorphic disk-action replay, cross-ratio consumer routing, TasteGate nontriviality, field faithfulness, provenance, transport, replay, and local naming for BEDC.Derived.MobiusTransformUp.

Chapter 5111

A Concrete Naming Certificate for $\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}$

Following Heine and Borel's interval compactness theorem as read through Bishop–Bridges constructive analysis, the $\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}$ packet records a finite dyadic cover-refinement ledger over a closed bounded $\mathsf{Real}^{\uparrow}$ interval. It sits over the closed bounded interval source of chapter 1591, the dyadic arithmetic core of chapter 291, the terminal real-name seal of chapter 38, the compact-metric carrier of chapter 129, and the uniform-modulus source of chapter 369. The chapter names finite dyadic cover and refinement data for the active L10 Real and Completion frontier; it is not a general open-cover compactness theorem, an unrestricted Heine–Borel principle, a selected-subcover functional, or an ambient $\mathsf{Real}^{\uparrow}$ completeness assertion.

Definition 5111.1 (Constructive Heine–Borel interval carrier)**.** *A* $\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, D, R, S, E, M, U, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, exposing endpoint order, interval membership, and the interval-source readback.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for dyadic endpoints, mesh scales, refinement inclusions, and positive slack comparisons.*
3. *R is the finite refinement row, listing the dyadic partition cells and the parent-child refinement map used by cover readers.*
4. *S is the finite subcover ledger, recording the selected cell witnesses already displayed by the cover-refinement row.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint and radius seal reached only after I, D, R, S have been displayed.*
6. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *compatibility row, read only as the metric finite-net surface induced by the same interval and dyadic ledger.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *compatibility row, recording the modulus-facing refinement scale consumed by uniform-continuity readers over the same packet.*
8. *H records componentwise* hsame *transport for the interval source, dyadic ledger, refinement row, subcover ledger, Real seal, compact-metric row, uniform-modulus row, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a dyadic cover request through* I, D, R, S, E, M, U.
10. *P is the* Pkg *provenance over* $\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, R, S, E, M, U, H, C, P, N$. It has no coordinate for arbitrary open covers, choice-selected subcovers, quotient interval representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ConstructiveHeineBorelIntervalUp.ConstructiveHeineBorelIntervalTasteGate`
`single carrier alignment`

Theorem 5111.2 (Constructive Heine–Borel interval NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}$ *carrier* $K = (I, D, R, S, E, M, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveHeineBorelIn}}$ *surface consists exactly of five finite obligations:*

1. *carrier admission for the closed bounded interval source, dyadic endpoint ledger, finite refinement row, finite subcover ledger, Real seal, compact-metric compatibility row, uniform-modulus compatibility row, transport, replay, provenance, and local naming rows;*
2. *cover-refinement classifier stability, requiring two accepted reads to agree only through I, D, R, H, C, P, N before their refinement cells are compared;*
3. *finite-subcover ledger exactness, requiring each exported witness in S to be one of the displayed finite cover reads attached to a dyadic cell of R;*
4. *dyadic endpoint transport, requiring endpoint and mesh comparisons to pass through D before reaching the terminal* $\mathsf{Real}^{\uparrow}$ *seal E;*
5. *nonescape from selected subcovers, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness, requiring M, U, H, C, P, N to transport, replay, source, and name only the displayed finite packet.*

Proof. Carrier admission is projection from Definition 5111.1. The tuple displays exactly the closed bounded interval source, dyadic endpoint ledger, finite refinement row, finite subcover ledger, Real seal, compact-metric compatibility row, uniform-modulus compatibility row, and structural rows.

Classifier stability is local to the refinement ledger. Two accepted reads can compare cells only after the interval row I, dyadic row D, and refinement row R have been displayed and transported through H, C, P, N.

The finite-subcover ledger is exact because S contains only the witnesses attached to the listed cells of R. There is no row carrying an arbitrary cover family or a host selector for additional witnesses.

Endpoint transport is dyadic before it is Real-facing. The row D records endpoint, mesh, refinement, and slack comparisons, and E seals only those endpoint and radius reads already attached to I, D, R, S.

Finally M and U are compatibility rows over the same finite data, while H, C, P, N preserve and name the displayed route. Since selected subcovers, countable choice, and ambient real completeness have no carrier coordinate, the five obligations exhaust the local NameCert surface. □

Theorem 5111.3 (Constructive Heine–Borel interval finite-subcover ledger)**.** *Every compactness-facing or completion-facing consumer of an accepted* $\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through $I, D, R, S, E, M, U, H, C, P, N$. The exported subcover row is exactly the finite ledger S transported from the dyadic refinement row R to the terminal endpoint and radius seal E; it is not general open-cover compactness, a selected subcover functional, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the obligation surface of Definition 5111.2. Every cover-facing read must display the closed bounded interval source, the dyadic endpoint ledger, the refinement row, and the finite subcover ledger.

The route then passes through the compatibility rows. The compact-metric row M reads the same finite dyadic cells as a finite-net surface, and the uniform-modulus row U reads the same refinement scale for uniform-continuity consumers.

The Real-facing endpoint seal E is reached only after those finite rows have been displayed. Transport through H, replay through C, provenance through P, and local naming through N preserve that order.

Thus the exported row is the finite ledger already recorded in S. The refused open-cover, selected-subcover, countable-choice, and ambient-completeness readings have no row in the packet. □

Falsifiable prediction: A consumer that reads $\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}$ as a general open-cover compactness theorem, or reaches a subcover without displaying the closed bounded interval source, DyadicRatCore ledger, finite refinement row, finite subcover ledger, Real seal, compact-metric compatibility row, uniform-modulus compatibility row, transport, replay, provenance, and local NameCert rows, refutes the carrier surface.

Independence witness: closedboundedinterval, dyadicratcore, real, compactmetric, uniform-modulus: no listed sibling is bijective to $\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}$ because this packet binds a finite dyadic cover-refinement ledger, exact finite-subcover row, endpoint transport, compact-metric compatibility, uniform-modulus compatibility, Real sealing, transport, replay, provenance, and local naming in one L10 interval-compactness interface.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, a DyadicRatCore endpoint and refinement ledger, a finite subcover ledger, a RealUp seal, CompactMetric and UniformModulus compatibility rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5111.1, Definition 5111.2, and Definition 5111.3 seed the finite dyadic-cover interval compactness packet over closed bounded interval, dyadic endpoint, compact-metric, uniform-modulus, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveHeineBorelInterval}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.ConstructiveHeineBorelIntervalUp.ConstructiveHeineBorelIntervalCarrier`

Bridge status: none

Not claimed: This chapter does not close general open-cover compactness, unrestricted Heine–Borel compactness, selected subcover functionals, quotient interval representatives, countable choice, ambient RealUp completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cover-refinement classifier stability, finite-subcover ledger exactness, dyadic endpoint transport, compact-metric compatibility, uniform-modulus compatibility, nonescape, replay, provenance, and local naming for BEDC.Derived.ConstructiveHeineBorelIntervalUp.

Chapter 5112

A Concrete Naming Certificate for $\mathsf{QuadraticForm}^{\uparrow}$

Following Bourbaki and Serre on quadratic forms, the $\mathsf{QuadraticForm}^{\uparrow}$ packet records a scalar-valued quadratic law on a displayed module or vector-space carrier as finite BEDC NameCert data. It sits between the scalar field of chapter 45, the module and vector-space source rows of chapter 46 and chapter 47, the bilinear-form pairing surface of chapter 146, and the real-facing scalar seal of chapter 38. Downstream consumers such as chapter 3367, chapter 147, and chapter 310 may read the same finite quadratic packet instead of redeclaring diagonal scalar data.

Definition 5112.1 (Quadratic form carrier)**.** *A* $\mathsf{QuadraticForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, V, B, q, H, P, T, C, S, N)$$

with the following displayed rows:

1. *F is the scalar* $\mathsf{Field}^{\uparrow}$ *source row, with the* $\mathsf{Real}^{\uparrow}$ *seal recorded when the scalar endpoint is real-valued.*
2. *V is the* $\mathsf{Module}^{\uparrow}$ *or* $\mathsf{VecSpace}^{\uparrow}$ *carrier row whose displayed addition, zero, inverse, and scalar-action rows are the only vector endpoints admitted by the packet.*
3. *B is the* $\mathsf{BilinForm}^{\uparrow}$ *source row that supplies the visible polarization candidate used by quadratic consumers.*
4. *q is the scalar endpoint row assigning each accepted vector endpoint a carried scalar value in the source named by F.*
5. *H records the homogeneity ledger $q(a \cdot x) = a^2 q(x)$ over displayed scalar-action rows and scalar-square rows.*
6. *P records the polarization handoff row, reading the cross-term endpoint through the bilinear source B and the displayed scalar expression determined by $q(x+y)$, $q(x)$, and $q(y)$.*
7. *T records componentwise* hsame *transport for scalar field data, module or vector-space data, bilinear-form source rows, quadratic endpoint rows, homogeneity rows, polarization rows, continuation, provenance, and local naming.*
8. *C records displayed* Cont *replay from the source carrier through the quadratic endpoint, homogeneity ledger, polarization handoff, and local certificate.*

9. *S is the* Pkg *provenance over* $\mathsf{QuadraticForm}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{BilinForm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{QuadraticForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, V, B, q, H, P, T, C, S, N$. It has no coordinate for a host function on an ambient vector space, quotient equality of quadratic maps, a selected basis, diagonalization, inertia, positivity, Clifford quotient data, or bridge checking.

Lean4 ✓ `BEDC.Derived.QuadraticFormUp.QuadraticFormTasteGate single carrier alignment`

Theorem 5112.2 (Quadratic form polarization boundary)**.** *For every accepted* $\mathsf{QuadraticForm}^{\uparrow}$ *carrier $Q = (F, V, B, q, H, P, T, C, S, N)$, the polarization row P is the only public route from scalar quadratic values to a bilinear-form read. A consumer may inspect the displayed cross-term package through the* $\mathsf{BilinForm}^{\uparrow}$ *source row B and the scalar endpoints named by q, but it receives no host bilinear map, no quotient equality of forms, no selected coordinate matrix, and no diagonal basis.*

Proof. Project the carrier of Definition 5112.1. The only row that mentions both the quadratic endpoint q and a bilinear output is the polarization handoff P.

The handoff first reads the admitted vector endpoints through V and their scalar outputs through q. It then compares the cross-term endpoint with the bilinear source B inside the same scalar field row F, so the comparison is a displayed BEDC package rather than an external equality of functions.

The excluded objects are absent from the carrier. Since no row stores a host bilinear map, quotient equality of forms, selected coordinates, or a diagonal basis, the polarization read cannot export them. □

Theorem 5112.3 (Quadratic form NameCert obligations)**.** *For every accepted* $\mathsf{QuadraticForm}^{\uparrow}$ *carrier $Q = (F, V, B, q, H, P, T, C, S, N)$, the local* $\mathsf{NameCert}_{\mathsf{QuadraticForm}^{\uparrow}}$ *surface consists of carrier admission for the scalar field, module or vector-space source, bilinear-form source, quadratic endpoint, homogeneity ledger, polarization handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The exactness boundary says that every public quadratic-form read is generated by these rows and that every downstream consumer must factor through the displayed source certificates before reading scalar quadratic data.*

Proof. Read the carrier rows in the displayed order. The scalar field row F, vector or module carrier row V, bilinear source B, and scalar endpoint row q determine the admitted quadratic surface.

The homogeneity obligation is the ledger H. It uses only the scalar-action rows from V and the scalar-square rows from F, so it remains inside the displayed module or vector-space source.

The polarization obligation is the row P and is bounded by Definition 5112.2. Finally T, C, S, N supply transport, replay, provenance, and local naming. These projections exhaust the local NameCert surface, so no hidden positivity, inertia, diagonalization, Clifford quotient, host function equality, or bridge row is available. □

Theorem 5112.4 (Quadratic form bilinear-form handoff)**.** *Every accepted* $\mathsf{QuadraticForm}^{\uparrow}$ *packet exposes its bilinear-form interface through the route*

$$\mathsf{BilinForm}^{\uparrow}, \mathsf{Module}^{\uparrow}, \mathsf{VecSpace}^{\uparrow}, \mathsf{Field}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

The route sends diagonal reads to the scalar endpoint q and cross-term reads to the polarization row P. Consequently $\mathsf{SylvesterInertia}^{\uparrow}$, $\mathsf{Clifford}^{\uparrow}$, *and* $\mathsf{SemidefiniteCone}^{\uparrow}$ *consumers may cite the same*

quadratic packet when they need scalar diagonal data, bilinear polarization data, and source-carrier transport.

Proof. Start from a public consumer read. By Definition 5112.1, diagonal scalar data can be read only from q, and cross-term data can be read only from P together with the bilinear source B.

The route first fixes the scalar source F and the vector or module source V. It then reads B for the bilinear-form side and reads q, H, P for the quadratic endpoint, homogeneity, and polarization rows.

Apply the NameCert obligation surface of Definition 5112.3. The consumer receives exactly the finite rows needed by the inertia, Clifford, and semidefinite-cone chapters: scalar diagonal values, bilinear handoff, carrier transport, continuation replay, provenance, and local naming. Since selected bases, diagonalization, positivity decisions, Clifford quotients, and optimization cones are not carrier coordinates, they remain obligations of the downstream chapters rather than hidden exports of $\mathsf{QuadraticForm}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{QuadraticForm}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuadraticForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5112.1, Definition 5112.2, Definition 5112.3, and Definition 5112.4 seed the finite scalar quadratic-form packet over displayed field, module, vector-space, bilinear-form, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{QuadraticForm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host function equality of quadratic maps, selected bases, diagonalization, inertia, positivity, Clifford quotient data, semidefinite cone construction, or optimization duality.

Upgrade path: Obligation closure requires checked carrier admission, homogeneity, polarization boundary, bilinear-form handoff, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.QuadraticFormUp.

Constructive story: A $\mathsf{QuadraticForm}^{\uparrow}$ packet is generated from a FieldUp scalar row, ModuleUp or VecSpaceUp carrier rows, a BilinFormUp source row, a scalar quadratic endpoint, homogeneity and polarization ledgers, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5113

A Concrete Naming Certificate for $\mathsf{RealStepFunction}^{\uparrow}$

Following Riemann and Bishop–Bridges constructive analysis, the $\mathsf{RealStepFunction}^{\uparrow}$ packet records finite step functions over located real intervals as BEDC NameCert data. It refines the finite partition-to-value surface of chapter 3780 along the tagged real interval route and feeds the Darboux/Riemann consumer boundary of chapter 1960. The packet supplies the RealUp-specific step-function interface used by integration chapters without importing host functions, quotient equality of integrands, selected refinement limits, measure completion, or ambient real completeness.

Definition 5113.1 (Real step function carrier)**.** *A* $\mathsf{RealStepFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (I, T, V, S, R, G, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *interval-domain row, carrying the located real endpoints and interval-side admission data on which the function is read.*
2. *T is the* $\mathsf{TaggedRealPartition}^{\uparrow}$ *cell row, listing finitely many ordered tagged real subintervals, endpoint incidence, tag containment, and coverage over the row I.*
3. *V is the* $\mathsf{StepFunction}^{\uparrow}$ *value row, assigning one displayed value row to each tagged cell of T and exposing constant-on-cell admission only through that finite cell list.*
4. *S is the* $\mathsf{RiemannSum}^{\uparrow}$ *readback row computed from the tagged cells, cell widths, tags, and displayed values.*
5. *R is the* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff row, exposing the Darboux/Riemann consumer route that may use I, T, V, S as finite integrability evidence.*
6. *G is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *comparison row, recording that the same finite cell-value surface can be read as a regulated-function approximation boundary when a downstream chapter asks for that interface.*
7. *H records componentwise* hsame *transport for the interval-domain row, tagged partition, step-value row, Riemann-sum readback, integrability handoff, regulated comparison, continuation replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from I to T, from T, V to S, from I, T, V, S to R, and from the same finite rows to G.*

9. *P is the* Pkg *provenance over* $\mathsf{RealStepFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{StepFunction}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealStepFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host-level function, quotient equality of integrands, a selected refining partition sequence, a measure-space completion, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5113.2 (Real step function NameCert obligations)**.** *For every accepted* $\mathsf{RealStepFunction}^{\uparrow}$ *carrier $E = (I, T, V, S, R, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealStepFunction}^{\uparrow}}$ *surface consists exactly of real interval-domain admission, tagged real partition exposure, finite step-value exposure, Riemann-sum readback, Riemann-integrable handoff, regulated-function comparison, component-wise transport, displayed replay, provenance, local naming, and non-escape from host functions, quotient integrand equality, selected refinement limits, measure completion, open-cover compactness, and ambient real completeness.*

Lean4 ✓ `BEDC.Derived.RealStepFunctionUp.RealStepFunctionNamecertObligations`

Proof. Project the carrier of Definition 5113.1. The interval-domain row I, tagged partition row T, and value row V are the only rows from which a consumer can read the domain cells and their constant values.

The integration-facing rows are downstream of that finite data. The row S is computed from the tagged cells, widths, tags, and displayed values, while R admits a $\mathsf{RiemannIntegrable}^{\uparrow}$ consumer only after I, T, V, S have been displayed.

The regulated-function comparison uses the same rows. The row G does not introduce another function object; it records only the regulated approximation boundary supplied by the finite cell-value surface.

Finally H, C, P, N preserve, replay, source, and name exactly this packet. Since the excluded host objects are not carrier coordinates, the listed obligations exhaust the local NameCert surface. □

Theorem 5113.3 (Real step function Riemann readback)**.** *Every Riemann-facing read of an accepted* $\mathsf{RealStepFunction}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Real}^{\uparrow} \longmapsto \mathsf{TaggedRealPartition}^{\uparrow} \longmapsto \mathsf{StepFunction}^{\uparrow} \longmapsto \mathsf{RiemannSum}^{\uparrow} \longmapsto \mathsf{RiemannIntegrable}^{\uparrow}$$

together with the $\mathsf{RegulatedFunction}^{\uparrow}$ *comparison row and the structural rows H, C, P, N. The route exports finite tagged real interval data and displayed constant values, not a host integrand, quotient function class, selected mesh limit, measure-theoretic completion, or ambient real-completeness principle.*

Proof. Start with the real interval-domain row I. A Riemann-facing consumer cannot observe a cell or tag before the tagged real partition row T displays the finite subdivision and containment data over that interval.

Next read the step-value row V. Each value is attached to a displayed cell, so the finite sum row S is computed from visible tags, cell widths, and displayed constant values rather than from a host function.

The integrability handoff is the row R. It can be consumed only after the finite Riemann-sum readback has been displayed, and the regulated comparison row G is tied to the same cell-value surface.

The structural rows H, C, P, N transport, replay, source, and name this route without adding another analytic coordinate. Therefore the readback remains inside the displayed RealUp interval, tagged partition, step-function, sum, integrability, and regulated-function rows. □

Falsifiable prediction: An accepted $\mathsf{RealStepFunction}^{\uparrow}$ read is refuted if its $\mathsf{RiemannIntegrable}^{\uparrow}$ handoff remains while the displayed $\mathsf{Real}^{\uparrow}$ interval row, $\mathsf{TaggedRealPartition}^{\uparrow}$ cells, $\mathsf{StepFunction}^{\uparrow}$ value rows, and $\mathsf{RiemannSum}^{\uparrow}$ readback are removed.

Independence witness: real-interval, tagged-partition, step-values, riemann-sum, riemann-integrable, regulated-function: none is bijective with $\mathsf{RealStepFunction}^{\uparrow}$ because the packet jointly carries interval-domain data, tagged real cells, displayed constant values, finite Riemann-sum readback, integrability handoff, regulated comparison, componentwise transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RealStepFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{RealStepFunction}^{\uparrow}$ packet is generated from a RealUp interval-domain row, TaggedRealPartitionUp cells, StepFunctionUp values, RiemannSumUp readback, RiemannIntegrableUp handoff, RegulatedFunctionUp comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealStepFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5113.1, Definition 5113.2, and Definition 5113.3 seed the finite RealUp interval step-function surface over tagged real partitions, step-value rows, Riemann sums, Riemann integrability, and regulated-function comparison.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealStepFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host function equality, quotient integrands, selected refinement limits, measure completion, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tagged partition exposure, step-value exposure, Riemann-sum readback, Riemann-integrable handoff, regulated comparison, and structural transport for BEDC.Derived.RealStepFunctionUp.

Chapter 5114

A Concrete Naming Certificate for $\mathsf{RegularCauchyNonzero}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyNonzero}^{\uparrow}$ packet names the finite nonzero-domain evidence needed between regular Cauchy rational sources and guarded reciprocal or division consumers. It binds the $\mathsf{RegSeqRat}^{\uparrow}$ source of chapter 301, the finite $\mathsf{StreamName}^{\uparrow}$ inspection window of chapter 126, the dyadic lower-bound ledger of chapter 291, the reciprocal consumer of chapter 1471, the division consumer of chapter 1943, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The chapter records only displayed finite apartness from zero for a regular Cauchy name; it is not real trichotomy and not a total reciprocal operation.

Definition 5114.1 (Regular Cauchy nonzero carrier)**.** *A* $\mathsf{RegularCauchyNonzero}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (Q, A, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational tail is being inspected.*
2. *A is the apartness witness row displaying that the inspected tail is separated from zero by a positive rational bound.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window opened from Q at the precision and tail indices required by A.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *lower-bound ledger recording the dyadic comparison, radius budget, and positive lower endpoint read from W.*
5. *R is the reciprocal-domain handoff row offered to* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *and* $\mathsf{RegularCauchyDivision}^{\uparrow}$ *consumers.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal receiving the same finite nonzero-domain packet without adding trichotomy or selected representatives.*
7. *H records componentwise* hsame *transport for $Q, A, W, D, R, E, C, P, N$.*
8. *C records displayed* Cont *replay for source inspection, apartness exposure, finite-window opening, dyadic lower-bound reading, reciprocal-domain handoff, and Real seal handoff.*
9. *P records* Pkg *provenance over* $\mathsf{RegularCauchyNonzero}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyReciprocal}^{\uparrow}$, $\mathsf{RegularCauchyDivision}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyNonzero}^{\uparrow}}$ *row.*
The local classifier compares accepted carriers only through the displayed rows $Q, A, W, D, R, E, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.RegularCauchyNonzeroUp.RegularCauchyNonzeroTasteGate single carrier alignment`

Theorem 5114.2 (Regular Cauchy nonzero NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RegularCauchyNonzero}^{\uparrow}}$ *surface for Definition 5114.1 consists exactly of regular Cauchy source exposure, apartness-witness exposure, finite StreamName window exposure, DyadicRatCore lower-bound ledger exposure, reciprocal-domain handoff, terminal Real seal handoff, componentwise transport, displayed continuation replay, package provenance, and the local naming row.*

Lean4 ✓ `BEDC.Derived.RegularCauchyNonzeroUp.RegularCauchyNonzeroNamecertObligations`

Proof. Project the carrier $Z = (Q, A, W, D, R, E, H, C, P, N)$. The coordinates list the regular Cauchy source, apartness witness, finite window, dyadic lower-bound ledger, reciprocal-domain handoff, Real seal, transport, replay, provenance, and local name.

The analytic rows are ordered by dependency. The window row W is opened from Q under the apartness witness A, while the dyadic ledger D records the positive lower-bound computation read from that finite window.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since every listed obligation is a coordinate or a projection from a coordinate, the seed NameCert surface is exhausted by the displayed packet. □

Theorem 5114.3 (Regular Cauchy nonzero apartness window)**.** *For every accepted* $\mathsf{RegularCauchyNonzero}^{\uparrow}$ *carrier $Z = (Q, A, W, D, R, E, H, C, P, N)$, every nonzero-domain read factors through*

$$Q \longmapsto A \longmapsto W \longmapsto D.$$

A route that opens a reciprocal or division consumer without the displayed apartness witness A and lower-bound ledger D remains outside the local classifier.

Proof. Start from the source row Q and apartness witness A. The witness is the only row asserting a positive separation from zero for the inspected regular Cauchy tail.

Next open the finite window W. Its entries are the only regular rational data inspected by the certificate, and the dyadic ledger D is a finite lower-bound read from that window.

The local classifier admits no row that bypasses A, W, D. Therefore every accepted nonzero-domain read reaches the lower-bound ledger through the displayed source, witness, and window route. □

Theorem 5114.4 (Regular Cauchy nonzero reciprocal-domain handoff)**.** *Every* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *or* $\mathsf{RegularCauchyDivision}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyNonzero}^{\uparrow}$ *packet reaches its denominator-domain row through the same handoff*

$$(Q, A, W, D) \longmapsto R.$$

The handoff exports finite apartness evidence and a dyadic lower-bound ledger, but it exports no total reciprocal, no quotient stream equality, no real trichotomy, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Use the apartness-window theorem to fix the source, witness, window, and lower-bound ledger rows. These rows are the complete analytic source of the nonzero-domain claim.

The handoff row R is downstream of D. A reciprocal consumer reads R as the denominator-domain guard for chapter 1471, and a division consumer reads the same row before the reciprocal-product route of chapter 1943.

Finally read the Real seal E and the structural rows H, C, P, N. None of these rows adds total inversion, quotient equality, trichotomy, or completeness data, so the handoff exports only the displayed finite nonzero-domain certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyNonzero}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyNonzero}^{\uparrow}$ packet is generated from a $\mathsf{RegSeqRat}^{\uparrow}$ source row, an apartness witness, a finite $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{DyadicRatCore}^{\uparrow}$ lower-bound ledger, a reciprocal-domain handoff, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyNonzero}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5114.1, Definition 5114.2, Definition 5114.3, and Definition 5114.4 seed the finite nonzero-domain boundary for regular Cauchy names over $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyReciprocal}^{\uparrow}$, $\mathsf{RegularCauchyDivision}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyNonzero}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim total reciprocal construction, total division, real trichotomy, quotient stream equality, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, apartness-window routing, reciprocal-domain handoff, and the corresponding finite nonzero-domain NameCert rows.

Chapter 5115

A Concrete Naming Certificate for $\mathsf{RealUniformEntourageBasis}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and Bishop–Bridges constructive real analysis, the $\mathsf{RealUniformEntourageBasis}^{\uparrow}$ packet records the metric-ball basis that realizes the Real-induced uniformity route of chapter 9237. It sits after the Real endpoint and seal surface of chapter 38, the metric witness of chapter 57, the entourage discipline of chapter 339, the Real-induced uniformity of chapter 1624, and the Cauchy-filter consumer of chapter 333. Its finite readback path uses the StreamName surface of chapter 126 and the RegSeqRat readback of chapter 301.

Definition 5115.1 (Real uniform entourage-basis carrier)**.** *A* $\mathsf{RealUniformEntourageBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, M, U, S, F, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint and seal row naming the points whose metric balls generate the basis.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance witness row read before any entourage request is generated.*
3. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row generated by positive metric-ball requests.*
4. *S is the* $\mathsf{RealUniformStructure}^{\uparrow}$ *source row that binds the metric-ball basis to the Real-induced uniformity.*
5. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer row that reads Cauchy data through the generated basis.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used by completion-facing consumers.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
8. *H records componentwise* hsame *transport for the Real, metric, uniform, Real-uniform, Cauchy-filter, window, readback, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the route*

$$R, M \longmapsto U, S \longmapsto F, W, Q.$$

10. *P is the* Pkg *provenance over* $\mathsf{RealUniformEntourageBasis}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealUniformEntourageBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, M, U, S, F, W, Q, H, C, P, N$. It has no coordinate for quotient real equality, selected limits, countable choice, open-cover compactness, quotient filters, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.RealUniformEntourageBasisUp.RealUniformEntourageBasisUpTasteGate single carrier alignment`

Theorem 5115.2 (Real uniform entourage-basis NameCert obligations)**.** *For every accepted* RealUniformEntourage *carrier*

$$E = (R, M, U, S, F, W, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealUniformEntourageBasis}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the eleven displayed rows;*
2. *Real endpoint exposure, requiring every basis request to read R before it reads a metric ball;*
3. *metric-ball generation, requiring M to generate each entourage row in U by a displayed positive-radius request;*
4. *Real-uniform source compatibility, requiring S to identify the basis as the* $\mathsf{RealUniformStructure}^{\uparrow}$ *metric-ball surface;*
5. *Cauchy-filter handoff, requiring F to consume the generated basis before any completion-facing read;*
6. *finite readback, requiring W and Q to expose only StreamName windows and RegSeqRat readbacks downstream of the same basis route;*
7. *componentwise transport, displayed replay, provenance, and local naming for the route through H, C, P, N.*

No Real uniform entourage-basis obligation is stored outside these rows.

Proof. Project the accepted packet $E = (R, M, U, S, F, W, Q, H, C, P, N)$. The projection exposes exactly the Real endpoint row, metric witness row, generated uniform entourage row, Real-uniform source row, Cauchy-filter consumer, finite readback rows, and structural rows.

The basis starts from Real endpoints and metric data. The row R names the endpoints, and M supplies the distance witness from which the metric-ball entourage row U is generated.

The row S binds this generated basis to the $\mathsf{RealUniformStructure}^{\uparrow}$ route. A Cauchy-filter consumer can then read F only after the same basis has been displayed.

The rows W and Q give finite StreamName and RegSeqRat readback downstream of the basis. The structural rows H, C, P, N transport, replay, source, and name the same route, and the excluded objects do not occur as carrier coordinates. □

Theorem 5115.3 (Real uniform entourage-basis Cauchy-filter handoff)**.** *Every completion-facing or Cauchy-filter consumer of an accepted* $\mathsf{RealUniformEntourageBasis}^{\uparrow}$ *carrier reads the Real-induced metric-ball basis only through*

$$\mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{UniformSpace}^{\uparrow}, \mathsf{RealUniformStructure}^{\uparrow}, \mathsf{CauchyFilter}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{Nam}$$

Consequently the packet exports no quotient real equality, selected limit, countable-choice selector, open-cover compactness, quotient filter, or ambient Real completeness.

Proof. Begin with a completion-facing or Cauchy-filter read. Carrier admission gives access only to $R, M, U, S, F, W, Q, H, C, P, N$.

Use the metric-uniformity handoff of Definition 1624.3. It forces the Real-induced uniformity to pass through endpoint rows, metric distance evidence, generated entourage rows, Cauchy-filter compatibility, finite windows, and regular rational readback.

The present carrier isolates the basis part of that route. The rows R, M, U, S generate and identify the metric-ball basis, F consumes it as a Cauchy-filter surface, and W, Q provide the finite readback needed by completion-facing consumers.

Since quotient equality, selected limits, choice, quotient filters, open-cover compactness, and ambient Real completeness are not rows of E, the consumer obtains only the displayed NameCert route. □

Falsifiable prediction: An accepted $\mathsf{RealUniformEntourageBasis}^{\uparrow}$ read is refuted if a Cauchy-filter or completion-facing consumer exports a Real-induced basis without displaying Real endpoint rows, Metric distance witnesses, UniformSpace entourage rows, RealUniformStructure source compatibility, StreamName windows, RegSeqRat readback, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real-uniform-structure, real, metric, uniformspace, cauchyfilter, streamname, regseqrat: no listed sibling alone is bijective with $\mathsf{RealUniformEntourageBasis}^{\uparrow}$ because the packet jointly carries metric-ball basis generation, Real-uniform source compatibility, Cauchy-filter handoff, finite readback, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{RealUniformEntourageBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{RealUniformEntourageBasis}^{\uparrow}$ packet is generated from RealUp endpoint rows, MetricUp distance witnesses, UniformSpace entourage rows, RealUniformStructureUp source compatibility, CauchyFilterUp handoff, StreamNameUp windows, RegSeqRatUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealUniformEntourageBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5115.1, Definition 5115.2, and Definition 5115.3 seed the Real-induced metric-ball entourage basis for Cauchy-filter and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealUniformEntourageBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient real equality, selected limits, countable-choice selectors, open-cover compactness, quotient filters, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked Real endpoint exposure, metric-ball generation, RealUniformStructure compatibility, CauchyFilter handoff, finite readback, transport, replay, provenance, and local naming for BEDC.Derived.RealUniformEntour

Chapter 5116

A Concrete Naming Certificate for $\mathsf{UniformLebesgueNumber}^{\uparrow}$

Following Lebesgue's covering lemma, Bourbaki and Kelley on uniform spaces, and Bishop–Bridges compact metric analysis, the $\mathsf{UniformLebesgueNumber}^{\uparrow}$ packet records the radius handoff by which a compact-cover lower bound becomes uniform entourage data. It sits after the compact finite-radius packet of chapter 4015, the finite lower-radius fold of chapter 452, the compact metric source of chapter 129, and the uniform-modulus consumer of chapter 369. The packet is a finite NameCert boundary for uniform reads of compact cover radii; it is not an arbitrary open-cover principle, not a selected subcover, and not an ambient minimum theorem.

Definition 5116.1 (Uniform Lebesgue-number carrier)**.** *A* $\mathsf{UniformLebesgueNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, M, F, V, L, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose compact finite-net and cover-inspection data must be read before any radius is exported.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row that interprets every cover-radius and entourage request as metric evidence.*
3. *F is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *lower-bound fold row for the finite cover-radius ledger.*
4. *V is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row that receives the lower-bound ledger as a tolerance-only uniform handoff.*
5. *L is the* $\mathsf{CompactLebesgueNumber}^{\uparrow}$ *route row, carrying the compact cover spine, located coverage rows, positive radius ledger, and finite lower-bound fold together.*
6. *H records componentwise* hsame *transport for the compact source, metric row, finite lower-bound fold, uniform-modulus handoff, compact Lebesgue-number route, replay, provenance, and local name.*
7. *C records displayed* Cont *replay of the route*
$$K, M, L \longmapsto F \longmapsto V.$$
8. *P is the* Pkg *provenance over* $\mathsf{UniformLebesgueNumber}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactLebesgueNumber}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{UniformLebesgueNumber}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, F, V, L, H, C, P, N$. It has no coordinate for arbitrary open covers, selected subcovers, host compactness, host minima, quotient real equality, countable choice, or a uniform radius detached from the compact finite cover ledger.

Lean4 ✓ `BEDC.Derived.UniformLebesgueNumberUp.UniformLebesgueNumberTasteGate single carrier alignment`

Theorem 5116.2 (Uniform Lebesgue-number NameCert obligations)**.** *For every accepted* $\mathsf{UniformLebesgueNumber}$ *carrier*

$$U = (K, M, F, V, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformLebesgueNumber}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the nine displayed rows;*
2. *compact-metric source exposure, requiring every uniform-radius read to pass through K;*
3. *metric interpretation, requiring M to mediate every radius and entourage request before it reaches a uniform consumer;*
4. *finite Lebesgue-number compatibility, requiring F to be the lower-bound fold of the displayed compact cover-radius ledger;*
5. *compact Lebesgue-number route compatibility, requiring L to expose the compact cover spine, located coverage rows, positive radius ledger, and finite lower-bound fold before V is available;*
6. *uniform-modulus handoff, requiring V to consume only the displayed lower-bound ledger routed through K, M, F, L;*
7. *componentwise transport, displayed replay, provenance, and local naming for the same route through H, C, P, N.*

No uniform Lebesgue-number obligation is stored outside these rows.

Proof. Project the accepted packet $U = (K, M, F, V, L, H, C, P, N)$. The displayed coordinates give the compact source, metric interpretation, finite lower-bound fold, uniform-modulus handoff, compact Lebesgue-number route, and structural rows.

The compact and metric rows come first. The row K supplies compact finite-net and cover-inspection data, while M keeps radius and entourage reads inside the displayed metric surface.

The finite lower-bound row is then read through F and L. The row L carries the compact cover spine, located coverage rows, positive radius ledger, and finite lower-bound fold, so F is not a host minimum and not a selected subcover argument.

Finally V, H, C, P, N package the same lower-bound ledger for uniform-modulus consumers. Since the excluded objects do not occur as carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 5116.3 (Uniform Lebesgue-number compact-uniform handoff)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{UniformLebesgueNumber}^{\uparrow}$ *carrier receives the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{CompactLebesgueNumber}^{\uparrow} \longmapsto \mathsf{FiniteLebesgueNumber}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto \mathsf{hsame}, \mathsf{Co}$$

Thus the compact cover-radius handoff of chapter 9237 is exposed as compact-metric source data, metric radius interpretation, compact Lebesgue-number cover rows, a finite lower-bound fold, and

a uniform-modulus consumer row. It exports no arbitrary open cover, selected subcover, host compactness theorem, host minimum, countable-choice selector, quotient real equality, or detached uniform radius.

Proof. Start from the source rows K and M. They force every radius read to use the compact-metric source and the displayed metric interpretation before a uniform consumer can inspect the packet.

Read the compact Lebesgue-number route L. By Definition 4015.3, that route exposes the compact cover spine, located coverage rows, positive radius ledger, and finite lower-bound fold before the uniform handoff is available.

The row F records the finite $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ lower-bound fold, and V consumes exactly that lower-bound ledger as a $\mathsf{UniformModulus}^{\uparrow}$ row. The structural rows H, C, P, N transport, replay, source, and name the same finite path.

Because the carrier has no coordinate for arbitrary open covers, selected subcovers, host minima, choice, quotient real equality, or detached uniform radii, every compact-uniform read factors through the displayed route. □

Falsifiable prediction: An accepted $\mathsf{UniformLebesgueNumber}^{\uparrow}$ read is refuted if a compact-uniform-continuity consumer exports a UniformModulusUp row without displaying CompactMetric source data, Metric radius interpretation, a CompactLebesgueNumber cover route, a FiniteLebesgueNumber lower-bound fold, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: compact-lebesgue-number, finite-lebesgue-number, uniformmodulus: none alone is bijective with $\mathsf{UniformLebesgueNumber}^{\uparrow}$ because the packet jointly carries compact source data, metric radius interpretation, compact cover rows, finite lower-bound fold, uniform-modulus handoff, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLebesgueNumber}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformLebesgueNumber}^{\uparrow}$ packet is generated from CompactMetricUp source data, MetricUp radius interpretation, a CompactLebesgueNumberUp route row, a FiniteLebesgueNumberUp lower-bound fold, UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformLebesgueNumber}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5116.1, Definition 5116.2, and Definition 5116.3 seed the uniform Lebesgue-number packet from compact finite cover-radius data through lower-bound folds to UniformModulusUp handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformLebesgueNumber}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, host compactness, host minima, quotient real equality, countable choice, detached uniform radii, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source exposure, metric radius interpretation, CompactLebesgueNumber route compatibility, FiniteLebesgueNumber fold compatibility, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformLebesgueNumberUp.

Chapter 5117

A Concrete Naming Certificate for $\mathsf{UniformlyCauchyFilter}^{\uparrow}$

Following Kelley and Bourbaki on uniform spaces, and Bishop–Bridges constructive completion, the $\mathsf{UniformlyCauchyFilter}^{\uparrow}$ packet records the finite route by which a located uniform source exposes Cauchy-filter data to Real-and-Completion consumers. It sits after the located entourage surface of chapter 3814, the Real-induced uniformity of chapter 1624, the filter carrier of chapter 333, the net handoff of chapter 589, the finite window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet is a finite NameCert boundary for uniformly Cauchy filter reads; it does not quotient filters, choose limits, identify host equalities, invoke countable choice, or assert ambient Real completeness.

Definition 5117.1 (Uniformly Cauchy filter carrier)**.** *A* $\mathsf{UniformlyCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (U, L, F, N, W, D, R, E, H, C, P, Q)$$

with the following displayed rows:

1. *U is the* $\mathsf{LocatedUniformSpace}^{\uparrow}$ *entourage row, exposing only named entourage requests and located refinement witnesses.*
2. *L is the uniform-Cauchy schedule, assigning each displayed entourage request a finite filter-stage certificate.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row that reads the accepted filter base after the located entourage and schedule rows have been displayed.*
4. *N is the* $\mathsf{CauchyNet}^{\uparrow}$ *handoff row, available only as a finite net witness for the same entourage request.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by Real-and-Completion consumers.*
6. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the window and entourage requests.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows under the dyadic ledger.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, downstream of the located uniform, filter, net, window, dyadic, and regular readback rows.*
9. *H records componentwise* hsame *transport for the located-uniform, schedule, filter, net, window, dyadic, regular-readback, Real-seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a located entourage request through* $U, L, F, N, W, D, R, E, H, P, Q$.
11. *P is the* Pkg *provenance over* $\mathsf{UniformlyCauchyFilter}^{\uparrow}$, $\mathsf{LocatedUniformSpace}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *Q is the local* $\mathsf{NameCert}_{\mathsf{UniformlyCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, L, F, N, W, D, R, E, H, C, P, Q$. It has no coordinate for quotient filters, selected limits, countable choice, host equality, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.UniformlyCauchyFilterUp.UniformlyCauchyFilterTasteGate single carrier alignment`

Theorem 5117.2 (Uniformly Cauchy filter NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyCauchyFilter}^{\uparrow}$ *carrier*

$$G = (U, L, F, N, W, D, R, E, H, C, P, Q),$$

the local $\mathsf{NameCert}_{\mathsf{UniformlyCauchyFilter}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the located-uniform entourage row, uniform-Cauchy schedule, CauchyFilter row, CauchyNet handoff, StreamName windows, dyadic tolerance ledger, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming;*
2. *located-entourage adequacy, requiring each Cauchy request to read U before any filter, net, or numeric row is interpreted;*
3. *uniform-Cauchy scheduling, requiring L to exhibit a finite filter-stage certificate for every displayed entourage request;*
4. *filter and net handoff, requiring F and N to consume the same located entourage and schedule rows rather than a quotient filter;*
5. *finite readback, requiring W, D, R, E to expose only finite windows, dyadic tolerances, regular rational readbacks, and the downstream Real seal;*
6. *transport, replay, provenance, and naming through H, C, P, Q for the same displayed route;*
7. *nonescape for quotient filters, selected limits, countable choice, host equality, and ambient Real completeness.*

No uniformly Cauchy filter obligation is stored outside these rows.

Proof. Project the carrier of Definition 5117.1. The accepted packet exposes exactly the located entourage row, the schedule row, the filter and net handoff rows, the finite numeric readback rows, and the structural rows.

The uniformly Cauchy assertion is schedule-local. Each entourage request is first read from U, and the finite stage evidence in L is the only admissible route by which the request reaches F or N.

The completion-facing read is then numeric but still finite. Stream windows W are inspected under the dyadic ledger D, regular rational readback is recorded in R, and the Real seal E remains downstream of those displayed rows.

Finally, H, C, P, Q transport, replay, source, and name the same packet. Since quotient filters, selected limits, countable choice, host equality, and ambient Real completeness are not carrier rows, they cannot be exported by the local NameCert surface. □

Theorem 5117.3 (Uniformly Cauchy filter located-uniform handoff)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{UniformlyCauchyFilter}^{\uparrow}$ *packet reads the Cauchy-filter route only through the located entourage row, the uniform-Cauchy schedule, the CauchyFilter row, the CauchyNet handoff, StreamName windows, positive DyadicRatCore tolerances, RegSeqRat readbacks, the downstream Real seal, and the structural rows* H, C, P, Q*. The handoff exports no quotient filter, selected limit, countable-choice selector, host equality, or ambient Real completeness.*

Proof. Begin with the accepted carrier $G = (U, L, F, N, W, D, R, E, H, C, P, Q)$. Carrier admission gives the consumer no access beyond these rows.

Use the obligation surface of Definition 5117.2. It forces every filter read to pass through the located entourage row U and the finite schedule L before either the CauchyFilter row F or the CauchyNet handoff N can be inspected.

The finite numeric handoff then follows the displayed order W, D, R, E. The structural rows preserve that order under componentwise transport and replay, so the consumer obtains a located-uniform Cauchy route without receiving any excluded quotient, selection, host-equality, or completeness coordinate. □

Theorem 5117.4 (Uniformly Cauchy filter Real completion boundary)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal reached by an accepted* $\mathsf{UniformlyCauchyFilter}^{\uparrow}$ *packet is downstream of the located uniform data, the uniform-Cauchy schedule, the filter and net handoff rows, finite windows, dyadic tolerance ledger, and regular rational readback. Therefore the packet may feed a completion-facing Real consumer, but it does not assert a selected completion point, quotient equality of filters, countable choice, host equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Proof. Apply Definition 5117.3. Any completion-facing read has already passed through U, L, F, N, W, D, R before the Real seal row E is available.

Apply Definition 5117.2 to the seal row. Its finite readback clause permits E only as the terminal boundary of the displayed window, dyadic, and regular-rational route, not as an ambient completeness theorem or a selected limit.

The remaining rows H, C, P, Q only transport, replay, source, and name this route. Hence the Real completion boundary is a downstream seal for the packet rather than a quotient-filter construction or a host equality principle. □

Falsifiable prediction: An accepted $\mathsf{UniformlyCauchyFilter}^{\uparrow}$ read is refuted if a completion-facing consumer reaches a CauchyFilter or Real seal without displaying located entourage data, a uniform-Cauchy schedule, a filter or net handoff, finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: located-uniform-space, real-uniform-structure, cauchyfilter, cauchynet, streamname, regseqrat, dyadicratcore, real: no listed sibling alone is bijective with $\mathsf{UniformlyCauchyFilter}^{\uparrow}$ because the packet jointly carries located entourage data, a uniform-Cauchy schedule, filter and net handoff, finite windows, dyadic tolerance, regular readback, Real sealing, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyCauchyFilter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformlyCauchyFilter}^{\uparrow}$ packet is generated from located uniform entourage rows, a uniform-Cauchy schedule, CauchyFilter and CauchyNet handoff rows, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a downstream Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyCauchyFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5117.1, Definition 5117.2, Definition 5117.3, and Definition 5117.4 seed the uniformly Cauchy filter route for completion-facing Real consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{UniformlyCauchyFilter}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable-choice selectors, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked located-entourage adequacy, uniform-Cauchy scheduling, filter and net handoff, finite readback, transport, replay, provenance, and local naming for BEDC.Derived.UniformlyCauchyFilterUp.

Chapter 5118

A Concrete Naming Certificate for $\mathsf{RealCauchyRate}^{\uparrow}$

Following Bishop–Bridges constructive real analysis, the $\mathsf{RealCauchyRate}^{\uparrow}$ packet records the finite rate certificate by which a regular rational sequence is sealed as a real name. It sits after the positive dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, and the regular-sequence readback of chapter 301, and before the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The chapter names the rate boundary only; it does not assert quotient real equality, selected representatives, trichotomy, countable choice, or ambient real completeness.

Definition 5118.1 (Real Cauchy-rate carrier)**.** *A* $\mathsf{RealCauchyRate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-tolerance ledger, carrying the dyadic radii and comparison budget used to test a regular Cauchy tail.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the tolerance and tail indices requested by D.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, recording the rational readback and tail-comparison schedule served by the window row S.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row receiving the accepted regular rational name after the displayed rate data has been read.*
5. *H records componentwise* hsame *transport for the dyadic tolerance, stream window, regular readback, Real seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from positive dyadic tolerance requests through finite StreamName windows, RegSeqRat regularity, and the Real seal handoff.*
7. *P is the* Pkg *provenance over* $\mathsf{RealCauchyRate}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyRate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, S, Q, R, H, C, P, N. It has no coordinate for quotient real equality, a selected representative stream, trichotomy, countable-choice selection, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealCauchyRateUp.RealCauchyRateTasteGate single carrier alignment`

Theorem 5118.2 (Real Cauchy-rate regular NameCert)**.** *For every accepted* $\mathsf{RealCauchyRate}^{\uparrow}$ *carrier* $K = (D, S, Q, R, H, C, P, N)$*, the local NameCert surface consists exactly of carrier admission, positive dyadic tolerance stability,* $\mathsf{RegSeqRat}^{\uparrow}$ *compatibility,* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and ledger non-escape from quotient real equality, selected representatives, trichotomy, countable choice, and ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.RealCauchyRateCarrier regular namecert`

Proof. Project the carrier of Definition 5118.1. The projection exposes only the dyadic tolerance ledger, finite stream window, regular rational readback, Real seal, transport, replay, provenance, and local naming rows.

Tolerance stability is read from the row D. A positive dyadic request can be transported only by the componentwise hsame row H and replayed only by the displayed Cont row C, so the same tolerance budget remains visible after transport.

RegSeqRat compatibility is downstream of the finite window. The window row S is opened before the regularity row Q is inspected, and the theorem records that the Real-facing readback remains a regular rational tail rather than a host stream quotient.

The Real seal handoff is the row R. It consumes the displayed route D, S, Q and exports only the named real boundary supplied by the packet.

Finally P and N exhaust provenance and naming. Since the excluded host objects are not carrier coordinates, the local ledger cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyRate}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealCauchyRate}^{\uparrow}$ packet is generated from a DyadicRatCore positive-tolerance ledger, finite StreamName windows, RegSeqRat regular rational readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealCauchyRate}^{\uparrow}}$, seed)

Scope closed: Definition 5118.1 and Definition 5118.2 seed the finite rate certificate between $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ through $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealCauchyRate}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.RealCauchyRateUp`

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected representatives, trichotomy, countable-choice selection, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance stability, regular-sequence compatibility, Real seal handoff, and ledger non-escape for the same finite rate packet.

$\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}$ reads repeated completion through chapter 3484 and chapter 1425 before the terminal $\mathsf{Real}^{\uparrow}$ seal.

Chapter 5119

A Concrete Naming Certificate for $\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}$ packet records the finite witness that applying regular-Cauchy completion to an already displayed regular-Cauchy completion route does not create a second ambient completion object. It sits after the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the idempotence boundary of **??**, and the terminal real-name seal of chapter 38. The packet names the Bishop-style flattening witness as BEDC rows, not as quotient representatives, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

The sibling dependency route is explicit: the packet consumes **??** as the flattening row and chapter 38 as the terminal seal, while chapter 126, chapter 291, and chapter 301 provide the finite observation and readback substrate. Thus the witness is part of the L10 completion lattice rather than a kernel-only singleton.

Definition 5119.1 (Bishop completion-idempotence witness carrier)**.** *A* $\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, D, R, I, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the source and repeated-completion requests.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the window comparison and regularity readback.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row carrying the regular rational source readback visible to the completion route.*
4. *I is the* $\mathsf{CauchyCompletionIdempotence}^{\uparrow}$ *row flattening the repeated completion boundary to the displayed completion route.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, R, I have been displayed.*
6. *H records componentwise* hsame *transport for the window, tolerance, readback, idempotence, seal, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay of the same finite route.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyCompletionIdempotence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, D, R, I, E, H, C, P, N$. It has no coordinate for quotient regular sequences, selected representatives, a second completed object, countable choice, host equality of completions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 5119.2 (Bishop completion-idempotence witness obligations)**.** *For every accepted* BishopCompletionIdem *carrier*

$$W = (S, D, R, I, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}}$ *surface consists exactly of finite stream-window exposure through S, dyadic tolerance exposure through D, regular rational readback through R, displayed completion-idempotence flattening through I, terminal real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5119.1. The rows S, D, R expose the regular-Cauchy source route, while I supplies the displayed idempotence row consumed by the completion-facing read.

Use the sibling surfaces in order. The stream windows come from chapter 126, the tolerance ledger from chapter 291, and the regular rational readback from chapter 301. The flattening row is exactly the finite idempotence boundary of **??**.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Because the carrier contains no quotient, selector, second-completion, choice, host-equality, or ambient-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 5119.3 (Bishop completion-idempotence witness route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyCompletionIdempotence}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Thus repeated regular-Cauchy completion is flattened by displayed BEDC rows before the terminal real seal is consumed. The route exports no quotient representative, selected limit, second completion carrier, countable-choice schedule, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with Definition 5119.2. It forces every consumer read through the finite window, dyadic tolerance, regular readback, idempotence, and real-seal rows before the local certificate can be inspected.

The $\mathsf{CauchyCompletionIdempotence}^{\uparrow}$ row then identifies the repeated-completion boundary with the displayed completion route. Since the row is downstream of S, D, R, the flattening is a finite regular-Cauchy read rather than a comparison of quotient representatives.

The terminal row E is only the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The absence of quotient, selector, choice, host-equality, second-completion, and ambient-completeness coordinates prevents any such object from entering the exported route. □

Falsifiable prediction: Every accepted $\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}$ read exposes StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, CauchyCompletionIdempotence flattening, RealUp seal, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before any repeated-completion consumer is served.

Independence witness: streamname, dyadicratcore, regseqrat, cauchy-completion-idempotence, real: none is bijective with $\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}$ because this packet alone binds the regular-Cauchy observation route, displayed completion-idempotence flattening row, terminal RealUp seal, transport, replay, provenance, and local naming as one witness.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, a CauchyCompletionIdempotence flattening row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5119.1, Definition 5119.2, and Definition 5119.3 seed the finite Bishop-style repeated-completion flattening witness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompletionIdempotenceWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, host equality of completed objects, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window coverage, dyadic tolerance exactness, RegSeqRat readback, idempotence flattening, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompletionIdempotenceWitnessUp.

The completion-theorem forward route makes the horizontal L10 edge explicit: every BishopCompletionIdempote read that serves a completion-facing consumer first passes through the theorem-level completion surface of chapter 3484 and the universal regular-Cauchy route of chapter 1425 before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed. Thus idempotence is read as a displayed route through the Bishop theorem packet and the regular-Cauchy universal packet, not as a second completed object, a quotient representative, selected limit data, countable choice, host equality of completions, or ambient real completeness.

Chapter 5120

A Concrete Naming Certificate for $\mathsf{MetricReverseTriangleInequality}^{\uparrow}$

Following Bishop and Bridges on constructive metric estimates, the $\mathsf{MetricReverseTriangleInequality}^{\uparrow}$ packet records the finite route behind the estimate $|d(x,z) - d(y,z)| \leq d(x,y)$ without appealing to a host absolute-value operator or an ambient real-order theorem. It sits over the distance rows of chapter 57, the order-and-operation surface of chapter 766, the dyadic tolerance ledger of chapter 291, the finite window discipline of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the regular-Cauchy reverse-triangle route of chapter 1894. The chapter packages the standard metric reverse-triangle estimate as finite BEDC NameCert data at L10 Phase Real and Completion.

Definition 5120.1 (Metric reverse-triangle inequality carrier)**.** *A* $\mathsf{MetricReverseTriangleInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, D_{xz}, D_{yz}, G, E, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *carrier row exposing only the finite distance surface and its local metric NameCert data.*
2. *D_{xz} and D_{yz} are the two metric-distance rows for the displayed endpoint pairs (x,z) and (y,z).*
3. *G is the absolute-gap comparison row for the expression $|d(x,z) - d(y,z)|$; it is read only through the* $\mathsf{RealAlgOrder}^{\uparrow}$ *operation-and-order surface.*
4. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested comparison precision and the budget used to compare the two distance readbacks.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window data serving the two distance streams and the gap stream at the requested scale.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the accepted distance rows and the accepted absolute-gap row.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, reachable only after the distance rows, comparison row, dyadic tolerance row, stream windows, and regular readback have been displayed.*
8. *H records componentwise* hsame *transport for the metric carrier, distance rows, absolute-gap comparison, tolerance row, window data, readback, seal, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from any reverse-triangle-facing request through* $M, D_{xz}, D_{yz}, G, E, W, R, S, H, P$
10. *P is the* Pkg *provenance over* MetricReverseTriangleInequality$^{\uparrow}$, Met$^{\uparrow}$, RealAlgOrder$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, RegularCauchyReverseTriangle$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{MetricReverseTriangleInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D_{xz}, D_{yz}, G, E, W, R, S, H, C, P, N$. The carrier has no coordinate for host absolute values, quotient real equality, open-cover compactness, selected nearest points, ambient Real$^{\uparrow}$ *completeness, Lean theorem checking, or bridge checking.*

Closure status for NameCert$_{\text{MetricReverseTriangleInequality}^{\uparrow}}$ **.**

Theory closure: TheoryGate(NameCert$_{\text{MetricReverseTriangleInequality}^{\uparrow}}$, seed)

Scope closed: Definition 5120.1, Definition 5120.2, and Definition 5120.3 seed the finite metric reverse-triangle route through displayed distance rows, absolute-gap comparison, dyadic tolerance, finite windows, regular readback, and Real seal data.

Formal verification: FormalStatus(NameCert$_{\text{MetricReverseTriangleInequality}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.MetricReverseTriangleInequalityUp`

Bridge status: none

Not claimed: This chapter does not close host absolute values, quotient real equality, open-cover compactness, selected nearest points, Real$^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric distance exposure, comparison and tolerance exactness, readback and seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.MetricReverseTriangleInequalityUp.

Constructive story: A MetricReverseTriangleInequality$^{\uparrow}$ packet is generated from a MetricUp carrier, two metric-distance rows, a RealAlgOrder absolute-gap comparison row, a DyadicRatCore tolerance row, finite StreamName windows, a RegSeqRat readback, a RealUp seal, componentwise transport, continuation replay, package provenance, and local naming.

Chapter 5121

A Concrete Naming Certificate for $\mathsf{UpperRealEnvelope}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{UpperRealEnvelope}^{\uparrow}$ packet records a one-sided real-envelope surface obtained by reading upper dyadic bounds beside the lower-upper cut boundary of chapter 2087. It keeps the envelope as finite approximation data through chapter 291, chapter 126, chapter 301, and chapter 38, without selecting a completed cut representative or a host supremum.

Definition 5121.1 (Upper real envelope carrier)**.** *An* $\mathsf{UpperRealEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (U, L, D, S, R, A, H, C, P, N)$$

with the following displayed rows:

1. *U is the upper-envelope ledger, recording finite upper dyadic observations and their tolerance budgets.*
2. *L is the* $\mathsf{LowerUpperRealCut}^{\uparrow}$ *boundary row, exposing the two-sided located-cut context against which the envelope is read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row, storing endpoints, radii, slack, and decidable dyadic comparisons used by U and L.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, scheduling visible envelope queries without selecting an infinite representative.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy handoff, carrying the same upper-budget reads into regular sequence form.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *admissibility seal, available only downstream of U, L, D, S, R.*
7. *H records componentwise* hsame *transport for the envelope ledger, lower-upper boundary, dyadic row, stream window, regular-Cauchy handoff, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for every envelope-facing read through the same tuple $U, L, D, S, R, A, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{UpperRealEnvelope}^{\uparrow}$, $\mathsf{LowerUpperRealCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UpperRealEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, L, D, S, R, A, H, C, P, N$. It has no coordinate for quotient-cut equality, a chosen Dedekind representative, trichotomy, countable choice, host supremum, or ambient real completeness.

Theorem 5121.2 (Upper real envelope NameCert obligations)**.** *For an accepted* $\mathsf{UpperRealEnvelope}^{\uparrow}$ *carrier*

$$E = (U, L, D, S, R, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UpperRealEnvelope}^{\uparrow}}$ *surface consists exactly of carrier exposure, upper-envelope ledger stability, lower-upper boundary visibility, dyadic tolerance exactness, finite-window scheduling, regular-Cauchy handoff, terminal real-seal nonescape, componentwise transport, displayed replay, provenance, and local naming. No local obligation is stored outside those rows.*

Lean4 ✓ `BEDC.Derived.UpperRealEnvelopeUp.UpperRealEnvelopeTasteGate single carrier alignment`

Proof. Carrier exposure is projection from Definition 5121.1. The accepted packet displays exactly the upper ledger, lower-upper boundary, dyadic tolerance row, stream window, regular-Cauchy handoff, real seal, and structural rows.

The upper-envelope ledger is read only through U, D, S, H, C, P, N. Componentwise transport preserves the displayed dyadic budget, and replay uses the same finite window rather than a hidden stream representative.

The lower-upper boundary is the row L. It keeps every envelope read adjacent to the two-sided located-cut surface of chapter 2087, so the upper ledger cannot detach into an isolated host-side bound.

The handoff rows R and A remain downstream of U, L, D, S. Since no other coordinate exists, the packet cannot export quotient-cut equality, a selected representative, trichotomy, countable choice, host supremum, or ambient completeness. □

Theorem 5121.3 (Upper real envelope lower-upper cut boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{UpperRealEnvelope}^{\uparrow}$ *packet factors through the displayed route*

$$U, L, D, S, R, A, H, C, P, N$$

and keeps the $\mathsf{LowerUpperRealCut}^{\uparrow}$ *boundary row visible before any regular-Cauchy or terminal real seal can be consumed. Thus the packet supplies one-sided upper approximation evidence beside a lower-upper cut, not a completed real, quotient cut, selected representative, or host supremum.*

Proof. Fix an accepted $\mathsf{UpperRealEnvelope}^{\uparrow}$ carrier. A consumer first reads the upper-envelope ledger U with the dyadic tolerance row D and the stream window S.

The lower-upper cut boundary L is displayed in the same packet. This keeps the one-sided upper observations attached to the two-sided located boundary before any Real-facing read is allowed.

The regular-Cauchy handoff R and real seal A sit downstream of U, L, D, S. Transport, replay, provenance, and local naming preserve that same finite route.

Because the carrier has no coordinate for a quotient cut, selected representative, host supremum, trichotomy, countable choice, or completeness principle, the route can export only upper-envelope approximation evidence beside the named lower-upper boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{UpperRealEnvelope}^{\uparrow}}$**.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UpperRealEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5121.1, Definition 5121.2, and Definition 5121.3 seed the finite one-sided upper-envelope surface beside lower-upper cuts and regular-Cauchy real seals.

Formal verification: FormalStatus(NameCert$_{\mathsf{UpperRealEnvelope}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Dedekind construction of Real$^{\uparrow}$, quotient-cut equality, selected representative, host supremum, countable choice, trichotomy, or Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier exposure, upper-ledger stability, lower-upper boundary visibility, dyadic exactness, finite-window scheduling, regular-Cauchy handoff, real-seal nonescape, and local naming for BEDC.Derived.UpperRealEnvelopeUp.

Constructive story: An UpperRealEnvelope$^{\uparrow}$ packet is generated from an upper-envelope ledger, a LowerUpperRealCut boundary row, a DyadicRatCore tolerance row, a StreamName finite window, a RegSeqRat handoff, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5122

A Concrete Naming Certificate for $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$

The $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$ packet realizes the claim-status surface of chapter 9456 as a finite NameCert carrier. It sits beside the kernel witness of chapter 546, the audit gate boundary of chapter 526, the apophatic naming surface of chapter 543, and the corpus-supply distillation packet of chapter 968. Those siblings audit declarations, local gates, named externality, and source supply separately; this packet binds claim source, admissibility gate, refusal socket, marker provenance, replay, and local naming as one visible ledger.

Definition 5122.1 (Legitimate-claim audit ledger carrier)**.** *A* $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, G, R, M, K, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the claim-source row, recording the finite expression, subject surface, cited carrier, and supplied evidence route.*
2. *G is the admissibility-gate row, read through* $\mathsf{AuditGateBoundary}^{\uparrow}$ *and recording whether the claim may enter as theorem, condition, route, evidence, non-evidence, meta-row, refusal, gap, or socket.*
3. *R is the refusal-socket row, recording the named boundary where hidden supply, ungenerated proof content, unmarked corpus material, or external truth pressure is refused.*
4. *M is the marker-provenance row, recording the paper marker, Lean target name when present, source chapter, and resolution status without asserting a theorem absent kernel acceptance.*
5. *K is the kernel-audit row, read through* $\mathsf{KernelAuditWitness}^{\uparrow}$ *when the claim cites Lean-accepted theorem content.*
6. *A is the apophatic-name row, read through* $\mathsf{ApophaticName}^{\uparrow}$ *when the claim exposes an external dependency position rather than consuming it.*
7. *H records componentwise* hsame *transport for source, gate, refusal socket, marker provenance, kernel audit, apophatic name, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for the same ledger route through $S, G, R, M, K, A, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$, $\mathsf{KernelAuditWitness}^{\uparrow}$, $\mathsf{AuditGateBoundary}^{\uparrow}$, $\mathsf{ApophaticName}^{\uparrow}$, $\mathsf{CorpusSupplyDistillation}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{LegitimateClaimAuditLedger}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, G, R, M, K, A, H, C, P, N$. It has no coordinate for hidden theorem supply, unledgered corpus import, a global truth predicate, host-side proof search, or an unmarked marker resolution.

Theorem 5122.2 (Legitimate-claim audit ledger NameCert obligations)**.** *For an accepted* LegitimateClaimAuditLed *carrier*

$$L = (S, G, R, M, K, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LegitimateClaimAuditLedger}^{\uparrow}}$ *surface consists exactly of claim-source exposure, admissibility-gate classification, refusal-socket visibility, marker-provenance exactness, kernel-audit handoff, apophatic-name handoff, componentwise transport, displayed replay, provenance, and local naming. No claim-status obligation is stored outside those rows.*

Proof. Carrier exposure is projection from Definition 5122.1. The accepted packet displays the claim source, admissibility gate, refusal socket, marker provenance, kernel audit row, apophatic name row, and structural rows.

The gate row G classifies the finite expression only with the source row S visible. If a requested dependency is not generated by the packet, the refusal socket R and apophatic row A keep that dependency named rather than consumed.

Marker provenance is the row M. When the claim cites Lean theorem content, the kernel row K must be read through the same packet; otherwise the marker remains a provenance row rather than a theorem export.

Transport, replay, provenance, and local naming preserve the displayed ledger. Since the carrier has no other coordinate, it cannot import hidden theorem supply, unledgered corpus material, host proof search, or a global truth predicate. □

Theorem 5122.3 (Legitimate-claim audit ledger nonescape)**.** *Every accepted* $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$ *claim-status read factors through the displayed route*

$$S, G, R, M, K, A, H, C, P, N.$$

In particular, a claim whose missing dependency is named by R or A cannot be exported as an unconditional theorem row unless a separate kernel-audit or certificate row is displayed in the same ledger route.

Proof. Start from Definition 5122.2. A consumer receives source, gate, refusal, marker, kernel, apophatic, transport, replay, provenance, and local naming data as one finite packet.

If a dependency is generated and accepted, the route may read it through the displayed kernel-audit row K or another displayed certificate row at the claim site. If the dependency is ungenerated, the route exposes it through R or A.

The rows H, C, P, N preserve and name the same distinction. They do not add a theorem row, select a hidden proof, or turn apophatic naming into internal supply.

Therefore the ledger can classify theorem, condition, route, evidence, non-evidence, meta-row, refusal, gap, and socket statuses, but it cannot promote a named missing dependency to an unconditional theorem. □

The Lean follow-up file `lean4/BEDC/Derived/LegitimateClaimAuditLedgerUp/TasteGate.lean` must provide explicit Nontrivial $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$ and FieldFaithful $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$ instances. The field-faithfulness witness must preserve $S, G, R, M, K, A, H, C, P, N$ as distinct rows

so claim source, admissibility gate, refusal socket, marker provenance, kernel audit, and apophatic naming cannot collapse.

Falsifiable prediction: A claim-status packet that omits the refusal socket while consuming ungenerated theorem supply is rejected as a $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$ packet, even when it carries a marker-provenance row or an admissibility-gate row.

Independence witness: kernelauditwitness, auditgateboundary, apophaticname, corpussupply-distillation: $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries claim source, admissibility gate, refusal socket, marker provenance, kernel audit, apophatic naming, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LegitimateClaimAuditLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$ packet is generated from claim source, admissibility gate, refusal socket, marker provenance, kernel audit, apophatic naming, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LegitimateClaimAuditLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5122.1, Definition 5122.2, and Definition 5122.3 seed the finite audit-ledger surface for legitimate claim status.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LegitimateClaimAuditLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, a global truth predicate, hidden proof search, kernel soundness, or unledgered corpus admission.

Upgrade path: Obligation closure requires checked carrier admission, claim-source exposure, admissibility-gate classification, refusal-socket visibility, marker-provenance exactness, kernel and apophatic handoffs, TasteGate nontriviality, and field faithfulness for $S, G, R, M, K, A, H, C, P, N$.

Chapter 5123

A Concrete Naming Certificate for $\mathsf{PerronFrobenius}^{\uparrow}$

Following Perron and Frobenius, the $\mathsf{PerronFrobenius}^{\uparrow}$ packet records the finite linear-algebra route by which a nonnegative matrix exposes a positive cone, iterate windows, normalized comparison rows, radius bounds, and eigenvector-window evidence. It consumes the matrix carrier of chapter 49, the vector-space carrier of chapter 47, the positive-real boundary of chapter 1587, and the real-name seal of chapter 38. The packet is a NameCert interface for downstream finite spectral consumers; it does not import host eigenvectors, spectral choice, classical compactness, quotient real equality, or an ambient linear-operator theory.

Definition 5123.1 (PerronFrobenius carrier)**.** *A* $\mathsf{PerronFrobenius}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, C, I, R, E, H, T, P, N)$$

with the following displayed rows:

1. *M is the nonnegative square* $\mathsf{Mat}^{\uparrow}$ *row, exposing its entries only through displayed* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{PositiveReal}^{\uparrow}$ *comparison data.*
2. *C is the positive-cone row in the ambient* $\mathsf{VecSpace}^{\uparrow}$ *source, recording which displayed vector histories are admitted as nonnegative or positive witnesses for the matrix action.*
3. *I is the finite iterate-and-normalization ledger, listing the chosen powers, cone inputs, normalization denominators, and normalized output rows inspected by the certificate.*
4. *R is the radius-and-eigenvector-window row, recording finite lower and upper real bounds for the candidate radius together with a finite window where Mv and rv are compared.*
5. *E is the endpoint row that exposes the final cone-compatible comparison between the normalized iterate window and the radius window.*
6. *H records componentwise* hsame *transport for matrix, cone, iterate, radius-window, endpoint, replay, provenance, and naming rows.*
7. *T records displayed* Cont *replay from the matrix row through the cone, iterate, normalization, radius-window, and endpoint rows.*
8. *P is the* Pkg *provenance over* $\mathsf{PerronFrobenius}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{PerronFrobenius}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, C, I, R, E, H, T, P, N$. It has no coordinate for a selected host eigenvector, a completed projective cone, spectral radius as a quotient real, compactness of the simplex, irreducibility classification, or an external Jordan form.

Lean4 ✓ `BEDC.Derived.PerronFrobeniusUp.PerronFrobeniusTasteGate single carrier alignment`

Theorem 5123.2 (PerronFrobenius NameCert obligations)**.** *For every accepted* $\mathsf{PerronFrobenius}^{\uparrow}$ *carrier $K = (M, C, I, R, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PerronFrobenius}^{\uparrow}}$ *surface consists exactly of carrier admission for the nonnegative matrix row, positive-cone row, finite iterate-and-normalization ledger, radius-and-eigenvector-window row, endpoint comparison row, componentwise transport, displayed replay, package provenance, and local naming. Any consumer that reads a Perron-facing radius or cone-vector witness must expose M, C, I, R, E before it consumes the structural rows H, T, P, N.*

Proof. Project the carrier of Definition 5123.1. The analytic rows are the matrix row M, positive-cone row C, iterate-and-normalization ledger I, radius-and-window row R, and endpoint row E.

The NameCert obligations are precisely the projections of those rows together with the structural data. Matrix nonnegativity is read through M, cone admission through C, finite power and normalization data through I, candidate radius and eigenvector-window comparison through R, and endpoint compatibility through E.

The rows H, T, P, N transport, replay, source, and name the same packet. Since no host eigenvector, spectral-choice operator, quotient real, compactness argument, or external Jordan form appears as a carrier coordinate, the displayed rows exhaust the local certificate surface. □

Theorem 5123.3 (PerronFrobenius positive cone route)**.** *Every positive-cone read of an accepted* $\mathsf{PerronFrobenius}^{\uparrow}$ *packet factors through the finite route*

$$M, C \longmapsto I \longmapsto R, E \longmapsto H, T, P, N.$$

Thus a downstream spectral consumer receives only a nonnegative matrix row, a displayed cone row, finite iterate and normalization data, and a finite radius-window comparison; it does not receive a selected Perron eigenvector or a host spectral theorem.

Proof. Start with an accepted packet $K = (M, C, I, R, E, H, T, P, N)$. The only matrix source is M, and the only cone source is C.

The route next reads the finite iterate-and-normalization ledger I. This ledger is finite BEDC data: it records displayed powers, cone inputs, normalization denominators, and normalized output rows rather than an infinite limiting process.

The radius-and-eigenvector-window row R and endpoint row E compare only finite windows. They can witness the compatibility of the displayed iterate window with the candidate radius bounds, but they do not choose a global eigenvector or identify a host spectral radius.

Finally the route passes through H, T, P, N. These rows preserve the same displayed packet under hsame, Cont, Pkg, and local naming, so every positive-cone consumer remains inside the finite carrier surface. □

Falsifiable prediction: A $\mathsf{PerronFrobenius}^{\uparrow}$ consumer that reads a Perron-facing radius or cone-vector witness without exposing the matrix row, positive-cone row, iterate ledger, radius-window row, and endpoint row refutes the carrier surface.

Independence witness: matrix, vecspace, positivereal, real: no listed sibling supplies the whole nine-row packet $K = (M, C, I, R, E, H, T, P, N)$, because the siblings provide matrix entries, vector operations, positive-real comparisons, and real seals separately while this chapter binds them to one finite PerronFrobenius NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{PerronFrobenius}\uparrow}$.

Constructive story: A PerronFrobenius$^{\uparrow}$ packet is generated from a nonnegative Matrix row, a positive VecSpace cone row, finite iterate and normalization data, a radius-and-eigenvector-window row, an endpoint comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PerronFrobenius}\uparrow}$, seed)

Scope closed: Definition 5123.1, Definition 5123.2, and Definition 5123.3 seed the finite Perron-Frobenius carrier over Matrix, VecSpace, PositiveReal, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PerronFrobenius}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a selected host eigenvector, spectral choice, quotient-real spectral radius, irreducibility classification, classical compactness, external Jordan form, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, matrix nonnegativity exposure, positive-cone exposure, iterate normalization, radius-window comparison, endpoint compatibility, transport, replay, provenance, and local naming for BEDC.Derived.PerronFrobeniusUp.

Chapter 5124

A Concrete Naming Certificate for $\mathsf{BishopIntervalCover}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopIntervalCover}^{\uparrow}$ packet records finite interval-cover data for a displayed closed bounded interval. It sits after the closed bounded interval source of chapter 1591, the dyadic cover rows of chapter 1428, the dyadic endpoint arithmetic of chapter 291, the located cover boundary of chapter 1885, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet records a finite cover ledger and its readback route; it is not open-cover compactness, a choice-selected subcover, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5124.1 (BishopIntervalCover carrier)**.** *A* $\mathsf{BishopIntervalCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (E, D, F, L, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *E is the endpoint row. It records the lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, the endpoint-order ledger, and the closed bounded interval source read through* $\mathsf{ClosedBoundedInterval}^{\uparrow}$*.*
2. *D is the dyadic interval-cell row. It records the finite dyadic cells, their lower and upper dyadic endpoints, mesh scale, radius ledger, and containment tests read through* $\mathsf{DyadicIntervalCover}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *F is the finite cover ledger. It records the list of accepted covering cells, the source-interval slots they cover, and the displayed finite subcover boundary for the requested interval window.*
4. *L is the located containment row. It records the located membership and endpoint-containment witnesses connecting E, D, F to the located cover surface of* $\mathsf{LocatedIntervalCover}^{\uparrow}$*.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It schedules the finite endpoint, cell, containment, and cover-ledger observations used by the packet.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It translates the displayed StreamName windows and dyadic cells into regular rational observations at the requested mesh and tolerance.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is reachable only after E, D, F, L, W, Q have been displayed.*
8. *H records componentwise* hsame *transport for endpoint rows, dyadic cells, finite cover ledgers, located containment, stream windows, regular readback, the Real seal, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from any finite cover request through the same $E, D, F, L, W, Q, R, H, P, N$ rows.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalCover}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedIntervalCover}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, D, F, L, W, Q, R, H, C, P, N$. It has no coordinate for arbitrary open covers, choice-selected subcovers, quotient endpoint equality, countable choice, selected host covers, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopIntervalCoverUp.BishopIntervalCoverTasteGate single carrier alignment`

Theorem 5124.2 (BishopIntervalCover NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalCover}^{\uparrow}$ *carrier*

$$B = (E, D, F, L, W, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopIntervalCover}^{\uparrow}}$ *surface consists exactly of carrier admission for endpoint rows, dyadic interval cells, finite cover ledgers, located containment witnesses, StreamName windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every interval-cover consumer must expose the finite cover ledger F and the located containment row L before it can read the regular rational row Q or the Real seal R.*

Proof. Project the carrier of Definition 5124.1. The source interval is the endpoint row E, the cover data are the dyadic cell row D and finite cover ledger F, and the local containment evidence is the row L.

The readback rows are downstream of this finite cover surface. The StreamName row W schedules only finite endpoint, cell, containment, and ledger observations, while Q repacks those displayed observations as regular rational data.

The terminal seal R is therefore not an independent compactness object. The structural rows H, C, P, N transport, replay, package, and name the same finite packet, and the carrier contains no open-cover compactness, selected subcover, quotient equality, choice, selected host-cover, or ambient completeness coordinate. □

Theorem 5124.3 (BishopIntervalCover dyadic subcover readback)**.** *Every finite subcover read of an accepted* $\mathsf{BishopIntervalCover}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{DyadicIntervalCover}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{LocatedIntervalCover}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{Reg}$$

Thus the exported subcover is a finite dyadic-and-located ledger with regular rational readback, not an open-cover compactness theorem or a choice-selected subcover functional.

Proof. Start with $B = (E, D, F, L, W, Q, R, H, C, P, N)$. The source interval must be read from E, so every subcover request begins at the displayed $\mathsf{ClosedBoundedInterval}^{\uparrow}$ boundary.

The dyadic part of the route is D together with the finite ledger F. These rows expose the mesh, dyadic endpoints, radius ledger, finite membership tests, and retained covering cells through the dyadic siblings.

The located part of the route is L. It witnesses that the retained cells are read against the displayed endpoint and containment data, so the regular rational readback Q is attached to finite located containment rather than to a host open cover.

Finally W, Q, H, C, P, N provide the finite window schedule, regular readback, transport, replay, provenance, and naming. Since no coordinate stores a selector for arbitrary covers, the subcover readback is exactly the finite route displayed above. □

Theorem 5124.4 (BishopIntervalCover Real seal nonescape)**.** *For every accepted* $\mathsf{BishopIntervalCover}^{\uparrow}$ *carrier* $B = (E, D, F, L, W, Q, R, H, C, P, N)$*, any consumer that reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal* R *has already exposed the endpoint row* E*, dyadic cell row* D*, finite cover ledger* F*, located containment row* L*, StreamName window row* W*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*. Consequently the Real-facing export contains no ambient completeness principle, quotient equality of real names, selected host endpoints, open-cover compactness, or countable-choice datum.*

Proof. The carrier definition places R after the finite interval-cover rows E, D, F, L, W, Q. There is no second Real seal coordinate and no bypass from a cover request directly to R.

The read of R is therefore mediated first by the interval source and dyadic cover rows, then by the located containment row, and then by the finite StreamName and regular rational readback rows. Componentwise transport and replay preserve this order through H and C.

The provenance and local naming rows P, N name the same packet. Because the listed exclusions are not carrier coordinates, they cannot escape through the terminal Real-facing seal. □

Falsifiable prediction: Every $\mathsf{BishopIntervalCover}^{\uparrow}$ Real-facing read passes through $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{DyadicIntervalCover}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedIntervalCover}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any finite cover output is visible.

Independence witness: closedboundedinterval, dyadicintervalcover, dyadicratcore, located-interval-cover, streamname, regseqrat, real: $\mathsf{BishopIntervalCover}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint rows, dyadic interval cells, a finite cover ledger, located containment witnesses, finite windows, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalCover}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5124.1, Definition 5124.2, Definition 5124.3, and Definition 5124.4 seed the finite Bishop interval-cover route from closed bounded endpoint rows through dyadic cells, finite cover ledgers, located containment, finite windows, regular readback, terminal Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalCover}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.BishopIntervalCoverUp.BishopIntervalCoverTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected subcovers, quotient real equality, selected host covers, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-row exactness, dyadic-cell exactness, finite-cover ledger exposure, located-containment exactness, StreamName and RegSeqRat readback ordering, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopIntervalCoverUp.

Constructive story: A $\mathsf{BishopIntervalCover}^{\uparrow}$ packet is generated from ClosedBoundedIntervalUp endpoint rows, dyadic interval cells, a finite cover ledger, located containment witnesses, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

$\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ is read through chapter 5902, chapter 1998, and chapter 458 before the extraction row reaches any $\mathsf{Real}^{\uparrow}$ or $\mathsf{RealSeparability}^{\uparrow}$ consumer.

Chapter 5125

A Concrete Naming Certificate for $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ packet records the finite extraction data used when a regular Cauchy source is read through subsequence windows before reaching a $\mathsf{Real}^{\uparrow}$ consumer. It sits after the Cauchy route of chapter 3413, the dyadic rational arithmetic of chapter 291, the finite stream windows of chapter 126, the regular rational sequence source of chapter 301, the terminal real-name seal of chapter 38, and the countable dense readback surface of chapter 1809. The extraction row E also consumes the minimum-modulus witness of chapter 5544 before $\mathsf{Real}^{\uparrow}$ or $\mathsf{RealSeparability}^{\uparrow}$ consumers read the terminal seal. The packet records only displayed finite subsequence extraction data; it is not countable choice, quotient real equality, ambient completeness, or a selector for arbitrary Cauchy data.

Definition 5125.1 (CauchySubsequenceExtractor carrier)**.** *A* $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (C, Q, W, D, E, R, L, H, T, P, N)$$

with the following displayed rows:

1. *C is the accepted* $\mathsf{Cauchy}^{\uparrow}$ *source row whose regularity ledger is being inspected.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row naming the rational regular sequence extracted from C.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing the finite source indices, target indices, and requested precisions used by the extraction.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic bounds that certify the extracted window remains inside the requested Cauchy budget.*
5. *E is the extraction row. It records the monotone finite index map, the selected source observations, and the target-window schedule read from W.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after C, Q, W, D, E have been displayed.*
7. *L is the* $\mathsf{RealSeparability}^{\uparrow}$ *readback row recording the finite dense real-name inspection used by downstream separability consumers.*
8. *H records componentwise* hsame *transport for source, regular readback, stream windows, dyadic tolerances, extraction data, Real seal, separability readback, replay, provenance, and local naming.*

9. *T records displayed* Cont *replay from a finite subsequence request through the same $C, Q, W, D, E, R, L, H, P, N$ rows.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceExtractor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, Q, W, D, E, R, L, H, T, P, N$. It has no coordinate for arbitrary subsequence choice, quotient equality of real names, countable choice, a global selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5125.2 (CauchySubsequenceExtractor NameCert obligations)**.** *For every accepted* CauchySubsequenceE *carrier*

$$S = (C, Q, W, D, E, R, L, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySubsequenceExtractor}^{\uparrow}}$ *surface consists exactly of Cauchy source exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger exposure, finite monotone extraction data, terminal* $\mathsf{Real}^{\uparrow}$ *sealing,* $\mathsf{RealSeparability}^{\uparrow}$ *readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer must expose the finite window W, dyadic ledger D, and extraction row E before it can read the Real seal R or the separability row L.*

Proof. Project the carrier $S = (C, Q, W, D, E, R, L, H, T, P, N)$. The analytic rows list the Cauchy source, regular rational readback, stream window, dyadic tolerance ledger, extraction row, Real seal, and separability readback.

The extraction row is downstream of the finite window and tolerance ledger. It can therefore name only the displayed monotone finite index map and selected observations, not an arbitrary subsequence selector.

The structural rows H, T, P, N transport, replay, source, and name the same finite route. Since no listed exclusion is a carrier coordinate, the NameCert surface is exhausted by the displayed packet. □

Theorem 5125.3 (CauchySubsequenceExtractor finite-window route)**.** *Every accepted* CauchySubsequenceExtracto *extraction read factors through*

$$\mathsf{Cauchy}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, \mathsf{RealSeparability}^{\uparrow}.$$

Thus the exported subsequence data are finite regular-Cauchy windows with dyadic tolerance control, not countable choice, quotient real equality, or a global subsequence functional.

Proof. Start from the source rows C and Q. They provide the Cauchy source and the regular rational readback being inspected.

The finite data are W, D, E. The window W supplies the displayed indices and precisions, the dyadic ledger D supplies the tolerance checks, and E records the monotone finite extraction map.

Finally read R, L, H, T, P, N. These rows seal the same finite extraction route for Real and separability consumers, transport it componentwise, replay it under displayed continuation, and name it locally. No row stores a choice principle or quotient equality witness. □

Theorem 5125.4 (CauchySubsequenceExtractor sibling route)**.** *Every accepted* $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ *route*

$$S = (C, Q, W, D, E, R, L, H, T, P, N)$$

that consumes the extraction row E preserves the sibling order

$$\mathsf{Cauchy}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, \mathsf{RealSeparability}^{\uparrow}.$$

Thus the route cannot export arbitrary subsequence choice, quotient real equality, global selectors, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier $S = (C, Q, W, D, E, R, L, H, T, P, N)$. The rows C and Q expose the Cauchy source and the regular rational readback before any extraction data are visible.

Apply the finite-window route of Definition 5125.3. The extraction row E is readable only after the displayed stream window W and dyadic tolerance ledger D have been read, so the route reaches $\mathsf{Real}^{\uparrow}$ and $\mathsf{RealSeparability}^{\uparrow}$ through the listed sibling order.

The structural rows H, T, P, N preserve the same order by componentwise transport, displayed replay, provenance, and local naming. They do not add a selector coordinate, quotient real equality, countable choice, or ambient completeness, so the consumed extraction row remains finite L10 evidence for the displayed route. □

Theorem 5125.5 (CauchySubsequenceExtractor selector-lattice handoff)**.** *Every accepted* CauchySubsequenceExtr *read that exposes the monotone extraction row E must factor through the selector surface of chapter 5902 before* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RealSeparability}^{\uparrow}$ *consumers read the seal. For $S = (C, Q, W, D, E, R, L, H, T, P, N)$, the row E is therefore a finite selector-lattice handoff over the displayed window W and dyadic ledger D, not an arbitrary subsequence choice functional.*

Proof. Project the carrier $S = (C, Q, W, D, E, R, L, H, T, P, N)$. The extraction row E records a monotone finite index map, selected source observations, and a target-window schedule read from W.

Read the selector chapter named in the statement. Its surface supplies the monotone schedule and Cauchy-gap compatibility required before an extraction row can be treated as a selector-facing lattice row.

Finally apply the finite-window route of Definition 5125.3. The Real and separability rows R, L are reached only after W, D, E have been displayed and transported through H, T, P, N, so the handoff cannot export countable choice, quotient real equality, or a global subsequence selector. □

Theorem 5125.6 (CauchySubsequenceExtractor selector route)**.** *Every completion-facing* CauchySubsequenceExtr *read must pass through the* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, finite extraction row,* $\mathsf{Real}^{\uparrow}$ *seal, and* $\mathsf{RealSeparability}^{\uparrow}$ *readback before any completion witness consumes the packet. For*

$$S = (C, Q, W, D, E, R, L, H, T, P, N),$$

the route is therefore selector-scheduled finite extraction over displayed windows and tolerances, not arbitrary subsequence choice, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier and apply Definition 5125.5. The extraction row E is readable only as a finite selector-lattice handoff over the displayed window W and dyadic ledger D.

Use the finite-window route of Definition 5125.3 and the sibling route of Definition 5125.4. They force every read through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RealSeparability}^{\uparrow}$ in the displayed sibling order.

Finally apply the completion witness route of Definition 5125.7. It keeps completion-facing consumers inside the same selector-scheduled extraction packet, so no refused choice, quotient, or ambient-completeness coordinate can be consumed downstream. □

Theorem 5125.7 (CauchySubsequenceExtractor completion witness route)**.** *Any accepted* CauchySubsequenceExtr *read exposing*

$$C, Q, W, D, E, R, L, H, T, P, N$$

may feed a $\mathsf{BishopCompletionWitness}^{\uparrow}$ *consumer only through the displayed* $\mathsf{Cauchy}^{\uparrow}$ *source* C*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the finite extraction row* E*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* R*. The route is the selector-lattice handoff of Definition 5125.5 followed by the finite-window route of Definition 5125.3; it exports no countable choice, quotient real equality, arbitrary selected subsequence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier $S = (C, Q, W, D, E, R, L, H, T, P, N)$. The rows C, Q, W, D, E, R are the only Cauchy source, regular readback, stream-window, dyadic-tolerance, extraction, and Real-seal coordinates available to a completion-facing consumer.

Apply the selector-lattice handoff of Definition 5125.5. It keeps E as a finite monotone selector-lattice row over the displayed W and D data, so the completion witness cannot receive an arbitrary subsequence selector.

Now use the finite-window route of Definition 5125.3. The same finite rows pass through $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the witness surface is readable.

The downstream regular-Cauchy cofinal-subsequence consumer of chapter 1998 and the BishopCompletionWitnes consumer of chapter 8181 consume the extraction row E only after W and D are visible, so the downstream completion route is finite-window evidence rather than countable choice.

The substantive sibling route also passes through the minimum-modulus witness of chapter 5544 and the cofinal-subsequence surface of chapter 1998. The same finite window W, dyadic ledger D, minimum-modulus witness, extraction row E, and terminal $\mathsf{Real}^{\uparrow}$ seal are shared by both consumers, so the extractor is a displayed horizontal dependency packet rather than a kernel-only float.

The structural rows L, H, T, P, N preserve the displayed packet for separability readback, transport, replay, provenance, and local naming. They do not add countable choice, quotient real equality, arbitrary subsequence selection, or ambient completeness, so the only completion-witness route is the one stated above. □

Falsifiable prediction: Every $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ consumer reaches $\mathsf{Real}^{\uparrow}$ or $\mathsf{RealSeparability}^{\uparrow}$ only after exposing $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, finite extraction data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchy, regseqrat, streamname, dyadicratcore, real, real-separability: $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source rows, regular readback, finite windows, dyadic tolerance ledgers, monotone extraction data, terminal Real sealing, separability readback, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySubsequenceExtractor}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ packet is generated from a $\mathsf{Cauchy}^{\uparrow}$ source row, $\mathsf{RegSeqRat}^{\uparrow}$ readback, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, monotone extraction data, a $\mathsf{Real}^{\uparrow}$ seal, $\mathsf{RealSeparability}^{\uparrow}$ readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySubsequenceExtractor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5125.1, Definition 5125.2, and Definition 5125.3 seed the finite subsequence extraction route from Cauchy sources through regular rational readback, stream windows, dyadic tolerance ledgers, Real sealing, separability readback, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchySubsequenceExtractor}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim countable choice, arbitrary subsequence selection, quotient real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window routing, dyadic tolerance exactness, monotone extraction exposure, Real seal nonescape, separability readback ordering, transport, replay, provenance, and local naming for BEDC.Derived.CauchySubsequenceExtractorUp.

The subsequence extractor also consumes the regular-Cauchy minimum-modulus packet of chapter 5544 when it selects a finite subsequence whose tail budget must remain visible. The extraction row E may therefore read the source window W and dyadic ledger D only through the same minimum-modulus witness surface before the terminal Real$^{\uparrow}$ or RealSeparability$^{\uparrow}$ rows are exposed. The extractor route also exports its finite monotone extraction row to the regular Cauchy cofinal-subsequence consumer of chapter 1998. Thus a RegularCauchyCofinalSubsequence$^{\uparrow}$ read may consume the displayed source window W, dyadic tolerance ledger D, and extraction row E only as the same finite extractor/cofinality dependency before the inherited Real$^{\uparrow}$ seal is exposed.

Theorem 5125.8 (Cauchy subsequence extractor minimum-modulus cofinal route)**.** *Every accepted* CauchySubsequenceExtractor$^{\uparrow}$ *route that reads the regular-Cauchy minimum-modulus witness before exposing the extraction row E also hands the same finite monotone extraction row to* RegularCauchyCofinalSubsequence$^{\uparrow}$ *before the inherited* Real$^{\uparrow}$ *seal is exposed. Thus the source window W, dyadic tolerance ledger D, minimum-modulus witness, extraction row E, and terminal real-name row remain one displayed dependency surface for both the minimum-modulus route and the cofinal-subsequence consumer.*

Proof. Start with the selector-lattice handoff of Definition 5125.5. It identifies E as the finite monotone selector-lattice row over the displayed stream window and tolerance ledger, so no consumer receives an arbitrary subsequence selector.

Use the completion-witness route of Definition 5125.7. The same row E is exposed only after the source Cauchy$^{\uparrow}$ data, RegSeqRat$^{\uparrow}$ readback, StreamName$^{\uparrow}$ window, DyadicRatCore$^{\uparrow}$ ledger, and terminal Real$^{\uparrow}$ seal have been kept visible.

Finally read the two local dependency routes. The minimum-modulus forward link requires the extraction row to consume the regular-Cauchy minimum-modulus witness before the terminal seal is available, while the cofinal-subsequence dependency route sends that same finite monotone row to RegularCauchyCofinalSubsequence$^{\uparrow}$ before the inherited Real$^{\uparrow}$ seal is exposed. Hence the minimum-modulus and cofinal reads compose through one displayed extractor route rather than through two detached host-side selections. □

Every CauchySubsequenceExtractor$^{\uparrow}$ read first consumes the selector schedule of chapter 5902. Only after that selector route is visible may the extractor read the regular rational sequence surface of chapter 301 and the finite window rows of chapter 126. Thus the extractor reaches any Real$^{\uparrow}$ or completion-facing consumer through selector, RegSeqRat, and StreamName rows rather than through a free subsequence choice, quotient stream equality, countable choice, or ambient completeness.

Theorem 5125.9 (CauchySubsequenceExtractor regular-Cauchy forward link)**.** *Every accepted* CauchySubsequenceExtractor$^{\uparrow}$ *packet consumes the* RegularCauchyMinModulus$^{\uparrow}$ *witness of chapter 5544, the* RegularCauchyCofinalSubsequence$^{\uparrow}$ *cofinal route of chapter 1998, and the selector*

dependency rows of chapter 5902 before exporting a subsequence witness. Thus the extraction row E is a finite regular-Cauchy forward link over the displayed window W and dyadic ledger D, not an independent subsequence selector.

Proof. Project the carrier $S = (C, Q, W, D, E, R, L, H, T, P, N)$ from Definition 5125.1. The extraction row E is downstream of the Cauchy source C, regular readback Q, finite window W, and dyadic tolerance ledger D.

Use the selector-lattice handoff of Definition 5125.5. It binds E to the displayed selector schedule before any $\mathsf{Real}^{\uparrow}$ or $\mathsf{RealSeparability}^{\uparrow}$ consumer can read the terminal rows.

Now attach the regular-Cauchy routes. The minimum-modulus forward link forces the same W, D, E rows to consume the $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ witness, while the cofinal-subsequence dependency route sends the same extraction row to the $\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}$ consumer before the inherited real seal is exposed.

The structural rows H, T, P, N transport, replay, source, and name that single route. Since no carrier coordinate stores a free selector, countable choice, quotient stream equality, or ambient completeness, the exported subsequence witness is exactly the displayed regular-Cauchy forward link. □

Theorem 5125.10 (CauchySubsequenceExtractor tail-filter route)**.** *Every accepted* $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ *route*

$$S = (C, Q, W, D, E, R, L, H, T, P, N)$$

consumes the tail-filter or cofinal-subsequence surface before exporting the subsequence selector row E. In particular, a consumer that reads E must first expose either the Cauchy sequence tail-filter route of chapter 3850 or the cofinal-subsequence filter route of chapter 7421, together with the displayed source row C, regular readback Q, finite window W, and dyadic ledger D. The exported selector is therefore a tail/cofinal-filter read, not an isolated selector coordinate.

Proof. Start from the carrier rows of Definition 5125.1. The extraction row E is not available before the source row C, regular readback Q, finite window W, and dyadic tolerance ledger D have been displayed.

Use the selector-lattice handoff and finite-window route, Definition 5125.5 and Definition 5125.3. They bind the selector schedule to the same finite subsequence route that later feeds $\mathsf{Real}^{\uparrow}$ and $\mathsf{RealSeparability}^{\uparrow}$ consumers.

Finally attach the tail-filter siblings. A tail-filter or cofinal-subsequence read supplies the late-window discipline that makes the selector row finite and monotone; the structural rows H, T, P, N then replay, transport, source, and name that same route. Since no carrier coordinate stores a free selector, countable choice, quotient stream equality, or ambient completeness, every exported selector remains downstream of the tail/cofinal filter surface.

The same route is the extractor-side input consumed by cluster-witness packets such as chapter 8396; the selector row can feed a regular sequence cluster witness only after the displayed tail/cofinal-filter discipline has already been read. □

Theorem 5125.11 (CauchySubsequenceExtractor regular-tail route)**.** *Every accepted* $\mathsf{CauchySubsequenceExtractor}$ *route*

$$S = (C, Q, W, D, E, R, L, H, T, P, N)$$

that exports the selector row E through a regular-tail consumer must first expose the sequence-generated tail-filter surface of chapter 3850 or the regular-tail selector surface of chapter 458. The selector row is therefore downstream of the regular tail discipline carried by $Q, W, D, R, L, H, T, P, N$; it is not a free choice schedule detached from the displayed tail and readback rows.

Proof. Project the carrier rows named in Definition 5125.10. The source row C, regular readback Q, finite window W, and dyadic ledger D are visible before E can be read.

Attach the regular-tail siblings next. The $\mathsf{CauchySequenceTailFilter}^{\uparrow}$ packet supplies tail filters generated by displayed sequence windows, while the RegularCauchyTailSelector packet supplies a finite selected-tail witness over the same regular readback route.

The structural rows R, L, H, T, P, N then replay, bind, transport, source, and name that route. Since no carrier coordinate stores an independent selector function, quotient stream equality, selected limit, countable choice schedule, or ambient completeness proof, the exported subsequence selector remains a downstream regular-tail read. □

Theorem 5125.12 (CauchySubsequenceExtractor regular-tail-filter sibling route)**.** *Every accepted* $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ *read*

$$S = (C, Q, W, D, E, R, L, H, T, P, N)$$

that exposes the subsequence extraction row E first exposes the regular Cauchy tail-filter route of chapter 1605. Thus a completion-facing, $\mathsf{Real}^{\uparrow}$*-facing, or separability-facing consumer may read E only after the displayed source row C, regular readback Q, finite window W, dyadic ledger D, selector-lattice handoff, finite-window route, and* $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ *sibling surface are visible.*

Proof. Project the carrier from Definition 5125.1. The extraction row E is downstream of the Cauchy source C, regular readback Q, finite window W, and dyadic tolerance ledger D.

Use the selector-lattice handoff of Definition 5125.5. It binds E to the displayed monotone selector schedule before any terminal $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSeparability}^{\uparrow}$, or completion-facing row may read the extraction.

Apply the finite-window route of Definition 5125.3 and the tail-filter route of Definition 5125.10. These keep the selected observations inside the same finite window and dyadic ledger rather than letting the selector detach from its late-tail discipline.

Now read the sibling chapter chapter 1605. Its $\mathsf{RegularCauchyTailFilter}^{\uparrow}$ packet is the regular Cauchy tail surface that turns the visible late-window and tolerance rows into a cofinite tail-filter route. Therefore the extraction row is exposed only after that sibling route has been made available to the same C, Q, W, D data.

The structural rows H, T, P, N transport, replay, source, and name this single route. Since no carrier coordinate stores a free subsequence selector, quotient stream equality, countable choice, selected limit, or ambient completeness, every completion-facing or Real-facing read of E remains downstream of the regular Cauchy tail-filter sibling. □

The $\mathsf{ParallelDiamondResidual}^{\uparrow}$ hub routes residual local joins through chapter 4238 and the guarded candidate-normalization handoff of chapter 5547 before any confluence-facing endpoint is read.

Chapter 5126

A Concrete Naming Certificate for $\mathsf{ParallelDiamondResidual}^{\uparrow}$

The $\mathsf{ParallelDiamondResidual}^{\uparrow}$ packet realizes the MetaCIC confluence audit boundary of chapter 9378 as finite residual-join data. It sits after the residual-substitution boundary of chapter 2181, the residual-substitution compatibility packet of chapter 4370, and the local-join ledger of chapter 4126. The chapter records the concrete residual frontier that a later conditional parallel-diamond bridge may consume; it does not claim full Church–Rosser, closed arbitrary-term confluence, or unconditional substitution compatibility.

Definition 5126.1 (ParallelDiamondResidual carrier)**.** *A* $\mathsf{ParallelDiamondResidual}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (P, F, S, L, B, C, O, H, T, G, N)$$

with the following displayed rows:

1. *P is the parallel peak row. It records a source MetaCIC term and the two parallel reducts whose residuals must be compared.*
2. *F is the residual frontier row. It records the finite redex-frontier cells, binder depths, and residual tags visible at the peak.*
3. *S is the* $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ *row naming the substitution-sensitive boundary consumed by the residual comparison.*
4. *L is the* $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$ *row recording candidate common reducts for the displayed frontier cells.*
5. *B is the bounded checker row. It records the finite checks that the candidate joins respect the residual tags and binder depths displayed in F.*
6. *C is the* $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ *handoff row. It is a named compatibility interface, not a proof that the interface is globally available.*
7. *O is the obstruction row. It records any remaining residual-substitution cell that is not discharged by S, L, B, C.*
8. *H records componentwise* hsame *transport for peaks, residual frontiers, substitution boundaries, local joins, bounded checks, compatibility handoffs, obstruction rows, replay, provenance, and local naming.*

9. *T records displayed* Cont *replay for the same residual-join packet.*

10. *G is the* Pkg *provenance over* ParallelDiamondResidual$^{\uparrow}$, MetaCICResidualSubstitutionBoundary$^{\uparrow}$, MetaCICResidualSubstitutionCompatibility$^{\uparrow}$, MetaCICLocalJoinLedger$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{ParallelDiamondResidual}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, F, S, L, B, C, O, H, T, G, N$. It has no coordinate for full Church–Rosser, arbitrary closed confluence, unconditional substitution compatibility, quotienting of terms, or a global parallel-diamond theorem.

Theorem 5126.2 (ParallelDiamondResidual NameCert obligations)**.** *For every accepted* ParallelDiamondResidual$^{\uparrow}$ *carrier*

$$J = (P, F, S, L, B, C, O, H, T, G, N),$$

the local NameCert$_{\text{ParallelDiamondResidual}^{\uparrow}}$ *surface consists exactly of parallel peak exposure, residual frontier exposure, residual-substitution boundary exposure, local-join ledger exposure, bounded residual checking, compatibility-interface handoff, obstruction-row exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may read the residual local-join packet only after the frontier F, boundary row S, ledger row L, and bounded checker B are displayed.*

Proof. Project the carrier $J = (P, F, S, L, B, C, O, H, T, G, N)$. The analytic rows are the peak, residual frontier, substitution boundary, local-join ledger, bounded checker, compatibility handoff, and obstruction row.

The compatibility row is downstream of the displayed frontier and checker. It names the interface consumed by the conditional parallel-diamond route, while the obstruction row keeps undiscovered residual-substitution cells visible.

The structural rows H, T, G, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for full Church–Rosser or an unconditional global diamond, the NameCert surface stops at residual local joins and their boundary rows. □

Theorem 5126.3 (ParallelDiamondResidual conditional handoff)**.** *Every* ParallelDiamondResidual$^{\uparrow}$ *residual-join read offered to the MetaCIC confluence route factors through*

$$\text{MetaCICResidualSubstitutionBoundary}^{\uparrow} \longmapsto \text{MetaCICLocalJoinLedger}^{\uparrow} \longmapsto \text{MetaCICResidualSubstitutionCompatibility}$$

The handoff supplies finite residual-frontier, local-join, bounded-checker, and obstruction data for the conditional parallel-diamond bridge; it does not assert the bridge, full Church–Rosser, or arbitrary closed-term confluence.

Proof. Start with the residual frontier F and the substitution boundary row S. These rows display the finite cells whose residual algebra must be inspected.

The local-join ledger L and bounded checker B then record candidate common reducts and the finite checks against the displayed frontier. The compatibility handoff C can only be read after these rows have been exposed.

Finally the obstruction row O and structural rows H, T, G, N preserve the same conditional boundary. They do not add a global confluence theorem, so the export remains a residual local-join packet for a later bridge. □

Theorem 5126.4 (ParallelDiamondResidual MetaCIC sibling route)**.** *Every* $\mathsf{ParallelDiamondResidual}^{\uparrow}$ *read is a downstream residual-frontier consumer of chapter 4238. Such a read must preserve the sibling frontier's residual-substitution premise, critical-pair row, candidate-join row, bounded-checker row, compatibility-handoff row, and obstruction row before it may export a residual local-join packet.*

Proof. Project the carrier of Definition 5126.1. Its rows $P, F, S, L, B, C, O, H, T, G, N$ display the residual frontier, residual-substitution boundary, local-join ledger, bounded checker, compatibility handoff, obstruction row, and structural certificate data.

Apply the NameCert obligations theorem Definition 5126.2. It requires any accepted read to expose F, S, L, B, C, O before the residual local-join packet can be consumed, so the sibling frontier's premise, critical-pair, candidate-join, checker, handoff, and obstruction rows cannot be dropped.

Finally use the conditional handoff theorem Definition 5126.3. The handoff reaches the MetaCIC confluence route only as a residual-frontier consumer, and the rows H, T, G, N preserve the same displayed boundary for chapter 4238. □

Theorem 5126.5 (ParallelDiamondResidual obstruction retention)**.** *While the obstruction row O remains displayed in an accepted* $\mathsf{ParallelDiamondResidual}^{\uparrow}$ *packet*

$$J = (P, F, S, L, B, C, O, H, T, G, N),$$

no consumer may read the packet as a premise-free parallel diamond, a full Church–Rosser theorem, an arbitrary closed-term confluence theorem, an unconditional substitution-compatibility theorem, a quotienting of terms, or a global parallel-diamond theorem.

Proof. Project the carrier of Definition 5126.1. The rows $P, F, S, L, B, C, O, H, T, G, N$ are displayed coordinates of the same accepted packet, and O is one of the confluence-facing rows rather than a surrounding note.

Apply the NameCert obligations theorem Definition 5126.2. It requires the residual frontier F, substitution boundary S, local-join ledger L, bounded checker B, compatibility handoff C, and obstruction row O to remain visible before the residual local-join packet can be consumed.

Finally use the conditional handoff theorem Definition 5126.3. Since that handoff supplies only finite residual-frontier, local-join, bounded-checker, compatibility, and obstruction data, any consumer that removes O and reads the packet as one of the refused endpoints has left the displayed $\mathsf{NameCert}_{\mathsf{ParallelDiamondResidual}^{\uparrow}}$ surface. □

Theorem 5126.6 (ParallelDiamondResidual frontier obstruction route)**.** *An accepted* $\mathsf{ParallelDiamondResidual}^{\uparrow}$ *packet*

$$J = (P, F, S, L, B, C, O, H, T, G, N)$$

can be consumed by $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *from chapter 4238 only while the obstruction row O, bounded checker B, residual frontier F, and substitution boundary S remain displayed. The frontier consumer receives a residual-frontier dependency packet over F, S, B, O, H, T, G, N, not a premise-free diamond, full Church–Rosser theorem, closed arbitrary-term confluence theorem, or discharged substitution boundary.*

Proof. Project the residual packet $J = (P, F, S, L, B, C, O, H, T, G, N)$. The rows F, S, B, O expose the residual frontier, substitution-sensitive boundary, bounded checker, and obstruction data that a frontier consumer must inspect.

Apply obstruction retention, Definition 5126.5. It forbids any consumer from reading the packet as a premise-free parallel diamond while O is still a displayed coordinate.

Now read the MetaCIC frontier chapter named in the statement. Its residual-join surface consumes finite frontier, checker, substitution-boundary, and obstruction rows before any candidate diamond read is public, so the same F, S, B, O rows remain part of the dependency rather than surrounding prose.

Finally transport and replay the packet through H, T, G, N. These structural rows preserve the displayed dependency for $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ and add no global confluence, quotienting, or substitution-discharge coordinate. □

Theorem 5126.7 (ParallelDiamondResidual seed obligation)**.** *Every seed-level* $\mathsf{ParallelDiamondResidual}^{\uparrow}$ *consumer must preserve the rows*

$$P, F, S, L, B, C, O, H, T, G, N$$

before any local join is exported. In particular, the residual frontier F, substitution boundary S, local join ledger L, bounded checker B, compatibility handoff C, and obstruction row O remain visible as finite obligations of the seed packet.

The seed obligation refuses premise-free parallel diamond, full Church–Rosser, arbitrary closed-term confluence, unconditional substitution compatibility, quotienting of terms, and a global parallel-diamond theorem.

Proof. Start with Definition 5126.2. It identifies $P, F, S, L, B, C, O, H, T, G, N$ as the displayed local NameCert surface and requires F, S, L, B, C, O before a residual local-join packet can be consumed.

Use Definition 5126.3. The handoff reaches the MetaCIC confluence route only through the residual-substitution boundary, local-join ledger, bounded checker, compatibility interface, and obstruction data.

Apply Definition 5126.4 and Definition 5126.6. The sibling and frontier consumers keep the residual frontier, substitution boundary, bounded checker, compatibility handoff, and obstruction rows visible before any local join is exported.

Finally invoke Definition 5126.5. Since O remains a displayed coordinate, the packet cannot be read as a premise-free parallel diamond, full Church–Rosser theorem, arbitrary closed-term confluence theorem, unconditional substitution-compatibility theorem, quotienting of terms, or global parallel-diamond theorem. □

Theorem 5126.8 (ParallelDiamondResidual normalization frontier handoff)**.** *Every* $\mathsf{ParallelDiamondResidual}^{\uparrow}$ *residual-join read handed to candidate-normalization or confluence consumers must first display the parallel peak row P, residual frontier F,* $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ *row S,* $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$ *row L, bounded checker B,* $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ *handoff C, obstruction row O, and structural rows H, T, G, N. The downstream consumers include chapter 5547 and chapter 4238. The handoff refuses premise-free parallel diamond, full Church–Rosser, arbitrary closed-term confluence, unconditional substitution compatibility, quotienting of terms, and global conversion decidability.*

Proof. Start with the conditional handoff theorem, Definition 5126.3. It routes every confluence-facing read through the residual-substitution boundary, local-join ledger, bounded checker, compatibility interface, and obstruction data before any residual local join is exported.

Apply obstruction retention, Definition 5126.5. Since the row O remains displayed, the residual packet cannot be reread as a premise-free parallel diamond, full Church–Rosser theorem, arbitrary closed-term confluence theorem, unconditional substitution-compatibility theorem, quotienting of terms, or global conversion decidability.

Now use the frontier obstruction route, Definition 5126.6. It keeps F, S, B, O visible for the MetaCIC parallel-diamond frontier, and the same displayed rows feed the candidate-normalization confluence handoff named in the statement.

Finally transport and replay through H, T, G, N. These structural rows preserve the displayed peak, frontier, boundary, ledger, checker, compatibility, and obstruction packet for the downstream consumers without adding any global confluence or conversion-decidability coordinate. □

Falsifiable prediction: Every $\mathsf{ParallelDiamondResidual}^{\uparrow}$ handoff reaches $\mathsf{MetaCICResidualSubstitutionCompatibility}$ only through displayed parallel peaks, residual frontiers, $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$, $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$, bounded residual checks, obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: metacic-residual-substitution-boundary, metacic-residual-substitution-compatibility, metacic-local-join-ledger: $\mathsf{ParallelDiamondResidual}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries parallel peaks, residual frontiers, boundary rows, local-join ledgers, bounded checks, compatibility handoffs, obstruction rows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ParallelDiamondResidual}^{\uparrow}}$.

Constructive story: A $\mathsf{ParallelDiamondResidual}^{\uparrow}$ packet is generated from a parallel peak row, residual frontier, $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ row, $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$ row, bounded checker, $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$ handoff, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ParallelDiamondResidual}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5126.1, Definition 5126.2, and Definition 5126.3 seed the finite residual local-join route for the conditional MetaCIC parallel-diamond boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ParallelDiamondResidual}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full Church–Rosser, arbitrary closed-term confluence, unconditional substitution compatibility, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual-frontier exactness, substitution-boundary routing, local-join ledger exposure, bounded-checker exactness, compatibility handoff nonescape, obstruction-row exposure, transport, replay, provenance, and local naming for BEDC.Derived.ParallelDiamondResidualUp.

The dossier position of $\mathsf{ParallelDiamondResidual}^{\uparrow}$ is downstream of two MetaCIC sibling surfaces: it consumes the residual-join and critical-pair surface of chapter 4238 and the candidate-normalization handoff of chapter 5547 before exposing its own residual diamond rows. The exported packet therefore remains a finite residual-diamond dependency route, not an isolated kernel island, global confluence theorem, quotient equality, or host evaluator fact.

Theorem 5126.9 (ParallelDiamondResidual frontier dependency)**.** *Every accepted* $\mathsf{ParallelDiamondResidual}^{\uparrow}$ *residual-join read consumes chapter 4238 before exporting any residual local-join packet. The read preserves the residual-substitution premise, critical-pair row, candidate-join row, bounded-checker row, compatibility-handoff row, and obstruction row through the same residual frontier dependency route.*

Proof. Project the carrier of Definition 5126.1. The rows $P, F, S, L, B, C, O, H, T, G, N$ display the peak, frontier, substitution boundary, local join, bounded checker, compatibility handoff, obstruction, and structural certificate data.

Apply the MetaCIC sibling route of Definition 5126.4. It makes the residual packet a downstream consumer of the frontier chapter before the local-join packet can be exported.

Use the conditional handoff theorem Definition 5126.3. The handoff preserves the residual-substitution premise, local-join ledger, bounded checker, compatibility interface, and obstruction

row, so the frontier dependency is a displayed packet route rather than an ambient confluence claim. □

The $\mathsf{ParallelDiamondResidual}^{\uparrow}$ packet is a residual-frontier consumer for the MetaCIC parallel-diamond boundary of chapter 4238. Any residual-join read from this hub must keep the MetaCIC frontier row upstream of the residual-substitution boundary, local-join ledger, compatibility handoff, and obstruction row; the dependency remains a finite confluence-facing route, not full Church–Rosser, subject reduction, quotient term equality, or an unconditional parallel-diamond theorem.

Proposition 5126.10 (ParallelDiamondResidual MetaCIC frontier sibling route)**.** *Every* $\mathsf{ParallelDiamondResidual}^{\uparrow}$ *residual-join consumer reads the local residual row through chapter 4238 and the residual-normalization route before exporting confluence data. The consumer must keep the residual-substitution boundary, local-join ledger, bounded checker, compatibility handoff, obstruction row, transport, replay, provenance, and local* $\mathsf{NameCert}$ *rows visible while the MetaCIC frontier is read.*

Proof. Start with the local carrier of Definition 5126.1. It displays the residual frontier, substitution boundary, local-join ledger, bounded checker, compatibility handoff, obstruction row, and structural certificate rows.

Read the sibling frontier through chapter 4238. That frontier supplies the confluence-facing residual-substitution and critical-pair context, but it does not discharge the local residual rows carried here.

Finally apply the residual-normalization route already recorded by the hub siblings. The residual row can be exported as confluence data only with the MetaCIC frontier and the local residual-normalization rows simultaneously displayed. □

Theorem 5126.11 (ParallelDiamondResidual MetaCIC parallel frontier sibling route)**.** *Every* $\mathsf{ParallelDiamondResidual}^{\uparrow}$ *residual-diamond read that consumes chapter 4238 must expose the frontier sibling's retained-premise rows and candidate-normalization rows before the residual packet is treated as a local join route. The read therefore preserves the residual frontier, substitution boundary, local-join ledger, bounded checker, compatibility handoff, obstruction row, transport, replay, provenance, and local name.*

Proof. Start with the residual carrier of Definition 5126.1. Its rows $P, F, S, L, B, C, O, H, T, G, N$ display the peak, residual frontier, substitution boundary, local-join ledger, bounded checker, compatibility handoff, obstruction row, and structural certificate data.

Read the sibling frontier of chapter 4238. Its retained-premise and candidate-normalization rows are the upstream data that make a residual-diamond read visible as a conditional MetaCIC frontier consumer.

Finally apply the existing sibling route Definition 5126.4 and the frontier obstruction route Definition 5126.6. Together they keep $F, S, L, B, C, O, H, T, G, N$ displayed before any local join route is exported, so the new sibling edge changes only the dependency lattice and not the residual theorem meaning. □

Theorem 5126.12 (ParallelDiamondResidual MetaCIC route)**.** *Every* $\mathsf{ParallelDiamondResidual}^{\uparrow}$ *residual-join packet is a downstream consumer of* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *from chapter 4238. Before any confluence-facing read is exported, the packet must preserve the residual-substitution boundary, local-join ledger, compatibility handoff, bounded checker, and obstruction rows displayed by the frontier route.*

Proof. Project the residual packet of Definition 5126.1. Its rows F, S, L, B, C, O expose the residual frontier, substitution boundary, local-join ledger, bounded checker, compatibility handoff, and obstruction boundary.

Apply the MetaCIC sibling route of Definition 5126.4. It makes the residual packet a downstream consumer of the frontier chapter and keeps the frontier premise, critical-pair row, candidate-join row, checker row, handoff row, and obstruction row visible.

Finally use the frontier obstruction route of Definition 5126.6. Since the frontier consumer receives only the displayed dependency packet over the residual rows and structural transports, no confluence-facing read can bypass the listed boundary rows. □

Theorem 5126.13 (ParallelDiamondResidual MetaCIC frontier dependency)**.** *Every* $\mathsf{ParallelDiamondResidual}^{\uparrow}$ *residual-frontier consumer must cite chapter 4238 before any confluence-facing read is exported. The consumer preserves the residual-substitution boundary, local-join ledger, compatibility handoff, bounded checker, and obstruction row of the residual packet before it may read the packet as confluence-facing data.*

Proof. Project the carrier of Definition 5126.1. The rows $P, F, S, L, B, C, O, H, T, G, N$ expose the residual frontier, residual-substitution boundary, local-join ledger, bounded checker, compatibility handoff, obstruction row, and structural transport data, so the cited MetaCIC frontier remains part of the displayed packet route.

Apply the sibling route Definition 5126.4 and the frontier obstruction route Definition 5126.6. They keep the residual-substitution boundary, local-join ledger, bounded checker, compatibility handoff, and obstruction row visible before a confluence-facing consumer can read the packet, and the structural rows preserve that boundary without adding full Church–Rosser, quotient term equality, or an unconditional parallel-diamond theorem. □

Theorem 5126.14 (ParallelDiamondResidual residual-join consumer route)**.** *Every accepted* ParallelDiamondResid *local-join row used by the MetaCIC residual audit is consumed by chapter 8134 and chapter 7258 before any confluence handoff is read. The route exposes residual branch rows, candidate joins, retained premise data, obstruction rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming, and it does not export a premise-free parallel diamond or closed Church–Rosser theorem.*

Proof. Project the residual local-join carrier through the sibling routes already named by the chapter. The branch rows and candidate joins are retained as finite BHist coordinates, while the transport, replay, provenance, and naming rows remain local to the $\mathsf{ParallelDiamondResidual}^{\uparrow}$ packet.

The matrix consumer of chapter 8134 reads two residual branches together with retained residual-substitution premise data. The grid consumer of chapter 7258 reads the same residual handoff as a finite residual-vertex and candidate-join grid.

Thus the forward route is a consumer dependency for the residual audit surface. Since neither consumer receives a coordinate discharging the retained premises or the obstruction row, the route cannot be retyped as a premise-free confluence theorem. □

Chapter 5127

A Concrete Naming Certificate for $\mathsf{GramDeterminant}^{\uparrow}$

Following Gram and classical finite-dimensional inner-product theory, the $\mathsf{GramDeterminant}^{\uparrow}$ packet records the finite determinant surface obtained from displayed inner products of a finite vector family. It consumes the inner-product rows of chapter 86, the matrix-entry carrier of chapter 49, the determinant boundary of chapter 84, and the finite coordinate discipline of chapter 4758. The packet names the finite Gram matrix, its determinant row, and its principal-minor ledger; it is not a Hilbert-space compactness theorem, a selected orthonormal basis, a quotient-vector equality principle, or a positive-definiteness theorem outside the displayed rows.

Definition 5127.1 (Gram determinant carrier)**.** *A* $\mathsf{GramDeterminant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (V, I, A, M, D, J, T, R, H, C, P, N)$$

with the following displayed coordinates:

1. *V is the finite vector-row bundle whose entries are the carried vectors $v_1, \ldots, v_n$;*
2. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row over the same vector endpoints, exposing the scalar reads $\langle v_i, v_j \rangle$ for every displayed pair;*
3. *A is the scalar-entry ledger that records each inner-product value as a finite BEDC scalar history;*
4. *M is the* $\mathsf{Mat}^{\uparrow}$ *row whose (i, j) entry is read from the scalar row $\langle v_i, v_j \rangle$;*
5. *D is the* $\mathsf{Determinant}^{\uparrow}$ *row naming the determinant of the displayed matrix row M;*
6. *J is the finite principal-minor ledger, one determinant row for each displayed principal submatrix of M;*
7. *T stores transport data for reindexing the finite vector rows, scalar inner-product rows, matrix-entry rows, determinant row, and principal-minor rows;*
8. *R stores replay data from vector rows to scalar entries, from scalar entries to matrix rows, and from matrix rows to determinant and principal-minor rows;*
9. *H records componentwise* hsame *transport for $V, I, A, M, D, J, T, R, C, P, N$;*
10. *C records the displayed* Cont *routes by which determinant and principal-minor consumers read the packet;*

11. *P is the* Pkg *provenance over* $\mathsf{GramDeterminant}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Determinant}^{\uparrow}$, *finite vector bundles,* BHist, hsame, Cont, *and* NameCert*;*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{GramDeterminant}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the finite vector rows, scalar inner-product rows, matrix-entry rows, determinant rows, principal-minor rows, transport, replay, provenance, continuation, and local naming data.

Lean4 ✓ `BEDC.Derived.GramDeterminantUp.GramDeterminantTasteGate single carrier alignment`

Theorem 5127.2 (Gram determinant NameCert obligations)**.** *For the carrier of Definition 5127.1, the local* $\mathsf{NameCert}_{\mathsf{GramDeterminant}^{\uparrow}}$ *surface consists exactly of five finite obligations: carrier admission for $G = (V, I, A, M, D, J, T, R, H, C, P, N)$; scalar-entry exactness requiring every matrix entry in M to be read from the corresponding* $\mathsf{InnerProduct}^{\uparrow}$ *scalar row in A; determinant exactness requiring D to consume only the displayed* $\mathsf{Mat}^{\uparrow}$ *row M; principal-minor exactness requiring each row of J to consume a displayed principal submatrix of M; and transport-replay stability for T, R, H, C, P, N under the same finite row inventory.*

Proof. Carrier admission is projection from Definition 5127.1. The accepted packet lists vector rows, inner-product scalar rows, matrix-entry rows, determinant rows, principal-minor rows, transport, replay, componentwise hsame, continuation, provenance, and local naming.

The scalar-entry and determinant clauses are read in order. First I and A expose the finite family of scalar inner-products. Then M records those scalars as matrix entries, and D reads only that displayed matrix row through the determinant certificate of chapter 84.

The principal-minor clauses are finite subpacket reads of the same matrix row. Each minor in J is indexed by displayed rows of V and by the matching submatrix entries in M, so no ambient matrix quotient or host positivity theorem is imported.

Finally T, R, H, C, P, N preserve and replay the same inventory. Since the carrier has no coordinate for a selected orthonormal basis, quotient-vector equality, Hilbert completion, or external positive-definiteness principle, the five obligations exhaust the local certificate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{GramDeterminant}^{\uparrow}}$.

Constructive story: A $\mathsf{GramDeterminant}^{\uparrow}$ packet is generated from a finite vector-row bundle, inner-product scalar rows, a matrix-entry row, determinant and principal-minor rows, transport, replay, componentwise hsame, Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GramDeterminant}^{\uparrow}}$, seed)

Scope closed: Definition 5127.1 and Definition 5127.2 declare the finite carrier and NameCert obligation surface for Gram determinant packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GramDeterminant}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim positive semidefiniteness, Gram determinant vanishing criteria, quotient-vector equality, selected orthonormal bases, Hilbert completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked scalar-entry exactness, determinant exactness, principal-minor exactness, transport, replay, provenance, and local naming for the same finite packet.

Chapter 5128

A Concrete Naming Certificate for $\mathsf{ModulusOfUniformContinuity}^{\uparrow}$

Following Bishop and Bridges constructive metric analysis, the $\mathsf{ModulusOfUniformContinuity}^{\uparrow}$ packet records the finite BEDC surface by which an explicit dyadic tolerance request for a continuous map is answered by a displayed source-radius schedule before any compactness, completion, or $\mathsf{Real}^{\uparrow}$ consumer reads the result. It sits next to the pointwise map surface of chapter 130, the source and target metric rows of chapter 4230, the finite compact-metric coverage route of chapter 129, the terminal real-name seal of chapter 38, and the dyadic tolerance ledger of chapter 291. The certificate is a displayed modulus schedule for downstream compact-metric uniform-continuity and Heine–Cantor consumers; it is not open-cover compactness, a selected finite subcover, a quotient real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5128.1 (Modulus of uniform continuity carrier)**.** *A* $\mathsf{ModulusOfUniformContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Y, F, D, S, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, naming the source distance ledger, source-point comparison interface, and source-radius requests.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row, naming the target distance ledger and target-radius comparison interface consumed by the map row.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row from X to Y, carrying the pointwise continuity route and the displayed source-to-target graph read.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance request ledger, recording the target dyadic tolerance and the finite dyadic comparison rows used to ask for a uniform answer.*
5. *S is the modulus schedule row, assigning the displayed dyadic tolerance in D to a source-radius row over X and recording the finite lookup by which the same schedule is replayed for every accepted source pair.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary, reached only after X, Y, F, D, S have been displayed and only as the terminal real-name readback for the target estimate.*

7. *H records componentwise* hsame *transport for the source metric, target metric, continuous-map row, dyadic tolerance request, modulus schedule, Real seal boundary, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a dyadic tolerance request through D, then through S, into the source metric row X, the map row F, the target metric row Y, and finally the Real seal row E.*
9. *P is the* Pkg *provenance over* $\mathsf{ModulusOfUniformContinuity}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ModulusOfUniformContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows, their componentwise transports, their replay route, their provenance, and their local naming row. It has no coordinate for open-cover compactness, selected subcovers, quotient real equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ModulusOfUniformContinuityUp.ModulusOfUniformContinuityTasteGate single carrier alignment`

Theorem 5128.2 (Modulus of uniform continuity NameCert obligations)**.** *For every accepted* $\mathsf{ModulusOfUniformContinuity}^{\uparrow}$ *carrier $M = (X, Y, F, D, S, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ModulusOfUniformContinuity}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source* $\mathsf{Met}^{\uparrow}$ *row, target* $\mathsf{Met}^{\uparrow}$ *row,* $\mathsf{ContinuousMap}^{\uparrow}$ *row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance request, modulus schedule,* $\mathsf{Real}^{\uparrow}$ *seal boundary, transport, replay, provenance, and local naming row;*
2. *tolerance-source exactness, requiring every requested target tolerance to be read from the displayed dyadic ledger D before the schedule row S is inspected;*
3. *source-radius schedule exactness, requiring S to return only a source-radius row over X and to reuse that row for each accepted source-pair read of the same tolerance;*
4. *continuous-map handoff, requiring the source-radius evidence to pass through the pointwise* $\mathsf{ContinuousMap}^{\uparrow}$ *route F before the target* $\mathsf{Met}^{\uparrow}$ *row Y and the Real seal row E are exposed;*
5. *compact-metric compatibility, requiring any downstream* $\mathsf{CompactMetric}^{\uparrow}$ *consumer to read finite-net or compact-metric data only as an external consumer of the displayed schedule, not as a hidden source of S;*
6. *transport and replay stability, requiring componentwise* hsame *transport in H and displayed* Cont *replay in C to preserve the ordered route D, S, X, F, Y, E;*
7. *provenance exhaustion, requiring P and N to name only the displayed rows and to export no open-cover compactness, selected subcover, quotient real equality, selected limit, countable choice, trichotomy, or ambient Real completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier. Its analytic rows are the source metric X, target metric Y, continuous-map route F, dyadic tolerance ledger D, modulus schedule S, and Real seal boundary E; the remaining rows transport, replay, source, and name that same packet.

Read the tolerance route in order. A target-radius request first enters the dyadic ledger D, then the modulus schedule S, and only then the source metric row X where the displayed source radius is used.

The map and target estimates are downstream of that schedule. The continuous-map row F consumes the source-radius evidence before the target metric row Y and the terminal $\mathsf{Real}^{\uparrow}$ boundary E can be inspected.

Compact-metric data is therefore only a consumer-side row. A $\mathsf{CompactMetric}^{\uparrow}$ finite-net argument may cite the displayed schedule, but it cannot supply an unrecorded open cover, selected subcover, or choice principle inside the $\mathsf{ModulusOfUniformContinuity}^{\uparrow}$ carrier.

Finally, componentwise transport through H, replay through C, provenance through P, and local naming through N preserve the same ordered rows. Since the excluded quotient, selection, trichotomy, and completeness objects are absent from the carrier inventory, the listed obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusOfUniformContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{ModulusOfUniformContinuity}^{\uparrow}$ packet is generated from source and target $\mathsf{Met}^{\uparrow}$ rows, a $\mathsf{ContinuousMap}^{\uparrow}$ row, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance requests, a displayed source-radius modulus schedule, a terminal $\mathsf{Real}^{\uparrow}$ seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ModulusOfUniformContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5128.1 and Definition 5128.2 seed the finite displayed modulus-of-uniform-continuity dyadic tolerance-to-source-radius schedule packet over $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows for continuous-map and compact-metric uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ModulusOfUniformContinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected finite subcovers, quotient real equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-source exactness, source-radius schedule exactness, continuous-map handoff, compact-metric compatibility, transport, replay, provenance, and local naming for BEDC.Derived.ModulusOfUniformContinuityUp and the same finite packet.

Chapter 5129

A Concrete Naming Certificate for $\mathsf{ModulusOfContinuity}^{\uparrow}$

Following Bishop and Bridges on constructive continuity, the $\mathsf{ModulusOfContinuity}^{\uparrow}$ packet records the finite data by which a pointwise continuity certificate exposes tolerance-to-precision information before Real, Completion, compactness, or uniform-continuity consumers inspect it. It sits between the source metric carrier of chapter 57, the real-name seal of chapter 38, the continuous-map graph of chapter 130, and the uniform-modulus handoff of chapter 369. The packet names the displayed modulus ledger itself; it is not a host theorem asserting continuity, a chosen global modulus, quotient equality of functions, or an ambient real-completeness principle.

Definition 5129.1 (ModulusOfContinuityUp carrier)**.** *A* $\mathsf{ModulusOfContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Y, T, P, L, U, H, C, V, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, including the distance request surface and the source-point histories that the modulus may inspect.*
2. *Y is the* $\mathsf{Real}^{\uparrow}$ *target carrier or target metric row through which output tolerances are read.*
3. *T is the tolerance history, recording the requested positive rational or dyadic output tolerance.*
4. *P is the precision history, recording the source-radius response attached to the same request.*
5. *L is the pointwise modulus ledger, assigning the displayed precision row P to the displayed tolerance row T at the named source point.*
6. *U is an optional uniform ledger over a finite source packet, present exactly when the same precision row is licensed without rereading a source point.*
7. *H records componentwise* hsame *transport for the metric, real, tolerance, precision, pointwise, optional uniform, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through T, P, L and, when available, through U.*
9. *V is the* Pkg *provenance over* $\mathsf{ModulusOfContinuity}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ModulusOfContinuity}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host continuity theorem, a choice-selected modulus, quotient equality of functions, real trichotomy, countable choice, a completed function space, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5129.2 (ModulusOfContinuityUp NameCert obligations)**.** *For every accepted* $\mathsf{ModulusOfContinuity}^{\uparrow}$ *carrier*

$$M = (X, Y, T, P, L, U, H, C, V, N),$$

the local $\mathsf{NameCert}_{\mathsf{ModulusOfContinuity}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source metric, target real or target metric, tolerance, precision, pointwise ledger, optional uniform ledger, transport, replay, provenance, and local naming rows;*
2. *tolerance admission, requiring every output request to be read through* T *before a precision response is visible;*
3. *pointwise precision admission, requiring* P *and* L *to record the source-radius response attached to the same tolerance request and source history;*
4. *optional uniform admission, requiring* U *to be displayed before any consumer treats the precision row as source-point independent;*
5. *continuous-map replay, requiring* C *to factor the displayed request through the* Cont *route licensed by the continuous-map surface;*
6. *transport stability, requiring* H *to preserve the source, target, tolerance, precision, ledger, replay, provenance, and local naming rows componentwise;*
7. *nonescape from host continuity theorems, choice-selected moduli, quotient function equality, real trichotomy, countable choice, completed function spaces, and ambient real completeness.*

No $\mathsf{ModulusOfContinuity}^{\uparrow}$ *naming obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5129.1. The accepted packet displays exactly the source metric row, target row, tolerance history, precision history, pointwise ledger, optional uniform ledger, and the structural rows H, C, V, N.

Tolerance and pointwise precision admission follow from the displayed request order. A consumer first reads the requested output tolerance in T, then reads the source-radius response in P, and then checks that L attaches that response to the same source history.

If a uniform read is requested, inspect U. The carrier permits a source-point independent precision only when this row is present, so a compact-uniform-continuity consumer cannot infer uniformity from the pointwise ledger alone.

Replay and transport are structural. The Cont row C repeats the continuous-map request through the same tolerance and precision rows, while H preserves each displayed coordinate componentwise.

Finally inspect V and N. Provenance and local naming mention only the displayed rows, so the excluded host theorem, selected modulus, quotient equality, trichotomy, choice, completed function-space, and ambient-completeness data have no projection from the packet. □

Theorem 5129.3 (ModulusOfContinuityUp uniformization handoff)**.** *Let*

$$M = (X, Y, T, P, L, U, H, C, V, N)$$

be an accepted $\mathsf{ModulusOfContinuity}^{\uparrow}$ *carrier. Any compact-uniform-continuity, completion, or continuous-map consumer that reads a uniform precision from* M *must first read the source metric*

row X, the target row Y, the tolerance history T, the precision history P, the pointwise ledger L, and the optional uniform ledger U when source-point independence is claimed.

Thus the handoff from pointwise continuity data to a $\mathsf{UniformModulus}^{\uparrow}$*-facing ledger factors through finite BEDC rows over* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. It does not export a host-selected modulus, function extensionality, quotient equality of functions, open-cover compactness, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5129.1. The only rows that can answer a tolerance request are T, P, L and, for a source-point independent read, U.

Apply Definition 5129.2. The NameCert surface forces every read to pass through the displayed source metric and target rows, then through the tolerance and precision histories, and then through the pointwise ledger before any optional uniform row can be consumed.

Now compare the sibling interfaces. The source distance and point histories are supplied by chapter 57, target real-name reads by chapter 38, continuous replay by chapter 130, and the source-point independent handoff by chapter 369.

The structural rows H, C, V, N preserve, replay, source, and name exactly that route. Since the excluded host-continuity, selected-modulus, quotient, open-cover, choice, and completeness objects are absent from the carrier, a downstream consumer cannot recover them while claiming to read the same $\mathsf{ModulusOfContinuity}^{\uparrow}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusOfContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{ModulusOfContinuity}^{\uparrow}$ packet is generated from source MetricUp rows, target RealUp or target metric rows, tolerance histories, precision histories, pointwise modulus ledgers, optional uniform ledgers, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ModulusOfContinuity}^{\uparrow}}$, seed)

Scope closed: Definition 5129.1, Definition 5129.2, and Definition 5129.3 seed the finite pointwise-modulus route from metric and real rows through continuous replay into optional uniform-modulus consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ModulusOfContinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, a host-selected modulus, quotient equality of functions, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, pointwise ledger exactness, optional uniform-ledger handoff, transport, replay, provenance, and local naming for BEDC.Derived.ModulusOfContinuityUp.

Chapter 5130

A Concrete Naming Certificate for $\mathsf{DirichletBoxApproximation}^{\uparrow}$

Following Dirichlet's approximation theorem and Bishop–Bridges constructive analysis, the DirichletBoxApproximati packet names the finite pigeonhole route from a rational source row and a denominator box ledger to a rational approximation surface. It sits after the rational source of chapter 37, the adjacent rational routes of chapter 1759 and chapter 1704, the dyadic tolerance ledger of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet records only finite box partitions, displayed adjacent-rational handoffs, tolerance rows, readback windows, transport, replay, provenance, and local naming.

Definition 5130.1 (Dirichlet box approximation carrier)**.** *A* $\mathsf{DirichletBoxApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, L, F, A, D, W, G, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *source row. It records the rational input data, finite numerator observations, and rational endpoints inspected by the approximation request.*
2. *L is the denominator-box ledger. It stores the positive finite denominator bound, the box count, the inspected residue slots, and the finite comparison rows used to expose two entries in the same box.*
3. *F is the finite box-partition row. It records the displayed partition of the unit interval or rational bracket into denominator-controlled cells.*
4. *A is the adjacent-rational handoff row. It sends the same-pigeonhole pair to the* $\mathsf{FareySequence}^{\uparrow}$ *or* $\mathsf{SternBrocot}^{\uparrow}$ *adjacency surface before any approximant is exported.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It stores the dyadic error request, slack ledger, and endpoint comparisons used to validate the rational difference produced by L, F, A.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row. It schedules the finite observations of Q, L, F, A, D that downstream real-facing requests may inspect.*
7. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It repackages the displayed windows and rational differences as regular rational data before the terminal real seal is available.*

8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It is reachable only after the rational source, box ledger, partition, adjacency handoff, dyadic tolerance, finite windows, and regular readback rows have been displayed.*
9. *H records componentwise* hsame *transport for rational sources, denominator boxes, partitions, adjacency handoffs, dyadic tolerances, finite windows, regular readback, Real seals, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a box-approximation request through $Q, L, F, A, D, W, G, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{DirichletBoxApproximation}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{FareySequence}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DirichletBoxApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, L, F, A, D, W, G, E, H, C, P, N$. It has no coordinate for selected best approximants, quotient real equality, trichotomy, countable choice, a host pigeonhole selector outside the finite ledger, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DirichletBoxApproximationUp.DirichletBoxApproximationTasteGate single carrier alignment`

Theorem 5130.2 (Dirichlet box approximation NameCert obligations)**.** *For every accepted* DirichletBoxApproximat *carrier*

$$B = (Q, L, F, A, D, W, G, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DirichletBoxApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the rational source, denominator-box ledger, finite partition, adjacency handoff, dyadic tolerance, StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *box partition exposure, requiring L and F to display the finite denominator-controlled cells and the same-box pair before an approximating rational difference can be exported;*
3. *adjacency transport, requiring A to route the displayed same-box pair through the* $\mathsf{FareySequence}^{\uparrow}$ *or* $\mathsf{SternBrocot}^{\uparrow}$ *sibling surface;*
4. *dyadic-error control, requiring D to record the requested dyadic tolerance, slack, and endpoint comparisons used by the approximation read;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *nonescape, requiring W, G, E to stay downstream of the finite box and adjacency rows;*
6. *local naming, requiring H, C, P, N to preserve and source exactly the displayed packet.*

No Dirichlet-box obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5130.1. The accepted packet displays exactly the rational source, denominator-box ledger, finite partition, adjacency handoff, dyadic tolerance, finite windows, regular readback, terminal Real seal, and structural rows listed in the statement.

The box partition exposure is finite. The row L stores the denominator bound, box count, residue slots, and same-box comparison, while F records the displayed partition cells. Together they supply the pigeonhole surface without invoking a host selector beyond the stored finite ledger.

Adjacency transport is read next. The row A sends the same-box pair to the Farey and Stern–Brocot siblings of chapter 1759 and chapter 1704, so the exported rational difference is attached to displayed adjacent-rational data.

The dyadic and real-facing rows remain downstream. The tolerance row D supplies the error and slack comparisons, the window row W schedules only finite observations, and G reads those windows as $\mathsf{RegSeqRat}^{\uparrow}$ data before E seals the route as a $\mathsf{Real}^{\uparrow}$-facing packet.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no coordinate for selected best approximants, quotient real equality, trichotomy, countable choice, a host pigeonhole selector outside the finite ledger, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 5130.3 (Dirichlet box approximation finite pigeonhole route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read exported by an accepted* $\mathsf{DirichletBoxApproximation}^{\uparrow}$ *carrier*

$$B = (Q, L, F, A, D, W, G, E, H, C, P, N)$$

factors through the finite route

$$Q, L, F, A, D, W \longmapsto G, E.$$

Thus the exported approximation is witnessed by rational source data, a denominator-box ledger, a finite partition row, an adjacent-rational handoff, a dyadic tolerance row, and a finite StreamName window, not by quotient real equality, trichotomy, countable choice, selected best approximants, or ambient Real completeness.

Proof. Start with a regular-rational or Real-facing read from the accepted carrier. The only rows with that target are G and E, and the carrier places them after Q, L, F, A, D, W.

The source and box rows determine the finite pigeonhole data. The row Q supplies the rational observations, while L and F expose the denominator bound, partition cells, and same-box comparison needed for the approximating rational difference.

The adjacency and tolerance rows then control the exported approximation. The row A records the Farey or Stern–Brocot handoff, and D records the dyadic error and slack comparisons attached to that handoff.

Only after the finite window row W is fixed can G read the packet as regular rational data and E seal it as Real-facing. Transport, replay, provenance, and local naming preserve this route through H, C, P, N, so none of the excluded ambient principles can enter the exported read. □

Falsifiable prediction: Every $\mathsf{DirichletBoxApproximation}^{\uparrow}$ Real-facing read passes through $\mathsf{Rat}^{\uparrow}$, $\mathsf{FareySequence}^{\uparrow}$ or $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any approximation output is visible.

Independence witness: rat, farey-sequence, stern-brocot, dyadicratcore, streamname, regseqrat, real: $\mathsf{DirichletBoxApproximation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a rational source row, denominator-box ledger, finite partition, adjacent-rational handoff, dyadic tolerance row, finite windows, regular readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletBoxApproximation}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirichletBoxApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5130.1, Definition 5130.2, and Definition 5130.3 seed the finite pigeonhole route from rational source rows through denominator boxes, finite partitions, adjacency handoffs, dyadic tolerance, finite windows, regular readback, terminal Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirichletBoxApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected best approximants, quotient real equality, trichotomy, countable choice, host pigeonhole selectors outside the displayed finite ledger, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, box partition exposure, adjacency transport, dyadic-error control, StreamName and RegSeqRat readback ordering, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DirichletBoxApproximationUp.

Constructive story: A DirichletBoxApproximation$^{\uparrow}$ packet is generated from RatUp source rows, a denominator-box ledger, a finite partition row, a FareySequenceUp or SternBrocotUp adjacency handoff, a DyadicRatCoreUp tolerance row, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5131

A Concrete Naming Certificate for $\mathsf{RiemannStieltjesIntegrationParts}^{\uparrow}$

Following Riemann, Stieltjes, and Bishop–Bridges, the $\mathsf{RiemannStieltjesIntegrationParts}^{\uparrow}$ packet records integration by parts as finite NameCert data over a regulated integrand and a bounded-variation integrator. It consumes the Riemann–Stieltjes surface of chapter 1637, the variation ledger of chapter 398, the regulated-function schedule of chapter 1906, the tagged finite-sum row of chapter 1615, the dyadic step approximation row of chapter 428, and the terminal real seal of chapter 38. The packet names only displayed endpoint rows, finite partition rows, transported jump rows, two Riemann–Stieltjes handoff rows, and the boundary-term ledger; it does not add measure integration, quotient functions, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5131.1 (Riemann–Stieltjes integration-by-parts carrier)**.** *A* $\mathsf{RiemannStieltjesIntegrationParts}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, G, V, R, S, D, B, E, H, C, P, N)$$

with displayed rows: F *is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *integrand row;* G *is the regulated integrator row;* V *is the* $\mathsf{BoundedVariation}^{\uparrow}$ *ledger for* G*;* R *is the forward* $\mathsf{RiemannStieltjes}^{\uparrow}$ *handoff for* $\int F\,dG$*;* S *is the reverse handoff for* $\int G\,dF$ *when the displayed variation rows license it;* D *is the common* $\mathsf{RiemannSum}^{\uparrow}$ *partition ledger;* B *is the endpoint boundary row* $F(b)G(b) - F(a)G(a)$*;* E *is the* $\mathsf{Real}^{\uparrow}$ *seal of the accepted identity; and* H, C, P, N *are the componentwise* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{RiemannStieltjesIntegrationParts}^{\uparrow}}$ *rows.*

Theorem 5131.2 (Riemann–Stieltjes integration-by-parts NameCert obligations)**.** *For every accepted carrier* $I = (F, G, V, R, S, D, B, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RiemannStieltjesIntegrationParts}^{\uparrow}}$ *surface consists exactly of carrier admission; regulated-function exposure for* F, G*; bounded-variation control through* V*; common tagged-partition exposure through* D*; forward and reverse Riemann–Stieltjes handoffs through* R, S*; endpoint-boundary exactness through* B, E*; componentwise transport, replay, provenance, and local naming through* H, C, P, N*; and non-escape from measure spaces, quotient functions, selected limits, and ambient completeness.*

Lean4 ✓ `BEDC.Derived.RiemannStieltjesIntegrationPartsUp.RiemannStieltjesIntegrationPartsTasteGate`
`single carrier alignment`

Proof. Project the displayed carrier. The rows F, G, V, D expose the regulated and bounded-variation data before either integration row is read.

The rows R and S are then checked over the same finite partition ledger. Since both handoffs use the same D and the same endpoint transports, their finite summand ledgers can be compared without introducing a host limit.

Finally B records the two endpoint products and E seals the displayed equality. Transport and replay through H, C, P, N preserve the same rows, so no hidden measure, function quotient, choice of representatives, selected limit, or ambient completeness coordinate remains available. □

Theorem 5131.3 (Riemann–Stieltjes integration-by-parts boundary)**.** *Every accepted* RiemannStieltjesIntegrationP *packet exposes the integration-by-parts boundary only through the finite route*

$$F, G, V, D \longmapsto R, S \longmapsto B \longmapsto E.$$

Thus a consumer may read the boundary term $F(b)G(b)-F(a)G(a)$ only after the regulated-function rows, bounded-variation ledger, common Riemann-sum partition row, and both Riemann–Stieltjes handoff rows have been displayed.

Proof. Start with a boundary-facing consumer. The carrier has no boundary row except B, and B is downstream of the endpoint reads supplied by the regulated rows F, G.

The common finite partition row D aligns the two integration handoffs. Reading R and S over D accounts for the forward and reverse summand ledgers before the endpoint product row is exposed.

The real seal E is therefore read only after B. The structural rows H, C, P, N transport, replay, source, and name the same route, so the packet exports the integration-by-parts identity as finite NameCert data rather than as a host theorem about completed integrals. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannStieltjesIntegrationParts}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannStieltjesIntegrationParts}^{\uparrow}$ packet is generated from regulated-function rows, a bounded-variation ledger, common Riemann-sum partition data, two Riemann–Stieltjes handoffs, endpoint boundary rows, componentwise transport, displayed replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannStieltjesIntegrationParts}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5131.1, Definition 5131.2, and Definition 5131.3 seed the finite integration-by-parts packet over displayed Riemann–Stieltjes, bounded-variation, regulated-function, Riemann-sum, dyadic-step, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannStieltjesIntegrationParts}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure-theoretic integration, quotient function equality, selected limits, global variation measures, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, common-partition stability, two handoff rows, endpoint-boundary exactness, transport, replay, provenance, and local naming for the same packet.

$\mathsf{BishopBarInductionModulus}^{\uparrow}$ is consumed by the Real-facing equality-modulus lattice through chapter 7601, and it depends on the finite fan-depth route of chapter 400 before any $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or terminal $\mathsf{Real}^{\uparrow}$ read.

Chapter 5132

A Concrete Naming Certificate for $\mathsf{BishopBarInductionModulus}^{\uparrow}$

Following Brouwer's barred-spread analysis, Troelstra–van Dalen's treatment of bar induction, and Bishop–Bridges constructive Real practice, the $\mathsf{BishopBarInductionModulus}^{\uparrow}$ packet records the finite modulus surface that Real and Completion consumers may read from a barred spread. It sits after the barred-spread packet of chapter 1675, the finite fan surface of chapter 400, the finite stream-window discipline of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a displayed modulus handoff; it is not countable choice, open-cover compactness, quotient stream equality, selected branch data, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5132.1 (Bishop bar induction modulus carrier)**.** *A* $\mathsf{BishopBarInductionModulus}^{\uparrow}$ *carrier is a finite barred-spread modulus packet*

$$K = (B, T, I, W, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the barred-spread row inherited from* $\mathsf{BrouwerBarInduction}^{\uparrow}$*. It records the finite bar decisions, monotone coverage, and local backwards induction replay visible in the current prefix tree.*
2. *T is the finite tree-depth ledger. It records the displayed root, visible extensions, retained prefix levels, and the finite fan boundary consumed by* $\mathsf{FanTheorem}^{\uparrow}$*.*
3. *I is the induction replay row. It records the local step converting displayed barred children into the displayed parent prefix, without selecting an infinite branch.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It schedules the finite prefix observations requested by Real and Completion consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, including the rational tolerances used to read the visible prefix depth.*
6. *M is the modulus output row. It records the displayed natural bound after which every accepted window read is determined by the barred-spread replay.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, T, I, W, R, M have been displayed.*

8. *H stores componentwise* hsame *transport for barred-spread data, tree-depth ledgers, induction replay, StreamName windows, RegSeqRat readback, modulus output, Real sealing, continuation, provenance, and local naming.*

9. *C stores displayed* Cont *replay from any finite-window request through the same $B, T, I, W, R, M, E, H, P, N$ route.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopBarInductionModulus}^{\uparrow}$, $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopBarInductionModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, T, I, W, R, M, E, H, C, P, N$. It has no coordinate for countable choice, arbitrary open covers, quotient stream equality, a selected infinite branch, a host continuity theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5132.2 (Bishop bar induction modulus NameCert obligations)**.** *For every accepted* $\mathsf{BishopBarInductionModulus}^{\uparrow}$ *carrier*

$$K = (B, T, I, W, R, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopBarInductionModulus}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for barred-spread data, finite tree-depth ledgers, induction replay, StreamName windows, RegSeqRat readback, modulus output, Real sealing, transport, continuation, provenance, and local naming;*

2. *barred-spread ancestry, requiring every modulus read to expose the* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *row B before using M;*

3. *fan-boundary exactness, requiring the displayed depth ledger T to be the only finite fan surface used in the modulus computation;*

4. *readback ordering, requiring every* $\mathsf{RegSeqRat}^{\uparrow}$ *read to pass through the* $\mathsf{StreamName}^{\uparrow}$ *window row before reaching M and E;*

5. *analytic nonescape, requiring every Real or Completion-facing consumer to use the route $B, T, I, W, R, M, E, H, C$ and no hidden choice, cover, branch-selection, quotient, or ambient-completeness coordinate.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5132.1. The carrier admission row is exactly the tuple $B, T, I, W, R, M, E, H, C, P, N$, so the first obligation is a coordinate projection.

The barred-spread ancestry clause is forced by the placement of M after B and I. A consumer cannot read a modulus output without first displaying the bar decisions, monotone coverage, and local backwards replay already named by $\mathsf{BrouwerBarInduction}^{\uparrow}$.

The fan-boundary exactness clause is the role of T. The packet records only a finite depth ledger and visible prefix levels; it does not add an infinite branch or a separate compactness principle.

For readback ordering, the StreamName row W schedules the requested finite observations, the RegSeqRat row R reads them with rational tolerances, and only then does the modulus row M report the displayed bound. The Real seal E is downstream of that same route.

Finally H, C, P, N transport, replay, package, and name no further data. Since hidden choice, arbitrary covers, selected branches, quotient stream equality, and ambient Real completeness are not carrier coordinates, they cannot be local NameCert obligations. □

Theorem 5132.3 (Bishop bar induction modulus window boundary)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or Completion-facing read of an accepted* $\mathsf{BishopBarInductionModulus}^{\uparrow}$ *carrier factors through the displayed finite route*

$$\mathsf{BrouwerBarInduction}^{\uparrow}, \mathsf{FanTheorem}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{BishopBarInductionModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

Equivalently, the exported modulus is determined by the rows $B, T, I, W, R, M, E, H, C, P, N$ *and cannot expose countable choice, open-cover compactness, quotient stream equality, selected infinite branches, host continuity, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an analytic-facing read of K. The only window interface in the carrier is W, so the request must first become a displayed finite $\mathsf{StreamName}^{\uparrow}$ observation.

The readback row R is attached to that same finite observation. It supplies regular rational tolerances for the visible prefix depth, not a quotient stream representative or a completed branch.

The modulus row M is downstream of B, T, I, W, R. Thus its bound is read only after the barred-spread row, finite fan-depth ledger, induction replay, window schedule, and rational readback have all been displayed.

The terminal seal E can therefore carry only the same finite route to Real or Completion consumers. Componentwise transport, continuation replay, provenance, and local naming preserve this route through H, C, P, N, and the carrier has no additional coordinate from which the excluded principles could be recovered. □

Falsifiable prediction: Every accepted $\mathsf{BishopBarInductionModulus}^{\uparrow}$ Real or Completion-facing read exposes barred-spread data, a finite tree-depth ledger, induction replay, StreamName windows, RegSeqRat readback, a modulus output, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any modulus boundary is visible.

Independence witness: brouwer-bar-induction, fantheorem, streamname, regseqrat, real: BishopBarInductionMo is not bijective to any listed sibling because it jointly carries barred-spread ancestry, finite fan-depth data, induction replay, finite windows, regular rational readback, a modulus output, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopBarInductionModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopBarInductionModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5132.1, Definition 5132.2, and Definition 5132.3 seed the finite barred-spread modulus route from Brouwer bar induction and fan-depth rows through StreamName windows, RegSeqRat readback, terminal Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopBarInductionModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, open-cover compactness, quotient stream equality, selected infinite branches, host continuity, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, barred-spread ancestry, fan-boundary exactness, readback ordering, modulus-window boundary, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopBarInductionModulusUp.

Constructive story: A $\mathsf{BishopBarInductionModulus}^{\uparrow}$ packet is generated from BrouwerBarInductionUp barred-spread rows, FanTheoremUp finite depth ledgers, induction replay, StreamName windows, RegSeqRat readback, a displayed modulus output, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theorem 5132.4 (Bishop bar-induction modulus fan-theorem dependency)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{BishopBarInductionModulus}^{\uparrow}$ *packet must first read the* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *barred-spread row and the* $\mathsf{FanTheorem}^{\uparrow}$ *finite-fan row before the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *seal rows can be consumed. In carrier terms, the barred-spread row* B *and finite tree-depth*

ledger T precede the window row W, readback row R, modulus output M, terminal seal E, transport rows H, continuation rows C, provenance row P, and local naming row N. The packet exports a finite modulus handoff, not countable choice, open-cover compactness, quotient stream equality, selected branch data, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5132.1. The rows B and T are displayed before the analytic window route; B records the barred-spread ancestry and T records the finite fan boundary.

Apply the NameCert obligations of Definition 5132.2. The barred-spread ancestry clause requires the $\mathsf{BrouwerBarInduction}^{\uparrow}$ row before a modulus read, and the fan-boundary exactness clause confines the finite fan surface to T.

Route the remaining rows through the window boundary of Definition 5132.3. The $\mathsf{StreamName}^{\uparrow}$ row W, $\mathsf{RegSeqRat}^{\uparrow}$ readback R, modulus output M, and $\mathsf{Real}^{\uparrow}$ seal E are consumed only after the barred-spread and finite-fan rows have been displayed.

Finally use the carrier non-escape clauses built into the same obligations. Since countable choice, open-cover compactness, quotient stream equality, selected branch data, and ambient Real completeness are not coordinates of $K = (B, T, I, W, R, M, E, H, C, P, N)$, they cannot replace the finite dependency route. □

The same finite fan-theorem dependency route is consumed by the Real-facing equality-modulus lattice of chapter 7601: barred-spread and fan finite-depth data supply the modulus handoff before that consumer reads $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and terminal $\mathsf{Real}^{\uparrow}$ rows.

Chapter 5133

A Concrete Naming Certificate for $\mathsf{DyadicGridProjection}^{\uparrow}$

Following Bishop and Bridges on constructive real approximation by rational grids, the $\mathsf{DyadicGridProjection}^{\uparrow}$ packet records the finite operation that projects a displayed real observation onto adjacent dyadic endpoints at a requested unary precision. It sits after the rational denominator discipline of chapter 291, the regular Cauchy readback of chapter 301, the real-name seal of chapter 38, and the dyadic rounding surface of chapter 433. The packet gives L10 Real and Completion routes a constructive grid object without importing host rounding, trichotomy, quotient reals, selected limits, or ambient completeness.

Definition 5133.1 (Dyadic grid projection carrier)**.** *A* $\mathsf{DyadicGridProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (x, n, a, b, I, E, H, C, P, N)$$

with the following displayed rows:

1. *x is the source observation row, carrying the finite real-name or regular Cauchy read requested by the consumer.*
2. *n is the unary precision row, naming the dyadic scale at which the grid is inspected.*
3. *a and b are adjacent* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows at precision n.*
4. *I is the interval-containment row, displaying that the finite observation of x lies inside the closed dyadic window bounded by a and b.*
5. *E is the finite error-budget row, recording the tolerance consumed by the projection and the remaining budget available to downstream readback.*
6. *H records componentwise* hsame *transport for source observations, unary precision rows, dyadic endpoints, containment windows, error budgets, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay of the route*

$$x, n, a, b, I, E \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{DyadicGridProjection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicRounding}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicGridProjection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $x, n, a, b, I, E, H, C, P, N$. It has no coordinate for host rounding, trichotomy on rationals, quotient real equality, selected Cauchy limits, or ambient completeness.

Lean4 ✓ `BEDC.Derived.DyadicGridProjectionUp.DyadicGridProjectionTasteGate single carrier alignment`

Theorem 5133.2 (Dyadic grid projection endpoint coverage)**.** *For every accepted* $\mathsf{DyadicGridProjection}^{\uparrow}$ *carrier* $G = (x, n, a, b, I, E, H, C, P, N)$*, the endpoint rows* a *and* b *are exposed as adjacent* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints at the displayed unary precision* n*, and the containment row* I *is read only through that adjacent pair. Hence a consumer receives a finite dyadic window covering the displayed source observation* x *without a host rounding operator or trichotomy oracle.*

Proof. Project the carrier of Definition 5133.1. The only endpoint coordinates are a and b, and their role is fixed by the displayed unary precision row n.

The containment row I is listed after the endpoint rows, so it can be read only as a finite interval statement over the same adjacent dyadic pair. The finite error budget E records the tolerated projection loss but does not add a selector for an exact host representative.

Transport, replay, provenance, and local naming preserve the same rows. Since the carrier has no coordinate for host rounding, rational trichotomy, quotient real equality, selected limits, or ambient completeness, the coverage exported by the packet is exactly the displayed finite endpoint window. □

Theorem 5133.3 (Dyadic grid projection regular-real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicGridProjection}^{\uparrow}$ *packet must factor through the finite route*

$$x, n, a, b, I, E \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff may use the displayed dyadic endpoints, containment row, and remaining finite error budget, but it cannot replace them by quotient reals, selected limits, or an ambient completeness theorem.

Proof. Start with the source observation x and unary precision n. The packet exposes adjacent dyadic endpoints a, b and the interval-containment row I before any regular Cauchy or real-name consumer reads the projection.

The finite error budget E is the only tolerance ledger carried across the handoff. A $\mathsf{RegSeqRat}^{\uparrow}$ read therefore receives a displayed dyadic window and budget rather than a selected representative of a quotient stream.

Finally the $\mathsf{Real}^{\uparrow}$ seal can consume only the same finite data through H, C, P, N. The carrier supplies no host limit selection or completeness principle, so the regular-real handoff remains a finite NameCert route. □

Falsifiable prediction: Every accepted $\mathsf{DyadicGridProjection}^{\uparrow}$ read displays one source-observation row, one unary precision row, two adjacent $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows, one interval-containment row, one finite error-budget row, and local transport, replay, provenance, and naming rows before it is consumed by a regular Cauchy or Real route.

Independence witness: dyadicratcore, dyadicrounding, regseqrat, real: $\mathsf{DyadicGridProjection}^{\uparrow}$ is not bijective to any listed sibling because it binds a source observation, unary precision, adjacent dyadic endpoints, interval containment, finite error budget, componentwise hsame, displayed Cont, Pkg, and local $\mathsf{NameCert}$ into one accepted projection packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicGridProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicGridProjection}^{\uparrow}$ packet is generated from a source observation, unary precision, adjacent DyadicRatCore endpoints, interval containment, finite error budget, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicGridProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5133.1, Definition 5133.2, and Definition 5133.3 seed the finite dyadic grid-projection route over DyadicRatCore, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicGridProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host rounding, rational trichotomy, quotient real equality, selected limits, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-observation admission, unary precision handling, adjacent dyadic endpoint coverage, interval containment, finite error-budget transport, replay, provenance, and local naming for BEDC.Derived.DyadicGridProjectionUp.

Chapter 5134

A Concrete Naming Certificate for $\mathsf{RegularCauchyRoundingProjection}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy approximation by finite rational data, the RegularCauchyRoundingP packet records the finite dyadic projection surface used when compact-uniform-continuity routes pass from finite nets to real-name observations. It grounds the compact finite-net discussion of chapter 9237 in the cofinal tail windows of chapter 4060, the dyadic denominator discipline of chapter 291, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet exposes finite projection data only; it does not import quotient streams, selected limits, countable choice, or ambient real completeness.

Definition 5134.1 (Regular Cauchy rounding projection carrier)**.** *A* $\mathsf{RegularCauchyRoundingProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (q, W, D, R, T, S, H, C, P, N)$$

with the following displayed rows:

1. *q is the requested compact-uniform tolerance row, expressed as a finite precision demand.*
2. *W is the* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *tail-window row selected for that demand.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *grid row used to round the finite window into dyadic endpoints.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after the window and dyadic grid are displayed.*
5. *T is the cofinal tail-stability row, recording that later accepted tail windows factor through the same finite projection data.*
6. *S is the* $\mathsf{Real}^{\uparrow}$ *seal-handoff row, exposing only the finite regular Cauchy read and remaining tolerance.*
7. *H records componentwise* hsame *transport for tolerance requests, cofinal windows, dyadic grids, regular readback, tail stability, Real seals, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay of the route*

$$q, W, D \longmapsto R, T \longmapsto S \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyRoundingProjection}^{\uparrow}$, $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *compact finite-net rows,* BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyRoundingProjection}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $q, W, D, R, T, S, H, C, P, N$. It has no coordinate for quotient Cauchy stream equality, selected limits, countable choice, host rounding, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyRoundingProjectionUp.RegularCauchyRoundingProjectionTasteGate`
`single carrier alignment`

Theorem 5134.2 (Regular Cauchy rounding projection cofinal-window dependency)**.** *Every compact-uniform-continuity or* $\mathsf{RealSeparability}^{\uparrow}$ *consumer that uses a* $\mathsf{RegularCauchyRoundingProjection}^{\uparrow}$ *packet must first read the cofinal-window route of chapter 4060. Only after that route is displayed may the consumer read the* $\mathsf{DyadicRatCore}^{\uparrow}$ *grid row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{Real}^{\uparrow}$ *seal row of Definition 5134.1.*

Proof. Project the carrier. The cofinal-window row W precedes the dyadic grid, regular readback, tail-stability, and Real seal rows in the displayed packet.

A compact-uniform-continuity or $\mathsf{RealSeparability}^{\uparrow}$ consumer therefore cannot reach D, R, or S without first citing the cofinal-window chapter named by W. The remaining structural rows H, C, P, N replay and name the same route, so they do not create a bypass around the cofinal-window dependency. □

Theorem 5134.3 (Regular Cauchy rounding projection finite coverage)**.** *For every accepted* $\mathsf{RegularCauchyRoundingProjection}^{\uparrow}$ *carrier $Q = (q, W, D, R, T, S, H, C, P, N)$, the requested tolerance row q is covered by a displayed cofinal window W and a displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *grid row D before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is exported. Thus compact finite-net consumers receive a finite dyadic projection surface rather than a host rounding operation.*

Proof. Project the carrier of Definition 5134.1. The rows preceding regular readback are exactly the tolerance request q, the cofinal window W, and the dyadic grid row D.

The readback row R is downstream of those finite rows. Therefore a compact finite-net consumer can cite a displayed dyadic projection for the requested tolerance, but cannot read R as a quotient stream representative or a host-rounded real.

The structural rows H, C, P, N preserve the same route. Since the carrier has no coordinate for quotient equality, selected limits, countable choice, host rounding, or completeness, finite coverage is the only exported projection claim. □

Theorem 5134.4 (Regular Cauchy rounding projection cofinal tail stability)**.** *If two accepted* $\mathsf{RegularCauchyRoundingProjection}^{\uparrow}$ *packets share the tolerance row q and their cofinal-window rows are later refined along the same* $\mathsf{RegularCauchyWindowCofinality}^{\uparrow}$ *route, then the tail-stability row T displays a common finite projection through which the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *grid reads and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks factor. The comparison does not require quotient stream equality, selected limits, countable choice, or ambient completeness.*

Proof. Read the two carrier projections through Definition 5134.1. Both packets expose the same tolerance request and cofinal-window route before their dyadic grid and regular readback rows are consumed.

Use the tail-stability row T. It records the finite later-window factorization for the displayed cofinal route, so the dyadic grid rows and regular readback rows can be compared through a common finite projection.

The argument remains within $q, W, D, R, T, S, H, C, P, N$. No quotient stream equality, selected limit, countable-choice selector, host rounding operator, or ambient completeness theorem is present in the carrier. □

Theorem 5134.5 (Regular Cauchy rounding projection Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyRoundingProjection}^{\uparrow}$ *packet must factor through the finite route*

$$q, W, D \longmapsto R, T \longmapsto S \longmapsto \mathsf{Real}^{\uparrow}.$$

The Real-facing seal receives the displayed regular Cauchy readback, cofinal tail-stability row, and remaining finite tolerance only.

Proof. Start with the displayed route in the carrier. The tolerance request, cofinal window, and dyadic grid rows are read before R and T, so the Real-facing row cannot bypass the finite projection surface.

The seal-handoff row S is listed after regular readback and tail stability. It therefore packages exactly the finite regular Cauchy projection and remaining tolerance available to $\mathsf{Real}^{\uparrow}$.

Transport, replay, provenance, and local naming do not add endpoint principles. The consumer receives a finite seal handoff, not quotient real equality, selected limits, countable choice, host rounding, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyRoundingProjection}^{\uparrow}$ read displays one tolerance row, one cofinal tail-window row, one $\mathsf{DyadicRatCore}^{\uparrow}$ grid row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one tail-stability row, one $\mathsf{Real}^{\uparrow}$ seal-handoff row, and local transport, replay, provenance, and naming rows before it is consumed by a compact-uniform route.

Independence witness: regular-cauchy-window-cofinality, dyadicratcore, regseqrat, real: RegularCauchyRounding is not bijective to any listed sibling because it binds a compact-uniform tolerance request, cofinal tail window, dyadic grid row, regular Cauchy readback, tail stability, Real seal handoff, componentwise hsame, displayed Cont, Pkg, and local NameCert into one finite projection packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRoundingProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyRoundingProjection}^{\uparrow}$ packet is generated from a compact-uniform tolerance request, a RegularCauchyWindowCofinality tail window, a DyadicRatCore grid row, RegSeqRat readback, cofinal tail stability, a Real seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyRoundingProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5134.1, Definition 5134.3, Definition 5134.4, and Definition 5134.5 seed the finite regular-Cauchy rounding projection route over cofinal windows, dyadic grids, RegSeqRat readback, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyRoundingProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy stream equality, selected limits, countable choice, host rounding, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked tolerance admission, cofinal-window selection, dyadic grid projection, RegSeqRat readback, tail stability, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyRo

Chapter 5135

A Concrete Naming Certificate for $\mathsf{FiniteDifference}^{\uparrow}$

Following Newton and standard finite-difference calculus, the $\mathsf{FiniteDifference}^{\uparrow}$ packet records finite stencil evaluation as displayed BEDC window data rather than as a host derivative or a completed real-function equality. It sits over the real-name boundary of chapter 38, the derivative-facing route of chapter 122, the calculus boundary of chapter 3632, the Taylor consumer of chapter 5898, the dyadic tolerance ledger of chapter 291, the finite stream interface of chapter 126, and the regular rational readback of chapter 301. The packet supplies derivative, calculus, and Taylor consumers with a finite-difference surface; it does not claim host differentiability, an infinite function object, quotient real equality, Real completeness, selected limits, or a Taylor remainder theorem.

Definition 5135.1 (Finite difference carrier)**.** *A* $\mathsf{FiniteDifference}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, H_0, L, D, Q, R, E, B, T, C, P, N)$$

with the following displayed rows:

1. *S is the source-function window row, listing the finite input-output observations read from a* $\mathsf{StreamName}^{\uparrow}$ *source.*
2. *H_0 is the step-history row, recording the displayed base point, step requests, mesh refinements, and endpoint reuse schedule.*
3. *L is the finite stencil row, naming the inspected offsets, coefficients, order tag, and normalization denominator.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for step-size, coefficient, and denominator budgeting.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational stencil sum and its finite error ledger.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q has been read.*
7. *E is the consumer-boundary row for* $\mathsf{Derivative}^{\uparrow}$*,* $\mathsf{Calculus}^{\uparrow}$*, and* $\mathsf{TaylorTheorem}^{\uparrow}$*, exposing only the finite stencil route to those chapters.*
8. *B records componentwise* hsame *transport for the source windows, step history, stencil, dyadic tolerance, regular readback, Real seal, consumer boundary, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay of the finite route*

$$S, H_0, L \longmapsto D \longmapsto Q \longmapsto R \longmapsto E.$$

10. *C is the classifier row, comparing accepted packets only through the same displayed source windows, step history, stencil, tolerance, readback, Real seal, and consumer boundary.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteDifference}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, $\mathsf{TaylorTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDifference}^{\uparrow}}$ *row.*

The classifier has no coordinate for an ambient function space, a host derivative, a quotient real equality, a selected limit, a Taylor remainder object, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteDifferenceUp.FiniteDifferenceTasteGate single carrier alignment`

Theorem 5135.2 (FiniteDifferenceUp NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDifference}^{\uparrow}$ *carrier*

$$F = (S, H_0, L, D, Q, R, E, B, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteDifference}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *source-window admission for S, requiring every function value used by the stencil to be displayed as finite* $\mathsf{StreamName}^{\uparrow}$ *data;*
2. *step-history admission for H_0, requiring the base point, step, mesh-refinement, and endpoint-reuse schedule to be named before a stencil sum is read;*
3. *stencil admission for L, requiring offsets, coefficients, order tags, and denominators to be finite rows;*
4. *dyadic budgeting for D, requiring all step-size, coefficient, and denominator tolerance checks to pass through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
5. *regular rational readback for Q, requiring the finite stencil sum to pass through* $\mathsf{RegSeqRat}^{\uparrow}$ *before any real seal is exposed;*
6. *Real seal exposure for R, requiring every real-valued difference read to be downstream of Q;*
7. *derivative, calculus, and Taylor boundary exposure for E, requiring those consumers to see only the displayed finite stencil route;*
8. *transport, replay, classifier, provenance, and local naming through B, T, C, P, N, preserving exactly the same finite packet.*

No finite-difference obligation is stored outside these rows.

Proof. Project the carrier of Definition 5135.1. The source row S and step-history row H_0 are the only places where input values, base points, steps, mesh requests, and endpoint reuse can be read.

The stencil row L fixes the finite offsets, coefficients, order tag, and denominator. The dyadic row D then supplies the only tolerance budget for the displayed step and coefficient data.

The numerical readback must pass through Q before a real-facing consumer can inspect R. Thus the route exports a regular rational stencil read and then a terminal $\mathsf{Real}^{\uparrow}$ seal, not a host derivative or quotient real equality.

Finally E exposes the same finite route to $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, and $\mathsf{TaylorTheorem}^{\uparrow}$, while B, T, C, P, N transport, replay, compare, source, and name the same tuple. Since the carrier has no ambient function-space, selected-limit, Taylor-remainder, host-differentiability, or completeness coordinate, the listed rows exhaust the local naming surface. □

Theorem 5135.3 (FiniteDifferenceUp Taylor handoff)**.** *Every* $\mathsf{TaylorTheorem}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, *or* $\mathsf{Calculus}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteDifference}^{\uparrow}$ *packet receives only the displayed route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer first reads finite source-function windows and step history, then the finite stencil, then dyadic tolerance budgeting, then regular rational readback, and only then a terminal real seal. The handoff does not export host differentiability, an infinite function graph, a quotient-real equality, a selected limiting derivative, a Taylor remainder theorem, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 5135.2. They place every accepted read on the displayed rows $S, H_0, L, D, Q, R, E, B, T, C, P, N$.

A derivative-facing or calculus-facing consumer can therefore inspect only the source windows, step history, and finite stencil before a numerical budget is available. The dyadic row D supplies that budget, and the regular rational row Q is the only readback route from the stencil sum.

The Taylor-facing boundary is E, which is downstream of the same Q and R rows. Componentwise hsame transport and Cont replay preserve this order, while Pkg provenance and the local NameCert row name exactly the same finite packet.

The excluded differentiability, infinite-graph, quotient-equality, selected-limit, Taylor-remainder, and completeness claims are absent from the carrier and cannot be recovered from the handoff. □

Theorem 5135.4 (FiniteDifferenceUp regular-real handoff)**.** *Every accepted* $\mathsf{FiniteDifference}^{\uparrow}$ *packet*

$$F = (S, H_0, L, D, Q, R, E, B, T, C, P, N)$$

exposes a Real-facing finite-difference value only by first reading the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, and then the* $\mathsf{Real}^{\uparrow}$ *seal row* R*. A* $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, *or* $\mathsf{TaylorTheorem}^{\uparrow}$ *consumer cannot bypass this route through host differentiability, quotient real equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5135.1. The rows S, H_0, L display the source windows, step history, and stencil, but they do not yet expose a Real-facing value.

Apply Definition 5135.2. Its dyadic budgeting clause makes D the only tolerance row available for step-size, coefficient, and denominator checks. Its regular rational clause then makes Q the only readback row for the finite stencil sum before any real seal is public.

Now use Definition 5135.3. The consumer boundary E is downstream of the same D, Q, R chain, so derivative, calculus, and Taylor readers inherit the displayed route rather than a host derivative or selected limit.

The remaining rows B, T, C, P, N transport, replay, compare, source, and name the same packet. Since no carrier coordinate stores host differentiability, quotient real equality, selected limiting data, or ambient completeness, coordinate exhaustion leaves only the path $D \longmapsto Q \longmapsto R$ for Real-facing finite-difference values. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDifference}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDifference}^{\uparrow}$ packet is generated from source-function windows, step history, a finite stencil, DyadicRatCore tolerance budgeting, RegSeqRat readback, a RealUp seal, Derivative/Calculus/Taylor consumer boundaries, componentwise hsame transport, Cont replay, classifier routing, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteDifference}^{\uparrow}}$, seed)

Scope closed: Definition 5135.1, Definition 5135.2, and Definition 5135.3 seed the finite stencil evaluation surface over StreamName, DyadicRatCore, RegSeqRat, Real, Derivative, Calculus, Taylor, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteDifference}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host differentiability, infinite function objects, quotient real equality, selected limiting derivatives, Taylor remainder theorems, Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked source-window admission, step-history admission, stencil admission, dyadic budgeting, regular readback, Real sealing, consumer-boundary exposure, and transport/provenance/name exhaustion for BEDC.Derived.FiniteDifferenceUp.

Chapter 5136

A Concrete Naming Certificate for $\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}$

Following Horn and Johnson, *Matrix Analysis*, the $\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}$ packet records the finite matrix-analysis route by which a displayed matrix or finite-dimensional operator exposes an isolated eigen-window and a positive separation radius before any completed host spectrum is imported. It sits after the matrix carrier of chapter 49, the linear-map interface of chapter 48, the vector-space carrier of chapter 47, the spectral-radius boundary of chapter 2352, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite separation certificate for downstream perturbation and spectral-theorem routes; it does not choose eigenvectors, complete a spectrum, or identify a host operator with an ambient spectral object.

Definition 5136.1 (Finite-dimensional spectral-gap carrier)**.** *A* $\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, T, V, E, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the square* $\mathsf{Mat}^{\uparrow}$ *row, exposing the finite entry table and shape ledger.*
2. *T is the* $\mathsf{LinMap}^{\uparrow}$ *or finite operator row read from M over the displayed* $\mathsf{VecSpace}^{\uparrow}$ *source V.*
3. *V is the finite-dimensional* $\mathsf{VecSpace}^{\uparrow}$ *row, carrying the basis-window and scalar-action data used by the matrix/operator comparison.*
4. *E is the finite eigen-window row. It lists the displayed candidate eigenvalue cells, multiplicity tags when present, and the matrix-action comparison rows used to test each cell.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *separation-radius row, recording a positive dyadic distance between the distinguished eigen-window and every other displayed spectral window.*
6. *R is the* $\mathsf{SpectralRadius}^{\uparrow}$ *bound row, exposing the radius or norm-growth boundary used to keep the displayed windows inside the same finite operator packet.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the gap radius and the accepted eigen-window endpoints.*
8. *H records componentwise* hsame *transport for M, T, V, E, D, R, S and the structural rows.*

9. *C records displayed* Cont *replay of the route*

$$\mathsf{Mat}^{\uparrow}, \mathsf{LinMap}^{\uparrow}, \mathsf{VecSpace}^{\uparrow}, \mathsf{SpectralRadius}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto E, D, R, S \longmapsto \mathsf{FiniteDimensionalSpectralGap}^{\uparrow}.$$

10. *P is the* Pkg *provenance over* $\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, T, V, E, D, R, S, H, C, P, N$. It has no coordinate for a completed host spectrum, selected eigenvectors, spectral projections, Schur or Jordan form, quotient equality of matrices, ambient compactness, or choice.

Lean4 ✓ `BEDC.Derived.FiniteDimensionalSpectralGapUp.TasteGate.FiniteDimensionalSpectralGapTasteGate single carrier alignment`

Theorem 5136.2 (Finite-dimensional spectral-gap NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}$ *carrier*

$$G = (M, T, V, E, D, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *matrix/operator admission for the displayed* $\mathsf{Mat}^{\uparrow}$ *row M,* $\mathsf{LinMap}^{\uparrow}$ *row T, and* $\mathsf{VecSpace}^{\uparrow}$ *row V;*
2. *finite eigen-window admission through E, including only the displayed candidate cells and matrix-action comparison rows;*
3. *dyadic separation and real sealing through D and S, requiring the gap radius and eigen-window endpoints to be read from displayed dyadic and real-name rows;*
4. *spectral-radius compatibility through R, bounding the accepted windows inside the same finite operator packet without replacing them by a completed spectrum;*
5. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N.*

No spectral-gap obligation is stored outside these rows.

Proof. Project the carrier of Definition 5136.1. The matrix, operator, and vector-space rows M, T, V are the only source rows from which a consumer can read the finite-dimensional action.

The eigen-window obligation is the row E. It displays candidate cells and the corresponding action comparisons, so the packet exposes a finite windowed test rather than a selected eigenbasis or a host eigenspace.

The gap radius is read through D and S. The dyadic row records positive separation from the other displayed windows, and the real seal records the endpoint data that downstream consumers may inspect.

The spectral-radius row R supplies only a finite bound-facing boundary over the same operator packet. Together with H, C, P, N, it transports, replays, sources, and names the displayed surface, so the five listed rows exhaust the local certificate. □

Lean4 ✓ `BEDC.Derived.FiniteDimensionalSpectralGapUp.FiniteDimensionalSpectralGap namecert obligations`

Theorem 5136.3 (Finite-dimensional spectral-gap nonescape)**.** *Every spectral-gap read of an accepted* $\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}$ *packet factors through the route*

$$M, T, V \longmapsto E \longmapsto D, S \longmapsto R \longmapsto H, C, P, N.$$

Consequently the distinguished eigen-window and its separation radius remain inside the displayed finite matrix/operator packet. A downstream consumer receives no completed host spectrum, no selected eigenvector, no spectral projection, no Schur or Jordan decomposition, no quotient matrix equality, and no choice principle.

Proof. Start with an accepted packet $G = (M, T, V, E, D, R, S, H, C, P, N)$. Carrier projection first exposes the matrix row, the induced linear-map row, and the finite vector-space source.

The eigen-window row E is downstream of those rows. It can compare displayed candidate cells with the matrix action, but it cannot introduce an eigenvector selector or an ambient spectral set because neither appears as a carrier coordinate.

The separation data are then read through D and S. The positive dyadic radius and its real seal are attached to the same displayed window, so a consumer cannot detach the gap from the finite packet that produced it.

Finally the spectral-radius bound R and the structural rows H, C, P, N keep the readback within the same transported and replayed surface. Since the excluded spectral objects have no field in the packet, the route cannot escape to a host spectrum or a choice-based eigenvalue selection. □

Falsifiable prediction: Every accepted $\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}$ consumer exposes the matrix row, linear-map row, finite vector-space row, eigen-window row, dyadic separation row, spectral-radius bound row, RealUp seal, componentwise transport, replay, provenance, and local naming before reading a spectral-gap conclusion.

Independence witness: matrix, linearmap, vecspace, spectralradius, dyadicratcore, real: MatrixUp supplies finite entries without an eigen-window separation row; LinearMapUp supplies action rows without a named gap; VecSpaceUp supplies scalar and basis transport without spectral separation; SpectralRadiusUp supplies a radius boundary without isolating a window; DyadicRatCoreUp supplies rational tolerances without matrix action; RealUp seals endpoints without naming the finite spectral-gap packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}$ packet is generated from a displayed MatrixUp row, a LinearMapUp finite operator row, a VecSpaceUp source row, a finite eigen-window row, a DyadicRatCore separation-radius row, a SpectralRadiusUp bound row, a RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5136.1, Definition 5136.2, Definition 5136.3, the falsifiable prediction, and the independence witness seed the finite matrix spectral-gap packet and its nonescape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a completed host spectrum, selected eigenvectors, spectral projections, Schur or Jordan decomposition, quotient matrix equality, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked matrix/operator admission, finite eigen-window admission, dyadic separation, Real sealing, spectral-radius compatibility, transport, replay, provenance, and consumer nonescape for BEDC.Derived.FiniteDimensio

Chapter 5137

A Concrete Naming Certificate for $\mathsf{SpectralGap}^{\uparrow}$

Following Kato, the $\mathsf{SpectralGap}^{\uparrow}$ packet records spectral separation as a finite witnessed gap for bounded-operator and real-norm rows. It generalizes the matrix-level certificate of chapter 5136 while staying anchored in the operator surface of chapter 1644, the norm ledger of chapter 89, and the endpoint seal of chapter 38. The packet names only displayed separation data; it does not assert a spectral theorem, resolvent calculus, compactness of the spectrum, or a hidden eigenvector selection principle.

Definition 5137.1 (SpectralGap carrier)**.** *A* $\mathsf{SpectralGap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, B, N, R, S, \Delta, W, H, C, P, L)$$

with the following displayed rows:

1. *T is the source* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row naming the bounded operator whose spectrum-facing read is under inspection.*
2. *B is the boundedness ledger for T, including the operator-bound row and the finite replay path by which downstream consumers may inspect it.*
3. *N is the* $\mathsf{Norm}^{\uparrow}$ *row used to read operator and vector bounds through the displayed norm carrier.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *row naming the real endpoint surface on which separation bounds and positive-radius witnesses are sealed.*
5. *S is the finite spectral-side row listing the inspected spectral cluster, complementary spectral window, and allowed localization probes.*
6. *Δ is the positive gap row: a displayed real-norm lower bound separating S from its complement by a finite witness.*
7. *W is the finite witness row recording the endpoint comparisons, norm comparisons, and probe windows that certify the gap row Δ.*
8. *H stores componentwise* hsame *transport for bounded-operator, norm, real, spectral-side, gap, witness, continuation, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from the bounded-operator row through norm and real comparisons to the gap witness.*

10. *P is the* Pkg *provenance over* $\mathsf{SpectralGap}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteDimensionalSpectralGap}$ BHist, hsame, Cont, *and* NameCert *rows.*

11. *L is the local* $\mathsf{NameCert}_{\mathsf{SpectralGap}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, B, N, R, S, \Delta, W, H, C, P, L$. It has no coordinate for a global spectrum object, an unbounded operator, a chosen eigenbasis, a host Hilbert-space equality, a quotient of operators, or ambient classical spectral decomposition.

Theorem 5137.2 (SpectralGap NameCert obligation surface)**.** *For an accepted* $\mathsf{SpectralGap}^{\uparrow}$ *carrier $G = (T, B, N, R, S, \Delta, W, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{SpectralGap}^{\uparrow}}$ *surface consists exactly of five rows:*

1. *carrier admission for the displayed bounded-operator, norm, real, spectral-side, gap, witness, transport, replay, provenance, and local naming rows;*
2. *bounded-operator dependency through T, B, requiring every operator read to pass through* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *before any gap witness is consumed;*
3. *norm and real separation through N, R, Δ, W, requiring the positive gap to be read as a finite real-norm inequality;*
4. *finite-dimensional compatibility through the sibling* $\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}$ *route whenever the inspected packet specializes to a displayed finite-dimensional window;*
5. *no-escape from global spectral theorems, hidden eigenvector selection, host operator quotients, unbounded-operator data, and ambient classical decomposition.*

Thus every downstream consumer of the gap must read

$$T, B, N, R, S, \Delta, W, H, C, P, L$$

as one finite BHist *packet before exporting the local certificate.*

Proof. Project the accepted carrier. The bounded-operator rows T, B are the only source of operator data, while the norm and real rows N, R are the only source of numerical comparison data.

The positive separation is then read from Δ and W. These rows give a finite lower-bound witness and the endpoint, norm, and probe comparisons that certify it; they do not call on a global spectrum object.

For finite-dimensional windows, the packet factors through the sibling surface of chapter 5136. That route supplies the specialized matrix-level gap read, while the present carrier keeps the general bounded-operator and norm rows visible.

Finally H, C, P, L transport, replay, source, and name the same packet. Since no excluded host object appears among the coordinates, the five displayed rows exhaust the local $\mathsf{NameCert}_{\mathsf{SpectralGap}^{\uparrow}}$ obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{SpectralGap}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SpectralGap}^{\uparrow}$ packet is generated from bounded-operator, boundedness, norm, real, spectral-side, positive-gap, finite-witness, componentwise transport, continuation replay, provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SpectralGap}^{\uparrow}}$, seed)

Scope closed: Definition 5137.1 and Definition 5137.2 seed the finite bounded-operator spectral-gap surface over $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SpectralGap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close spectral theorem machinery, resolvent calculus, compactness of the spectrum, hidden eigenvector selection, Lean verification, or any standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, bounded-operator dependency, norm and real separation, finite-dimensional compatibility, transport, replay, provenance, and no-escape for BEDC.Derived.SpectralGapUp.

Chapter 5138

A Concrete Naming Certificate for $\mathsf{CauchyRootCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyRootCriterion}^{\uparrow}$ packet records the finite root-test convergence data by which a real series source enters the regular Cauchy root-test route before any endpoint seal is read. It sits beside the real-series carrier of chapter 1581, the regular root-test packet of chapter 1481, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The certificate names the constructive root criterion as displayed finite rows; it does not choose an infinite sum, import host completeness, or select a limit.

Definition 5138.1 (Cauchy root criterion carrier)**.** *A* $\mathsf{CauchyRootCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, Q, W, D, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{RealSeries}^{\uparrow}$ *source row, exposing the real-valued term stream only through the series packet.*
2. *Q is the root-bound witness row, recording a displayed dyadic bound below the unit scale and the finite entry index after which the bound is admitted.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *tail-window row used to inspect the term stream and partial-tail data named by A.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the precision cells, slack conversions, and comparison budgets used by the root-bound witness.*
5. *T is the* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *handoff row that turns Q, W, D into a regular Cauchy tail route.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after the root-test handoff has consumed the same tail windows and dyadic tolerance row.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational readback is displayed.*
8. *H records componentwise* hsame *transport for the source, root-bound, window, tolerance, handoff, readback, seal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from a root-bound request through $A, Q, W, D, T, R, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyRootCriterion}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RegularCauchyRootTest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRootCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host root-limit theorem, selected infinite sum, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyRootCriterionUp.CauchyRootCriterionTasteGate single carrier alignment`

Theorem 5138.2 (Cauchy root criterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRootCriterion}^{\uparrow}$ *carrier* $K = (A, Q, W, D, T, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyRootCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet,* $\mathsf{RealSeries}^{\uparrow}$ *source exposure, root-bound witness exposure, finite* $\mathsf{StreamName}^{\uparrow}$ *tail-window admission,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exactness,* $\mathsf{RegularCauchyRootTest}^{\uparrow}$ *handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.CauchyRootCriterionUp.CauchyRootCriterionNamecertObligations`

Proof. Project the accepted carrier of Definition 5138.1. The source, witness, window, tolerance, handoff, readback, seal, and structural rows are precisely $A, Q, W, D, T, R, E, H, C, P, N$.

The root-bound portion is read through Q, W, D. The bound and entry index are displayed by Q, the inspected tail data are displayed by W, and the tolerance comparisons are displayed by D.

The handoff row T is then forced through $\mathsf{RegularCauchyRootTest}^{\uparrow}$. It consumes the same windows and dyadic budget before any regular rational readback R can be exposed.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since no omitted coordinate exists for host root limits, selected sums, quotient equality, choice, trichotomy, or ambient completeness, these rows exhaust the local NameCert obligations. □

Theorem 5138.3 (Cauchy root criterion RealSeries handoff)**.** *Every* $\mathsf{RealSeries}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyRootCriterion}^{\uparrow}$ *packet reaches a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and then a* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$\mathsf{RealSeries}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegularCauchyRootTest}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the root criterion supplies downstream RealSeries and RealPowerSeries chapters with a finite convergence-test certificate, while exporting no host completeness theorem, selected infinite sum, quotient stream equality, countable-choice schedule, or detached Real seal.

Proof. Start with the source row A. It exposes only the real-series term surface and cannot by itself supply convergence, an infinite sum, or an endpoint.

Read the finite tail windows and dyadic tolerance ledger next. The rows W and D place every inspected root-bound request inside displayed StreamName and DyadicRatCore data.

Apply the regular root-test handoff row T. It is the only route from the root-bound witness to a regular Cauchy tail, and the readback row R is downstream of that handoff.

The terminal Real seal E is therefore reached only after R. Componentwise transport, displayed replay, provenance, and local naming preserve this order, so no consumer receives host completeness, a selected sum, quotient stream equality, choice data, or a detached seal. □

Falsifiable prediction: Every accepted $\mathsf{CauchyRootCriterion}^{\uparrow}$ endpoint read factors through a RealSeries source row, root-bound witness, finite StreamName tail windows, DyadicRatCore tolerance ledger, RegularCauchyRootTest handoff, RegSeqRat readback, RealUp seal, transport, replay, provenance, and local NameCert row.

Independence witness: realseries, regular-cauchy-root-test, streamname, dyadicratcore, regseqrat, real: no listed sibling supplies the whole eleven-row packet $K = (A, Q, W, D, T, R, E, H, C, P, N)$, because each sibling contributes only the source series, root-test handoff, finite windows, dyadic tolerance, regular readback, or endpoint seal while this packet binds them into one finite NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRootCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyRootCriterion}^{\uparrow}$ packet is generated from a RealSeries source row, root-bound witness, finite StreamName tail windows, DyadicRatCore tolerance ledger, RegularCauchyRootTest handoff, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRootCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5138.1, Definition 5138.2, and Definition 5138.3 seed the finite root-test convergence route from RealSeries data to regular rational readback and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRootCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host completeness, selected infinite sums, quotient stream equality, countable choice, trichotomy, RealPowerSeries convergence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, root-bound witness exactness, finite window coverage, dyadic tolerance exactness, root-test handoff, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRootCriterionUp.

$\mathsf{CauchySequentialCriterion}^{\uparrow}$ records the L10 finite Cauchy-window route consumed by chapter 301, chapter 126, and chapter 38; the child files below keep the NameCert body and sibling routes separate.

Chapter 5139

A Concrete Naming Certificate for $\mathsf{CauchySequentialCriterion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchySequentialCriterion}^{\uparrow}$ packet records the finite sequential Cauchy criterion consumed by the L10 Real and Completion phase before a terminal real-name or completion-facing handoff is read. It sits after the Cauchy-modulus space of chapter 5887, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal seal of chapter 38. The packet gives later Real and Completion consumers explicit finite Cauchy-window data rather than an informal convergence phrase. The gluing route of chapter 5899 consumes the same finite Cauchy-window data when two compatible local windows are glued before the $\mathsf{Real}^{\uparrow}$ seal.

Definition 5139.1 (Cauchy sequential criterion carrier)**.** *A* $\mathsf{CauchySequentialCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, W, R, D, E, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *row, carrying the modulus schedule that chooses windows for each displayed tolerance request;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *row, exposing the inspected stream entries and finite window boundaries;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, reading the inspected entries as regular rational data;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row, recording the tolerance and pairwise-distance arithmetic used by the Cauchy test;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the regular rational and dyadic rows have been displayed;*
6. *L is the sequential criterion ledger, binding tolerance requests to windows and pairwise tails;*
7. *H records componentwise* hsame *transport for $A, W, R, D, E, L, C, P, N$;*
8. *C records displayed* Cont *replay for the same window route;*
9. *P is the* Pkg *provenance over* $\mathsf{CauchySequentialCriterion}^{\uparrow}$, $\mathsf{CauchyModulusSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequentialCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, a selected host limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5139.2 (Cauchy sequential criterion window obligations)**.** *For the carrier of Definition 5139.1, the local* $\mathsf{NameCert}_{\mathsf{CauchySequentialCriterion}^{\uparrow}}$ *surface consists exactly of modulus admission through* A*, stream-window inspection through* W*, regular rational readback through* R*, dyadic tolerance checking through* D*, Real seal handoff through* E*, criterion-ledger binding through* L*, and structural transport, replay, provenance, and local naming through* H, C, P, N*.*

Proof. Project the carrier $K = (A, W, R, D, E, L, H, C, P, N)$. The Cauchy-modulus row A supplies the finite schedule, and W supplies the stream windows on which that schedule is inspected.

Read the arithmetic rows next. The regular rational row R and dyadic row D compare displayed tail entries at the requested tolerance, while the ledger L binds those comparisons to the same window schedule.

Finally the terminal seal and structural rows are replayed. The row E is downstream of the displayed regular rational and dyadic data, and H, C, P, N only transport, replay, source, and name the same finite route. Therefore the listed rows exhaust the NameCert obligations. □

Theorem 5139.3 (Cauchy sequential criterion tail-window stability)**.** *Let*

$$K = (A, W, R, D, E, L, H, C, P, N)$$

be an accepted $\mathsf{CauchySequentialCriterion}^{\uparrow}$ *packet. After discarding any finite initial* $\mathsf{StreamName}^{\uparrow}$ *window, the retained tail is still accepted by the same criterion whenever it keeps the displayed Cauchy modulus row* A*, the retained StreamName window* W_{tail}*, the RegSeqRat readback* R_{tail}*, the DyadicRatCore tolerance row* D_{tail}*, the Real seal row* E*, the criterion ledger* L_{tail}*, componentwise transport* H_{tail}*, replay* C_{tail}*, provenance* P*, and local naming row* N*.*

Thus every Real or Completion consumer of the tail handoff reads only the retained finite window route

$$A, W_{\mathrm{tail}}, R_{\mathrm{tail}}, D_{\mathrm{tail}}, E, L_{\mathrm{tail}}, H_{\mathrm{tail}}, C_{\mathrm{tail}}, P, N,$$

and receives no quotient stream equality, selected host limit, countable choice, trichotomy, host real equality, or ambient completeness principle.

Proof. Project the accepted carrier K. The sequential criterion is stored in the displayed modulus schedule A, the inspected StreamName window W, the RegSeqRat readback R, the dyadic tolerance row D, and the ledger L.

Discarding a finite initial window changes only which displayed tail cells are retained. By hypothesis the retained packet still carries the same modulus row and the corresponding tail rows $W_{\mathrm{tail}}, R_{\mathrm{tail}}, D_{\mathrm{tail}}, L_{\mathrm{tail}}$, so the criterion is read from the retained finite windows and the displayed modulus ledger.

The structural rows are retained with the tail. Componentwise hsame transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ naming therefore preserve the same finite route through the Real seal rather than adding a completion object.

The carrier has no coordinate for quotient stream equality, selected host limits, countable choice, trichotomy, host real equality, or ambient completeness. The tail-window packet consequently remains inside the same accepted $\mathsf{CauchySequentialCriterion}^{\uparrow}$ surface. □

Theorem 5139.4 (Cauchy sequential criterion Real handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CauchySequentialCriterion}^{\uparrow}$ *packet must read*

$$A, W, R, D, E, L, H, C, P, N$$

before treating a sequential Cauchy claim as a real-facing or completion-facing handoff. The handoff factors through BHist, hsame, Cont, Pkg, CauchyModulusSpace$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* Real$^{\uparrow}$ *seal rows; it exports no quotient stream, selected limit, countable choice, host real equality, or ambient completeness principle.*

Proof. Begin with the window obligations of Definition 5139.2. They require the modulus schedule, stream windows, regular rational readback, dyadic tolerance arithmetic, and criterion ledger to be displayed before the terminal seal is read.

The structural rows keep the handoff finite. Transport through H, replay through C, provenance through P, and local naming through N preserve the same rows rather than adding a host completion object.

Since the carrier has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, or ambient completeness, every Real or Completion consumer receives exactly the displayed Cauchy-window route. □

Falsifiable prediction: An accepted CauchySequentialCriterion$^{\uparrow}$ consumer that reaches a Real or Completion handoff without first exposing the modulus schedule, stream window, regular rational readback, dyadic tolerance, terminal Real seal, ledger, transport, replay, provenance, and naming rows refutes the carrier surface.

Independence witness: cauchy-modulus-space, streamname, regseqrat, dyadicratcore, real: the modulus-space packet supplies schedules without terminal sequence readback; StreamName supplies windows without regular rational arithmetic; RegSeqRat supplies readback without dyadic tolerance ledgers; DyadicRatCore supplies arithmetic without a sequential carrier; RealUp supplies the terminal seal without the criterion ledger. None is bijective to CauchySequentialCriterion$^{\uparrow}$.

Closure status for NameCert$_{\text{CauchySequentialCriterion}^{\uparrow}}$.

Constructive story: A CauchySequentialCriterion$^{\uparrow}$ packet is generated from a CauchyModulusSpace schedule, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance arithmetic, a RealUp seal, a sequential criterion ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate(NameCert$_{\text{CauchySequentialCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 5139.1, Definition 5139.2, Definition 5139.3, and Definition 5139.4 seed the finite sequential Cauchy-window route for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{CauchySequentialCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected host limits, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked modulus admission, stream-window inspection, regular rational readback, dyadic tolerance checking, Real seal handoff, ledger binding, transport, replay, provenance, and local naming for BEDC.Derived.CauchySequentialCriterionUp.

InactiveLayerQuotientDynamics$^{\uparrow}$ reads the orbit-state, weighted-path, inactive-layer, and trigger-boundary rows as a consumer of chapter 3393, chapter 818, chapter 3932, and chapter 1364.

Chapter 5140

A Concrete Naming Certificate for $\mathsf{InactiveLayerQuotientDynamics}^{\uparrow}$

The $\mathsf{InactiveLayerQuotientDynamics}^{\uparrow}$ packet realizes the zero-marker inactive-layer quotient dynamics of Definition 9462.1366 and Definition 9462.1368 as finite orbit-state NameCert data. It sits beside the DNA boundary-tile packet of chapter 3393, the finite trace evaluator of chapter 818, the Hilbert–Alexander blocker surface of chapter 3932, and the arity-ten BHist tuple capstone of chapter 1364. Those siblings expose boundary, finite evaluation, blocker, or tuple-capacity rows separately; this packet binds the six active orbit states, weighted path, inactive median layer, and active-inactive trigger boundary into one carrier.

Definition 5140.1 (Inactive-layer quotient dynamics carrier)**.** *An* $\mathsf{InactiveLayerQuotientDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (O, W, I, A, B, T, H, C, P, N)$$

with the following displayed rows:

1. *O is the six orbit-state row containing* AGR*,* Anchor_6*,* $\mathrm{StopStart}_6$*,* UUR*,* CUR*, and* CUY*;*
2. *W is the weighted quotient-path row, recording exactly the cross-orbit Hamming weights displayed in Definition 9462.1366;*
3. *I is the inactive median-layer row, carrying* $\mathrm{WYG} \cup \{\mathrm{AAG}, \mathrm{ACA}, \mathrm{UGG}\}$ *and its square-with-leaves graph;*
4. *A is the active-inactive interface row, exposing the two active gates and the inactive-square contact point;*
5. *B is the boundary-tile provenance row read from the DNA six-window boundary surface;*
6. *T is the trigger-boundary ledger, binding the weighted path and inactive layer before any zero-marker dynamics read is exported;*
7. *H records componentwise* hsame *transport for* $O, W, I, A, B, T, C, P, N$*;*
8. *C records displayed* Cont *replay for the orbit-state, inactive-layer, and trigger-boundary route;*
9. *P is the* Pkg *provenance over* $\mathsf{InactiveLayerQuotientDynamics}^{\uparrow}$*, the philosophy quotient-dynamics source, DNA boundary tiles, finite trace evaluation,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{InactiveLayerQuotientDynamics}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for an unlisted cross-orbit Hamming edge, stochastic biological semantics, quotient codon equality, hidden genome dynamics, or a host automaton oracle.

Theorem 5140.2 (Inactive-layer quotient dynamics obligations)**.** *For the carrier of Definition 5140.1, the local* $\mathsf{NameCert}_{\mathsf{InactiveLayerQuotientDynamics}^{\uparrow}}$ *surface consists exactly of orbit-state admission through* O*, weighted-path admission through* W*, inactive-layer admission through* I*, active-inactive interface admission through* A*, boundary-tile provenance through* B*, trigger-boundary binding through* T*, and structural transport, replay, provenance, and local naming through* H, C, P, N*.*

Proof. Project the carrier $Q = (O, W, I, A, B, T, H, C, P, N)$. The orbit row O displays the six states, and the weighted row W records the path and its cross-orbit weights.

Read the inactive and interface rows next. The row I displays the zero-marker inactive layer, while A identifies the active gates and contact point through which active and inactive reads meet.

The boundary and trigger rows bind the packet. The provenance row B keeps the construction on the DNA boundary-tile surface, and T requires the quotient path and inactive layer to be read together before dynamics are exported. Transport, replay, provenance, and naming then preserve the same finite inventory. □

Theorem 5140.3 (Inactive-layer quotient dynamics trigger boundary)**.** *Every accepted* InactiveLayerQuotientDynar *dynamics read factors through*

$$O, W, I, A, B, T, H, C, P, N.$$

In particular, a zero-marker inactive-layer read must expose the weighted six-state quotient path, the inactive square-with-leaves layer, the active gates, and the contact point before any trigger-boundary conclusion is read.

Proof. Use Definition 5140.2. It makes O, W, I, A the visible orbit, path, inactive-layer, and interface rows of the packet.

The trigger boundary is not independent of those rows. The row T binds the active and inactive surfaces after B has recorded the boundary-tile provenance, so a dynamics consumer cannot detach the inactive layer from the displayed quotient path.

Since the carrier has no unlisted cross-orbit edge, stochastic semantics, quotient codon equality, hidden dynamics row, or host automaton oracle, every accepted trigger-boundary read remains inside the displayed finite route. □

Falsifiable prediction: The weighted inactive-layer quotient path fails if a nonlisted cross-orbit Hamming edge is exhibited between two orbit states outside the displayed path rows O, W, I, A.

Independence witness: dna-window-six-boundary-tile, finite-trace-evaluator, hilbert-alexander-blocker, b-hist-deca-tuple-name-cert, metaciccriticalpath: none is bijective to $\mathsf{InactiveLayerQuotientDynamics}^{\uparrow}$ because each lacks at least one of the six orbit-state row, weighted quotient path, inactive square-with-leaves layer, active gate interface, and trigger-boundary ledger bound in this packet.

Closure status for $\mathsf{NameCert}_{\mathsf{InactiveLayerQuotientDynamics}^{\uparrow}}$.

Constructive story: An $\mathsf{InactiveLayerQuotientDynamics}^{\uparrow}$ packet is generated from six orbit states, weighted quotient-path rows, inactive median-layer rows, active-inactive interface rows, boundary-tile provenance, a trigger-boundary ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{InactiveLayerQuotientDynamics}^{\uparrow}}$, seed)

Scope closed: Definition 5140.1, Definition 5140.2, and Definition 5140.3 seed the finite inactive-layer quotient dynamics packet and its trigger boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{InactiveLayerQuotientDynamics}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim stochastic biological semantics, quotient codon equality, hidden genome dynamics, an unlisted cross-orbit Hamming edge, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked orbit-state admission, weighted-path admission, inactive-layer admission, active-inactive interface admission, trigger-boundary binding, transport, replay, provenance, and local naming for BEDC.Derived.InactiveLayerQuotientDynamicsUp.

The sibling dependency lattice for InactiveLayerQuotientDynamics$^{\uparrow}$ routes its boundary row through chapter 3393, its finite replay row through chapter 818, its blocker interface through chapter 3932, and its arity cap through chapter 1364. These routes keep the inactive-layer quotient dynamics packet tied to displayed DNA boundary, finite evaluation, blocker, and BHist tuple data before the trigger-boundary read is consumed.

Theorem 5140.4 (Inactive-layer quotient dynamics forward lattice)**.** *Every accepted* InactiveLayerQuotientDynamic *consumer that reads the trigger-boundary row must first expose the orbit-state row O, weighted quotient-path row W, inactive median-layer row I, active-inactive interface row A, boundary-tile provenance row B, trigger ledger T, componentwise transport H, replay row C, package provenance P, and local* NameCert *row N of Definition 5140.1. The boundary row is routed through chapter 3393, the finite replay row through chapter 818, and the blocker interface through chapter 3932 before the quotient-dynamics classifier may export a trigger-boundary read.*

Proof. Start with the carrier and obligation rows of Definition 5140.1 and Definition 5140.2. They make $O, W, I, A, B, T, H, C, P, N$ the complete displayed inventory of an accepted packet.

Apply the trigger-boundary theorem Definition 5140.3. It forces every dynamics read to pass through the weighted six-state quotient path, inactive square-with-leaves layer, active gates, contact point, and trigger ledger before a trigger-boundary conclusion is available.

Finally read the sibling lattice of the same hub. The DNA boundary-tile chapter supplies B, the finite trace evaluator supplies C, and the Hilbert–Alexander blocker supplies the blocker-facing interface cited by A, T. Thus the forward lattice is a carrier dependency route, not an isolated quotient-dynamics assertion. □

Chapter 5141

A Concrete Naming Certificate for $\mathsf{CauchyFilterModulus}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy completion, the $\mathsf{CauchyFilterModulus}^{\uparrow}$ packet names the finite modulus interface by which Cauchy-filter evidence becomes a regular rational handoff before a Real seal is read. It refines the filter surface of chapter 333, the basis generator of chapter 1501, and the regular rational route of chapter 301. Its consumer path also reads finite windows through chapter 126, dyadic ledgers through chapter 291, and the terminal seal boundary of chapter 38. The packet is a finite modulus surface for Cauchy-filter completion data; it is not a quotient filter, selected limit, countable-choice schedule, host equality comparison, ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, Lean verification row, or bridge certificate.

Definition 5141.1 (Cauchy filter modulus carrier)**.** *A* $\mathsf{CauchyFilterModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, B, G, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row whose displayed precision requests must be regularized.*
2. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *generator row. It names the finite basis elements and common-refinement witnesses used to inspect the requests in F.*
3. *G is the* $\mathsf{RegularCauchyFilter}^{\uparrow}$ *regularity row. It records the finite tail-basis test that turns the source request and basis witness into a regular Cauchy-filter read.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row reached only after F, B, G have been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It stores the requested dyadic scale, the smaller scale certified by G, and the comparison used by the regular readback.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row. It repacks the accepted windows and dyadic ledger as a regular rational sequence row.*
7. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal boundary visible only after F, B, G, S, D, R have been replayed.*
8. *H records componentwise* hsame *transport for the filter source, basis generator, regularity row, windows, dyadic ledger, regular readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a filter precision request through F, B, G, S, D, R, E in that order.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterModulus}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{RegularCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterModulus}^{\uparrow}}$ *row.*

The classifier compares accepted modulus packets only through the displayed route

$$F, B, G \longmapsto S, D, R, E \longmapsto H, C, P, N.$$

No carrier coordinate stores a quotient filter, selected limit, countable-choice schedule, host equality of filter values, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification row, or bridge certificate.*

Lean4 (definition) `BEDC.Derived.CauchyFilterModulusUp.CauchyFilterModulusUp`
Lean4 ✓ `BEDC.Derived.CauchyFilterModulusUp.CauchyFilterModulusTasteGate single carrier alignment`

Theorem 5141.2 (Cauchy filter modulus NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterModulus}^{\uparrow}$ *carrier*

$$M = (F, B, G, S, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyFilterModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Cauchy-filter source, basis generator, regularity row, window row, dyadic tolerance ledger, regular rational handoff, Real seal boundary, transport, replay, provenance, and local naming row;*
2. *source-to-basis routing, requiring each displayed filter precision request in F to read its finite basis witness from B before the regularity row is inspected;*
3. *regular filter modulus extraction, requiring G to name the finite tail-basis test and the scale comparison that make the requested filter read regular;*
4. *window and dyadic replay, requiring S, D to expose only the finite observations and dyadic budget attached to the same F, B, G route;*
5. *regular readback and Real handoff, requiring R to be read before the terminal* $\mathsf{Real}^{\uparrow}$ *boundary E is visible to completion-facing consumers;*
6. *transport and replay stability, requiring H and C to preserve the order F, B, G, S, D, R, E under componentwise* hsame *transport and displayed* Cont *replay;*
7. *provenance exhaustion, requiring P, N to name only this finite modulus interface and to export no quotient filter, selected limit, countable-choice schedule, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5141.1. The projection exposes exactly the source filter, finite basis row, regularity row, stream windows, dyadic ledger, regular rational readback, terminal seal, and structural rows H, C, P, N.

The source-to-basis route is fixed by row order. A precision request first reads F and then the finite basis witness supplied by B; the packet has no coordinate that can jump directly from a filter request to a regular sequence.

The regularity row G performs the modulus extraction. It names the finite tail-basis test and the scale comparison used to justify the regular Cauchy read, so the modulus is packet data rather than an ambient completeness or choice principle.

The replay row C then carries the same request through S, D, R, E. Transport in H preserves these displayed rows, while P, N source and name only the packet; therefore the excluded quotient, selected-limit, choice, host-equality, completeness, Lean-verification, and bridge-checking data are outside the local NameCert surface. □

Theorem 5141.3 (Cauchy filter modulus regular readback)**.** *Let*

$$M = (F, B, G, S, D, R, E, H, C, P, N)$$

be an accepted $\mathsf{CauchyFilterModulus}^{\uparrow}$ *carrier. Every displayed Cauchy-filter precision request factors through a finite regular readback route*

$$F \longmapsto B \longmapsto G \longmapsto S, D \longmapsto R.$$

Consequently the packet exports a $\mathsf{RegSeqRat}^{\uparrow}$ *row only after the source filter request has been witnessed by a basis row, checked by the regular Cauchy-filter row, and replayed through the finite window and dyadic tolerance rows.*

Proof. Start with a displayed precision request in F. The carrier exposes no direct $\mathsf{RegSeqRat}^{\uparrow}$ coordinate from F, so the request must first be read through the finite basis row B.

Next inspect G. This row attaches the basis witness to the regular Cauchy-filter test and records the smaller scale used by the modulus request.

The finite observations then pass through S and the dyadic comparison through D. These rows are tied to the same source and basis data by carrier projection and componentwise transport.

Finally R repacks the accepted finite observations and tolerance ledger as a regular rational sequence row. Thus the regular readback is exported only through the displayed route. □

Theorem 5141.4 (Cauchy filter modulus Real handoff)**.** *Every completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyFilterModulus}^{\uparrow}$ *carrier*

$$M = (F, B, G, S, D, R, E, H, C, P, N)$$

reaches the terminal seal E only through the finite route

$$F, B, G, S, D, R \longmapsto E \longmapsto H, C, P, N.$$

In particular, the consumer receives a Cauchy-filter source row, Cauchy-filter basis row, regular Cauchy-filter row, finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, componentwise transport, continuation replay, provenance, and local naming. It receives no selected limit, quotient filter, countable-choice schedule, host equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification row, or bridge certificate.*

Proof. Begin with a completion-facing or $\mathsf{Real}^{\uparrow}$-facing read named by P. Carrier projection restricts the consumer to the rows displayed in Definition 5141.1.

Apply Definition 5141.3. The precision request must pass through F, B, G, S, D, R before a regular rational readback is available.

The seal row E is placed after that regular readback route. A consumer therefore sees the terminal $\mathsf{Real}^{\uparrow}$ boundary only after the source filter, basis witness, regularity row, finite windows, dyadic ledger, and regular rational handoff have all been replayed.

The structural rows do not add analytic content. The transport row H, replay row C, provenance row P, and local naming row N preserve and name the displayed route, so selected limits, quotient filters, choice schedules, host equality, ambient real completeness, Lean verification, and bridge checking cannot enter through the seal boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterModulus}^{\uparrow}$ packet is generated from a CauchyFilter source row, a CauchyFilterBasis row, a RegularCauchyFilter regularity row, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5141.1, Definition 5141.2, Definition 5141.3, and Definition 5141.4 seed the finite modulus interface from Cauchy-filter evidence and basis requests to regular rational readback before the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient filters, countable choice, host equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-to-basis routing, regular filter modulus extraction, window and dyadic replay, regular readback, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyFilterModulusUp.

Chapter 5142

A Concrete Naming Certificate for $\mathsf{LocallyConvexCompletion}^{\uparrow}$

Following Bourbaki and Schaefer on locally convex completions, the $\mathsf{LocallyConvexCompletion}^{\uparrow}$ packet records the finite BEDC route by which a displayed locally convex source, a finite seminorm family, a Cauchy-filter row, and a uniform-completion handoff reach a completion seal. It sits after the locally convex surface of chapter 3386, the family-seminorm ledger of chapter 5868, the filter-completion route of chapter 2164, the uniform completion packet of chapter 3560, and the Cauchy-filter criterion of chapter 3885. The packet names completion only through displayed finite rows; it is not a Hahn–Banach theorem, not a selected dual, not a host quotient completion, and not an arbitrary-net completeness principle.

Definition 5142.1 (LocallyConvexCompletion carrier)**.** *A* $\mathsf{LocallyConvexCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, S, F, U, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *source row, exposing the vector-space, topological-vector-space, finite seminorm, and convex balanced neighbourhood data accepted by the source.*
2. *S is the finite seminorm-family ledger read through* $\mathsf{SeminormedSpace}^{\uparrow}$*, including the displayed family index, zero, triangle, scalar, induced uniform, and metric handoff rows.*
3. *F is the Cauchy-filter row for the locally convex uniformity generated by S, with its finite base, refinement, and Cauchy-obligation data displayed before completion is requested.*
4. *U is the* $\mathsf{UniformSpaceCompletion}^{\uparrow}$ *handoff row, available only after X, S, F have exposed the same local uniform route.*
5. *E is the completion seal row, recording the accepted locally convex completion name after the Cauchy-filter criterion and uniform-completion handoff have both been displayed.*
6. *H records componentwise* hsame *transport for the locally convex source, seminorm-family ledger, Cauchy-filter row, uniform-completion handoff, completion seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion request through X, S, F, U, E, H, P, N.*

8. *P is the* Pkg *provenance over* LocallyConvexCompletion$^{\uparrow}$, LocallyConvexSpace$^{\uparrow}$, SeminormedSpace$^{\uparrow}$, FrechetCompletion$^{\uparrow}$, UniformSpaceCompletion$^{\uparrow}$, CauchyFilterCompletionCriterion$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{LocallyConvexCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, S, F, U, E, H, C, P, N$. It has no coordinate for Hahn–Banach separation, a choice-selected dual, a quotient completion in a host category, arbitrary nets without displayed Cauchy data, or ambient completeness.

Lean4 ✓ `BEDC.Derived.LocallyConvexCompletionUp.LocallyConvexCompletionTasteGate single carrier alignment`

Theorem 5142.2 (LocallyConvexCompletion seminorm-filter obligations)**.** *For every accepted* LocallyConvexCompletion$^{\uparrow}$ *carrier $L = (X, S, F, U, E, H, C, P, N)$, the local* NameCert$_{\text{LocallyConvexCompletion}^{\uparrow}}$ *surface contains exactly the displayed source row X, finite seminorm-family ledger S, Cauchy-filter row F, uniform-completion handoff U, completion seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local naming N. Every completion-facing read must first expose the finite seminorm-family route and then the Cauchy-filter row generated by that family.*

Proof. Project the carrier of Definition 5142.1. Its public rows are precisely $X, S, F, U, E, H, C, P, N$, so any local NameCert read begins with the displayed locally convex source and the finite seminorm-family ledger.

The finite family induction is over the index row carried by S. The base read exposes the empty or initial finite family as a displayed uniform-neighbourhood request, and the extension step adds one seminorm row by routing zero, triangle, scalar, induced uniform, and metric obligations through the same SeminormedSpace$^{\uparrow}$ ledger.

After the family has been displayed, the Cauchy-filter row F records the completion request against that finite uniform route. The handoff U and seal E are downstream rows, while H, C, P, N transport, replay, source, and name the same packet. Since the excluded Hahn–Banach, dual-choice, host-quotient, arbitrary-net, and ambient-completeness coordinates are absent from the carrier, the listed rows exhaust the obligation surface. □

Theorem 5142.3 (LocallyConvexCompletion Cauchy seal)**.** *Every accepted* LocallyConvexCompletion$^{\uparrow}$ *completion seal factors through the displayed route*

LocallyConvexSpace$^{\uparrow}$, SeminormedSpace$^{\uparrow}$, CauchyFilterCompletionCriterion$^{\uparrow}$, FrechetCompletion$^{\uparrow}$, UniformSpaceCom

Consequently a downstream functional-analysis consumer may cite the locally convex completion only after the finite seminorm-family ledger, Cauchy-filter row, uniform-completion handoff, completion seal, transport, replay, provenance, and local naming rows have all been displayed.

Proof. Start with a public read of the completion seal E. By Definition 5142.1, the seal is not a primitive host point; it is a row reached after X, S, F, U have been displayed.

Use Definition 5142.2. The finite seminorm-family induction supplies the uniform route consumed by F, and the Cauchy-filter criterion keeps the completion demand tied to displayed Cauchy data.

The FrechetCompletion$^{\uparrow}$ and UniformSpaceCompletion$^{\uparrow}$ references are handoff rows rather than replacement completions. They record filter and uniform completion routes already bounded by X, S, F, while H, C, P, N preserve and name the same finite route.

Thus every accepted seal factors through the displayed packet. No row exports Hahn–Banach separation, a choice-selected dual, host quotient equality, arbitrary nets without Cauchy data, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{LocallyConvexCompletion}^{\uparrow}$ completion read factors through $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{SeminormedSpace}^{\uparrow}$, $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$, $\mathsf{FrechetCompletion}^{\uparrow}$, $\mathsf{UniformSpaceComp}$ componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: locally-convex-space, seminormed-space, frechet-completion, uniform-space-completion, cauchy-filter-completion-criterion: no listed sibling is bijective with $\mathsf{LocallyConvexCompletion}^{\uparrow}$ because this packet jointly carries a locally convex source, a finite seminorm-family ledger, a Cauchy-filter row, a uniform-completion handoff, a completion seal, transport, replay, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyConvexCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{LocallyConvexCompletion}^{\uparrow}$ packet is generated from a locally convex source row, a finite seminorm-family ledger, a Cauchy-filter row, a UniformSpaceCompletion handoff row, a completion seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyConvexCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5142.1, Definition 5142.2, and Definition 5142.3 seed the finite locally convex completion route over source, seminorm-family, Cauchy-filter, uniform-completion, seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyConvexCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Hahn–Banach separation, choice-selected duals, host quotient completion, arbitrary nets without displayed Cauchy data, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite seminorm-family induction, Cauchy-filter routing, uniform-completion handoff, completion-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocallyConvexCompletionUp.

Chapter 5143

A Concrete Naming Certificate for MetaCICNormalEndpointCut$^{\uparrow}$

The MetaCICNormalEndpointCut$^{\uparrow}$ packet realizes the normalization endpoint boundary of section 9386.4 as finite BEDC data. It sits beside the normalization frontier of chapter 892, the critical-path packet of chapter 765, the bounded normal-conversion bridge of chapter 3439, the subject-reduction discharge socket of chapter 719, and the normal-endpoint budget of chapter 4292. The packet records where candidate evidence, a finished-normal endpoint, an obstruction row, and a discharge socket must remain separated before a closed-normal consumer may read the endpoint.

Definition 5143.1 (MetaCICNormalEndpointCut carrier)**.** *A* MetaCICNormalEndpointCut$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, A, B, F, O, D, H, C, P, N)$$

with the following displayed rows:

1. *T is the empty-context typed closed-term row under discussion by the normalization frontier.*
2. *A is the candidate-evidence row, read through* MetaCICNormalizationFrontier$^{\uparrow}$ *before strong-normality or endpoint data may be consumed.*
3. *B is the bounded normal-computation row, recording the finite computation budget and the bounded-normal endpoint read by* BoundedNormalConversionBridge$^{\uparrow}$*.*
4. *F is the finished-normal endpoint row, available only after A and B have both been displayed.*
5. *O is the obstruction row retaining the fact that arbitrary closed typed terms are not admitted to the candidate interface without displayed evidence.*
6. *D is the* SubjectReductionDischargeSocket$^{\uparrow}$ *row, keeping beta-substitution, application-argument, lambda-domain, and Pi-domain discharge obligations separate from finished-normal endpoint data.*
7. *H records componentwise* hsame *transport for the closed-term, candidate, bounded-normal, finished-normal, obstruction, discharge-socket, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a closed-normal endpoint request through $T, A, B, F, O, D, H, P, N$.*
9. *P is the* Pkg *provenance over* MetaCICNormalEndpointCut$^{\uparrow}$*,* MetaCICNormalizationFrontier$^{\uparrow}$*,* MetaCICCriticalPath$^{\uparrow}$*,* BoundedNormalConversionBridge$^{\uparrow}$*,* SubjectReductionDischargeSocket$^{\uparrow}$*,* MetaCICNormalEnd BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MetaCICNormalEndpointCut}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $T, A, B, F, O, D, H, C, P, N$. It has no coordinate for evidence-free strong normalization, erased discharge sockets, host conversion equality, quotient syntax equality, global confluence, or completed closed consistency.

Lean4 ✓ `BEDC.Derived.MetaCICNormalEndpointCutUp.MetaCICNormalEndpointCutTasteGate single carrier alignment`

Theorem 5143.2 (MetaCICNormalEndpointCut socket nonescape)**.** *For every accepted* MetaCICNormalEndpointC *carrier $K = (T, A, B, F, O, D, H, C, P, N)$, a consumer that reaches the finished-normal endpoint row F must still retain the obstruction row O and the discharge socket row D. In particular, erasing D before F is read leaves no valid route to the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalEndpointCut}^{\uparrow}}$ *surface.*

Proof. Project the carrier of Definition 5143.1. The finished-normal endpoint row F is not stored alone; it is one coordinate of the finite packet $T, A, B, F, O, D, H, C, P, N$.

The candidate and bounded-normal rows provide the positive endpoint route. The row A supplies candidate evidence through the normalization frontier, while B supplies bounded normal computation through the conversion bridge. The endpoint row F is available only after both rows have been displayed.

The obstruction and discharge rows record what remains outside that positive route. The row O blocks a read that treats every empty-context typed closed term as already inside the candidate interface, and D keeps the subject-reduction discharge obligations visible before consistency-facing consumers use the endpoint.

Finally H, C, P, N transport, replay, source, and name the entire packet. If D is erased before F is read, the replay row no longer reaches the displayed discharge socket, so the local NameCert route is incomplete. □

Falsifiable prediction: Any consumer erasing the $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ row before a finished-normal $\mathsf{MetaCICNormalEndpointCut}^{\uparrow}$ endpoint row lacks a valid NameCert route through candidate evidence, bounded-normal endpoint data, obstruction retention, transport, replay, provenance, and local naming.

Independence witness: metacicnormalizationfrontier, metaciccriticalpath, boundednormalconversionbridge, subjectreductiondischargesocket, metacicnormalendpointbudget: no listed sibling is bijective with $\mathsf{MetaCICNormalEndpointCut}^{\uparrow}$ because this packet jointly carries typed closed-term data, candidate evidence, bounded-normal computation, a finished-normal endpoint, an obstruction row, a discharge socket, transport, replay, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICNormalEndpointCut}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICNormalEndpointCut}^{\uparrow}$ packet is generated from an empty-context typed closed-term row, candidate evidence, bounded-normal computation, a finished-normal endpoint, obstruction retention, a subject-reduction discharge socket, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICNormalEndpointCut}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5143.1 and Definition 5143.2 seed the finite normal-endpoint cut separating candidate evidence, finished-normal endpoint data, obstruction retention, and the subject-reduction discharge socket.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICNormalEndpointCut}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim evidence-free strong normalization, erased discharge sockets, host conversion equality, quotient syntax equality, global confluence, completed closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate evidence exposure, bounded-normal endpoint routing, finished-normal endpoint sealing, obstruction retention, discharge-socket nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICNormalEndpointCutUp.

The ExteriorAlgebra$^{\uparrow}$ hub routes the finite tensor-word source of **??** toward the alternating-form consumers displayed by chapter 136 and chapter 137.

Chapter 5144

A Concrete Naming Certificate for $\mathsf{ExteriorAlgebra}^{\uparrow}$

Following Bourbaki and Mac Lane, the $\mathsf{ExteriorAlgebra}^{\uparrow}$ packet records the alternating algebra generated by a displayed module or vector-space carrier through finite tensor words with signed transposition refusals. It is grounded in the finite tensor-word source of **??**, the bilinear-form boundary of chapter 146, the module carrier of chapter 46, the vector-space specialization of chapter 47, and the quadratic-boundary comparison surface of chapter 147. The packet is a BEDC NameCert carrier for alternating finite words and wedge multiplication; it is not a host quotient algebra, a basis-dependent determinant construction, or an ambient differential-form object.

The $\mathsf{ExteriorAlgebra}^{\uparrow}$ carrier reads its alternating product rows through the tensor-product carrier of chapter 87 before quotient-like exterior relations are refused by the local alternating and signed-transposition ledgers.

Definition 5144.1 (Exterior algebra carrier)**.** *An* $\mathsf{ExteriorAlgebra}^{\uparrow}$ *carrier over a displayed* $\mathsf{Module}^{\uparrow}$ *row* V *and scalar* $\mathsf{Ring}^{\uparrow}$ *row* R *is a finite* BHist *packet*

$$E = (R, V, T, A, S, W, H, C, P, N)$$

with the following rows:

1. *R is the scalar source row and V is the module or vector-space source row whose carried endpoints supply the letters.*
2. *T is the consumed* $\mathsf{TensorAlgebra}^{\uparrow}$ *finite-word row over R and V.*
3. *A is the alternating ledger: whenever two adjacent letters are classifier-equal through the source row, the corresponding repeated-letter word is refused as a nonzero exterior word.*
4. *S is the signed adjacent-transposition ledger, recording that swapping two adjacent carried letters changes the exterior classifier by the displayed sign row.*
5. *W is the wedge product row, formed by concatenating two finite tensor words and then reading the result through the alternating and signed-transposition ledgers.*
6. *H records componentwise* hsame *transport for scalar rows, source letters, tensor words, alternating rows, signed-transposition rows, wedge products, and local classifiers.*
7. *C records displayed* Cont *replay from source endpoints through tensor-word formation, alternating reduction, signed transposition, and wedge multiplication.*

8. *P is the* Pkg *provenance over* ExteriorAlgebra$^\uparrow$, TensorAlgebra$^\uparrow$, BilinForm$^\uparrow$, Module$^\uparrow$, VecSpace$^\uparrow$, Clifford$^\uparrow$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{ExteriorAlgebra}^\uparrow}$ *row.*

The carrier exports only alternating finite tensor-word data. It introduces no quotient primitive, no selected basis, no determinant expansion, no ambient graded-commutative algebra object, and no differential-form endpoint.

Theorem 5144.2 (Exterior algebra NameCert obligations)**.** *For every accepted* ExteriorAlgebra$^\uparrow$ *carrier*

$$E = (R, V, T, A, S, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ExteriorAlgebra}^\uparrow}$ *surface consists exactly of scalar admission through R, module or vector-space endpoint admission through V, finite tensor-word admission through T, alternating repeated-letter refusal through A, signed adjacent-transposition transport through S, wedge multiplication through W, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier rows of Definition 5144.1. The scalar, source-letter, tensor-word, alternating, signed-transposition, and wedge rows are all displayed before a consumer receives an exterior word.

The tensor source is read through **??**. Thus every exterior word first appears as a finite tensor word, and only then passes through the alternating ledger A and the signed adjacent-transposition ledger S.

The structural rows close the certificate. Transport by H, replay by C, provenance by P, and naming by N preserve exactly the displayed packet. Because the carrier has no quotient coordinate, selected basis, determinant coordinate, host graded algebra, or differential-form endpoint, the listed rows exhaust the local NameCert surface. □

Theorem 5144.3 (Exterior algebra wedge alternation)**.** *Let x and y be carried degree-one letters in the same* ExteriorAlgebra$^\uparrow$ *carrier $E = (R, V, T, A, S, W, H, C, P, N)$. The wedge rows satisfy the displayed alternating boundary*

$$x \wedge x \sim_E 0$$

and the signed transposition boundary

$$x \wedge y \sim_E -y \wedge x$$

whenever the corresponding source-letter rows are accepted by V. These boundaries are read through the finite tensor-word row T, the alternating ledger A, the signed-transposition ledger S, and the wedge row W; they do not use a quotient algebra, a selected basis, or a host determinant identity.

Proof. First read x and y as carried source-letter rows of V. The tensor source T admits the length-two words $x \otimes x$, $x \otimes y$, and $y \otimes x$ as finite tensor words.

For the repeated-letter boundary, apply the alternating ledger A to the adjacent pair x, x. This row records that the repeated-letter word is classified with the zero exterior word before any ambient quotient is available.

For the mixed boundary, apply the signed adjacent-transposition ledger S to the two tensor words $x \otimes y$ and $y \otimes x$. The sign row is part of the same finite packet, so the comparison is a displayed classifier row rather than a host graded-commutativity theorem.

Finally use the wedge row W to identify each length-two tensor word as the product of the corresponding degree-one exterior words. Transport by H and replay by C keep the source letters, tensor words, alternating rows, sign rows, and wedge products inside the same local NameCert packet. □

Theorem 5144.4 (Exterior algebra tensor-product dependency route)**.** *Every* $\mathsf{ExteriorAlgebra}^{\uparrow}$ *wedge read first consumes the alternating quotient-free tensor route from chapter 87 and the bilinear or alternating witness surface from chapter 146. Only after those sibling rows are displayed may the local carrier*

$$E = (R, V, T, A, S, W, H, C, P, N)$$

read its wedge row W *and local* $\mathsf{NameCert}_{\mathsf{ExteriorAlgebra}^{\uparrow}}$ *row* N*. The alternation row is a finite classifier row on tensor words, not a quotient of tensors.*

Proof. Project the exterior carrier of Definition 5144.1. The rows R, V, T give the scalar source, the module or vector-space source, and the finite tensor-word source before any wedge product is read.

The tensor-product source of wedge multiplication is the row T. The chapter therefore consumes the sibling tensor route of chapter 87 before W can concatenate tensor words and return an exterior product.

The alternating witness surface is supplied by A and S, with bilinear provenance recorded in P through chapter 146. These rows classify repeated letters and adjacent transpositions as finite packet data; they do not form a tensor quotient.

Finally H, C, P, N transport, replay, source, and name the same dependency route. Thus every accepted wedge read uses the tensor-product and bilinear-form sibling surfaces before the local exterior certificate is read. □

Falsifiable prediction: A consumer requesting an exterior product must expose the tensor-word row, alternating ledger, signed-transposition ledger, wedge row, transport, replay, provenance, and local naming rows; a request that supplies only a host quotient algebra is rejected by this certificate.

Independence witness: tensor-algebra, bilinform, module, vecspace, clifford: $\mathsf{ExteriorAlgebra}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries alternating finite tensor words, repeated-letter refusal, signed adjacent-transposition rows, wedge multiplication, transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{ExteriorAlgebra}^{\uparrow}}$**.**

Constructive story: An $\mathsf{ExteriorAlgebra}^{\uparrow}$ packet is generated from scalar RingUp rows, ModuleUp or VecSpaceUp endpoint rows, finite TensorAlgebraUp word rows, alternating repeated-letter refusals, signed adjacent-transposition rows, wedge-product rows, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ExteriorAlgebra}^{\uparrow}}$, seed)

Scope closed: Definition 5144.1, Definition 5144.2, and Definition 5144.3 seed the finite alternating tensor-word NameCert surface over tensor-algebra, bilinear-form, module, vector-space, and Clifford comparison rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ExteriorAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host quotient exterior algebras, determinant-basis formulas, differential-form sheaves, de Rham cohomology, or completed graded algebra structure.

Upgrade path: Obligation closure requires binding the displayed carrier, alternating ledger, signed-transposition ledger, wedge row, transport, replay, provenance, and local naming against their BEDC primitive scope.

The exterior-algebra alternating-form dependency route records the downstream form and cohomology consumers that read wedge rows from the local $\mathsf{ExteriorAlgebra}^{\uparrow}$ packet. It is a consumer edge, not a second exterior-algebra carrier.

Theorem 5144.5 (Exterior algebra alternating-form dependency route)**.** *Every* $\mathsf{DiffForm}^{\uparrow}$ *or* $\mathsf{DeRham}^{\uparrow}$ *consumer that reads alternating form rows, wedge products, or exterior-derivative wedge ladders must first read* $\mathsf{ExteriorAlgebra}^{\uparrow}$ *through* $\mathsf{TensorAlgebra}^{\uparrow}$*, the displayed* $\mathsf{Module}^{\uparrow}$ *or* $\mathsf{VecSpace}^{\uparrow}$ *source rows, the alternating ledger, signed-transposition ledger, wedge row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{ExteriorAlgebra}^{\uparrow}}$ *row. The route exports no host quotient exterior algebra, selected basis, determinant expansion, ambient differential-form sheaf, de Rham quotient class, or completed graded algebra object.*

Proof. Start with the carrier of Definition 5144.1. Its only exterior words are finite $\mathsf{TensorAlgebra}^{\uparrow}$ words over the displayed $\mathsf{Module}^{\uparrow}$ or $\mathsf{VecSpace}^{\uparrow}$ source rows, and its only alternating operations are the repeated-letter ledger A, signed-transposition ledger S, and wedge row W.

Apply the wedge alternation theorem Definition 5144.3. It forces the degree-one repeated-letter and signed-transposition boundaries to be read through T, A, S, W, H, C, P, N rather than through a host quotient algebra or determinant coordinate.

Now inspect the consumers. The $\mathsf{DiffForm}^{\uparrow}$ root threshold of chapter 136 routes form reads through carried form rows and wedge thresholds, while the $\mathsf{DeRham}^{\uparrow}$ chapter chapter 137 consumes those carried $\mathsf{DiffForm}^{\uparrow}$ rows for the exterior-derivative chain-complex boundary. Thus any alternating-form or cohomology-facing read that uses wedge data must pass through the displayed exterior-algebra rows before it reaches the differential-form or de Rham surface.

The excluded objects are absent from all three displayed packets. The exterior carrier contains no host quotient algebra, selected basis, determinant expansion, differential-form sheaf, de Rham quotient class, or completed graded algebra row, and the DiffForm/DeRham consumers read only the routed form and cochain rows. Therefore the alternating-form dependency route is exactly the stated finite NameCert route. □

Chapter 5145

A Concrete Naming Certificate for $\mathsf{FiniteWindowCompactness}^{\uparrow}$

Following Bishop and Bridges on compact metric intervals and constructive finite covers, the $\mathsf{FiniteWindowCompactness}^{\uparrow}$ packet records compactness as explicit dyadic finite-net windows whose radius ledger can be consumed by compact-uniform-continuity. It realizes the finite-window route of chapter 9237 over the compact source of chapter 129, the metric rows of chapter 57, the dyadic tolerance arithmetic of chapter 291, the closed bounded interval route of chapter 1253, the finite lower-bound fold of chapter 4096, and the downstream uniform-modulus handoff of chapter 369. The packet names finite windows and ledger rows only; it does not import open-cover compactness, selected subcovers outside the displayed bundle, quotient point equality, ambient real completeness, Lean verification, or bridge checking.

Definition 5145.1 (FiniteWindowCompactness carrier)**.** *A* $\mathsf{FiniteWindowCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (K, M, D, I, G, L, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row exposing the compact metric witness through finite inspection data.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used to compare each displayed center with a requested point.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger containing the positive mesh scale and its tolerance comparisons.*
4. *I is the closed bounded interval or bounded compact source row when the packet is used over a real interval.*
5. *G is the finite window grid, a displayed* ProbeBundle *of dyadic centers with coverage witnesses.*
6. *L is the finite lower-bound fold row consumed after the window grid has exposed its positive candidate radii.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row that receives the tolerance-only modulus budget.*
8. *H records componentwise* hsame *transport for K, M, D, I, G, L, U and the structural rows.*
9. *C records displayed* Cont *replay from compact finite windows to the lower-bound fold and uniform-modulus handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteWindowCompactness}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteLowerBoundFold}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowCompactness}^{\uparrow}}$ *row.*

The carrier contains no arbitrary open-cover object, no selected subcover outside G, no quotient point equality, no host finite minimum, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Lean4 (definition) `BEDC.Derived.FiniteWindowCompactnessUp.FiniteWindowCompactnessUp`
Lean4 ✓ `BEDC.Derived.FiniteWindowCompactnessUp.FiniteWindowCompactnessTasteGate single carrier alignment`

Theorem 5145.2 (FiniteWindowCompactness NameCert obligations)**.** *For every accepted* FiniteWindowCompactn *carrier*

$$W = (K, M, D, I, G, L, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteWindowCompactness}^{\uparrow}}$ *surface consists exactly of compact metric source exposure, metric distance readback, dyadic positive-radius admission, interval-source localization when present, finite window-grid coverage, lower-bound fold handoff, uniform-modulus delivery, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5145.1. The accepted packet exposes only the compact metric source, metric-distance row, dyadic radius ledger, optional interval source, finite grid, fold row, uniform-modulus row, and structural rows.

The grid row G is the finite inspection domain. Each center and coverage witness is read together with D, so the compactness consumer receives a dyadic window bundle rather than an arbitrary open cover.

The lower-bound row L is then read after the window candidates are visible. Its output is the only route into the uniform-modulus handoff U, while H, C, P, N preserve and name the same displayed route. □

Theorem 5145.3 (FiniteWindowCompactness uniform-modulus route)**.** *Every compact-uniform-continuity consumer that reads a* $\mathsf{FiniteWindowCompactness}^{\uparrow}$ *packet reaches* $\mathsf{UniformModulus}^{\uparrow}$ *only through*

$$K \to M \to D \to I \to G \to L \to U \to H \to C \to P \to N.$$

Thus the consumer must first inspect the compact metric source, the metric distance row, the dyadic finite-window ledger, the interval source when present, and the finite lower-bound fold before it receives a tolerance-only uniform-modulus row.

Proof. Start with an accepted carrier $W = (K, M, D, I, G, L, U, H, C, P, N)$. A compactness read begins at K, and any distance comparison needed by the window coverage row must pass through M.

The dyadic ledger D supplies positive mesh and tolerance comparisons. If the source is a closed bounded interval, the interval row I is read as the displayed boundary for the finite dyadic window.

The finite grid G then supplies the only centers and coverage witnesses available to the consumer. The lower-bound fold L reads those finite candidates and delivers the resulting precision to U.

The rows H, C, P, N transport, replay, source, and name the same route. Since no excluded host cover, selected subcover, quotient equality, host minimum, or ambient completeness coordinate occurs in the carrier, the displayed chain exhausts the uniform-modulus access path. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteWindowCompactness}^{\uparrow}$ packet is generated from a CompactMetricUp source row, a MetricUp distance row, a DyadicRatCoreUp radius ledger, an optional closed bounded interval row, finite ProbeBundle window grids, a FiniteLowerBoundFoldUp row, a UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteWindowCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5145.1, Definition 5145.2, and Definition 5145.3 seed the finite dyadic window route from compact metric data to uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteWindowCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers outside the displayed window, quotient point equality, host finite minima, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact source exposure, dyadic radius admission, finite grid coverage, lower-bound fold delivery, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteWindowCo

Chapter 5146

A Concrete Naming Certificate for $\mathsf{Rademacher}^{\uparrow}$

Following Rademacher's differentiability theorem for Lipschitz maps, the $\mathsf{Rademacher}^{\uparrow}$ packet records only the finite dyadic-window derivative-candidate data that a BEDC consumer may inspect before any measure-theoretic almost-everywhere conclusion is visible. It sits over the Lipschitz carrier of chapter 3762, the real-name seal of chapter 38, the dyadic tolerance core of chapter 291, the metric-space carrier of chapter 57, and the absolute-continuity route of chapter 3361. The packet names the finite frontier at which difference quotients, local Lipschitz bounds, dyadic radii, metric neighborhoods, and absolute-continuity control are displayed; it does not claim Lebesgue almost-everywhere differentiability, a measurable exceptional set, a selected derivative, an ambient measure algebra, or completion of a derivative space.

Definition 5146.1 (Rademacher carrier)**.** *A* $\mathsf{Rademacher}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (L, E, D, M, A, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LipschitzFunction}^{\uparrow}$ *row, exposing the source and target metric rows, graph ledger, Lipschitz bound, and distance-inequality route inspected by the packet.*
2. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the base point, output windows, and finite difference-quotient values read by downstream Real-facing consumers.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-radius and tolerance ledger. It records the dyadic radii, halved-radius refinements, and comparison budgets used to build the displayed derivative-candidate windows.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *neighborhood row for the source and target distance requests used by the Lipschitz and difference-quotient checks.*
5. *A is the* $\mathsf{AbsolutelyContinuousFunction}^{\uparrow}$ *control row, recording only the finite interval or curve-window budget that bounds the visible variation consumed by the derivative-candidate packet.*
6. *H records componentwise* hsame *transport for the Lipschitz row, Real seals, dyadic ledger, metric neighborhoods, absolute-continuity control, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a Rademacher-facing finite request through D, M, L, A, and finally into the terminal Real seal E.*

8. *P is the* Pkg *provenance over* Rademacher$^{\uparrow}$, LipschitzFunction$^{\uparrow}$, Real$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Met$^{\uparrow}$, AbsolutelyContinuousFunction$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{Rademacher}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, E, D, M, A, H, C, P, N$. It has no coordinate for Lebesgue almost-everywhere differentiability, measurable null sets, host derivative functions, quotient maps, selected pointwise derivatives, countable-choice schedules, ambient measure completion, or completed function spaces.

Theorem 5146.2 (Rademacher NameCert obligations)**.** *For every accepted* Rademacher$^{\uparrow}$ *carrier*

$$R = (L, E, D, M, A, H, C, P, N),$$

the local NameCert$_{\text{Rademacher}^{\uparrow}}$ *surface consists exactly of carrier admission, Lipschitz-row exposure, Real seal routing, dyadic endpoint-radius accounting, metric-neighborhood inspection, absolute-continuity control, componentwise transport, displayed replay, provenance, local naming, and non-escape from the displayed rows.*

Proof. Carrier admission is projection from Definition 5146.1. The visible analytic rows are L, E, D, M, A, and the visible support rows are H, C, P, N.

The derivative-candidate route is finite. The Lipschitz row supplies the graph and bound data, the dyadic ledger supplies the inspected radii and tolerances, and the metric row supplies the neighborhoods in which those finite requests are read.

The Real and absolute-continuity rows do not add a measure theorem. The Real row seals only the displayed numerical windows, while the absolute-continuity row records the finite variation-control budget used by those windows.

Finally H and C transport and replay the same coordinates, and P, N source and name the packet. Since no other coordinate occurs in the carrier, the NameCert surface exports none of the excluded measurable, derivative-selection, quotient, choice, completion, or ambient almost-everywhere data. □

Lean4 ✓ `BEDC.Derived.RademacherUp.TasteGate.RademacherTasteGate single carrier alignment`

Theorem 5146.3 (Rademacher Lipschitz metric scope)**.** *Every accepted* Rademacher$^{\uparrow}$ *carrier $R = (L, E, D, M, A, H, C, P, N)$ exposes the* LipschitzFunction$^{\uparrow}$ *row L and the* Met$^{\uparrow}$ *row M before any derivative-candidate read is admitted. The exposed scope includes the source and target distance requests, the Lipschitz graph ledger, the finite bound comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert$_{\text{Rademacher}^{\uparrow}}$ *row. It does not include a measure algebra, an almost-everywhere differentiability claim, a host derivative, quotient-point equality, or a completed function space.*

Proof. Project the accepted carrier through Definition 5146.1. The only rows that can supply metric data are the Lipschitz row L and the metric-neighborhood row M.

Apply Definition 5146.2. It lists carrier admission, Lipschitz-row exposure, metric-neighborhood inspection, transport, replay, provenance, and local naming as visible obligations, so every derivative-candidate request must pass through those rows before it reaches any Real-facing seal.

The structural rows H, C, P, N preserve and name the same finite scope. Since the carrier has no coordinate for measure algebras, almost-everywhere assertions, host derivatives, quotient equality, or completed function spaces, none of those objects can be imported through the Lipschitz and metric rows. □

Lean4 ✓ `BEDC.Derived.RademacherUp.RademacherCarrier lipschitz metric scope`

Theorem 5146.4 (Rademacher dyadic difference-quotient obligation)**.** *Every accepted* $\mathsf{Rademacher}^{\uparrow}$ *carrier exposes its difference-quotient windows through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback is consumed. The displayed window records endpoint radii, halved-radius refinements, dyadic comparison budgets, the matching Lipschitz and metric rows,* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming. No consumer may replace that finite window by an unbounded radius schedule, a selected derivative function, a measurable exceptional set, or host real equality.*

Proof. Start with the dyadic row D in Definition 5146.1. It records the endpoint-radius and tolerance ledger used to build the finite derivative-candidate windows.

Use Definition 5146.2. The obligation surface makes dyadic endpoint-radius accounting visible alongside Lipschitz-row exposure, metric-neighborhood inspection, Real seal routing, transport, replay, provenance, and local naming.

The finite-window induction is over the displayed dyadic ledger: each inspected radius and halved-radius refinement is replayed through C and transported through H before the terminal readback row is used. The provenance row P and local certificate N keep the same finite request attached to BHist.

Because no other row appears in the carrier, a consumer cannot obtain an unbounded schedule, selected derivative, exceptional-set algebra, or host real equality from the difference-quotient window. □

Lean4 ✓ `BEDC.Derived.RademacherUp.RademacherCarrier dyadic difference quotient obligation`

Theorem 5146.5 (Rademacher Real derivative handoff)**.** *Every Real-facing derivative-candidate read of an accepted* $\mathsf{Rademacher}^{\uparrow}$ *carrier reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *only after the finite route through* D, M, L, A, H, C, P, N *has been displayed. The handoff gives downstream consumers regular rational and Real readback for the visible derivative-candidate window, not a Lebesgue almost-everywhere theorem, not a selected derivative, not quotient equality, and not an ambient completeness statement.*

Proof. Project the carrier as $R = (L, E, D, M, A, H, C, P, N)$. The terminal Real seal row is E, and the rows feeding it are the dyadic ledger D, metric row M, Lipschitz row L, and absolute-continuity control row A.

Apply the NameCert obligations from Definition 5146.2. They force each Real-facing request to expose carrier admission, Real seal routing, dyadic accounting, metric inspection, Lipschitz exposure, absolute-continuity control, and the structural rows.

The readback route is finite. Replay through C and transport through H carry the displayed derivative-candidate window to P and N, so the $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer receives only the named window data.

Thus the handoff is a regular rational and Real readback of a displayed finite packet. It does not assert an almost-everywhere differentiability theorem, select a derivative outside the inspected windows, identify quotient representatives, or complete an ambient derivative space. □

Lean4 ✓ `BEDC.Derived.RademacherUp.RademacherCarrier real derivative handoff`

Theorem 5146.6 (Rademacher finite derivative-candidate packet)**.** *Every Real-facing read exported by an accepted* $\mathsf{Rademacher}^{\uparrow}$ *carrier factors through the finite route*

$$D, M, L, A \longmapsto E$$

before any derivative-candidate value is consumed. The displayed packet records dyadic radii, metric neighborhoods, Lipschitz distance bounds, absolute-continuity variation control, and terminal Real seals, but it does not assert that the derivative candidate exists on a Lebesgue almost-everywhere set or that the candidate is selected outside the displayed finite windows.

Proof. Begin with an accepted carrier $R = (L, E, D, M, A, H, C, P, N)$. By Definition 5146.2, the only Real-facing row is E, and it is downstream of the dyadic, metric, Lipschitz, and absolute-continuity rows.

The dyadic and metric rows are indispensable because the finite difference-quotient request needs displayed endpoint radii and the source and target neighborhoods in which the Lipschitz comparison is read. The Lipschitz row is indispensable because it supplies the graph and bound ledger for the same finite request.

The absolute-continuity row records the finite variation-control budget attached to the inspected windows. It is not a measure-completion row and does not select derivatives outside those windows.

Transport, replay, provenance, and local naming preserve the same route. Thus every Real-facing derivative-candidate read reaches the seal only through D, M, L, A, with no Lebesgue almost-everywhere theorem, exceptional-set algebra, selected derivative, quotient stream, countable-choice schedule, or ambient completeness coordinate added. □

Lean4 ✓ `BEDC.Derived.RademacherUp.RademacherCarrier finite derivative candidate packet`

Theorem 5146.7 (Rademacher difference-window obligation)**.** *Every accepted* $\mathsf{Rademacher}^{\uparrow}$ *carrier exposes derivative-candidate reads only through the finite dyadic-radius row D, metric-neighborhood row M, Lipschitz-bound row L, absolute-continuity control row A, terminal Real-seal row E, and the structural rows H, C, P, N already listed in Definition 5146.1. No derivative-candidate read bypasses those rows through a host derivative, a measurable exceptional set, a quotient representative, or an unbounded radius schedule.*

Proof. Project the accepted carrier as $R = (L, E, D, M, A, H, C, P, N)$. The carrier definition lists the Lipschitz row, Real seal, dyadic ledger, metric neighborhoods, absolute-continuity control, componentwise transport, replay, provenance, and local naming as the only visible coordinates.

Apply Definition 5146.2. It makes the local $\mathsf{NameCert}_{\mathsf{Rademacher}^{\uparrow}}$ surface exactly those rows, so a derivative-candidate request has no admissible public coordinate outside $L, E, D, M, A, H, C, P, N$.

Finally use Definition 5146.6. The Real-facing endpoint of the route is reached only after D, M, L, A have supplied the displayed dyadic radii, metric neighborhoods, Lipschitz bounds, and finite variation budget. Thus every candidate read remains inside the finite window and cannot import any excluded host, quotient, measurable, or unbounded schedule datum. □

Lean4 ✓ `BEDC.Derived.RademacherUp.RademacherCarrier difference window obligation`

Theorem 5146.8 (Rademacher difference-quotient window stability)**.** *Let*

$$R = (L, E, D, M, A, H, C, P, N)$$

and

$$R' = (L', E', D', M', A', H', C', P', N')$$

be accepted $\mathsf{Rademacher}^{\uparrow}$ *carriers. If D, D', M, M', L, L', A, A', and E, E' are componentwise* hsame *as dyadic endpoint-radius ledgers, metric-neighborhood rows, Lipschitz-bound rows, absolute-continuity control rows, and Real seal rows, then any finite derivative-candidate read exported*

through H, C, P, N and through H', C', P', N' remains the same displayed difference-quotient window.

Lean4 ✓ `BEDC.Derived.RademacherUp.RademacherCarrier difference quotient window stability`

Proof. Project the two accepted carriers. The only rows that can feed a derivative-candidate read are D, M, L, A before the terminal Real seal E, together with the structural rows H, C, P, N.

Use Definition 5146.2 and Definition 5146.6. These force every finite read through the dyadic radius ledger, the metric neighborhood request, the Lipschitz-bound ledger, and the absolute-continuity control before any Real-facing value is sealed.

Now apply the componentwise hsame assumptions. Since the two packets display the same D, M, L, A rows and the same E seal row, replay through C and C' follows the same finite row inventory. Transport through H and H' preserves that inventory, and P, N and P', N' only source and name the displayed packets.

Therefore the exported difference-quotient window is the same displayed window. The theorem asserts no Lebesgue almost-everywhere differentiability, measurable exceptional set, selected derivative, quotient map, countable choice, ambient measure completion, or completed derivative-space equality. □

Theorem 5146.9 (Rademacher absolute-continuity boundary)**.** *For every accepted* $\mathsf{Rademacher}^{\uparrow}$ *carrier $R = (L, E, D, M, A, H, C, P, N)$, the absolute-continuity row A may bound the displayed finite variation window used by the difference-quotient route, but it cannot be read as a measurable exceptional-set row, a Lebesgue almost-everywhere derivative theorem, a selected derivative function, a Lebesgue algebra, quotient equality, countable choice, or host real equality.*

Proof. Begin with the row inventory of Definition 5146.1. Row A is the absolute-continuity control row, and the definition assigns it only the finite interval or curve-window budget consumed by the displayed derivative-candidate packet.

The NameCert obligations keep that interpretation fixed. By Definition 5146.2, A is one of the exposed analytic rows, while H, C, P, N transport, replay, source, and name the same packet without adding coordinates.

Now apply Definition 5146.6 and Definition 5146.7. Both routes place A before the terminal Real seal and inside the finite dyadic and metric window, so it bounds the visible variation request only. Since the carrier contains no measurable exceptional-set row, a.e. derivative row, selected derivative function, Lebesgue algebra, quotient-equality row, choice row, or host equality row, none can be read from A. □

Lean4 ✓ `BEDC.Derived.RademacherUp.RademacherCarrier absolute continuity boundary`

Theorem 5146.10 (Rademacher finite derivative-candidate kernel scope)**.** *Every accepted* $\mathsf{Rademacher}^{\uparrow}$ *packet exposes its Lipschitz row L, metric-neighborhood row M, dyadic difference-quotient row D,* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *derivative handoff row E, and absolute-continuity boundary row A before any derivative claim is read. The scoped kernel is exactly the displayed carrier route*

$$L, D, M, A \longmapsto E \longmapsto H, C, P, N,$$

with the finite dyadic windows, metric requests, Lipschitz comparisons, Real-facing readback, absolute-continuity variation budget, componentwise transport, replay, provenance, and local naming all visible in the packet. It exports no Lebesgue almost-everywhere theorem, selected derivative, measurable exceptional set, quotient map, countable-choice schedule, host real equality, or completed derivative space.

Proof. Start from the accepted carrier $R = (L, E, D, M, A, H, C, P, N)$ of Definition 5146.1. The carrier projection exposes the only rows available to a derivative-candidate consumer.

Apply the Lipschitz and metric scope theorem Definition 5146.3. It places L and M before any derivative-candidate read and keeps the metric requests inside the displayed NameCert route.

Next apply the dyadic difference-quotient obligation Definition 5146.4. It forces the finite endpoint-radius ledger, halved-radius refinements, and comparison budgets through D before any regular rational or Real readback is consumed.

Use the Real derivative handoff Definition 5146.5 and the absolute-continuity boundary Definition 5146.9. These place the Real-facing derivative-candidate seal downstream of D, M, L, A and restrict A to finite variation-window control.

Finally replay the structural rows H, C, P, N. The same route is the paper-side counterpart of the existing Lean namespace around `BEDC.Derived.RademacherUp.RademacherCarrier_lipschitz_metric_sco` together with its dyadic, Real-handoff, and absolute-continuity neighbors. Since no carrier coordinate stores the excluded measurable, quotient, selected-derivative, choice, host-equality, or completion data, no derivative claim can be read before the scoped kernel rows are displayed. □

Lean4 ✓ `BEDC.Derived.RademacherUp.RademacherCarrier kernel scope`

Theorem 5146.11 (Rademacher scope-closure package)**.** *For every accepted* $\mathsf{Rademacher}^{\uparrow}$ *carrier*

$$R = (L, E, D, M, A, H, C, P, N),$$

the existing Lipschitz metric scope, dyadic difference-quotient obligation, Real derivative handoff, finite derivative-candidate packet, and difference-window stability rows form the scopedClosed *support over* $\mathsf{LipschitzFunction}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *The scoped package consists exactly of the Lipschitz row L, Real seal row E, dyadic endpoint-radius row D, metric-neighborhood row M, absolute-continuity control row A, transport row H, replay row C, provenance row P, and local naming row N; it exports no full almost-everywhere differentiability theorem, measure theory, selected derivative function, quotient map, countable-choice schedule, ambient Real completeness, or completed derivative space.*

Proof. Start with the Lipschitz and metric scope. The theorem Definition 5146.3 places the Lipschitz row L and metric row M before any derivative-candidate read and keeps their source and target distance requests inside the displayed NameCert route.

Next read the dyadic and Real-facing rows. Theorems 5146.4, 5146.5, and 5146.6 force the endpoint-radius ledger D, regular-rational or Real readback, terminal Real seal E, and absolute-continuity control A to appear as a finite candidate packet before any downstream derivative read is public.

Now use the difference-window rows. Theorems 5146.7 and 5146.8 keep every exported derivative-candidate read inside the displayed D, M, L, A, E window and preserve that window under componentwise hsame transport.

Finally apply the kernel-scope theorem Definition 5146.10. It repacks the same rows through H, C, P, N as the finite scoped route. Since the carrier has no coordinate for full almost-everywhere differentiability, measure algebras, selected derivative functions, quotient maps, countable choice, ambient Real completeness, or completed derivative spaces, the listed rows are exactly the scoped-closure support. □

Lean4 ✓ `BEDC.Derived.RademacherUp.RademacherCarrier scope closure package`

Closure status for $\mathsf{NameCert}_{\mathsf{Rademacher}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Rademacher}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 5146.1, Definition 5146.2, Definition 5146.10, and Definition 5146.11 close the finite derivative-candidate scoped surface over Lipschitz, Real, DyadicRatCore, MetricSpace, absolute-continuity, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{Rademacher}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.RademacherUp.RademacherCarrier\_scope\_closure\_package`

Bridge status: none

Not claimed: This chapter does not close Lebesgue almost-everywhere differentiability, measurable exceptional sets, selected derivatives, quotient maps, countable choice, ambient measure completion, completed derivative spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Lipschitz-row exposure, Real seal routing, dyadic endpoint-radius accounting, metric-neighborhood inspection, absolute-continuity control, transport stability, replay stability, provenance, local naming, and non-escape for BEDC.Derived.RademacherUp.

Constructive story: A Rademacher$^{\uparrow}$ packet is generated from a LipschitzFunction row, RealUp seal row, DyadicRatCore endpoint-radius ledger, MetricSpace neighborhood row, AbsolutelyContinuousFunction control row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5147

A Concrete Naming Certificate for $\mathsf{RegularTopologicalSpace}^{\uparrow}$

Following Kelley and Engelking, the $\mathsf{RegularTopologicalSpace}^{\uparrow}$ packet records the textbook separation surface in which a displayed point and a displayed closed-set row are separated by open neighbourhoods. It sits over the indexed-open carrier of chapter 88, beside the separation-function route of **??**, before the metrization route of chapter 3337, and beside the metric consumer surface of chapter 57. The packet names only a local regularity read over displayed open and closed rows; it does not import host powersets, classical complements, arbitrary normality, selected functions, or a host metric.

Definition 5147.1 (Regular topological space carrier)**.** *A* $\mathsf{RegularTopologicalSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, O, F, M, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, carrying the open-index classifier, open-neighbourhood membership reads, and finite closure witnesses available to the packet.*
2. *O is the open-neighbourhood row for the displayed point, recording the named open containing the point before any separation request is consumed.*
3. *F is the closed-set row disjoint from the displayed point, presented as a finite ledger over the same topology source rather than as a host complement.*
4. *M is the point-membership row, tying the inspected point to O and excluding it from F by displayed membership and nonmembership reads.*
5. *S is the separation-witness row, recording open rows U, V with the point in U, the closed row F contained in V, and no accepted overlap between U and V.*
6. *H records componentwise* hsame *transport for the topology source, open-neighbourhood row, closed-set row, point-membership row, separation witnesses, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a regularity request through T, O, F, M, S, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularTopologicalSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{UrysohnLemma}^{\uparrow}$, $\mathsf{UrysohnMetrization}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularTopologicalSpace}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $T, O, F, M, S, H, C, P, N$. It has no coordinate for host complements, external powersets, selected Urysohn functions, normal-space separation, metrization outside a displayed route, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularTopologicalSpaceUp.RegularTopologicalSpaceTasteGate single carrier alignment`

Theorem 5147.2 (Regular topological space NameCert obligations)**.** *For every accepted* $\mathsf{RegularTopologicalSpace}^{\uparrow}$ *carrier*

$$R = (T, O, F, M, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularTopologicalSpace}^{\uparrow}}$ *surface consists exactly of topology-source admission through T; open-neighbourhood admission through O; closed-set row admission through F; point-membership and point-nonmembership readback through M; regular separation exactness through S; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 5147.1. The accepted packet displays the topology source, the point neighbourhood, the closed-set row, the point-membership row, the separation witness, and the structural rows.

The open-neighbourhood and closed-set obligations are read before separation. The rows O, F, M identify the inspected point, the containing open, and the closed row avoided by that point over the same $\mathsf{Topology}^{\uparrow}$ source.

Regular separation exactness is the row S. It supplies the two separating open rows and their disjointness read, so the certificate has no need for a selected complement or an ambient powerset argument.

The rows H, C, P, N transport, replay, package, and name the same finite route. Since no further coordinate is present, the listed rows exhaust the local NameCert surface. □

Theorem 5147.3 (Regular topological space neighbourhood separation)**.** *Every neighbourhood-separation read exported by an accepted* $\mathsf{RegularTopologicalSpace}^{\uparrow}$ *packet must first display a* $\mathsf{Topology}^{\uparrow}$ *source row, a point-open row, a closed-set row disjoint from the displayed point, and the point-membership row tying them together. Only after those rows are visible may a consumer read the separating open-neighbourhood pair, and the later* $\mathsf{UrysohnLemma}^{\uparrow}$, $\mathsf{UrysohnMetrization}^{\uparrow}$, *or* $\mathsf{Met}^{\uparrow}$ *consumer receives only that displayed finite route.*

Proof. Begin with the topology source T. It supplies indexed open rows, but no regularity assertion is available until the packet displays the point-open row O, the closed-set row F, and the membership row M.

The separation witness is downstream of those rows. The row S records the two separating open neighbourhoods, the containment of the closed-set row in one of them, the displayed point membership in the other, and the disjointness read between the two open rows.

Transport and replay preserve the same order. The componentwise hsame row H and displayed Cont row C reread T, O, F, M, S before provenance or local naming can be inspected.

Thus a later Urysohn, metrization, or metric consumer receives a finite regularity route over the displayed topology source. It receives no host complement, external powerset, selected separating function, normal-space theorem, or host metric from the regular-space packet. □

Falsifiable prediction: Every accepted $\mathsf{RegularTopologicalSpace}^{\uparrow}$ read exposes a $\mathsf{Topology}^{\uparrow}$ source row, an open-neighbourhood row, a closed-set row, a point-membership row, a separation-witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: topology, urysohn-lemma, urysohn-metrization, metric: $\mathsf{RegularTopologicalSpace}^{\uparrow}$ is not bijective to any listed sibling because it binds point-versus-closed-set neighbourhood separation as a local finite packet between topology and metrization consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularTopologicalSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularTopologicalSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5147.1, Definition 5147.2, and Definition 5147.3 seed the finite point-versus-closed-set neighbourhood separation route over topology rows, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularTopologicalSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close normality, Hausdorff separation, Urysohn function construction, metrization, host powersets, selected complements, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, open-neighbourhood readback, closed-set row exactness, point-membership stability, separation-witness exactness, transport, replay, provenance, and local naming for BEDC.Derived.RegularTopologicalSpaceUp.

Constructive story: A $\mathsf{RegularTopologicalSpace}^{\uparrow}$ packet is generated from a Topology source row, point open-neighbourhood rows, closed-set rows, point-membership rows, separation witnesses, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5148

A Concrete Naming Certificate for $\mathsf{CauchyTailGluing}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailGluing}^{\uparrow}$ packet records the finite tail-gluing surface by which two regular rational names can be read as one Real-facing route after their late tails have been compared. It sits over the finite window discipline of chapter 126, the regular rational readback of chapter 301, the nonquotient comparison boundary of chapter 1820, the dyadic late-tail containment route of chapter 1633, and the terminal real-name seal of chapter 38. The packet names the finite gluing route consumed by L10 Real and Completion consumers; it is not quotient stream equality, a selected common representative, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5148.1 (Cauchy tail gluing carrier)**.** *A* $\mathsf{CauchyTailGluing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Y, S, T, n, D, B, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational name rows whose late tails are to be glued.*
2. *S and T are the corresponding* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows through which X and Y are observed.*
3. *n is the displayed tail index. A consumer may inspect only windows whose source positions lie at or beyond n.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the displayed tail index.*
5. *B is the* $\mathsf{DyadicTailBall}^{\uparrow}$ *evidence row stating that the two late-tail windows enter the same dyadic tail ball at the tolerance recorded in D.*
6. *Q is the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier row, read only after the paired windows, tail index, dyadic ledger, and tail-ball evidence have been displayed.*
7. *R is the glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the accepted late-tail comparison.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from $X, Y, S, T, n, D, B, Q, R$.*
9. *H records componentwise* hsame *transport for the two regular names, paired stream windows, tail index, dyadic ledger, tail-ball evidence, setoid classifier, glued readback, Real seal, replay, provenance, and local name.*

10. *C records displayed* Cont *replay from a gluing request through the paired stream windows, regular rational rows, dyadic tolerance ledger, tail-ball evidence, setoid classifier, glued readback, and Real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{CauchyTailGluing}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{DyadicTailBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailGluing}^{\uparrow}}$ *row.*

The carrier accepts only packets in which both source names are observed through displayed StreamName windows, the same tail index bounds the compared suffixes, the dyadic tail-ball row supplies the finite tolerance evidence, the Cauchy-equivalence classifier consumes that evidence, and the Real seal is reached only through the glued RegSeqRat readback.

The displayed tail index is part of the certificate surface:

$$\begin{aligned}\mathsf{tail}(G) &= n,\\ \mathsf{leftWindow}(G) &= S_{\geq n},\\ \mathsf{rightWindow}(G) &= T_{\geq n}.\end{aligned}$$

The dyadic tail-ball evidence row B is read only at the tolerance recorded in D, and the $\mathsf{Real}^{\uparrow}$ seal row E is unavailable until the route through B, Q, R has been replayed.

Theorem 5148.2 (Cauchy tail gluing NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailGluing}^{\uparrow}$ *carrier* $G = (X, Y, S, T, n, D, B, Q, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailGluing}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two regular rational names, paired stream windows, displayed tail index, dyadic ledger, tail-ball evidence, setoid classifier, glued readback, Real seal, transport, replay, provenance, and local naming rows;*

2. *classifier discipline, requiring Q to read the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison only after S, T, n, D, B have been displayed;*

3. *tail transport, requiring componentwise* hsame *transport in H to preserve the same tail index and the same paired suffix windows before the glued readback R is consumed;*

4. *Real seal compatibility, requiring E to remain downstream of the glued* $\mathsf{RegSeqRat}^{\uparrow}$ *row R and the classifier route Q;*

5. *ledger nonescape, excluding quotient stream equality, selected common representatives, countable choice, host real equality, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as certificate data.*

No gluing obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.CauchyTailGluingUp.CauchyTailGluingCarrier namecert obligations`

Proof. Project the carrier of Definition 5148.1. The projection exposes the two regular rational names X, Y, their stream windows S, T, the displayed tail index n, the dyadic ledger D, the tail-ball evidence B, the setoid classifier Q, the glued readback R, the Real seal E, and the structural rows H, C, P, N.

The classifier obligation is downstream of the finite tail data. A comparison request first reads the paired windows at the displayed suffix, then consumes the dyadic tolerance ledger and tail-ball evidence before the $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ row Q is available.

Transport preserves the same suffix route. The hsame row H acts componentwise on $X, Y, S, T, n, D, B, Q, R, E$, so a transported packet cannot replace the displayed tail index by a hidden tail selector or move the comparison outside the recorded windows.

Finally, the Real seal is terminal. The row E is reached through the glued RegSeqRat readback R after the classifier route has been replayed, and the carrier contains no coordinate for quotient stream equality, a selected representative, countable choice, host real equality, trichotomy, or ambient completeness. □

Theorem 5148.3 (Cauchy tail gluing Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyTailGluing}^{\uparrow}$ *packet reads the finite route*

$$X, Y, S, T, n, D, B \longmapsto Q \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

before consuming a glued real-name seal. Thus the Real-facing row is compatible with the StreamName windows, RegSeqRat readbacks, Cauchy-equivalence classifier, and DyadicTailBall evidence already displayed by the packet, and it exports no quotient stream equality, selected common representative, countable-choice selector, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a Real-facing read. Carrier admission gives only the terminal row E, and the definition places E after the two regular rational source rows, their stream windows, the displayed tail index, the dyadic ledger, the tail-ball evidence, the setoid classifier, and the glued readback.

The replay row C therefore sends the consumer through the same finite path. The classifier row Q receives exactly the dyadic tail-ball evidence B attached to D, and R repacks the accepted comparison as the only glued $\mathsf{RegSeqRat}^{\uparrow}$ row.

The remaining structural rows transport, replay, source, and name the same route. Since the carrier has no coordinate for the excluded quotient, choice, host-equality, trichotomy, or completeness data, the terminal Real seal cannot export them. □

Falsifiable prediction: Every $\mathsf{CauchyTailGluing}^{\uparrow}$ Real-facing read factors through two RegSeqRat source rows, paired StreamName suffix windows, one displayed tail index, a DyadicRatCore tolerance ledger, DyadicTailBall evidence, a CauchyEquivalenceSetoid classifier row, a glued RegSeqRat readback, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, cauchy-equivalence-setoid, dyadic-tail-ball, real: $\mathsf{CauchyTailGluing}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two regular names, paired suffix windows, one displayed tail index, dyadic tail-ball evidence, a setoid classifier, a glued readback, and a Real seal in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailGluing}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTailGluing}^{\uparrow}$ packet is generated from two RegSeqRat source rows, paired StreamName suffix windows, one displayed tail index, a DyadicRatCore tolerance ledger, DyadicTailBall evidence, a CauchyEquivalenceSetoid classifier row, a glued RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailGluing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5148.1, Definition 5148.2, and Definition 5148.3 seed the finite tail-gluing surface for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailGluing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected common representatives, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier discipline, tail transport, Real seal compatibility, ledger nonescape, replay, provenance, and local naming for BEDC.Derived.CauchyTailGluingUp.

Chapter 5149

A Concrete Naming Certificate for $\mathsf{BishopCauchyCriterionCompletion}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopCauchyCriterionCompletion}^{\uparrow}$ packet records the finite route by which an explicit Bishop Cauchy criterion becomes completion-facing BEDC data. It sits between the criterion carrier of chapter 3576, the modulus family of chapter 5887, the left-exact completion boundary of chapter 5888, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The chapter names the criterion-to-completion handoff as finite BHist data; it does not assert quotient stream equality, a selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5149.1 (Bishop Cauchy criterion completion carrier)**.** *A* $\mathsf{BishopCauchyCriterionCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, M, W, R, D, E, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the source* $\mathsf{BishopCauchyCriterion}^{\uparrow}$ *row, naming the finite Cauchy criterion request that will be consumed by completion-facing data.*
2. *M is the* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *row, recording the explicit modulus schedules and their precision requests for the same criterion.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the source sequence, modulus requests, and finite tail comparisons are inspected.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the windows in W and the tolerance schedule in M.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii and comparison budgets used by the criterion and readback rows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, M, W, R, D have been displayed.*
7. *L is the* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *handoff row, recording that completion-facing finite-limit reads consume the same criterion, modulus, window, readback, tolerance, and real-seal rows.*
8. *H records componentwise* hsame *transport for $Q, M, W, R, D, E, L, C, P, N$.*

9. *C records displayed* Cont *replay from a completion request through the criterion, modulus schedule, stream windows, rational readback, dyadic tolerance ledger, real seal, and left-exactness handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyCriterionCompletion}^{\uparrow}$, $\mathsf{BishopCauchyCriterion}^{\uparrow}$, $\mathsf{CauchyModulusSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyCriterionCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, M, W, R, D, E, L, H, C, P, N$. It has no coordinate for quotient stream equality, selected Cauchy representatives, selected limits, countable choice, trichotomy, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BishopCauchyCriterionCompletionUp.BishopCauchyCriterionCompletionTasteGate single carrier alignment`

Theorem 5149.2 (Bishop Cauchy criterion completion NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyCriterionCompletion}^{\uparrow}$ *carrier*

$$K = (Q, M, W, R, D, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyCriterionCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the Bishop Cauchy criterion row, explicit Cauchy modulus schedules, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure,* CauchyCompletionLeftExactn *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing read must expose Q, M, W, R, D, E, L before H, C, P, N can be consumed.*

Proof. Project the carrier of Definition 5149.1. The analytic rows are exactly Q, M, W, R, D, E, L, and the structural rows are exactly H, C, P, N.

The source criterion row Q supplies the Bishop Cauchy request, while the modulus row M makes the precision schedule explicit. The finite windows W are therefore the only observation surface through which the criterion can be read.

Next the readback and tolerance rows are forced through R and D. The terminal real seal E is downstream of those rational and dyadic rows, so no real-facing consumer can bypass the displayed criterion data.

Finally the completion handoff L records the left-exact completion-facing use of the same route, and H, C, P, N transport, replay, source, and name it. Since no excluded host object is present as a carrier coordinate, these rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyCriterionCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyCriterionCompletion}^{\uparrow}$ packet is generated from a BishopCauchyCriterion row, CauchyModulusSpace schedules, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a Real seal, a CauchyCompletionLeftExactness handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCauchyCriterionCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 5149.1 and Definition 5149.2 seed the finite criterion-to-completion route over the displayed Bishop, Cauchy, rational, dyadic, Real, and Completion rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCauchyCriterionCompletion}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.BishopCauchyCriterionCompletionUp.BishopCauchyCriterionCompletionTasteGate\_single\_car`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected Cauchy representatives, selected limits, countable choice, trichotomy, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion exposure, modulus schedule exposure, finite-window exposure, RegSeqRat readback exactness, DyadicRatCore tolerance exposure, Real seal nonescape, completion handoff preservation, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyCriterionCompletionUp.

Chapter 5150

A Concrete Naming Certificate for $\mathsf{SignedDecimalExpansion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{SignedDecimalExpansion}^{\uparrow}$ packet presents a real-facing decimal datum by a displayed sign row, finite digit-window rows, a carry ledger, the unsigned $\mathsf{DecimalExpansion}^{\uparrow}$ prefix surface of chapter 1417, the normalized real-decimal route of chapter 3952, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The point is not to select an infinite decimal expansion for a real. It is to name the finite BEDC certificate by which a signed decimal window can be normalized, replayed as a $\mathsf{RegSeqRat}^{\uparrow}$ route, and then handed to $\mathsf{Real}^{\uparrow}$ without quotient representatives, trichotomy, endpoint choice, or ambient completeness.

Definition 5150.1 (Signed decimal expansion carrier)**.** *A* $\mathsf{SignedDecimalExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, W, A, L, U, Z, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the sign row, recording either a nonnegative read or a negative read of the same finite magnitude surface.*
2. *D is the finite digit ledger, listing the inspected base-ten digits and the distinguished decimal point window.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window through which the digit ledger is read.*
4. *A is the unsigned* $\mathsf{DecimalExpansion}^{\uparrow}$ *magnitude row, exposing the finite decimal-prefix carrier and its dyadic place-value comparison.*
5. *L is the carry ledger, recording all local carry and borrow moves used inside the inspected window.*
6. *U is the normalized* $\mathsf{RealDecimalNormalForm}^{\uparrow}$ *row, reached only after S, D, W, A, L have been displayed.*
7. *Z is the zero-window boundary row, identifying the unique displayed route by which the positive and negative presentations of zero agree.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *replay row obtained from the signed normalized windows and the dyadic comparison data.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from R.*

10. *H records componentwise* hsame *transport for $S, D, W, A, L, U, Z, R, E, C, P, N$.*
11. *C records displayed* Cont *replay from a signed decimal request through digit windows, carry normalization, regular rational readback, and the Real seal.*
12. *P is the* Pkg *provenance over* SignedDecimalExpansion$^\uparrow$, DecimalExpansion$^\uparrow$, RealDecimalNormalForm$^\uparrow$, StreamName$^\uparrow$, DyadicRatCore$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{SignedDecimalExpansion}^\uparrow}$ *row.*

The classifier compares accepted signed decimal packets only through $S, D, W, A, L, U, Z, R, E, H, C, P, N$. It has no coordinate for a chosen infinite decimal stream, a quotient real representative, an endpoint convention selector, trichotomy, countable choice, or ambient Real$^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.SignedDecimalExpansionUp.SignedDecimalExpansionTasteGate single carrier alignment`

Theorem 5150.2 (Signed decimal expansion NameCert obligations)**.** *For every accepted* SignedDecimalExpansion$^\uparrow$ *carrier*

$$K = (S, D, W, A, L, U, Z, R, E, H, C, P, N),$$

the local NameCert$_{\text{SignedDecimalExpansion}^\uparrow}$ *surface consists exactly of sign exposure, finite digit-window exposure, unsigned* DecimalExpansion$^\uparrow$ *magnitude exposure, carry-ledger normalization,* RealDecimalNormalForm$^\uparrow$ *normalized-window exposure, zero-window agreement,* RegSeqRat$^\uparrow$ *replay, terminal* Real$^\uparrow$ *seal exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every real-facing consumer must read $S, D, W, A, L, U, Z, R, E$ before any structural row is consumed.*

Proof. Project the carrier of Definition 5150.1. The analytic rows are exactly $S, D, W, A, L, U, Z, R, E$, while H, C, P, N are the structural transport, replay, provenance, and naming rows.

The unsigned magnitude row A is read only after the sign and finite digit-window rows S, D, W. Thus the signed presentation cannot hide a second decimal magnitude or an infinite stream behind the sign.

The carry ledger L and normalized row U then force all local carry and borrow moves to be replayed inside the same finite window. The zero boundary Z identifies the only displayed agreement route between the two signed presentations of zero.

Finally R and E are downstream rows. The regular rational replay must be exposed before the terminal Real seal, and no carrier coordinate remains for quotient representatives, endpoint choice, trichotomy, choice schedules, or ambient completeness. □

Theorem 5150.3 (Signed decimal expansion decimal normalization route)**.** *Every accepted* SignedDecimalExpansio *packet routes its signed digit window through the unsigned* DecimalExpansion$^\uparrow$ *magnitude row and the* RealDecimalNormalForm$^\uparrow$ *normalization row before any* RegSeqRat$^\uparrow$ *replay or* Real$^\uparrow$ *seal can be read. In the notation of Definition 5150.1, every consumer of R or E first consumes*

$$S, D, W, A, L, U, Z.$$

Consequently the sign row and carry ledger are normalized as finite BEDC data, not by selecting a preferred infinite decimal expansion or an endpoint convention.

Proof. Begin with the carrier ordering in Definition 5150.1. The rows S, D, W expose the signed finite window, and A places its magnitude inside the existing DecimalExpansion$^\uparrow$ finite-prefix surface.

The carry ledger L is replayed before U is public. Since U is the $\mathsf{RealDecimalNormalForm}^{\uparrow}$ row, every normalized decimal read is attached to the displayed carry ledger rather than to a detached stream convention.

The rows R and E occur only after Z has recorded the zero-window boundary. Thus downstream consumers receive a normalized finite signed route, and the packet exports no shortcut from raw signed digits to a regular rational or real-facing value. □

Theorem 5150.4 (Signed decimal expansion Real seal handoff)**.** *For every accepted* $\mathsf{SignedDecimalExpansion}^{\uparrow}$ *packet, the terminal* $\mathsf{Real}^{\uparrow}$ *seal is reached only through the* $\mathsf{RegSeqRat}^{\uparrow}$ *replay row assembled from the signed normalized windows. The handoff factors through the displayed chain*

$$\mathsf{SignedDecimalExpansion}^{\uparrow} \longrightarrow \mathsf{DecimalExpansion}^{\uparrow} \longrightarrow \mathsf{RealDecimalNormalForm}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

It does not export quotient real equality, a selected decimal representative, trichotomy, countable choice, endpoint uniqueness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read R through the normalized-window route of Definition 5150.3. The signed carrier has already exposed the sign row, finite digit ledger, carry ledger, unsigned magnitude row, normalized row, and zero boundary before R can be consumed.

The terminal seal row E is downstream of R. Hence a Real-facing consumer sees only the regular rational replay produced by the signed normalized windows.

The nonescape clause follows from the carrier coordinates in Definition 5150.1. None of them is a quotient representative, selected decimal stream, trichotomy decision, countable-choice schedule, endpoint convention selector, or completeness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{SignedDecimalExpansion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SignedDecimalExpansion}^{\uparrow}$ packet is generated from a sign row, finite decimal digit windows, an unsigned DecimalExpansion magnitude row, a finite carry ledger, a RealDecimalNormalForm normalized row, a zero-window boundary, RegSeqRat replay, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SignedDecimalExpansion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5150.1, Definition 5150.2, Definition 5150.3, and Definition 5150.4 seed the finite signed decimal presentation and its RegSeqRat-to-Real handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SignedDecimalExpansion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected infinite decimal streams, endpoint uniqueness, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sign transport, carry-ledger normalization, zero-window agreement, RegSeqRat replay, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SignedDecimalExpansionUp.

Chapter 5151

A Concrete Naming Certificate for $\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}$ packet records a displayed Cauchy certificate as finite BEDC NameCert data before any Real seal or completion-facing read is consumed. It sits between the criterion surface of chapter 3576, the criterion-to-completion route of chapter 5149, the reusable tail certificate of chapter 1230, the modulus schedule surface of chapter 5887, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives L10 Real and Completion consumers a single finite display entry point; it is not a quotient stream equality theorem, a selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5151.1 (Bishop Cauchy display-certificate carrier)**.** *A* $\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, M, W, T, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{BishopCauchyCriterion}^{\uparrow}$ *row naming the finite Cauchy criterion whose display is being certified.*
2. *M is the* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *row recording the displayed modulus schedules and precision requests used by Q.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the source sequence, modulus requests, and tail comparisons are inspected.*
4. *T is the* $\mathsf{RegularCauchyTailCertificate}^{\uparrow}$ *row witnessing that the displayed windows supply the shared tail certificate required by Real and Completion consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from W, T, and the modulus schedule in M.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic radii, comparison budgets, and slack rows used by the displayed criterion and tail handoff.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, M, W, T, R, D have been displayed.*
8. *H records componentwise* hsame *transport for Q, M, W, T, R, D, E and the local naming row.*

9. *C records displayed* Cont *replay from a display request through the criterion, modulus schedule, stream windows, tail certificate, rational readback, dyadic tolerance ledger, and Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}$, $\mathsf{BishopCauchyCriterion}^{\uparrow}$, BishopCauchyCriterionCo CauchyModulusSpace$^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegularCauchyTailCertificate}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, M, W, T, R, D, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, selected limits, countable choice, trichotomy, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BishopCauchyDisplayCertificateUp.BishopCauchyDisplayCertificateTasteGate`
`single carrier alignment`

Theorem 5151.2 (Bishop Cauchy display-certificate NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}$ *carrier*

$$B = (Q, M, W, T, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}}$ *surface consists exactly of carrier admission for the Bishop Cauchy criterion row, explicit Cauchy modulus schedules, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegularCauchyTailCertificate}^{\uparrow}$ *tail handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer must expose Q, M, W, T, R, D, E before H, C, P, N can be consumed.*

Proof. Project the carrier of Definition 5151.1. The analytic display rows are exactly Q, M, W, T, R, D, E, and the structural support rows are exactly H, C, P, N.

The criterion row Q supplies the Bishop Cauchy request, while M makes the precision schedule explicit. The stream row W is therefore the only observation surface through which the sequence and modulus requests can be read.

The tail certificate T then binds the displayed windows to the shared regular Cauchy tail route. The readback row R and dyadic ledger D keep the rational and tolerance data visible before the terminal Real seal E is available.

Finally H, C, P, N transport, replay, source, and name the same rows. Since no excluded host object is present as a carrier coordinate, these rows exhaust the local NameCert obligations. □

Theorem 5151.3 (Bishop Cauchy display-certificate tail handoff)**.** *Every Real or Completion consumer accepted by a* $\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}$ *carrier reads the shared tail certificate through the finite route*

$$\mathsf{BishopCauchyCriterion}^{\uparrow} \longmapsto \mathsf{CauchyModulusSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailCertificate}^{\uparrow} \longmapsto \mathsf{RegSeq}$$

together with H, C, P, N. Consequently the consumer receives the displayed criterion, modulus schedule, finite windows, tail certificate, regular rational readback, dyadic tolerance ledger, and terminal Real seal, but it receives no selected limit, quotient stream equality, countable-choice schedule, trichotomy row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with a Real or Completion read of B. The source criterion and precision schedule appear only as Q and M, so the read must expose them before any window or tail row is available.

The row W supplies the finite inspection surface. The handoff row T is downstream of those windows and is the only coordinate that can expose a regular Cauchy tail certificate.

The rows R, D, E then perform the regular rational readback, dyadic tolerance accounting, and terminal Real sealing in order. The support rows H, C, P, N preserve that same route without adding analytic content.

Because quotient streams, selected limits, countable choice, trichotomy, and ambient completeness are absent from the carrier, no consumer can obtain them from the displayed tail handoff. □

Lean4 ✓ `BEDC.Derived.BishopCauchyDisplayCertificateUp.BishopCauchyDisplayCertificateCarrier tail handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}$ packet is generated from a BishopCauchyCriterion row, CauchyModulusSpace schedules, StreamName windows, a RegularCauchyTailCertificate handoff, RegSeqRat readback, DyadicRatCore tolerances, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5151.1, Definition 5151.2, and Definition 5151.3 seed the finite display-certificate route for the L10 Real and Completion surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected Cauchy representatives, selected limits, countable choice, trichotomy, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion exposure, modulus schedule exposure, finite-window exposure, tail-certificate handoff, RegSeqRat readback exactness, DyadicRatCore tolerance exposure, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyDisplayCertificateUp.

Chapter 5152

A Concrete Naming Certificate for $\mathsf{SequentiallyCompactCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SequentiallyCompactCompletion}^{\uparrow}$ packet records the finite route by which a totally bounded separated metric completion exposes sequential compactness through displayed subsequence windows. It sits between the total-bounded completion route of chapter 1573, the separated completion comparison of chapter 1612, the compact metric completion seal of chapter 1687, the finite sequence-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a completion-facing subsequence certificate; it is not open-cover compactness, a quotient completion, a selected limit-point operation, countable choice, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5152.1 (Sequentially compact completion carrier)**.** *A* $\mathsf{SequentiallyCompactCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, S, K, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *row. It records the source metric carrier, finite-net completion route, net refinement ledger, Cauchy-filter basis, dense embedding, and uniformly continuous handoff consumed by the sequential compactness request.*
2. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *row. It compares completed reads only through the displayed zero-distance and separated-equality route.*
3. *K is the* $\mathsf{CompactMetricCompletion}^{\uparrow}$ *row. It supplies the complete totally bounded metric completion surface from which compact-facing consumers may request finite sequence data.*
4. *W is the subsequence-window ledger. It stores the inspected* $\mathsf{StreamName}^{\uparrow}$ *windows, the monotone selected-index rows, the finite tail requests, and the bounded-window evidence used by the compact metric completion surface.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the selected windows, rational tail budgets, and completion-facing Cauchy data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after T, S, K, W, R have been displayed.*

7. *H records componentwise* hsame *transport for the total-bounded completion route, separated completion comparison, compact metric completion surface, subsequence windows, regular rational readback, Real seal, continuation replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite sequence request through T, S, K, W, R, E.*
9. *P is the* Pkg *provenance over* SequentiallyCompactCompletion$^{\uparrow}$, TotallyBoundedCompletion$^{\uparrow}$, SeparatedCompletion CompactMetricCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{SequentiallyCompactCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, S, K, W, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, quotient representatives, selected limit points outside W, countable-choice schedules, host sequence equality, host real equality, or detached ambient completeness of Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.SequentiallyCompactCompletionUp.SequentiallyCompactCompletionTasteGate`
`single carrier alignment`

Theorem 5152.2 (SequentiallyCompactCompletion NameCert obligations)**.** *For every accepted* SequentiallyCompactCompletion$^{\uparrow}$ *carrier*

$$Q = (T, S, K, W, R, E, H, C, P, N),$$

the local NameCert$_{\text{SequentiallyCompactCompletion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the total-bounded completion route, separated completion comparison, compact metric completion surface, subsequence-window ledger, regular rational readback, Real seal, componentwise transport, displayed replay, provenance, and local naming row;*
2. *completion-route exposure, requiring every sequential compactness request to read T and S before it may inspect the compact metric completion row K;*
3. *subsequence-window locality, requiring selected indices, finite tails, source windows, and compactness evidence to be precisely the displayed rows in W;*
4. RegSeqRat$^{\uparrow}$ *handoff exactness, requiring every convergence read to enter R only from the windows and tail budgets stored in W and transported through H;*
5. Real$^{\uparrow}$ *seal nonescape, requiring the terminal limit read to pass through E after R and forbidding quotient streams, host real equality, external selected limits, countable choice, and detached ambient completeness;*
6. *provenance and naming closure, requiring P and N to name only the displayed packet and no principle absent from its rows.*

No NameCert obligation is stored outside these displayed rows.

Proof. Carrier admission is projection from Definition 5152.1. The projected rows are exactly the total-bounded completion route T, separated comparison S, compact metric completion surface K, subsequence-window ledger W, regular rational readback R, Real seal E, and structural rows H, C, P, N.

Completion-route exposure follows the sibling order. The finite total-bounded completion route of chapter 1573 is read first through T, and the separated completion comparison of chapter 1612 is read through S before the compact metric completion surface K can be inspected.

Subsequence-window locality is internal to W. The packet stores the $\mathsf{StreamName}^{\uparrow}$ windows, selected-index rows, finite tail requests, and bounded-window evidence that the compact metric completion surface uses; there is no separate coordinate from which an external subsequence or selected limit point could be read.

The convergence handoff is then the row R. It accepts only the selected windows and rational tail budgets displayed by W, with componentwise transport supplied by H, so the handoff cannot be replaced by quotient stream equality or host sequence equality.

Finally, the terminal read is sealed by E, while C, P, N replay, source, and name the same route. Since the carrier has no coordinate for open-cover compactness, quotient completion, countable choice, host real equality, external selected limits, or detached ambient completeness of $\mathsf{Real}^{\uparrow}$, none of those data can be exported by the local NameCert surface. □

Theorem 5152.3 (SequentiallyCompactCompletion subsequence seal)**.** *Let $Q = (T, S, K, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{SequentiallyCompactCompletion}^{\uparrow}$ *carrier. Every sequential-compactness-facing consumer factors through the finite route*

$$T, S \longmapsto K \longmapsto W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives total-bounded completion data, separated completion comparison, compact metric completion, displayed subsequence windows, regular rational readback, Real seal, transport, replay, provenance, and local naming before it can read a completed subsequence limit.

Proof. Project the consumer read from the carrier. By Definition 5152.1, the only completion-facing rows available before the compact metric surface are T and S.

The compact metric completion row K is downstream of those completion rows. It exposes finite completion compactness only as the route already named in chapter 1687, so the consumer cannot bypass T and S by invoking an open-cover compactness theorem or a quotient completion.

The subsequence information is then exactly the ledger W. The regular rational readback R and terminal Real seal E are reachable only from the windows, selected indices, and tail budgets stored in that ledger.

Transport and replay through H and C preserve the same order, and P, N name only that packet. This proves the displayed factorization and excludes external selected limits, countable choice, host sequence equality, host real equality, and detached ambient Real completeness. □

Falsifiable prediction: Every $\mathsf{SequentiallyCompactCompletion}^{\uparrow}$ completed-subsequence read factors through TotallyBoundedCompletion, SeparatedCompletion, CompactMetricCompletion, StreamName subsequence windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: totallyboundedcompletion, separatedcompletion, compactmetriccompletion, streamname, regseqrat, real: $\mathsf{SequentiallyCompactCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries completion route exposure, separated comparison, compact metric completion, displayed subsequence windows, rational readback, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentiallyCompactCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentiallyCompactCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5152.1, Definition 5152.2, and Definition 5152.3 seed the finite route from total-bounded separated completion data to displayed subsequence compactness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentiallyCompactCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, quotient completion, selected limit points outside the displayed windows, countable choice, host sequence equality, host real equality, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-route exposure, subsequence-window locality, RegSeqRat handoff exactness, RealUp seal nonescape, provenance and naming closure, and TasteGate field faithfulness for BEDC.Derived.SequentiallyCompactCompletionUp.

Constructive story: A $\mathrm{SequentiallyCompactCompletion}^{\uparrow}$ packet is generated from a TotallyBoundedCompletion route, a SeparatedCompletion comparison, a CompactMetricCompletion surface, StreamName subsequence windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5153

A Concrete Naming Certificate for $\mathsf{LocaleSpace}^{\uparrow}$

Following Johnstone and constructive locale theory, the $\mathsf{LocaleSpace}^{\uparrow}$ packet records the point-free topology surface in which open observations are primary and point carriers are optional downstream reads. It sits after the indexed-open topology of chapter 88, the meet–join order interface of chapter 55, the Boolean endpoint discipline of chapter 3733, and the displayed membership surface of chapter 3668. The packet names finite frame rows, cover-refinement rows, and topology handoff rows without importing host powersets, quotient point spaces, selected points, excluded middle over opens, or choice over covers.

Definition 5153.1 (Locale space carrier)**.** *A* $\mathsf{LocaleSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (O, J, M, T, CV, B, S, H, R, P, N)$$

with the following displayed rows:

1. *O is the open-index carrier row, read point-free as the visible open observation surface.*
2. *J is the finite-join row, recording displayed finite unions of open indices.*
3. *M is the finite-meet row, recording displayed finite intersections of open indices.*
4. *T is the top and bottom row, naming the maximal and empty opens through finite BEDC observations.*
5. *CV is the cover-refinement row, recording when one finite open family refines another.*
6. *B is the* $\mathsf{BooleanAlgebra}^{\uparrow}$ *boundary row used only for clopen or complemented subledgers; it does not make the whole locale Boolean.*
7. *S is the* $\mathsf{SetLike}^{\uparrow}$ *membership-read row for consumers that later inspect a displayed point or probe, not a source of points for the locale itself.*
8. *H records componentwise* hsame *transport for the open carrier, lattice operations, cover row, Boolean boundary, membership-read row, replay, provenance, and local naming.*
9. *R records displayed* Cont *replay from a locale request through $O, J, M, T, CV, B, S, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{LocaleSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{BooleanAlgebra}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocaleSpace}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $O, J, M, T, CV, B, S, H, R, P, N$. It has no coordinate for host powersets, point-set extensionality, quotient spaces, selected points, choice-indexed covers, or a global Boolean algebra of all opens.

Theorem 5153.2 (Locale space NameCert obligations)**.** *For every accepted* $\mathsf{LocaleSpace}^{\uparrow}$ *carrier*

$$L = (O, J, M, T, CV, B, S, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocaleSpace}^{\uparrow}}$ *surface consists exactly of open-index admission through O; finite joins through J; finite meets through M; top and bottom open rows through T; cover-refinement exactness through CV; clopen boundary reads through B when a complemented subledger is displayed; point or probe membership reads through S only after the point-free rows are exposed; componentwise* hsame *transport through H; displayed* Cont *replay through R; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 5153.1. The rows O, J, M, T, CV display the point-free open surface before any point-facing or Boolean-facing consumer is consulted.

The Boolean boundary row B is local to complemented subledgers. It may certify a clopen or complemented finite fragment, but it cannot replace the locale carrier by a global $\mathsf{BooleanAlgebra}^{\uparrow}$ object because the carrier has no coordinate for excluded middle over all opens.

The membership row S is downstream of the open rows. A point or probe consumer may read displayed membership only after the locale has exposed the open-index, lattice, and cover-refinement rows.

Finally, H, R, P, N transport, replay, source, and name the same route. Since no carrier coordinate supplies host powersets, quotient point spaces, selected points, or choice-indexed covers, the listed rows exhaust the local certificate surface. □

Lean4 ✓ `BEDC.Derived.LocaleSpaceUp.LocaleSpaceTasteGate single carrier alignment`

Theorem 5153.3 (Locale space finite-meet cover route)**.** *Every accepted* $\mathsf{LocaleSpace}^{\uparrow}$ *consumer that compares a finite meet of opens against a cover must route the comparison through*

$$O, J, M, T \longmapsto CV \longmapsto B, S, H, R, P, N.$$

Thus a $\mathsf{Topology}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{BooleanAlgebra}^{\uparrow}$, *or* $\mathsf{SetLike}^{\uparrow}$ *consumer may inherit only the displayed open-index carrier, finite meet and join rows, top and bottom rows, cover-refinement row, optional complemented-subledger boundary, displayed membership reads, transport, replay, provenance, and local name. The route exports no host powerset of opens, no quotient point space, no selected point, no choice-indexed cover, and no global Boolean algebra of all opens.*

Proof. Start with the point-free open carrier O. The finite-meet request is read through M, while the finite-join and endpoint rows J, T keep the comparison inside the same lattice-facing open ledger.

The cover comparison is then the row CV. It refines finite families of displayed open indices and therefore consumes the open carrier and lattice rows before any complemented or point-facing read is available.

Only after that route may a consumer inspect B or S. The Boolean boundary row can name complemented finite fragments, and the membership row can serve a displayed point or probe, but neither row supplies the source carrier.

The rows H, R, P, N preserve the same route by transport, replay, provenance, and naming. Hence the finite-meet cover comparison is point-free until the optional downstream reads are explicitly displayed. □

Falsifiable prediction: Every accepted $\mathsf{LocaleSpace}^{\uparrow}$ read exposes open-index admission, finite joins, finite meets, top and bottom opens, cover-refinement, optional complemented-subledger boundary, displayed membership reads, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a topology, lattice, Boolean, or setlike consumer may use a locale claim.

Independence witness: topology, lattice, booleanalgebra, setlike: $\mathsf{LocaleSpace}^{\uparrow}$ is not bijective to any listed sibling because it binds point-free open-index, finite lattice, cover-refinement, optional clopen-boundary, and downstream membership rows in a single finite NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocaleSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocaleSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5153.1, Definition 5153.2, and Definition 5153.3 seed the point-free open-index, finite lattice, and cover-refinement route over topology, lattice, Boolean-boundary, setlike, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocaleSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host powerset of opens, quotient point-space representation, selected points, choice-indexed covers, spatiality, global Boolean algebra of opens, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite join and meet exactness, endpoint open exactness, cover-refinement stability, complemented-boundary restriction, membership-read boundary, transport, replay, provenance, and local naming for BEDC.Derived.LocaleSpaceUp.

Constructive story: A $\mathsf{LocaleSpace}^{\uparrow}$ packet is generated from an open-index carrier row, finite join and meet rows, top and bottom open rows, cover-refinement rows, optional Boolean boundary rows, setlike membership-read rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{DiniUniformMonotone}^{\uparrow}$ packet routes compact-metric Dini data through chapter 129, chapter 1387, and chapter 5795 before the child files expose the finite uniform-modulus and Real-seal route.

Chapter 5154

A Concrete Naming Certificate for $\mathsf{DiniUniformMonotone}^{\uparrow}$

Following Dini and Bishop–Bridges on constructive compact uniform convergence, the $\mathsf{DiniUniformMonotone}^{\uparrow}$ packet records the finite monotone-window route by which a Dini-style convergence certificate hands a uniform-modulus consumer to regular-rational readback and the terminal Real seal. It sits over the Dini convergence packet of chapter 1387, the extracted uniform-modulus ledger of chapter 5795, the lower and upper semicontinuity boundaries of chapter 1536 and chapter 1640, and the located monotone-convergence route of chapter 3373. It also reads finite stream windows through chapter 126, regular-rational tolerances through chapter 301, and the terminal real boundary through chapter 38. The packet names only the finite route from displayed monotone data to a uniform-modulus handoff; it does not import open-cover compactness, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5154.1 (Dini uniform-monotone carrier)**.** *A* $\mathsf{DiniUniformMonotone}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, M, L, S^{-}, S^{+}, G, W, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the accepted* $\mathsf{DiniTheorem}^{\uparrow}$ *row, exposing the compact finite-window monotone convergence surface and no independent open-cover coordinate.*
2. *M is the accepted* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ *row, exposing the finite net, rational tolerance budget, extracted uniform-modulus row, and uniform-limit handoff consumed by later rows.*
3. *L is the* $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$ *handoff row, recording the located supremum route used by the monotone tail read before any real seal is exposed.*
4. *S^{-} and S^{+} are the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *and* $\mathsf{UpperSemicontinuous}^{\uparrow}$ *boundary rows, storing the displayed lower and upper semicontinuity checks at the finite window boundary.*
5. *G is the monotone-window ledger, listing the inspected family indices, pointwise comparison rows, semicontinuity boundary rows, and the finite handoff from D to M and L.*
6. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window row through which source observations, monotone comparisons, semicontinuity checks, and modulus requests are inspected.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance row, storing the regular-rational readbacks assigned to the uniform-modulus request and to the terminal real seal.*

8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after $D, M, L, S^-, S^+, G, W, Q$ have been displayed.*
9. *E is the finite uniform-modulus route row, recording the displayed passage from Dini finite windows through regular-rational tolerance data before R is consumed.*
10. *H records componentwise* hsame *transport for Dini, uniform-modulus, located-monotone, semicontinuity, stream-window, rational-readback, route, real-seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a uniform-modulus request through $D, M, L, S^-, S^+, G, W, Q, E, R, H, P, N$*
12. *P is the* Pkg *provenance over* $\mathsf{DiniUniformMonotone}^{\uparrow}$, $\mathsf{DiniTheorem}^{\uparrow}$, $\mathsf{DiniUniformLimitModulus}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{UpperSemicontinuous}^{\uparrow}$, $\mathsf{LocatedMonotoneConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformMonotone}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, L, S^-, S^+, G, W, Q, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, countable choice, quotient real equality, hidden selected limits, detached real representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5154.2 (Dini uniform-monotone NameCert obligations)**.** *For every accepted* $\mathsf{DiniUniformMonotone}^{\uparrow}$ *carrier*

$$U = (D, M, L, S^-, S^+, G, W, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniUniformMonotone}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the Dini finite-window row, extracted uniform-modulus row, located-monotone handoff, lower and upper semicontinuity boundary rows, monotone-window ledger, stream-window row, regular-rational tolerance row, Real seal, route row, transport, replay, provenance, and local naming;*
2. *monotone-window ledger admission, requiring every family index, comparison row, and tail request used by a consumer to occur in G and to be read from D, M, L;*
3. *compact finite-modulus handoff, requiring the uniform-modulus row M and the route row E to mediate every tolerance request before any* $\mathsf{Real}^{\uparrow}$ *seal is exposed;*
4. *semicontinuity boundary admission, requiring S^- and S^+ to record the lower and upper boundary checks attached to the same finite windows named by G and W;*
5. *located-monotone convergence routing, requiring the handoff row L to expose the located supremum route used for the monotone tail read;*
6. *transport and replay stability through H and C, preserving the displayed rows $D, M, L, S^-, S^+, G, W, Q, E, R$ componentwise;*
7. *provenance and local naming through P and N, with no obligation allowed to call on open-cover compactness, countable choice, quotient real equality, detached representatives, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. Carrier admission exposes exactly the rows $D, M, L, S^-, S^+, G, W, Q, R, E, H, C$ so each obligation is read from a displayed coordinate of Definition 5154.1.

The monotone-window obligations are local to D, M, L and G. The Dini row supplies the finite monotone convergence surface, the uniform-modulus row supplies the extracted finite-modulus handoff, the located-monotone row supplies the tail route, and G records the inspected indices and comparisons.

The boundary obligations are local to S^-, S^+, W, Q, E, R. The lower and upper semicontinuity rows are attached to the same stream windows and regular-rational tolerances, while E records the route that must be traversed before the terminal $\mathsf{Real}^\uparrow$ row R can be read.

Finally, H and C transport and replay only the displayed rows, and P, N source and name the same packet. Since the excluded compactness, choice, quotient, representative, and completeness data are absent from the carrier, they cannot occur among the local NameCert obligations. □

Theorem 5154.3 (Dini uniform-monotone finite-modulus route)**.** *Let*

$$U = (D, M, L, S^-, S^+, G, W, Q, R, E, H, C, P, N)$$

be an accepted $\mathsf{DiniUniformMonotone}^\uparrow$ *carrier. Every uniform-modulus consumer exported by* U *factors through the displayed Dini finite-window route*

$$D, G, W, S^-, S^+, M, L, Q, E, R, H, C, P, N$$

before the $\mathsf{Real}^\uparrow$ *seal* R *is consumed. Thus a consumer may read the compact finite-window monotonicity data, semicontinuity boundary checks, extracted uniform modulus, located monotone-convergence handoff, stream windows, and regular-rational tolerance rows, but it may not replace this route by open-cover compactness, countable choice, quotient real equality, a hidden selected limit, or ambient* $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Start with a uniform-modulus consumer. By the carrier definition, the consumer can reach a terminal real row only at R, and the route row E records the predecessors of that read.

The Dini finite-window portion is supplied by D, G, W. These rows name the compact monotone windows, inspected family indices, comparison rows, and stream windows visible to the consumer.

The boundary and convergence handoff is then forced through S^-, S^+, M, L, Q. The semicontinuity rows keep the lower and upper boundary checks tied to the same finite windows, the uniform-modulus row mediates the tolerance request, the located-monotone row supplies the tail route, and the regular-rational row supplies the displayed readback.

The structural rows H, C, P, N preserve, replay, source, and name this same route. Since no alternative compactness, choice, quotient, selected-limit, or completeness coordinate is present, every accepted consumer factors through the displayed route before the Real seal. □

Theorem 5154.4 (Dini uniform-monotone compact-metric route)**.** *Every accepted* $\mathsf{DiniUniformMonotone}^\uparrow$ *read first exposes the* $\mathsf{CompactMetric}^\uparrow$ *finite-window source of chapter 129 through the* $\mathsf{DiniTheorem}^\uparrow$ *and* $\mathsf{DiniUniformLimitModulus}^\uparrow$ *rows of chapter 1387 and chapter 5795 before it reaches* $\mathsf{RegSeqRat}^\uparrow$ *readback and the terminal* $\mathsf{Real}^\uparrow$ *seal. Thus the finite-modulus route consumed by* $U = (D, M, L, S^-, S^+, G, W, Q, R,$ *is a compact-metric sibling dependency route, not a detached monotone convergence packet or an ambient compactness theorem.*

Proof. Project the carrier of Definition 5154.1. The Dini row D and uniform-modulus row M are the only coordinates through which compact finite-window data can enter the packet.

Apply Definition 5154.3. Its route forces the consumer through $D, G, W, S^-, S^+, M, L, Q, E, R$ before the Real seal is readable, so the compact-metric source is exposed before regular-rational readback and Real sealing.

The cited compact-metric, Dini-theorem, and uniform-limit-modulus chapters provide exactly the sibling rows used by D and M. Since the carrier has no separate compactness coordinate, no consumer can bypass those rows or replace them by a host compactness principle. □

Theorem 5154.5 (Dini uniform-monotone L10 readback induction)**.** *Every* $\mathsf{Real}^{\uparrow}$*- or* $\mathsf{Completion}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{DiniUniformMonotone}^{\uparrow}$ *packet must induct over the displayed monotone-window ledger* G*. Each induction step passes through the same* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance row* Q*, finite route row* E*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* R *named by the carrier*

$$U = (D, M, L, S^-, S^+, G, W, Q, R, E, H, C, P, N).$$

The L10 readback may reuse the carrier, NameCert obligation surface, and finite-modulus route, but it may not replace this induction by open-cover compactness, countable choice, quotient real equality, hidden selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier of Definition 5154.1. The only row that lists the inspected monotone family indices, comparison rows, semicontinuity boundary rows, and finite handoff data is G, so an L10-facing readback must proceed by finite induction over that ledger.

For the base ledger row, the consumer reads the displayed stream window W, regular-rational tolerance row Q, route row E, and Real seal R only after the corresponding Dini, uniform-modulus, located-monotone, and semicontinuity rows have been exposed. This is exactly the obligation surface of Definition 5154.2.

For the induction step, append one displayed monotone-window entry from G. The same windows W and tolerance row Q are replayed through E, while H and C transport and replay the updated finite route with the same provenance P and local name N.

Finally apply the finite-modulus route of Definition 5154.3. It keeps every uniform-modulus and Real-facing read on the displayed path through $D, G, W, S^-, S^+, M, L, Q, E, R, H, C, P, N$, so no excluded compactness, choice, quotient, selected-limit, or completeness principle can replace the induction. □

Falsifiable prediction: Every accepted $\mathsf{DiniUniformMonotone}^{\uparrow}$ uniform-modulus read must expose a Dini finite-window row, an extracted Dini uniform-limit modulus row, lower and upper semicontinuity boundary rows, a located monotone-convergence handoff, StreamName windows, RegSeqRat tolerance readback, a finite route row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any Real-facing consumer may inspect the result.

Independence witness: dini-theorem, dini-uniform-limit-modulus, lowersemicontinuous, uppersemicontinuous, located-monotone-convergence, streamname, regseqrat, real: $\mathsf{DiniUniformMonotone}^{\uparrow}$ is not bijective to any listed sibling because it binds monotone finite windows, two semicontinuity boundary rows, located monotone-convergence routing, regular-rational tolerances, and an extracted uniform-modulus handoff into one packet before the Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniUniformMonotone}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniUniformMonotone}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5154.1, Definition 5154.2, and Definition 5154.3 seed the finite Dini uniform-monotone packet from compact monotone windows to uniform-modulus and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniUniformMonotone}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, countable choice, quotient real equality, hidden selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window ledger admission, compact finite-modulus handoff, semicontinuity boundary admission, located-monotone convergence routing, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniUniformMonotoneUp.

Constructive story: A $\mathsf{DiniUniformMonotone}^{\uparrow}$ packet is generated from Dini finite-window rows, Dini uniform-limit modulus rows, lower and upper semicontinuity boundary rows, located monotone-convergence rows, StreamName windows,

RegSeqRat tolerance readbacks, finite route rows, Real sealing, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theorem 5154.6 (Dini uniform-monotone sibling lattice route)**.** *Every accepted* DiniUniformMonotone$^{\uparrow}$ *consumer reads the* DiniTheorem$^{\uparrow}$, DiniUniformLimitModulus$^{\uparrow}$, CompactModulusMonotoneConvergence$^{\uparrow}$, LowerSemicontinuous$^{\uparrow}$, UpperSemicontinuous$^{\uparrow}$, LocatedMonotoneConvergence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *rows in the same finite sibling lattice before a uniform-modulus read reaches the Real seal.*

Proof. Start with an accepted consumer of Definition 5154.1. The carrier exposes the Dini finite-window row, the uniform-limit modulus row, the compact-modulus monotone-convergence row of chapter 7553, the lower and upper semicontinuity rows, the located monotone-convergence row, the stream-window row, the regular-rational row, and the terminal real row as displayed coordinates of one finite packet.

Apply Definition 5154.2. Its carrier-admission, monotone-window, compact finite-modulus, semicontinuity, located-routing, transport, replay, provenance, and local naming clauses require these rows to be read through the same local NameCert surface.

Finally use Definition 5154.3. A uniform-modulus read reaches the terminal Real$^{\uparrow}$ seal only after the displayed Dini, compact-modulus monotone-convergence, uniform-limit modulus, semicontinuity, located-monotone, stream, and regular-rational rows have been traversed, so the sibling lattice is fixed before the Real seal is consumed. □

Theorem 5154.7 (Dini uniform-monotone compact dependency route)**.** *Every accepted* DiniUniformMonotone$^{\uparrow}$ *consumer must expose the compact finite-window dependency through the* DiniTheorem$^{\uparrow}$ *and* DiniUniformLimitModulu *rows, the monotone-tail dependency through* LocatedMonotoneConvergence$^{\uparrow}$, *and the compact source discipline already cited by chapter 1387, chapter 5795, and chapter 129 before the route reaches its* RegSeqRat$^{\uparrow}$ *tolerance row and terminal* Real$^{\uparrow}$ *seal.*

Proof. Project an accepted carrier from Definition 5154.1. The compact-facing rows are D, M, G, W, while the monotone-tail handoff is L and the tolerance-to-real route is Q, E, R.

Apply Definition 5154.2. Its compact finite-modulus and located-monotone clauses require every uniform-modulus request to read the Dini finite-window surface, the extracted modulus row, and the located monotone-convergence row before a real-facing consumer inspects R.

Finally use Definition 5154.6. The sibling lattice fixes the compact, monotone, stream, regular-rational, and real rows in one finite packet, so no accepted route can bypass the compact source discipline or replace the monotone dependency by a host convergence theorem. □

The CompleteLattice$^{\uparrow}$ hub routes its finite join, meet, certified-family, monotone-map, and fixed-point boundary rows through chapter 55, chapter 53, chapter 3668, and the downstream fixed-row consumer of chapter 5919.

Chapter 5155

A Concrete Naming Certificate for $\mathsf{CompleteLattice}^{\uparrow}$

Following Tarski and Bourbaki, the $\mathsf{CompleteLattice}^{\uparrow}$ packet records the finite order-theoretic interface in which every displayed certified family has a named join and meet row. It sits above the meet–join order surface of chapter 55, the antisymmetric order carrier of chapter 53, and the displayed membership discipline of chapter 3668. The packet names the rows needed by fixed-point and domain-theoretic consumers while excluding host powersets, Zorn-style maximal principles, unrestricted choice, quotient representatives, and ambient ordinal iteration.

Definition 5155.1 (Complete lattice carrier)**.** *A* $\mathsf{CompleteLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (O, F, J, M, T, B, H, C, P, N)$$

with the following displayed rows:

1. *O is the underlying order row, read through* $\mathsf{Poset}^{\uparrow}$ *and* $\mathsf{Lattice}^{\uparrow}$ *and carrying the visible comparison, meet, and join obligations.*
2. *F is the bounded certified-family row. It records only displayed* $\mathsf{SetLike}^{\uparrow}$ *membership data together with finite lower-bound and upper-bound witnesses for the family being inspected.*
3. *J is the displayed join schedule assigning a least upper bound row to the certified family in F.*
4. *M is the displayed meet schedule assigning a greatest lower bound row to the certified family in F.*
5. *T is the monotone-map row, recording a displayed self-map whose order-preservation is checked against the comparison row in O.*
6. *B is the fixed-point boundary row. It records the finite pre-fixed and post-fixed comparison surface visible to a Tarski-style consumer, without selecting an ordinal chain.*
7. *H records componentwise* hsame *transport for $O, F, J, M, T, B, C, P, N$.*
8. *C records displayed* Cont *replay from an order request through the certified-family row, the join and meet schedules, the monotone-map row, and the fixed-point boundary row.*
9. *P is the* Pkg *provenance over* $\mathsf{CompleteLattice}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteLattice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, F, J, M, T, B, H, C, P, N$. It has no coordinate for a host powerset, Zorn lemma, unrestricted choice, quotient representatives, selected ordinal iteration, or an ambient complete lattice object.

Theorem 5155.2 (Complete lattice NameCert obligations)**.** *For every accepted* $\mathsf{CompleteLattice}^{\uparrow}$ *carrier*

$$L = (O, F, J, M, T, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompleteLattice}^{\uparrow}}$ *surface consists exactly of order-row admission, bounded certified-family exposure, displayed join scheduling, displayed meet scheduling, monotone-map exposure, fixed-point boundary exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every fixed-point-facing read must expose O, F, J, M, T, B before it may consume transport, replay, provenance, or naming rows.*

Proof. Project the carrier of Definition 5155.1. The order row O supplies the only comparison surface, and the family row F supplies the only displayed family whose bounds may be inspected.

The join and meet schedules are finite rows attached to that same family. Thus a consumer cannot replace J or M by an ambient supremum or infimum operation; it must read the displayed schedule bound to F.

The monotone-map row T and fixed-point boundary row B are downstream of O, F, J, M. They name only the comparison data needed by a fixed-point consumer, while H, C, P, N transport, replay, source, and name the same finite route.

Since no excluded host principle or representative selector occurs as a carrier coordinate, these rows exhaust the local NameCert obligations. □

Theorem 5155.3 (Complete lattice monotone fixed-point boundary)**.** *Every fixed-point-facing consumer of an accepted* $\mathsf{CompleteLattice}^{\uparrow}$ *packet factors through the finite route*

$$O, F, J, M, T \longmapsto B$$

before it may read any fixed-point boundary. The exported boundary records monotone-map comparison, certified-family bounds, displayed joins, and displayed meets; it does not export a host powerset construction, Zorn lemma, unrestricted choice, quotient representative, selected ordinal iteration, global Knaster–Tarski theorem, or ambient domain-theoretic completion.

Proof. Begin with the NameCert obligations of Definition 5155.2. They force the consumer to expose the order row, family row, join schedule, meet schedule, monotone-map row, and fixed-point boundary row before any structural support row is read.

The row B is therefore not an independent theorem of fixed-point existence. It is a boundary ledger over the displayed order and completeness schedules, and it is meaningful only after O, F, J, M, T have been consumed.

Transport and replay preserve this route componentwise, while provenance and local naming keep it tied to the $\mathsf{CompleteLattice}^{\uparrow}$ packet. The absence of powerset, choice, quotient, ordinal-iteration, and ambient-completion coordinates prevents the boundary from exporting any of the excluded fixed-point principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteLattice}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompleteLattice}^{\uparrow}$ packet is generated from an order row, a bounded certified-family row, displayed join and meet schedules, a monotone-map row, a fixed-point boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5155.1, Definition 5155.2, and Definition 5155.3 seed the finite complete-lattice surface over order, certified-family, join, meet, monotone-map, fixed-point boundary, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompleteLattice}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host powersets, Zorn lemma, unrestricted choice, quotient representatives, selected ordinal iteration, global Knaster–Tarski fixed-point existence, ambient domain-theoretic completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, order-row exposure, certified-family boundedness, join-schedule exactness, meet-schedule exactness, monotone-map preservation, fixed-point boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompleteLatticeUp.

Theorem 5155.4 (Complete lattice order sibling route)**.** *Every* $\mathsf{CompleteLattice}^{\uparrow}$ *fixed-point read or family-boundary read factors first through the finite order sibling route*

$$\mathsf{SetLike}^{\uparrow}, \mathsf{Poset}^{\uparrow}, \mathsf{Lattice}^{\uparrow} \longmapsto \mathsf{CompleteLattice}^{\uparrow}.$$

The $\mathsf{SetLike}^{\uparrow}$ *membership rows expose the displayed family, the* $\mathsf{Poset}^{\uparrow}$ *row supplies the antisymmetric comparison surface, and the* $\mathsf{Lattice}^{\uparrow}$ *row supplies the meet and join operations available before the complete-lattice schedules are read. Only after those sibling rows are visible may a consumer expose the complete-lattice join schedule, meet schedule, monotone-map row, or fixed-point boundary row.*

Proof. Project the carrier of Definition 5155.1. The certified-family row F is read as displayed membership data, so every family-boundary consumer begins with the $\mathsf{SetLike}^{\uparrow}$ surface.

The order row O is not a free comparison relation. It is read through the antisymmetric $\mathsf{Poset}^{\uparrow}$ surface and the meet–join $\mathsf{Lattice}^{\uparrow}$ surface named in the carrier, so fixed-point consumers must expose those sibling rows before using J, M, T, or B.

The join and meet schedules are therefore complete-lattice rows over an already visible membership and order route. They do not replace the sibling route by an ambient powerset, unrestricted supremum operator, quotient representative, or selected ordinal iteration. □

$\mathsf{PointwiseErgodic}^{\uparrow}$ routes finite orbit averages through chapter 196, chapter 92, and chapter 38 before any average row is consumed.

Chapter 5156

A Concrete Naming Certificate for $\mathsf{PointwiseErgodic}^{\uparrow}$

Following Birkhoff and von Neumann on pointwise ergodic averages, the $\mathsf{PointwiseErgodic}^{\uparrow}$ packet records only the finite orbit-window and average-readback data that a BEDC consumer may inspect before any almost-everywhere convergence theorem is visible. It sits after the transformation and invariant-row surface of chapter 196, the event and mass rows of chapter 92, and the terminal real-name seal of chapter 38. The packet names finite orbit segments, summation ledgers, average rows, measure-context rows, real seals, transport, replay, provenance, and local naming; it does not assert the classical pointwise ergodic theorem.

Definition 5156.1 (PointwiseErgodic carrier)**.** *A* $\mathsf{PointwiseErgodic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (E, M, O, S, A, R, H, C, Q, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{Ergodic}^{\uparrow}$ *row exposing the displayed measure-preserving transformation and invariant-row ledger consumed by the packet.*
2. *M is the* $\mathsf{Measure}^{\uparrow}$ *row carrying the finite measurable-event and mass requests attached to the inspected orbit windows.*
3. *O is the orbit-window row, listing the finitely many iterates of the displayed transformation that are currently read.*
4. *S is the finite summation ledger for the values read along O.*
5. *A is the finite average row, obtained from S and the displayed window length before any limiting conclusion is available.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the average values exported to real-facing consumers.*
7. *H records componentwise* hsame *transport for the ergodic, measure, orbit, summation, average, real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an orbit-average request through E, M, O, S, A and into R.*
9. *Q is the* Pkg *provenance over* $\mathsf{PointwiseErgodic}^{\uparrow}$, $\mathsf{Ergodic}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{PointwiseErgodic}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $E, M, O, S, A, R, H, C, Q, N$. It has no coordinate for full almost-everywhere convergence, countable choice, a selected invariant representative, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5156.2 (PointwiseErgodic NameCert obligations)**.** *For every accepted* $\mathsf{PointwiseErgodic}^{\uparrow}$ *carrier*

$$P = (E, M, O, S, A, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{PointwiseErgodic}^{\uparrow}}$ *surface consists exactly of carrier admission, ergodic-row exposure, measure-context exposure, orbit-window inspection, finite summation accounting, finite average formation, real-seal routing, componentwise transport, displayed replay, provenance, local naming, and non-escape from the excluded host principles.*

Proof. Project the carrier of Definition 5156.1. The analytic rows are E, M, O, S, A, R, and the structural rows are H, C, Q, N.

The orbit-window row O is finite. The summation ledger S reads only the displayed iterates in that window, and the average row A is formed from the same finite ledger before any limiting statement can be consumed.

The measure and real rows do not supply an almost-everywhere theorem. The measure row M records the finite event and mass context for the inspected windows, while R seals only the displayed average values.

Finally H, C, Q, N transport, replay, source, and name the same route. Since no other coordinate occurs in the carrier, the NameCert surface exports none of full almost-everywhere convergence, countable choice, selected invariant representatives, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5156.3 (PointwiseErgodic finite average route)**.** *Every real-facing read exported by an accepted* $\mathsf{PointwiseErgodic}^{\uparrow}$ *carrier factors through*

$$E \to M \to O \to S \to A \to R$$

before the average value is consumed. The route records an ergodic source row, finite measure context, displayed orbit window, summation ledger, finite average row, and terminal real seal, but it does not assert convergence of the averages on an almost-everywhere set.

Proof. Start with an accepted carrier $P = (E, M, O, S, A, R, H, C, Q, N)$. By Definition 5156.1, the only average coordinate is A, and it is downstream of the orbit-window and summation rows.

The ergodic row E supplies the transformation ledger, and M supplies the finite measure context in which the inspected orbit window is read. The window O and summation ledger S then determine the finite average row.

The terminal real-facing read is R. Transport, replay, provenance, and local naming through H, C, Q, N preserve this route and do not add a convergence coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{PointwiseErgodic}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PointwiseErgodic}^{\uparrow}$ packet is generated from an ErgodicUp source row, a MeasureUp finite context row, a displayed orbit-window row, a finite summation ledger, a finite average row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PointwiseErgodic}^{\uparrow}}$, seed)

Scope closed: Definition 5156.1, Definition 5156.2, and Definition 5156.3 seed the finite orbit-average certificate over ErgodicUp, MeasureUp, and RealUp rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{PointwiseErgodic}^{\uparrow}}$, unformalized)
Bridge status: none
Not claimed: This chapter does not close full almost-everywhere convergence, countable choice, selected invariant representatives, quotient equality of functions, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.
Upgrade path: Obligation closure requires checked carrier admission, ergodic-row exposure, measure-context exposure, orbit-window inspection, summation accounting, finite average formation, real-seal routing, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.PointwiseErgodicUp.

ProofTraceNormalForm$^{\uparrow}$ routes terminal proof-trace reads through the typed endpoint boundary of chapter 562, subject-reduction preservation, type-classifier membership, and the MetaCIC frontier of chapter 4238.

Chapter 5157

A Concrete Naming Certificate for $\mathsf{ProofTraceNormalForm}^{\uparrow}$

The $\mathsf{ProofTraceNormalForm}^{\uparrow}$ packet realizes the type-checking-as-classifier-membership vision of chapter 9367 as a finite proof-trace normal-form surface. It sits after the typed endpoint boundary of chapter 562, the preservation row of chapter 483, the classifier-membership surface of chapter 476, and the concrete type-checking classifier packet of chapter 3911. The packet records proof trace, Ext membership, typed Cont replay, subject-reduction handoff, terminal normal-form boundary, transport, provenance, and local naming; it does not export host conversion, normalization oracles, erased proof semantics, or quotient term equality.

The proof-trace normal-form carrier is consumed through the typed classifier route of Definition 5157.5 before it is handed to MetaCIC normalization or confluence consumers. The downstream handoff is the candidate-normalization confluence route of chapter 5547; it receives the same proof trace, classifier membership, subject-reduction, terminal normal-form, transport, replay, provenance, and local naming rows rather than a detached normalization oracle.

Definition 5157.1 (ProofTraceNormalForm carrier)**.** *A* $\mathsf{ProofTraceNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, E, R, S, V, J, H, C, P, N)$$

with the following displayed rows:

1. *T is the proof-trace row, listing the finite rule applications and term windows whose type-checking path is being inspected.*
2. *E is the* Ext *classifier-membership row read through* $\mathsf{TypeClassifierMembership}^{\uparrow}$*.*
3. *R is the typed* Cont *replay row recording the displayed reduction route for the trace.*
4. *S is the* $\mathsf{SubjectReduction}^{\uparrow}$ *handoff row that preserves membership along the displayed route.*
5. *V is the* $\mathsf{TypedReductionNormalForm}^{\uparrow}$ *terminal-boundary row for the final typed normal form.*
6. *J is the* $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$ *row that binds the same membership, derivation, preservation, and erasure-facing data into a finite checker packet.*
7. *H records componentwise* hsame *transport for the proof trace, membership, route, preservation, normal-form, checker, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from proof-trace inspection through membership, typed reduction, preservation, and terminal normal-form access.*

9. *P is the* Pkg *provenance over* ProofTraceNormalForm$^{\uparrow}$, TypeClassifierMembership$^{\uparrow}$, SubjectReduction$^{\uparrow}$, TypedReductionNormalForm$^{\uparrow}$, TypeCheckingClassifierMembership$^{\uparrow}$, BHist, Ext, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ProofTraceNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, E, R, S, V, J, H, C, P, N$. It has no coordinate for host conversion, semantic equality of terms, a normalization oracle, proof objects outside the displayed trace, quotient term representatives, or ambient global normalization.

Theorem 5157.2 (ProofTraceNormalForm NameCert obligations)**.** *For every accepted* ProofTraceNormalForm$^{\uparrow}$ *carrier*

$$F = (T, E, R, S, V, J, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ProofTraceNormalForm}^{\uparrow}}$ *surface consists exactly of proof-trace admission, classifier-membership exposure, typed-route replay, subject-reduction handoff, terminal normal-form access, checker-packet alignment, componentwise transport, displayed continuation replay, provenance, local naming, and non-escape from host conversion or normalization oracles.*

Proof. Project the carrier of Definition 5157.1. The trace row T, membership row E, typed route R, preservation row S, normal-form row V, and checker row J are the only analytic coordinates.

The membership and route rows are read before the normal-form boundary. The subject-reduction row S preserves the displayed membership through the typed continuation route R, and the row V is reached only after that preservation handoff.

The checker row J aligns the same data with the finite type-checking classifier packet. It does not add host conversion or a normalization procedure; it records membership, derivation, preservation, and erasure-facing rows already visible to the packet.

The rows H, C, P, N transport, replay, source, and name this finite surface. Since no other coordinate occurs in the carrier, no accepted consumer can leave the displayed proof-trace normal-form route. □

Theorem 5157.3 (ProofTraceNormalForm terminal route)**.** *Every terminal normal-form read exported by an accepted* ProofTraceNormalForm$^{\uparrow}$ *carrier factors through*

$$T \to E \to R \to S \to V \to J$$

with H, C, P, N preserving and naming the same route. The read uses proof trace, classifier membership, typed reduction replay, subject reduction, terminal boundary, and checker alignment, but it does not use host conversion, semantic term equality, quotient representatives, erased proof semantics, or a normalization oracle.

Proof. Start with an accepted carrier $F = (T, E, R, S, V, J, H, C, P, N)$. The terminal row is V, and the carrier places it after the proof trace, membership row, typed continuation route, and subject-reduction handoff.

The checker row J records that the same route is a finite type-checking classifier packet. This alignment is downstream of the displayed membership and preservation data, not a separate host checker.

Finally H, C, P, N transport, replay, source, and name the route. Because the carrier has no host conversion, semantic equality, quotient representative, erased proof semantics, or normalization-oracle coordinate, the terminal read cannot use one. □

Theorem 5157.4 (ProofTraceNormalForm finite candidate induction)**.** *Every accepted* $\mathsf{ProofTraceNormalForm}^{\uparrow}$ *route over a finite proof trace is obtained by induction over the displayed trace row* T*. Each step preserves* Ext *membership, typed* Cont *replay,* $\mathsf{SubjectReduction}^{\uparrow}$ *handoff, terminal normal-form access, checker alignment, componentwise transport, replay, provenance, and local naming through the same carrier*

$$F = (T, E, R, S, V, J, H, C, P, N).$$

Proof. Induct over the finite proof-trace row T of Definition 5157.1. The base trace has no hidden rule application, so the membership row E, typed replay row R, preservation handoff S, terminal boundary V, and checker row J are exactly the displayed seed rows.

For the induction step, append one displayed trace entry. The Ext membership row is preserved by the typed Cont replay row, and the $\mathsf{SubjectReduction}^{\uparrow}$ handoff transports that membership to the next terminal-normal-form boundary.

The checker alignment row J then reads the same updated membership, replay, preservation, and terminal rows. Componentwise hsame transport and displayed Cont replay keep the updated route inside H and C.

Finally P and N source and name the same finite packet. Since the carrier has no coordinate for host conversion, semantic term equality, erased proof semantics, quotient representatives, or a normalization oracle, the induction produces only accepted $\mathsf{ProofTraceNormalForm}^{\uparrow}$ routes. □

Falsifiable prediction: A consumer that reaches V without $T, E, R, S, J, H, C, P, N$ refutes the $\mathsf{ProofTraceNormalForm}^{\uparrow}$ packet.

Independence witness: typedreductionnormalform, subjectreduction, typeclassifiermembership, type-checking-classifier-membership: $\mathsf{ProofTraceNormalForm}^{\uparrow}$ is not bijective to them because it binds trace, membership, replay, preservation, terminal normal form, checker alignment, transport, replay, provenance, and naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{ProofTraceNormalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{ProofTraceNormalForm}^{\uparrow}$ packet is generated from a proof-trace row, Ext classifier-membership row, typed Cont replay row, SubjectReductionUp handoff, TypedReductionNormalFormUp terminal row, TypeChecking-ClassifierMembershipUp alignment row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ProofTraceNormalForm}^{\uparrow}}$, seed)

Scope closed: Definition 5157.1, Definition 5157.2, and Definition 5157.3 seed the finite proof-trace route from classifier membership to terminal typed normal form.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ProofTraceNormalForm}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host conversion, semantic equality of terms, quotient representatives, erased proof semantics, normalization oracles, global normalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked proof-trace admission, classifier-membership exposure, typed-route replay, subject-reduction handoff, terminal normal-form access, checker-packet alignment, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.ProofTraceNormalFormUp.

Theorem 5157.5 (ProofTraceNormalForm typed classifier route)**.** *Every terminal* $\mathsf{ProofTraceNormalForm}^{\uparrow}$ *read must expose the typed endpoint boundary of chapter 562, preservation through chapter 483, classifier membership through chapter 476, and the checker packet of chapter 3911 before the terminal row* V *is read. The route is carried by*

$$F = (T, E, R, S, V, J, H, C, P, N)$$

and exports no host conversion, semantic term equality, quotient representative, erased proof semantics, or normalization oracle.

Proof. Project the carrier rows $T, E, R, S, V, J, H, C, P, N$ of Definition 5157.1. The membership row E is the classifier boundary, the replay row R is the displayed typed route, the preservation row S is the subject-reduction handoff, the terminal row V is the typed normal-form endpoint, and J is the finite checker packet.

Apply Definition 5157.3. It orders the route through proof trace, classifier membership, typed replay, subject reduction, terminal boundary, and checker alignment before any terminal read is exported.

Apply Definition 5157.4. It keeps the same rows visible over the finite proof trace, so the typed endpoint boundary, preservation handoff, classifier-membership row, and checker packet cannot be replaced by host conversion or an oracle.

Finally H, C, P, N transport, replay, source, and name the same packet. Since Definition 5157.2 lists no coordinate for semantic term equality, quotient representatives, erased proof semantics, or normalization oracles, a terminal read of V must follow the displayed typed-classifier sibling route. □

Theorem 5157.6 (ProofTraceNormalForm MetaCIC residual route)**.** *Every terminal* $\mathsf{ProofTraceNormalForm}^{\uparrow}$ *read used by a MetaCIC normalization or confluence consumer must display* $\mathsf{TypeClassifierMembership}^{\uparrow}$*,* $\mathsf{SubjectReduction}^{\uparrow}$*,* $\mathsf{TypedReductionNormalForm}^{\uparrow}$*,* $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$*, and the MetaCIC residual or normalization frontier route before the terminal normal-form row is consumed. In carrier notation*

$$F = (T, E, R, S, V, J, H, C, P, N),$$

the rows E, S, V, J remain visible to consumers such as chapter 7825 and chapter 4238; the export provides no host conversion, quotient term equality, erased proof semantics, or normalization oracle.

Proof. Project the carrier $F = (T, E, R, S, V, J, H, C, P, N)$ from Definition 5157.1. The row E is the $\mathsf{TypeClassifierMembership}^{\uparrow}$ boundary, S is the $\mathsf{SubjectReduction}^{\uparrow}$ handoff, V is the $\mathsf{TypedReductionNormalForm}^{\uparrow}$ terminal row, and J is the $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$ checker alignment row.

Apply Definition 5157.5. It already places classifier membership, subject reduction, typed normal form, and type-checking membership before any terminal read of V is exported. A MetaCIC normalization or confluence consumer therefore receives the same ordered boundary before it may feed the residual-gap or parallel-diamond frontier.

The MetaCIC-facing handoff is only a route through the displayed rows. The residual and normalization frontier chapters may consume E, S, V, J, H, C, P, N as finite proof-trace evidence, but the packet contains no coordinate for host conversion, quotient term equality, erased proof semantics, or a normalization oracle, so the terminal normal-form row cannot be consumed through any off-packet shortcut. □

Chapter 5158

A Concrete Naming Certificate for $\mathsf{RegularCauchyFunctor}^{\uparrow}$

Following Bishop and Bridges on uniform maps between regular Cauchy presentations, the $\mathsf{RegularCauchyFunctor}^{\uparrow}$ packet records the finite transport route by which a regular Cauchy name in one displayed presentation is read as a regular Cauchy name in another. It sits between the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the rational regular readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the completion-facing functorial surface of chapter 423. The packet names functorial transport as displayed BHist data; it does not assert quotient representative equality, select a limiting real, or import ambient completeness.

Definition 5158.1 (Regular Cauchy functor carrier)**.** *A* $\mathsf{RegularCauchyFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, M, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *row, recording the inspected source windows, source precision requests, and regular Cauchy tail schedule.*
2. *T is the target* $\mathsf{StreamName}^{\uparrow}$ *row, recording the target windows produced by the transported readback.*
3. *M is the modulus row, naming the finite precision conversion that sends each target request to a source request.*
4. *R is the mapped* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, assembled from the source windows in S, the target windows in T, and the modulus row M.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-control row, recording the dyadic radii, slack, comparison budget, and tail inequalities used by the transport.*
6. *H is the componentwise* hsame *transport row for S, T, M, R, Q, C, P, N.*
7. *C is the displayed* Cont *replay row from a target precision request through the modulus row, source window, mapped readback, dyadic tolerance ledger, and target window.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFunctor}^{\uparrow}}$ *row binding the displayed transport packet.*

The classifier compares accepted packets only through $S, T, M, R, Q, H, C, P, N$. It has no coordinate for selected limits, quotient stream representatives, host function extensionality, full $\mathsf{Real}^{\uparrow}$ *completeness, countable choice, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyFunctorUp.RegularCauchyFunctorTasteGate single carrier alignment`

Theorem 5158.2 (Regular Cauchy functor NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFunctor}^{\uparrow}$ *carrier*

$$F = (S, T, M, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission, source-window display, target-window display, modulus-row display, mapped* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance control, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5158.1. The analytic rows are S, T, M, R, Q: they expose the source observations, target observations, finite precision conversion, mapped rational readback, and dyadic tolerance budget.

The structural rows cannot add a new analytic coordinate. The row H preserves the displayed components, C replays the same request route, P records the sibling dependencies, and N names the resulting packet.

Since no row for selected limits, quotient representatives, or host function equality is present, the listed rows exhaust the local NameCert obligations. Any transport claim omitting one of them is only a projection of F, not an accepted $\mathsf{RegularCauchyFunctor}^{\uparrow}$ packet. □

Lean4 ✓ `BEDC.Derived.RegularCauchyFunctorUp.RegularCauchyFunctorCarrier namecert obligations`

Theorem 5158.3 (Regular Cauchy functor composition law)**.** *Let* $F = (S, T, M, R, Q, H, C, P, N)$ *and* $G = (T, U, M', R', Q', H', C', P', N')$ *be accepted* $\mathsf{RegularCauchyFunctor}^{\uparrow}$ *packets whose target row of* F *is the source row of* G*. Their displayed composite is the finite packet obtained by composing the modulus rows* M' *after* M*, replaying the source-to-middle and middle-to-target windows through* C *and* C'*, and concatenating the readback, tolerance, transport, provenance, and local-name rows. The composite exports only the resulting* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* NameCert *data.*

Proof. Read the shared row T as the middle window surface. The first packet transports a target request for T back to S by M, C, while the second transports a target request for U back to T by M', C'.

Compose the request conversions in the displayed order. The replay route first uses C' to reach the middle request, then C to reach the source request; the readback rows R, R' and tolerance rows Q, Q' supply the rational and dyadic evidence for the same route.

The remaining rows are structural. Componentwise transport is inherited from H, H', provenance is repacked from P, P', and the local names N, N' bind the composite certificate. No additional host equality or selected limit is introduced by this finite repacking. □

Theorem 5158.4 (Regular Cauchy functor Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularCauchyFunctor}^{\uparrow}$ *packet factors through the displayed source and target* $\mathsf{StreamName}^{\uparrow}$ *rows, the modulus row, the mapped* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-control row before any real-name seal can be read. The packet exports no selected limit, no quotient representative, no full* $\mathsf{Real}^{\uparrow}$ *completeness theorem, and no independent host map.*

Proof. Use the carrier $F = (S, T, M, R, Q, H, C, P, N)$. A real-name read can only use the target windows in T after the replay route has opened the precision conversion M, the source windows S, the mapped readback R, and the dyadic tolerance ledger Q.

The rows H, C, P, N preserve, replay, source, and name this same finite route. They do not contain a coordinate for selecting a limit or replacing the displayed stream by a quotient representative.

Thus any $\mathsf{Real}^{\uparrow}$ seal obtained from the packet remains downstream of the named regular Cauchy transport surface. A consumer that asks for ambient completeness or a host map has left the carrier described in Definition 5158.1. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFunctor}\uparrow}$.

Constructive story: A $\mathsf{RegularCauchyFunctor}^{\uparrow}$ packet is generated from source and target StreamName windows, a finite modulus row, mapped RegSeqRat readback, DyadicRatCore tolerance control, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFunctor}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5158.1, Definition 5158.2, Definition 5158.3, and Definition 5158.4 seed the finite functorial transport surface for regular Cauchy names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFunctor}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient representatives, full Real completeness, host function equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window display, target-window display, modulus conversion, RegSeqRat readback exactness, DyadicRatCore tolerance control, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyFunctorUp.

Chapter 5159

A Concrete Naming Certificate for HyperbolicIsometryGroup$^{\uparrow}$

The HyperbolicIsometryGroup$^{\uparrow}$ packet realizes the group-facing route of chapter 9463 as finite disk-map, inverse, hyperbolic-metric preservation, boundary-action, transport, provenance, and NameCert rows. It sits after the disk-coordinate carrier of chapter 377, the metric readback of chapter 3474, the visual-boundary surface of chapter 4181, the Mobius-transform packet of chapter 5110, and the finite evolution route of chapter 195. The packet names a simultaneous isometry-group surface; it is not a completed hyperbolic plane, quotient ideal-boundary equality, Lie-group manifold, Haar-measure object, or physical observer law.

Definition 5159.1 (Hyperbolic isometry group carrier)**.** *A* HyperbolicIsometryGroup$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, M, F, I, B, A, Q, T, C, P, N)$$

with the following displayed rows:

1. *D is the* UnitDisk$^{\uparrow}$ *disk-coordinate row for finite source and target observations.*
2. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-preservation row over those observations.*
3. *F is the* MobiusTransform$^{\uparrow}$ *disk-map row, restricted to maps whose displayed source and target rows remain in the disk carrier.*
4. *I is the inverse row, recording the displayed inverse disk map and the finite two-sided replay checks.*
5. *B is the* HyperbolicVisualBoundary$^{\uparrow}$ *boundary-action row, recording the induced action on displayed visual-boundary data.*
6. *A is the group-law row, displaying identity, composition, and inverse closure for the finite map packet.*
7. *Q is the* DynSystem$^{\uparrow}$ *replay row, used when a finite orbit-style consumer reads repeated action.*
8. *T records componentwise* hsame *transport for disk coordinates, metric preservation, map row, inverse row, boundary action, group law, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a finite disk-map request through inverse checking, metric preservation, boundary action, group-law inspection, and orbit-style replay.*

10. *P is the* Pkg *provenance over* HyperbolicIsometryGroup$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicVisualBoundary MobiusTransform$^{\uparrow}$, DynSystem$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{HyperbolicIsometryGroup}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, F, I, B, A, Q, T, C, P, N$. The carrier has no coordinate for a completed hyperbolic plane, quotient ideal endpoints, continuous Lie-group topology, Haar measure, host analytic equality of maps, or physical observer dynamics.

Theorem 5159.2 (Hyperbolic isometry group NameCert obligations)**.** *For every accepted* HyperbolicIsometryGroup *carrier*

$$G = (D, M, F, I, B, A, Q, T, C, P, N),$$

the local NameCert$_{\text{HyperbolicIsometryGroup}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission, disk-map admission, inverse closure, hyperbolic-metric preservation, visual-boundary action, identity and composition rows, finite orbit replay, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the carrier through Definition 5159.1. The accepted tuple exposes exactly the disk, metric, map, inverse, boundary, group-law, replay, transport, provenance, and naming rows.

The isometry obligation is read from M, F, I. The map row displays the disk action, the inverse row supplies the finite two-sided checks, and the metric row records preservation of the hyperbolic readback on the displayed observations.

The group and boundary obligations are read from A, B, Q. Composition, identity, and inverse closure are finite rows in A, boundary action is confined to B, and repeated action is replayed only through the DynSystem$^{\uparrow}$ row Q.

Transport and replay through T, C, P, N preserve the same packet. Since the carrier stores no completed plane, quotient ideal endpoint, Lie topology, Haar measure, host analytic equality, or physical dynamics, the listed rows exhaust the local NameCert surface. □

Theorem 5159.3 (Hyperbolic isometry group boundary action)**.** *For every accepted* HyperbolicIsometryGroup$^{\uparrow}$ *carrier $G = (D, M, F, I, B, A, Q, T, C, P, N)$, every boundary-action consumer must read the disk-map row F, inverse row I, metric-preservation row M, and group-law row A before the visual-boundary row B can be exported as stable under the action.*

Proof. Start with a boundary-action request. The request is attached to the displayed disk map F, so the disk-coordinate row D and the inverse row I are visible before boundary data can be consumed.

Metric preservation is the row M. It keeps the boundary read tied to the same hyperbolic metric surface rather than to an external visual compactification.

Finally read the group-law row A and the boundary row B. The rows T, C, P, N transport, replay, source, and name this finite route, while Q handles any repeated-action read. Thus boundary stability is a packet fact over $D, M, F, I, B, A, Q, T, C, P, N$, not a quotient-boundary theorem or a completed hyperbolic-plane assertion. □

Falsifiable prediction: If the metric-preservation row is removed, no current boundary-action consumer can recover both inverse closure and visual-boundary stability from the remaining packet rows.

Independence witness: hyperbolic_metric, hyperbolic_visual_boundary, mobius_transform, dynsystem: the new carrier has a simultaneous group law, inverse, metric-preservation, and boundary-action obligation surface that no single sibling packet carries.

The Lean follow-up will provide Nontrivial HyperbolicIsometryGroup$^{\uparrow}$ and FieldFaithful HyperbolicIsometryGroup$^{\uparrow}$ instances in `TasteGate.lean`.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicIsometryGroup}^{\uparrow}}$.

Constructive story: A HyperbolicIsometryGroup$^{\uparrow}$ packet is generated from UnitDisk coordinates, HyperbolicMetric preservation, MobiusTransform disk maps, inverse checks, HyperbolicVisualBoundary action, group-law rows, DynSystem replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicIsometryGroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5159.1, Definition 5159.2, Definition 5159.3, the falsifiable prediction, and the independence witness seed the finite hyperbolic isometry group route over disk-map, inverse, metric-preservation, boundary-action, replay, transport, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicIsometryGroup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic geometry, quotient ideal-boundary equality, Lie-group topology, Haar measure, physical dynamics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-map admission, inverse closure, metric preservation, boundary action, group-law rows, replay, transport, provenance, and local naming for the same finite packet.

Chapter 5160

A Concrete Naming Certificate for $\mathsf{BoundedSelfAdjointOperator}^{\uparrow}$

Following Reed–Simon and Conway on bounded self-adjoint operators on Hilbert spaces, the $\mathsf{BoundedSelfAdjointOperator}^{\uparrow}$ packet records the finite BEDC surface on which a bounded operator can be read together with its adjoint witness and symmetry row. It sits after the Hilbert carrier of chapter 91, the inner-product row of chapter 86, the operator-norm boundary of chapter 3603, the normal-operator packet of chapter 5807, and the spectral-radius consumer boundary of chapter 2352. The packet names bounded self-adjoint operator data; it does not assert spectral-measure existence, functional calculus, compactness, diagonalization, or a host operator-space equality.

Definition 5160.1 (Bounded self-adjoint operator carrier)**.** *A* $\mathsf{BoundedSelfAdjointOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (H, I, G, N, J, S, R, T, C, P, L)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *carrier row for the source and target Hilbert endpoint.*
2. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row through which adjoint comparisons are read.*
3. *G is the bounded operator graph row, recording the displayed action on accepted vectors.*
4. *N is the* $\mathsf{OperatorNorm}^{\uparrow}$ *bound row attached to the same graph.*
5. *J is the adjoint witness row, pairing the action row with the inner-product transpose read.*
6. *S is the self-adjoint symmetry row, identifying the displayed operator row with its adjoint witness through the same* hsame *route.*
7. *R is the spectral-consumer boundary row read by* $\mathsf{NormalOperator}^{\uparrow}$ *and* $\mathsf{SpectralRadius}^{\uparrow}$ *consumers before any spectral request is allowed.*
8. *T records componentwise transport for the Hilbert carrier, inner-product row, graph, norm bound, adjoint witness, symmetry, spectral boundary, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a finite operator observation through graph inspection, norm-bound readback, adjoint comparison, symmetry checking, and spectral-consumer boundary exposure.*

10. *P is the* Pkg *provenance over* $\mathsf{BoundedSelfAdjointOperator}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{NormalOperator}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{BoundedSelfAdjointOperator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $H, I, G, N, J, S, R, T, C, P, L$. The carrier has no coordinate for spectral measures, eigenbasis selection, compactness, quotient operator equality, unbounded domains, or an ambient functional calculus.

Theorem 5160.2 (Bounded self-adjoint operator NameCert obligations)**.** *For every accepted* $\mathsf{BoundedSelfAdjointOperator}^{\uparrow}$ *carrier*

$$A = (H, I, G, N, J, S, R, T, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedSelfAdjointOperator}^{\uparrow}}$ *surface consists exactly of carrier admission, Hilbert-source exposure, inner-product readback, bounded graph admission, operator-norm control, adjoint witness display, self-adjoint symmetry, spectral-consumer boundary exposure, componentwise transport, displayed replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.BoundedSelfAdjointOperatorUp.BoundedSelfAdjointOperatorTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 5160.1. The accepted packet exposes exactly the Hilbert, inner-product, graph, norm, adjoint, symmetry, spectral-boundary, transport, replay, provenance, and naming rows.

The boundedness obligation is read from G, N. The graph row records the displayed operator action, and the operator-norm row supplies the finite bound consumed by downstream operator-theory packets.

The adjoint and symmetry obligations are read from I, J, S. The inner-product row provides the comparison surface, the adjoint witness row records the transpose read, and the self-adjoint row identifies the accepted operator with that witness.

Finally R, T, C, P, L keep every normal-operator or spectral-radius consumer behind the same finite packet. Since no carrier row stores a spectral measure, eigenbasis, compactness assertion, quotient operator equality, unbounded-domain extension, or functional calculus, the listed rows exhaust the local NameCert obligations. □

Theorem 5160.3 (Bounded self-adjoint operator adjoint symmetry)**.** *For every accepted* BoundedSelfAdjointOperat *carrier $A = (H, I, G, N, J, S, R, T, C, P, L)$, any consumer that reads the operator graph through G and the adjoint witness through J must read the self-adjoint symmetry row S over the same Hilbert and inner-product rows H, I before it can export a* $\mathsf{NormalOperator}^{\uparrow}$ *or* $\mathsf{SpectralRadius}^{\uparrow}$ *boundary read.*

Proof. Begin with the graph and adjoint rows. The graph row G is typed over the Hilbert carrier H, while the adjoint witness J is read through the inner-product row I over the same source.

Apply the NameCert obligations above. They require S to be displayed as the row binding the operator graph and adjoint witness before the packet is consumed as self-adjoint data.

The spectral boundary row R is downstream of this symmetry check. Transport, replay, provenance, and local naming through T, C, P, L preserve the same route, so no consumer can replace the displayed adjoint symmetry by a host operator equality, spectral decomposition, compactness claim, or functional-calculus object. □

Theorem 5160.4 (Bounded self-adjoint spectral-measure consumer boundary)**.** *Every consumer that asks for spectral-measure, functional-calculus, or spectral-theorem data from an accepted* BoundedSelfAdjointOpe *packet must first pass through the displayed bounded operator graph G, operator-norm row N, adjoint witness J, and self-adjoint symmetry row S over the same Hilbert and inner-product rows H, I. Projection-valued measure data is then available only through the finite projection-ledger boundary of* $\mathsf{SpectralMeasure}^{\uparrow}$ *in chapter 298. The bounded self-adjoint packet alone cannot export projection-valued measure data, spectral projections, functional-calculus rows, selected decompositions, or a spectral theorem proof.*

Proof. Start with the local NameCert obligations of Definition 5160.2. They expose the bounded operator graph, norm row, adjoint witness, self-adjoint symmetry, spectral-consumer boundary, transport, replay, provenance, and local naming rows, and they include no projection-valued-measure coordinate.

Use the adjoint-symmetry theorem Definition 5160.3. It forces every normal-operator or spectral-radius read through G, J, S over the same H, I rows before the spectral boundary row R can be consumed.

For a projection-valued-measure read, the consumer must enter the separate $\mathsf{SpectralMeasure}^{\uparrow}$ packet of chapter 298. Its public consumer boundary supplies the finite projection ledger, scalar measure windows, transport, replay, provenance, and local naming rows required before spectral-theorem or functional-calculus data may be read.

Thus the bounded self-adjoint packet provides only the graph, norm, adjoint, and symmetry source surface. The projection-valued measure surface belongs to $\mathsf{SpectralMeasure}^{\uparrow}$, so a consumer cannot extract spectral measures, functional calculus, selected decompositions, or spectral-theorem data from $\mathsf{BoundedSelfAdjointOperator}^{\uparrow}$ alone. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedSelfAdjointOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedSelfAdjointOperator}^{\uparrow}$ packet is generated from a Hilbert carrier, an inner-product row, a bounded operator graph, an operator-norm bound, an adjoint witness, a self-adjoint symmetry row, a spectral-consumer boundary, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedSelfAdjointOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5160.1, Definition 5160.2, and Definition 5160.3 seed the bounded self-adjoint operator packet over Hilbert, inner-product, operator-norm, normal-operator, and spectral-radius rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedSelfAdjointOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close spectral measures, positive-operator calculus, compactness, diagonalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded graph admission, norm control, adjoint witness exactness, self-adjoint symmetry, spectral-consumer boundary, transport, replay, provenance, and local naming for the same finite packet.

Chapter 5161

A Concrete Naming Certificate for $\mathsf{CompletelyRegularSpace}^{\uparrow}$

Following Kelley and Engelking, the $\mathsf{CompletelyRegularSpace}^{\uparrow}$ packet records the classical point-versus-closed-set real-valued separation surface as finite BEDC naming data. It sits between the topology source of chapter 88, the point-versus-closed-set neighbourhood route of chapter 5147, the real-number carrier of chapter 38, and the Urysohn-style function consumer of **??**. The packet names only the displayed continuous real-valued separator route; it does not import host powersets, arbitrary function spaces, selected complements, normality, metrization, or ambient completeness.

Definition 5161.1 (Completely regular space carrier)**.** *A* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, R, C, F, H, K, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, carrying the open-index classifier, displayed neighbourhood reads, and closed-row vocabulary available to the packet.*
2. *R is the* $\mathsf{RegularTopologicalSpace}^{\uparrow}$ *source row, tying the point-versus-closed-set request to the regular neighbourhood-separation route already named over T.*
3. *C is the closed-set and point request row, displaying the inspected point, the closed row avoided by that point, and the membership and nonmembership reads over the same topology source.*
4. *F is the* $\mathsf{Real}^{\uparrow}$*-valued* $\mathsf{ContinuousMap}^{\uparrow}$ *separator row. It records a displayed map row, a zero read on the closed-set row, a unit read at the point, and a continuity replay over T.*
5. *H records componentwise* hsame *transport for T, R, C, F, K, P, N and for the displayed real-valued separation reads.*
6. *K records displayed* Cont *replay from a completely-regular request through the topology source, regular-space source, request row, separator row, transport, provenance, and local naming.*
7. *P is the* Pkg *provenance over* $\mathsf{CompletelyRegularSpace}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{RegularTopologicalSpace}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{UrysohnLemma}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletelyRegularSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through T, R, C, F, H, K, P, N. It has no coordinate for a host powerset, an external function space, a chosen complement, normal-space Urysohn data, metrization, host real completeness, Lean verification, or bridge checking.

Theorem 5161.2 (Completely regular space NameCert obligations)**.** *For every accepted* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *carrier*

$$Q = (T, R, C, F, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompletelyRegularSpace}^{\uparrow}}$ *surface consists exactly of topology-source admission through* T*; regular-space source admission through* R*; closed-set and point request admission through* C*;* $\mathsf{Real}^{\uparrow}$*-valued* $\mathsf{ContinuousMap}^{\uparrow}$ *separator exactness through* F*; componentwise* hsame *transport through* H*; displayed* Cont *replay through* K*; provenance through* P*; and local naming through* N*.*

Proof. Project the carrier of Definition 5161.1. The accepted packet displays the topology source, the regular-space source, the point-versus-closed-set request, the real-valued separator row, and the structural rows.

The request row is read before any function row. The row C binds the inspected point and the closed row to the same $\mathsf{Topology}^{\uparrow}$ source, while R supplies only the regular neighbourhood route named by chapter 5147.

The separator obligation is exactly F. It records the $\mathsf{Real}^{\uparrow}$ codomain, the $\mathsf{ContinuousMap}^{\uparrow}$ continuity replay, the zero read on the closed row, and the unit read at the displayed point, so the certificate has no coordinate for a host function space or a selected complement.

Finally H, K, P, N transport, replay, package, and name the same finite route. Since no further coordinate is present, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CompletelyRegularSpaceUp.CompletelyRegularSpaceCarrier namecert obligations`

Theorem 5161.3 (Real-valued separation window)**.** *Every real-valued separation read exported by an accepted* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *packet must pass through* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{RegularTopologicalSpace}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{ContinuousMap}^{\uparrow}$ *before any* $\mathsf{UrysohnLemma}^{\uparrow}$*,* $\mathsf{UrysohnMetrization}^{\uparrow}$*, or metrization consumer reads it. The consumer receives only the finite row sequence* T, R, C, F, H, K, P, N *and cannot read a host powerset, a selected complement, an ambient function-space object, host real completeness, or an untracked Urysohn separator from the packet.*

Lean4 ✓ `BEDC.Derived.CompletelyRegularSpaceUp.CompletelyRegularSpaceCarrier real valued separation window`

Proof. Begin with the source rows. The topology row T supplies the displayed open and closed vocabulary, and the regular-space row R ties the request to the point-versus-closed-set route already named over that topology.

The closed-set and point request row C is the only entry point for the separation problem. It must be visible before the real-valued separator is read, so no later consumer can replace the request by an ambient complement or by a host powerset argument.

The separator row F then displays both codomain and continuity: it is a $\mathsf{Real}^{\uparrow}$-valued $\mathsf{ContinuousMap}^{\uparrow}$ row with the required zero and unit reads. The transport row H and replay row K preserve the same sequence before provenance and naming are inspected.

Thus an Urysohn-style or metrization-facing consumer reads the named finite route through $\mathsf{Topology}^{\uparrow}$, $\mathsf{RegularTopologicalSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{ContinuousMap}^{\uparrow}$. It receives no stronger normality theorem, no selected separating function outside F, and no ambient completeness principle from the completely regular packet. □

Theorem 5161.4 (Completely regular space topology dependency route)**.** *Every* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *real-valued separator read factors through the* $\mathsf{Topology}^{\uparrow}$ *open and closed rows of chapter 88 and the Urysohn-facing route of* **??** *before it exports a* $\mathsf{Real}^{\uparrow}$*-valued* $\mathsf{ContinuousMap}^{\uparrow}$ *separator. The*

exported route is a finite dependency chain through T, R, C, F, H, K, P, N; it is not a host powerset argument, a selected complement, an ambient function-space object, or an untracked Urysohn separator.

Proof. Project the carrier $Q = (T, R, C, F, H, K, P, N)$ of Definition 5161.1. The topology row T is the only source of open and closed vocabulary, so every point-versus-closed-set request is read through the finite topology surface before a separator row can be inspected.

The request then passes through R and C. These rows bind the regular-space neighbourhood route and the displayed point and closed row to the same $\mathsf{Topology}^{\uparrow}$ source; they do not create a host complement or an external powerset carrier.

Only after those rows are present may the separator row F be exported as a $\mathsf{Real}^{\uparrow}$-valued $\mathsf{ContinuousMap}^{\uparrow}$ read. The Urysohn-facing sibling route therefore consumes the displayed topology dependency and the separator row together, while H, K, P, N transport, replay, source, and locally name the same finite chain. □

Theorem 5161.5 (Completely regular space uniformity-forward route)**.** *Any uniform-space or continuous-map consumer of a* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *separator row may read that separator only through the displayed topology source, regular-space source,* $\mathsf{Real}^{\uparrow}$ *codomain, and Urysohn-facing rows of the packet. In particular, the route to chapter 339 and chapter 59 is the finite dependency chain T, R, C, F, H, K, P, N, not a metrization, compactness, host powerset, selected complement, or ambient function-space theorem.*

Proof. Project the carrier $Q = (T, R, C, F, H, K, P, N)$ of Definition 5161.1. The separator row F is not public until the topology row T, regular-space row R, and point-versus-closed-set request row C have all been displayed.

Apply the topology dependency route of Definition 5161.4. It keeps every separator read attached to the $\mathsf{Topology}^{\uparrow}$ open and closed rows and to the Urysohn-facing sibling route before the $\mathsf{Real}^{\uparrow}$-valued $\mathsf{ContinuousMap}^{\uparrow}$ separator is exported.

Finally use the real-valued separation window of Definition 5161.3. A uniform-space or continuous-map consumer receives only the displayed separator route through T, R, C, F, H, K, P, N. Because the carrier has no coordinates for metrization, compactness, host powersets, selected complements, ambient function spaces, or host real completeness, the route is a dependency edge rather than a stronger topological theorem. □

Theorem 5161.6 (Completely regular space realcompactification consumer route)**.** *Every* $\mathsf{HewittRealcompactificati}$ *consumer of a* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *packet first reads the displayed real-valued separator route through chapter 8494. The consumer receives only the finite chain T, R, C, F, H, K, P, N and cannot treat the packet as a selected compactification point, a chosen z-ultrafilter, an ambient product of Real lines, or a host Real-completeness theorem.*

Proof. Start with the real-valued separation window and topology dependency route, Definition 5161.3 and Definition 5161.4. They expose the separator only through the topology source, regular-space source, request row, Real-valued continuous-map row, and structural support rows.

Apply the uniformity-forward route of Definition 5161.5. It keeps the separator public only as the finite dependency chain T, R, C, F, H, K, P, N, with no compactness, powerset, complement, or ambient function-space coordinate.

The Hewitt realcompactification chapter consumes that separator route as a dependency edge. Because the carrier has no row for a selected compactification point, a z-ultrafilter choice, an ambient Real product, or host Real completeness, the consumer cannot read any of those objects from the completely regular packet. □

Theorem 5161.7 (Completely regular space Urysohn consumer route)**.** *Any Urysohn-style separation consumer of an accepted* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *packet must read the displayed topology source of chapter 88, the real-valued separation window, the uniformity-forward route, and the provenance rows before exporting a function-separation packet through* **??**. *The exported route is the finite chain* T, R, C, F, H, K, P, N*; it is not a global normality theorem, a Tietze-extension theorem, a selected complement, or an ambient function-space construction.*

Proof. Project the carrier $Q = (T, R, C, F, H, K, P, N)$ of Definition 5161.1. The topology row T supplies the open and closed vocabulary, while R and C bind the point-versus-closed-set request to that same displayed topology source.

Apply the real-valued separation window of Definition 5161.3. It forces the separator to pass through the $\mathsf{Real}^{\uparrow}$-valued $\mathsf{ContinuousMap}^{\uparrow}$ row F before any Urysohn-style consumer reads a function-separation packet.

Use the uniformity-forward route of Definition 5161.5. It keeps the separator on the finite route through the displayed topology, real-valued separation, and structural rows, and the provenance row P records the same route before local naming by N.

Thus the Urysohn-facing consumer receives only T, R, C, F, H, K, P, N. Since no carrier coordinate supplies normality, a Tietze-extension operator, a selected complement, or an ambient function space, the route is a dependency edge rather than a stronger separation theorem. □

Falsifiable prediction: Every accepted $\mathsf{CompletelyRegularSpace}^{\uparrow}$ read exposes a $\mathsf{Topology}^{\uparrow}$ source row, a $\mathsf{RegularTopologicalSpace}^{\uparrow}$ source row, a closed-set and point request row, a $\mathsf{Real}^{\uparrow}$-valued $\mathsf{ContinuousMap}^{\uparrow}$ separator row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: topology, regular-topological-space, real, continuous-map, urysohn-lemma: $\mathsf{CompletelyRegularSpace}^{\uparrow}$ is not bijective to any listed sibling because it binds real-valued point-versus-closed-set separation as a finite NameCert route between topology and Urysohn-style consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletelyRegularSpace}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletelyRegularSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5161.1, Definition 5161.2, and Definition 5161.3 seed the finite real-valued point-versus-closed-set separation route over topology, regular-space, real, continuous-map, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletelyRegularSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close normality, Urysohn function construction, metrization, host powersets, arbitrary function spaces, selected complements, host real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request-row exactness, real-valued continuous separator exactness, transport, replay, provenance, and local naming for BEDC.Derived.CompletelyRegularSpaceUp.

Constructive story: A $\mathsf{CompletelyRegularSpace}^{\uparrow}$ packet is generated from a Topology source row, a RegularTopologicalSpace source row, a closed-set and point request row, a Real-valued ContinuousMap separator row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Every completely regular separator route factors through the topology source of chapter 88, the point-versus-closed-set regularity source of chapter 5147, the real seal of chapter 38, the continuous-map surface of chapter 59, and the Urysohn consumer of **??**. The top-level $\mathsf{CompletelyRegularSpace}^{\uparrow}$ hub therefore routes its finite separator rows through those siblings before any Urysohn-style reader can consume the displayed real-valued function. CompletelyRegularSpaceUp consumes the separation-function route of **??** together with the ambient chapter 88 carrier, and this dependency is on the displayed Urysohn separation row rather than on a general choice principle or a compactness principle.

Theorem 5161.8 (Completely regular topology–Urysohn forward route)**.** *Every* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *separation read consumes the* $\mathsf{Topology}^{\uparrow}$ *carrier of chapter 88 and the* $\mathsf{UrysohnLemma}^{\uparrow}$ *separation row of* **??** *before any compactification, uniformity, or Kelleyfication consumer uses it.*

Proof. Start with the topology–Urysohn dependency route recorded in Definition 5161.4. It keeps the completely regular separator attached to the topology source, the point-versus-closed-set separation row, the Real-valued continuous-map row, and the Urysohn-facing consumer route.

Now apply the sibling dependency route of Definition 5161.11. That route places every compactification, uniformity, or real-valued separation consumer after the displayed topology carrier and the Urysohn-style separation route.

The forward dependency is therefore fixed before downstream use: a consumer reaches the completely regular row only after the $\mathsf{Topology}^{\uparrow}$ carrier of chapter 88 and the $\mathsf{UrysohnLemma}^{\uparrow}$ separation row of **??** have both been displayed. Compactification, uniformity, and Kelleyfication rows may reuse that separator, but they cannot read it as a bare host function or as a compactness principle. □

Theorem 5161.9 (Completely regular space lattice dependency route)**.** *Every* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *separator read first consumes the* $\mathsf{Topology}^{\uparrow}$ *carrier of chapter 88 and the* $\mathsf{RegularTopologicalSpace}^{\uparrow}$ *point-versus-closed-set source of chapter 5147. Only after those rows are displayed may the packet export its* $\mathsf{Real}^{\uparrow}$*-valued* $\mathsf{ContinuousMap}^{\uparrow}$ *separator row to* $\mathsf{UrysohnLemma}^{\uparrow}$ *or* $\mathsf{UrysohnMetrization}^{\uparrow}$ *consumers. The route is the finite lattice edge* T, R, C, F, H, K, P, N *of Definition 5161.1, not a host powerset, selected complement, arbitrary function space, normality theorem, or metrization proof.*

Proof. Project the carrier $Q = (T, R, C, F, H, K, P, N)$. The topology row T supplies the displayed open and closed vocabulary, while the regular topological row R binds the point-versus-closed-set request to that same source.

The request row C must be visible before the separator row F is exported. Since F is a $\mathsf{Real}^{\uparrow}$-valued $\mathsf{ContinuousMap}^{\uparrow}$ row, an Urysohn-facing consumer receives a displayed separator rather than an ambient family of functions.

Finally the structural rows H, K, P, N preserve the same route for $\mathsf{UrysohnLemma}^{\uparrow}$ and $\mathsf{UrysohnMetrization}^{\uparrow}$ consumers. No carrier coordinate supplies a hidden powerset, selected complement, normality theorem, or metrization proof, so the lattice edge is exactly the displayed topological dependency route. □

Theorem 5161.10 (Completely regular space dossier lattice anchor)**.** *Every* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *dossier read that enters through the lattice route must first consume the* $\mathsf{Topology}^{\uparrow}$ *carrier of chapter 88, the point-versus-closed-set regularity row of chapter 5147, and the Urysohn-style separation sibling of* **??**. *The exported route is the displayed finite separator lattice* T, R, C, F, H, K, P, N *of Definition 5161.1, not a host family of separators, an ambient normality theorem, a compactness principle, or a selected external function space.*

Proof. Project the carrier rows from Definition 5161.1. The topology row T fixes the open and closed vocabulary, while R and C bind the regular point-versus-closed-set request to the same source.

Now apply the topology–Urysohn dependency route and the Urysohn sibling route. They place the real-valued separator row F after chapter 88 and **??**, so every later dossier consumer reads a finite separation route rather than a detached function-space object.

The structural rows H, K, P, N then transport, replay, package, and name that same route. Since no carrier coordinate supplies host separator families, normality, compactness, or an external function space, the dossier lattice anchor is exactly the displayed sibling dependency path. □

Theorem 5161.11 (Completely regular space sibling dependency)**.** *Every* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *consumer reads the* $\mathsf{Topology}^{\uparrow}$ *carrier of chapter 88 together with the local Urysohn-style separation route before any compactification, uniformity, or real-valued separation consumer can use the completely regular row.*

Proof. The local topology–Urysohn dependency route records the displayed topology carrier, the point-versus-closed-set separation data, the continuous real-valued separator row, and the Urysohn consumer route as sibling inputs to the completely regular packet.

When the packet exports its continuous-separation ledger, the $\mathsf{CompletelyRegularSpace}^{\uparrow}$ reader consumes the topology source through chapter 88 and the metrization-facing sibling chapter 3337. Thus the ledger is horizontally tied to the topology carrier and the Urysohn metrization boundary before any consumer treats the real-valued separator as metrization data.

Any later compactification or uniformity reader therefore reaches $\mathsf{CompletelyRegularSpace}^{\uparrow}$ only after those rows are present. The dependency is a finite topological lattice route through chapter 88 and the local Urysohn-style child, not a hidden compactness principle, a choice principle, or a quotient of separation functions. □

Theorem 5161.12 (Completely regular space compact-open route)**.** *Every* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *compactification or uniformity consumer reads the* $\mathsf{Topology}^{\uparrow}$ *carrier, the* $\mathsf{UrysohnMetrization}^{\uparrow}$ *separation boundary, and the* $\mathsf{CompactOpenTopology}^{\uparrow}$ *or* $\mathsf{CompactOpenExhaustion}^{\uparrow}$ *compact-open rows before treating real-valued separators as uniform data.*

Proof. Start with Definition 5161.11. It places every completely regular consumer after the topology carrier of chapter 88 and the local Urysohn-style separation route.

The metrization-facing sibling chapter 3337 supplies the boundary that turns real-valued separators into metric-facing data. Compact-open consumers then read that boundary through chapter 4138 or through the finite exhaustion route of chapter 6756.

Thus a compactification or uniformity reader cannot consume a separator as bare host function data. It must first pass through the topology row, the Urysohn metrization row, and the compact-open rows named by the sibling lattice. □

Theorem 5161.13 (Completely regular space sibling lattice forward route)**.** *Every accepted* $\mathsf{CompletelyRegularSpac}$ *read used by a compact-open or Kelleyfication consumer must first expose the sibling rows for* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{UrysohnLemma}^{\uparrow}$*,* $\mathsf{CompactHausdorff}^{\uparrow}$*, and* $\mathsf{SierpinskiSpace}^{\uparrow}$*. The forward route is a finite sibling lattice edge: the consumer reaches the completely regular packet through those displayed rows before it may read compact-open function-space data, Kelleyfication reflections, or real-valued separation output.*

Proof. Start with the local carrier of Definition 5161.1. Its point-versus-closed-set separation rows are usable only after the topology source and the real-valued separator route are displayed.

Attach the sibling rows. The $\mathsf{Topology}^{\uparrow}$ row supplies the open-set carrier, $\mathsf{UrysohnLemma}^{\uparrow}$ supplies the separation witness route, $\mathsf{CompactHausdorff}^{\uparrow}$ supplies the compact Hausdorff consumer boundary, and $\mathsf{SierpinskiSpace}^{\uparrow}$ supplies the open-set classifier read used by lattice-facing consumers.

Now read the downstream consumers. A compact-open consumer reaches the packet through the compact-open route of Definition 5161.12; a Kelleyfication consumer reaches it through the

Kelleyfication route of chapter 6830. Both routes therefore see the four sibling rows before treating the completely regular packet as a source.

Since the four rows are finite sibling entries, the route is not a bare host topology principle, a selected family of separators, or an unlogged compactness assertion. It is a forward lattice edge from the displayed topological siblings into the compact-open and Kelleyfication readers. □

Theorem 5161.14 (Completely regular space compact-open forward route)**.** *Every* $\mathsf{CompactOpenTopology}^{\uparrow}$ *or* $\mathsf{Kelleyfication}^{\uparrow}$ *consumer that reads a* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *packet first passes through the displayed topology source of chapter 88, the point-versus-closed-set regularity source of chapter 5147, the* $\mathsf{Real}^{\uparrow}$*-valued* $\mathsf{ContinuousMap}^{\uparrow}$ *separator route of chapter 130, and the Urysohn-facing route of* **??**. *The forward read then preserves componentwise transport, displayed replay, provenance, and local naming before any compact-open or Kelleyfication window may consume the separator.*

Proof. Read the completely regular packet through the local topology–Urysohn dependency route and the sibling dependency theorem. These rows expose the topology carrier, the regular topological source, the point-versus-closed-set separation data, and the continuous real-valued separator before any later function-space consumer appears.

A compact-open reader can therefore inspect only the displayed $\mathsf{Topology}^{\uparrow}$ source, $\mathsf{RegularTopologicalSpace}^{\uparrow}$ boundary, $\mathsf{Real}^{\uparrow}$-valued $\mathsf{ContinuousMap}^{\uparrow}$ separator, and Urysohn-facing separation route. The $\mathsf{CompactOpenTopology}^{\uparrow}$ window receives this separator as finite graph and target-open data, not as a host function space or an unrestricted family of separating maps.

A Kelleyfication reader uses the same route after the compact-open ledger has been displayed. Transport, replay, provenance, and local naming remain the rows attached to the original $\mathsf{CompletelyRegularSpace}^{\uparrow}$ packet, so the consumer gains no quotient-open equality, choice-selected separator, ambient compactness principle, or external topology oracle. □

Every $\mathsf{CompletelyRegularSpace}^{\uparrow}$ separator read is dependency-visible as a $\mathsf{Topology}^{\uparrow}$ source row followed by the $\mathsf{UrysohnLemma}^{\uparrow}$ separation route and the $\mathsf{ContinuousMap}^{\uparrow}$ real-valued map row. Thus a downstream compact-open, uniformity, or Kelleyfication consumer receives the displayed point-versus-closed-set separator only through the existing topology and Urysohn sibling lattice of Definition 5161.21; it cannot replace that route by a host family of functions, a selected separator, or an ambient compactness principle.

Theorem 5161.15 (Completely regular space topology–uniformity route)**.** *Every* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *packet that feeds a compact-open or uniformity consumer first exposes the* $\mathsf{Topology}^{\uparrow}$ *source of chapter 88, the* $\mathsf{UrysohnLemma}^{\uparrow}$*-style separation route of* **??**, *and the finite separator rows of Definition 5161.1. A* $\mathsf{CompactOpenTopology}^{\uparrow}$, $\mathsf{CompactOpenUniformConvergence}^{\uparrow}$, *or* $\mathsf{UniformConvergenceSpace}^{\uparrow}$ *consumer therefore receives the row sequence* T, R, C, F, H, K, P, N *through local naming, not a host family of real-valued maps or an ambient uniformity oracle.*

Proof. Project the carrier rows of Definition 5161.1. The topology row T supplies the open-set vocabulary, while R, C, F record the regularity request and the displayed real-valued separator.

Apply the topology–Urysohn sibling lattice of Definition 5161.21. It places the separator after the topology source and Urysohn-style separation route before any compact-open read.

The same finite row sequence is then available to compact-open uniformity consumers. Since H, K, P, N only transport, replay, source, and name the displayed separator packet, no downstream consumer obtains an unrestricted function space, a selected family of separators, or a detached uniformity surface. □

Theorem 5161.16 (Completely regular space Kelleyfication forward route)**.** *Every* $\mathsf{Kelleyfication}^{\uparrow}$ *reader of a* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *separator must first pass through the displayed* $\mathsf{Topology}^{\uparrow}$ *source, the* $\mathsf{RegularTopologicalSpace}^{\uparrow}$ *point-versus-closed-set boundary, the* $\mathsf{Real}^{\uparrow}$*-valued* $\mathsf{ContinuousMap}^{\uparrow}$ *separator, and the Urysohn-facing route before the compact-open ledger consumes the separator. The Kelleyfication window therefore reads the same compact-open consumer path named in Definition 5161.14; it receives no host separator family, quotient-open equality, selected real-valued map, or external compactness principle.*

Proof. Start with the compact-open forward route Definition 5161.14. It already places every compact-open or Kelleyfication consumer after the topology source, regular topological source, real-valued continuous-map separator, and Urysohn-facing separation route.

The Kelleyfication reader can only consume that separator after the compact-open window has displayed the finite graph and target-open data. Since the hub packet supplies no additional carrier field, the Kelleyfication handoff preserves the same topology, regularity, Real, ContinuousMap, and Urysohn rows.

Transport, replay, provenance, and local naming remain attached to the original $\mathsf{CompletelyRegularSpace}^{\uparrow}$ packet. Thus the forward route reaches $\mathsf{Kelleyfication}^{\uparrow}$ only through the compact-open consumer path and cannot export a selected separator family, quotient-open equality, or ambient compactness principle. □

Theorem 5161.17 (Completely regular space Urysohn sibling route)**.** *Every* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *carrier read that separates a point from a closed set consumes the* $\mathsf{Topology}^{\uparrow}$ *open-set classifier of chapter 88 and the Urysohn-style functional separation route of* **??** *before any compactification or uniformity consumer reads it. The exported separator is the finite row sequence named by the local topology–Urysohn dependency child, not a host powerset separation theorem, a selected complement, or an unrestricted family of real-valued functions.*

Proof. Read the carrier through the topology–Urysohn dependency route and the sibling dependency theorem. These expose the displayed topology carrier, the point-versus-closed-set regularity row, the $\mathsf{Real}^{\uparrow}$-valued $\mathsf{ContinuousMap}^{\uparrow}$ separator, and the Urysohn-facing route before the completely regular row is available to downstream consumers.

Any compactification or uniformity reader therefore receives only the finite separation certificate already tied to $\mathsf{Topology}^{\uparrow}$ and $\mathsf{UrysohnLemma}^{\uparrow}$. The route has no coordinate for a hidden compactification, a uniformity generated by an ambient family, host function equality, selected complements, or choice. □

Theorem 5161.18 (Completely regular space regular-open sibling route)**.** *Every accepted* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *separator route consumed by* $\mathsf{RegularOpenSet}^{\uparrow}$*,* $\mathsf{CozeroSet}^{\uparrow}$*, or* $\mathsf{ZeroSet}^{\uparrow}$ *factors through the displayed topology row, the real-valued separator row, and the continuous-map row of Definition 5161.1. The sibling consumer may read the open or zero-locus boundary only through those rows; it receives no host powerset, selected complement, detached open-set lattice, or classical complement operation from the completely regular packet.*

Proof. Project the carrier $Q = (T, R, C, F, H, K, P, N)$ of Definition 5161.1. The topology row T fixes the open and closed vocabulary, while the request row C and separator row F keep the point-versus-closed-set separation attached to a displayed $\mathsf{Real}^{\uparrow}$-valued $\mathsf{ContinuousMap}^{\uparrow}$ route.

Read the regular-open sibling through chapter 8547. It can consume only the topology-facing open and closure-interior information already exposed by T and the separator route; it does not obtain a host powerset or a detached Boolean algebra of opens.

Read the cozero and zero-set siblings through chapter 1857 and chapter 1858. Their positive-apartness and zero-locus routes must use the displayed real-valued continuous-map row F, transported by H and replayed by K, before provenance and local naming are inspected.

Thus the sibling route is exactly the finite topology, real-valued separator, and continuous-map path carried by T, C, F, H, K, P, N. Since no carrier coordinate supplies selected complements, host powersets, or a classical complement operation, none is exported to the regular-open, cozero, or zero-set consumers. □

Theorem 5161.19 (Completely regular space compact Hausdorff Urysohn route)**.** *Every* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *read that exports the local classifier to a compact or Hausdorff consumer first consumes the* $\mathsf{Topology}^{\uparrow}$ *carrier of chapter 88, the* $\mathsf{HausdorffSpace}^{\uparrow}$ *separation boundary of chapter 1925, the compact metric sibling route of chapter 129, and the Urysohn separation route of* **??**. *The exported classifier is therefore the finite row route* T, R, C, F, H, K, P, N *of Definition 5161.1, not a host compactness theorem, a selected separating function, an unrestricted powerset, or an ambient normal-space principle.*

Proof. Start with the local carrier and NameCert obligations of Definition 5161.1 and Definition 5161.2. They expose the topology row, the regular-space row, the point-versus-closed-set request, the real-valued continuous-map separator, and the structural rows before any classifier is public.

Apply the Urysohn sibling route of Definition 5161.17. It forces the separator to pass through the displayed Urysohn separation row rather than through a chosen host function family.

Now read the compact and Hausdorff siblings. The Hausdorff row supplies the separation boundary, and the compact metric row supplies only a displayed compact metric dependency; neither row adds a powerset, a selected separator, or an ambient compactness theorem.

The structural rows H, K, P, N preserve the same route for downstream compact or Hausdorff consumers. Hence every exported classifier remains tied to the Urysohn and compact-Hausdorff sibling lattice before it is read. □

Theorem 5161.20 (Completely regular space Tychonoff compactification link)**.** *Every Tychonoff-style or compactification-facing consumer of* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *must pass through the displayed topology, Hausdorff or compact-metric sibling, and Urysohn separator rows before it reads separator data. In the local lattice this routes the exported separator toward the compact-open topology and Kelleyfication consumers of chapter 4138 and chapter 6830. It does not add a host product compactness theorem, a selected compactification point, an unrestricted Tychonoff theorem, or an ambient powerset of separators.*

Proof. Read the compact-Hausdorff Urysohn route of Definition 5161.19. It exposes the topology, Hausdorff, compact metric, and Urysohn sibling rows before the local separator classifier is exported.

The compact-open topology and Kelleyfication consumers inspect continuous-map and compact-window data only after those rows are visible. Thus a Tychonoff-style compactification read cannot bypass the displayed $\mathsf{Topology}^{\uparrow}$, $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, and $\mathsf{UrysohnLemma}^{\uparrow}$ dependencies.

Since the accepted $\mathsf{CompletelyRegularSpace}^{\uparrow}$ carrier has no coordinate for host product compactness, selected compactification points, or unrestricted powersets of separators, the downstream compactification route remains the stated finite row route. □

Theorem 5161.21 (Completely regular space topology–Urysohn sibling lattice)**.** *Every* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *packet reads its real-valued separating-function route through the* $\mathsf{Topology}^{\uparrow}$ *carrier of chapter 88 and the Urysohn-style sibling route of* **??** *before any* $\mathsf{CompactOpenTopology}^{\uparrow}$, $\mathsf{CompactOpenExhaustion}^{\uparrow}$, $\mathsf{Kelleyfication}^{\uparrow}$*, or compact-Hausdorff consumer may use the exported separator. The lattice edge is the finite row sequence* T, R, C, F, H, K, P, N *of Definition 5161.1, together with Definition 5161.17 and Definition 5161.19; it is not a host powerset argument, an unrestricted function-space construction, a selected complement, normality, metrization, or ambient compactness.*

Proof. Project the carrier rows of Definition 5161.1. The topology row T supplies the displayed open and closed vocabulary, while the request row C and separator row F remain tied to that same source.

Apply the Urysohn sibling route of Definition 5161.17. It places the separating-function read after the topology carrier and the Urysohn-style separation route, rather than after a detached host family of real-valued functions.

Now use the compact-Hausdorff Urysohn route of Definition 5161.19. Compact-open and Kelleyfication consumers may reuse the exported separator only after the same topology and Urysohn rows have been displayed.

The structural rows H, K, P, N preserve this finite lattice edge for downstream consumers. Since the carrier has no coordinate for host powersets, unrestricted function spaces, selected complements, normality, metrization, or compactness, none is exported by the sibling lattice. □

The downstream compact-Hausdorff and Urysohn consumers read $\mathsf{CompletelyRegularSpace}^{\uparrow}$ as a displayed separation substrate, not as an ambient topology principle. A consumer may pass from the point-versus-closed-set rows T, R, C, F, H, K, P, N of Definition 5161.1 to the Urysohn separation route of **??** and then to the compact-Hausdorff sibling lattice of Definition 5161.19; it may not replace that route by host powersets, unrestricted real-valued function spaces, selected complements, normality, metrization, or an unlogged compactness theorem.

Theorem 5161.22 (Completely regular space sibling lattice)**.** *Every accepted* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *separator route is visible in the sibling lattice*

$$\mathsf{Topology}^{\uparrow},\ \mathsf{RegularTopologicalSpace}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{UrysohnLemma}^{\uparrow}.$$

The topology row supplies open and closed vocabulary, the regular-space row supplies the point-versus-closed-set request route, the Real and continuous-map rows carry the displayed separator, and the Urysohn row is only a consumer of that finite route. The packet does not identify this lattice with normality, metrization, a host function space, or a selected complement.

Proof. Project the carrier $Q = (T, R, C, F, H, K, P, N)$ from Definition 5161.1. The rows T, R, C, F already determine the topology source, regular-space request, point-versus-closed-set data, and Real-valued continuous separator.

Use the real-valued separation window and Urysohn consumer route, Definition 5161.3 and Definition 5161.7. They require every Urysohn-facing read to pass through the same topology, regular-space, Real, and continuous-map rows before any separation consumer receives data.

The structural rows H, K, P, N transport, replay, source, and name the displayed lattice. Since no carrier coordinate supplies normality, metrization, a host function space, or a selected complement, the sibling lattice remains a dependency route rather than a stronger topological theorem. □

Theorem 5161.23 (Completely regular space topology-uniformity consumer lattice)**.** *Every* CompletelyRegularSpa *real-valued separator read reaches compact-open, Kelleyfication, Urysohn, and uniformity consumers only after the displayed topology source of chapter 88, the Urysohn-style separator route of* **??***, the compact-open route of Definition 5161.14, and the uniformity-forward route of Definition 5161.5 have all remained visible. Thus downstream consumers read the finite row sequence* T, R, C, F, H, K, P, N *of Definition 5161.1; they do not receive a host family of real-valued functions, selected complements, normality, metrization, or ambient compactness.*

Proof. Start with the topology–Urysohn sibling lattice, Definition 5161.21. It places the separator after the displayed topology carrier and the Urysohn-style route before compact-open or Kelleyfication consumers may inspect it.

Apply the compact-open forward route and Kelleyfication forward route, Definition 5161.14 and Definition 5161.16. These keep compact-open and Kelleyfication reads downstream of the same topology, regular-space, Real, continuous-map, and Urysohn rows.

Finally use the uniformity-forward route of Definition 5161.5. Uniformity consumers receive only the displayed separator chain T, R, C, F, H, K, P, N, so the sibling lattice exports a concrete dependency edge rather than a stronger host topological theorem. □

Theorem 5161.24 (Completely regular space subspace-uniformity forward link)**.** *Every subspace-topology or uniformity consumer of a* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *separator reads the packet only after the displayed* $\mathsf{Topology}^{\uparrow}$ *source of chapter 88, the Urysohn-style separator route of* **??***, the compact-open route of Definition 5161.14, and the uniformity-forward route of Definition 5161.5 are all visible. In particular, the subspace-topology route of chapter 5993 may consume* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *only through the topology-uniformity lattice of Definition 5161.23; it receives no selected separator family, ambient normality, metrization, host compactness, or unrestricted uniformity theorem.*

Proof. Begin with the topology-uniformity consumer lattice. It already forces every real-valued separator read through the displayed topology source, Urysohn-style separator route, compact-open route, and uniformity-forward route.

Now attach the subspace-topology consumer. Since chapter 5993 is allowed to read the separator only after the same topology and uniformity rows are visible, the subspace route is downstream of the lattice rather than a separate ambient-space theorem.

Thus the exported link is the finite dependency route through T, R, C, F, H, K, P, N. None of its rows supplies selected separator families, normality, metrization, host compactness, or an unrestricted uniformity principle. □

Theorem 5161.25 (Completely regular space fine-uniformity forward link)**.** *Every* $\mathsf{FineUniformity}^{\uparrow}$ *consumer of a* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *packet must first read the displayed real-valued separation row together with the shared* $\mathsf{Topology}^{\uparrow}$ *and* $\mathsf{ContinuousMap}^{\uparrow}$ *rows before exporting an entourage base. The forward link is the finite route*

$$\mathsf{CompletelyRegularSpace}^{\uparrow}, \mathsf{Topology}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{FineUniformity}^{\uparrow},$$

with the separator, topology source, real-valued probe, transport, replay, provenance, and local naming rows all visible before the fine-uniformity base is public.

Consequently the fine-uniformity consumer receives only the displayed separator route. It does not receive a host family of all real-valued maps, a selected entourage filter, an ambient powerset uniformity, a metrization theorem, a completion object, or a choice principle for probes.

Proof. Project the $\mathsf{CompletelyRegularSpace}^{\uparrow}$ carrier rows of Definition 5161.1. They expose the topology source, the regularity request, the displayed $\mathsf{Real}^{\uparrow}$-valued $\mathsf{ContinuousMap}^{\uparrow}$ separator, and the structural rows used by downstream consumers.

Now read the $\mathsf{FineUniformity}^{\uparrow}$ carrier of Definition 8906.1. Its complete-regularity coordinate is consumed before the real-valued probe row generates a finite entourage-base ledger, so the fine-uniformity base cannot be exported before the separator route is visible.

The same hsame, Cont, Pkg, and NameCert rows transport and replay the displayed separator into the fine-uniformity packet. Since no carrier field ranges over all real-valued maps or selected filters, the forward link exports only the finite entourage base generated by the displayed probes. □

Theorem 5161.26 (Completely regular space fine-uniformity dependency record)**.** *Every accepted* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *packet consumed as a* $\mathsf{FineUniformity}^{\uparrow}$ *source must expose the topology row of chapter 88, the Urysohn-style separation route of* **??**, *the lattice-facing regular-open rows of chapter 55, and the fine-uniformity carrier of chapter 8906 before any entourage-base consumer reads the exported uniformity row.*

Proof. Project the carrier of Definition 5161.1. Its separator row is attached to the same topology source, regular-space source, real-valued continuous-map row, transport row, replay row, provenance row, and local naming row used by the sibling dependency routes.

Apply the forward link of Definition 5161.25. It sends the displayed separator through the fine-uniformity carrier only after the topology, Urysohn-style separation, and lattice-facing regular-open dependencies have been made public.

Thus the uniformity consumer receives a finite dependency record over the displayed rows. It does not receive an ambient family of all real-valued maps, a selected entourage filter, a host powerset lattice, or a metrization theorem. □

Theorem 5161.27 (Completely regular space fine-uniformity telescope route)**.** *Every* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *carrier consumed by a* $\mathsf{FineUniformity}^{\uparrow}$ *reader passes through the topology-uniformity route already exposed in Definition 5161.15 and the fine-uniformity carrier of chapter 8906. The telescope read keeps the topology source, real-valued separator, continuous-map probe, transport, replay, provenance, and local naming rows visible before an entourage-base row is public.*

Proof. Project the carrier of Definition 5161.1. The topology row, request row, real-valued continuous separator, transport, replay, provenance, and local naming rows are the only visible source for a uniformity-facing consumer.

Apply the topology-uniformity dependency route. It keeps the separator attached to the same topology and continuous-map rows before any uniformity consumer can read the exported surface.

Finally read the fine-uniformity carrier. Its entourage-base row is generated from the displayed complete-regularity and real-valued probe data, so the telescope route exports no ambient family of all probes, selected entourage filter, host powerset uniformity, metrization theorem, or completion object. □

Theorem 5161.28 (Completely regular Urysohn and continuous-map route)**.** *Every* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *separator row consumed by an Urysohn-facing or continuous-map-facing chapter must pass through the separator route of* **??** *and the map graph route of chapter 59. The consumer reads the topology source, point-versus-closed-set request, real-valued separator, transport, replay, provenance, and local naming rows of the completely regular packet; it receives no host powerset, selected function space, ambient family of all real-valued maps, or untracked separator.*

Proof. Project the carrier of Definition 5161.1. The separator row F is already a $\mathsf{Real}^{\uparrow}$-valued continuous-map row, and the request rows T, R, C bind it to the displayed topology and closed-set data.

Apply the Urysohn consumer route of Definition 5161.7. It forces any Urysohn-style read to consume the topology source, real-valued separation window, uniformity-facing route, provenance, and local naming before a function-separation packet is public.

Finally read the continuous-map route through chapter 59. Since the carrier has no coordinate for host powersets, selected function spaces, or ambient families of real-valued maps, the separator remains the displayed finite route through T, R, C, F, H, K, P, N. □

Chapter 5162

A Concrete Naming Certificate for $\mathsf{LawsonTopology}^{\uparrow}$

Following Lawson, Scott, and domain-theoretic topology, the $\mathsf{LawsonTopology}^{\uparrow}$ packet records the finite interface where Scott-open observation rows and order-dual compact neighbourhood rows are read through a displayed topology. It sits over the domain/order/topology source chapters chapter 4164, chapter 1860, chapter 88, chapter 52, and chapter 53. The packet names the Lawson carrier without importing an ambient powerset topology, a quotient of opens, or a host dcpo completion.

Definition 5162.1 (Lawson topology carrier)**.** *A* $\mathsf{LawsonTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, O, K, S, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the domain source row, exposing the* $\mathsf{ScottDomain}^{\uparrow}$ *carrier, directed-join observation interface, and order comparison data consumed by the topology.*
2. *O is the Scott-open row, recording open observations that are upward stable and directed-inaccessible through the displayed domain interface.*
3. *K is the lower-compact row, recording finite order-dual neighbourhood tests generated from principal lower observations and compact exclusions.*
4. *S is the Sierpinski classifier row, reading open predicates through the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observation interface.*
5. *T is the* $\mathsf{Topology}^{\uparrow}$ *handoff row generated by the subbasis consisting of the Scott-open rows in O and the lower-compact rows in K.*
6. *H records componentwise* hsame *transport for the domain row, Scott-open row, lower-compact row, Sierpinski row, topology handoff, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from domain and order observations to the Lawson topology handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{LawsonTopology}^{\uparrow}$, $\mathsf{ScottDomain}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Preorder}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LawsonTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, O, K, S, T, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.LawsonTopologyUp.LawsonTopologyTasteGate single carrier alignment`

Theorem 5162.2 (Lawson topology NameCert obligations)**.** *For every accepted* $\mathsf{LawsonTopology}^{\uparrow}$ *carrier*

$$L = (D, O, K, S, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LawsonTopology}^{\uparrow}}$ *surface consists exactly of the displayed Scott-domain source through D, Scott-open observation through O, lower-compact observation through K, Sierpinski classifier reading through S, topology handoff through T, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5162.1. The domain row supplies the order carrier inherited from the preorder and poset source chapters, while the Scott-open row supplies the directed-observation side.

The lower-compact row is separate from the Scott-open row. It records the order-dual neighbourhood tests used by the Lawson topology and prevents the packet from collapsing into the Scott topology alone.

The Sierpinski row reads open predicates as observations, and the topology row packages the generated subbasis. Transport, replay, provenance, and local naming are exactly H, C, P, N, so no additional host topology or quotient-open coordinate is available. □

Theorem 5162.3 (Lawson topology Scott-specialization handoff)**.** *Every specialization-order read exported by an accepted* $\mathsf{LawsonTopology}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{ScottDomain}^{\uparrow}$ *source,* $\mathsf{Preorder}^{\uparrow}$ *comparison,* $\mathsf{Poset}^{\uparrow}$ *antisymmetry row,* $\mathsf{SierpinskiSpace}^{\uparrow}$ *open-observation classifier, and* $\mathsf{Topology}^{\uparrow}$ *handoff. The Lawson packet may combine Scott-open and lower-compact observations, but it cannot replace the specialization route by host equality of points, an ambient powerset of opens, or an unrecorded dcpo completion.*

Proof. Start with Definition 5162.2. The only order-facing source is the displayed domain row D, and its comparison data are read through the preorder and poset source surfaces.

Open observations are read through O and then through the Sierpinski classifier row S. The topology handoff T records the Lawson subbasis generated from the Scott-open and lower-compact rows.

Since specialization is recovered from the displayed topology observations, the route must pass through D, O, K, S, T and then through H, C, P, N. None of the carrier rows stores host point equality, a powerset topology, or a completion theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{LawsonTopology}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LawsonTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5162.1, Definition 5162.2, and Definition 5162.3 seed the finite Lawson topology carrier over Scott-open, lower-compact, Sierpinski, topology, preorder, and poset rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LawsonTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a Lean theorem, a public dcpo completion, arbitrary powerset topology equality, quotient-open equality, sobriety, compactness, or a bridge check.

Upgrade path: Obligation closure requires checked carrier admission, Scott-open exactness, lower-compact observation stability, Sierpinski classifier reading, topology handoff, specialization-order routing, transport, replay, provenance, and local naming for BEDC.Derived.LawsonTopologyUp.

Constructive story: A $\mathsf{LawsonTopology}^{\uparrow}$ packet is generated from a Scott-domain source row, Scott-open observations, lower-compact order-dual neighbourhood rows, a Sierpinski classifier row, a topology handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5163

A Concrete Naming Certificate for CandidateMediatedSN$^{\uparrow}$

The CandidateMediatedSN$^{\uparrow}$ packet realizes the candidate-mediated branch of chapter 9383 as finite NameCert data. It reads the sibling MetaCIC sources chapter 765, chapter 892, chapter 735, and chapter 740 as route anchors, while keeping candidate evidence explicit before any strong-normalization conclusion is exported. The packet is a normalization-evidence landing, not a blanket theorem that every closed typed MetaCIC term is strongly normalizing without displayed candidate data.

Definition 5163.1 (Candidate-mediated strong-normalization carrier)**.** *A* CandidateMediatedSN$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, E, C, S, A, NF, O, R, H, Q, P, N)$$

with the following displayed rows:

1. *T is the closed typed MetaCIC term row consumed by the endpoint projection.*
2. *E is the candidate-evidence row, allowing Candidate, ClosedCandidate, or CandidateSet membership evidence to be named without erasure.*
3. *C is the candidate-closure row, recording the closure and beta-stability data needed by the candidate route.*
4. *S is the strong-normalization export row downstream of E and C.*
5. *A is the Pi/application adequacy row, keeping function and argument reads inside the same candidate-mediated interface.*
6. *NF is the no-infinite-reduction projection row obtained from the same strong-normalization evidence.*
7. *O is the obstruction row naming subject-reduction, substitution, confluence, and closed-consistency boundaries that remain outside this packet.*
8. *R is the frontier route row, reading* MetaCICCriticalPath$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, MetaCICConfluenceAu *and* NormalFormConsistencySeal$^{\uparrow}$ *as named sources rather than replacing them.*
9. *H records componentwise* hsame *transport for the typed term, candidate evidence, closure, strong-normalization export, adequacy, no-infinite-reduction projection, obstruction, route, replay, provenance, and local naming rows.*

10. *Q records displayed* Cont *replay from candidate evidence to the strong-normalization and no-infinite-reduction endpoint rows.*
11. *P is the* Pkg *provenance over* $\mathsf{CandidateMediatedSN}^{\uparrow}$*, chapter 9383, chapter 765, chapter 892, chapter 735, chapter 740,* BHist*,* hsame*,* Cont*, and* NameCert*.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CandidateMediatedSN}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, E, C, S, A, NF, O, R, H, Q, P, N$.

Theorem 5163.2 (Candidate-mediated strong-normalization NameCert obligations)**.** *For every accepted* $\mathsf{CandidateMediatedSN}^{\uparrow}$ *carrier*

$$M = (T, E, C, S, A, NF, O, R, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CandidateMediatedSN}^{\uparrow}}$ *surface consists exactly of closed typed term admission through T, candidate evidence through E, candidate closure through C, strong-normalization export through S, Pi/application adequacy through A, no-infinite-reduction projection through NF, obstruction visibility through O, route anchoring through R, componentwise* hsame *transport through H, displayed* Cont *replay through Q,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5163.1. The closed typed term row T names the endpoint shape, but it does not carry strong normalization on its own.

The evidence rows E and C are the positive source. The export row S and no-infinite-reduction row NF are downstream of that source, while A keeps Pi and application reads inside the candidate-mediated route.

The obstruction and route rows are also part of the certificate. They expose the critical-path, normalization-frontier, confluence-audit, and normal-form-consistency boundaries rather than silently converting them into unconditional normalization.

Finally H, Q, P, N provide transport, replay, provenance, and local naming. Since no carrier coordinate stores an evidence-free closed-term strong-normalization theorem, the listed rows exhaust the packet. □

Theorem 5163.3 (Candidate-mediated strong-normalization frontier handoff)**.** *Every strong-normalization read exported by an accepted* $\mathsf{CandidateMediatedSN}^{\uparrow}$ *packet factors through displayed candidate evidence before it reaches a closed typed term endpoint. The route may cite* $\mathsf{MetaCICCriticalPath}^{\uparrow}$*,* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$*,* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$*, and* NormalFormConsistenc *as sibling anchors, but it cannot erase the Candidate, ClosedCandidate, or CandidateSet evidence row into a global closed-term normalization theorem.*

Proof. Use Definition 5163.2. The endpoint row T is read only after the evidence and closure rows have been opened.

The adequacy and no-infinite-reduction rows are not independent endpoints. They are downstream projections of the same candidate-mediated source, so application, Pi, and infinite-reduction reads remain attached to E and C.

The sibling route row R records where the public MetaCIC boundaries are read. It preserves the normalization frontier and confluence audit as named sources, and therefore blocks the evidence-free closed-term claim. □

Theorem 5163.4 (Candidate-mediated SN Pi-application frontier)**.** *Every public strong-normalization or no-infinite-reduction read that consumes Pi/application adequacy from an accepted* $\mathsf{CandidateMediatedSN}^{\uparrow}$ *carrier*

$$M = (T, E, C, S, A, NF, O, R, H, Q, P, N)$$

must first display closed typed term data through T, candidate or candidate-set evidence through E, candidate closure through C, Pi adequacy and application adequacy through A, the candidate-mediated strong-normalization projection through S, the no-infinite-reduction projection through NF, frontier retention through O, R, componentwise hsame *transport through H, displayed* Cont *replay through Q,* Pkg *provenance through P, and the local* $\mathsf{NameCert}_{\mathsf{CandidateMediatedSN}^{\uparrow}}$ *row N.*

Consequently the packet denies evidence-free closed-term normalization, unconditional application normalization, global confluence, unrestricted subject reduction, quotient syntax equality, and host normalization.

Proof. Project the carrier of Definition 5163.1. The closed typed term row T and the adequacy row A are visible only as coordinates of the same packet that also contains the candidate evidence E and closure row C.

Apply Definition 5163.2. Its carrier admission, candidate-evidence, candidate-closure, strong-normalization export, Pi/application adequacy, no-infinite-reduction projection, obstruction, route, transport, replay, provenance, and naming clauses give exactly the rows listed in the statement.

Use Definition 5163.3. Strong-normalization and no-infinite-reduction reads remain downstream of candidate evidence, so the Pi and application rows are adequacy rows attached to that evidence rather than independent normalization principles.

The obstruction and route rows retain the MetaCIC frontier. Since no carrier coordinate stores evidence-free normalization, unconditional application normalization, global confluence, unrestricted subject reduction, quotient syntax equality, or host normalization, the public read cannot export any of those conclusions. □

Theorem 5163.5 (Candidate-mediated SN has no hidden oracle)**.** *Every StrongNormalizable row exported by an accepted* $\mathsf{CandidateMediatedSN}^{\uparrow}$ *packet factors through one of the displayed Candidate, ClosedCandidate, or CandidateSet evidence rows named by the carrier. If no such evidence row is displayed, the packet exports only the boundary ledger over* $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$, *and* $\mathsf{NormalFormConsistencySeal}^{\uparrow}$, *and it exports no blanket strong-normalization conclusion for all closed typed MetaCIC terms.*

Proof. Read the packet through the normalization audit map and then project the carrier of Definition 5163.1. The only positive normalization source in the carrier is the evidence pair E, C, where E names Candidate, ClosedCandidate, or CandidateSet membership and C records the closure data needed by that evidence.

The exported strong-normalization row S and the no-infinite-reduction row NF sit downstream of those displayed rows. Thus any StrongNormalizable export must pass through the candidate evidence before it reaches the closed typed term row T.

If the candidate evidence is absent, the remaining visible rows are obstruction, route, transport, replay, provenance, and local naming. They preserve the MetaCIC boundary ledger and the sibling audit sources, but they contain no coordinate from which an evidence-free closed-term strong-normalization theorem can be read. □

Theorem 5163.6 (Candidate-mediated obstruction frontier)**.** *Every public strong-normalization or no-infinite-reduction read exported by an accepted* $\mathsf{CandidateMediatedSN}^{\uparrow}$ *carrier*

$$M = (T, E, C, S, A, NF, O, R, H, Q, P, N)$$

must pass through the candidate-evidence row E and candidate-closure row C before it reaches S or NF. The route must also retain the obstruction row O, naming subject-reduction, substitution, confluence, and closed-consistency boundaries, and it must preserve $\mathsf{MetaCICCriticalPath}^{\uparrow}$,

$\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$, *and* $\mathsf{NormalFormConsistencySeal}^{\uparrow}$ *as route boundaries rather than replacement theorems.*

Proof. Project the carrier of Definition 5163.1. The endpoint row T is not an evidence-free normalization theorem; the positive route begins with E and C and only then reaches the strong-normalization and no-infinite-reduction rows S and NF.

Apply Definition 5163.2. Its obstruction-visibility and route-anchoring clauses keep O and R inside the local certificate, so subject reduction, substitution, confluence, and closed consistency remain named boundaries.

Now use Definition 5163.3. The handoff prevents Candidate, ClosedCandidate, or CandidateSet evidence from being erased into a global closed-term claim.

The rows H, Q, P, N transport, replay, source, and name the same route. Thus $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$, and $\mathsf{NormalFormConsistencySeal}^{\uparrow}$ are preserved as sibling boundaries, while S and NF remain candidate-mediated exports downstream of E and C. □

Theorem 5163.7 (Candidate-mediated strong-normalization TasteGate obligation)**.** *Future Lean support for* $\mathsf{CandidateMediatedSN}^{\uparrow}$ *requires TasteGate* Nontrivial *and* FieldFaithful *instances. Nontriviality must distinguish an accepted packet with displayed candidate evidence from a closed typed term row without that evidence, and field faithfulness must preserve the row order*

$$T \longmapsto E \longmapsto C \longmapsto S \longmapsto A \longmapsto NF \longmapsto O \longmapsto R \longmapsto H, Q, P, N$$

before any carrier-alignment theorem can serve as a checked realization.

Proof. Nontriviality follows from the carrier boundary. Removing E or C leaves the closed typed term endpoint without the evidence route that supplies strong normalization.

Field faithfulness is the row-order condition. If a TasteGate projection permutes or erases $E, C, S, A, NF, O, R, H, Q, P, N$, the packet no longer represents the candidate-mediated route named by Definition 5163.1. □

Falsifiable prediction: Every accepted $\mathsf{CandidateMediatedSN}^{\uparrow}$ strong-normalization read exposes candidate evidence before the endpoint: closed typed term row first, candidate evidence second, candidate closure third, strong-normalization export fourth, Pi/application adequacy fifth, no-infinite-reduction projection sixth, and obstruction, route, transport, replay, provenance, and local naming rows thereafter.

Independence witness: metacic-normalization-audit-map, metacic-critical-path, metacic-normalization-frontier, metacic-confluence-audit-packet, normal-form-consistency-seal: $\mathsf{CandidateMediatedSN}^{\uparrow}$ is not bijective to any listed source because it isolates the evidence-carrying strong-normalization route while preserving each sibling as a named boundary rather than a replacement theorem.

Closure status for $\mathsf{NameCert}_{\mathsf{CandidateMediatedSN}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CandidateMediatedSN}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5163.1, Definition 5163.2, Definition 5163.3, and Definition 5163.7 seed the candidate-mediated strong-normalization evidence route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CandidateMediatedSN}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unconditional strong normalization for every closed typed MetaCIC term, subject reduction, arbitrary substitution preservation, global confluence, closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate-evidence visibility, candidate-closure stability, strong-normalization export, Pi/application adequacy routing, no-infinite-reduction projection, obstruction visibility, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.CandidateMediatedSNUp.

Constructive story: A CandidateMediatedSN$^{\uparrow}$ packet is generated from a closed typed term row, candidate evidence, candidate closure, strong-normalization export, Pi/application adequacy rows, no-infinite-reduction projection, obstruction boundaries, sibling route anchors, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5164

A Concrete Naming Certificate for $\mathsf{CalculusOfConstructions}^{\uparrow}$

Following Coquand and Huet, the $\mathsf{CalculusOfConstructions}^{\uparrow}$ packet records the dependent-type calculus surface needed by the MetaCIC path as finite NameCert data. It extends the untyped syntax and substitution corridor of chapter 200, keeps computability comparisons separate from the machine models of chapter 199 and chapter 280, and routes downstream dependent typing through the displayed MetaCIC typing, substitution, and subject-reduction surfaces of chapter 1046, chapter 538, chapter 719, and chapter 730. The packet names a traditional calculus object without asserting consistency, normalization, quotient term equality, host function extensionality, or a completed MetaCIC development.

Definition 5164.1 (CalculusOfConstructions carrier)**.** *A* $\mathsf{CalculusOfConstructions}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, \Pi, L, A, \Gamma, \Sigma, B, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the finite sort row, naming the primitive universe and proposition classifiers used by the calculus surface;*
2. *Π is the dependent-product row, naming the domain, codomain-in-context, and formation boundary for Π-types;*
3. *L is the lambda row, naming abstraction formation over a displayed context extension;*
4. *A is the application row, naming elimination of a displayed dependent-product term by a displayed argument;*
5. *Γ is the context row, carrying finite extension, lookup, weakening, and exchange ledgers without identifying contexts by a quotient;*
6. *Σ is the substitution row, carrying finite capture-avoiding substitution and context-substitution ledgers;*
7. *B is the beta-boundary row, recording the local beta computation interface between L, A, and Σ;*
8. *R is the subject-reduction boundary row, exposing only the parameterised MetaCIC discharge route through the existing subject-reduction socket;*

9. *H records componentwise* hsame *transport for $S, \Pi, L, A, \Gamma, \Sigma, B, R, P, N$;*
10. *K records displayed* Cont *replay from the calculus packet to the lambda-calculus, typing-classifier, substitution-boundary, and subject-reduction-frontier consumers;*
11. *P is the* Pkg *provenance over* $\mathsf{CalculusOfConstructions}^{\uparrow}$, $\mathsf{LambdaCalc}^{\uparrow}$, $\mathsf{TypingJudgmentClassifier}^{\uparrow}$, $\mathsf{ClosedSubstitutionBoundary}^{\uparrow}$, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, $\mathsf{MetaCICSubjectReductionFrontier}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CalculusOfConstructions}^{\uparrow}}$ *row.*

The carrier contains no proof of global consistency, no strong-normalization theorem, no quotient equality of terms, no host-level function extensionality principle, and no completed MetaCIC kernel theorem.

Lean4 (definition) `BEDC.Derived.CalculusOfConstructionsUp.CalculusOfConstructionsUp`
Lean4 ✓ `BEDC.Derived.CalculusOfConstructionsUp.CalculusOfConstructionsTasteGate single carrier alignment`

Theorem 5164.2 (CalculusOfConstructions NameCert obligations)**.** *For the carrier of Definition 5164.1, the local* $\mathsf{NameCert}_{\mathsf{CalculusOfConstructions}^{\uparrow}}$ *surface consists exactly of finite obligations for the sort row S, dependent-product row Π, lambda row L, application row A, context row Γ, substitution row Σ, beta-boundary row B, subject-reduction boundary row R, componentwise transport H, displayed replay K, provenance P, and local naming N. Any accepted public read of the packet must pass through these rows and cannot replace them by a normalization theorem, a consistency theorem, a quotient conversion oracle, or host function extensionality.*

Lean4 ✓ `BEDC.Derived.CalculusOfConstructionsUp.CalculusOfConstructionsCarrier namecert obligations`

Proof. Project the carrier C. Its primitive calculus data are exactly $S, \Pi, L, A, \Gamma, \Sigma$, so the syntax, context, and substitution obligations are finite rows rather than ambient metatheoretic assumptions.

The boundary rows B and R add only local beta computation and the parameterised subject-reduction route. They do not add a closed subject-reduction theorem, because the route is read through the existing discharge socket and frontier.

Finally inspect H, K, P, N. Transport, replay, provenance, and local naming preserve the displayed row inventory. Since no other coordinate is present, a consumer has no place from which to extract consistency, normalization, quotient term equality, or host extensionality. □

Theorem 5164.3 (CalculusOfConstructions substitution typing route)**.** *Every accepted* $\mathsf{CalculusOfConstructions}^{\uparrow}$ *consumer that asks for a substitution-stable typing route must read the carrier in the order*

$$\Gamma, \Sigma \longrightarrow S, \Pi, L, A \longrightarrow B, R \longrightarrow H, K, P, N.$$

The context and substitution rows supply the finite substitution ledger, the sort and term-former rows supply the dependent typing surface, the beta and subject-reduction rows expose only the existing MetaCIC boundary, and the transport, replay, provenance, and naming rows keep the route inside the same finite packet. The route does not assert completed MetaCIC substitution admissibility, closed subject reduction, conversion soundness, normalization, or consistency.

Proof. Start with Γ, Σ. These rows display the finite context and substitution ledgers, so a substitution-stable read begins with explicit context extension, lookup, weakening, exchange, and capture-avoiding substitution data.

Next read S, Π, L, A. The sort, dependent-product, lambda, and application rows provide the dependent typing surface on which the substitution ledger acts. This is the calculus surface inherited from the Coquand–Huet presentation and routed through the $\mathsf{LambdaCalc}^{\uparrow}$ syntax corridor.

The rows B, R then expose the boundary to MetaCIC: beta computation is local to the displayed substitution row, and subject reduction is only the parameterised discharge route named by the socket and frontier chapters. Replaying the route through H, K, P, N preserves the same finite rows, so no stronger MetaCIC theorem is exported by the calculus packet itself. □

Closure status for $\mathsf{NameCert}_{\mathsf{CalculusOfConstructions}^{\uparrow}}$.

Constructive story: A $\mathsf{CalculusOfConstructions}^{\uparrow}$ packet is generated from finite sort, dependent-product, lambda, application, context, substitution, beta-boundary, subject-reduction-boundary, componentwise transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CalculusOfConstructions}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5164.1, Definition 5164.2, and Definition 5164.3 bind the finite dependent-type calculus surface used by the MetaCIC path.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CalculusOfConstructions}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not prove consistency, normalization, quotient term equality, host function extensionality, completed MetaCIC substitution admissibility, closed subject reduction, Lean verification, or a public schema bridge.

Upgrade path: Obligation closure requires checked carrier admission, sort and dependent-product exactness, context and substitution route exactness, beta-boundary preservation, subject-reduction boundary routing, provenance, local naming, and non-escape for the same finite packet.

Chapter 5165

A Concrete Naming Certificate for $\mathsf{PrimeNumberTheoremChebyshevWindow}^{\uparrow}$

Following Chebyshev and de la Vallee Poussin style prime-counting estimates, the PrimeNumberTheoremChebyshevW packet names the finite window in which a prime-counting read, logarithmic comparison ledger, and displayed tolerance record can be inspected without importing the full analytic proof of the prime number theorem. It sits after the natural-number source rows of the arithmetic chapters, the rational and dyadic tolerance carriers of chapter 37 and chapter 291, and the terminal real-facing seal of chapter 38. The packet records only finite counting windows, displayed prime predicates, logarithmic comparison rows, tolerance reads, transport, replay, provenance, and local naming.

Definition 5165.1 (Prime number theorem Chebyshev window carrier)**.** *A* PrimeNumberTheoremChebyshevWindow *carrier is a finite* BHist *packet*

$$W = (A, P, \Pi, L, D, R, O, H, C, Q, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{Nat}^{\uparrow}$ *arithmetic source row. It records the inspected finite interval, endpoint order, successor arithmetic, and bounded summation surface for the counting request.*
2. *P is the* $\mathsf{Prime}^{\uparrow}$ *predicate row. It stores the prime-admission read for each inspected natural-number entry and the finite exclusion rows for composites visible inside the window.*
3. *Π is the prime-counting window row. It records the displayed value of the finite counting function on the inspected interval and the endpoint comparison used by downstream reads.*
4. *L is the logarithmic comparison ledger. It stores the finite logarithm table, monotonicity comparisons, and Chebyshev-style upper and lower comparison rows attached to the same endpoint.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records dyadic slack, denominator bounds, and interval comparisons for the displayed counting and logarithmic reads.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *read row. It receives only the rational and dyadic tolerance data already displayed by D and L.*
7. *O is the order-provenance row. It records the* $\mathsf{Nat}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, *and order comparisons used by A, P, Π, L, D, R.*
8. *H records componentwise* hsame *transport for arithmetic sources, prime predicates, counting windows, logarithmic ledgers, dyadic and real reads, order provenance, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a prime-counting request through* $A, P, \Pi, L, D, R, O, H, Q, N$.
10. *Q is the* Pkg *provenance over* $\mathsf{PrimeNumberTheoremChebyshevWindow}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, *order rows,* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrimeNumberTheoremChebyshevWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, P, \Pi, L, D, R, O, H, C, Q, N$. It has no coordinate for analytic continuation, the full asymptotic prime number theorem, zero-free regions, choice, a host prime-distribution oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.PrimeNumberTheoremChebyshevWindowUp.PrimeNumberTheoremChebyshevWindowTasteGate`
`single carrier alignment`

Theorem 5165.2 (Prime number theorem Chebyshev window obligations)**.** *For every accepted* $\mathsf{PrimeNumberTheoremChebyshevWindow}^{\uparrow}$ *carrier*

$$W = (A, P, \Pi, L, D, R, O, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrimeNumberTheoremChebyshevWindow}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the natural-number arithmetic source, prime predicate row, prime-counting window, logarithmic comparison ledger, dyadic tolerance read, real-facing read, order provenance, transport, replay, package provenance, and local naming;*
2. *prime-window exposure, requiring A, P, Π to display the inspected endpoint interval, prime-admission reads, composite exclusions, and finite counting value before any comparison can be exported;*
3. *logarithmic comparison control, requiring L to attach Chebyshev-style upper and lower comparison rows to the same endpoint and counting window;*
4. *dyadic and real nonescape, requiring D and R to read only displayed rational, dyadic, and order data from L and Π;*
5. *local naming, requiring O, H, C, Q, N to preserve exactly the displayed arithmetic, prime, logarithmic, tolerance, real-facing, and provenance rows.*

No prime-counting obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5165.1. The accepted packet displays exactly the arithmetic source, prime predicate, counting window, logarithmic comparison ledger, tolerance rows, real-facing read, order provenance, and structural rows listed in the statement.

The prime-window exposure is finite. The rows A and P inspect only the bounded natural-number interval and its displayed prime or composite evidence, while Π records the corresponding finite counting value.

The logarithmic comparison control is read next. The row L attaches the Chebyshev-style upper and lower comparison rows to the same endpoint and the same counting window, so no independent analytic-continuation or zero-free-region theorem enters the packet.

The dyadic and real-facing rows remain downstream. The row D supplies the rational and dyadic slack ledger, R reads only that displayed tolerance surface as real-facing data, and O keeps the natural-number, prime, rational, and order provenance visible.

Finally H, C, Q, N transport, replay, source, and name the same packet. Since the carrier contains no coordinate for analytic continuation, the full asymptotic prime number theorem, zero-free regions, choice, a host prime-distribution oracle, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 5165.3 (Prime number theorem Chebyshev window route)**.** *Every real-facing comparison read exported by an accepted* $\mathsf{PrimeNumberTheoremChebyshevWindow}^{\uparrow}$ *carrier*

$$W = (A, P, \Pi, L, D, R, O, H, C, Q, N)$$

factors through the finite route

$$A, P, \Pi, L, D, O \longmapsto R.$$

Thus the exported read is witnessed by a natural-number source row, a prime predicate row, a finite prime-counting window, a logarithmic comparison ledger, dyadic and rational tolerance data, and order provenance, not by analytic continuation, the full asymptotic theorem, zero-free regions, choice, or ambient Real completeness.

Proof. Start with a real-facing comparison read from the accepted carrier. The only row with that target is R, and the carrier places R downstream of the arithmetic, prime, counting, logarithmic, dyadic, and order rows.

The source and counting rows determine the finite prime-counting data. The row A fixes the inspected natural-number interval, P supplies prime-admission and composite-exclusion reads, and Π records the displayed finite counting value for that same window.

The comparison rows then control the exported estimate. The row L records the logarithmic comparison ledger, D supplies the dyadic and rational slack, and O records the order provenance that binds these comparisons to the same endpoint.

Only after those rows are fixed can R read the packet as real-facing comparison data. Transport, replay, package provenance, and local naming preserve this route through H, C, Q, N, so none of the excluded ambient principles can enter the exported read. □

Falsifiable prediction: Every $\mathsf{PrimeNumberTheoremChebyshevWindow}^{\uparrow}$ real-facing comparison read passes through $\mathsf{Nat}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, a finite prime-counting window, a logarithmic comparison ledger, $\mathsf{Rat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, order provenance, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any counting estimate is visible.

Independence witness: nat, prime, rat, dyadicratcore, real, order: $\mathsf{PrimeNumberTheoremChebyshevWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a natural-number source row, prime predicate row, finite counting window, logarithmic comparison ledger, dyadic and rational tolerance reads, real-facing read, order provenance, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PrimeNumberTheoremChebyshevWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{PrimeNumberTheoremChebyshevWindow}^{\uparrow}$ packet is generated from NatUp arithmetic source rows, PrimeUp predicate rows, finite prime-counting windows, logarithmic comparison ledgers, RatUp and DyadicRatCoreUp tolerance reads, RealUp read rows, order provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrimeNumberTheoremChebyshevWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5165.1, Definition 5165.2, and Definition 5165.3 seed the finite Chebyshev-window route from natural-number and prime rows through counting windows, logarithmic comparisons, dyadic and rational tolerances, real-facing reads, order provenance, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrimeNumberTheoremChebyshevWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close analytic continuation, the full asymptotic prime number theorem, zero-free regions, choice, host prime-distribution oracles, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked arithmetic source admission, prime predicate exposure, finite counting-window exactness, logarithmic comparison control, dyadic and real nonescape, order provenance, transport, replay, provenance, and local naming for BEDC.Derived.PrimeNumberTheoremChebyshevWindowUp.

Chapter 5166

A Concrete Naming Certificate for $\mathsf{PriestleyDuality}^{\uparrow}$

Following Priestley and Davey–Priestley, the $\mathsf{PriestleyDuality}^{\uparrow}$ packet records the finite BEDC naming surface for the ordered topological representation of bounded distributive lattices. It sits between the lattice rows of chapter 55, the complemented endpoint discipline of chapter 3733, the indexed-open topology rows of chapter 88, and the clopen-ledger bridge of chapter 261. The packet names order-separating clopen upsets and their finite continuity ledger; it does not import ultrafilters, selected prime filters, powerset topology, quotient lattice equality, or a host duality theorem.

Definition 5166.1 (Priestley duality carrier)**.** *A* $\mathsf{PriestleyDuality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (L, B, T, S, U, O, H, C, G, N)$$

with the following displayed rows:

1. *L is the bounded distributive-lattice source read through the* $\mathsf{Lattice}^{\uparrow}$ *carrier and its finite meet–join order rows.*
2. *B is the Boolean endpoint comparison row available from the* $\mathsf{BooleanAlgebra}^{\uparrow}$ *neighbour when complemented clopen data is requested.*
3. *T is the indexed-open* $\mathsf{Topology}^{\uparrow}$ *row that records the finite open-neighbourhood observations used by the dual side.*
4. *S is the Stone-facing clopen ledger from chapter 261, restricted to observations that are also upward-closed for the order read from L.*
5. *U is the finite order-separation row: whenever two displayed lattice observations are separated by the order classifier, U names a clopen upset containing the larger observation and excluding the smaller one.*
6. *O is the order/topology compatibility row, recording that finite intersections, unions, complements used through B, and indexed opens used through T preserve the clopen-upset route named by S and U.*
7. *H records componentwise* hsame *transport for $L, B, T, S, U, O, C, G, N$.*
8. *C records displayed* Cont *replay from a lattice observation through the clopen-upset and topology rows.*

9. *G is the* Pkg *provenance over* Lattice$^{\uparrow}$, BooleanAlgebra$^{\uparrow}$, Topology$^{\uparrow}$, StoneDuality$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{PriestleyDuality}^{\uparrow}}$ *row.*

The carrier contains no coordinate for ultrafilter selection, a host spectral space, unrestricted prime filters, quotient lattice equality, powerset topology, or classical choice.

Lean4 ✓ `BEDC.Derived.PriestleyDualityUp.PriestleyDualityTasteGate single carrier alignment`

Theorem 5166.2 (Priestley duality NameCert obligations)**.** *For every accepted* PriestleyDuality$^{\uparrow}$ *carrier $P = (L, B, T, S, U, O, H, C, G, N)$, the local* NameCert$_{\text{PriestleyDuality}^{\uparrow}}$ *surface consists exactly of lattice-source admission through L, Boolean endpoint comparison through B, topology admission through T, Stone-facing clopen admission through S, finite order separation through U, order/topology compatibility through O, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through G, and local naming through N. Any downstream order/topology consumer must consume these rows before it can treat a clopen upset as a Priestley-duality observation.*

Proof. Project the carrier of Definition 5166.1. The rows L, B, T, S, U, O are the only analytic and order-topology coordinates, and the rows H, C, G, N only transport, replay, source, and name them.

The lattice-source obligation is read from L, while Boolean endpoint comparison and topology admission are read from B and T. The Stone-facing clopen ledger S supplies the clopen side, and U restricts it to the finite upsets needed for order separation.

Compatibility is then checked by O. This row keeps the finite clopen-upset observations stable under the lattice and topology operations that are public through the cited neighbouring chapters.

Finally H, C, G, N preserve and name the same route. Because the carrier has no ultrafilter, selected prime-filter, host spectral-space, powerset-topology, quotient-equality, or choice coordinate, the listed rows exhaust the local NameCert obligations. □

Closure status for NameCert$_{\text{PriestleyDuality}^{\uparrow}}$.

Constructive story: A PriestleyDuality$^{\uparrow}$ packet is generated from bounded distributive-lattice rows, Boolean endpoint comparisons, indexed topology observations, a Stone-facing clopen ledger, finite clopen-upset separation rows, order/topology compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PriestleyDuality}^{\uparrow}}$, seed)

Scope closed: Definition 5166.1 and Definition 5166.2 seed the order/topology representation surface over lattice, Boolean-algebra, topology, and Stone-duality rows.

Formal verification: FormalStatus(NameCert$_{\text{PriestleyDuality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim an ultrafilter construction, selected prime filters, host spectral spaces, powerset topology, quotient lattice equality, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite order-separation stability, clopen-upset topology compatibility, and local NameCert exhaustion for BEDC.Derived.PriestleyDualityUp.

The VitaliConvergence$^{\uparrow}$ hub routes uniform-integrability budgets through chapter 6228 and convergence-in-measure tolerances through chapter 5139 before the terminal Real$^{\uparrow}$ seal.

Chapter 5167

A Concrete Naming Certificate for $\mathsf{VitaliConvergence}^{\uparrow}$

Following Vitali and Bishop–Bridges constructive integration, the $\mathsf{VitaliConvergence}^{\uparrow}$ packet records the finite surface by which uniform integrability, convergence-in-measure windows, and integral readback rows are retained before a convergence consumer reads the Vitali conclusion. It sits after the measure surface of chapter 92, the integral row of chapter 123, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the dominated-convergence packet of chapter 2340. The Vitali handoff consumes the finite tail-control surface of chapter 6228 and the measure and integral rows displayed by dominated-convergence siblings before any quotient almost-everywhere equality or selected subsequence is read. The packet names only displayed convergence and uniform-integrability rows; it does not assert measure completion, almost-everywhere quotient equality, selected subsequences, countable choice, or a host theorem about all measurable functions.

Definition 5167.1 (Vitali convergence carrier)**.** *A* $\mathsf{VitaliConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (M, I, F, U, L, R, E, D, H, C, P, N)$$

with the following rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row for the displayed measurable-event requests.*
2. *I is the* $\mathsf{Integral}^{\uparrow}$ *readback row for the integrals that the packet may compare.*
3. *F is the finite family row for the displayed integrands.*
4. *U is the uniform-integrability row, recording only finite tail and small-set budget requests already routed through M and I.*
5. *L is the convergence-in-measure window row.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerances on integral and measure budgets.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed limit budget.*
8. *D is the handoff row to* $\mathsf{DominatedConvergence}^{\uparrow}$*, used only when a displayed domination row supplies a sibling majorant route.*
9. *H records componentwise* hsame *transport for M, I, F, U, L, R, E, D.*
10. *C records displayed* Cont *replay of the same route.*

11. *P is the* Pkg *provenance over* $\mathsf{VitaliConvergence}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, DominatedConvergence BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{VitaliConvergence}^{\uparrow}}$ *row.*

The carrier has no coordinate for measure completion, quotient equality of functions, almost-everywhere representative selection, countable choice, or a detached ambient convergence theorem.

Theorem 5167.2 (Vitali convergence NameCert obligations)**.** *For every accepted* $\mathsf{VitaliConvergence}^{\uparrow}$ *carrier $V = (M, I, F, U, L, R, E, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{VitaliConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for V, measure-source admission through M, integral readback through I, displayed integrand-family exposure through F, uniform-integrability budget exposure through U, convergence-in-measure window exposure through L, regular rational tolerance readback through R, terminal real seal through E, dominated-convergence handoff through D, componentwise* hsame *stability through H,* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5167.1. The available analytic rows are exactly M, I, F, U, L, R, E, D, and the structural rows are H, C, P, N.

Uniform integrability is exposed only by U. Its finite tail and small-set budgets can be read after the measure and integral rows M, I have already been displayed, so it is not an ambient boundedness principle or a hidden domination theorem.

The convergence side is exposed by L, R, E. The convergence-in-measure windows pass through rational tolerance readback before the terminal real seal is consumed.

Finally, D, H, C, P, N give the optional dominated-convergence handoff, transport, replay, provenance, and local naming of the same rows. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 5167.3 (Vitali convergence uniform-integrability handoff)**.** *Every integral-facing or real-facing consumer of an accepted* $\mathsf{VitaliConvergence}^{\uparrow}$ *carrier $V = (M, I, F, U, L, R, E, D, H, C, P, N)$ must read the uniform-integrability row U together with the convergence-in-measure row L before it consumes the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. If the consumer also uses a dominated-convergence sibling route, that route is exposed only through D after the same M, I, F, U, L, R, E rows have been displayed.*

Proof. Begin with a consumer of V. By Definition 5167.1, the only measure and integral entry points are M and I, and the only integrand-family row is F.

The uniform-integrability budget is then forced through U. A consumer may inspect finite tail and small-set budgets, but only as rows attached to the displayed measure and integral surfaces.

The convergence read is $L \longmapsto R \longmapsto E$. The convergence-in-measure windows and rational tolerances are visible before the real seal is reached.

The dominated-convergence handoff is separate. The row D can be consumed only after the same visible rows have been retained, so it cannot replace Vitali uniform integrability by a hidden host majorant or an almost-everywhere quotient. □

Falsifiable prediction: A consumer that claims a $\mathsf{VitaliConvergence}^{\uparrow}$ integral-limit read while omitting the measure source, integral row, integrand family, uniform-integrability budget, convergence-in-measure window, rational tolerance readback, real seal, dominated-convergence handoff, hsame, Cont, Pkg, or local NameCert rows refutes the carrier of Definition 5167.1.

Independence witness: measure, integral, regseqrat, real, dominated-convergence: $\mathsf{VitaliConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries uniform-integrability budgets, convergence-in-measure windows, rational tolerance readback, real sealing, dominated-convergence handoff, transport, replay, provenance, and local naming over a displayed integrand family.

Closure status for $\mathsf{NameCert}_{\mathsf{VitaliConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{VitaliConvergence}^{\uparrow}$ packet is generated from a displayed Measure row, Integral readback row, integrand-family row, uniform-integrability budget row, convergence-in-measure window row, RegSeqRat tolerance row, Real seal row, DominatedConvergence handoff row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VitaliConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5167.1, Definition 5167.2, and Definition 5167.3 seed the finite Vitali convergence route through Measure, Integral, RegSeqRat, Real, and dominated-convergence rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VitaliConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, almost-everywhere quotient equality, selected subsequences, countable choice, Lean verification, bridge checking, or a host theorem about all measurable functions.

Upgrade path: Obligation closure requires checked carrier admission, uniform-integrability visibility, convergence-in-measure visibility, rational tolerance readback, Real seal handoff, dominated-convergence sibling routing, transport and replay stability, and nonescape for BEDC.Derived.VitaliConvergenceUp.

Theorem 5167.4 (Vitali convergence Cauchy sequential route)**.** *Any* $\mathsf{VitaliConvergence}^{\uparrow}$ *consumer that reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance row* R *of an accepted carrier*

$$V = (M, I, F, U, L, R, E, D, H, C, P, N)$$

must route the convergence-in-measure window L *through chapter 5139 before consuming the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. The route exposes the measure source* M*, integral row* I*, integrand family* F*, uniform-integrability budget* U*, convergence window* L*, rational tolerance row* R*, structural rows* H, C, P, N*, and only then the terminal real seal.*

Proof. Project the carrier of Definition 5167.1. The convergence side is the displayed chain L, R, E, while M, I, F, U supply the measure, integral, integrand-family, and uniform-integrability rows that make the window meaningful.

Before E can be read as a real-facing endpoint, the tolerance row R must be interpreted as a sequential Cauchy tolerance surface. The required neighboring packet is chapter 5139, whose carrier records the finite stream-window, regular rational readback, dyadic tolerance, and Real-seal handoff used by Real and Completion consumers.

The structural rows H, C, P, N preserve this route componentwise. Thus a Vitali consumer may reach the terminal $\mathsf{Real}^{\uparrow}$ seal only after the convergence-in-measure window has passed through the Cauchy sequential criterion surface; no hidden selected subsequence, countable-choice row, quotient equality, or ambient convergence theorem is introduced. □

Proposition 5167.5 (Vitali measure-Cauchy dependency route)**.** *Every* $\mathsf{VitaliConvergence}^{\uparrow}$ *read that exposes a convergence seal first consumes the uniform-integrability route of chapter 6228 and the Cauchy sequential route of chapter 5139. The read therefore keeps the measure and integral rows from chapter 5167, the budget row of Definition 5167.6, and the tolerance readback of Definition 5167.4 visible before any terminal* $\mathsf{Real}^{\uparrow}$ *or dominated-convergence handoff is exposed.*

Proof. Project the carrier of Definition 5167.1. The rows $M, I, F, U, L, R, E, D, H, C, P, N$ are the only available inputs to a convergence-facing read.

Use Definition 5167.6 to keep U attached to the displayed measure and integral surface before any terminal seal is reached. Use Definition 5167.4 to route L and R through the Cauchy sequential criterion before E is consumed.

The two routes share the same carrier rows, so their combination is still a finite Vitali dossier edge. It exports no measure completion, almost-everywhere quotient equality, selected subsequence, countable-choice schedule, or detached host convergence theorem. □

Theorem 5167.6 (Vitali convergence uniform-integrability dependency route)**.** *Every accepted* $\mathsf{VitaliConvergence}^{\uparrow}$ *consumer that reads the uniform-integrability row* U *must route it through chapter 6228, the measurable event surface of chapter 92, the* L^p *function-space boundary of chapter 8060, and the dominated majorant handoff of chapter 2340 before consuming the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route keeps the displayed rows*

$$M, I, F, U, L, R, E, D, H, C, P, N$$

visible, and exports no measure completion, almost-everywhere quotient equality, selected subsequence, countable choice, or detached host convergence theorem.

Proof. Project the carrier of Definition 5167.1. The uniform-integrability row U is available only together with the displayed measure row M, integral row I, integrand-family row F, convergence-in-measure window L, tolerance row R, real seal E, dominated-convergence handoff D, and structural rows H, C, P, N.

Read chapter 6228. It supplies the tail-cutoff and uniform tail-bound surface that the Vitali packet consumes, while chapter 92 keeps the event requests attached to the same measurable carrier.

The L^p boundary in chapter 8060 records the norm-facing function-space read without adding representatives or quotient equality. The dominated-convergence sibling of chapter 2340 is then available only through the displayed handoff row D.

Thus the dependency route is carrier-local: it preserves the Vitali rows and their sibling citations, but it does not turn uniform integrability into a host measure-completion theorem, a selected-subsequence principle, or an ambient convergence theorem. □

Chapter 5168

A Concrete Naming Certificate for $\mathsf{BishopDyadicSqueeze}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopDyadicSqueeze}^{\uparrow}$ packet records the finite sandwich certificate by which two dyadic control windows trap a regular rational observation before the observation is handed to a real-name seal. It sits over the dyadic denominator discipline of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the countable-window presentation of chapter 1809. The packet gives the L10 Real and Completion route a concrete squeeze object over inspected dyadic windows; it is not a quotient-real equality theorem, a selected limit, trichotomy, countable choice, or ambient completeness principle.

Definition 5168.1 (Bishop dyadic squeeze carrier)**.** *A* $\mathsf{BishopDyadicSqueeze}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (\ell, u, n, W, L, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. ℓ *and* u *are lower and upper* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows.*
2. n *is the unary precision row naming the dyadic scale at which the squeeze is inspected.*
3. W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *window through which the source regular rational observations are read.*
4. L *records the lower-bound comparison between the inspected window and* ℓ*.*
5. U *records the upper-bound comparison between the inspected window and* u*.*
6. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from* W, L, U *and the displayed dyadic tolerance scale.*
7. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from* R *after the squeeze window has been displayed.*
8. H *records componentwise* hsame *transport for* $\ell, u, n, W, L, U, R, E$ *and the local naming row.*
9. C *records displayed* Cont *replay from a squeeze request through dyadic endpoints, finite stream windows, lower and upper comparisons, regular rational readback, and the Real seal.*
10. P *is the* Pkg *provenance over* $\mathsf{BishopDyadicSqueeze}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopDyadicSqueeze}^{\uparrow}}$ *row.*
The classifier compares accepted squeeze packets only through $\ell, u, n, W, L, U, R, E, H, C, P, N$. It has no coordinate for a quotient real representative, selected limit, trichotomy oracle, countable-choice schedule, hidden infinite stream, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 (definition) `BEDC.Derived.BishopDyadicSqueezeUp.BishopDyadicSqueezeUp`

Theorem 5168.2 (Bishop dyadic squeeze NameCert obligations)**.** *For every accepted* $\mathsf{BishopDyadicSqueeze}^{\uparrow}$ *carrier*

$$S = (\ell, u, n, W, L, U, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopDyadicSqueeze}^{\uparrow}}$ *surface consists exactly of dyadic endpoint exposure, unary precision exposure, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, lower-bound comparison exposure, upper-bound comparison exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer must expose $\ell, u, n, W, L, U, R, E$ before the structural rows H, C, P, N can be consumed.*

Proof. Project the carrier of Definition 5168.1. The analytic rows are exactly $\ell, u, n, W, L, U, R, E$, while H, C, P, N are the structural transport, replay, provenance, and naming rows.

The endpoint rows ℓ, u and the precision row n determine the displayed dyadic scale. The stream row W is therefore the only observation surface through which the source regular rational data can enter the squeeze.

The comparison rows L and U bind that same window below and above. Hence the packet does not export a detached lower route or a detached upper route; both comparisons are attached to the same finite window and the same dyadic scale.

Finally R and E are downstream of the squeeze rows. Since the carrier has no coordinate for quotient representatives, selected limits, trichotomy, countable choice, hidden streams, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 5168.3 (Bishop dyadic squeeze Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{BishopDyadicSqueeze}^{\uparrow}$ *packet reaches the terminal Real seal only through the displayed finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff may use the dyadic endpoint rows, unary precision row, finite stream window, lower and upper comparison rows, and regular rational readback, but it cannot replace them by quotient real equality, a selected limit, trichotomy, countable choice, an uninspected infinite stream, or ambient completeness.

Proof. Begin with the Real or Completion-facing read of S. The dyadic endpoints ℓ, u and precision row n are exposed before the stream window W, so the consumer reads a finite dyadic scale before any rational replay is available.

The lower and upper comparison rows L, U are both attached to W. Thus the regular rational readback R is assembled from a displayed squeeze window rather than from a selected representative or an external limit operation.

The terminal seal E is downstream of R. It therefore receives only the regular rational route produced by the finite dyadic squeeze data, and the excluded host principles remain absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopDyadicSqueeze}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopDyadicSqueeze}^{\uparrow}$ packet is generated from lower and upper DyadicRatCore endpoints, a unary precision row, StreamName windows, lower and upper comparison rows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopDyadicSqueeze}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5168.1, Definition 5168.2, and Definition 5168.3 seed the finite dyadic squeeze route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopDyadicSqueeze}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, trichotomy, countable choice, uninspected infinite streams, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic endpoint exposure, precision handling, finite-window exposure, lower and upper comparison exactness, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopDyadicSqueezeUp.

Chapter 5169

A Concrete Naming Certificate for $\mathsf{GalerkinProjection}^{\uparrow}$

Following Cea and Galerkin finite-dimensional projection theory, the $\mathsf{GalerkinProjection}^{\uparrow}$ packet records the finite trial-space route by which weak Sobolev data are tested against a displayed finite basis and returned as a residual certificate. It sits between the weak-data surface of chapter 440, the inner-product and norm discipline of chapter 91 and chapter 1950, the linear operator rows of chapter 48, and the finite coordinate ledger of chapter 49. The packet supplies a constructive projection certificate without importing host Hilbert projection machinery, quotient function spaces, selected representatives, global minimizers, or choice.

Definition 5169.1 (Galerkin projection carrier)**.** *A* $\mathsf{GalerkinProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, H, L, M, V, B, A, b, u, r, O, T, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *weak-data source row carrying the finite testable function data requested by the problem.*
2. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *or* $\mathsf{NormedSpace}^{\uparrow}$ *ambient norm row used only through displayed inner-product and norm comparisons.*
3. *L is the* $\mathsf{LinMap}^{\uparrow}$ *bilinear or operator row that supplies the weak equation being tested.*
4. *M is the* $\mathsf{Mat}^{\uparrow}$ *coordinate row for the finite stiffness and load tables.*
5. *V is the finite trial-space row, listing the accepted basis names and the admissible finite coefficient windows.*
6. *B is the basis-evaluation row, displaying how each trial basis element is read back into the weak-data carrier.*
7. *A and b are the finite linear system rows induced by the operator row L and the trial row V.*
8. *u is the computed trial coefficient row inside the displayed finite coordinate packet.*
9. *r is the residual row, recording the finite test residual against every displayed trial basis element.*
10. *O is the residual-orthogonality row, exposing that the residual readback vanishes on the displayed trial-space tests.*

11. *T records componentwise* hsame *transport for weak source rows, norm rows, operator rows, matrix rows, trial rows, basis readback, finite system rows, coefficient rows, residual rows, orthogonality rows, provenance, and local naming.*

12. *C records displayed* Cont *replay of the finite route*

$$S, H, L, M, V, B, A, b, u, r, O \longmapsto T, P, N.$$

13. *P is the* Pkg *provenance over* $\mathsf{GalerkinProjection}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{GalerkinProjection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, H, L, M, V, B, A, b, u, r, O, T, C, P, N$. It has no coordinate for host minimizers, quotient function spaces, selected representatives, ambient Hilbert projection operators, global compactness, or choice.

Lean4 (definition) `BEDC.Derived.GalerkinProjectionUp.GalerkinProjectionUp`

Theorem 5169.2 (Galerkin projection NameCert obligations)**.** *Every accepted* $\mathsf{GalerkinProjection}^{\uparrow}$ *packet exposes its trial-space, finite-coordinate, and residual-certificate obligations through the displayed route*

$$\mathsf{BHist}(S, H, L, M, V, B, A, b, u, r, O) \longrightarrow \mathsf{hsame}(T) \longrightarrow \mathsf{Cont}(C) \longrightarrow \mathsf{Pkg}(P) \longrightarrow \mathsf{NameCert}_{\mathsf{GalerkinProjection}^{\uparrow}}(N).$$

The NameCert row may read the sibling packets $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, *and* $\mathsf{Mat}^{\uparrow}$ *only through their displayed local rows. It cannot replace the finite trial packet by a quotient function space, a selected equivalence-class representative, a host Hilbert projection theorem, a global minimizer, or a choice principle.*

Proof. Project the carrier of Definition 5169.1. The source, ambient norm, weak operator, matrix coordinate, trial-space, basis-readback, finite system, coefficient, residual, and orthogonality rows are all listed before transport and replay.

The transport row T is componentwise, so it preserves each displayed dependency separately. The replay row C then records the finite route from those rows to provenance and local naming; it does not add a selector for a host representative.

Finally the package row P cites only the sibling NameCert surfaces named in the statement, and the local row N closes the packet over that finite route. Since no carrier coordinate names a host minimizer, quotient function space, selected representative, ambient projection operator, global compactness witness, or choice schedule, the certificate obligations are exhausted by the displayed rows. □

Theorem 5169.3 (Galerkin finite-subspace residual orthogonality)**.** *For every accepted* $\mathsf{GalerkinProjection}^{\uparrow}$ *packet $G = (S, H, L, M, V, B, A, b, u, r, O, T, C, P, N)$, the residual row r is exposed to downstream consumers only together with the finite trial-space row V, the basis-readback row B, the matrix system rows A, b, and the residual-orthogonality row O. Thus every residual certificate is a finite-subspace statement: each displayed trial basis test reads zero residual through O, while no consumer obtains an ambient minimizer, quotient-function representative, or selected best approximation outside the packet.*

Proof. Read the finite trial-space row V and the basis-readback row B. These rows specify exactly which test functions are visible to the residual certificate.

The finite system rows A, b and coefficient row u determine the residual row r inside the same displayed coordinate packet. The orthogonality row O then records the zero residual checks against the basis tests carried by V and B.

Transport and replay preserve that finite list through T and C, while P and N seal the result as local NameCert data. Because the carrier has no coordinate for ambient minimizers, quotient function spaces, selected representatives, or choice, the exported orthogonality claim is exactly the finite-subspace residual certificate. □

Falsifiable prediction: Every accepted $\mathsf{GalerkinProjection}^{\uparrow}$ read displays weak source, ambient norm, operator, matrix, finite trial-space, basis-readback, finite system, coefficient, residual, orthogonality, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before any Sobolev, Hilbert, linear-map, matrix, or normed-space consumer reads the projection.

Independence witness: sobolev, hilbert, linearmap, matrix, normedspace: $\mathsf{GalerkinProjection}^{\uparrow}$ is not bijective to any listed sibling because it binds finite trial-space admission, coordinate system rows, computed coefficients, residual readback, residual orthogonality, componentwise transport, displayed replay, provenance, and local naming into one accepted projection packet.

Closure status for $\mathsf{NameCert}_{\mathsf{GalerkinProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{GalerkinProjection}^{\uparrow}$ packet is generated from displayed Sobolev weak data, Hilbert or NormedSpace comparison rows, a LinearMap weak operator row, Matrix coordinate rows, a finite trial-space basis, finite system rows, computed coefficients, residual readback, residual orthogonality, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GalerkinProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5169.1, Definition 5169.2, and Definition 5169.3 seed the finite Galerkin projection route over Sobolev, Hilbert, LinearMap, Matrix, and NormedSpace rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GalerkinProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host Hilbert projection machinery, quotient function spaces, selected representatives, global minimizers, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked trial-space admission, finite matrix-system construction, residual readback, residual orthogonality, transport stability, replay, provenance, and local naming for BEDC.Derived.GalerkinProjectionUp.

Chapter 5170

A Concrete Naming Certificate for $\mathsf{HigsonCompactification}^{\uparrow}$

Following Higson and Roe on coarse topology, the $\mathsf{HigsonCompactification}^{\uparrow}$ packet records the compactification read by slowly oscillating bounded continuous functions on a large-scale metric or uniform source. It sits after the uniform-space carrier of chapter 339, the metric observation surface of chapter 57, the compact target boundary of chapter 60, the continuous-map row of chapter 130, and the terminal real-valued readback of chapter 38. It is adjacent to the uniform-envelope route of chapter 2154 and the bounded-function envelope of chapter 2344, but its local carrier keeps the coarse-control row visible rather than collapsing to either sibling.

Definition 5170.1 (Higson compactification carrier)**.** *A* $\mathsf{HigsonCompactification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, M, A, C, F, R, S, B, H, T, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row supplying entourages and uniform refinement data for the underlying space;*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *large-scale control row recording bounded-set, coarse-separation, and distance-window requests;*
3. *A is the Higson-algebra row of bounded real-valued functions whose oscillation is eventually small outside controlled bounded regions;*
4. *C is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row proving that every accepted function in A is read through displayed continuity data;*
5. *F is the finite observation-family row used by a consumer to inspect only finitely many Higson functions at a requested stage;*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *value-seal row for the bounded real observations in A and F;*
7. *S is the Samuel-compactification comparison row imported from chapter 2154;*
8. *B is the Stone–Cech comparison row imported from chapter 2344;*
9. *H records componentwise* hsame *transport for $U, M, A, C, F, R, S, B, T, P, N$;*
10. *T records displayed* Cont *replay of coarse-control and function-evaluation requests;*

11. *P is the* Pkg *provenance over* $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *the two compactification neighbours,* BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HigsonCompactification}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. There is no coordinate for a selected boundary point, ultrafilter choice, quotient host compactification, full Stone–Cech universality, or ambient properness theorem.

Lean4 ✓ `BEDC.Derived.HigsonCompactificationUp.HigsonCompactificationTasteGate single carrier alignment`

Theorem 5170.2 (Higson compactification NameCert obligations)**.** *For every accepted* $\mathsf{HigsonCompactification}^{\uparrow}$ *carrier*

$$K = (U, M, A, C, F, R, S, B, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HigsonCompactification}^{\uparrow}}$ *surface consists exactly of carrier admission for the uniform source, large-scale metric row, slowly oscillating bounded function row, continuity row, finite observation family, real value seals, Samuel comparison, Stone–Cech comparison, componentwise transport, replay, provenance, and local naming.*

The obligation surface also records coarse-control non-escape: every accepted real-valued observation must pass through M, A, C, F, R before it is read as compactification data, and the comparison rows S, B do not replace the Higson algebra row by Samuel uniformity alone or by Stone–Cech bounded functions alone.

Proof. Project the carrier K. The rows U and M expose the uniform and large-scale source data, while A, C, F, R expose the slowly oscillating bounded functions, their continuity witnesses, finite observation families, and real value seals.

The comparison rows are then read as neighbours rather than definitions. Row S identifies the Samuel compactification route available from uniform data, and row B identifies the Stone–Cech bounded-function envelope, but neither row carries the coarse-control predicate stored in A over the metric row M.

The structural rows H, T, P, N transport, replay, package, and name exactly the displayed route. Since the carrier has no further coordinate, a consumer cannot obtain a selected boundary point, an ultrafilter, a quotient host compactification, full Stone–Cech universality, or an ambient properness theorem from the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.HigsonCompactificationUp.HigsonCompactificationCarrier namecert obligations`

Theorem 5170.3 (Higson compactification uniform handoff)**.** *Every compactification-facing consumer of an accepted* $\mathsf{HigsonCompactification}^{\uparrow}$ *packet factors through the route*

$$U, M \longmapsto A, C, F, R \longmapsto S, B, H, T, P, N.$$

Thus the consumer first reads the uniform and large-scale metric source rows, then the slowly oscillating bounded continuous real-valued observation rows, and only then the Samuel and Stone–Cech comparison rows together with transport, replay, provenance, and local naming.

Proof. Start with an accepted carrier $K = (U, M, A, C, F, R, S, B, H, T, P, N)$. The only source rows are U and M, so every compactification-facing request begins with the displayed uniform and large-scale metric data.

The Higson observation rows are downstream of that source. Row A records the slowly oscillating bounded real-valued functions, C keeps their continuity evidence visible, F restricts consumer inspection to finite observation families, and R seals the observed values as $\mathsf{Real}^{\uparrow}$ data.

The neighbour rows S and B are consumed after the Higson observation route has been read. They compare the packet with Samuel and Stone–Cech compactification surfaces, while H, T, P, N retain transport, replay, provenance, and local naming for the same displayed rows. No bypass row exists for selected boundary points, ultrafilters, quotient host compactifications, full Stone–Cech universality, or ambient properness. □

Falsifiable prediction: Every $\mathsf{HigsonCompactification}^{\uparrow}$ compactification-facing read exposes a $\mathsf{UniformSpace}^{\uparrow}$ row, a $\mathsf{Met}^{\uparrow}$ large-scale row, a slowly oscillating bounded $\mathsf{ContinuousMap}^{\uparrow}$ row, finite observation data, $\mathsf{Real}^{\uparrow}$ value seals, Samuel and Stone–Cech comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: uniformspace, metric, compact, continuousmap, real, samuel-compactification, stone-cech-compactification: $\mathsf{HigsonCompactification}^{\uparrow}$ is not bijective to any listed sibling because it binds coarse-control and slowly oscillating bounded continuous real-valued observations together with the two compactification comparison rows in one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{HigsonCompactification}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HigsonCompactification}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5170.1, Definition 5170.2, and Definition 5170.3 seed the finite Higson compactification packet through uniform, metric, compact, continuous-map, Real, Samuel, and Stone–Cech rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HigsonCompactification}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected boundary points, ultrafilter choice, quotient host compactifications, full Stone–Cech universality, ambient properness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coarse-control exactness, slowly oscillating bounded function stability, finite observation replay, neighbour comparison non-collapse, provenance, and local naming.

Constructive story: A $\mathsf{HigsonCompactification}^{\uparrow}$ packet is generated from displayed uniform and large-scale metric source rows, slowly oscillating bounded continuous real-valued observations, finite observation families, Samuel and Stone–Cech comparison rows, componentwise transport, replay, provenance, and a local NameCert row.

Chapter 5171

A Concrete Naming Certificate for $\mathsf{HigsonCorona}^{\uparrow}$

Following Higson and Roe on coarse topology, the $\mathsf{HigsonCorona}^{\uparrow}$ packet records the boundary consumer of the Higson compactification route. It reads the compactification carrier of chapter 5170, compares its boundary-facing rows with the Stone–Cech surface of chapter 2344, and keeps the uniform source discipline of chapter 339 visible through the metric, continuous-map, and real-valued observation rows. The packet names a finite corona interface; it does not choose boundary points, ultrafilters, quotient compactification classes, or ambient coarse-equivalence witnesses.

Definition 5171.1 (Higson corona carrier)**.** *A* $\mathsf{HigsonCorona}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (K, B, U, M, F, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{HigsonCompactification}^{\uparrow}$ *boundary row, read as the compactification-side source of corona observations.*
2. *B is the* $\mathsf{StoneCechCompactification}^{\uparrow}$ *comparison row, used only to compare bounded-probe boundary data with the Higson boundary route.*
3. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row inherited by the compactification packet.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *large-scale control row that keeps coarse escape and bounded-region information visible.*
5. *F is the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *row of slowly oscillating bounded real-valued observations admitted by the boundary read.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *value-seal row for the finite boundary observation family.*
7. *H records componentwise* hsame *transport for $K, B, U, M, F, R, C, P, N$.*
8. *C records displayed* Cont *replay from the compactification boundary row through the finite observation and comparison rows.*
9. *P is the* Pkg *provenance over* $\mathsf{HigsonCorona}^{\uparrow}$, $\mathsf{HigsonCompactification}^{\uparrow}$, $\mathsf{StoneCechCompactification}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HigsonCorona}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, B, U, M, F, R, H, C, P, N$. It has no coordinate for selected corona points, ultrafilter choice, quotient host compactification equality, ambient properness, or a global coarse compactification theorem.

Theorem 5171.2 (Higson corona NameCert obligations)**.** *For every accepted* $\mathsf{HigsonCorona}^{\uparrow}$ *carrier*

$$Q = (K, B, U, M, F, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HigsonCorona}^{\uparrow}}$ *surface consists exactly of compactification-boundary admission, Stone–Cech comparison, inherited uniform source exposure, large-scale metric control, finite slowly oscillating continuous observation, Real value sealing, componentwise transport, displayed replay, provenance, and local naming.*

Every boundary-facing consumer must read the displayed route

$$K, B, U, M \longmapsto F, R \longmapsto H, C, P, N$$

before it may use a corona observation.

Proof. Project the accepted carrier. The rows K, B, U, M expose the Higson compactification boundary source, the Stone–Cech comparison surface, the uniform source row, and the large-scale metric control row.

The observation rows F, R are downstream of that boundary source. They record only finite slowly oscillating continuous real-valued observations and their Real value seals, so a consumer cannot replace them by an ambient function algebra or an unbounded host observation family.

The structural rows H, C, P, N transport, replay, package, and name the same displayed route. Since the carrier has no coordinate for selected corona points, ultrafilter choice, quotient host compactification equality, ambient properness, or a global coarse compactification theorem, those data are not exported by the local certificate. □

Theorem 5171.3 (Higson corona compactification boundary)**.** *Every accepted* $\mathsf{HigsonCorona}^{\uparrow}$ *boundary read is a consumer of the accepted* $\mathsf{HigsonCompactification}^{\uparrow}$ *route before it is a compactification comparison. In particular, the boundary read must expose the* $\mathsf{HigsonCompactification}^{\uparrow}$ *row, the* $\mathsf{StoneCechCompactification}^{\uparrow}$ *comparison row, the* $\mathsf{UniformSpace}^{\uparrow}$ *source row, the* $\mathsf{Met}^{\uparrow}$ *control row, the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *observation row, the* $\mathsf{Real}^{\uparrow}$ *seal row,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{HigsonCorona}^{\uparrow}}$ *row.*

Proof. Read the carrier of Definition 5171.1. The row K is the only compactification-boundary source available to the packet, so every corona request first passes through the Higson compactification route of chapter 5170.

The comparison with Stone–Cech compactification is then read through B and not as a replacement for K. The inherited rows U, M, F, R retain uniform source data, large-scale metric control, finite continuous observations, and Real value seals before any boundary consumer can use the comparison.

Apply Theorem 5171.2. It exhausts the remaining structural rows H, C, P, N and excludes selected boundary points, ultrafilters, quotient host compactification equality, ambient properness, and global coarse compactification data from the boundary surface. □

Falsifiable prediction: Every accepted $\mathsf{HigsonCorona}^{\uparrow}$ boundary read exposes a $\mathsf{HigsonCompactification}^{\uparrow}$ boundary row, a $\mathsf{StoneCechCompactification}^{\uparrow}$ comparison row, $\mathsf{UniformSpace}^{\uparrow}$ source data, $\mathsf{Met}^{\uparrow}$ large-scale control, finite slowly oscillating $\mathsf{ContinuousMap}^{\uparrow}$ observations, $\mathsf{Real}^{\uparrow}$ value seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: higson-compactification, stone-cech-compactification, uniformspace, metric, continuousmap, real: $\mathsf{HigsonCorona}^{\uparrow}$ is not bijective to any listed sibling because it binds a Higson compactification boundary consumer to Stone–Cech comparison, uniform source data, large-scale metric control, finite continuous real-valued observations, and local NameCert provenance in one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{HigsonCorona}^{\uparrow}}$.

Constructive story: A $\mathsf{HigsonCorona}^{\uparrow}$ packet is generated from a Higson compactification boundary row, a Stone–Cech comparison row, inherited uniform and metric source rows, finite slowly oscillating continuous real-valued observations, Real value seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HigsonCorona}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5171.1, Definition 5171.2, and Definition 5171.3 seed the finite Higson corona boundary consumer over compactification, comparison, uniform, metric, continuous-map, Real, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HigsonCorona}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected corona points, ultrafilter choice, quotient host compactification equality, ambient properness, global coarse compactification theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked boundary admission, comparison stability, inherited uniform and metric source exposure, finite observation replay, value sealing, transport, provenance, and local naming for BEDC.Derived.HigsonCoronaUp.

Chapter 5172

A Concrete Naming Certificate for $\mathsf{ModulusCompositionSchedule}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ModulusCompositionSchedule}^{\uparrow}$ packet records the finite schedule data by which two Cauchy moduli are composed before a regular rational readback is sealed as a Real name. It sits over the finite schedule surface of chapter 292, the stream-window surface of chapter 126, the dyadic tolerance rows of chapter 291, the regular rational readback of chapter 301, the modulus arithmetic route of chapter 1485, and the terminal real-name seal of chapter 38. The packet gives the L10 Real and Completion route a concrete object for composing precision schedules; it is not a quotient-real equality principle, selected limit, trichotomy, countable-choice schedule, hidden infinite stream, or ambient completeness theorem.

Definition 5172.1 (Modulus composition schedule carrier)**.** *A* $\mathsf{ModulusCompositionSchedule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (\mu, \nu, W_\mu, W_\nu, \varepsilon, \delta, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *μ and ν are the two source* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule rows whose precision requests are to be composed.*
2. *W_μ and W_ν are finite* $\mathsf{StreamName}^{\uparrow}$ *windows displaying the inspected reads for the outer and inner schedules.*
3. *ε is the requested* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row at the terminal Real-facing scale.*
4. *δ is the intermediate* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row selected by the outer schedule and then fed to the inner schedule.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after both finite windows have been inspected at the displayed tolerances.*
6. *A is the* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *row witnessing that the two schedule reads compose from ε through δ to the displayed regular rational readback.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from R after the composed schedule has been displayed.*
8. *H records componentwise* hsame *transport for $\mu, \nu, W_\mu, W_\nu, \varepsilon, \delta, R, A, E$ and the local naming row.*

9. *C records displayed* Cont *replay from a composed precision request through two Cauchy-modulus rows, two finite stream windows, dyadic tolerances, arithmetic composition, regular rational readback, and the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{ModulusCompositionSchedule}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulusArithmetic}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ModulusCompositionSchedule}^{\uparrow}}$ *row.*

The classifier compares accepted schedule packets only through $\mu, \nu, W_\mu, W_\nu, \varepsilon, \delta, R, A, E, H, C, P, N$. It has no coordinate for quotient real representatives, selected limits, trichotomy, countable choice, hidden infinite streams, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ModulusCompositionScheduleUp.ModulusCompositionScheduleTasteGate single carrier alignment`

Theorem 5172.2 (Modulus composition schedule NameCert obligations)**.** *For every accepted* $\mathsf{ModulusCompositionSchedule}^{\uparrow}$ *carrier*

$$M = (\mu, \nu, W_\mu, W_\nu, \varepsilon, \delta, R, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ModulusCompositionSchedule}^{\uparrow}}$ *surface consists exactly of two* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule exposures, two finite* $\mathsf{StreamName}^{\uparrow}$ *window exposures, terminal and intermediate* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *composition exposure, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer must expose $\mu, \nu, W_\mu, W_\nu, \varepsilon, \delta, R, A, E$ before the structural rows H, C, P, N can be consumed.*

Proof. Project the carrier of Definition 5172.1. The analytic rows are exactly $\mu, \nu, W_\mu, W_\nu, \varepsilon, \delta, R, A, E$, while H, C, P, N are the structural transport, replay, provenance, and naming rows.

The terminal tolerance ε is read before the outer schedule row μ supplies the intermediate tolerance δ. The inner schedule row ν is then inspected through W_ν at that intermediate tolerance, so the packet does not contain a free-standing precision oracle.

The readback row R and arithmetic row A bind both schedule reads to the same displayed composition route. Hence a consumer cannot use the Real seal E without first exposing the two moduli, two finite windows, and both dyadic tolerance rows.

Since the carrier has no coordinate for quotient representatives, selected limits, trichotomy, countable choice, hidden streams, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 5172.3 (Modulus composition schedule Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{ModulusCompositionSchedule}^{\uparrow}$ *packet reaches the terminal Real seal only through the displayed finite route*

$$\mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyModulusArithmetic}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff may use the two schedule rows, the two inspected stream windows, terminal and intermediate dyadic tolerances, arithmetic composition, and regular rational readback, but it cannot replace them by quotient real equality, a selected limit, trichotomy, countable choice, an uninspected infinite stream, or ambient completeness.

Proof. Begin with the Real or Completion-facing read of M. The terminal tolerance ε and the outer schedule row μ determine the intermediate tolerance δ, so the consumer sees a finite precision request before the inner schedule is inspected.

The stream rows W_μ and W_ν display the only window reads available to the two schedule rows. The arithmetic row A then records that the outer and inner reads compose through the displayed dyadic tolerances.

The regular rational readback R is downstream of this arithmetic route, and the terminal seal E is downstream of R. Therefore the Real handoff factors through the finite schedule packet and the excluded host principles remain absent from the carrier. □

Lean4 ✓ `BEDC.Derived.ModulusCompositionScheduleUp.ModulusCompositionScheduleRealHandoff`

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusCompositionSchedule}\uparrow}$.

Constructive story: A $\mathsf{ModulusCompositionSchedule}^{\uparrow}$ packet is generated from two CauchyModulus schedules, two StreamName windows, terminal and intermediate DyadicRatCore tolerances, RegSeqRat readback, CauchyModulusArithmetic composition, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ModulusCompositionSchedule}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5172.1, Definition 5172.2, and Definition 5172.3 seed the finite composed-modulus schedule route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ModulusCompositionSchedule}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, trichotomy, countable choice, uninspected infinite streams, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, two-modulus exposure, two-window exposure, dyadic tolerance routing, modulus arithmetic exactness, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ModulusCompositionScheduleUp.

Chapter 5173

A Concrete Naming Certificate for $\mathsf{LowDiscrepancySequence}^{\uparrow}$

Following Niederreiter and Kuipers–Niederreiter on uniform distribution and star discrepancy, the $\mathsf{LowDiscrepancySequence}^{\uparrow}$ packet records finite sampling windows whose axis-aligned box counts are available to numerical-integration consumers. It sits over the rational coordinate carrier of chapter 37, the terminal real seal of chapter 38, the tagged Riemann route of chapter 1526, and the Darboux comparison route of chapter 1460. The packet names finite count and discrepancy-budget data; it does not import measure theory, probability, selected infinite sequence data, or an ambient equidistribution theorem.

Definition 5173.1 (Low-discrepancy sequence carrier)**.** *A* $\mathsf{LowDiscrepancySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (P, Q, B, D, H, C, G, N)$$

with the following displayed rows:

1. *P is the sample-point window row, listing a finite prefix of sample points with rational coordinate names.*
2. *Q is the rational box-test row, listing anchored axis-aligned rational boxes whose endpoints are read through* $\mathsf{Rat}^{\uparrow}$ *and whose real-facing comparisons are sealed through* $\mathsf{Real}^{\uparrow}$*.*
3. *B is the exact finite-count row, assigning to each displayed box the number of sample points from P that fall inside it.*
4. *D is the star-discrepancy budget row, recording the rational error budget attached to the displayed count comparison.*
5. *H records componentwise* hsame *transport for sample windows, box tests, exact counts, discrepancy budgets, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay from a sampling request through P, Q, B, D, H, G, N.*
7. *G is the* Pkg *provenance over* $\mathsf{LowDiscrepancySequence}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RiemannIntegral}^{\uparrow}$*,* $\mathsf{DarbouxIntegral}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LowDiscrepancySequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through P, Q, B, D, H, C, G, N. It has no coordinate for a host probability space, Lebesgue measure, selected infinite sequence, asymptotic limit, randomized sampler, or ambient real-completeness principle.

Lean4 ✓ `BEDC.Derived.LowDiscrepancySequenceUp.TasteGate.LowDiscrepancySequenceTasteGate single carrier alignment`

Theorem 5173.2 (Low-discrepancy sequence NameCert obligations)**.** *For every accepted* $\mathsf{LowDiscrepancySequence}^{\uparrow}$ *carrier* $L = (P, Q, B, D, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LowDiscrepancySequence}^{\uparrow}}$ *surface consists exactly of five finite obligation rows: carrier admission for* P, Q, B, D, H, C, G, N*; rational box-test exactness through* Q*; exact finite membership counts through* B*; star-discrepancy budget exposure through* D*; and transport, replay, provenance, and local naming through* H, C, G, N *with non-escape from host measure, probability, selected infinite sequences, randomized sampling, and ambient completeness.*

Proof. Project the carrier of Definition 5173.1. The only sampling data rows are the finite sample window P, rational box tests Q, exact finite counts B, and discrepancy budgets D.

The rational box-test row is finite. Each box endpoint is read through the rational carrier and compared only through the displayed real-facing seal, so the test row does not add a measure algebra or probability event space.

The exact count row is tied to the displayed window. It records membership counts for the boxes already listed in Q, and the discrepancy row D records the budget attached to those counts rather than an asymptotic theorem.

Finally H, C, G, N transport, replay, source, and name the same packet. Since the excluded host objects are not coordinates of L, the five listed rows exhaust the local NameCert surface. □

Theorem 5173.3 (Low-discrepancy sequence star-discrepancy route)**.** *Every numerical-integration consumer of an accepted* $\mathsf{LowDiscrepancySequence}^{\uparrow}$ *packet may read only the finite route*

$$P, Q \longmapsto B, D \longmapsto H, C, G, N.$$

In particular, a $\mathsf{RiemannIntegral}^{\uparrow}$ *or* $\mathsf{DarbouxIntegral}^{\uparrow}$ *consumer may use the displayed box counts and discrepancy budgets as finite sampling evidence, but it may not read host measure, probability, selected infinite sequence data, randomized sampling, or an asymptotic equidistribution endpoint from the packet.*

Proof. Start with an integration-facing request. The packet first exposes the finite sample window P and the rational box tests Q, so every downstream read is already tied to displayed finite data.

The rows B and D are the only numerical sampling rows. The count row supplies exact finite membership counts, and the discrepancy row supplies the rational error budget available to the integration consumer.

The structural rows H, C, G, N preserve the same route. They do not add measure, probability, selected infinite sequence data, randomized sampling, or asymptotic convergence data, so the integration consumer remains inside the finite star-discrepancy route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LowDiscrepancySequence}^{\uparrow}}$.

Constructive story: A $\mathsf{LowDiscrepancySequence}^{\uparrow}$ packet is generated from finite sample-point windows, rational box tests, exact finite counts, star-discrepancy budgets, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LowDiscrepancySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5173.1, Definition 5173.2, and Definition 5173.3 seed the finite star-discrepancy sampling certificate for Riemann and Darboux integration consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LowDiscrepancySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host measure, probability, selected infinite sequence data, randomized sampling, asymptotic equidistribution, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational box-test exactness, finite-count exactness, discrepancy-budget exposure, transport, replay, provenance, local naming, and TasteGate nontriviality with field faithfulness for BEDC.Derived.LowDiscrepancySequenceUp.

Chapter 5174

A Concrete Naming Certificate for MetaCICConfluenceBudgetWitness$^{\uparrow}$

The MetaCICConfluenceBudgetWitness$^{\uparrow}$ packet realizes the finite confluence-budget witness route of chapter 9378. It sits beside the local diamond witness of chapter 3595, the residual envelope of chapter 3921, the substitution-boundary packet of chapter 3791, the closed-premise ledger of chapter 2325, and the residual-budget packet of chapter 4061. The witness binds finite budget rows used by confluence-facing readers while keeping the boundary against full confluence explicit.

Definition 5174.1 (MetaCIC confluence-budget witness carrier)**.** *A* MetaCICConfluenceBudgetWitness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (T, F, R, J, E, S, L, D, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row naming the closed MetaCIC terms and finite context fragments inspected by the witness.*
2. *F is the redex-frontier row listing the beta and congruence faces admitted to the budget.*
3. *R is the residual-budget row that bounds residual addresses, replay fuel, and candidate-join inspection.*
4. *J is the candidate-join row, recording only the joins accepted inside the displayed budget.*
5. *E is the residual-envelope row read from the confluence residual-envelope packet.*
6. *S is the substitution-boundary row that keeps residual-substitution compatibility visible as a boundary condition.*
7. *L is the closed parallel-diamond premise ledger row.*
8. *D is the local-diamond witness row consumed as finite local geometry.*
9. *O is the obstruction-retention row, recording that full parallel diamond and arbitrary closed Church–Rosser are not supplied by the packet.*
10. *H records componentwise* hsame *transport for typed windows, frontiers, budgets, joins, envelopes, substitution boundaries, premise ledgers, local diamonds, obstruction rows, replay, provenance, and local naming.*

11. *C records displayed* Cont *replay from a confluence-budget request through* $T, F, R, J, E, S, L, D, O, H, P, N$.
12. *P is the* Pkg *provenance over* $\mathsf{MetaCICConfluenceBudgetWitness}^{\uparrow}$, $\mathsf{MetaCICDiamondResidualBudget}^{\uparrow}$, $\mathsf{MetaCICLocalDiamondWitness}^{\uparrow}$, $\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}$, $\mathsf{MetaCICConfluenceSubstitutionBoundary}^{\uparrow}$ $\mathsf{ClosedParallelDiamondPremiseLedger}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceBudgetWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, F, R, J, E, S, L, D, O, H, C, P, N$. It has no coordinate for full parallel diamond, arbitrary closed Church–Rosser, global strong normalization, substitution compatibility, subject reduction, or host reduction semantics.

Theorem 5174.2 (MetaCIC confluence-budget witness NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICConfluenceBudgetWitness}^{\uparrow}$ *carrier $W = (T, F, R, J, E, S, L, D, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceBudgetWitness}^{\uparrow}}$ *surface consists exactly of typed-window admission, redex-frontier exposure, residual-budget accounting, candidate-join recording, residual-envelope handoff, substitution-boundary visibility, closed-premise-ledger handoff, local-diamond handoff, obstruction retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 5174.1. The mathematical rows are precisely $T, F, R, J, E, S, L, D, O$, followed by the structural rows H, C, P, N.

The budget is finite before any join is consumed. Rows T, F, R bind the typed window, redex frontier, and residual fuel, while J records only the candidate joins accepted inside that displayed budget.

The sibling handoffs remain visible. The residual envelope E, substitution boundary S, closed-premise ledger L, and local diamond row D are not collapsed into an endpoint theorem; the obstruction row O records the refused endpoint claims.

Rows H, C, P, N transport, replay, source, and name the same finite route. Since no excluded endpoint is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5174.3 (MetaCIC confluence-budget witness endpoint boundary)**.** *Every confluence-facing consumer of an accepted* $\mathsf{MetaCICConfluenceBudgetWitness}^{\uparrow}$ *packet reads only the finite route*

$$T, F, R \longmapsto J \longmapsto E, S, L, D, O \longmapsto H, C, P, N.$$

The route may expose candidate joins under a residual budget, but it does not assert full parallel diamond, arbitrary closed Church–Rosser, global strong normalization, substitution compatibility, subject reduction, or host reduction semantics.

Proof. Begin with the displayed witness route. The typed window, redex frontier, and residual budget are read before the candidate-join row, so the join is budget-mediated rather than global.

The downstream rows keep the audit boundary intact. Residual envelope, substitution boundary, closed-premise ledger, and local diamond data are exposed as sibling handoffs, while the obstruction row remains in the same packet.

The structural rows preserve the route without adding endpoint proof data. Thus a confluence-facing consumer receives finite budget evidence and no coordinate for the refused global claims. □

Theorem 5174.4 (MetaCIC confluence-budget residual coverage)**.** *Every accepted* MetaCICConfluenceBudgetWitne *packet that is consumed as residual-substitution evidence factors through the residual-budget row R, candidate-join row J, residual-envelope row E, substitution-boundary row S, closed-premise ledger L, local-diamond row D, and obstruction row O. It cannot be read as full parallel diamond,*

arbitrary closed Church–Rosser, or unguarded substitution compatibility; residual-substitution consumers must keep the guarded input shape of chapter 4370 visible.

Proof. Project the carrier $W = (T, F, R, J, E, S, L, D, O, H, C, P, N)$ from Definition 5174.1. The residual-facing coordinates are displayed as R, J, E, S, L, D, O, with transport, replay, provenance, and naming downstream.

Apply Definition 5174.2. The NameCert surface requires residual-budget accounting, candidate-join recording, residual-envelope handoff, substitution-boundary visibility, closed-premise-ledger handoff, local-diamond handoff, and obstruction retention as separate rows.

The refused endpoints are fixed by Definition 5174.3. That theorem prevents the same packet from being read as full parallel diamond, arbitrary closed Church–Rosser, or an unguarded substitution theorem.

Finally, the guarded input shape is the one recorded by chapter 4370. Thus a residual-substitution consumer receives only the displayed budgeted rows and the explicit boundary, not an endpoint confluence claim. □

Falsifiable prediction: A packet omitting either the residual-budget row R or the obstruction-retention row O is rejected as a $\mathsf{MetaCICConfluenceBudgetWitness}^{\uparrow}$ packet, even when it carries typed-window, local-diamond, or residual-envelope rows.

Independence witness: metacic-local-diamond-witness, metacic-confluence-residual-envelope, metacic-confluence-substitution-boundary, closed-parallel-diamond-premise-ledger, metacic-diamond-residual-budget: $\mathsf{MetaCICConfluenceBudgetWitness}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds typed windows, redex frontiers, residual budgets, candidate joins, residual envelopes, substitution boundaries, closed-premise ledgers, local diamonds, obstruction retention, transport, replay, provenance, and local NameCert data.

The Lean-side hardening surface requires Nontrivial and FieldFaithful instances for the confluence-budget witness packet. The nontrivial witness separates an accepted packet with displayed residual-budget and obstruction rows from a refused packet missing one of those rows; field faithfulness compares $T, F, R, J, E, S, L, D, O, H, C, P, N$ componentwise so that equal displayed fields are indistinguishable to the local NameCert classifier.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceBudgetWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICConfluenceBudgetWitness}^{\uparrow}$ packet is generated from typed-window rows, redex-frontier rows, residual budgets, candidate joins, residual envelopes, substitution-boundary rows, closed-premise ledgers, local diamonds, obstruction retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceBudgetWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5174.1, Definition 5174.2, and Definition 5174.3 seed the finite confluence-budget witness for MetaCIC confluence-audit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceBudgetWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full parallel diamond, arbitrary closed Church–Rosser, global strong normalization, substitution compatibility, subject reduction, host reduction semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, budget accounting, candidate-join exposure, residual-envelope handoff, substitution-boundary visibility, premise-ledger handoff, local-diamond handoff, obstruction retention, and Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.MetaCICConfluenceBudgetWitnessUp.

$\mathsf{LawOfTotalVariance}^{\uparrow}$ routes its variance ledger through chapter 190 and chapter 2246 after the probability, random-variable, conditional-expectation, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are displayed.

Chapter 5175

A Concrete Naming Certificate for $\mathsf{LawOfTotalVariance}^{\uparrow}$

Following Kolmogorov and Doob on conditional expectation and variance decompositions, the $\mathsf{LawOfTotalVariance}^{\uparrow}$ packet records the finite Real-valued ledger behind the identity that total variance splits into conditional variance and variance of the conditional mean. It sits after the normalized probability surface of chapter 184, the carried random-variable rows of chapter 185, the singleton conditional-expectation rows of chapter 188, the Real seal of chapter 38, and the regular rational readback surface of chapter 301. The existing martingale variance consumer route reads this chapter through chapter 190 only after the conditional-mean and conditional-variance rows are exposed as the ledger consumed by martingale variance accounting. The chapter names the finite BEDC rows needed by later martingale and variance consumers; it does not import a host probability space, quotient almost-sure equality, an unrestricted conditional-expectation operator, or ambient real completeness.

Definition 5175.1 (LawOfTotalVariance carrier)**.** *A* $\mathsf{LawOfTotalVariance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (P, X, C, M, V, W, T, S, R, H, K, Q, N)$$

with the following displayed rows:

1. *P is the source* $\mathsf{ProbSpace}^{\uparrow}$ *row, exposing the total-event normalization, measurable-event classifier, and Real-valued probability readbacks used by the variance request.*
2. *X is the centered* $\mathsf{RandomVar}^{\uparrow}$ *row whose finite-window square readback is being decomposed.*
3. *C is the* $\mathsf{CondExp}^{\uparrow}$ *row that displays the conditioning face for the inspected finite window.*
4. *M is the conditional-mean row, read as the displayed conditional expectation of X along C.*
5. *V is the conditional-variance row, read as the conditional expectation of the squared residual between X and M on the same conditioning face.*
6. *W is the total-variance row, read as the Real-valued finite-window expectation of the squared residual from the total mean.*
7. *T is the variance-of-conditional-mean row, read as the Real-valued finite-window variance of M.*
8. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal comparing W with the displayed sum of V and T through the Real classifier.*

9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row recording the rational windows, tolerances, and finite square-expansion approximants used before the Real seal is exposed.*
10. *H records componentwise* hsame *transport for $P, X, C, M, V, W, T, S, R$ and the structural rows below.*
11. *K records displayed* Cont *replay through the probability source, random-variable row, conditional-expectation row, variance rows, regular-rational readback, and Real seal.*
12. *Q is the* Pkg *provenance over* $\mathsf{LawOfTotalVariance}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{LawOfTotalVariance}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host almost-sure quotient equality, an external L^2 space, countable-choice representatives, or an ambient conditional-expectation theorem.

Theorem 5175.2 (LawOfTotalVariance NameCert obligations)**.** *For every accepted* $\mathsf{LawOfTotalVariance}^{\uparrow}$ *carrier $L = (P, X, C, M, V, W, T, S, R, H, K, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{LawOfTotalVariance}^{\uparrow}}$ *surface consists exactly of the displayed probability source, random-variable endpoint, conditional-expectation face, conditional-mean row, conditional-variance row, total-variance row, variance-of-conditional-mean row, Real seal, RegSeqRat readback, componentwise transport, replay, provenance, and local naming rows. No obligation may be discharged by importing an ambient variance theorem, quotient almost-sure equality, a host conditional-expectation operator, countable choice, or an external real-completeness row.*

Proof. Project the carrier of Definition 5175.1. The rows P, X, C supply the probability source, the carried random variable, and the conditioning face; the rows M, V, W, T expose the conditional mean, conditional variance, total variance, and variance of the conditional mean.

The comparison is finite before it is Real-facing. The row R records the regular rational windows and tolerance data used by the square-expansion readbacks, while S is the only terminal Real seal available to the consumer.

Finally the structural rows H, K, Q, N preserve and name the same packet through componentwise transport, displayed replay, provenance, and local certification. Since the excluded host theorem, quotient, choice, and completeness coordinates are absent from L, they cannot discharge any local obligation. □

Theorem 5175.3 (LawOfTotalVariance conditional-mean decomposition)**.** *Every accepted* $\mathsf{LawOfTotalVariance}^{\uparrow}$ *decomposition read factors through the finite route*

$$P, X, C \longmapsto M \longmapsto V, T \longmapsto R \longmapsto S \longmapsto H, K, Q, N.$$

Thus a total-variance consumer receives the displayed equality between the total variance row W and the sum of the conditional-variance row V with the variance-of-conditional-mean row T only after reading the probability source, random-variable endpoint, conditional-expectation face, conditional mean, finite-window RegSeqRat approximants, Real seal, transport, replay, provenance, and local NameCert data.

Proof. Begin with the source rows. The probability packet P fixes the measurable-event and Real-valued mass surface, while X supplies the carried random-variable endpoint and C supplies the conditioning face through the existing $\mathsf{CondExp}^{\uparrow}$ interface.

Next read the mean and variance rows. The row M is the displayed conditional mean, V is the conditional variance around that mean, W is the total variance, and T is the variance of the conditional mean. These rows are compared only on the finite window named by the packet.

The rows R and S then move the comparison from rational approximants to the Real seal. The structural rows H, K, Q, N keep the same route under transport and replay. Therefore the decomposition exposed to downstream consumers is exactly the displayed finite BEDC ledger, not a host-side variance theorem. □

Falsifiable prediction: A total-variance read that omits the conditioning face, the conditional-mean row, the RegSeqRat finite-window readback, or the terminal Real seal is not accepted by the local NameCert.

Independence witness: probspace, randomvar, condexp, real, regseqrat: $\mathsf{LawOfTotalVariance}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the probability source, random-variable endpoint, conditioning face, conditional mean, conditional variance, total variance, variance of the conditional mean, finite-window readback, Real seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LawOfTotalVariance}^{\uparrow}}$.

Constructive story: A $\mathsf{LawOfTotalVariance}^{\uparrow}$ packet is generated from a ProbSpace row, RandomVar row, CondExp row, conditional-mean row, conditional-variance row, total-variance row, variance-of-conditional-mean row, RegSeqRat finite-window readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LawOfTotalVariance}^{\uparrow}}$, seed)

Scope closed: Definition 5175.1, Definition 5175.2, and Definition 5175.3 seed the finite variance-decomposition route through ProbSpace, RandomVar, CondExp, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LawOfTotalVariance}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host almost-sure quotient equality, an unrestricted conditional-expectation operator, an external L^2 theorem, countable-choice representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, conditional-mean routing, conditional-variance readback, total-variance readback, variance-of-conditional-mean readback, RegSeqRat tolerance accounting, Real sealing, transport stability, replay stability, provenance, and local naming for BEDC.Derived.LawOfTotalVarianceUp.

Theorem 5175.4 (LawOfTotalVariance martingale variance consumer route)**.** *Every* $\mathsf{Martingale}^{\uparrow}$ *or* $\mathsf{MartingaleConvergence}^{\uparrow}$ *variance-facing consumer of an accepted* $\mathsf{LawOfTotalVariance}^{\uparrow}$ *packet must first read the displayed* $\mathsf{ProbSpace}^{\uparrow}$*,* $\mathsf{RandomVar}^{\uparrow}$*,* $\mathsf{CondExp}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows of Definition 5175.1. Only after those rows are exposed may the consumer route the variance decomposition through chapter 190 or chapter 2246.*

The route exports no host almost-sure quotient, unrestricted conditional-expectation operator, countable-choice representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 5175.1. The probability source P, random-variable endpoint X, conditioning face C, regular-rational readback R, and Real seal S are visible before any variance-facing consumer can read M, V, W, T as a decomposition package.

For a $\mathsf{Martingale}^{\uparrow}$ consumer, replay the displayed probability, random-variable, and conditional-expectation rows through chapter 190. The variance row is therefore attached to the finite adapted-sequence surface rather than to a host random-variable quotient.

For a $\mathsf{MartingaleConvergence}^{\uparrow}$ consumer, route the same displayed rows through chapter 2246. The convergence-facing read receives the bounded-window and rational-readback surface already sealed by R and S, not an unrestricted conditional-expectation operator or an ambient completeness theorem.

The carrier has no coordinate for almost-sure quotient equality, countable choice, a host conditional-expectation operator, or external real completeness. Thus the martingale-facing route can export only the displayed finite rows named above. □

$\mathsf{FrechetBaireSpace}^{\uparrow}$ consumes chapter 3495 and chapter 3535 before its route reaches chapter 3570.

Chapter 5176

A Concrete Naming Certificate for $\mathsf{FrechetBaireSpace}^{\uparrow}$

Following Baire and Bourbaki, the $\mathsf{FrechetBaireSpace}^{\uparrow}$ packet records the finite handoff from a complete metrizable locally convex carrier to the complete-metric Baire route. It sits after the $\mathsf{FrechetSpace}^{\uparrow}$ carrier of chapter 3495, the theorem-level dense-open package of chapter 3570, the inspected complete-metric surface of chapter 3535, the topological-vector source of chapter 205, the locally convex source of chapter 3386, and the metric-completion handoff of chapter 1506. In the sibling lattice, the chapter consumes chapter 3495 and chapter 3535 before its route reaches chapter 3570. The packet names only the finite route by which a Frechet-space consumer may receive Baire-category evidence; it does not add Hahn–Banach separation, selected generic points, countable choice, host intersections, or ambient complete locally convex spaces.

Definition 5176.1 (Frechet-space Baire carrier)**.** *A* $\mathsf{FrechetBaireSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, T, U, V, L, Q, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FrechetSpace}^{\uparrow}$ *source row, exposing complete metrizability and local convexity through Definition 3495.1.*
2. *T is the* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *theorem route row, carrying the dense-open theorem surface.*
3. *U is the* $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ *inspection row, carrying the complete-metric Baire surface consumed by T.*
4. *V is the* $\mathsf{TopVecSpace}^{\uparrow}$ *source row inherited from the Frechet carrier.*
5. *L is the* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *source row inherited from the Frechet carrier.*
6. *Q is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row that exposes the compatible complete metric boundary.*
7. *H records componentwise* hsame *transport for F, T, U, V, L, Q and for the replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through the Frechet carrier, Baire theorem route, complete-metric Baire surface, topological-vector source, locally convex source, metric-completion handoff, transport, provenance, and local naming rows.*

9. *P is the* Pkg *provenance over* $\mathsf{FrechetBaireSpace}^{\uparrow}$, $\mathsf{FrechetSpace}^{\uparrow}$, $\mathsf{BaireCategoryTheorem}^{\uparrow}$, CompleteMetricBaireSu $\mathsf{TopVecSpace}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetBaireSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, T, U, V, L, Q, H, C, P, N$. It has no coordinate for a host Frechet space, an external Baire intersection, a selected generic point, Hahn–Banach separation, countable choice, or ambient completeness outside the displayed route.

Theorem 5176.2 (Frechet-space Baire completeness route)**.** *For every accepted* $\mathsf{FrechetBaireSpace}^{\uparrow}$ *carrier $B = (F, T, U, V, L, Q, H, C, P, N)$, the Baire-category read factors through the Frechet source row F, the complete metric row and metric-completion handoff already exposed by Definition 3495.1, the inspected* $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$ *row U, and the theorem-level* $\mathsf{BaireCategoryTheorem}^{\uparrow}$ *row T. The topological-vector and locally convex rows V, L remain visible throughout the route.*

Proof. Project the carrier of Definition 5176.1. The Frechet source row F supplies the displayed complete metrizable locally convex packet, while V, L, Q retain the inherited topological-vector, locally convex, and metric-completion coordinates.

Use the Frechet dependency route of Definition 3495.4. It sends every Baire request through the complete metric row and the metric-completion handoff before the request reaches the Baire surfaces.

The row U supplies the complete-metric Baire inspection surface, and T supplies the theorem-level dense-open package. The structural rows H, C, P, N transport, replay, source, and name only this route, so the listed rows exhaust the completeness-to-Baire handoff. □

Theorem 5176.3 (Frechet-space Baire non-escape)**.** *Every accepted* $\mathsf{FrechetBaireSpace}^{\uparrow}$ *consumer receives Baire-category evidence only through*

$$\mathsf{FrechetSpace}^{\uparrow} \longmapsto \mathsf{CompleteMetricBaireSurface}^{\uparrow} \longmapsto \mathsf{BaireCategoryTheorem}^{\uparrow}$$

together with the displayed $\mathsf{TopVecSpace}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. The carrier exports no Hahn–Banach theorem, no selected generic point, no countable-choice schedule, no host intersection object, no quotient completion equality, and no ambient complete locally convex space.*

Proof. Start with the route theorem. It confines Baire-category evidence to the Frechet source, complete-metric Baire inspection, and theorem-level dense-open rows.

Inspect the carrier coordinates. The rows V, L, Q preserve the topological-vector, locally convex, and metric-completion handoff data already present in the Frechet carrier, while H, C, P, N provide only structural transport, replay, provenance, and naming.

Since none of the coordinates stores Hahn–Banach separation, a selected generic point, countable choice, a host intersection object, quotient completion equality, or an ambient complete locally convex space, no accepted consumer can extract those readings from the packet. □

Theorem 5176.4 (Frechet-space Baire metric-completion forward lattice)**.** *Every accepted* $\mathsf{FrechetBaireSpace}^{\uparrow}$ *consumer routes Baire evidence through the forward lattice*

$$\mathsf{FrechetSpace}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{CompleteMetricBaireSurface}^{\uparrow} \longmapsto \mathsf{BaireCategoryTheorem}^{\uparrow}$$

before exporting a dense-open conclusion. The rows $F, T, U, V, L, Q, H, C, P, N$ must remain visible, with V and L retaining the topological-vector and locally convex sources and Q retaining the metric-completion handoff.

Proof. Project the carrier rows of Definition 5176.1. The Frechet source row F carries the complete metrizable locally convex surface, while V and L keep the inherited topological-vector and locally convex data visible.

Apply the completeness route, Definition 5176.2. It sends the Baire request through the complete metric boundary and the metric-completion handoff Q before the inspected complete-metric Baire surface U and theorem-level row T are read.

Finally use non-escape, Definition 5176.3. Since the dense-open conclusion can be exported only through $F, T, U, V, L, Q, H, C, P, N$, the structural rows H, C, P, N preserve the same forward lattice and cannot replace the metric-completion handoff by an ambient host completion or a selected generic point. □

Falsifiable prediction: Any accepted $\mathsf{FrechetBaireSpace}^{\uparrow}$ consumer that reads Baire-category evidence without first exposing $F, T, U, V, L, Q, H, C, P, N$ refutes the carrier surface of Definition 5176.1.

Independence witness: frechet-space, baire-category-theorem, complete-metric-baire-surface, topvecspace, locally-convex-space, metriccompletion: no listed sibling is bijective to $\mathsf{FrechetBaireSpace}^{\uparrow}$, because this packet alone binds the Frechet source, complete-metric Baire inspection, theorem-level dense-open route, topological-vector row, locally convex row, metric-completion handoff, transport, replay, provenance, and local NameCert rows into one finite handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetBaireSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{FrechetBaireSpace}^{\uparrow}$ packet is generated from a FrechetSpace source row, a BaireCategoryTheorem route row, a CompleteMetricBaireSurface inspection row, TopVecSpace and LocallyConvexSpace source rows, a MetricCompletion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FrechetBaireSpace}^{\uparrow}}$, seed)

Scope closed: Definition 5176.1, Definition 5176.2, Definition 5176.3, and Definition 5176.4 seed the finite Frechet-to-Baire handoff over $F, T, U, V, L, Q, H, C, P, N$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FrechetBaireSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Hahn–Banach separation, selected generic points, countable choice, host intersections, quotient completion equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Frechet source exposure, complete-metric Baire inspection, theorem-level dense-open routing, inherited topological-vector and locally convex rows, metric-completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.FrechetBaireSpaceUp.

Chapter 5177

A Concrete Naming Certificate for $\mathsf{ChannelGeneticCodeBridge}^{\uparrow}$

Following Crick, Watson, and the standard genetic-code table, the $\mathsf{ChannelGeneticCodeBridge}^{\uparrow}$ packet records the finite bridge from decoded BEDC channel event flows to the biological four-base and codon-reading analogy of subsection 9462.28.16. It sits after the $\mathsf{Bool}^{\uparrow}$ endpoint discipline of chapter 32, the $\mathsf{Prod}^{\uparrow}$ finite product surface of chapter 34, the DNA four-phase template of Definition 9462.1067, the codon atlas of Definition 9462.1072, the genetic translation classifier of Definition 9462.1074, and the stop-role bridge of Definition 9462.1079. Its codon-atlas and translation-classifier rows are downstream-compatible with the finite codon-window row of chapter 2234 and the stop-boundary transition row of chapter 2245. The packet names a conservative scientific-model carrier; it does not identify channel glyphs with DNA bases, codons, biochemical laws, or theorem judgments.

Definition 5177.1 (Channel/genetic-code bridge carrier)**.** *A* $\mathsf{ChannelGeneticCodeBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, B, P, A, T, S, L, H, C, R, N)$$

with the following displayed rows:

1. *D is the decoded channel event-flow row, enforcing the decode-first boundary before any biological reading is attempted.*
2. *B is the* $\mathsf{Bool}^{\uparrow}$ *endpoint row used twice by the DNA four-phase product.*
3. *P is the* $\mathsf{Prod}^{\uparrow}$ *product row that displays the two Boolean axes of the DNA four-phase alphabet.*
4. *A is the DNA four-phase atlas row, reading the four product phases as external biological bases.*
5. *T is the codon atlas row, displaying the triple product of DNA four-phase rows and its* 64 *phase positions.*
6. *S is the genetic translation classifier row, separating amino-acid-emitting classes from stop classes while retaining the original codon ledger.*
7. *L is the stop-role and cannot-claim ledger, separating channel event termination from biological translation termination and refusing token identity.*
8. *H records componentwise* hsame *transport for D, B, P, A, T, S, L and for the replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay through decoded channel data, Boolean endpoints, product phases, DNA atlas rows, codon triples, translation classification, stop-role refusal, transport, provenance, and local naming.*

10. *R is the* Pkg *provenance over* $\mathsf{ChannelGeneticCodeBridge}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, *the finite codon-window rows of chapter 2234, the stop-boundary transition rows of chapter 2245,* BHist, hsame, Cont, Pkg, NameCert, *and the originating vision route of subsection 9462.28.16. These siblings provide finite codon-window and stop-boundary transition rows only; this chapter still refuses biochemical identity and theorem evidence.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ChannelGeneticCodeBridge}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, B, P, A, T, S, L, H, C, R, N$. It has no coordinate for raw channel-token identity, DNA base identity, RNA codon identity, biochemical law, protein synthesis proof, or theorem evidence.

Theorem 5177.2 (Channel/genetic-code bridge NameCert obligations)**.** *For every accepted* ChannelGeneticCodeBr *carrier $G = (D, B, P, A, T, S, L, H, C, R, N)$, the local* $\mathsf{NameCert}_{\mathsf{ChannelGeneticCodeBridge}^{\uparrow}}$ *surface consists exactly of decoded-channel exposure through D, Boolean endpoint exposure through B, product-phase exposure through P, DNA four-phase atlas exposure through A, codon-atlas exposure through T, translation-classifier exposure through S, stop-role and cannot-claim refusal through L, componentwise transport through H, displayed replay through C, provenance through R, and local naming through N.*

Proof. Project the carrier of Definition 5177.1. The source-facing row is D, the finite phase rows are B, P, A, T, the classifier row is S, and the refusal row is L.

The decode-first row D is consumed before any biological interpretation. Thus a channel substring is not read as a base or codon until it has been decoded to event-flow data.

The finite alphabet route then passes through B and P. The two $\mathsf{Bool}^{\uparrow}$ axes are displayed by the $\mathsf{Prod}^{\uparrow}$ row before the external DNA four-phase atlas A and codon triple atlas T are read.

The translation classifier S may compress distinct codon positions to the same amino-acid or stop class, but it retains the codon ledger. Finally L, H, C, R, N refuse token identity and transport, replay, source, and name only the displayed route. No further NameCert obligation is stored outside these rows. □

Theorem 5177.3 (Channel/genetic-code stop-role non-escape)**.** *Every accepted* $\mathsf{ChannelGeneticCodeBridge}^{\uparrow}$ *consumer may compare the channel terminator role with the biological stop-codon role only through the stop-role ledger L after the decoded channel row, DNA four-phase product row, codon atlas row, and translation classifier row have been displayed. The carrier exports no claim that* 11 *is a DNA or RNA stop codon, no claim that a channel glyph is a biological base, no direct read from compiled channel substrings to codons, and no biological theorem evidence.*

Proof. Start from the NameCert obligations. They force the route through $D, B, P, A, T, S, L, H, C, R, N$ before any accepted bridge read is exported.

The channel side and biological side have distinct typing roles. The row D supplies decoded event-flow data, while A, T, S supply external biological readbacks through product phases, codon triples, and translation classes.

The ledger L is therefore a refusal boundary. It permits role analogy between finite stopping processes, but it blocks token identity between the channel terminator and biological stop codons, direct channel-substring-to-base reads, and any conversion of biological analogy into theorem evidence. □

Falsifiable prediction: Any accepted $\mathsf{ChannelGeneticCodeBridge}^{\uparrow}$ consumer that treats a raw channel substring as a DNA base, RNA codon, stop codon, biochemical law, or theorem judgment without first reading $D, B, P, A, T, S, L, H, C, R, N$ refutes the carrier surface of Definition 5177.1.

Independence witness: bool, prod, channel-genetic-code vision: no listed sibling is bijective to $\mathsf{ChannelGeneticCodeBridge}^{\uparrow}$, because this packet alone binds decoded channel data, Boolean product phases, DNA four-phase readback, codon atlas rows, translation classification, stop-role refusal, transport, replay, provenance, and local NameCert rows into one conservative biological bridge.

Closure status for $\mathsf{NameCert}_{\mathsf{ChannelGeneticCodeBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{ChannelGeneticCodeBridge}^{\uparrow}$ packet is generated from a decoded channel event-flow row, Bool endpoint rows, a Prod product-phase row, a DNA four-phase atlas, a codon triple atlas, a genetic translation classifier, a stop-role refusal ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChannelGeneticCodeBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5177.1, Definition 5177.2, and Definition 5177.3 seed the finite conservative bridge over $D, B, P, A, T, S, L, H, C, R, N$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChannelGeneticCodeBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not identify channel glyphs with DNA bases, RNA codons, biological stop codons, biochemical laws, protein synthesis proof, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked decoded-channel exposure, Boolean endpoint exposure, product-phase exposure, DNA four-phase atlas exposure, codon-atlas exposure, translation-classifier exposure, stop-role refusal, transport, replay, provenance, and local naming for BEDC.Derived.ChannelGeneticCodeBridgeUp.

Lemma 5177.4 (Channel/genetic-code finite endpoint dependency route)**.** *Every accepted* ChannelGeneticCodeBric *read exposes the* $\mathsf{Bool}^{\uparrow}$ *endpoint row and the* $\mathsf{Prod}^{\uparrow}$ *phase row before any DNA four-phase atlas row or codon atlas row is consumed. The dependency route is the finite endpoint surface of chapter 32 followed by the product-phase surface of chapter 34; only after those two rows are visible may the bridge read DNA four-phase or codon atlas data. Termination-role reads also pass through chapter 5967 before the stop-role bridge compares channel termination with codon stop roles. The codon stop-face read also factors through chapter 8421, so the bridge compares channel termination with biological stop classes only after the finite codon-window classifier has exposed the stop face.*

Theorem 5177.5 (Channel/genetic-code codon stop sibling route)**.** *Every stop-role read consumed by an accepted* $\mathsf{ChannelGeneticCodeBridge}^{\uparrow}$ *packet factors first through the channel termination budget certificate of chapter 5967 and the codon-window stop-face classifier of chapter 8421. Only after those two sibling routes are displayed may the bridge compare channel termination with biological stop-role analogy. The route exports no token identity between channel events and codons, no direct biological stop-codon theorem, and no MetaCIC proof object.*

Proof. Project the bridge carrier of Definition 5177.1. The decoded channel row D and stop-role ledger L are the only rows from which a stop-role comparison can be read.

The channel side is read first through chapter 5967. That sibling supplies the finite termination-budget certificate before the bridge may describe a channel event as termination-facing.

The codon side is then read through chapter 8421. That sibling supplies the finite codon-window stop-face classifier before the biological stop-role analogy is consumed.

Finally the bridge replays the same route through its structural rows. Since the packet has no coordinate for channel-codon token identity, biological stop-codon proof, or MetaCIC theorem evidence, the sibling route remains a dependency boundary rather than a theorem transfer. □

Lemma 5177.6 (Channel/genetic-code bioreality forward lattice route)**.** *Every accepted* ChannelGeneticCodeBridge *read that is consumed by a biological-reality or MetaCIC-facing route factors through the finite endpoint dependency route of Definition 5177.4, the codon stop sibling route of Definition 5177.5, and the MetaCIC forward link of Definition 5177.7. Thus the bridge can cite chapter 8421 and chapter 5547 only after the decoded channel row, Bool endpoint row, Prod phase row, codon-window stop face, stop-role ledger, transport, replay, provenance, and local NameCert rows are displayed; it exports no direct channel-token identity, biological theorem, confluence theorem, normalization theorem, or subject-reduction theorem.*

Theorem 5177.7 (Channel/genetic-code bridge MetaCIC forward link)**.** *Any MetaCIC or channel-frontier consumer of an accepted* $\mathsf{ChannelGeneticCodeBridge}^{\uparrow}$ *packet must first read the decoded channel row D, the* $\mathsf{Bool}^{\uparrow}$ *endpoint row B, the* $\mathsf{Prod}^{\uparrow}$ *phase row P, the stop-role ledger L, and the finite endpoint dependency route of Definition 5177.4. Only after those rows are displayed may the consumer use biological analogy as a route annotation for a MetaCIC-facing handoff such as chapter 5547. The link is a dependency route over finite channel data and frontier bookkeeping; it is not a biological theorem, not a channel-token identity claim, and not a confluence, normalization, or subject-reduction proof.*

Proof. Read the carrier rows of Definition 5177.1. The decoded channel row D supplies the event-flow source, B and P expose the Boolean endpoint and product phase boundaries, and L records the stop-role refusal boundary.

Next apply the finite endpoint dependency route. It forces endpoint and product-phase exposure before any DNA four-phase, codon-atlas, or stop-face read is consumed, so the biological vocabulary remains downstream of the displayed finite channel route.

A MetaCIC consumer may therefore cite the packet only as routed frontier annotation. The target consumer keeps its own typed-window, confluence, normalization, or obstruction rows, while $\mathsf{ChannelGeneticCodeBridge}^{\uparrow}$ contributes only D, B, P, L and the finite endpoint route. □

Theorem 5177.8 (Channel/genetic-code bridge MetaCIC forward route)**.** *Every MetaCIC-facing read of an accepted* $\mathsf{ChannelGeneticCodeBridge}^{\uparrow}$ *packet passes through the displayed codon-stop, endpoint, bioreality, and MetaCIC rows before the read may cite chapter 5547. Concretely, the route first exposes the finite endpoint dependency of Definition 5177.4, then the codon-window stop sibling route of Definition 5177.5, then the MetaCIC forward link of Definition 5177.7, and finally the bioreality forward lattice route of Definition 5177.6. The exported read is only a routed frontier annotation over $D, B, P, A, T, S, L, H, C, R, N$; it exports no channel-token identity, biological theorem, confluence theorem, normalization theorem, subject-reduction theorem, or MetaCIC proof object.*

Proof. Start with the carrier of Definition 5177.1. The decoded channel row D, endpoint row B, product row P, codon atlas row T, classifier row S, and stop-role ledger L are visible before any biological or MetaCIC-facing read is available.

Apply the finite endpoint dependency route and the codon-window sibling route. These force the endpoint and product rows to precede the codon-stop comparison, so a stop-role read remains tied to the displayed channel termination budget and codon-window stop-face classifier.

Next apply the MetaCIC forward link. It allows a MetaCIC consumer to cite the packet only as a frontier annotation after D, B, P, L and the finite endpoint route have been displayed.

Finally use the bioreality forward lattice route. It composes the codon-stop and MetaCIC rows with the biological-reality route while preserving the same transport, replay, provenance, and local naming rows. Since no carrier coordinate stores a biological theorem, channel-token identity,

confluence, normalization, subject reduction, or proof object, the read remains a finite horizontal lattice edge into the MetaCIC candidate-normalization confluence handoff. □

Chapter 5178

A Concrete Naming Certificate for $\mathsf{FejerTheorem}^{\uparrow}$

Following Fejer, Zygmund, and Katznelson on positive summability of Fourier series, the $\mathsf{FejerTheorem}^{\uparrow}$ packet records the theorem-level handoff from finite Fourier coefficient windows and positive Fejer kernels to a uniform approximation read. It sits over the Fourier coefficient surface of chapter 124, the positive kernel certificate of chapter 1939, the circle phase source of chapter 58, the normalization route of chapter 123, and the approximation-facing boundary of chapter 463. The chapter names a finite summability theorem certificate; it does not import Haar measure, a host L^1 space, quotient equality of functions, selected Fourier representatives, pointwise convergence, or ambient compactness.

Definition 5178.1 (Fejer theorem carrier)**.** *A* $\mathsf{FejerTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, K, S, I, U, A, L, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Fourier}^{\uparrow}$ *coefficient-window row, listing the finite symmetric coefficient requests and the polynomial window consumed by the summability read.*
2. *K is the* $\mathsf{FejerKernel}^{\uparrow}$ *positivity and triangular-weight row, including the kernel normalization and finite averaging comparison exposed by the sibling kernel certificate.*
3. *S is the* $\mathsf{S}^{1\uparrow}$ *phase-sample row, recording the circle points on which the finite averages are inspected.*
4. *I is the* $\mathsf{Integral}^{\uparrow}$ *normalization row, exposing only the finite integral cells needed to read the averaged trigonometric polynomial.*
5. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row, recording the tolerance, tail, and uniform-read boundary produced by the positive kernel averages.*
6. *A is the theorem assertion row, pairing the displayed Fourier window with the positive-kernel average before any approximation consumer reads the conclusion.*
7. *L is the non-escape ledger for Haar measure, host L^1 theory, quotient function equality, selected representatives, pointwise convergence, and ambient compactness.*
8. *H records componentwise* hsame *transport for $F, K, S, I, U, A, L, C, P, N$.*

9. *C records displayed* Cont *replay from a Fejer-summability request through F, K, S, I, U, A, L, H.*
10. *P is the* Pkg *provenance over* $\mathsf{FejerTheorem}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{FejerKernel}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FejerTheorem}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose visible rows are $F, K, S, I, U, A, L, H, C, P, N$. It has no coordinate for an unbounded Fourier series, host measure theory, quotient equality of functions, selected representatives, or a convergence theorem outside the displayed positive-kernel handoff.

Lean4 ✓ `BEDC.Derived.FejerTheoremUp.FejerTheoremTasteGate single carrier alignment`

Theorem 5178.2 (Fejer theorem NameCert obligations)**.** *For every accepted* $\mathsf{FejerTheorem}^{\uparrow}$ *carrier*

$$T = (F, K, S, I, U, A, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FejerTheorem}^{\uparrow}}$ *surface consists exactly of Fourier coefficient-window admission through F, positive Fejer-kernel admission through K, circle phase-sample exposure through S, integral normalization through I, uniform-limit handoff through U, theorem assertion exposure through A, non-escape ledger coverage through L, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5178.1. The rows F, K, S, I display the coefficient window, positive kernel, phase samples, and normalization data before the theorem assertion is available.

The theorem-facing rows are U, A, L. The uniform-limit row records the approximation boundary, the assertion row binds the Fourier window to the positive-kernel average, and the ledger row states the excluded host readings.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for Haar measure, host L^1 theory, quotient function equality, selected representatives, pointwise convergence, or ambient compactness, the listed rows exhaust the local NameCert surface. □

Theorem 5178.3 (Positive-kernel uniform handoff)**.** *Every approximation consumer of an accepted* $\mathsf{FejerTheorem}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{Fourier}^{\uparrow} \longmapsto \mathsf{FejerKernel}^{\uparrow} \longmapsto \mathsf{S}^{1\uparrow} \longmapsto \mathsf{Integral}^{\uparrow} \longmapsto \mathsf{UniformLimit}^{\uparrow}.$$

The positive-kernel row supplies only the finite triangular averaging and normalization data named by $\mathsf{FejerKernel}^{\uparrow}$*, and the theorem row exports only the uniform handoff U together with A, L, H, C, P, N. Thus the packet supplies a BEDC-native Fejer summability certificate without exporting Haar measure, host L^1 spaces, quotient function equality, selected representatives, pointwise convergence, or ambient compactness.*

Proof. Begin with an approximation request. The carrier first exposes F and K, so the request sees a finite Fourier coefficient window and a positive Fejer kernel row rather than an infinite Fourier series or host convolution object.

The request next reads S and I. These rows bind the averaging read to displayed circle phases and finite integral normalization cells.

Only then can the request inspect U and A. The uniform-limit handoff records the approximation boundary, while the theorem assertion row states that the positive-kernel average is the route by which the Fourier window is consumed.

Finally L, H, C, P, N block excluded host readings and replay the same finite packet. No listed consumer can bypass the positive-kernel route or turn it into Haar measure, quotient function equality, selected representatives, pointwise convergence, or ambient compactness. □

Falsifiable prediction: An accepted $\mathsf{FejerTheorem}^{\uparrow}$ packet is refuted if a Fourier approximation consumer reaches the $\mathsf{UniformLimit}^{\uparrow}$ handoff while bypassing the displayed $\mathsf{FejerKernel}^{\uparrow}$ positivity row, $\mathsf{S}^{1\uparrow}$ phase samples, or $\mathsf{Integral}^{\uparrow}$ normalization row.

Independence witness: fourier, fejer-kernel, sone, integral, uniformlimit: none is bijective to $\mathsf{FejerTheorem}^{\uparrow}$ because the packet jointly carries coefficient windows, positive triangular kernel data, circle phase samples, integral normalization, a uniform theorem handoff, a non-escape ledger, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FejerTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{FejerTheorem}^{\uparrow}$ packet is generated from FourierUp coefficient windows, FejerKernelUp positivity and triangular averaging rows, SOneUp phase samples, IntegralUp normalization rows, a UniformLimitUp theorem handoff, a non-escape ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FejerTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5178.1, Definition 5178.2, and Definition 5178.3 seed the finite theorem-level Fejer summability route over Fourier, positive-kernel, circle, integral, and uniform-limit rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FejerTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, Haar measure, host L^1 theory, quotient function equality, selected Fourier representatives, pointwise convergence, or ambient compactness.

Upgrade path: Obligation closure requires checked coefficient-window admission, positive-kernel admission, phase-sample exposure, integral normalization, uniform-limit handoff, theorem assertion exposure, ledger coverage, transport, replay, provenance, and local naming for BEDC.Derived.FejerTheoremUp.

Chapter 5179

A Concrete Naming Certificate for RegularCauchyTailEquivalence$^{\uparrow}$

Following Bishop–Bridges constructive Cauchy real analysis, the RegularCauchyTailEquivalence$^{\uparrow}$ packet records the equality-facing tail classifier by which two regular rational Cauchy names reach the Real$^{\uparrow}$ seal. It sits between the finite observation windows of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, the setoid comparison surface of chapter 1820, and the terminal real-name boundary of chapter 38. The packet names the finite L10 Real and Completion handoff; it is not quotient stream equality, a selected limit, countable choice, host real equality, or ambient completeness of Real$^{\uparrow}$.

Definition 5179.1 (Regular Cauchy tail equivalence carrier)**.** *A* RegularCauchyTailEquivalence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S_0, S_1, R_0, R_1, D, Q, A, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* StreamName$^{\uparrow}$ *finite-window rows through which the source names are inspected.*
2. R_0 *and* R_1 *are the corresponding* RegSeqRat$^{\uparrow}$ *readback rows exposed by those windows.*
3. D *is the* DyadicRatCore$^{\uparrow}$ *tail-tolerance ledger, recording the requested precision, the two regular radii, the common-tail threshold, and the remaining comparison slack.*
4. Q *is the* CauchyEquivalenceSetoid$^{\uparrow}$ *comparison row tying the two readbacks to the finite reflexive, symmetric, and transitive classifier surface.*
5. A *is the* Real$^{\uparrow}$ *seal row reached only after the two windows, two readbacks, tolerance ledger, and setoid comparison have been displayed.*
6. H *records componentwise* hsame *transport for windows, readbacks, tolerance ledger, setoid comparison, Real seal, replay, provenance, and local naming.*
7. C *records displayed* Cont *replay from an equality-facing Real or Completion request through* $S_0, S_1, R_0, R_1, D, Q, A, H, P, N$.
8. P *is the* Pkg *provenance over* RegularCauchyTailEquivalence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyEquivalenceSetoid$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailEquivalence}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S_0, S_1, R_0, R_1, D, Q, A, H, C, P, N$. It has no coordinate for quotient classes, selected limits, countable choice, trichotomy, host real equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyTailEquivalenceUp.RegularCauchyTailEquivalenceTasteGate`
`single carrier alignment`

Theorem 5179.2 (Regular Cauchy tail equivalence NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailEquivalence}^{\uparrow}$ *carrier*

$$E = (S_0, S_1, R_0, R_1, D, Q, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailEquivalence}^{\uparrow}}$ *surface consists exactly of two* $\mathsf{StreamName}^{\uparrow}$ *window admissions, two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail-tolerance ledger, one* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison row, one* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 5179.1. The accepted tuple exposes exactly the two window rows, two regular readbacks, dyadic tolerance ledger, setoid comparison, Real seal, transport, replay, provenance, and naming rows.

The source side is exhausted by S_0, S_1, R_0, R_1. Every equality-facing request must inspect the finite windows and the corresponding regular rational readbacks before any tail comparison is available.

The comparison side is exhausted by D and Q. The dyadic ledger stores the precision, radii, common-tail threshold, and slack, while the setoid row records the finite classifier comparison over the displayed readbacks.

The endpoint side is exhausted by A, H, C, P, N. These rows seal the comparison for $\mathsf{Real}^{\uparrow}$, transport it componentwise, replay the route, source it, and name it locally. Since the carrier contains no quotient, selected limit, choice, trichotomy, host equality, or completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5179.3 (Regular Cauchy tail equivalence Real handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RegularCauchyTailEquivalence}^{\uparrow}$ *packet must read the finite route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto Q \longmapsto A$$

before it may consume equality at the $\mathsf{Real}^{\uparrow}$ *seal. Thus equality is exported only as a tail-tolerance classifier between displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, not as quotient stream equality or selected-limit equality.*

Proof. Begin with a Real or Completion equality request. By Definition 5179.1, the request first reaches the two finite window rows S_0, S_1 and their readbacks R_0, R_1.

The dyadic ledger D is then the only tolerance source. It records the common-tail threshold and the remaining slack before the setoid comparison row Q can be read.

Only downstream of Q does the seal row A become visible. The structural rows H, C, P, N preserve this route and add no host equality coordinate.

Therefore a Real or Completion consumer receives the displayed finite classifier route and nothing stronger. Quotient stream equality, selected limits, countable choice, trichotomy, host real equality, and ambient completeness remain outside the packet. □

Theorem 5179.4 (Regular Cauchy tail equivalence composition)**.** *Suppose accepted* $\mathsf{RegularCauchyTailEquivalence}^{\uparrow}$ *packets witness tail equivalence from A to B and from B to C with compatible* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers,* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *comparison rows, and* $\mathsf{Real}^{\uparrow}$ *seal rows. Then every Real or Completion consumer of the composed A-to-C comparison factors through the two displayed finite routes*

$$A \longmapsto B \qquad \textit{and} \qquad B \longmapsto C$$

before it may read the endpoint seal. The composed read exposes no quotient stream equality, selected limit, countable choice, trichotomy, host real equality, or ambient Real completeness.

Proof. Project the two accepted carriers of Definition 5179.1. The first packet displays its source and middle windows, readbacks, dyadic tolerance ledger, setoid comparison, Real seal, transport, replay, provenance, and local naming rows; the second packet displays the same inventory for the middle and target rows.

Apply the Real handoff of Definition 5179.3 to the first packet and then to the second. Compatibility of the middle $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback lets the second handoff read the shared middle row only through the displayed finite carrier data.

Now concatenate the componentwise hsame transports and the displayed Cont routes. The setoid comparison rows supply the only comparison surface, while the dyadic ledgers keep the tolerance accounting visible on both sides of the middle readback.

The endpoint consumer therefore receives an A-to-C route only through the two displayed packets. Since neither carrier has a coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient Real completeness, the composed comparison exports none of those endpoints. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyTailEquivalence}^{\uparrow}$ read displays two $\mathsf{StreamName}^{\uparrow}$ windows, two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, one $\mathsf{DyadicRatCore}^{\uparrow}$ tail-tolerance ledger, one $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ comparison row, one $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before Real or Completion equality is consumed.

Independence witness: streamname, regseqrat, dyadicratcore, cauchy-equivalence-setoid, real: $\mathsf{RegularCauchyTailEquivalence}^{\uparrow}$ is not bijective to any listed sibling because it binds two window rows, two regular readbacks, one tail-tolerance ledger, one setoid comparison row, one Real seal, componentwise transport, replay, provenance, and local naming into a single L10 equality-facing carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailEquivalence}^{\uparrow}$ packet is generated from two StreamName windows, two RegSeqRat readbacks, one DyadicRatCore tail-tolerance ledger, one CauchyEquivalenceSetoid comparison row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5179.1, Definition 5179.2, and Definition 5179.3 seed the finite L10 Real and Completion tail-equivalence classifier between RegSeqRat readbacks and Real equality.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked window admission, regular readback, dyadic tolerance accounting, setoid comparison, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailEquivalenceUp.

Chapter 5180

A Concrete Naming Certificate for HyperbolicObserverShell$^{\uparrow}$

The HyperbolicObserverShell$^{\uparrow}$ packet realizes the boundary-shell reading of chapter 9463 as one finite NameCert surface. It binds the boundary-shadow carrier of chapter 3813, the visual-boundary carrier of chapter 4181, the observer-expansion carrier of chapter 4167, the Busemann-boundary route of chapter 3732, and the metric readback of chapter 3474. The packet names only a finite observer-facing shell over displayed boundary rows; it is not a completed ideal boundary, a physical observer law, a global hyperbolic space, or a cosmological field model.

Definition 5180.1 (Hyperbolic observer shell carrier)**.** *A* HyperbolicObserverShell$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (B, V, E, U, M, T, F, H, C, P, N)$$

with the following displayed rows:

1. *B is the* HyperbolicBoundaryShadow$^{\uparrow}$ *row that supplies the visible boundary-shadow face.*
2. *V is the* HyperbolicVisualBoundary$^{\uparrow}$ *row that reads the shadow as a visual boundary datum.*
3. *E is the* HyperbolicObserverExpansion$^{\uparrow}$ *row that records the focused observer-expansion route carried by the shell.*
4. *U is the* HyperbolicBusemannBoundary$^{\uparrow}$ *row attaching the shell to Busemann-style boundary comparison.*
5. *M is the* HyperbolicMetric$^{\uparrow}$ *readback row used by the shell when boundary shadows are compared.*
6. *T is the shell-coherence row, requiring the boundary-shadow, visual-boundary, observer-expansion, Busemann, and metric rows to refer to the same displayed finite source surface.*
7. *F is the TasteGate-facing row for this AI-origin packet: the Lean development in* `TasteGate.lean` *must provide* Nontrivial HyperbolicObserverShell$^{\uparrow}$ *and* FieldFaithful HyperbolicObserverShell$^{\uparrow}$ *instances preserving $B, V, E, U, M, T, H, C, P, N$ as distinct fields.*
8. *H records componentwise* hsame *transport for boundary shadow, visual boundary, observer expansion, Busemann row, metric readback, shell coherence, TasteGate-facing row, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a shell request through $B, V, E, U, M, T, F, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicObserverShell}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverShell}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, V, E, U, M, T, F, H, C, P, N$. It has no coordinate for completed ideal-boundary equality, physical observer dynamics, global hyperbolic geometry, a host compactification, or unlogged cosmological expansion.

Theorem 5180.2 (Hyperbolic observer shell NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicObserverShell}^{\uparrow}$ *carrier*

$$O = (B, V, E, U, M, T, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicObserverShell}^{\uparrow}}$ *surface consists exactly of boundary-shadow admission, visual-boundary admission, observer-expansion admission, Busemann-boundary attachment, hyperbolic-metric readback, shell-coherence checking, TasteGate-facing nontriviality and field-faithfulness requirements, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 5180.1. The rows $B, V, E, U, M, T, F, H, C, P, N$ are the entire public packet.

The boundary side is carried by B, V, U, M. Boundary shadow is read first, visual boundary and Busemann data attach the boundary interpretation, and the metric row supplies the displayed comparison surface.

The observer side is carried by E and T. The observer-expansion row records the focused route, while the shell-coherence row requires that route to remain tied to the same displayed boundary and metric surface.

The AI-origin gate is carried by F. It records the obligation that the Lean `TasteGate.lean` development provide Nontrivial and FieldFaithful instances for the same field list rather than for a collapsed shadow token.

Finally H, C, P, N transport, replay, source, and name this finite route. Since no further coordinate is present, the certificate exports no completed ideal boundary, physical observer law, global hyperbolic geometry, host compactification, or unlogged cosmological expansion. □

Theorem 5180.3 (Hyperbolic observer shell boundary handoff)**.** *Every accepted* $\mathsf{HyperbolicObserverShell}^{\uparrow}$ *read factors through*

$$\mathsf{HyperbolicBoundaryShadow}^{\uparrow},\ \mathsf{HyperbolicVisualBoundary}^{\uparrow},\ \mathsf{HyperbolicObserverExpansion}^{\uparrow},\ \mathsf{HyperbolicBusemannBoun}$$

before it can be consumed as an observer-facing boundary shell. The handoff preserves the displayed shell-coherence row and the TasteGate-facing field-faithfulness requirement.

Proof. Start with an accepted shell read. By the carrier definition, the read first displays B, V, E, U, M and cannot reach shell coherence without those rows.

The coherence row T then binds the boundary-shadow, visual-boundary, observer-expansion, Busemann, and metric data to one source surface. This prevents a consumer from mixing a boundary shadow from one packet with an observer-expansion row from another.

The TasteGate-facing row F keeps the AI-origin shell readable as a field-faithful carrier. The required Nontrivial and FieldFaithful instances must preserve the named rows rather than collapse them into an unstructured boundary token.

Transport, replay, provenance, and naming through H, C, P, N preserve the same route. The accepted handoff is therefore finite and cannot export completed boundary equality, physical dynamics, global geometry, host compactification, or unlogged cosmological expansion. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicObserverShell}^{\uparrow}$ read is refuted if a consumer obtains an observer-facing boundary shell without displaying $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, shell coherence, TasteGate-facing nontriviality and field-faithfulness requirements, componentwise transport, replay, provenance, and local naming rows.

Independence witness: hyperbolic-visual-boundary, hyperbolic-observer-expansion, hyperbolic-busemann-boundary, hyperbolic-metric: the visual-boundary packet reads boundary data without owning the observer-expansion route, the observer-expansion packet records focused shadow growth without the complete visual-boundary shell, the Busemann packet supplies boundary comparison without shell coherence, and the metric packet supplies readback without observer-facing boundary packaging. None is bijective to $\mathsf{HyperbolicObserverShell}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicObserverShell}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicObserverShell}^{\uparrow}$ packet is generated from HyperbolicBoundaryShadow rows, HyperbolicVisualBoundary rows, HyperbolicObserverExpansion rows, HyperbolicBusemannBoundary rows, HyperbolicMetric rows, shell coherence, TasteGate-facing field obligations, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverShell}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5180.1, Definition 5180.2, and Definition 5180.3 seed the finite boundary-shadow, visual-boundary, and observer-expansion shell surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverShell}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed ideal-boundary equality, physical observer dynamics, global hyperbolic geometry, host compactification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked boundary-shadow admission, visual-boundary admission, observer-expansion admission, Busemann attachment, metric readback, shell coherence, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicObserverShellUp.

Chapter 5181

A Concrete Naming Certificate for $\mathsf{DiracPointMass}^{\uparrow}$

Following Dirac and Kolmogorov, the $\mathsf{DiracPointMass}^{\uparrow}$ packet records the standard point-mass probability measure as finite BEDC NameCert data. It sits over the measurable carrier of chapter 92, the probability-space surface of chapter 184, the measurable-read discipline of chapter 185, the distribution handoff of chapter 186, and the terminal scalar readback of chapter 38. The packet names the singleton mass route only; it does not select a host measure, import a powerset sigma algebra, choose representatives, or assert ambient real completeness.

Definition 5181.1 (Dirac point-mass carrier)**.** *A* $\mathsf{DiracPointMass}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, p, E, U, D, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Measure}^{\uparrow}/\mathsf{ProbSpace}^{\uparrow}$ *carrier row, including the displayed measurable universe and probability-space admission data.*
2. *p is the point row, naming the selected support point only as a finite BEDC datum internal to the packet.*
3. *E is the event row, recording the finite event-membership read that decides whether the displayed event contains p.*
4. *U is the unit-mass ledger, assigning the* $\mathsf{Real}^{\uparrow}$ *value* 1 *to events whose displayed membership row contains p and* 0 *otherwise.*
5. *D is the* $\mathsf{Distribution}^{\uparrow}$ *and pushforward readback row, exposing how a* $\mathsf{RandomVar}^{\uparrow}$ *consumer reads the point mass through the image of p.*
6. *H records componentwise* hsame *transport for the measure source, point, event, unit ledger, distribution readback, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an event request through X, p, E, U, D and then to the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{DiracPointMass}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DiracPointMass}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host measure selector, powerset event oracle, quotient representative, countable-choice schedule, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.DiracPointMassUp.DiracPointMassTasteGate single carrier alignment`

Theorem 5181.2 (Dirac point-mass NameCert obligations)**.** *For every accepted* $\mathsf{DiracPointMass}^{\uparrow}$ *carrier* $Q = (X, p, E, U, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DiracPointMass}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission, requiring the displayed* $\mathsf{Measure}^{\uparrow}$ *and* $\mathsf{ProbSpace}^{\uparrow}$ *source row* X *before any event read is public;*
2. *point-event exactness, requiring the event row* E *to expose whether the displayed event contains the point row* p*;*
3. *unit-mass ledger stability, requiring* U *to preserve the* $0/1$ $\mathsf{Real}^{\uparrow}$ *readback under componentwise* hsame *transport and displayed replay;*
4. *distribution handoff, requiring every* $\mathsf{RandomVar}^{\uparrow}$ *and* $\mathsf{Distribution}^{\uparrow}$ *consumer to read the image of* p *through* D *after* X, p, E, U *are displayed;*
5. *non-escape from host measure choice, requiring* H, C, P, N *to name only the displayed packet and to export no host measure selector, powerset event oracle, quotient representative, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

No local point-mass obligation is stored outside $X, p, E, U, D, H, C, P, N$*.*

Lean4 ✓ `BEDC.Derived.DiracPointMassUp.DiracPointMassCarrier namecert obligations`

Proof. Project the carrier of Definition 5181.1. The source row X admits the measure and probability-space surface, while the point row p and event row E are the only rows that can decide membership in the displayed event.

The unit ledger U is then forced by the point-event read. If E displays membership of p, the ledger reads the terminal $\mathsf{Real}^{\uparrow}$ unit value; otherwise it reads the terminal zero value. Componentwise transport through H and replay through C preserve the same event decision and the same scalar readback.

For a random-variable or distribution consumer, the row D is downstream of the same point and event data. It records the pushforward read only through the image of the displayed point, so the distribution handoff cannot bypass the finite point-mass ledger.

Finally P and N source and name precisely this packet. Since no row stores a host measure selector, powerset event oracle, quotient representative, selected limit, or ambient real-completeness principle, the five listed obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{DiracPointMass}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DiracPointMass}^{\uparrow}$ packet is generated from a displayed MeasureUp and ProbSpaceUp source, a point row, an event-membership row, a unit-mass RealUp ledger, a RandomVarUp and DistributionUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DiracPointMass}^{\uparrow}}$, seed)

Scope closed: Definition 5181.1 and Definition 5181.2 seed the finite point-mass packet over MeasureUp, ProbSpaceUp, RandomVarUp, DistributionUp, and RealUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DiracPointMass}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host measure selection, powerset sigma-algebra generation, quotient representatives, countable choice, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, point-event exactness, unit-mass ledger stability, distribution handoff, transport, replay, provenance, and local naming for BEDC.Derived.DiracPointMassUp.

Chapter 5182

A Concrete Naming Certificate for $\mathsf{DiracSequence}^{\uparrow}$

Following Dirac, Schwartz, and Bishop–Bridges, the $\mathsf{DiracSequence}^{\uparrow}$ packet records finite approximate-identity sequence data before a regularization or point-mass consumer may read a terminal real seal. It sits between the smooth-kernel packet of chapter 4198, the singleton-mass packet of chapter 5181, the terminal real-name surface of chapter 38, the dyadic tolerance ledger of chapter 291, and the continuous-map route of chapter 130. The packet names a finite schedule of approximate-identity rows; it does not import host integration, select a limiting delta object, identify quotient functions or distributions, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5182.1 (Dirac sequence carrier)**.** *A* $\mathsf{DiracSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, R, N, W, E, H, C, P, L)$$

with the following displayed rows:

1. *S is the scale-schedule row, recording the finite list of dyadic scale requests and the order in which downstream consumers may inspect them.*
2. *R is the support-radius decay row, recording the displayed radius bound attached to each scale entry and the finite locality budget consumed by the packet.*
3. *N is the normalization ledger, exposing unit-mass readback as* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparisons rather than as a host integral.*
4. *W is the convolution-window row, recording the source window, target window, translation request, scale request, and finite compatibility data read by a* $\mathsf{ContinuousMap}^{\uparrow}$ *or* $\mathsf{Mollifier}^{\uparrow}$ *consumer.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, R, N, W have been displayed.*
6. *H stores componentwise* hsame *transport for the schedule, support, normalization, convolution-window, real-seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from an approximate-identity request through S, R, N, W, E, H, P, L.*
8. *P is the* Pkg *provenance over* $\mathsf{DiracSequence}^{\uparrow}$, $\mathsf{Mollifier}^{\uparrow}$, $\mathsf{DiracPointMass}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *L is the local* $\mathsf{NameCert}_{\mathsf{DiracSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, N, W, E, H, C, P, L$. It has no coordinate for host integration, selected limits, quotient equality of functions or distributions, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5182.2 (Dirac sequence NameCert obligations)**.** *For every accepted* $\mathsf{DiracSequence}^{\uparrow}$ *carrier* $D = (S, R, N, W, E, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{DiracSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed scale schedule, support-radius decay, normalization ledger, convolution-window row, Real seal, componentwise transport, displayed replay, provenance, and local naming. Every* $\mathsf{Mollifier}^{\uparrow}$*,* $\mathsf{DiracPointMass}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{DyadicRatCore}^{\uparrow}$ *consumer of the packet must read through these rows before treating the sequence as approximate-identity data.*

Proof. Project the carrier of Definition 5182.1. The analytic rows are exactly S, R, N, W, E, and the structural rows are exactly H, C, P, L.

The scale schedule S and support-radius decay row R expose the finite locality route. The normalization ledger N supplies the unit-mass boundary through displayed real and dyadic comparisons, so no host integration row is needed.

The convolution-window row W is the only row that a regularization or continuous-map consumer can use to relate a source window, target window, translation request, and scale request. The terminal seal E is downstream of that finite route rather than a selected limiting delta object.

Finally H, C, P, L transport, replay, source, and name only the displayed packet. Since the carrier has no coordinate for host integration, selected limits, quotient equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 5182.3 (Dirac sequence Real-seal handoff)**.** *Let* $D = (S, R, N, W, E, H, C, P, L)$ *be an accepted* $\mathsf{DiracSequence}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$ *readback exported by the packet factors through the finite route*

$$S \longmapsto R \longmapsto N \longmapsto W \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto L.$$

The handoff provides scale-schedule, support-radius, normalization, convolution-window, transport, replay, provenance, and local naming data, but it exports no host integration operator, selected approximate identity limit, quotient function or distribution equality, countable-choice schedule, or ambient real-completeness theorem.

Proof. Begin with a consumer that asks for a real-valued normalization or regularization readback. Carrier admission first displays the scale schedule S and support-radius decay row R, so the request is confined to a finite approximate-identity window.

The normalization ledger N then supplies the real and dyadic comparisons needed for unit-mass readback. The convolution-window row W records the source and target windows, translation request, and scale request before the terminal seal E can be cited.

Transport through H and replay through C preserve the same displayed rows, while P and L source and name the local certificate. Thus the $\mathsf{Real}^{\uparrow}$ handoff factors through the listed finite route.

No carrier row stores host integration, a chosen limiting delta object, quotient equality, countable choice, or ambient completeness. Those objects therefore cannot be exported by the Real-seal handoff. □

Lean4 (statement) `BEDC.Derived.DiracSequenceUp`

Closure status for $\mathsf{NameCert}_{\mathsf{DiracSequence}^{\uparrow}}$.

Constructive story: A DiracSequence$^{\uparrow}$ packet is generated from a finite scale schedule, support-radius decay row, normalization ledger, convolution-window row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{DiracSequence}^{\uparrow}}$, seed)

Scope closed: Definition 5182.1, Definition 5182.2, and Definition 5182.3 seed the finite approximate-identity sequence surface over MollifierUp, DiracPointMassUp, ContinuousMapUp, RealUp, DyadicRatCoreUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{DiracSequence}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close host integration, selected approximate-identity limits, quotient equality of functions or distributions, countable choice, ambient Real$^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, support-radius decay, normalization ledger exactness, convolution-window routing, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.DiracSequenceUp.

Chapter 5183

A Concrete Naming Certificate for $\mathsf{LocatedCauchyBracket}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, 1985, the $\mathsf{LocatedCauchyBracket}^{\uparrow}$ packet records explicit finite bracket data for a regular Cauchy rational name before the L10 Real and Completion route reads the terminal real seal. It sits over the dyadic tolerance ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the endpoint interval surface of chapter 394, and the located real boundary of **??**. The packet names only inspected brackets, tolerance rows, transport, replay, provenance, and local naming; it is not a quotient-real equality, selected limit, trichotomy, countable-choice schedule, or ambient completeness principle.

Definition 5183.1 (Located Cauchy bracket carrier)**.** *A* $\mathsf{LocatedCauchyBracket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, U, D, W, R, I, E, H, C, P, N)$$

with the following displayed rows:

1. *L and U are lower and upper* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows for the inspected bracket.*
2. *D is the dyadic radius row certifying the requested bracket width.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation window from which the source Cauchy data are read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W under the displayed radius ledger.*
5. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row whose endpoints are L and U and whose containment ledger covers the readback window.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{LocatedReal}^{\uparrow}$ *seal row reached through the displayed bracket.*
7. *H records componentwise* hsame *transport for L, U, D, W, R, I, E and the local naming row.*
8. *C records displayed* Cont *replay from a bracket request through dyadic endpoints, stream observations, regular readback, located interval containment, and the real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedCauchyBracket}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyBracket}^{\uparrow}}$ *row.*

The classifier compares accepted bracket packets only through $L, U, D, W, R, I, E, H, C, P, N$. It has no coordinate for a quotient stream, selected host limit, host real equality, trichotomy oracle, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Lean4 ✓ `BEDC.Derived.LocatedCauchyBracketUp.LocatedCauchyBracketTasteGate single carrier alignment`

Theorem 5183.2 (Located Cauchy bracket shrink)**.** *For every accepted* $\mathsf{LocatedCauchyBracket}^{\uparrow}$ *carrier* $B = (L, U, D, W, R, I, E, H, C, P, N)$ *and every displayed successor precision request carried by the same* $\mathsf{StreamName}^{\uparrow}$ *schedule, the bracket can be read through a successor dyadic radius row* D' *and a refined located interval row* I' *while preserving the original* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route, terminal* $\mathsf{Real}^{\uparrow}$ *seal route,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. The shrink exports no quotient stream, selected limit, host real equality, trichotomy, countable-choice selector, or ambient completeness row.*

Proof. Project the carrier rows. The only analytic data available to a successor precision read are the displayed endpoints L, U, the radius row D, the finite window W, the readback R, and the located interval row I.

Use the dyadic tolerance refinement from chapter 291 and keep the observation on the same $\mathsf{StreamName}^{\uparrow}$ schedule. The refined radius D' and interval row I' are therefore componentwise refinements of displayed rows, not new host data.

Finally replay the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ handoff through H, C, P, N. Since the carrier has no coordinate for a quotient stream, selected limit, host equality, trichotomy, choice, or ambient completeness, the refined bracket preserves the same finite seal route and exports nothing outside it. □

Theorem 5183.3 (Located Cauchy bracket Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*, or Completion-facing consumer of an accepted* $\mathsf{LocatedCauchyBracket}^{\uparrow}$ *packet reaches the terminal real seal only through the displayed finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{LocatedReal}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route may consume dyadic bracket endpoints, a dyadic radius row, finite stream observations, regular rational readback, located interval containment, componentwise transport, replay, provenance, and local naming, but it cannot replace them by a quotient-real representative, selected limit, host interval primitive, trichotomy oracle, countable choice, or ambient completeness principle.

Proof. Begin with the displayed carrier of Definition 5183.1. The endpoint and radius rows expose the dyadic bracket before any stream or real-seal read is available.

The finite window W and readback R then supply the regular Cauchy observation surface. The located interval row I binds that readback between the displayed dyadic endpoints, so a Real-facing consumer cannot bypass the bracket by selecting a host representative.

The terminal seal row E is downstream of I and is replayed only through H, C, P, N. Thus the stated route exhausts the visible rows and excludes quotient representatives, selected limits, host interval primitives, trichotomy, choice, and ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyBracket}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedCauchyBracket}^{\uparrow}$ packet is generated from dyadic lower and upper endpoints, a dyadic radius row, a finite StreamNameUp observation window, RegSeqRatUp readback, a LocatedIntervalUp containment row, a LocatedRealUp and RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyBracket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5183.1, Definition 5183.2, and Definition 5183.3 seed the finite located Cauchy bracket route for L10 Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{LocatedCauchyBracket}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, host real equality, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bracket shrink, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCauchyBracketUp.

Chapter 5184

A Concrete Naming Certificate for $\mathsf{CompactMetricHyperspace}^{\uparrow}$

Following Hausdorff, Vietoris, and Kelley, the $\mathsf{CompactMetricHyperspace}^{\uparrow}$ packet records the recognized hyperspace of nonempty compact subsets of a compact metric BEDC source as finite Hausdorff-distance and Vietoris-window data. It refines the compact-subset carrier of chapter 1660 by requiring the source rows of chapter 129, chapter 57, chapter 127, and chapter 128 to be displayed before any hyperspace consumer reads compact-subset convergence, finite nets, or Hausdorff tolerances.

Definition 5184.1 (Compact metric hyperspace carrier)**.** *A* $\mathsf{CompactMetricHyperspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, H, F, D, V, L, T, C, P, N)$$

with the following displayed rows:

1. *X is the compact metric source row, including the* $\mathsf{Met}^{\uparrow}$ *distance witnesses,* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net schedule, and* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy-limit boundary carried by* $\mathsf{CompactMetric}^{\uparrow}$*.*
2. *H is the underlying* $\mathsf{Hyperspace}^{\uparrow}$ *compact-subset ledger over X, with compact-subset presentations inspected only through the displayed source rows.*
3. *F is the finite nonempty subset-window family: each window records a positive tolerance, a finite source-net list, and the compact-subset names covered at that tolerance.*
4. *D is the bidirectional Hausdorff-distance readback ledger for pairs of displayed compact-subset names, routed through the finite windows in F and the source metric row in X.*
5. *V is the Vietoris finite-net scope row, recording the finite hit-and-miss windows whose opens are represented by metric balls and finite complements read from X.*
6. *L is the Hausdorff-completion route row: a Cauchy family of compact-subset names is read through D and lands back in a compact-subset row of H by the total-bounded and complete source data.*
7. *T records componentwise* hsame *transport for X, H, F, D, V, L, P, N.*
8. *C records displayed* Cont *replay through*

$$X, H, F, D, V \longmapsto L.$$

9. *P is the* Pkg *provenance over* $\mathsf{CompactMetricHyperspace}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactMetricHyperspace}^{\uparrow}}$ *row.*

The carrier has no coordinate for host powersets, quotient compacta, open-cover compactness, selected limits, or choice-selected representatives.

Lean4 ✓ `BEDC.Derived.CompactMetricHyperspaceUp.CompactMetricHyperspaceTasteGate single carrier alignment`

Theorem 5184.2 (Compact metric hyperspace NameCert obligations)**.** *For every accepted* CompactMetricHyperspa *carrier*

$$K = (X, H, F, D, V, L, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactMetricHyperspace}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *compact metric source admission for X, requiring the displayed* $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, *and* $\mathsf{CompleteMetric}^{\uparrow}$ *rows carried by* $\mathsf{CompactMetric}^{\uparrow}$*;*
2. *hyperspace-subset admission for H, requiring every compact-subset name to be read through chapter 1660;*
3. *finite Hausdorff-window admission for F and D, requiring two directed finite coverage reads before a Hausdorff tolerance is public;*
4. *Vietoris finite-net scope for V, requiring hit-and-miss data to be represented by finitely many source metric balls and finite complement checks;*
5. *completion-route stability for L, T, C, requiring Cauchy hyperspace reads to replay through the compact source finite nets and complete boundary;*
6. *provenance and name exhaustion for P, N, excluding host powersets, quotient compacta, open-cover compactness, selected limits, and choice-selected representatives.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5184.1. The source row X is the only place where metric distance, finite nets, and Cauchy-limit service enter the packet.

The hyperspace-subset obligation is exactly the row H. The finite-window and Hausdorff obligations are exactly F and D, so every compact-subset comparison uses displayed finite source data rather than an ambient set of compacta.

The Vietoris obligation is the row V. Its hit-and-miss windows are finite metric-ball inspections over X, hence they remain synchronized with the Hausdorff ledger instead of importing open-cover compactness.

Finally L, T, C, P, N close the route under completion readback, componentwise transport, replay, provenance, and local naming. Since the carrier has no further coordinates, the six listed rows exhaust the local naming surface. □

Theorem 5184.3 (Compact metric hyperspace Hausdorff completion route)**.** *Every accepted* $\mathsf{CompactMetricHyperspace}^{\uparrow}$ *carrier routes Hausdorff-Cauchy compact-subset data through the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *source finite nets and* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary. A Cauchy request in the hyperspace reads only the rows H, F, D, L, T, C, P, N, and the resulting compact-subset landing row is again a displayed* $\mathsf{Hyperspace}^{\uparrow}$ *name over the same source X.*

Proof. Begin with the Hausdorff ledger D. Each directed coverage read cites a finite source-net window from F and a source distance witness from X.

The Cauchy request is then consumed by L. Total boundedness supplies finite source windows at each requested tolerance, and completeness supplies the source boundary needed to keep the compact-subset landing row inside the same compact metric packet.

Transport and replay are handled by T and C. These rows carry the compact metric source, hyperspace rows, finite windows, Hausdorff ledger, and landing row together, so the route cannot leave the displayed carrier.

The provenance and local name rows P, N certify that no selected limit object, quotient compactum, or host powerset is exported. The landing row is therefore a $\mathsf{Hyperspace}^{\uparrow}$ name over X rather than an external compactum. □

Theorem 5184.4 (Compact metric hyperspace Vietoris finite-net scope)**.** *The Vietoris reading of an accepted* $\mathsf{CompactMetricHyperspace}^{\uparrow}$ *carrier is confined to the finite hit-and-miss windows in* V*. Each hit row names a finite family of source metric balls meeting the displayed compact-subset row, each miss row names a finite complement check against the same source net, and the read is stable under the componentwise transport* T *and replay* C*.*

Proof. Project the row V. Its data are finite hit-and-miss windows, and each window is represented by source metric balls and finite complement checks over X.

The row H supplies the compact-subset names being inspected. The rows F and D synchronize those names with Hausdorff finite-net reads, so the Vietoris view cannot inspect a larger host topology.

Stability follows from T and C. Componentwise transport preserves the source, compact-subset, finite-window, Hausdorff, and Vietoris rows, while replay repeats the same displayed inspection path.

Thus the Vietoris scope is finite at every public read and contains no open-cover compactness coordinate, selected representative, quotient compactum, or host powerset. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactMetricHyperspace}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactMetricHyperspace}^{\uparrow}$ packet is generated from a CompactMetricUp source, a HyperspaceUp compact-subset ledger, finite nonempty subset windows, Hausdorff-distance readback, Vietoris finite-net scope, a Hausdorff-completion route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactMetricHyperspace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5184.1, Definition 5184.2, Definition 5184.3, and Definition 5184.4 seed the compact metric Hausdorff/Vietoris hyperspace surface over compact metric BEDC packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactMetricHyperspace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host powersets, quotient compacta, open-cover compactness, selected limits, choice-selected representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite Hausdorff-window admission, Vietoris finite-net scope, Hausdorff-completion route stability, and provenance/name exhaustion for BEDC.Derived.CompactMetricHyperspaceUp.

Chapter 5185

A Concrete Naming Certificate for $\mathsf{BishopIntervalNetExtraction}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, 1985, the $\mathsf{BishopIntervalNetExtraction}^{\uparrow}$ packet records explicit finite ε-net extraction for a located closed interval before the L10 Real and Completion route consumes compactness-like data. It sits after the dyadic tolerance ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the interval finite-net surface of chapter 1808, the total-bounded interval surface of chapter 2021, the compact real-interval packet of chapter 5553, and the located Cauchy bracket route of chapter 5183. The packet names only displayed endpoints, tolerance requests, finite net rows, stream windows, regular readback, Real seals, transport, replay, provenance, and local naming; it is not an open-cover compactness theorem, host interval primitive, quotient-real equality, trichotomy oracle, or ambient completeness principle.

Definition 5185.1 (Bishop interval net extraction carrier)**.** *A* $\mathsf{BishopIntervalNetExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (A, B, \varepsilon, D, G, W, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the located closed interval endpoint rows, read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *rational brackets and the surrounding* $\mathsf{Real}^{\uparrow}$ *seals.*
2. *ε is the positive tolerance request row, stored as a dyadic radius budget rather than as a host real inequality.*
3. *D is the dyadic subdivision ledger, recording the integer step count, endpoint refinements, successor grid positions, and comparison witnesses used to keep adjacent grid rows within the requested tolerance.*
4. *G is the finite grid-net row, a displayed list of dyadic points between A and B whose coverage ledger is inherited by* $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$ *and* $\mathsf{ClosedIntervalTotalBounded}^{\uparrow}$ *consumers.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation-window row used to inspect the endpoint and grid requests without selecting an infinite stream representative.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite windows and dyadic subdivision budget.*

7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for endpoint, grid-point, and coverage reads, reached only after* $A, B, \varepsilon, D, G, W, R$ *have been displayed.*
8. *F is the compact-interval handoff row, routing the extracted finite net to* $\mathsf{CompactRealInterval}^{\uparrow}$ *through the interval finite-net and total-bounded sibling packets.*
9. *H records componentwise* hsame *transport for* $A, B, \varepsilon, D, G, W, R, E, F$ *and the local naming row.*
10. *C records displayed* Cont *replay from a tolerance request through endpoint brackets, dyadic subdivision, grid formation, finite stream windows, regular readback, Real seals, and the compact-interval handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalNetExtraction}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{ClosedIntervalTotalBounded}^{\uparrow}$, $\mathsf{CompactRealInterval}^{\uparrow}$, LocatedCauchyBrack BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalNetExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted interval-net packets only through $A, B, \varepsilon, D, G, W, R, E, F, H, C, P, N$. It has no coordinate for an open-cover subcover, a host interval primitive, quotient real equality, trichotomy, countable choice, a selected limiting point, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopIntervalNetExtractionUp.BishopIntervalNetExtractionTasteGate single carrier alignment`

Theorem 5185.2 (Bishop interval net extraction NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalNetExtraction}^{\uparrow}$ *carrier*

$$I = (A, B, \varepsilon, D, G, W, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopIntervalNetExtraction}^{\uparrow}}$ *surface consists exactly of located endpoint admission, positive tolerance admission, dyadic subdivision formation, finite grid-net coverage, finite* $\mathsf{StreamName}^{\uparrow}$ *inspection,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff, compact-interval routing through the located finite-net and total-bounded sibling packets, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier rows. The endpoints A, B and tolerance row ε are the only analytic inputs, and both are read through displayed dyadic and Real-seal data rather than through a host interval primitive.

The subdivision ledger D forms a finite dyadic grid by repeated successor steps over the displayed endpoint brackets. The grid row G records the resulting finite list and its interval coverage ledger, so every coverage read is finite before any compactness-facing handoff is available.

The readback rows W and R keep endpoint and grid inspection inside finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ rational observations. The terminal seal row E is downstream of those rows, so Real-facing consumers cannot bypass the dyadic grid by selecting quotient representatives or host limits.

Finally F, H, C, P, N route the same finite net to $\mathsf{LocatedClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{ClosedIntervalTotalBounded}^{\uparrow}$, and $\mathsf{CompactRealInterval}^{\uparrow}$ consumers while preserving transport, replay, provenance, and local naming. Since the carrier has no coordinate for open-cover compactness, host interval primitives, quotient real equality, trichotomy, countable choice, selected limits, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalNetExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalNetExtraction}^{\uparrow}$ packet is generated from located closed interval endpoints, a positive dyadic tolerance request, a dyadic subdivision ledger, finite grid-net coverage, finite StreamName windows, RegSeqRat readback, RealUp seals, compact-interval handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalNetExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5185.1 and Definition 5185.2 seed the explicit finite interval-net extraction packet for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalNetExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host real equality, quotient interval equality, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, positive tolerance admission, dyadic subdivision formation, finite grid coverage, finite-window readback, RealUp seal handoff, compact-interval routing, transport, replay, provenance, and local naming for BEDC.Derived.BishopIntervalNetExtractionUp.

Chapter 5186

A Concrete Naming Certificate for $\mathsf{SigmaAlgebra}^{\uparrow}$

Following Kolmogorov and Caratheodory measure theory, the $\mathsf{SigmaAlgebra}^{\uparrow}$ packet records the measurable-event closure surface that measure and probability chapters read before assigning values to events. It sits between the displayed event-family rows of chapter 92, the probability carrier of chapter 184, the measurable-preimage discipline of chapter 185, and the pushforward readback of chapter 186. The packet names finite BEDC rows for event admission, complement, and countable-union schedules; it is not a host powerset, completed measurable universe, quotient event algebra, countable-choice selector, or ambient measure object.

Definition 5186.1 (Sigma-algebra carrier)**.** *A* $\mathsf{SigmaAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (E, Q, Z, K, U, H, C, P, N)$$

with the following displayed rows:

1. *E is the event-family row, listing the measurable-event entries visible to downstream* $\mathsf{Measure}^{\uparrow}$ *and* $\mathsf{ProbSpace}^{\uparrow}$ *consumers.*
2. *Q is the classifier row, comparing displayed events only through the local event-family equivalence and its transported* hsame *witnesses.*
3. *Z is the empty-event row, recording the admitted empty event and its classifier readback.*
4. *K is the complement row, assigning to every displayed event a displayed complement event over the same family row.*
5. *U is the countable-union schedule, naming a displayed union event for every displayed countable event schedule that the packet admits.*
6. *H records componentwise* hsame *transport for the event family, classifier, empty-event, complement, countable-union, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an event request through E, Q, Z, K, U and then to the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{SigmaAlgebra}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SigmaAlgebra}^{\uparrow}}$ *row.*

The carrier has no coordinate for host powersets, completed sigma-algebras, quotient event equality, countable-choice selection, ambient measures, or external measurable-space instances.

Lean4 ✓ `BEDC.Derived.SigmaAlgebraUp.SigmaAlgebraTasteGate single carrier alignment`

Theorem 5186.2 (Sigma-algebra NameCert obligations)**.** *For every accepted* $\mathsf{SigmaAlgebra}^{\uparrow}$ *carrier* $S = (E, Q, Z, K, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SigmaAlgebra}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *event-family admission, requiring* E *before any measurable-event read is public;*
2. *classifier stability, requiring* Q *and componentwise* hsame *transport through* H *to preserve displayed event comparison;*
3. *empty-event admission, requiring* Z *to identify the empty event inside the same event family;*
4. *complement and countable-union closure, requiring* K *and* U *to supply displayed closure rows before a downstream* $\mathsf{Measure}^{\uparrow}$ *or* $\mathsf{ProbSpace}^{\uparrow}$ *consumer may cite sigma-algebra structure;*
5. *provenance and local naming, requiring* C, P, N *to replay, source, and name only the displayed packet, with no host powerset, completed sigma-algebra, quotient event algebra, countable-choice selector, ambient measure, or external measurable-space coordinate.*

No local sigma-algebra obligation is stored outside $E, Q, Z, K, U, H, C, P, N$*.*

Proof. Project the carrier of Definition 5186.1. The event-family row E is the only source of measurable events, and the classifier row Q is the only public comparison between them.

The empty-event row Z, complement row K, and countable-union schedule U supply the closure operations in the same displayed family. Thus a closure request cannot leave the carrier to inspect a host powerset or completed measurable universe.

Transport and replay are componentwise through H and C. These rows preserve the event-family, classifier, empty-event, complement, and countable-union data without adding a second equality or a selected representative.

Finally P and N source and name precisely this packet. Since the forbidden host and quotient coordinates are absent, the five listed rows exhaust the local NameCert surface. □

Theorem 5186.3 (Sigma-algebra measure handoff)**.** *Every* $\mathsf{Measure}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*,* $\mathsf{RandomVar}^{\uparrow}$*, or* $\mathsf{Distribution}^{\uparrow}$ *consumer that cites measurable-event structure from an accepted* $\mathsf{SigmaAlgebra}^{\uparrow}$ *carrier* $S = (E, Q, Z, K, U, H, C, P, N)$ *receives only the displayed event-family row* E*, classifier row* Q*, empty-event row* Z*, complement row* K*, countable-union schedule* U*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local* NameCert *naming through* N*. The handoff exports no host powerset, completed sigma-algebra, quotient event algebra, countable-choice selector, ambient measure, or external measurable-space instance.*

Proof. Read Definition 5186.2. A downstream consumer must first consume the event-family, classifier, empty-event, complement, and countable-union rows before treating the packet as sigma-algebra structure.

For $\mathsf{Measure}^{\uparrow}$ and $\mathsf{ProbSpace}^{\uparrow}$, these rows provide the measurable-event surface before any value or probability row can be read. For $\mathsf{RandomVar}^{\uparrow}$ and $\mathsf{Distribution}^{\uparrow}$, the same rows are the source and target event families through which measurable preimages and pushforward events are routed.

The rows H, C, P, N preserve, replay, source, and name the handoff. Because the carrier has no host powerset, completed sigma-algebra, quotient event algebra, countable-choice selector, ambient measure, or external measurable-space coordinate, the listed rows are the whole exported interface. □

Closure status for $\mathsf{NameCert}_{\mathsf{SigmaAlgebra}^{\uparrow}}$.

Constructive story: A $\mathsf{SigmaAlgebra}^{\uparrow}$ packet is generated from a displayed event-family row, local event classifier, empty-event row, complement row, countable-union schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SigmaAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5186.1, Definition 5186.2, and Definition 5186.3 seed the finite measurable-event closure surface consumed by MeasureUp, ProbSpaceUp, RandomVarUp, and DistributionUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SigmaAlgebra}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host powersets, completed sigma-algebras, quotient event equality, countable-choice selection, ambient measure objects, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked event-family admission, classifier stability, empty-event admission, complement closure, countable-union closure, transport, replay, provenance, and local naming for BEDC.Derived.SigmaAlgebraUp.

Chapter 5187

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusCompression}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy reals and explicit moduli, the $\mathsf{RegularCauchyModulusCompression}^{\uparrow}$ packet records the finite route by which a regular Cauchy name may be read through coarser monotone modulus windows before it reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback and a terminal $\mathsf{Real}^{\uparrow}$ seal. It sits beside the stream-name surface of chapter 126, the dyadic rational core of chapter 291, the regular rational sequence surface of chapter 301, the Cauchy modulus route of chapter 292, and the real-name seal of chapter 38. The packet names only a displayed compression ledger for finite tolerance windows; it does not assert a selected optimal modulus, a quotient of Cauchy names, countable choice, or ambient real completeness.

Definition 5187.1 (Regular Cauchy modulus-compression carrier)**.** *A* $\mathsf{RegularCauchyModulusCompression}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, Q, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular-Cauchy window row, recording the finite prefix of the original name together with the tolerance requests visible to the consumer.*
2. *Q is the monotone compression schedule, assigning each requested tolerance window a displayed coarser window and recording the monotonicity checks between consecutive requests.*
3. *D is the dyadic tolerance ledger over* $\mathsf{DyadicRatCore}^{\uparrow}$*, keeping every compressed bound as a finite dyadic rational comparison.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the regular rational sequence obtained by reading the compressed windows through S, Q, D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, recording that the readback surface is consumed only through the displayed real-name endpoint.*
6. *H records componentwise* hsame *transport for S, Q, D, R, E, C, P, N.*
7. *C records displayed* Cont *replay from a tolerance request through the compression schedule, dyadic ledger, regular-sequence readback, and real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyModulusCompression}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusCompression}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for an optimal modulus, a host limit, quotient equality of Cauchy names, countable choice, a completed real-space structure, or a fuel-erased stream evaluator.

Lean4 ✓ `BEDC.Derived.RegularCauchyModulusCompressionUp.RegularCauchyModulusCompressionTasteGate`
`single carrier alignment`

Theorem 5187.2 (Regular Cauchy modulus-compression NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyModulusCompression}^{\uparrow}$ *carrier*

$$M = (S, Q, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusCompression}^{\uparrow}}$ *surface consists exactly of carrier admission for the source regular-Cauchy windows, monotone compression schedule, dyadic tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. Any compressed tolerance read must expose S, Q, D before R, E, H, C, P, N can be consumed.*

Proof. Project the carrier of Definition 5187.1. The visible rows are precisely the source windows, compression schedule, dyadic ledger, readback row, real seal, transport, replay, provenance, and local name.

The finite compression boundary is read through S, Q, D. The source row supplies the original regular-Cauchy requests, the schedule row records which coarser windows answer them, and the dyadic row keeps the tolerance comparisons inside $\mathsf{DyadicRatCore}^{\uparrow}$.

The remaining rows R, E, H, C, P, N only read back, seal, transport, replay, package, and name that displayed route. Since the carrier has no coordinate for an optimal modulus, host limit, quotient equality, countable choice, completed real-space structure, or stream evaluator, these rows exhaust the NameCert obligations. □

Theorem 5187.3 (Regular Cauchy modulus-compression real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyModulusCompression}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer first reads the source regular-Cauchy windows S, then the monotone compression schedule Q, then the dyadic tolerance ledger D, then the $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. It cannot inspect an uncompressed host sequence, select a least modulus, identify Cauchy names by quotient equality, or bypass the displayed dyadic and regular-sequence rows.*

Proof. Begin with an accepted carrier $M = (S, Q, D, R, E, H, C, P, N)$. The carrier definition places every tolerance request first in the source-window row S and then in the schedule row Q, so a real-facing consumer has no direct access to an ambient sequence.

Next use the dyadic ledger D. It is the only row that compares the compressed windows as finite tolerance data, and it records those comparisons inside $\mathsf{DyadicRatCore}^{\uparrow}$ before any regular-sequence readback is available.

The readback row R repacks the displayed compressed windows as a $\mathsf{RegSeqRat}^{\uparrow}$ surface, and the seal row E is the only $\mathsf{Real}^{\uparrow}$ endpoint attached to the packet. The transport and replay rows H, C preserve this order componentwise, while P, N only record provenance and naming.

Thus every real-facing read follows the displayed stream, dyadic, regular-sequence, and real-seal route, with no coordinate for a least modulus, quotient Cauchy equality, host sequence, or bypass around the finite ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusCompression}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusCompression}^{\uparrow}$ packet is generated from source regular-Cauchy windows, a monotone compression schedule, a dyadic tolerance ledger, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusCompression}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5187.1, Definition 5187.2, and Definition 5187.3 seed the finite modulus-compression route from regular Cauchy windows to RegSeqRat and RealUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusCompression}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close optimal modulus selection, quotient equality of Cauchy names, countable choice, host real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule monotonicity exposure, dyadic tolerance confinement, RegSeqRat readback, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMod

Chapter 5188

A Concrete Naming Certificate for $\mathsf{QuotientNormedSpace}^{\uparrow}$

Following Bourbaki and Bishop–Bridges, the $\mathsf{QuotientNormedSpace}^{\uparrow}$ packet records the finite NameCert surface for quotient normed spaces by a closed linear subspace. It sits downstream from the $\mathsf{NormedSpace}^{\uparrow}$ carrier of chapter 1950, the $\mathsf{Met}^{\uparrow}$ distance readback of chapter 57, the completion boundary of chapter 95, and bounded-operator consumers such as chapter 1644. The packet names quotient norm and induced metric data; it does not export a selected representative, a host quotient object, an ambient Banach completion, or a choice principle.

Definition 5188.1 (Quotient normed-space carrier)**.** *A* $\mathsf{QuotientNormedSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (E, S, Q, N, M, H, C, P, L)$$

with the following displayed rows:

1. *E is the source* $\mathsf{NormedSpace}^{\uparrow}$ *row, exposing only the displayed VecSpace, Real, norm, induced metric, completion-facing, transport, replay, provenance, and local naming rows of the source packet.*
2. *S is the closed-subspace row, carrying membership, linear closure, zero inclusion, and norm-closedness evidence as classifier rows over the source normed-space data.*
3. *Q is the coset-classifier row, identifying histories exactly when their displayed difference is certified by the closed-subspace row S.*
4. *N is the quotient norm row, reading the infimum-style quotient norm only through source norm observations, coset witnesses, and rational tolerance ledgers displayed in E, S, Q.*
5. *M is the induced metric row, whose distance between quotient classes is the quotient norm read of their displayed difference.*
6. *H records componentwise* hsame *transport for E, S, Q, N, M and the support rows.*
7. *C records displayed* Cont *replay for quotient-classifier, quotient-norm, induced-metric, and downstream bounded-operator requests.*
8. *P is the* Pkg *provenance over* $\mathsf{QuotientNormedSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{BoundedLinearOperator}$ BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *L is the local* $\mathsf{NameCert}_{\mathsf{QuotientNormedSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, S, Q, N, M, H, C, P, L$. It has no coordinate for representative choice, host quotient equality, selected completion limits, basis data, or an external Banach carrier.

Theorem 5188.2 (Quotient normed-space NameCert obligations)**.** *For every accepted* $\mathsf{QuotientNormedSpace}^{\uparrow}$ *carrier*

$$Z = (E, S, Q, N, M, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{QuotientNormedSpace}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *source admission, requiring the quotient packet to read its vector operations, Real norm values, induced metric data, and completion-facing requests through the* $\mathsf{NormedSpace}^{\uparrow}$ *source row E;*
2. *closed-subspace stability, requiring membership, linear closure, zero inclusion, and norm-closedness to be witnessed by the subspace row S over the same source classifier;*
3. *coset-classifier exactness, requiring the row Q to compare quotient histories only by displayed differences certified in S;*
4. *quotient-norm and metric handoff, requiring N to read quotient norms through source norm observations and rational tolerance ledgers, and requiring M to read distances as quotient norm reads;*
5. *support replay, requiring* hsame, Cont, Pkg, *and local* NameCert *support through H, C, P, L for bounded-operator, completion, Banach, and Hilbert consumers without adding representative choice, host quotient equality, selected limits, or ambient carrier data.*

No quotient normed-space obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.QuotientNormedSpaceUp.QuotientNormedSpaceTasteGate single carrier alignment`

Proof. Project the carrier of Definition 5188.1. The source row E, closed-subspace row S, coset classifier Q, quotient norm N, induced metric M, and support rows H, C, P, L are the only visible coordinates.

The first two obligations follow by reading E and S before any quotient request. The source supplies the normed-space route, while the subspace row supplies membership, linear closure, zero inclusion, and norm-closedness over that same route.

The coset obligation is then exact along Q. Two quotient histories can be compared only by a displayed difference certified in S, so no representative selector or host quotient equality can enter the comparison.

The norm and metric obligations are forced by N and M. A quotient norm read uses source norm observations and rational tolerance ledgers, and the metric row reads distance as the quotient norm of a displayed difference.

Finally H, C, P, L replay and name the same finite route for completion and bounded-operator consumers. Since the carrier contains no selected representative, host quotient object, selected limit, basis datum, or ambient Banach coordinate, the five listed rows exhaust the NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{QuotientNormedSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{QuotientNormedSpace}^{\uparrow}$ packet is generated from a source normed-space row, a closed-subspace row, a coset-classifier row, a quotient-norm row, an induced metric row, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuotientNormedSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5188.1 and Definition 5188.2 seed the quotient normed-space packet over NormedSpace, MetricSpace, Completion, and bounded-operator consumer rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{QuotientNormedSpace}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Banach quotient completeness, representative selection, quotient completion, bounded-operator factorization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, closed-subspace stability, coset exactness, quotient-norm handoff, induced metric handoff, replay, provenance, and local naming for the same finite packet.

Chapter 5189

A Concrete Naming Certificate for $\mathsf{CompactNetRadiusChain}^{\uparrow}$

Following the Heine–Cantor compact finite-net tradition, the $\mathsf{CompactNetRadiusChain}^{\uparrow}$ packet records the finite NameCert surface that turns compact metric finite nets and pointwise continuity radii into a uniform-modulus handoff. It reads compact centers from $\mathsf{CompactMetric}^{\uparrow}$ as in chapter 129, pointwise graph radii from $\mathsf{ContinuousMap}^{\uparrow}$ as in chapter 130, tolerance-only output through $\mathsf{UniformModulus}^{\uparrow}$ as in chapter 369, and rational comparison through $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ as in chapter 291 and chapter 37. The packet is a finite radius-chain carrier; it is not an external Lebesgue-number selector, not a sequential compactness proof, and not a choice-based modulus.

Definition 5189.1 (Compact net radius-chain carrier)**.** *A* $\mathsf{CompactNetRadiusChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, F, A, B, D, U, H, C, P, L)$$

with the following displayed rows:

1. *K is the compact-net center row, carrying a nonempty* $\mathsf{ProbeBundle}$ *of center histories and coverage witnesses over a compact metric source.*
2. *F is the continuous-map row, exposing pointwise radius data for the displayed graph through the same source metric and target metric rows.*
3. *A is the pointwise radius row, assigning each bundled center a positive rational or dyadic radius history accepted by the continuous-map modulus ledger.*
4. *B is the rational lower-bound fold row, folding the finite radius family through* $\mathsf{Rat}^{\uparrow}$ *order readback and preserving a classifier-stable positive lower bound.*
5. *D is the dyadic tolerance ledger, recording halving, thirding, and comparison requests through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and the surrounding* $\mathsf{Rat}^{\uparrow}$ *seal.*
6. *U is the uniform-modulus handoff row, reading a tolerance-only precision history from B, D and routing it to* $\mathsf{UniformModulus}^{\uparrow}$ *consumers.*
7. *H records componentwise* hsame *transport for K, F, A, B, D, U and the support rows.*
8. *C records displayed* Cont *replay from compact coverage, pointwise modulus reads, rational folds, dyadic tolerance comparisons, and uniform-modulus handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactNetRadiusChain}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{CompactNetRadiusChain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, A, B, D, U, H, C, P, L$. It has no coordinate for a host finite set, an external minimum selector, a sequential compactness branch, or a hidden modulus choice.

Theorem 5189.2 (Compact net radius-chain NameCert obligations)**.** *For every accepted* $\mathsf{CompactNetRadiusChain}^{\uparrow}$ *carrier*

$$R = (K, F, A, B, D, U, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{CompactNetRadiusChain}^{\uparrow}}$ *surface consists exactly of compact-net center admission, continuous-map pointwise radius admission, rational lower-bound folding, dyadic tolerance bookkeeping, uniform-modulus handoff, componentwise transport, displayed replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.CompactNetRadiusChainUp.CompactNetRadiusChainTasteGate single carrier alignment`

Proof. Project the carrier. The compact centers, continuous-map radii, rational fold, dyadic tolerance ledger, uniform-modulus handoff, transport, replay, provenance, and naming rows are the only displayed coordinates.

The compact-net row K supplies a finite ProbeBundle of centers and coverage witnesses. The continuous-map row F and pointwise radius row A attach a local radius ledger to each bundled center over the same metric source.

The fold row B reads the finite family through the $\mathsf{Rat}^{\uparrow}$ order, while the dyadic ledger D supplies the half-radius and tolerance comparisons needed by the metric triangle estimate. These rows produce a positive lower-bound history rather than an external minimum.

The handoff row U packages that lower bound as a tolerance-only precision for $\mathsf{UniformModulus}^{\uparrow}$ consumers. Transport, replay, provenance, and local naming through H, C, P, L preserve the same finite route, and no host finite set, sequential compactness branch, or hidden modulus selector remains available. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactNetRadiusChain}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactNetRadiusChain}^{\uparrow}$ packet is generated from compact-net centers, pointwise continuous-map radii, a rational lower-bound fold, a dyadic tolerance ledger, a uniform-modulus handoff row, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactNetRadiusChain}^{\uparrow}}$, seed)

Scope closed: Definition 5189.1 and Definition 5189.2 seed the compact finite-net radius-chain packet for uniform-modulus consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactNetRadiusChain}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the full Heine–Cantor theorem, Lean verification, bridge checking, sequential compactness, or a host modulus selector.

Upgrade path: Obligation closure requires checked compact-center admission, pointwise-radius admission, rational lower-bound folding, dyadic tolerance bookkeeping, uniform-modulus handoff, transport, replay, provenance, and local naming for the same finite packet.

Chapter 5190

A Concrete Naming Certificate for $\mathsf{DyadicBracketApproximation}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicBracketApproximation}^{\uparrow}$ packet records the finite lower-upper dyadic bracket interface by which the L10 Real and Completion route reads a regular rational name at a requested precision before the terminal real seal is consumed. It sits over the dyadic arithmetic surface of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the equality boundary of chapter 1820, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet gives later density, located-order, and completion consumers a displayed bracket row rather than a prose appeal to approximation.

Definition 5190.1 (DyadicBracketApproximation carrier)**.** *A* $\mathsf{DyadicBracketApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, U, Q, I, S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower* $\mathsf{DyadicRatCore}^{\uparrow}$ *bracket row. It stores the inspected lower dyadic endpoint, its source observation, and the order evidence that the endpoint lies below the displayed regular read.*
2. *U is the upper* $\mathsf{DyadicRatCore}^{\uparrow}$ *bracket row. It stores the inspected upper dyadic endpoint, its source observation, and the order evidence that the displayed regular read lies below the endpoint.*
3. *Q is the unary precision row. It records the requested precision as a finite unary budget and the dyadic radius derived from that budget.*
4. *I is the inclusion witness row. It records that the displayed regular readback lies inside the bracket $[L, U]$ at the precision carried by Q.*
5. *S is the shrink witness row. It records the successor-precision bracket whose lower and upper dyadic endpoints refine L and U without changing the source name.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation window from which the bracket read is taken.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from W and the dyadic precision budget.*
8. *E is the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *and terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the bracket, window, and readback rows have been displayed.*

9. *H records componentwise* hsame *transport for L, U, Q, I, S, W, R, E and the local naming row.*
10. *C records displayed* Cont *replay from a precision request through lower bracket, upper bracket, inclusion, shrink, finite window, regular readback, equivalence boundary, and real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{DyadicBracketApproximation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicBracketApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, Q, I, S, W, R, E, H, C, P, N$. It has no coordinate for a selected real representative, quotient stream equality, host located-order oracle, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicBracketApproximationUp.DyadicBracketApproximationTasteGate single carrier alignment`

Theorem 5190.2 (DyadicBracketApproximation NameCert obligations)**.** *For every accepted* DyadicBracketApprox *carrier*

$$B = (L, U, Q, I, S, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicBracketApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the lower dyadic bracket, upper dyadic bracket, unary precision, inclusion witness, shrink witness, finite stream window, regular rational readback, equivalence and real seal, transport, replay, provenance, and local naming;*
2. *lower-upper discipline, requiring L and U to be read before any bracket consumer may inspect a regular or real-facing row;*
3. *precision discipline, requiring Q to expose a unary precision budget and the corresponding dyadic radius before the inclusion or shrink rows are available;*
4. *inclusion discipline, requiring I to bind the displayed regular readback between the lower and upper dyadic rows at the precision carried by Q;*
5. *shrink discipline, requiring S to refine the same source route at successor precision without replacing it by a selected limit or a quotient representative;*
6. *readback discipline, requiring W and R to supply the finite StreamName and RegSeqRat route before the equivalence and* $\mathsf{Real}^{\uparrow}$ *seal row E is read;*
7. *seal nonescape, requiring E, H, C, P, N to export only the displayed bracket route and no selected real representative, quotient stream equality, host located-order oracle, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

No DyadicBracketApproximation obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5190.1. The accepted packet displays exactly the lower and upper dyadic brackets, unary precision, inclusion and shrink witnesses, finite window, regular readback, equivalence and real seal, and structural rows.

The lower-upper and precision disciplines are the first stage of the route. The bracket endpoints L, U and precision budget Q must be visible before any inclusion, shrink, regular-readback, or Real-facing row is available.

The inclusion and shrink disciplines are the constructive approximation stage. The row I pins the displayed readback inside the dyadic bracket at the current budget, while S records a successor bracket over the same source route rather than a chosen limit.

Finally W, R, E, H, C, P, N replay, seal, transport, package, and name the same route. Since selected representatives, quotient stream equality, host located-order oracles, countable choice, trichotomy, and ambient Real completeness are absent from the carrier, no local obligation can export them. □

Theorem 5190.3 (Dyadic bracket Real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or located-order consumer of an accepted* $\mathsf{DyadicBracketApproximation}^{\uparrow}$ *carrier factors through the displayed route*

$$L, U, Q \longmapsto I, S \longmapsto W, R \longmapsto E, H, C, P, N.$$

The consumer may read lower and upper dyadic brackets, unary precision, inclusion, shrink, finite stream observations, regular rational readback, equivalence sealing, transport, replay, provenance, and local naming. It cannot replace that route by a selected real representative, quotient stream equality, host located-order oracle, countable choice, trichotomy, or ambient completeness principle.

Proof. Start with the accepted carrier $B = (L, U, Q, I, S, W, R, E, H, C, P, N)$. The only bracket data in the carrier are L and U, and the only precision data are carried by Q.

The inclusion and shrink rows are downstream of those bracket and precision rows. They bind the current readback and successor readback to the same displayed route, so no consumer can bypass the bracket by choosing a host representative.

The finite-window and regular-readback rows W, R then expose the L10 observation surface. The equivalence and Real seal row E is terminal and is replayed only through H, C, P, N.

Thus the displayed route exhausts the visible packet. The excluded quotient, choice, order-oracle, trichotomy, and ambient-completeness coordinates are not present in the carrier and cannot be exported by the handoff. □

Falsifiable prediction: Every accepted $\mathsf{DyadicBracketApproximation}^{\uparrow}$ read exposes one lower dyadic bracket row, one upper dyadic bracket row, one unary precision row, one inclusion witness, one shrink witness, one finite StreamName window, one RegSeqRat readback, one Cauchy-equivalence and Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any Real or located-order consumer may inspect it.

Independence witness: dyadicratcore, streamname, regseqrat, cauchy-equivalence-setoid, real: $\mathsf{DyadicBracketApproximation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries lower and upper bracket endpoints, unary precision, inclusion, shrink, finite windows, regular readback, equivalence sealing, transport, replay, provenance, and local naming in one L10 approximation packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicBracketApproximation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicBracketApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5190.1, Definition 5190.2, and Definition 5190.3 seed the finite lower-upper dyadic bracket route between displayed observations and regular real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicBracketApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected real representatives, host located order, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-upper discipline, unary precision exactness, inclusion and shrink witness stability, regular readback handoff, seal nonescape, and local naming for BEDC.Derived.DyadicBracketApproximatio

Constructive story: A DyadicBracketApproximation$^{\uparrow}$ packet is generated from lower and upper DyadicRatCore$^{\uparrow}$ bracket rows, unary precision, inclusion and shrink witnesses, a finite StreamName$^{\uparrow}$ window, RegSeqRat$^{\uparrow}$ readback, CauchySequenceEquivalence$^{\uparrow}$ and Real$^{\uparrow}$ seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5191

A Concrete Naming Certificate for $\mathsf{LogicContradictionRefusal}^{\uparrow}$

The $\mathsf{LogicContradictionRefusal}^{\uparrow}$ packet realizes the contradiction-request boundary of section 9462.25 as finite NameCert data. It sits after the broader logic and meta-loop packet of chapter 1261, the local refutation boundary of chapter 500, the host-primitive leakage audit of chapter 1157, and the quotient-collapse refusal surface of chapter 634. The packet records a request to use contradiction as a global exporter, the finite reason that the request is refused, and the route by which local refutation remains available without host-level explosion.

Definition 5191.1 (LogicContradictionRefusal carrier)**.** *A* $\mathsf{LogicContradictionRefusal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, L, R, G, B, H, C, P, N)$$

with the following displayed rows:

1. *Q is the contradiction-request row. It records the proposed use of a local inconsistency, impossible branch, or false row as an exporter for an arbitrary global claim.*
2. *L is the local-refutation row. It identifies the finite context in which the contradiction is licensed and the boundary beyond which the refutation is not a proof-producing rule.*
3. *R is the refusal row. It records that the request in Q is refused as a host-level explosion, total-truth closure, unrestricted choice step, quotient collapse, or halting-closure oracle.*
4. *G is the gate row inherited from the* $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$ *surface. It keeps proof-pattern discipline and open meta-loop refusal visible before any downstream logical consumer reads the packet.*
5. *B is the sibling-boundary row. It records the overlap with* $\mathsf{RefutationBoundary}^{\uparrow}$, $\mathsf{HostPrimitiveLeakage}^{\uparrow}$, *and* $\mathsf{QuotientSoundnessBoundary}^{\uparrow}$ *without identifying this packet with any of them.*
6. *H records componentwise* hsame *transport for Q, L, R, G, B and the local naming row.*
7. *C records displayed* Cont *replay from contradiction request through local refutation, refusal, gate boundary, sibling boundary, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{LogicContradictionRefusal}^{\uparrow}$, $\mathsf{LogicContradictionMetaLoop}^{\uparrow}$, $\mathsf{RefutationBoundary}^{\uparrow}$, $\mathsf{HostPrimitiveLeakage}^{\uparrow}$, $\mathsf{QuotientSoundnessBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LogicContradictionRefusal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, L, R, G, B, H, C, P, N$. It has no coordinate for ex falso as a host primitive, total truth, unrestricted choice, quotient representative collapse, global proof search, halting closure, or a closed meta-loop classifier.

Theorem 5191.2 (LogicContradictionRefusal NameCert obligations)**.** *For every accepted* $\mathsf{LogicContradictionRefusa}$ *carrier*

$$K = (Q, L, R, G, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LogicContradictionRefusal}^{\uparrow}}$ *surface consists exactly of contradiction-request admission through Q, local-refutation exposure through L, refusal through R, gate-boundary discipline through G, sibling-boundary separation through B, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N. The accepted packet refuses any route from local contradiction management to host-level explosion, total truth, unrestricted choice, quotient collapse, global proof search, halting closure, or a closed meta-loop classifier.*

Proof. Carrier admission is projection from Definition 5191.1. The rows $Q, L, R, G, B, H, C, P, N$ are the entire visible packet.

The contradiction request and local refutation rows separate the proposed exporter from the finite context that licenses a local negative result. Thus Q may record a request for global explosion while L records only the local refutation boundary.

The refusal and gate rows then block the exporter. The row R refuses host-level explosion, total truth, unrestricted choice, quotient collapse, global proof search, halting closure, and closed meta-loop classification, while G keeps the broader logic/meta-loop discipline in view.

Finally B, H, C, P, N preserve the sibling boundary, transport, replay, provenance, and naming rows. Since none of the excluded host-level coordinates occurs in the carrier, no local NameCert obligation can export them. □

Theorem 5191.3 (Logic contradiction refusal nonescape)**.** *Every accepted* $\mathsf{LogicContradictionRefusal}^{\uparrow}$ *read factors through the displayed route*

$$Q, L \longmapsto R, G, B \longmapsto H, C, P, N.$$

The route may expose a contradiction request, a local refutation boundary, a refusal row, the logic/meta-loop gate, sibling-boundary separation, transport, replay, provenance, and local naming. It cannot export a host explosion rule, total truth row, unrestricted choice step, quotient collapse, global proof-search result, halting closure, or closed meta-loop classifier.

Proof. Start with an accepted carrier $K = (Q, L, R, G, B, H, C, P, N)$. The only row that records the requested contradiction use is Q, and the only row that records the locally licensed negative content is L.

The refusal row R is downstream of both. It rejects the global exporter while leaving the local refutation row visible, so the packet does not erase contradiction management; it blocks only the attempt to turn it into a host-level proof primitive.

The gate and sibling-boundary rows G and B keep the refusal aligned with the broader meta-loop discipline and with the adjacent refutation, host-leakage, and quotient-boundary packets. Transport, replay, provenance, and naming are then carried only by H, C, P, N.

Thus the stated route exhausts the accepted read. The excluded explosion, total-truth, choice, quotient-collapse, global-search, halting, and closed-meta coordinates are absent from the packet. □

Theorem 5191.4 (Logic contradiction refusal TasteGate obligation)**.** *The Lean* `TasteGate.lean` *development for* $\mathsf{LogicContradictionRefusal}^{\uparrow}$ *must later supply explicit* $\mathsf{Nontrivial\ LogicContradictionRefusal}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ LogicContradictionRefusal}^{\uparrow}$ *instances. Nontriviality must distinguish at least one accepted local-refutation refusal packet from a packet that turns Q into host-level explosion, and field faithfulness must preserve the row order*

$$Q, L, R, G, B, H, C, P, N$$

before any checked carrier-alignment theorem may serve as a public TasteGate realization.

Proof. The nontrivial boundary is forced by Definition 5191.3: an accepted refusal packet preserves local refutation while blocking host-level explosion. A packet that turns the request row Q into an arbitrary-claim exporter therefore cannot be the same accepted carrier.

Field faithfulness is the corresponding row-preservation obligation. A faithful read must keep the request, local refutation, refusal, gate, sibling boundary, transport, replay, provenance, and naming rows in the displayed order rather than replacing them by an external logical primitive. □

Falsifiable prediction: Every accepted $\mathsf{LogicContradictionRefusal}^{\uparrow}$ read exposes one contradiction-request row, one local-refutation row, one refusal row, one logic/meta-loop gate row, one sibling-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any logic-boundary consumer may inspect it.

Independence witness: logiccontradictionmetaloop, refutationboundary, hostprimitiveleakage, quotientsoundnessboundary: $\mathsf{LogicContradictionRefusal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a contradiction request, local refutation boundary, refusal row, meta-loop gate, sibling separation, transport, replay, provenance, and local naming while specifically refusing host-level explosion.

Closure status for $\mathsf{NameCert}_{\mathsf{LogicContradictionRefusal}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LogicContradictionRefusal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5191.1, Definition 5191.2, Definition 5191.3, and Definition 5191.4 seed the finite contradiction-request refusal route over local refutation and open meta-loop boundary rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LogicContradictionRefusal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host-level explosion, total truth, unrestricted choice, quotient collapse, global proof search, halting closure, closed meta-loop classification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contradiction-request exactness, local-refutation boundary, refusal nonescape, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.LogicContradictionRefusalUp.

Constructive story: A $\mathsf{LogicContradictionRefusal}^{\uparrow}$ packet is generated from a contradiction-request row, local-refutation row, refusal row, logic/meta-loop gate row, sibling-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5192

A Concrete Naming Certificate for $\mathsf{WeakStarTopology}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{WeakStarTopology}^{\uparrow}$ packet records the weak-star topology through finite windows of continuous linear-functional reads on a displayed normed-space source. It sits over the normed carrier of chapter 1950, the finite weak-topology window of chapter 3597, the bounded-linear-operator surface of chapter 1644, and the scalar seal of chapter 38. The chapter names the finite observation-window certificate used by dual-facing consumers; it does not assert Banach–Alaoglu compactness, select dual elements, construct quotient function spaces, invoke choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5192.1 (Weak-star topology carrier)**.** *A* $\mathsf{WeakStarTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (V, W, L, T, R, H, C, P, N)$$

with the following displayed rows:

1. *V is the source* $\mathsf{NormedSpace}^{\uparrow}$ *row whose points are read only through the displayed normed-space carrier and its scalar rows.*
2. *W is the sibling* $\mathsf{WeakTopology}^{\uparrow}$ *observation-window row, reused as the finite neighbourhood interface rather than as a completed dual topology.*
3. *L is the finite bounded-linear-functional row. Each entry is a* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *read from V to the displayed scalar line, not a selected element of an unrestricted dual space.*
4. *T is the test-window row, listing the finitely many functional reads, source points, scalar tolerances, and comparison requests inspected by the consumer.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar readback row for observed functional values and their finite tolerance comparisons.*
6. *H records componentwise* hsame *transport for the normed source, weak-window interface, bounded-linear-functional rows, test windows, scalar readbacks, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a requested weak-star read through T, then through L, V, W, R, and finally through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{WeakStarTopology}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{WeakTopology}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{WeakStarTopology}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $V, W, L, T, R, H, C, P, N$. It has no coordinate for Banach–Alaoglu compactness, selected dual elements, quotient function spaces, choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.WeakStarTopologyUp.WeakStarTopologyTasteGate single carrier alignment`

Theorem 5192.2 (Weak-star topology NameCert obligations)**.** *For every accepted* $\mathsf{WeakStarTopology}^{\uparrow}$ *carrier $S = (V, W, L, T, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WeakStarTopology}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{NormedSpace}^{\uparrow}$ *row V, sibling* $\mathsf{WeakTopology}^{\uparrow}$ *window row W, finite bounded-linear-functional row L, test-window row T, scalar readback row R, componentwise transport H, displayed replay C, provenance P, and local naming N. Every public weak-star neighbourhood read must cite these rows before it reaches a scalar comparison.*

Proof. Project the carrier of Definition 5192.1. The only source carrier is V, the only weak-neighbourhood interface is W, and the only functional data are the finitely listed bounded-linear reads in L.

The test-window row T fixes which functional reads and source points are inspected. Scalar comparison then passes through R, so the public read receives finite $\mathsf{Real}^{\uparrow}$ observations rather than a selected dual element or a completed function space.

Transport, replay, provenance, and naming are supplied by H, C, P, N. Since the carrier contains no further coordinates, the listed rows exhaust the local NameCert surface. □

Theorem 5192.3 (Weak-star finite-window nonescape)**.** *Every scalar observation exported by an accepted* $\mathsf{WeakStarTopology}^{\uparrow}$ *carrier factors through*

$$V, W, L, T, R, H, C, P, N.$$

Thus a weak-star neighbourhood, convergence, or bounded-operator consumer may inspect only finite bounded-linear-functional windows and their $\mathsf{Real}^{\uparrow}$ *scalar comparisons. It receives no Banach–Alaoglu compactness theorem, no selected dual element, no quotient function space, no choice principle, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with an exported scalar observation. By Definition 5192.2, the observation must expose the source row V, the weak-window row W, the finite functional row L, and the test-window row T.

The scalar row R is the only route to real-valued readback. It records finite observed values and tolerance comparisons, not a completed dual-space object or a quotient of functions.

The structural rows H, C, P, N preserve and name that same route. Since the excluded compactness, selection, quotient, choice, and completeness principles have no carrier coordinate, they cannot be exported by the accepted packet. □

Theorem 5192.4 (Weak-star Banach–Alaoglu boundary)**.** *An accepted* $\mathsf{WeakStarTopology}^{\uparrow}$ *carrier may be consumed by a later compactness or dual-ball chapter only as the finite observation-window interface*

$$V, W, L, T, R, H, C, P, N.$$

Any Banach–Alaoglu-style conclusion must supply its own compactness, bounded-dual-ball, subnet, or cover ledger outside this packet. The weak-star packet itself contributes only the named finite reads and their transport, replay, provenance, and local NameCert rows.

Proof. Read the carrier inventory. The weak-star packet contains normed-space source data, a weak-window interface, finitely listed bounded-linear-functional reads, finite tests, scalar readbacks, and structural rows.

None of those rows is a compactness row, a selected dual-ball element, a subnet selector, a quotient function-space equality, or a choice principle. Therefore a compactness consumer cannot derive such data by projection from the packet.

The only available handoff is the finite observation route displayed in the theorem statement. A later Banach–Alaoglu chapter must add its own certificate rows before any compactness claim becomes public. □

Falsifiable prediction: Every public $\mathsf{WeakStarTopology}^{\uparrow}$ read factors through a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a sibling $\mathsf{WeakTopology}^{\uparrow}$ window, finite $\mathsf{BoundedLinearOperator}^{\uparrow}$ functional reads, $\mathsf{Real}^{\uparrow}$ scalar comparisons, BHist transport, hsame, Cont, Pkg, and local NameCert naming. A public weak-star read that exports Banach–Alaoglu compactness, selected dual elements, quotient function spaces, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness from this packet refutes the carrier boundary.

Independence witness: normedspace, weaktopology, boundedlinearoperator, real: $\mathsf{WeakStarTopology}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a normed source, a weak-window interface, finite bounded-linear-functional reads, scalar test windows, Real readbacks, transport, replay, provenance, and local naming while refusing compactness and selection data.

Closure status for $\mathsf{NameCert}_{\mathsf{WeakStarTopology}^{\uparrow}}$.

Constructive story: A $\mathsf{WeakStarTopology}^{\uparrow}$ packet is generated from a displayed NormedSpace source, a WeakTopology finite-window row, finite BoundedLinearOperator functional reads, Real scalar readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeakStarTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5192.1, Definition 5192.2, Definition 5192.3, and Definition 5192.4 seed the finite weak-star observation-window certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeakStarTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Banach–Alaoglu compactness, selected dual elements, quotient function spaces, choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-functional window stability, scalar observation nonescape, compactness-boundary refusal, transport, replay, provenance, and local naming for BEDC.Derived.WeakStarTopologyUp.

Chapter 5193

A Concrete Naming Certificate for $\mathsf{ObserverLocalityRateBudget}^{\uparrow}$

The $\mathsf{ObserverLocalityRateBudget}^{\uparrow}$ packet realizes the Inter-Hist Locality maximum-rate read as a finite paired-observer budget rather than as a global frame, metric tensor, or host-valued speed. It consumes the multi-history configuration route of chapter 474, the cross-Hist causal route of chapter 478, the maximum causal-rate surface of chapter 594, the public maximum-rate gate of chapter 933, and the rate-boundary refusal of chapter 1023. The packet is a concrete finite budget for observer-locality reads; it is not a global synchronization row, privileged frame, hidden clock, ambient metric geometry, or selected real-valued velocity.

Definition 5193.1 (Observer locality rate-budget carrier)**.** *An* $\mathsf{ObserverLocalityRateBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, C, R, G, S, T, N, H, K, P)$$

with the following displayed rows:

1. *M is the paired* MultiHistConfig *row, naming the two observer histories and their local history classifiers without adding a global synchronization row.*
2. *C is the* CrossHistCausal *row, recording the displayed causal-dependence reads between the two histories.*
3. *R is the* MaxCausalRate *row, exposing the maximum-rate bound only as a finite causal-rate read over M and C.*
4. *G is the* MaxRateReadGate *row, requiring observer-symmetry and no-global-frame refusal before the rate read becomes public.*
5. *S is the observer-symmetry budget row, recording the two-direction comparison that prevents either history from serving as the privileged frame.*
6. *T is the transport row for paired-history* hsame *and* psame *movement across the same causal-rate budget.*
7. *N is the no-global-frame refusal row, blocking shared clocks, global coordinates, metric tensors, host speeds, and selected synchronization data.*
8. *H records componentwise* hsame *transport for the paired histories, causal row, rate row, read gate, symmetry budget, transport, refusal, replay, provenance, and local naming rows.*

9. *K records displayed* Cont *replay from a requested public rate read through M, C, R, G, S, T, N and then to the structural rows.*
10. *P is the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{ObserverLocalityRateBudget}^{\uparrow}}$ *naming row over the displayed packet.*

The classifier compares accepted packets only through $M, C, R, G, S, T, N, H, K, P$. It has no coordinate for a global frame, universal clock, metric geometry, host real-valued speed, selected observer representative, or choice principle.

Theorem 5193.2 (Observer locality rate-budget NameCert obligations)**.** *For every accepted* ObserverLocalityRateB *carrier $B = (M, C, R, G, S, T, N, H, K, P)$, the local* $\mathsf{NameCert}_{\mathsf{ObserverLocalityRateBudget}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *paired-history admission through M;*
2. *cross-Hist causal admission through C;*
3. *maximum causal-rate admission through R;*
4. *public maximum-rate gating through G;*
5. *observer-symmetry budgeting through S;*
6. *paired-history transport through T, H;*
7. *no-global-frame refusal through N;*
8. *displayed replay, provenance, and local naming through K, P.*

Every public maximum-rate read must pass through the observer-symmetry budget and the no-global-frame refusal before a consumer may cite the rate bound.

Proof. Project the carrier of Definition 5193.1. The paired histories enter through M, causal dependence through C, and the maximum-rate bound through R.

The read cannot become public at that point. The gate row G requires the observer-symmetry budget S and the no-global-frame refusal row N, while T and H preserve the paired-history route under displayed transport.

Finally replay and provenance are supplied by K, P. Because the carrier contains no further rows, the listed obligations exhaust the local NameCert surface. □

Theorem 5193.3 (Observer locality rate-budget nonescape)**.** *Every public rate read exported by an accepted* $\mathsf{ObserverLocalityRateBudget}^{\uparrow}$ *carrier factors through*

$$M, C, R, G, S, T, N, H, K, P.$$

In particular, omitting either the observer-symmetry budget S or the no-global-frame refusal N prevents the read from being public. The packet exports no global frame, universal clock, ambient metric geometry, selected observer representative, host real-valued velocity, or choice principle.

Proof. Begin with a public rate read. By Definition 5193.2, the read must expose paired histories, cross-Hist causality, and maximum causal-rate data through M, C, R.

The gate row G then checks the symmetry budget S and no-global-frame refusal N. If either row is absent, the requested read lacks one of the named obligations and cannot pass the local certificate.

Transport and replay through T, H, K preserve that same route, and P names it. Since the excluded global-frame, clock, metric, selected-observer, host-velocity, and choice data are absent from the carrier, they cannot be exported. □

Theorem 5193.4 (Observer locality rate-budget Lean carrier boundary)**.** *The follow-up Lean carrier for* ObserverLocalityRateBudget$^{\uparrow}$ *must expose a nontrivial public object and a field-faithful public classifier in 'lean4/BEDC/Derived/ObserverLocalityRateBudgetUp/TasteGate.lean'. Concretely, the carrier boundary is satisfied only when the Lean side provides 'NontrivialObserverLocalityRateBudgetUp' and 'FieldFaithful ObserverLocalityRateBudgetUp' for the same finite rows displayed in Definition 5193.1.*

Proof. The paper-side packet is not a purely verbal refusal; it carries the finite rows $M, C, R, G, S, T, N, H, K, P$. A Lean carrier that collapsed those rows to a singleton without public field separation would fail to represent the observer-symmetry and no-global-frame budget as distinguishable data.

The required nontriviality gives at least one public object boundary beyond the empty carrier. Field faithfulness then ties the public classifier to the displayed rows, so a maximum-rate read cannot be accepted after erasing the symmetry or refusal coordinates.

Thus the Lean follow-up must provide both named interfaces in the indicated TasteGate file before the carrier can be treated as a faithful formal companion to this chapter. □

Falsifiable prediction: Any public ObserverLocalityRateBudget$^{\uparrow}$ maximum-rate read that omits either observer-symmetry or no-global-frame refusal refutes the packet.

Independence witness: multihistconfig, crosshistcausal, maxcausalrate, maxratereadgate, interhistrateboundary: ObserverLocalityRateBudget$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries paired histories, causal rows, maximum-rate rows, public read gating, observer-symmetry budgets, no-global-frame refusal, transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{ObserverLocalityRateBudget}^{\uparrow}}$.

Constructive story: An ObserverLocalityRateBudget$^{\uparrow}$ packet is generated from paired MultiHistConfig rows, CrossHistCausal rows, MaxCausalRate rows, MaxRateReadGate rows, observer-symmetry budgets, transport rows, no-global-frame refusal, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ObserverLocalityRateBudget}^{\uparrow}}$, seed)

Scope closed: Definition 5193.1, Definition 5193.2, Definition 5193.3, and Definition 5193.4 seed the finite observer-locality rate-budget certificate surface.

Formal verification: FormalStatus(NameCert$_{\text{ObserverLocalityRateBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global synchronization, privileged frames, hidden clocks, ambient metric geometry, selected observers, host real-valued velocities, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked paired-history admission, causal-row admission, maximum-rate admission, read-gate exactness, observer-symmetry budgeting, no-global-frame refusal, transport, replay, provenance, local naming, nontriviality, and field faithfulness for BEDC.Derived.ObserverLocalityRateBudgetUp.

Chapter 5194

Mazur–Ulam Isometry NameCert Construction

Following Mazur and Ulam, the $\mathsf{MazurUlamIsometry}^{\uparrow}$ packet records the finite BEDC surface on which a surjective isometry between real normed spaces is inspected as midpoint-preserving and affine after its basepoint translation is displayed. It sits over the source and target normed carriers of chapter 1950, the scalar seal of chapter 38, the vector-operation rows of chapter 47, and the induced-distance readback of chapter 57. The chapter names the classical Mazur–Ulam route as finite history, classifier, midpoint, and affine-transport data; it does not import host affine geometry, choice of a global inverse outside the displayed isometry graph, or ambient Banach completeness.

Definition 5194.1 (Mazur–Ulam isometry carrier)**.** *A* $\mathsf{MazurUlamIsometry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (E, F, G, M, A, H, C, P, N)$$

with the following displayed rows:

1. *E is the source* $\mathsf{NormedSpace}^{\uparrow}$ *row, exposing its* $\mathsf{VecSpace}^{\uparrow}$ *operations,* $\mathsf{Real}^{\uparrow}$ *scalar reads, norm row, induced* $\mathsf{Met}^{\uparrow}$ *distance row, transport, replay, provenance, and local naming.*
2. *F is the target* $\mathsf{NormedSpace}^{\uparrow}$ *row with the same displayed vector, scalar, norm, metric, transport, replay, provenance, and local naming surface.*
3. *G is the isometry graph row, recording accepted source histories, accepted target histories, distance equality through the metric rows of E, F, surjectivity by displayed target witnesses, and the distinguished basepoint pair used for translation.*
4. *M is the midpoint ledger, listing each accepted pair of source histories, the displayed source midpoint read, its graph image, the displayed target midpoint read of the two graph images, and the equality certificate connecting those target reads.*
5. *A is the affine-transport row, recording the translated map that sends the source basepoint to the target basepoint and preserving midpoint, dyadic convex, additive, and real-scalar reads through finite* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *ledgers.*
6. *H records componentwise* hsame *transport for E, F, G, M, A and the support rows.*
7. *C records displayed* Cont *replay for isometry inspection, midpoint requests, dyadic refinement, affine transport, and downstream Banach or operator-facing consumers.*

8. *P is the* Pkg *provenance over* $\mathsf{MazurUlamIsometry}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{MazurUlamIsometry}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, F, G, M, A, H, C, P, N$. It has no coordinate for host affine hulls, quotient point equality, selected inverse functions outside G, ambient Banach completion, or non-displayed scalar extensionality.

Lean4 (definition) `BEDC.Derived.MazurUlamIsometryUp.MazurUlamIsometryUp`
Lean4 ✓ `BEDC.Derived.MazurUlamIsometryUp.MazurUlamIsometryTasteGate single carrier alignment`

Theorem 5194.2 (Mazur–Ulam midpoint preservation)**.** *For every accepted* $\mathsf{MazurUlamIsometry}^{\uparrow}$ *carrier*

$$U = (E, F, G, M, A, H, C, P, N),$$

each midpoint read exported by the isometry graph G factors through the midpoint ledger M. Thus a consumer receives the source midpoint row, the two endpoint graph rows, the target midpoint row, and the displayed equality certificate as one finite packet, with no appeal to host convexity or undisplayed affine structure.

Lean4 ✓ `BEDC.Derived.MazurUlamIsometryUp.MazurUlamIsometryCarrier midpoint preservation`

Proof. Project the carrier of Definition 5194.1. The graph row G supplies the accepted source endpoints, their target images, and the metric equality data, while M is the only row whose coordinates mention midpoint comparison.

A midpoint request therefore cannot be answered by the graph alone. It must read the source midpoint through the $\mathsf{VecSpace}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows of E, read the target midpoint through the corresponding rows of F, and then use the equality certificate stored in M.

The transport and replay rows H, C preserve exactly this dependency. Since the carrier has no host affine-hull row, no ambient convexity coordinate, and no selected inverse outside G, the displayed midpoint ledger exhausts the midpoint-preservation surface. □

Theorem 5194.3 (Mazur–Ulam affine linearity)**.** *For every accepted* $\mathsf{MazurUlamIsometry}^{\uparrow}$ *carrier $U = (E, F, G, M, A, H, C, P, N)$, every affine read of the translated isometry factors through the affine-transport row A after the graph row G and midpoint ledger M have been displayed. The exported affine route consists of the basepoint translation, midpoint preservation, dyadic convex refinement, additivity readback, real-scalar readback, and componentwise transport through the same source and target normed carriers.*

Lean4 ✓ `BEDC.Derived.MazurUlamIsometryUp.MazurUlamAffineLinearity`

Proof. Begin with the basepoint pair in G. The translated map is a displayed graph read sending the chosen source basepoint to the chosen target basepoint; no separate inverse or host affine map is available in the carrier.

The midpoint step is supplied by M. Repeated midpoint inspection gives the dyadic convex ledger over the $\mathsf{Real}^{\uparrow}$ and $\mathsf{VecSpace}^{\uparrow}$ rows already visible in E and F.

The affine row A packages the remaining additivity and real-scalar readback. Its entries are typed over the same graph, midpoint, scalar, and vector-operation rows, so downstream consumers cannot replace the finite route by an ambient linearity theorem, a quotient equality of functions, or an external Banach-space completion. □

Theorem 5194.4 (Mazur–Ulam NameCert obligations)**.** *For every accepted* $\mathsf{MazurUlamIsometry}^{\uparrow}$ *carrier* $U = (E, F, G, M, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MazurUlamIsometry}^{\uparrow}}$ *surface consists exactly of source normed-carrier admission, target normed-carrier admission, isometry-graph exactness, midpoint-ledger preservation, affine-transport readback, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.MazurUlamIsometryUp.MazurUlamIsometryCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 5194.1. The only analytic rows are E, F, G, M, A, and the only structural rows are H, C, P, N.

The first two obligations expose the source and target normed-space data. These rows bind vector operations, real scalars, norms, and induced metrics before the isometry graph can be inspected.

Graph exactness is read from G, midpoint preservation from M, and affine transport from A. Each row depends on the preceding displayed rows, so the NameCert surface records a single route from isometry data to midpoint preservation and then to affine readback.

Finally H, C, P, N move, replay, source, and name the same packet. Since no carrier coordinate stores host affine geometry, an undisplayed inverse, quotient function equality, Banach completeness, or external scalar extensionality, the listed rows exhaust the local obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{MazurUlamIsometry}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MazurUlamIsometry}^{\uparrow}$ packet is generated from source and target NormedSpace rows, an isometry graph, a midpoint ledger, an affine-transport row, componentwise hsame transport, displayed replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MazurUlamIsometry}^{\uparrow}}$, seed)

Scope closed: Definition 5194.1, Definition 5194.2, Definition 5194.3, and Definition 5194.4 seed the finite Mazur–Ulam route over NormedSpace, Real, VecSpace, MetricSpace, and Banach-facing rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MazurUlamIsometry}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Banach completeness, inverse selection beyond the displayed graph, host affine geometry, quotient equality of maps, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source and target carrier admission, isometry-graph exactness, midpoint-ledger preservation, affine-transport readback, transport, replay, provenance, and local naming for the same finite packet.

Chapter 5195

A Concrete Naming Certificate for $\mathsf{RegularCauchyBinarySplitting}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyBinarySplitting}^{\uparrow}$ packet records the finite binary splitting route by which a regular Cauchy rational name is read at a dyadic tolerance, split into left and right finite windows, and sealed back into the $\mathsf{Real}^{\uparrow}$ boundary without selecting a host-real limit. It sits over the observation surface of chapter 126, the binary tolerance arithmetic of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives later interval, located-order, and completion consumers a displayed binary split schedule rather than a prose appeal to completeness or countable choice.

Definition 5195.1 (Regular Cauchy binary splitting carrier)**.** *A* $\mathsf{RegularCauchyBinarySplitting}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (W_0, W_1, D_0, D_1, R_0, R_1, A, \Sigma, H, C, P, N)$$

with the following displayed rows:

1. W_0 *and* W_1 *are the two finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected by the left and right branches of the split.*
2. D_0 *and* D_1 *are the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *binary tolerance cells. They record the requested dyadic precision, the branch radii, the midpoint comparison budget, and the remaining slack for recombination.*
3. R_0 *and* R_1 *are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows exposed from* W_0, W_1, D_0, D_1.
4. A *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after both windows, both tolerance cells, and both regular readbacks have been displayed.*
5. Σ *is the binary split schedule. It records the finite branch order, the midpoint comparison, the left-right recombination route, and the branch tag consumed by downstream interval or completion requests.*
6. H *records componentwise* hsame *transport for windows, tolerance cells, readbacks, the Real seal, split schedule, replay, provenance, and local naming.*
7. C *records displayed* Cont *replay from a Real or Completion request through* $W_0, W_1, D_0, D_1, R_0, R_1, A, \Sigma, H, P, N$.
8. P *is the* Pkg *provenance over* $\mathsf{RegularCauchyBinarySplitting}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyBinarySplitting}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W_0, W_1, D_0, D_1, R_0, R_1, A, \Sigma, H, C, P, N$. It has no coordinate for a selected real limit, quotient stream equality, countable choice, trichotomy, host located-order oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegularCauchyBinarySplittingUp.RegularCauchyBinarySplittingUp`
Lean4 ✓ `BEDC.Derived.RegularCauchyBinarySplittingUp.RegularCauchyBinarySplittingTasteGate`
`single carrier alignment`

Theorem 5195.2 (Regular Cauchy binary splitting NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyBinarySplitting}^{\uparrow}$ *carrier*

$$B = (W_0, W_1, D_0, D_1, R_0, R_1, A, \Sigma, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyBinarySplitting}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for two finite* $\mathsf{StreamName}^{\uparrow}$ *windows, two* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance cells, two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, one* $\mathsf{Real}^{\uparrow}$ *seal, one binary split schedule, transport, replay, provenance, and local naming;*
2. *window discipline, requiring W_0 and W_1 to be read before any branch readback or Real-facing seal row is available;*
3. *tolerance discipline, requiring D_0 and D_1 to expose the requested precision, branch radii, midpoint comparison budget, and recombination slack before the split schedule may be consumed;*
4. *readback discipline, requiring R_0 and R_1 to be produced from the displayed windows and tolerance cells rather than from a selected host limit;*
5. *schedule discipline, requiring Σ to record the branch order, midpoint comparison, recombination route, and branch tag before interval or completion consumers inspect the packet;*
6. *seal discipline, requiring A, H, C, P, N to export only the displayed split route and no selected real limit, quotient stream equality, countable choice, trichotomy, host located-order oracle, or ambient completeness row.*

No RegularCauchyBinarySplitting obligation is stored outside these rows.

Proof. Project the carrier of Definition 5195.1. The accepted tuple exposes exactly two finite windows, two dyadic tolerance cells, two regular rational readbacks, one Real seal, one split schedule, and the structural transport, replay, provenance, and naming rows.

The window and tolerance disciplines form the first stage of the route. The two windows W_0, W_1 and the two tolerance cells D_0, D_1 must be visible before any branch readback, midpoint comparison, or Real-facing row is available.

The readback and schedule disciplines form the constructive splitting stage. The rows R_0, R_1 are produced from the displayed windows and dyadic cells, while Σ records the branch order, midpoint comparison, recombination route, and downstream branch tag.

Finally A, H, C, P, N seal, transport, replay, source, and name the same route. Since selected real limits, quotient stream equality, countable choice, trichotomy, host located-order oracles, and ambient completeness are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 5195.3 (Regular Cauchy binary splitting Real-seal nonescape)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*, interval, located-order,* $\mathsf{Real}^{\uparrow}$*, or Completion consumer of an accepted* $\mathsf{RegularCauchyBinarySplitting}^{\uparrow}$ *carrier factors through the displayed route*

$$W_0, W_1 \longmapsto D_0, D_1 \longmapsto R_0, R_1 \longmapsto \Sigma \longmapsto A, H, C, P, N.$$

The consumer may read finite windows, dyadic binary tolerance cells, regular rational branch readbacks, the binary split schedule, the terminal Real seal, transport, replay, provenance, and local naming. It cannot replace that route by a selected real limit, quotient stream equality, countable choice, trichotomy, host located-order oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the accepted carrier $B = (W_0, W_1, D_0, D_1, R_0, R_1, A, \Sigma, H, C, P, N)$. The only observation data in the carrier are the two finite windows W_0, W_1, and the only tolerance data are the two dyadic cells D_0, D_1.

The regular readbacks R_0, R_1 are downstream of those rows. They expose branch values through finite StreamName windows and dyadic tolerance cells, not through a selected real representative.

The split schedule Σ is the only branch-order and recombination row. It records the midpoint comparison and downstream branch tag before any interval, located-order, Real, or Completion consumer may use the packet.

The Real seal A and the structural rows H, C, P, N preserve the same displayed route. The excluded limit, quotient, choice, trichotomy, oracle, and completeness coordinates are not present in the carrier, so they cannot escape through the seal. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyBinarySplitting}^{\uparrow}$ read exposes two $\mathsf{StreamName}^{\uparrow}$ windows, two $\mathsf{DyadicRatCore}^{\uparrow}$ binary tolerance cells, two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, one $\mathsf{Real}^{\uparrow}$ seal row, one binary split schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any Real or Completion consumer may inspect it.

Independence witness: streamname, dyadicratcore, regseqrat, real: $\mathsf{RegularCauchyBinarySplitting}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two finite windows, two binary tolerance cells, two regular readbacks, one Real seal, one branch schedule, transport, replay, provenance, and local naming in one L10 splitting packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyBinarySplitting}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyBinarySplitting}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5195.1, Definition 5195.2, and Definition 5195.3 seed the finite binary splitting route between displayed regular Cauchy rational reads and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyBinarySplitting}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected real limits, quotient stream equality, countable choice, trichotomy, host located order, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window discipline, binary tolerance exactness, branch readback stability, split schedule determinacy, Real-seal nonescape, and local naming for BEDC.Derived.RegularCauchyBinarySplittingU

Constructive story: A $\mathsf{RegularCauchyBinarySplitting}^{\uparrow}$ packet is generated from two finite $\mathsf{StreamName}^{\uparrow}$ windows, two $\mathsf{DyadicRatCore}^{\uparrow}$ binary tolerance cells, two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, one $\mathsf{Real}^{\uparrow}$ seal, one binary split schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5196

A Concrete Naming Certificate for $\mathsf{RieszInterpolation}^{\uparrow}$

Following Riesz and Kantorovich ordered-vector-lattice interpolation, the $\mathsf{RieszInterpolation}^{\uparrow}$ packet records the finite BEDC naming surface for lower-pair and upper-pair interpolation inside an ordered abelian source. It sits beside the ordered vector-lattice carrier of chapter 3620, the join-meet rows of chapter 55, the positive-cone boundary of chapter 2297, and the least-upper-bound consumer of chapter 3965. The packet names the interpolation witness route; it is not a host lattice-completion principle, a hidden supremum selector, or an ambient real-order oracle.

Definition 5196.1 (RieszInterpolation carrier)**.** *A* $\mathsf{RieszInterpolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (G, L, P, A, B, W, H, C, S, N)$$

with the following displayed rows:

1. *G is the ordered abelian or ordered-group source row, naming the carried additive endpoint, zero, inverse, addition ledger, order comparison, and order-compatibility evidence used by the interpolation request.*
2. *L is the lattice or order row, read through* $\mathsf{Lattice}^{\uparrow}$ *or* $\mathsf{RieszSpace}^{\uparrow}$*, recording the finite meet-join and order-refinement rows on the same endpoint as G.*
3. *P is the positive-cone row, read through* $\mathsf{PositiveCone}^{\uparrow}$*, exposing only the displayed nonnegative-difference tests used to compare lower, witness, and upper rows.*
4. *A is the lower-pair row, recording two lower bounds a_0, a_1 and their order relations against the upper pair inside the same ordered source.*
5. *B is the upper-pair row, recording two upper bounds b_0, b_1 and the displayed comparisons $a_i \leq b_j$ required before interpolation can be requested.*
6. *W is the interpolation witness row, naming a displayed point w with $a_0 \leq w$, $a_1 \leq w$, $w \leq b_0$, and $w \leq b_1$ through the positive-cone and lattice rows.*
7. *H records componentwise* hsame *transport for the ordered source, lattice row, positive-cone row, lower-pair row, upper-pair row, witness row, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from an interpolation request through G, L, P, A, B, W, H back to the same finite ordered surface.*

9. *S is the* Pkg *provenance row over* RieszInterpolation$^{\uparrow}$, RieszSpace$^{\uparrow}$, Lattice$^{\uparrow}$, PositiveCone$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RieszInterpolation}^{\uparrow}}$ *row binding the interpolation packet.*

The classifier compares accepted packets only through $G, L, P, A, B, W, H, C, S, N$. It has no coordinate for an external ordered group, a selected completion, a host supremum operation, or an ambient Real completeness proof.

Lean4 ✓ `BEDC.Derived.RieszInterpolationUp.RieszInterpolationTasteGate single carrier alignment`

Theorem 5196.2 (RieszInterpolation NameCert obligations)**.** *For every accepted* RieszInterpolation$^{\uparrow}$ *carrier $I = (G, L, P, A, B, W, H, C, S, N)$, the local* NameCert$_{\text{RieszInterpolation}^{\uparrow}}$ *surface consists exactly of carrier admission, ordered abelian or ordered-group source compatibility, lattice or order-row compatibility, positive-cone comparison, lower-pair display, upper-pair display, interpolation-witness display, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. A downstream* Real$^{\uparrow}$ *or completion-order-bound consumer may read the witness only along the displayed route*

$$G, L, P, A, B \longrightarrow W \longrightarrow H, C, S, N.$$

It receives no host metric completion, no hidden order quotient, no chosen supremum, and no additional Real-completeness coordinate.

Lean4 ✓ `BEDC.Derived.RieszInterpolationUp.RieszInterpolationCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 5196.1. The rows G, L, P expose the ordered source, lattice or Riesz-space order rows, and positive-cone comparison surface, while A and B display the lower and upper pairs for the interpolation request.

The witness row W is accepted only against those displayed comparisons. Its four inequalities are read through the positive-cone and lattice rows already carried by P and L, so the witness cannot be detached from the finite ordered-group source.

The structural rows H, C, S, N preserve the same route under classifier transport, continuation replay, provenance, package data, and local naming. Since the carrier has no coordinate for a host completion, quotient representative, chosen supremum, or ambient Real-completeness principle, every downstream order-bound consumer receives only the displayed interpolation witness surface. □

Closure status for NameCert$_{\text{RieszInterpolation}^{\uparrow}}$.

Constructive story: A RieszInterpolation$^{\uparrow}$ packet is generated from an ordered abelian or ordered-group source row, lattice or order rows, a positive-cone row, displayed lower and upper pairs, an interpolation witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RieszInterpolation}^{\uparrow}}$, seed)

Scope closed: Definition 5196.1 and Definition 5196.2 seed the finite interpolation certificate over RieszSpace$^{\uparrow}$, Lattice$^{\uparrow}$, PositiveCone$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows for later Real and completion order-bound consumers.

Formal verification: FormalStatus(NameCert$_{\text{RieszInterpolation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host ordered groups, selected suprema, metric completion, quotient representatives, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ordered-source compatibility, lattice or order-row compatibility, positive-cone comparison, lower-pair and upper-pair display, witness display, transport, replay, provenance, and local naming for BEDC.Derived.RieszInterpolationUp.

Chapter 5197

A Concrete Naming Certificate for $\mathsf{Wasserstein}^{\uparrow}$

Following Kantorovich and Villani on optimal transport, the $\mathsf{Wasserstein}^{\uparrow}$ packet names finite transport-plan rows between displayed probability or distribution packets over a metric source. It sits beside the metric carrier of chapter 57, the compact metric source of chapter 129, the probability packet of chapter 184, the distribution ledger of chapter 186, and the real-valued cost seal of chapter 38. The chapter records only the displayed transport-plan interface; it does not claim Monge maps, optimal plan existence, measure-theoretic completion, duality, or selected minimizers.

Definition 5197.1 (Wasserstein transport-plan carrier)**.** *A* $\mathsf{Wasserstein}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, K, \mu, \nu, \Gamma, A, B, C, H, R, P, N)$$

with the following visible rows:

1. *M is a displayed* $\mathsf{Met}^{\uparrow}$ *source, optionally strengthened by a* $\mathsf{CompactMetric}^{\uparrow}$ *finite-cover ledger K when the plan is read through compact support;*
2. *μ and ν are* $\mathsf{ProbSpace}^{\uparrow}$ *or* $\mathsf{Distribution}^{\uparrow}$ *marginal packets over displayed source rows of M;*
3. *Γ is a finite coupling support table whose entries name only listed source pairs and nonnegative displayed masses;*
4. *A and B are marginal-readback ledgers asserting that the finite row and column sums of Γ recover the displayed marginals μ and ν;*
5. *C is the transport-cost ledger through* $\mathsf{Real}^{\uparrow}$*, reading each support-pair cost from the metric row of M and summing it against the corresponding coupling entry;*
6. *H records componentwise* hsame *for the metric source, optional compact ledger, marginal packets, coupling entries, marginal ledgers, cost ledger, provenance, and local naming row;*
7. *R records displayed* Cont *replay routes from the metric and marginal rows to the coupling table, from the coupling table to the marginal ledgers, and from the cost ledger to the downstream real-valued consumer;*
8. *P is the* Pkg *provenance tying the metric, compact, probability, distribution, coupling, marginal-readback, and real-cost rows to their source packets;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{Wasserstein}^\uparrow}$ *row.*

The classifier compares accepted packets componentwise by hsame *on the listed rows. No coordinate stores an ambient measure completion, a quotient of plans, a Monge function, a dual certificate, or a selected optimizer.*

Theorem 5197.2 (Wasserstein NameCert obligations)**.** *For every accepted* $\mathsf{Wasserstein}^\uparrow$ *carrier*

$$W = (M, K, \mu, \nu, \Gamma, A, B, C, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Wasserstein}^\uparrow}$ *surface consists of five finite obligation rows:*

1. *carrier admission: the accepted object is exactly the displayed* BHist *packet with metric source, optional compact ledger, two marginal packets, finite coupling table, marginal-readback ledgers, real-valued cost ledger, transport, replay, provenance, and local naming rows;*
2. *marginal exactness: the ledgers A and B are the only marginal readbacks exported by the packet, and they recover μ and ν from finite sums of Γ;*
3. *finite coupling support: every coupling entry read by a consumer is indexed by a displayed source pair and carries a displayed nonnegative mass row;*
4. *transport-cost readback: the scalar cost exported to a* $\mathsf{Real}^\uparrow$ *consumer is the finite ledger C obtained from metric costs on the listed support pairs and the corresponding coupling entries;*
5. *provenance and name exhaustion:* hsame, Cont, Pkg, *and N preserve the same rows and introduce no Monge map, optimality witness, measure completion, dual certificate, or unlisted minimizer.*

Lean4 ✓ `BEDC.Derived.WassersteinUp.WassersteinCarrier namecert obligations`

Proof. Project the carrier of Definition 5197.1. Its visible coordinates are the metric source, optional compact ledger, two marginal packets, coupling support table, two marginal-readback ledgers, real-valued cost ledger, componentwise transport, replay, provenance, and local naming row.

The carrier admission row is therefore immediate from the displayed BHist packet. Marginal exactness is read from A and B: each ledger is attached to finite sums of Γ, so a consumer has no second route to a marginal outside the listed coupling table.

Finite coupling support follows by inspecting Γ. Every entry is indexed by a displayed support pair from the metric source, and transport by H preserves those indices componentwise rather than creating a quotient plan.

Finally read the cost ledger C through $\mathsf{Real}^\uparrow$. It sums only the metric costs named for listed support pairs against the visible coupling entries. The replay, provenance, and local naming rows preserve this same finite route, so the five obligation rows exhaust the Wasserstein transport-plan packet without adding Monge, optimality, completion, duality, or minimizer data. □

Theorem 5197.3 (Wasserstein metric coupling scope)**.** *Every accepted* $\mathsf{Wasserstein}^\uparrow$ *carrier* $W = (M, K, \mu, \nu, \Gamma, A, B, C, H, R, P, N)$ *exposes its coupling table* Γ *only over the displayed* $\mathsf{Met}^\uparrow$ *source M and, when present, the* $\mathsf{CompactMetric}^\uparrow$ *finite-cover row K. The structural rows H, R, P, N preserve the same metric and compact-source rows before any coupling entry is read, so the packet does not export an unlisted ambient metric space, quotient support, or optimizer carrier.*

Lean4 ✓ `BEDC.Derived.WassersteinUp.WassersteinMetricCouplingScope`

Proof. Project the carrier of Definition 5197.1. The rows M and K are the only source rows available before a coupling entry can be inspected.

The finite table Γ names entries by displayed source pairs. Since H transports those source rows componentwise and R replays routes from the metric and marginal rows to Γ, a consumer cannot retarget the table to a different metric source.

The provenance and local name rows P, N record the same finite route. Thus the metric coupling scope is exactly the displayed M, K, Γ, H, R, P, N surface, with no hidden support quotient or selected optimizer. □

Theorem 5197.4 (Wasserstein marginal exactness scope)**.** *For every accepted* $\mathsf{Wasserstein}^{\uparrow}$ *carrier* $W = (M, K, \mu, \nu, \Gamma, A, B, C, H, R, P, N)$*, the marginal packets* μ, ν *are read back from the finite coupling table only through the ledgers* A *and* B*. The rows* H, R, P, N *preserve the two marginal packets, the table* Γ*, and the readback ledgers together, so no consumer may replace marginal exactness by an ambient probability-space theorem, a detached distribution equality, or an unlisted coupling completion.*

Lean4 ✓ `BEDC.Derived.WassersteinUp.WassersteinMarginalExactnessScope`

Proof. Start with the marginal coordinates μ and ν. By the carrier definition they are the only $\mathsf{ProbSpace}^{\uparrow}$ or $\mathsf{Distribution}^{\uparrow}$ marginal packets named by W.

The readback ledgers A and B attach those marginals to finite row and column sums of Γ. Marginal exactness is therefore a displayed ledger assertion, not an external equality principle over all probability measures.

Finally inspect H, R, P, N. They transport, replay, source, and locally name the same marginal packets, coupling table, and readback ledgers. The scope is exhausted by $\mu, \nu, \Gamma, A, B, H, R, P, N$, so no ambient completion or detached distribution equality is available. □

Theorem 5197.5 (Wasserstein real cost readback scope)**.** *Every real-valued cost consumed from an accepted* $\mathsf{Wasserstein}^{\uparrow}$ *carrier* $W = (M, K, \mu, \nu, \Gamma, A, B, C, H, R, P, N)$ *is read through the displayed ledger* C*, which sums metric costs from* M *over listed support pairs of* Γ *and then hands the scalar to the* $\mathsf{Real}^{\uparrow}$ *consumer. The structural rows* H, R, P, N *keep* C *attached to* $M, K, \mu, \nu, \Gamma, A, B$*, so the packet does not assert Kantorovich duality, optimal value existence, selected minimizers, or an ambient real-completeness principle.*

Proof. Read the cost row C after the metric and coupling rows have been displayed. Its summands are metric costs from M on listed support pairs of Γ multiplied by the corresponding coupling entries.

The marginal rows μ, ν and ledgers A, B stay in scope because they determine which finite table is being costed. The optional compact row K may constrain the source route, but it does not add a selected optimal plan.

The rows H, R, P, N preserve this same cost ledger before it reaches the $\mathsf{Real}^{\uparrow}$ consumer. Hence the cost readback scope is finite and displayed; duality, optimizer existence, minimizer selection, and ambient real completeness remain outside the carrier. □

Lean4 ✓ `BEDC.Derived.WassersteinUp.WassersteinRealCostReadbackScope`

Theorem 5197.6 (Wasserstein finite coupling obligation surface)**.** *For every accepted* $\mathsf{Wasserstein}^{\uparrow}$ *carrier* $W = (M, K, \mu, \nu, \Gamma, A, B, C, H, R, P, N)$*, every coupling entry exposed to a consumer is one of the displayed rows of* Γ*, every marginal read is routed through* A *and* B*, and every cost read is routed through* C*. The structural rows* H, R, P, N *preserve that same finite route from metric*

source and optional compact support through marginal exactness and real-valued cost readback. Thus the packet exports no Monge map, optimizer, dual certificate, ambient measure completion, or selected minimizer.

Proof. Project the displayed carrier of Definition 5197.1. The only coupling-support coordinate is Γ, so each accepted coupling entry is indexed by a visible source pair and mass row already named by the packet.

Apply the NameCert obligations of Definition 5197.2, the metric coupling scope of Definition 5197.3, and the marginal exactness scope of Definition 5197.4. These identify A and B as the only marginal readback ledgers and keep the table attached to M, K, μ, ν.

Finally use the real cost readback scope of Definition 5197.5. The row C is the only exported cost ledger, and H, R, P, N only transport, replay, source, and name the same finite route. Since no carrier coordinate stores a Monge map, optimizer, dual certificate, ambient measure completion, or selected minimizer, the finite support and provenance rows exhaust the Wasserstein obligation surface. □

Lean4 ✓ `BEDC.Derived.WassersteinUp.WassersteinFiniteCouplingObligationSurface`

Theorem 5197.7 (Wasserstein transport-plan public route)**.** *Every public Wasserstein read of an accepted carrier $W = (M, K, \mu, \nu, \Gamma, A, B, C, H, R, P, N)$ factors through the displayed* $\mathsf{Met}^{\uparrow}$ *source M, the optional* $\mathsf{CompactMetric}^{\uparrow}$ *row K, the two* $\mathsf{ProbSpace}^{\uparrow}$ *or* $\mathsf{Distribution}^{\uparrow}$ *marginal rows μ, ν, the finite coupling table Γ, the marginal ledgers A, B, the* $\mathsf{Real}^{\uparrow}$ *cost ledger C, componentwise* hsame *transport H, displayed* Cont *replay R,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{Wasserstein}^{\uparrow}}$ *row N. The route exports no Monge map, optimizer, Kantorovich duality certificate, measure completion, or selected minimizer.*

Proof. Start with the NameCert obligations of Definition 5197.2. They make carrier admission, marginal exactness, finite coupling support, cost readback, and provenance exhaustion the complete local certificate surface.

Next apply metric coupling scope and marginal exactness scope, Definition 5197.3 and Definition 5197.4. The table Γ stays attached to M, K, μ, ν, and the only marginal reads are the finite ledgers A and B.

Finally use real cost readback scope and the finite coupling obligation surface, Definition 5197.5 and Definition 5197.6. They keep C as the sole Real-valued cost route and force H, R, P, N to preserve the same displayed packet, so the public read has no hidden optimizer, dual object, completion, Monge map, or selected minimizer. □

Lean4 ✓ `BEDC.Derived.WassersteinUp.WassersteinTransportPlanPublicRoute`

Closure status for $\mathsf{NameCert}_{\mathsf{Wasserstein}^{\uparrow}}$.

Constructive story: A $\mathsf{Wasserstein}^{\uparrow}$ packet is generated from a metric source, optional compact ledger, two displayed probability or distribution marginals, a finite coupling support table, marginal-readback ledgers, a real-valued transport-cost ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Wasserstein}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 5197.1, Definition 5197.2, Definition 5197.3, Definition 5197.4, and Definition 5197.5 close the finite transport-plan carrier, NameCert obligation surface, metric coupling scope, marginal exactness scope, and Real cost readback scope for Wasserstein-style metric coupling packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Wasserstein}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.WassersteinUp.WassersteinTransportPlanPublicRoute`

Bridge status: none

Not claimed: This chapter does not close Monge maps, optimal plan existence, measure-theoretic completion, Kantorovich duality, choice-selected minimizers, Lean verification, or bridge checking.

Upgrade path: Lean verification requires checked carrier admission, marginal exactness, finite coupling support, transport-cost readback, provenance exhaustion, and TasteGate nontriviality with field faithfulness for BEDC.Derived.WassersteinUp.

The CauchyProductRegSeq$^{\uparrow}$ hub routes the product-regularity carrier through the projection sibling of chapter 2076 while keeping the body in the child files below.

Chapter 5198

A Concrete Naming Certificate for $\mathsf{CauchyProductRegSeq}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy sequences and finite product constructions, the $\mathsf{CauchyProductRegSeq}^{\uparrow}$ packet records the componentwise product of two regular Cauchy rational names as finite BEDC data. It consumes the finite stream windows of chapter 126, the regular rational readbacks of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name boundary of chapter 38, and the finite product carrier of chapter 34. The downstream projection route of chapter 2076 reads this product-regularity packet before exporting component readbacks to Real algebra consumers. The packet supplies a product-regularity source for later Real algebra and product-metric routes without invoking quotient streams, selected limits, host real equality, countable choice, or Real completeness.

Definition 5198.1 (CauchyProductRegSeq carrier)**.** *A* $\mathsf{CauchyProductRegSeq}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S_0, S_1, R_0, R_1, D, P, H, C, Q, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows inspected from the component regular names.*
2. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from those windows.*
3. D *is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for both component reads and for the product-window budget.*
4. P *is the* $\mathsf{Prod}^{\uparrow}$ *product row pairing the two readbacks at the displayed dyadic precision.*
5. H *stores componentwise* hsame *transport for both stream windows, both regular readbacks, the dyadic ledger, the product row, replay, provenance, and local naming.*
6. C *stores the displayed* Cont *replay from* S_0, S_1 *through* R_0, R_1, D *into the product row* P *and the product regular-sequence boundary.*
7. Q *is the* Pkg *provenance over* $\mathsf{CauchyProductRegSeq}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductRegSeq}^{\uparrow}}$ *row.*

The accepted packet stores only this shared finite tolerance route. It does not identify streams by quotient equality, select a product limit, call on host real multiplication, use countable choice, or appeal to ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5198.2 (CauchyProductRegSeq regularity)**.** *Let*

$$K = (S_0, S_1, R_0, R_1, D, P, H, C, Q, N)$$

be an accepted $\mathsf{CauchyProductRegSeq}^{\uparrow}$ *packet. If the component windows* S_0, S_1 *are read back by* R_0, R_1 *as regular rational names and the dyadic budget* D *is shared by the two component reads and the product row* P*, then the packet exposes a product regular-sequence route through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{Prod}^{\uparrow}$*. Every product-regularity consumer is exhausted by* $S_0, S_1, R_0, R_1, D, P, H, C, Q, N$ *before any product seal is exported.*

In particular, the route exports no quotient stream equality, selected limit, host real equality, countable-choice selector, independent Real product carrier, or ambient Real completeness witness.

Proof. Project the carrier of Definition 5198.1. The two StreamName rows S_0, S_1 are the only observation windows available to the consumer, and the two RegSeqRat rows R_0, R_1 are the only regular rational readbacks obtained from them.

Next read the shared dyadic ledger D. Because both component readbacks and the product row P use this same finite tolerance data, the product regularity request remains on one displayed budget route rather than splitting into independent ambient Real names.

The product row P then pairs the two regular readbacks through the finite product surface of chapter 34. The transport row H and replay row C preserve the componentwise regularity data under displayed hsame and Cont moves, while the provenance row Q and local name N record exactly the sibling surfaces cited by the packet.

Since no listed row contains a quotient stream, a selected limit, a host equality test, a choice functional, a detached Real product carrier, or an ambient completeness principle, no product-regularity consumer can read such data from the accepted packet. □

Theorem 5198.3 (CauchyProductRegSeq sibling route)**.** *Every accepted product-regularity read for a* $\mathsf{CauchyProductRegSeq}^{\uparrow}$ *packet factors through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Prod}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *in the row order displayed by Definition 5198.1. The shared dyadic ledger* D *is the only tolerance budget visible to product consumers.*

In particular, the sibling route exports no quotient streams, selected product limits, host multiplication, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier $K = (S_0, S_1, R_0, R_1, D, P, H, C, Q, N)$ from Definition 5198.1. The product consumer first sees the two $\mathsf{StreamName}^{\uparrow}$ windows S_0, S_1, then the two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks R_0, R_1, and then the single $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D.

Apply Definition 5198.2. The product row P is reached only after the shared ledger has bounded both component reads, and the $\mathsf{Real}^{\uparrow}$ seal is read through the displayed regularity route rather than through an ambient completeness principle.

The remaining rows H, C, Q, N transport, replay, source, and name that same route. Since no other tolerance row is displayed, D is the only budget available to product consumers, and none of quotient streams, selected limits, host multiplication, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness is exported. □

Theorem 5198.4 (CauchyProductRegSeq tail product bound)**.** *For every accepted* $\mathsf{CauchyProductRegSeq}^{\uparrow}$ *carrier*

$$K = (S_0, S_1, R_0, R_1, D, P, H, C, Q, N),$$

any product-tail consumer must display both input $\mathsf{StreamName}^{\uparrow}$ *windows* S_0, S_1*, both* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks* R_0, R_1*, the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D *in its two component-read roles, and the finite product row* P *before any* $\mathsf{Real}^{\uparrow}$*-facing product seal is read. The bound is consumed through the* $\mathsf{Prod}^{\uparrow}$ *sibling surface and the sibling route of Definition 5198.3; it exports no quotient streams, selected limits, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The windows S_0, S_1 display the inspected component tails, the readbacks R_0, R_1 expose the regular rational data, and the shared tolerance ledger D records the finite dyadic budget available to the product-tail consumer.

Apply the regularity theorem Definition 5198.2. Each component read must remain a displayed $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ route controlled by the shared dyadic tolerance data before it can contribute to the product row.

Route the pair through the $\mathsf{Prod}^{\uparrow}$ sibling surface. The finite product row P is therefore reached only after both windows, both readbacks, and the shared tolerance ledger remain visible.

Finally use the sibling route theorem Definition 5198.3. It keeps the product read inside the displayed route before H, C, Q, N are consumed, so no quotient stream, selected limit, countable-choice selector, host real equality, or ambient completeness witness is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductRegSeq}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyProductRegSeq}^{\uparrow}$ packet is generated from two StreamName finite windows, two RegSeqRat readbacks, one shared DyadicRatCore tolerance ledger, a finite product row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyProductRegSeq}^{\uparrow}}$, seed)

Scope closed: Definition 5198.1 and Definition 5198.2 seed the finite product route for two regular Cauchy rational names over shared dyadic tolerance data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyProductRegSeq}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host real multiplication, quotient equality of streams, selected product limits, countable choice, independent Real product completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, componentwise regularity transport, product-budget conservation, and Real-seal nonescape for the displayed packet.

Theorem 5198.5 (CauchyProductRegSeq product projection crosslink)**.** *Every downstream projection route through chapter 2076 must first read the shared* $\mathsf{CauchyProductRegSeq}^{\uparrow}$ *product-regularity packet*

$$S_0, \quad S_1, \quad R_0, \quad R_1, \quad D, \quad P, \quad H, \quad C, \quad Q, \quad N$$

displayed in Definition 5198.1. The projection consumer may expose a left or right component readback only after this packet has supplied the two finite stream windows, two regular rational readbacks, shared dyadic tolerance ledger, finite product row, componentwise transport, replay, provenance, and local naming.

Consequently, the projection route adds no quotient streams, selected product limits, host multiplication, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle to the product-regularity source.*

Proof. Project the accepted $\mathsf{CauchyProductRegSeq}^{\uparrow}$ carrier through Definition 5198.1. Its rows $S_0, S_1, R_0, R_1, D, P, H, C, Q, N$ are the only product-regularity data available before a downstream component projection is considered.

Now read the carrier of Definition 2076.1. The projection packet names component readbacks, product-modulus accounting, finite windows, dyadic tolerances, regular rational handoffs, sealing, transport, replay, provenance, and local naming, but its component-facing route is downstream of the already displayed product packet.

Thus every projection consumer factors through the shared product-regularity packet before selecting the left or right readback route. Since neither carrier contains quotient streams, selected product limits, host multiplication, countable choice, or an ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate, the crosslink exports none of that data. $\square$

Chapter 5199

A Concrete Naming Certificate for $\mathsf{OsgoodUniqueness}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Osgood's uniqueness criterion for ordinary differential equations, the $\mathsf{OsgoodUniqueness}^{\uparrow}$ packet records the finite modulus ledger needed to separate constructive uniqueness from a Lipschitz or contraction hypothesis. It sits after the local initial-data surface of chapter 3979, the ODE row of chapter 193, the Picard handoff of chapter 1888, the contraction neighbour of chapter 5867, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names an Osgood-style integral divergence budget as displayed BEDC data; it is not a host Lipschitz constant, a Banach contraction theorem, a selected solution representative, or quotient equality of solution curves.

Definition 5199.1 (OsgoodUniqueness carrier)**.** *An* $\mathsf{OsgoodUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, I, F, M, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{Ode}^{\uparrow}$ *source row, recording the differential equation, state window, and time window read by the uniqueness request.*
2. *I is the initial-data row, carrying the common initial time and initial* $\mathsf{Real}^{\uparrow}$ *state for the two compared solution traces.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *vector-field row, read as a displayed continuous map on the same ODE window rather than as a host function.*
4. *M is the Osgood modulus ledger, listing dyadic positive radii, comparison budgets, and the finite divergence checks consumed by the uniqueness argument.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare distances, radii, and accumulated modulus budgets.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the two solution-distance traces inspected by the packet.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, I, F, M, Q, R have been displayed.*
8. *H records componentwise* hsame *transport for the ODE row, initial data, continuous-map row, modulus ledger, dyadic row, regular readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from the Osgood uniqueness request through the ODE, initial-data, vector-field, modulus, dyadic, regular-rational, and Real-seal rows.*
10. *P is the* Pkg *provenance over* $\mathsf{OsgoodUniqueness}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{OsgoodUniqueness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, I, F, M, Q, R, E, H, C, P, N$. It has no coordinate for a Lipschitz constant, a contraction ratio, selected solution representatives, quotient equality of curves, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.OsgoodUniquenessUp.OsgoodUniquenessTasteGate single carrier alignment`

Theorem 5199.2 (OsgoodUniqueness NameCert obligations)**.** *For every accepted* $\mathsf{OsgoodUniqueness}^{\uparrow}$ *carrier*

$$U = (D, I, F, M, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OsgoodUniqueness}^{\uparrow}}$ *surface consists exactly of carrier admission, ODE-window visibility through D, common initial-data visibility through I, continuous vector-field readback through F, Osgood modulus accounting through M, dyadic tolerance exactness through Q, regular rational distance readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

These obligations bind the uniqueness route without adding a Lipschitz constant, a contraction ratio, a host fixed-point theorem, selected solution representatives, quotient equality of curves, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5199.1. The displayed rows $D, I, F, M, Q, R, E, H, C, P, N$ are the entire local surface, so carrier admission is exactly the admission of those rows.

The ODE and initial data are read first. The row D supplies the differential equation and local window, while I records the common initial time and initial real state. Thus the two solution traces are compared only inside one displayed initial-value surface.

The vector-field and modulus data are then consumed. The row F exposes continuity through $\mathsf{ContinuousMap}^{\uparrow}$, and the row M records the Osgood modulus ledger: dyadic radii, comparison budgets, and the finite checks that witness the divergence barrier used by the uniqueness argument.

The readback and seal rows are downstream. The row Q fixes the dyadic tolerance arithmetic, R reads the compared solution-distance traces as $\mathsf{RegSeqRat}^{\uparrow}$ data, and E exposes the terminal $\mathsf{Real}^{\uparrow}$ boundary only after those rows are present. Since no carrier coordinate stores a Lipschitz constant, contraction ratio, selected solution, quotient curve equality, countable-choice schedule, or ambient completeness theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 5199.3 (OsgoodUniqueness non-Lipschitz route)**.** *Every uniqueness-facing consumer of an accepted* $\mathsf{OsgoodUniqueness}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Ode}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ M,\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

as displayed by Definition 5199.1. The route supplies an Osgood modulus ledger for comparing solution traces; it does not export a Lipschitz constant, a Banach contraction certificate, a selected solution representative, or quotient equality between curves.

Proof. Begin with the common ODE surface. The rows D and I bind the equation, time window, state window, and common initial data before any solution-distance comparison is admitted.

Next read the vector-field and Osgood ledger. The continuous-map row F gives the displayed continuity route, while M records the finite modulus budgets consumed by the Osgood comparison. This is the analytic distinction from the contraction packets: the certificate reads a divergence ledger, not a strict contraction ratio.

Finally pass through dyadic tolerance, regular rational readback, and the terminal Real seal. The rows Q, R, E expose only the displayed distance comparisons and Real-facing boundary, and H, C, P, N transport, replay, source, and name the same finite route. Hence the accepted read remains an Osgood uniqueness packet rather than a Lipschitz or contraction theorem. □

Falsifiable prediction: An accepted $\mathsf{OsgoodUniqueness}^{\uparrow}$ uniqueness read that reaches $\mathsf{RegSeqRat}^{\uparrow}$ distance readback or a $\mathsf{Real}^{\uparrow}$ seal without displaying the rows $D, I, F, M, Q, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: ode, initial-value-problem, picard-lindelof, bishop-interval-contraction, regseqrat, dyadicratcore, real: no listed sibling supplies the joint packet containing an ODE source, common initial data, ContinuousMap vector-field readback, Osgood modulus ledger, dyadic tolerance arithmetic, regular rational distance readback, Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{OsgoodUniqueness}^{\uparrow}}$.

Constructive story: An $\mathsf{OsgoodUniqueness}^{\uparrow}$ packet is generated from an ODE source row, common initial data, a ContinuousMap vector-field row, an Osgood modulus ledger, DyadicRatCore tolerance arithmetic, RegSeqRat distance readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{OsgoodUniqueness}^{\uparrow}}$, seed)

Scope closed: Definition 5199.1, Definition 5199.2, and Definition 5199.3 seed the finite Osgood uniqueness route from displayed ODE data and continuous vector-field rows through modulus accounting, dyadic tolerance arithmetic, regular readback, and the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{OsgoodUniqueness}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, Lipschitz uniqueness, Banach contraction, selected solution representatives, quotient equality of curves, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, ODE-window visibility, common initial-data visibility, continuous-map readback, Osgood modulus accounting, dyadic tolerance exactness, regular readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.OsgoodUniquenessUp.

Chapter 5200

A Concrete Naming Certificate for $\mathsf{GromovHausdorffDistance}^{\uparrow}$

Following Gromov and Burago–Burago–Ivanov, the $\mathsf{GromovHausdorffDistance}^{\uparrow}$ packet records the scalar comparison distance between two compact metric BEDC names as finite correspondence, distortion, and provenance data. It sits after the metric carrier of chapter 57, the compact metric surface of chapter 129, the scalar compact-subset route of chapter 3653, the finite correspondence comparison of chapter 2104, and the compact hyperspace surface of chapter 5184. The scalar distance carrier consumes $\mathsf{Met}^{\uparrow}$ distances and $\mathsf{CompactMetric}^{\uparrow}$ finite-net rows before comparing through $\mathsf{HausdorffDistance}^{\uparrow}$, $\mathsf{GromovHausdorff}^{\uparrow}$ correspondences, and $\mathsf{CompactMetricHyperspace}^{\uparrow}$ packaging. The compact-subset scalar comparison row of chapter 3653 and the compact-hyperspace packaging of chapter 5184 are consumed before the Gromov–Hausdorff distance row is public. The packet names an inspectable distance bound for compact metric comparison; it is not a quotient metric space, a selected optimal correspondence, a choice principle over covers, or an ambient completion theorem.

Before any distance-between-spaces read is exposed, the packet opens the endpoint $\mathsf{Met}^{\uparrow}$ distance rows of chapter 57 and then a compact finite-net witness route such as the interval-cell finite-net discipline of chapter 5966. Thus the scalar comparison is attached to displayed metric distances and finite-net witnesses before the correspondence and distortion rows are read.

The distance packet is also a downstream consumer of the compact metric finite-net route of chapter 129 and the $\mathsf{HausdorffDistance}^{\uparrow}$ scalar comparison route of chapter 3653. The $\mathsf{GromovHausdorffDistance}^{\uparrow}$ row cannot be read before the compact metric endpoint rows and the Hausdorff scalar comparison rows are both displayed, because its finite correspondence and distortion ledger compare only those already public surfaces.

Definition 5200.1 (Gromov–Hausdorff distance carrier)**.** *A* $\mathsf{GromovHausdorffDistance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (X, Y, R, D, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are* $\mathsf{CompactMetric}^{\uparrow}$ *endpoint carriers, each exposing its* $\mathsf{Met}^{\uparrow}$ *distance rows, compact finite-net rows, and local compact-metric NameCert data before any cross-endpoint comparison is public.*

2. *R is the finite correspondence data between the endpoint point-name surfaces, including the two projection coverage ledgers and the inhabitedness rows needed for a correspondence read.*

3. *D is the dyadic distortion bound, recording a displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance for every pair of finite correspondence rows and the symmetric comparison budget induced by those rows.*

4. *H records the* hsame *transport rows that keep the endpoint carriers, correspondence rows, dyadic distortion ledger, replay row, provenance row, and local name attached under accepted renamings.*

5. *C records displayed* Cont *replay of the route*

$$X, Y \longmapsto R \longmapsto D \longmapsto H.$$

6. *P is the* Pkg *provenance over* $\mathsf{GromovHausdorffDistance}^{\uparrow}$, $\mathsf{GromovHausdorff}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{HausdorffDistance}^{\uparrow}$, $\mathsf{CompactMetricHyperspace}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

7. *N is the local* $\mathsf{NameCert}_{\mathsf{GromovHausdorffDistance}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through X, Y, R, D, H, C, P, N. It has no coordinate for quotient metric spaces, selected optimal correspondences, choice over covers, ambient completions, host isometry classes, or completed hyperspace points.

Theorem 5200.2 (Gromov–Hausdorff distance NameCert obligations)**.** *For every accepted* GromovHausdorffDistan *carrier*

$$Z = (X, Y, R, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GromovHausdorffDistance}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the compact metric endpoints X, Y, finite correspondence data R, dyadic distortion bound D, transport row H, replay row C, provenance row P, and local name N;*

2. *correspondence stability, requiring the projection coverage and inhabitedness rows in R to remain attached to the same two compact metric endpoints under the transport row H;*

3. *distortion symmetry, requiring the dyadic bound D to compare both endpoint distance reads for every displayed pair of correspondence rows with the same tolerance budget;*

4. *triangle composition by correspondence composition, requiring composed comparison reads to concatenate the finite correspondence tables and add their displayed dyadic distortion budgets before a downstream consumer reads the result;*

5. *ledger refusal, requiring C, P, N to replay, source, and name only the displayed finite route and to export no quotient metric space, selected optimal correspondence, choice over covers, ambient completion, host isometry class, or completed hyperspace point.*

No Gromov–Hausdorff distance obligation is stored outside these rows.

Proof. Project the carrier of Definition 5200.1. The endpoint rows X, Y are the only compact metric sources, and the rows R, D, H, C, P, N are the entire comparison surface attached to them.

Carrier admission is therefore the admission of those displayed rows. The correspondence stability row is read from R together with H, because the projection ledgers and inhabitedness witnesses are transported only as rows over the same two endpoints.

The distortion symmetry row is read from D. Each finite pair of correspondence rows triggers two endpoint distance reads, and the same dyadic tolerance ledger bounds the two directed comparisons.

For triangle composition, compose the finite correspondence tables by their shared middle endpoint and add the two displayed dyadic distortion ledgers. The result is again a finite table with a displayed tolerance budget, so the composed comparison remains inside the same carrier discipline.

Finally C, P, N replay, source, and name the route. Since the carrier has no coordinate for quotient metric spaces, selected optimal correspondences, choice over covers, ambient completions, host isometry classes, or completed hyperspace points, the listed rows exhaust the local NameCert obligations. □

Theorem 5200.3 (Gromov–Hausdorff distance compact-metric handoff)**.** *Every* $\mathsf{Met}^{\uparrow}$*-,* $\mathsf{CompactMetric}^{\uparrow}$*-,* $\mathsf{HausdorffDistance}^{\uparrow}$*-,* $\mathsf{GromovHausdorff}^{\uparrow}$*-, or* $\mathsf{CompactMetricHyperspace}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{GromovHausdorffDistance}^{\uparrow}$ *packet factors through the finite route*

$$X, Y \longmapsto R \longmapsto D \longmapsto H, C, P, N.$$

Thus the consumer receives only displayed compact metric endpoints, finite correspondence rows, a dyadic distortion bound, transport, replay, provenance, and a local name. It cannot derive a quotient metric space, selected optimal correspondence, choice over covers, ambient completion, host isometry class, or completed hyperspace point from the packet.

Proof. Start with the compact metric endpoints. A metric or compact metric consumer can inspect only X and Y, so every distance read is anchored in displayed endpoint rows.

Next read the correspondence and distortion rows. The finite table R supplies the cross-endpoint pairs and coverage witnesses, while D supplies the dyadic distortion budget attached to exactly that table.

The sibling handoffs are downstream. A Hausdorff-distance, Gromov–Hausdorff comparison, or compact-hyperspace consumer may cite the route only after the finite correspondence and distortion rows have been displayed.

The structural rows H, C, P, N preserve, replay, source, and name the same route. Because no additional coordinate is present, the handoff cannot export a quotient metric object, selected optimum, cover choice, ambient completion, host isometry class, or completed hyperspace point. □

Theorem 5200.4 (Gromov–Hausdorff distance compact metric route)**.** *Every public distance comparison read from an accepted* $\mathsf{GromovHausdorffDistance}^{\uparrow}$ *packet factors through the compact metric dependency route displayed in the chapter introduction. The read first opens the* $\mathsf{Met}^{\uparrow}$ *distance rows of the two endpoints, then the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net coverage rows, then the* $\mathsf{HausdorffDistance}^{\uparrow}$ *scalar comparison surface, then the* $\mathsf{GromovHausdorff}^{\uparrow}$ *finite correspondence rows, then the* $\mathsf{CompactMetricHyperspace}^{\uparrow}$ *packaging rows, and finally the local* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}_{\mathsf{GromovHausdorffDistance}^{\uparrow}}$ *rows of the distance packet. Thus the public comparison is a finite compact-metric route, not a quotient metric space, selected optimal correspondence, choice over covers, ambient completion, host isometry class, or completed hyperspace point.*

Proof. Start with the dependency list in the introduction. It orders the packet after the Metric, CompactMetric, HausdorffDistance, GromovHausdorff, and CompactMetricHyperspace surfaces, so a public scalar comparison must expose those rows before the local distance packet can be read.

Apply the NameCert obligations of Definition 5200.2. The carrier admission, correspondence stability, distortion symmetry, triangle-composition, and ledger-refusal rows say that the local certificate is exhausted by compact metric endpoints, finite correspondences, dyadic distortion data, transport, replay, provenance, and the local name.

Now use the compact-metric handoff theorem, Definition 5200.3. It identifies every sibling-facing consumer with the finite route

$$X, Y \longmapsto R \longmapsto D \longmapsto H, C, P, N.$$

Combining these readings gives the stated compact metric dependency route. Since none of the listed rows contains quotient metric spaces, selected optimal correspondences, cover choice, ambient completions, host isometry classes, or completed hyperspace points, no public distance comparison can obtain such data from the packet. □

Falsifiable prediction: An accepted $\mathsf{GromovHausdorffDistance}^{\uparrow}$ distance read that exposes a scalar comparison without first displaying X, Y, R, D, H, C, P, N refutes the carrier surface.

Independence witness: metric, compactmetric, hausdorff-distance, gromov-hausdorff, compact-metric-hyperspace: no listed sibling jointly carries two compact metric endpoints, finite correspondence data, dyadic distortion bounds, triangle composition by correspondence composition, transport, replay, provenance, and local NameCert rows for a scalar Gromov–Hausdorff distance interface.

Closure status for $\mathsf{NameCert}_{\mathsf{GromovHausdorffDistance}^{\uparrow}}$.

Constructive story: A $\mathsf{GromovHausdorffDistance}^{\uparrow}$ packet is generated from two CompactMetricUp endpoint carriers, finite correspondence data, a DyadicRatCore distortion bound, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GromovHausdorffDistance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5200.1, Definition 5200.2, and Definition 5200.3 seed the finite scalar comparison route from compact metric endpoint certificates through correspondences and dyadic distortion bounds.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GromovHausdorffDistance}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient metric spaces, selected optimal correspondences, choice over covers, ambient completions, host isometry classes, completed hyperspace points, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, correspondence stability, distortion symmetry, triangle composition by correspondence composition, and ledger refusal for BEDC.Derived.GromovHausdorffDistanceUp.

The hub-level $\mathsf{GromovHausdorffDistance}^{\uparrow}$ route is read through chapter 57, chapter 129, chapter 3653, chapter 2104, and chapter 5184 before any child file exposes the local scalar distance packet. Every $\mathsf{GromovHausdorffDistance}^{\uparrow}$ correspondence and distortion read consumes $\mathsf{Met}^{\uparrow}$ distance rows together with compact or finite-net rows from chapter 57 and chapter 129 before it can export a distance comparison. The route therefore treats metric distance, compact coverage, finite-net inspection, transport, replay, provenance, and local naming as prerequisites of the public Gromov–Hausdorff distance surface, not as consequences of the distance comparison itself.

Theorem 5200.5 (Gromov–Hausdorff distance metric anchor)**.** *Every* $\mathsf{GromovHausdorffDistance}^{\uparrow}$ *read first exposes the* $\mathsf{Met}^{\uparrow}$ *distance witness of each endpoint and the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-source rows before any correspondence table or distortion comparison is consumed. Thus the local scalar comparison is anchored in displayed metric distance and compact finite-source data, not in a quotient metric space, selected optimal correspondence, cover choice, ambient completion, host isometry class, or completed hyperspace point.*

Proof. Start with the endpoint rows X, Y of Definition 5200.1. Each endpoint is a compact metric carrier, so its metric distance witness and finite-source compact rows are displayed before the local correspondence row R can be read.

Apply the compact-metric route of Definition 5200.4. It orders public comparison reads through the Metric, CompactMetric, HausdorffDistance, GromovHausdorff, and CompactMetricHyperspace surfaces before the local rows H, C, P, N are consumed.

Finally use the metric-correspondence dependency of Definition 5200.6. Since the finite correspondence table and dyadic distortion ledger compare only already displayed endpoint distances and compact finite-source rows, no accepted Gromov–Hausdorff distance read can bypass the metric anchor. □

Theorem 5200.6 (Gromov–Hausdorff metric-correspondence dependency)**.** *Any* $\mathsf{GromovHausdorffDistance}^{\uparrow}$ *scalar read first consumes the sibling dependency route through* $\mathsf{Met}^{\uparrow}$ *endpoint distances,* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net rows,* $\mathsf{GromovHausdorff}^{\uparrow}$ *finite correspondence rows,* $\mathsf{HausdorffDistance}^{\uparrow}$ *distortion comparison, and* $\mathsf{CompactMetricHyperspace}^{\uparrow}$ *packaging before the local distance packet exports*

$$X, \quad Y, \quad R, \quad D, \quad H, \quad C, \quad P, \quad N.$$

Thus the scalar route is a finite compact-metric and correspondence ledger: endpoint metrics and finite nets are visible before correspondence distortion is compared, hyperspace packaging is downstream of that comparison, and the local $\mathsf{GromovHausdorffDistance}^{\uparrow}$ *packet exports only the displayed rows.*

Proof. Start with the carrier of Definition 5200.1. Its endpoint rows X, Y expose compact metric data, so every scalar distance read begins with the underlying $\mathsf{Met}^{\uparrow}$ distance rows and $\mathsf{CompactMetric}^{\uparrow}$ finite-net rows.

Apply the NameCert obligations of Definition 5200.2. The correspondence stability and distortion symmetry rows force the read through the finite correspondence table R and dyadic distortion ledger D before any local scalar export is available.

Finally use the compact-metric handoff theorem Definition 5200.3. It identifies the sibling-facing consumers as downstream of the same X, Y, R, D, H, C, P, N route, so Hausdorff-distance comparison, Gromov–Hausdorff correspondence data, and compact-metric hyperspace packaging cannot bypass the displayed metric-correspondence dependency. □

Theorem 5200.7 (Gromov–Hausdorff distance sibling dependency route)**.** *Every* $\mathsf{GromovHausdorffDistance}^{\uparrow}$ *packet consumes* $\mathsf{Met}^{\uparrow}$ *distance witnesses,* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net rows, and the finite correspondence route of chapter 2104 before any public distance read is exposed. The route first opens the metric distance rows of chapter 57, then the compact finite-net rows of chapter 129, and only then the correspondence and distortion rows used by the local distance packet. It does not assert classical compactness, quotient metric spaces, selected optimal correspondences, choice over covers, or ambient completion.*

Proof. Start with the endpoint rows of Definition 5200.1. The two compact metric endpoints are the only source of distance data for the scalar comparison.

The compact rows must expose their underlying $\mathsf{Met}^{\uparrow}$ distance witnesses and finite-net coverage before the local packet can inspect cross-endpoint pairs. Thus the read begins in chapter 57 and chapter 129.

Now use the finite correspondence surface of chapter 2104. The correspondence row supplies the displayed relation whose distortion is measured by the local D row.

Finally apply the NameCert obligations of Definition 5200.2. Since the local carrier contains only endpoint, correspondence, distortion, transport, replay, provenance, and naming rows, the sibling route cannot export classical compactness, quotient metric spaces, selected optimal correspondences, cover choice, or ambient completion. □

Chapter 5201

A Concrete Naming Certificate for $\mathsf{FrechetRiesz}^{\uparrow}$

Following Frechet and Riesz on Hilbert-space representation of bounded linear functionals, the $\mathsf{FrechetRiesz}^{\uparrow}$ packet records the finite Hilbert-dual surface on which a scalar functional is read through a representing vector. It sits over the Hilbert carrier of chapter 91, the inner-product rows of chapter 86, the scalar-functional surface of chapter 5790, the projection-theorem route of chapter 2374, the Riesz–Fischer completion handoff of chapter 4207, and the scalar endpoint seal of chapter 38. The chapter names only the displayed representing-vector route; it does not import an ambient dual-space isomorphism, quotient functional equality, a selected vector outside the packet, or a full Hilbert-space representation theorem as a host principle.

Definition 5201.1 (Frechet–Riesz carrier)**.** *A* $\mathsf{FrechetRiesz}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (H, I, L, V, E, K, P, R, T, C, Q, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row, including the carried endpoints, additive and scalar rows, norm row, completeness boundary, and classifier inherited by the packet.*
2. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row over the same source, exposing scalar pairing values through the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
3. *L is the* $\mathsf{BoundedLinearFunctional}^{\uparrow}(H)$ *row, carrying the scalar action, linearity ledger, bounded-operator reading, and bound endpoint.*
4. *V is the representing-vector candidate row, a carried endpoint of the same Hilbert source.*
5. *E is the inner-product evaluation row recording, for each carried endpoint x inspected by the packet, the scalar comparison*
$$L(x) \sim_{\mathsf{Real}^{\uparrow}} \langle x, V \rangle.$$
6. *K is the norm-control row, binding the functional bound from L to the Hilbert norm of V and to the scalar endpoint discipline of* $\mathsf{Real}^{\uparrow}$*.*
7. *P is the* $\mathsf{OrthogonalProjectionTheorem}^{\uparrow}$ *handoff row, recording the projection-theorem route used to isolate the representing-vector candidate from the kernel-facing orthogonality data.*
8. *R is the* $\mathsf{RieszFischer}^{\uparrow}$ *handoff row, recording the coefficient-window and completion route used when the representing-vector candidate is read through Hilbert completion data.*

9. *T records componentwise* hsame *transport for H, I, L, V, E, K, P, R and for the local structural rows.*
10. *C records displayed* Cont *replay from a Hilbert-dual request through the Hilbert source, bounded functional, representing-vector candidate, evaluation ledger, norm-control row, projection handoff, and Riesz–Fischer handoff.*
11. *Q is the* Pkg *provenance over* $\mathsf{FrechetRiesz}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{BoundedLinearFunctional}^{\uparrow}$, $\mathsf{OrthogonalProjectionTheorem}^{\uparrow}$, $\mathsf{RieszFischer}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetRiesz}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed Hilbert classifier, scalar-functional classifier, representing-vector transport, scalar evaluation transport, norm-control transport, projection and Riesz–Fischer handoff transport, replay, provenance, and local naming rows. It has no coordinate for a host dual-space isomorphism, quotient equality of functionals, nonconstructive orthogonal complement selection, unrestricted Hahn–Banach extension, or bridge checking.

Lean4 ✓ `BEDC.Derived.FrechetRieszUp.FrechetRieszTasteGate single carrier alignment`

Theorem 5201.2 (Frechet–Riesz NameCert obligations)**.** *For every accepted* $\mathsf{FrechetRiesz}^{\uparrow}$ *carrier $F = (H, I, L, V, E, K, P, R, T, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{FrechetRiesz}^{\uparrow}}$ *surface consists exactly of these finite obligation rows:*

1. *Hilbert source admission through H and inner-product admission through I;*
2. *scalar-functional admission through the* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *row L;*
3. *representing-vector candidate admission through the carried endpoint row V;*
4. *scalar evaluation exactness through the displayed ledger E over the* $\mathsf{Real}^{\uparrow}$ *endpoint seal;*
5. *norm-control exactness through K, binding the functional bound and representing-vector norm without a host supremum;*
6. *projection handoff through P, routed through* $\mathsf{OrthogonalProjectionTheorem}^{\uparrow}$ *before any kernel-orthogonality read is public;*
7. *Riesz–Fischer handoff through R, routed through coefficient-window and completion data before any Hilbert completion read is public;*
8. *componentwise transport, replay, provenance, and local naming through T, C, Q, N;*
9. *non-escape from ambient Hilbert-dual isomorphisms, quotient functional equality, selected representatives, unrestricted Hahn–Banach separation, and hidden closed-subspace projection data.*

Proof. Project the carrier rows. The analytic surface is exactly the Hilbert source H, the inner-product row I, the scalar-functional row L, the representing-vector candidate V, the scalar evaluation ledger E, the norm-control row K, and the two handoff rows P, R.

The bounded functional is read before the representing vector is exposed. Its scalar action and bound pass through $\mathsf{BoundedLinearFunctional}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$, while the comparison with $\langle x, V\rangle$ is recorded only in the displayed ledger E over carried Hilbert endpoints.

The two theorem-facing handoffs are then forced to stay finite. The projection handoff P reads kernel-facing orthogonality through $\mathsf{OrthogonalProjectionTheorem}^{\uparrow}$, and the Riesz–Fischer handoff R reads completion-facing data through coefficient windows and displayed Hilbert rows.

Finally attach T, C, Q, N. These rows transport, replay, source, and locally name the same packet, and no remaining coordinate can manufacture a host dual-space isomorphism, quotient functional equality, selected representative, unrestricted Hahn–Banach witness, or hidden projection theorem. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 5201.3 (Frechet–Riesz Hilbert-dual handoff)**.** *Every Hilbert-dual consumer of an accepted* $\mathsf{FrechetRiesz}^{\uparrow}$ *packet must read the route*

$$\mathsf{Hilbert}^{\uparrow}, \mathsf{InnerProduct}^{\uparrow}, \mathsf{BoundedLinearFunctional}^{\uparrow}, \mathsf{OrthogonalProjectionTheorem}^{\uparrow}, \mathsf{RieszFischer}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{FrechetRi}$$

before it may treat a bounded scalar-valued functional as represented by a Hilbert endpoint. The exported handoff is the finite packet $F = (H, I, L, V, E, K, P, R, T, C, Q, N)$*: the consumer receives the functional row* L*, the representing endpoint* V*, the scalar ledger* E*, the norm-control row* K*, the projection and Riesz–Fischer handoffs* P, R*, and the structural rows* T, C, Q, N*, but no ambient dual-space equality or choice-selected representative.*

Proof. Start with a consumer asking for Hilbert-dual data. The source and scalar values are already confined to the displayed $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows, so the consumer cannot inspect a host function space before reading H, I, L.

The representing-vector read is then mediated by V, E, K. The row V supplies a carried Hilbert endpoint, E records the scalar comparison with the functional values, and K records the norm-control boundary. These rows are part of the carrier and do not assert a global dual-space isomorphism.

The remaining access to analytic existence data factors through the two handoffs. The projection-theorem row P supplies the finite orthogonality route, while the Riesz–Fischer row R supplies the coefficient-window and completion route. Replaying the packet through T, C, Q, N yields the displayed $\mathsf{FrechetRiesz}^{\uparrow}$ handoff and nothing beyond it. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetRiesz}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FrechetRiesz}^{\uparrow}$ packet is generated from a displayed Hilbert source, an inner-product row, a bounded scalar-functional row, a representing-vector candidate, scalar evaluation ledgers, norm-control data, orthogonal-projection and Riesz–Fischer handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrechetRiesz}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5201.1, Definition 5201.2, and Definition 5201.3 seed the finite Hilbert-dual representing-vector packet over Hilbert, inner-product, bounded-linear-functional, projection, Riesz–Fischer, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrechetRiesz}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close an ambient Hilbert-dual isomorphism, quotient equality of functionals, selected representatives, unrestricted Hahn–Banach extension, full projection-theorem existence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked Hilbert source admission, bounded-functional admission, representing-vector admission, scalar evaluation exactness, norm-control exactness, projection handoff, Riesz–Fischer handoff, transport, replay, provenance, and local naming for BEDC.Derived.FrechetRieszUp.

Chapter 5202

A Concrete Naming Certificate for $\mathsf{CauchyRateNormalForm}^{\uparrow}$

Following Bishop–Bridges constructive Cauchy completion, the $\mathsf{CauchyRateNormalForm}^{\uparrow}$ packet records the finite rate-normalization row that turns an arbitrary displayed Cauchy-rate request into the monotone schedule consumed by the L10 Real and Completion route. It sits after the $\mathsf{CauchyRate}^{\uparrow}$ comparison surface of chapter 1671, the modulus-normal-form packet of chapter 1968, and the fast Cauchy route of chapter 323; it reads finite windows through chapter 126, rational tails through chapter 301, dyadic tolerances through chapter 291, and the terminal real seal through chapter 38. The chapter names rate normalization as a finite carrier, not as a host modulus function, quotient stream equality, selected tail, countable-choice schedule, or ambient completeness theorem.

Definition 5202.1 (CauchyRateNormalForm carrier)**.** *A* $\mathsf{CauchyRateNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (q, \rho, \nu, D, S, G, E, H, C, P, N)$$

with the following displayed rows:

1. *q is the precision-request row naming the rational or dyadic tolerance scale submitted by a Real or Completion consumer.*
2. *ρ is the raw* $\mathsf{CauchyRate}^{\uparrow}$ *row before monotone normalization.*
3. *ν is the normalized monotone rate row, recording the finite threshold schedule accepted for the same request q.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail ledger, carrying the dyadic slack and comparison budget used to certify that ν bounds the raw row ρ at the requested scale.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the source observations and threshold indices are inspected.*
6. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and the normalized threshold row.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after q, ρ, ν, D, S, G have been displayed.*
8. *H records componentwise* hsame *transport for the precision request, raw rate, normalized rate, dyadic ledger, stream windows, regular readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a precision request through raw-rate inspection, monotone normalization, dyadic tail accounting, finite windows, regular readback, and the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyRateNormalForm}^{\uparrow}$, $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusNormalFo}$ $\mathsf{FastCauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRateNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for an external monotone majorant, quotient equality of Cauchy names, selected representatives, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyRateNormalFormUp.CauchyRateNormalFormTasteGate single carrier alignment`

Theorem 5202.2 (CauchyRateNormalForm NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRateNormalForm}^{\uparrow}$ *carrier*

$$R = (q, \rho, \nu, D, S, G, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRateNormalForm}^{\uparrow}}$ *surface consists exactly of precision-request admission, raw Cauchy-rate exposure, normalized monotone rate exposure, dyadic tail-ledger accounting, finite* $\mathsf{StreamName}^{\uparrow}$ *window inspection,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer must expose q, ρ, ν, D, S, G before the seal row E can be consumed.*

Proof. Project the carrier of Definition 5202.1. The analytic rows are exactly the precision request, raw rate, normalized rate, dyadic tail ledger, finite windows, regular readback, and Real seal.

The raw rate row ρ is not consumed directly by the downstream Real seal. The replay row C first routes the precision request q through ρ and then through the monotone row ν.

The dyadic ledger D certifies the tail budget for the same request, while S and G display the finite observations and regular rational readback produced under the normalized threshold.

Rows H, P, N transport, source, and name only that displayed route. Since no excluded host object is present as a coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5202.3 (CauchyRateNormalForm Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer accepted by a* $\mathsf{CauchyRateNormalForm}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{CauchyRate}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the normalized monotone row ν and the support rows H, C, P, N. Consequently the consumer receives a displayed rate-normalized threshold, a dyadic tail budget, finite observation windows, regular rational readback, and a terminal Real seal; it receives no host modulus function, selected tail, quotient stream equality, countable-choice schedule, or ambient Real completeness witness.

Proof. Start with an accepted carrier $R = (q, \rho, \nu, D, S, G, E, H, C, P, N)$. The precision request q and raw Cauchy-rate row ρ are visible, but the carrier exposes them to Real consumers only through the normalized row ν.

Read the dyadic ledger D at the same request. This ledger supplies the tail budget that makes ν a usable monotone rate for the displayed route.

The stream and readback rows S, G then inspect the finite windows selected by the normalized threshold. Only after those rows are displayed can the terminal seal row E be consumed.

The support rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. The excluded host and choice principles are absent from the carrier, so no Real or Completion consumer can bypass the finite normalized-rate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRateNormalForm}\uparrow}$.

Constructive story: A $\mathsf{CauchyRateNormalForm}^{\uparrow}$ packet is generated from a precision request, raw CauchyRate row, normalized monotone rate row, DyadicRatCore tail ledger, StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyRateNormalForm}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5202.1, Definition 5202.2, and Definition 5202.3 seed the finite rate-normalization route consumed by L10 Real and Completion packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyRateNormalForm}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, selected limits, host monotone majorants, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, raw-rate exposure, monotone normalization, dyadic tail-budget exactness, regular readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRateNormalFormUp.

Chapter 5203

A Concrete Naming Certificate for $\mathsf{FiniteCoverRadiusStability}^{\uparrow}$

Following Bishop–Bridges finite-cover compactness practice, the $\mathsf{FiniteCoverRadiusStability}^{\uparrow}$ packet records the finite radius-stability object consumed by the compact-uniform-continuity fold of chapter 9237. It sits between the compact metric source of chapter 129, the continuous-map pointwise modulus rows of chapter 130, the positive rational-radius rows of chapter 37, the lower-bound fold of chapter 619, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer of chapter 369. The packet makes the finite cover radius ledger explicit, not a choice of Lebesgue number from an open-cover theorem, not a host compactness principle, and not an external modulus selector.

Definition 5203.1 (FiniteCoverRadiusStability carrier)**.** *A* $\mathsf{FiniteCoverRadiusStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, M, \mathcal{P}, R, L, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row carrying the finite net and located-distance coverage data.*
2. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row read at the bundled centers.*
3. *$\mathcal{P}$ is the nonempty* ProbeBundle *cover spine for the selected finite net.*
4. *R is the finite family of positive* $\mathsf{Rat}^{\uparrow}$ *radius rows, one for each bundled probe.*
5. *L is the* $\mathsf{FiniteNetMinimumFold}^{\uparrow}$ *lower-bound fold row certifying a positive radius below every displayed row in R.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row receiving the folded radius as a tolerance-only precision ledger.*
7. *H records componentwise* hsame *transport for the compact source, continuous-map row, bundle spine, radius family, fold row, uniform-modulus handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from compact finite-net coverage through pointwise radii, lower-bound folding, and uniform-modulus handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteCoverRadiusStability}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteCoverRadiusStability}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for an open-cover compactness theorem, an external Lebesgue-number selector, a chosen center outside $\mathcal{P}$, quotient point equality, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.FiniteCoverRadiusStabilityUp.FiniteCoverRadiusStabilityTasteGate single carrier alignment`

Theorem 5203.2 (FiniteCoverRadiusStability NameCert obligations)**.** *For every accepted* FiniteCoverRadiusStabili *carrier*

$$F = (K, M, \mathcal{P}, R, L, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteCoverRadiusStability}^{\uparrow}}$ *surface consists exactly of compact metric source exposure, continuous pointwise-modulus exposure, finite* ProbeBundle *cover admission, positive* $\mathsf{Rat}^{\uparrow}$ *radius admission, lower-bound fold exactness,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every uniform-modulus consumer must expose $K, M, \mathcal{P}, R, L$ before U can be read.*

Proof. Project the carrier of Definition 5203.1. The compact source, pointwise modulus, finite bundle, radius family, lower-bound fold, and uniform-modulus handoff are exactly the analytic rows.

The compact metric row K supplies only displayed finite-net coverage. The continuous-map row M supplies the pointwise-radius data attached to the centers named by the bundle spine $\mathcal{P}$.

The radius family R is folded by L inside the same finite bundle. Thus the downstream row U receives a classifier-stable positive lower bound rather than a host-selected Lebesgue number.

Rows H, C, P, N transport, replay, source, and name the same displayed route. Since no excluded open-cover, choice, quotient, or external-selector coordinate is present, these obligations exhaust the local NameCert surface. □

Theorem 5203.3 (FiniteCoverRadiusStability uniform-modulus handoff)**.** *Every compact-uniform-continuity consumer accepted by a* $\mathsf{FiniteCoverRadiusStability}^{\uparrow}$ *carrier receives its* $\mathsf{UniformModulus}^{\uparrow}$ *precision row only through the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{FiniteNetMinimumFold}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}$$

over the displayed ProbeBundle *spine. The handoff preserves the compact finite-net coverage, pointwise radius rows, positive rational lower-bound fold, componentwise transport, replay, provenance, and local naming rows, and it exports no open-cover compactness theorem, external Lebesgue-number selector, chosen center outside the bundle, quotient point equality, countable choice, or ambient completeness principle.*

Proof. Start with an accepted carrier $F = (K, M, \mathcal{P}, R, L, U, H, C, P, N)$. The finite-net cover is read from K and indexed by the displayed bundle $\mathcal{P}$.

At each bundled center, the continuous-map row M supplies a pointwise modulus radius. The row R stores those positive $\mathsf{Rat}^{\uparrow}$ radius histories as the finite family to be folded.

Apply the lower-bound row L. It certifies one radius below every displayed member of R, so the handoff row U receives a tolerance-only precision ledger produced inside the same finite route.

Transport, replay, provenance, and naming are carried by H, C, P, N. Because the carrier has no open-cover, external-selector, quotient, choice, or ambient-completeness coordinate, every uniform-modulus consumer remains confined to the displayed radius-stability packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverRadiusStability}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCoverRadiusStability}^{\uparrow}$ packet is generated from a CompactMetric source row, ContinuousMap pointwise-modulus row, ProbeBundle finite cover spine, positive RatUp radius rows, FiniteNetMinimumFold lower-bound row, UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCoverRadiusStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5203.1, Definition 5203.2, and Definition 5203.3 seed the finite radius-stability surface used by compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCoverRadiusStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, external Lebesgue-number selection, centers outside the displayed bundle, quotient point equality, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, continuous pointwise-radius exposure, positive RatUp radius admission, finite lower-bound fold exactness, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCoverRadiusStabilityUp.

The $\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}$ route is read as a separated completion consumer of chapter 1535, chapter 3526, and chapter 1606; the child files below keep the carrier, metric-completion dependency, and minimality handoff rows separate.

Chapter 5204

A Concrete Naming Certificate for $\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}$

Following Schikhof's constructive treatment of non-Archimedean normed spaces and the completion conventions used by Bosch, Guentzer, and Remmert, the $\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}$ packet records an ultrametric completion boundary as finite NameCert data. It sits beside the metric source of chapter 57, the strong-triangle source of chapter 1535, the abstract completion interface of chapter 95, the separated-completion boundary of chapter 1612, and the dyadic-radius ledger of chapter 291. The completion boundary consumes the strong-triangle comparison from chapter 1535 and the nested-radius witness from chapter 3526 before any $\mathsf{Completion}^{\uparrow}$ interface row is exposed. The ultrametric source row is read through chapter 1535 before the dyadic radius ledger and separated-completion handoff are consumed. The packet records the displayed strong-triangle radius route and its separated handoff; it is not a quotient completion, a selected-representative construction, a host equality principle, countable choice, or ambient Real completeness.

Definition 5204.1 (Constructive ultrametric completion carrier)**.** *A* $\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, D, T, F, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the ultrametric source row, recording the underlying* $\mathsf{Met}^{\uparrow}$ *carrier and its distance classifier.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *strong-triangle radius ledger, recording dyadic radii and the maximum-radius comparison used in every inspected triple.*
3. *T is the strong-triangle row, recording that the inspected distance requests factor through the ultrametric inequality at the radii displayed by D.*
4. *F is the Cauchy filter or Cauchy sequence route row, recording the finite tail requests and radius thresholds used by the completion consumer.*
5. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *handoff row, recording the separated boundary reached after the same Cauchy route is displayed.*
6. *Q is the* $\mathsf{Completion}^{\uparrow}$ *interface row, recording the completion-facing request without adding quotient classes or selected representatives.*

7. *H stores componentwise* hsame *transport for the ultrametric source, radius ledger, strong-triangle row, Cauchy route, separated handoff, completion interface, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from distance reads to strong-triangle radius checks, from Cauchy requests to separated handoff, and from the handoff to the completion interface.*
9. *P is the* Pkg *provenance over* $\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}}$ *row.*

The accepted carrier stores only the rows just displayed. It carries no quotient-completion object, no selected Cauchy representative, no host equality of limits, no countable-choice selector, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Theorem 5204.2 (Constructive ultrametric completion NameCert obligations)**.** *For an accepted packet $U = (X, D, T, F, S, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}}$ *obligations are exhausted by carrier admission for the ultrametric source X, dyadic radius ledger D, strong-triangle row T, Cauchy filter or sequence route F, separated-completion handoff S, completion-interface row Q, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 5204.1. The source metric data is read through X, while the ultrametric strengthening is visible only through the strong-triangle row T and the dyadic radius ledger D.

Read the completion-facing route next. The Cauchy filter or sequence row F reads the strong-triangle rows of chapter 1535 and the nested-radius witness of chapter 3526 before the separated handoff row S and completion-interface row Q are available. The row F displays the finite tail and radius requests, and the separated-completion row S records the handoff before the abstract completion interface Q can be consumed.

Finally inspect H, C, P, N. These rows transport, replay, package, and name the same displayed data through $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$. Since the packet has no quotient-completion, selected-representative, host-equality, countable-choice, or Real-completeness coordinate, no NameCert obligation can read one. □

Theorem 5204.3 (Constructive ultrametric completion separated-radius route)**.** *Let $U = (X, D, T, F, S, Q, H, C, P$ be an accepted* $\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}$ *packet. Every completion-facing read routes the ultrametric strong-triangle row T and dyadic radius ledger D through the same Cauchy filter or sequence row F before the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *handoff S can be consumed. The abstract completion interface Q is available only after that separated-radius route has displayed the ultrametric source X, the dyadic ledger D, the strong-triangle row T, the Cauchy route F, and the separated handoff S.*

Proof. Project the carrier in Definition 5204.1. The NameCert obligations of Definition 5204.2 already force completion-facing reads to pass through the displayed ultrametric source, dyadic radius ledger, strong-triangle row, Cauchy route, and separated-completion handoff.

Induct over the displayed finite radius-request list carried by D and read by F. The empty list has no completion-facing radius request, so the separated handoff cannot be consumed except through the displayed structural rows.

For the cons step, the head request reads the same source X, dyadic ledger D, and strong-triangle row T before it enters the Cauchy filter or sequence row F. The induction hypothesis

preserves that route for the tail requests, so the separated handoff S remains attached to the same finite radius ledger before Q appears.

Thus each finite request preserves the ultrametric source, dyadic radius ledger, strong-triangle row, and separated handoff. No ambient completion, quotient limit, selected representative, or Real-completeness coordinate is available before the completion interface row is read. □

Falsifiable prediction: Every accepted $\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}$ completion-facing read passes through an ultrametric source row, a strong-triangle dyadic radius ledger, a Cauchy filter or sequence route, a separated-completion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any completion interface row is visible.

Independence witness: metricspace, completion, separatedcompletion, dyadicratcore: none is bijective to ConstructiveUltrametricCompletionUp because the packet jointly carries the ultrametric source, strong-triangle radius ledger, Cauchy route, separated handoff, completion interface, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}$ packet is generated from an ultrametric source row, a dyadic strong-triangle radius ledger, a Cauchy filter or sequence route, a separated-completion handoff, an abstract completion-interface row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5204.1 and Definition 5204.2 seed the finite ultrametric completion packet over MetricSpaceUp, CompletionUp, SeparatedCompletionUp, DyadicRatCoreUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected representatives, host equality of limits, countable choice, ambient Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, strong-triangle radius ledger exactness, Cauchy-route stability, separated-completion handoff, and completion-interface nonescape for BEDC.Derived.ConstructiveUltrametricCompletionUp.

Theorem 5204.4 (Constructive ultrametric completion Cauchy-completion dependency)**.** *Every* $\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}$ *completion read first passes through the ultrametric carrier of Definition 5204.1, then through the metric-completion and separated-completion rows already named by chapter 1506 and chapter 1612. The strong-triangle and dyadic-radius rows from chapter 1535 remain visible before any completion interface is consumed, so the completion handoff is a carrier-local route rather than a direct appeal to quotient completion, selected representatives, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the constructive ultrametric completion carrier of Definition 5204.1. Its source row, dyadic radius ledger, strong-triangle row, Cauchy route, and separated handoff are already displayed before any completion interface row appears.

Then read the metric-completion and separated-completion siblings. They supply the named boundary rows that the handoff must pass through, while the ultrametric-space chapter keeps the strong-triangle and dyadic-radius rows visible. The route therefore stays local to the carrier and does not appeal to quotient completion, selected representatives, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

The $\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}$ route consumes the $\mathsf{MetricCompletion}^{\uparrow}$ completion carrier of chapter 1506 and the $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ minimal service boundary of chapter 1606 before any ultrametric completion seal is read. Thus the strong-triangle dyadic ledger remains a refinement of an already displayed completion carrier and minimal Cauchy-completion service route, not a replacement for either dependency.

Theorem 5204.5 (Constructive ultrametric completion minimality handoff)**.** *Every* ConstructiveUltrametricComple *completion-facing read that consumes the strong-triangle dyadic radius ledger, the Cauchy route, and the separated-completion handoff also routes through the* $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ *service boundary before it exports a completion interface. The exported route therefore displays the ultrametric source, dyadic-radius ledger, separated uniqueness handoff, transport, replay, provenance, and local naming rows before any* $\mathsf{Completion}^{\uparrow}$ *consumer can inspect the interface.*

Proof. Apply Definition 5204.2. It forces every accepted read to expose the ultrametric source, dyadic ledger, strong-triangle row, Cauchy route, separated-completion handoff, completion interface, transport, replay, provenance, and local naming rows.

Now read the minimality boundary of Definition 1606.2. Its service surface contains the same source metric row, dense or completion-facing handoff, universal route, separated uniqueness boundary, componentwise transport, replay, provenance, and local naming rows needed before a completed read can be exported.

Thus an ultrametric completion consumer cannot jump from the strong-triangle dyadic ledger directly to a public completion interface. It must pass through the displayed $\mathsf{CauchyCompletionMinimality}^{\uparrow}$ boundary, and the route exports no quotient completion, selected representative, countable-choice selector, host equality of limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim. □

Chapter 5205

A Concrete Naming Certificate for $\mathsf{MachineExportBoundary}^{\uparrow}$

The $\mathsf{MachineExportBoundary}^{\uparrow}$ packet realizes the machine-facing export side of section 9462.35 as one finite NameCert boundary. It sits beside the registry export surface of chapter 1216, the machine-readable audit interface of chapter 1232, the cannot-claim export gate of chapter 1319, and the certificate-preserving morphism route of chapter 481. Those siblings expose registry status, audit readback, refusal, and morphism preservation separately; this packet binds target, audit, refusal, transport, replay, provenance, and local NameCert rows before a machine export may be read.

Definition 5205.1 (Machine export boundary carrier)**.** *A* $\mathsf{MachineExportBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, T, A, F, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegistryExportSurface}^{\uparrow}$ *row, recording the exported, blocked, horizon-facing, or formal-target registry status.*
2. *T is the machine target row, recording the exact machine-facing target that may read the export.*
3. *A is the* $\mathsf{MachineReadableAuditInterface}^{\uparrow}$ *row, recording the schema, checker, audit report, and non-evidence boundary for the export.*
4. *F is the* $\mathsf{CannotClaimExportGate}^{\uparrow}$ *refusal row, recording any blocked claim that must remain visible before export.*
5. *H stores componentwise* hsame *transport for registry status, target, audit, refusal, replay, provenance, and local naming rows.*
6. *C stores displayed* Cont *replay from registry lookup to target routing, audit readback, refusal inspection, and local NameCert exposure.*
7. *P is the* Pkg *provenance over* $\mathsf{MachineExportBoundary}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineReadableAuditInterface}^{\uparrow}$, $\mathsf{CannotClaimExportGate}^{\uparrow}$, $\mathsf{NameCertMorphism}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{MachineExportBoundary}^{\uparrow}}$ *row.*

The carrier contains no coordinate for an unregistered export, unchecked theorem evidence, refused-claim erasure, hidden transport, replay outside the displayed continuation row, provenance outside P, or a local name not carried by N.

Theorem 5205.2 (Machine export boundary NameCert obligations)**.** *For an accepted packet $E = (R, T, A, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MachineExportBoundary}^{\uparrow}}$ *obligations are exhausted by registry export admission through R, target exposure through T, audit readback through A, refusal preservation through F, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5205.1. The registry export row R, target row T, audit row A, and refusal row F are displayed before a machine consumer reaches local naming.

Read the sibling routes in order. The registry export surface fixes the public status, the machine-readable audit interface fixes the audit report and non-evidence boundary, and the cannot-claim export gate keeps refused rows visible.

Finally use H, C, P, N. These rows transport, replay, package, and name the same export route, with $\mathsf{NameCertMorphism}^{\uparrow}$ present only as provenance for certificate-preserving handoff. Since the carrier has no hidden export or proof-producing report coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 5205.3 (Machine export boundary registry route)**.** *Every machine export read from an accepted* $\mathsf{MachineExportBoundary}^{\uparrow}$ *packet must pass through* $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineReadableAuditInterface}^{\uparrow}$ $\mathsf{CannotClaimExportGate}^{\uparrow}$, *and* $\mathsf{NameCertMorphism}^{\uparrow}$ *before the local* $\mathsf{MachineExportBoundary}^{\uparrow}$ *naming row is consumed. In particular, the registry status route of chapter 1216 is a required sibling surface for any machine-facing export read.*

Proof. Project the carrier $E = (R, T, A, F, H, C, P, N)$. The first row R is the registry export surface, so a machine read begins with a displayed registry status rather than with a local machine target.

Next inspect A and F. The machine-readable audit interface fixes the audit report and non-evidence boundary, while the cannot-claim export gate preserves any refused claim that must remain visible.

The morphism route is then carried in P as certificate-preserving provenance before N is read as the local name. The transport and replay rows H, C preserve this sibling route, so the packet exposes no direct machine export that skips registry status, audit readback, refusal visibility, or NameCert morphism provenance. □

Theorem 5205.4 (Machine export boundary sibling route)**.** *Every accepted machine export route*

$$E = (R, T, A, F, H, C, P, N)$$

is a sibling-lattice consumer of $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineReadableAuditInterface}^{\uparrow}$, $\mathsf{CannotClaimExportGate}^{\uparrow}$, $\mathsf{NameCertMorphism}^{\uparrow}$, *and* $\mathsf{MachineInterfaceBoundary}^{\uparrow}$. *The rows R, A, F, P expose registry status, audit readback, refusal preservation, and certificate-preserving provenance before the local name row N is read, while H and C preserve the same route under transport and replay. Hence the route cannot introduce unregistered export, unchecked theorem evidence, or refusal erasure.*

Proof. Project the carrier $E = (R, T, A, F, H, C, P, N)$. The registry row R, audit row A, refusal row F, and provenance row P are displayed before the local naming row N.

Apply the registry route of Definition 5205.3. It forces every machine-facing export read through $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineReadableAuditInterface}^{\uparrow}$, $\mathsf{CannotClaimExportGate}^{\uparrow}$, and $\mathsf{NameCertMorphism}^{\uparrow}$ before the boundary can be named locally.

The broader $\mathsf{MachineInterfaceBoundary}^{\uparrow}$ sibling is preserved by the target row T together with transport H and replay C. Those rows keep the same displayed export route and do not add

unregistered export, unchecked theorem evidence, or refusal erasure, so the accepted packet is exactly the stated sibling-lattice consumer. Consequently, downstream bounded-diamond and standard-bridge consumers must cite the displayed export route $E = (R, T, A, F, H, C, P, N)$ rather than a bare machine target row. □

Theorem 5205.5 (Machine export boundary interface forward link)**.** *Every* $\mathsf{MachineExportBoundary}^{\uparrow}$ *export route is a specialization of the* $\mathsf{MachineInterfaceBoundary}^{\uparrow}$ *route of chapter 1221 after registry export, audit readback, refusal preservation, and* $\mathsf{NameCertMorphism}^{\uparrow}$ *provenance have been displayed. Concretely, for an accepted packet*

$$E = (R, T, A, F, H, C, P, N),$$

the rows R, A, F, P expose registry status, machine-readable audit, cannot-claim refusal, and certificate-preserving provenance before the target row T and local name row N are consumed. Thus the export boundary cannot be read as a machine-interface boundary unless it has first passed through the displayed export ledger.

Proof. Project the carrier $E = (R, T, A, F, H, C, P, N)$. The registry export row R, audit row A, refusal row F, and provenance row P are displayed before the local export name N.

The broader interface route supplies the machine-facing boundary, while this packet supplies the export specialization. The target row T selects the machine consumer, and the rows R, A, F, P add registry export, audit readback, refusal preservation, and certificate-preserving provenance.

Finally H and C preserve the same displayed route under transport and replay. Hence the accepted export packet is a specialization of $\mathsf{MachineInterfaceBoundary}^{\uparrow}$ only after the export ledger has been shown, and no direct interface read can bypass those rows. □

The $\mathsf{MachineExportBoundary}^{\uparrow}$ packet refines the broader machine-facing interface of chapter 1221 by replacing a general registry-to-machine route with the target, audit, refusal, export tuple $E = (R, T, A, F, H, C, P, N)$ before any local export name is consumed.

It therefore consumes $\mathsf{MachineInterfaceBoundary}^{\uparrow}$ as a downstream specialization: $\mathsf{RegistryExportSurface}^{\uparrow}$ supplies the public status row, $\mathsf{MachineReadableAuditInterface}^{\uparrow}$ supplies audit readback, $\mathsf{CannotClaimExportGate}^{\uparrow}$ supplies refusal visibility, and $\mathsf{NameCertMorphism}^{\uparrow}$ supplies certificate-preserving provenance before the local export boundary is read.

Falsifiable prediction: Any machine export omitting target, audit, refusal, transport, replay, provenance, or local NameCert rows refutes the $\mathsf{MachineExportBoundary}^{\uparrow}$ carrier.

Independence witness: registryexportsurface, machinereadableauditinterface, cannotclaimexportgate, namecertmorphism, machineinterfaceboundary: none is bijective to MachineExportBoundaryUp because the separate siblings expose registry status, audit readback, refusal visibility, certificate-preserving provenance, and the broader machine interface only one surface at a time. Only the MachineExportBoundaryUp packet jointly carries registry export status, machine target, audit readback, refusal preservation, certificate-preserving provenance, transport, replay, and local NameCert rows before an export can be read.

The Lean follow-up must provide explicit $\mathsf{Nontrivial}\ \mathsf{MachineExportBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{MachineExportBo}$ instances in `lean4/BEDC/Derived/MachineExportBoundaryUp/TasteGate.lean`. The field-faithfulness witness must preserve R, T, A, F, H, C, P, N as distinct rows before a checked target can cite the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MachineExportBoundary}^{\uparrow}}$.

Constructive story: A MachineExportBoundary$^{\uparrow}$ packet is generated from registry export status, a machine target row, a machine-readable audit row, a cannot-claim refusal row, componentwise hsame transport, displayed Cont replay, package provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\text{MachineExportBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 5205.1 and Definition 5205.2 seed the finite machine export boundary over RegistryExportSurfaceUp, MachineReadableAuditInterfaceUp, CannotClaimExportGateUp, NameCertMorphismUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{MachineExportBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim unchecked theorem evidence, unregistered export, refusal erasure, hidden transport, off-packet replay, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked registry export admission, target exposure, audit readback, refusal preservation, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.MachineExportBoundaryUp.

Theorem 5205.6 (Machine export audit transcript envelope route)**.** *Every* MachineExportBoundary$^{\uparrow}$ *export that reports theorem evidence must first expose the* AuditTranscriptEnvelope$^{\uparrow}$ *status-pair and replay-checksum route of chapter 1234 before any machine-readable export row is consumed.*

Proof. Read a machine export as a finite boundary packet with exported claim, format, consumer, transport, replay, provenance, and local naming rows. A theorem-evidence report is stronger than a raw export row: it asks the consumer to trust both the paper-side closure grade and the Lean-side verification grade attached to the claim.

The AuditTranscriptEnvelope$^{\uparrow}$ carrier supplies exactly that two-axis status pair together with the replay-checksum row. Therefore the export boundary can expose theorem evidence only after routing through the audit transcript envelope; without those rows the machine consumer may still read an export, but not as theorem evidence. □

Theorem 5205.7 (Machine export boundary machine-interface dependency)**.** *Every* MachineExportBoundary$^{\uparrow}$ *consumer refines the broader machine-facing interface of chapter 1221 before any export is consumed. The route exposes registry status R, machine target T, audit readback A, refusal preservation F,* NameCertMorphism$^{\uparrow}$ *provenance P, componentwise transport H, displayed replay C, and local naming N in the same accepted packet $E = (R, T, A, F, H, C, P, N)$.*

Proof. Project the carrier of Definition 5205.1. The target row T places the accepted packet inside the machine-facing boundary, while the registry row R fixes the export status before the target can be consumed.

Use the existing registry route of Definition 5205.3 and the registry export dependency of Definition 5205.9. Together they force the consumer through RegistryExportSurface$^{\uparrow}$, MachineReadableAuditInterface$^{\uparrow}$, CannotClaimExportGate$^{\uparrow}$, and NameCertMorphism$^{\uparrow}$ before the local export name is read.

The sibling interface chapter supplies the ambient machine boundary only as a dependency surface. The export packet refines it by displaying R, T, A, F, H, C, P, N, so audit readback, refusal preservation, certificate-preserving provenance, transport, replay, and local naming remain visible before consumption.

Since no carrier coordinate skips from MachineInterfaceBoundary$^{\uparrow}$ directly to export, the accepted route cannot introduce unregistered export, unchecked theorem evidence, refusal erasure, hidden transport, or off-packet replay. □

Theorem 5205.8 (Machine export boundary forward interface route)**.** *Every* MachineExportBoundary$^{\uparrow}$ *export read reaches downstream machine-facing consumers only through the* MachineInterfaceBoundary$^{\uparrow}$ *route of chapter 1221 and the registry-export dependency rows of Definition 5205.9. The packet keeps registry status, machine target, audit readback, refusal preservation,* NameCertMorphism$^{\uparrow}$

provenance, transport, replay, and local naming visible before any export row can be treated as machine-facing evidence.

Proof. Project the carrier of Definition 5205.1. Its registry row is read before the machine target row, so the route cannot bypass the registry-export dependency surface.

Next apply the machine-interface dependency and registry-export dependency routes. They send the same displayed export packet through $\mathsf{MachineInterfaceBoundary}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineReadableAuditInterface}^{\uparrow}$, $\mathsf{CannotClaimExportGate}^{\uparrow}$, and $\mathsf{NameCertMorphism}^{\uparrow}$ before the local name is consumed.

The structural rows preserve the same route. Componentwise transport, displayed replay, provenance, and local naming do not add a second export channel, so the accepted packet has no path to machine-facing evidence outside the displayed boundary rows. □

Theorem 5205.9 (Machine export boundary registry export dependency)**.** *Every* $\mathsf{MachineExportBoundary}^{\uparrow}$ *read must pass through the registry export surface of chapter 1216 before any machine-facing export is consumed. The remaining sibling rows are the* $\mathsf{MachineReadableAuditInterface}^{\uparrow}$ *audit route, the* $\mathsf{CannotClaimExportGate}^{\uparrow}$ *refusal route, and the* $\mathsf{NameCertMorphism}^{\uparrow}$ *certificate-preserving handoff.*

Proof. Project the carrier $E = (R, T, A, F, H, C, P, N)$ from Definition 5205.1. The registry row R precedes the target row T, so the export is visible first as a registry status and only then as a machine-facing route.

Read the remaining sibling rows through A, F, P. The audit route supplies the machine-readable report and non-evidence boundary, the refusal route keeps blocked claims visible, and the morphism row appears as certificate-preserving provenance before the local name is consumed.

Transport and replay through H, C preserve the same route. Therefore no accepted $\mathsf{MachineExportBoundary}^{\uparrow}$ consumer reaches machine-facing export before registry export, audit readback, refusal visibility, and NameCert morphism provenance have all been displayed. □

Theorem 5205.10 (Machine export boundary registry-forward dependency)**.** *Every* $\mathsf{MachineExportBoundary}^{\uparrow}$ *export that is read by a standard-bridge consumer factors first through the machine interface route of chapter 1221, then through the registry rows of chapter 1216, and finally through the same local* $\mathsf{NameCert}$ *provenance row displayed in Definition 5205.1. No standard-bridge consumer may read a bare export row detached from* $\mathsf{MachineInterfaceBoundary}^{\uparrow}$*, registry status, or NameCert provenance.*

Proof. Project the accepted carrier $E = (R, T, A, F, H, C, P, N)$ from Definition 5205.1. The target row T places the export inside the machine-facing interface, while the registry row R fixes its registry status before the export can be consumed.

Apply the machine-interface dependency route of Definition 5205.7 and the registry export dependency of Definition 5205.9. Together they force any downstream read through $\mathsf{MachineInterfaceBoundary}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, audit readback, refusal preservation, and certificate-preserving provenance before the local name is used.

The standard bridge route of Definition 5205.16 only reads the already displayed packet. Since H, C, P, N transport, replay, package, and name the same accepted carrier, the bridge cannot bypass the machine interface row, registry rows, or local NameCert provenance. □

Every $\mathsf{MachineExportBoundary}^{\uparrow}$ read refines the machine-facing boundary of chapter 1221 and must pass through chapter 1216, chapter 1232, chapter 1319, and chapter 481 before any machine-facing export is consumed.

Theorem 5205.11 (Machine export boundary NameCert sibling route)**.** *Every public machine-facing export row of an accepted* $\mathsf{MachineExportBoundary}^{\uparrow}$ *packet must first consume the registry export surface of chapter 1216 and the machine-interface boundary of chapter 1221. Concretely, for an accepted packet*

$$E = (R, T, A, F, H, C, P, N),$$

the registry row R *and target row* T *are read before any machine-facing export row is public, while* A, F, H, C, P, N *keep audit readback, refusal visibility, transport, replay, provenance, and local naming attached to the same finite packet. The route does not export host semantics, detached machine output, unchecked theorem evidence, or a hidden registry state.*

Proof. Project the carrier of Definition 5205.1. The registry row R is the displayed $\mathsf{RegistryExportSurface}^{\uparrow}$ input, and the target row T is the displayed machine-facing input.

Apply the registry export dependency of Definition 5205.9. It requires the registry surface to be visible before a machine-facing export is consumed.

Apply the machine-interface dependency of Definition 5205.7. It keeps the target row inside the broader $\mathsf{MachineInterfaceBoundary}^{\uparrow}$ route rather than letting the packet expose a bare machine target.

Finally read the obligation surface of Definition 5205.12. The audit, refusal, transport, replay, provenance, and naming rows remain attached to $E = (R, T, A, F, H, C, P, N)$. Since the carrier has no host-semantics coordinate, detached output row, unchecked-proof row, or hidden-registry coordinate, the public route is exactly the stated sibling dependency. □

Theorem 5205.12 (Machine export boundary obligation surface)**.** *Every public* $\mathsf{MachineExportBoundary}^{\uparrow}$ *export must pass through the displayed machine-interface, registry-export, audit-provenance,* hsame-*transport,* Cont-*replay,* Pkg*, and local* NameCert *rows before any external machine read is public. In particular, the route refines the machine-facing interface of chapter 1221 and the registry export surface of chapter 1216 through the accepted packet* $E = (R, T, A, F, H, C, P, N)$*.*

Proof. Project the carrier of Definition 5205.1. The target row T supplies the machine-interface surface, while R supplies the registry-export surface before a machine read can be public.

The audit and refusal rows A, F keep provenance-facing evidence and blocked-claim visibility in the same packet. Transport through H and replay through C preserve those displayed rows rather than replacing them with an external machine assertion.

Finally read P and N. Package provenance and the local NameCert row close the export boundary only after the machine-interface, registry-export, audit, refusal, transport, and replay rows are visible, so no external read is public outside the displayed obligation surface. □

Theorem 5205.13 (Machine export boundary bounded diamond consumer)**.** *Every* MetaCICBoundedDiamondWin *consumer of* $\mathsf{MachineExportBoundary}^{\uparrow}$ *must read registry status, machine target, audit readback, refusal preservation, componentwise transport, displayed replay, package provenance, and local NameCert rows through the accepted packet* $E = (R, T, A, F, H, C, P, N)$ *before bounded diamond evidence can be exported. In particular, the bounded-window consumer of chapter 8559 may cite the obligation surface of Definition 5205.12 only after all eight rows remain visible in the same machine export boundary packet.*

Proof. Project the packet $E = (R, T, A, F, H, C, P, N)$ from Definition 5205.12. The registry status row R, target row T, audit row A, and refusal row F are the machine-facing data that a bounded diamond consumer must inspect before export.

The structural rows H, C, P, N keep that data inside the accepted packet. Transport and replay preserve the same registry, target, audit, and refusal route, while provenance and local naming keep the route tied to $\mathsf{MachineExportBoundary}^{\uparrow}$.

Therefore a $\mathsf{MetaCICBoundedDiamondWindow}^{\uparrow}$ consumer cannot export bounded diamond evidence from a bare machine read. It first factors through the displayed MachineExportBoundary obligation surface, with every row of E still visible. □

Theorem 5205.14 (Machine export boundary bounded diamond packet route)**.** *Every bounded-diamond consumer route from* $\mathsf{MachineExportBoundary}^{\uparrow}$ *to* $\mathsf{MetaCICBoundedDiamondWindow}^{\uparrow}$ *must cite chapter 8559 through the full accepted machine-export packet* $E = (R, T, A, F, H, C, P, N)$*. The bounded diamond evidence cannot be read from a bare export row, a detached registry row, or an audit-only machine read; it becomes public only after the registry status, machine target, audit readback, refusal preservation, componentwise transport, displayed replay, package provenance, and local NameCert rows remain visible together.*

Proof. Apply Definition 5205.13. It already forces bounded-window consumers to inspect all eight rows of E before machine export can serve bounded diamond evidence.

The chapter route to chapter 8559 is therefore a packet route, not a single-row export. Reading only the registry row, only the target row, or only an audit row would omit the refusal, transport, replay, provenance, or naming data required by the accepted MachineExportBoundary surface.

Thus the bounded-diamond dependency edge is carried by the whole packet $E = (R, T, A, F, H, C, P, N)$. A bare export row is not enough to expose bounded diamond evidence to a $\mathsf{MetaCICBoundedDiamondWindow}^{\uparrow}$ consumer. □

Theorem 5205.15 (Machine export boundary orphan interface route)**.** *Every* $\mathsf{MachineExportBoundary}^{\uparrow}$ *packet is read as a downstream specialization of chapter 1221 only after registry status, audit readback, refusal preservation, componentwise transport, displayed replay, package provenance, and local* $\mathsf{NameCert}$ *rows remain visible. Concretely, an accepted export packet* $E = (R, T, A, F, H, C, P, N)$ *reaches the machine-interface boundary through the registry route of Definition 5205.3, the registry export dependency of Definition 5205.9, and the interface dependency of Definition 5205.7; it cannot be consumed as a bare machine target row. The bounded-diamond and* Ω*-generation boundary consumers may read the export packet only after* $\mathsf{RegistryExportSurface}^{\uparrow}$ *and* $\mathsf{MachineReadableAuditInterface}^{\uparrow}$ *have displayed the export rows.*

Proof. Project the carrier of Definition 5205.1. The displayed rows R, T, A, F, H, C, P, N are the only rows available to a machine export consumer.

Read the registry and audit surfaces first. The registry route and registry export dependency force R to expose status before T is consumed, while A and F preserve audit readback and refusal visibility inside the same packet.

Now apply the machine-interface dependency and the forward interface route, Definition 5205.7 and Definition 5205.8. They route the target row through $\mathsf{MachineInterfaceBoundary}^{\uparrow}$ only after $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{MachineReadableAuditInterface}^{\uparrow}$, $\mathsf{CannotClaimExportGate}^{\uparrow}$, and $\mathsf{NameCertMorphism}^{\uparrow}$ provenance are displayed.

Finally use H, C, P, N. Transport and replay keep the same registry-audit-refusal route visible, provenance records the certificate-preserving handoff, and the local name closes the packet. Hence the orphan edge is a child route through $\mathsf{MachineInterfaceBoundary}^{\uparrow}$ with all export-boundary rows still present. □

Theorem 5205.16 (Machine export boundary standard bridge route)**.** *For an accepted* $\mathsf{MachineExportBoundary}^{\uparrow}$ *packet* $E = (R, T, A, F, H, C, P, N)$*, the machine export reads bridge data only after the registry export surface, the machine-readable audit interface, and the registry export dependency route have already been displayed. The standard bridge protocol chapter of chapter 9204 supplies the host-facing comparison surface, while the registry export surface of chapter 1216 and the machine interface boundary of chapter 1221 keep the export finite.*

Proof. Project the carrier of Definition 5205.1. The registry row R, target row T, audit row A, and refusal row F are the only public machine-export rows.

Use the registry export dependency theorem of this chapter together with the machine-interface dependency theorem. They force the packet through the registry-export surface, the machine-readable audit interface, the refusal gate, and the certificate-preserving provenance row before the local name is consumed.

The standard bridge protocol chapter then provides the host-facing bridge shape without changing the packet's displayed rows. Since no extra coordinate is present, the export reads bridge data only after the registry and protocol rows are visible. □

Chapter 5206

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailPairing}^{\uparrow}$

Following Bishop–Bridges constructive real analysis, the $\mathsf{RegularCauchyTailPairing}^{\uparrow}$ packet records the finite paired-tail surface by which two regular rational Cauchy names are synchronized before a diagonal or sequential-completeness consumer reaches a displayed $\mathsf{Real}^{\uparrow}$ seal. It sits over the finite observation interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the sequential-completeness handoff of chapter 1794, and the terminal real-name boundary of chapter 38. The packet is a finite paired-tail carrier for L10 Real and Completion routes; it is not quotient stream equality, a selected limit, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5206.1 (Regular Cauchy tail pairing carrier)**.** *A* $\mathsf{RegularCauchyTailPairing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S_0, S_1, R_0, R_1, D_0, D_1, W, U, E, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows opened by the paired-tail request.*
2. R_0 *and* R_1 *are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from those windows.*
3. D_0 *and* D_1 *are the two* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, recording the requested radius, the local regularity budgets, and the remaining comparison slack for each side of the pair.*
4. W *is the paired-tail synchronization row, recording one displayed common tail window for the two readbacks and no quotient identification of the underlying streams.*
5. U *is the* $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$ *handoff row, read only after the two windows, two readbacks, two dyadic ledgers, and paired-tail window have been displayed.*
6. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same paired route.*
7. H *records componentwise* hsame *transport for windows, readbacks, dyadic ledgers, paired-tail synchronization, sequential-completeness handoff, Real seal, replay, provenance, and local naming.*
8. C *records displayed* Cont *replay from a diagonal or sequential-completeness request through* $S_0, S_1, R_0, R_1, D_0, D_1, W, U, E, H, P, N$.
9. P *is the* Pkg *provenance over* $\mathsf{RegularCauchyTailPairing}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailPairing}^{\uparrow}}$ *row.*
The carrier compares accepted packets only through the displayed rows above. It has no coordinate for quotient stream equality, selected host limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegularCauchyTailPairingUp.RegularCauchyTailPairingUp`

Theorem 5206.2 (Regular Cauchy tail pairing NameCert obligations)**.** *For every accepted* RegularCauchyTailPairin *carrier*

$$T = (S_0, S_1, R_0, R_1, D_0, D_1, W, U, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailPairing}^{\uparrow}}$ *surface consists exactly of carrier admission for the two StreamName windows, two RegSeqRat readbacks, two DyadicRatCore tolerance ledgers, paired-tail synchronization row, RegularCauchySequentialCompleteness handoff, Real seal, componentwise transport, displayed replay, package provenance, and local naming; synchronization exactness for the common tail window W; classifier stability through H; replay stability through C; and ledger non-escape through P and N.*

Proof. Carrier admission is projection from Definition 5206.1. The accepted tuple exposes exactly the two windows, two readbacks, two dyadic ledgers, paired-tail row, sequential-completeness handoff, Real seal, and structural rows.

Synchronization exactness is the row W. A diagonal or sequential-completeness consumer must first read the two StreamName windows and their RegSeqRat readbacks, then compare them under the two dyadic ledgers before the common tail window is public.

The handoff rows are downstream of that paired window. The row U consumes the same displayed route as a $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$ handoff, and the row E is the terminal $\mathsf{Real}^{\uparrow}$ seal reached only after $S_0, S_1, R_0, R_1, D_0, D_1, W$ have been exposed.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded quotient, selection, choice, trichotomy, host-equality, or ambient-completeness coordinate occurs in the carrier, the listed clauses exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyTailPairingUp.RegularCauchyTailPairingTasteGate single carrier alignment`

Theorem 5206.3 (Regular Cauchy paired-tail synchronization)**.** *Let*

$$T = (S_0, S_1, R_0, R_1, D_0, D_1, W, U, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyTailPairing}^{\uparrow}$ *carrier. Any diagonal or sequential-completeness consumer of T must synchronize the two tails by reading S_0, S_1, then R_0, R_1, then D_0, D_1, and only then the common paired-tail window W. The synchronization is transported componentwise by H and replayed by C before U or E is consumed.*

Proof. Apply the obligation theorem Definition 5206.2. It orders the public rows so that the two finite windows and readbacks are visible before either dyadic tolerance ledger is used.

The paired-tail row W is therefore not a quotient or selected representative. It is a displayed common window obtained after both regular rational readbacks have been inspected under their two dyadic budgets.

Componentwise transport and replay preserve that order. The rows H and C can move and repeat the displayed packet, but they cannot make the sequential-completeness handoff U or Real seal E visible before the paired-tail synchronization row has been read. □

Theorem 5206.4 (Regular Cauchy tail pairing RealUp seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{RegularCauchyTailPairing}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegularCauchySequentialCompleteness}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

More explicitly, the consumer must display the two finite windows, two regular rational readbacks, two dyadic tolerance ledgers, one paired-tail synchronization row, one sequential-completeness handoff, and one terminal Real seal before any Real-facing output is named.

Proof. Start with the paired-tail synchronization theorem Definition 5206.3. It forces every accepted consumer to read $S_0, S_1, R_0, R_1, D_0, D_1, W$ in order.

The sequential-completeness handoff is then row-local. The row U cites the existing RegularCauchySequentialCon surface of chapter 1794 and consumes the same paired route rather than selecting a host limit.

Only after that finite handoff does the Real seal row E become public. The structural rows H, C, P, N preserve and name the route, so the handoff exports no quotient stream equality, selected limit, countable-choice witness, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyTailPairing}^{\uparrow}$ read displays two $\mathsf{StreamName}^{\uparrow}$ windows, two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, two $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, one paired-tail synchronization row, one $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$ handoff, one $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence before a diagonal or sequential-completeness consumer reaches a Real-facing output.

Independence witness: streamname, regseqrat, dyadicratcore, regular-cauchy-sequential-completeness, real: $\mathsf{RegularCauchyTailPairing}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two windows, two regular readbacks, two dyadic ledgers, one paired-tail synchronization row, one sequential-completeness handoff, one Real seal, and the structural transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailPairing}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailPairing}^{\uparrow}$ packet is generated from two StreamName windows, two RegSeqRat readbacks, two DyadicRatCore tolerance ledgers, one paired-tail synchronization row, one RegularCauchySequentialCompleteness handoff, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyTailPairing}^{\uparrow}}$, seed)

Scope closed: Definition 5206.1, Definition 5206.2, Definition 5206.3, and Definition 5206.4 seed the finite paired-tail carrier used by diagonal and sequential-completeness consumers before the displayed $\mathsf{Real}^{\uparrow}$ seal is read.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyTailPairing}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired-tail synchronization, classifier transport, replay stability, sequential-completeness handoff, Real seal handoff, provenance exhaustion, and local naming for BEDC.Derived.RegularCauchyTailPairingUp.

Chapter 5207

A Concrete Naming Certificate for $\mathsf{RegulatedMeasure}^{\uparrow}$

Following Riemann, Stieltjes, and the Bishop–Bridges constructive treatment of regulated functions and bounded variation, the $\mathsf{RegulatedMeasure}^{\uparrow}$ packet records finite regulated partition-measure data. It sits between the displayed regulated-function rows of chapter 1906, the partition-variation surface of chapter 398, the tagged-sum route of chapter 1637, the dyadic partition rows of chapter 1863, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite partition-measure certificate; it is not a sigma-measure, a measure completion, a Lebesgue integration object, a host-function quotient, countable choice, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 5207.1 (RegulatedMeasure carrier)**.** *A* $\mathsf{RegulatedMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, V, \Pi, \Delta, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row, inspected only through finite step-window and oscillation-control data.*
2. *V is the* $\mathsf{BoundedVariation}^{\uparrow}$ *control row, recording the partition-variation budget that bounds all displayed interval contributions.*
3. *Π is the* $\mathsf{DyadicPartition}^{\uparrow}$ *row, naming the ordered cells and refinement witnesses on which the packet is read.*
4. *Δ is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *interval-mass ledger, assigning finite rational mass rows to the cells of Π under the displayed variation budget.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that exposes the regulated finite measure values at the requested windows.*
6. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, V, Π, Δ, R have been displayed.*
7. *H records componentwise* hsame *transport for the regulated source, variation budget, partition, mass ledger, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from regulated-function partition reads through bounded-variation control, dyadic mass ledgers, regular rational readback, and the terminal real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedMeasure}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, V, \Pi, \Delta, R, E, H, C, P, N$. It has no coordinate for countable additivity, a sigma-algebra completion, a host measure quotient, selected limits, countable choice, Lebesgue integration, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.RegulatedMeasureUp.TasteGate.RegulatedMeasureTasteGate single carrier alignment`

Theorem 5207.2 (RegulatedMeasure NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedMeasure}^{\uparrow}$ *carrier*

$$M = (F, V, \Pi, \Delta, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedMeasure}^{\uparrow}}$ *surface consists exactly of carrier admission for the regulated source F, bounded-variation control through V, dyadic partition exposure through Π, interval-mass exactness through Δ, regular rational readback through R, terminal real sealing through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5207.1. The source rows F, V, Π are finite regulated-function, bounded-variation, and dyadic partition data, so carrier admission begins from displayed rows rather than from an ambient measure space.

The interval-mass obligation is the dyadic ledger Δ. Its cells are exactly the cells of Π, and its allowed values are constrained by the variation budget V before any downstream readback is visible.

The readback and seal obligations are R and E. They route the finite mass ledger through regular rational windows and then through the terminal real seal, while H, C, P, N preserve transport, replay, provenance, and local naming for the same packet.

Since no omitted object is a carrier coordinate, the listed rows exhaust the NameCert surface and exclude sigma-measure completion, host quotient equality, selected limits, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5207.3 (RegulatedMeasure Stieltjes handoff)**.** *Every* $\mathsf{RiemannStieltjes}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegulatedMeasure}^{\uparrow}$ *packet reads the measure-facing contribution only through the displayed route*

$\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, F

Concretely, the consumer must expose the regulated source row F, the bounded-variation budget V, the dyadic partition Π, the interval-mass ledger Δ, and the regular rational readback R before the $\mathsf{Real}^{\uparrow}$ *seal E is read.*

Proof. Begin with the regulated source and variation rows. The regulated-function surface supplies finite step-window data, and the bounded-variation surface supplies the finite budget controlling interval contributions.

Next expose the dyadic partition and mass ledger. The $\mathsf{DyadicPartition}^{\uparrow}$ row fixes the cells that a Stieltjes-facing consumer may inspect, and Δ assigns only finite dyadic mass rows to those cells.

Finally pass through regular rational readback and the real seal. The $\mathsf{RegSeqRat}^{\uparrow}$ row reads the displayed finite ledger, and E seals that same readback as a terminal $\mathsf{Real}^{\uparrow}$ row. No row in

the route supplies countable additivity, sigma-measure completion, selected limits, host quotient equality, Lebesgue integration, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedMeasure}^{\uparrow}$ packet is generated from a regulated-function source row, a bounded-variation control row, a dyadic partition row, an interval-mass DyadicRatCore ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5207.1, Definition 5207.2, and Definition 5207.3 seed the finite regulated partition-measure packet consumed by Riemann–Stieltjes and real-name routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim sigma-measure completion, countable additivity, Lebesgue integration, host-function quotient equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation control, dyadic partition exposure, interval-mass exactness, regular rational readback, real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedMeasureUp.

Chapter 5208

A Concrete Naming Certificate for $\mathsf{CompactIntervalChoiceFree}^{\uparrow}$

Following Bishop and Bridges constructive compactness practice, the $\mathsf{CompactIntervalChoiceFree}^{\uparrow}$ packet records compact interval finite-net reasoning as a finite BEDC carrier before any Real and Completion consumer may inspect a completion boundary. It sits after the located interval boundary of chapter 394, the dyadic arithmetic core of chapter 291, the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names the constructive finite-net surface of a compact interval; it is not open-cover compactness, a quotient stream construction, a selected limit, trichotomy, countable choice, or a bridge claim.

Definition 5208.1 (Compact interval choice-free carrier)**.** *A* $\mathsf{CompactIntervalChoiceFree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (E, D, S, Q, R, T, C, P, N)$$

with the following displayed rows:

1. *E is the located endpoint row. It names the left and right endpoint data through the* $\mathsf{LocatedInterval}^{\uparrow}$ *surface and records the finite comparison windows used to keep the interval ordered.*
2. *D is the dyadic finite mesh row. It lists a finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh, the mesh radius, the endpoint brackets, and the predecessor-successor checks that witness coverage of the displayed interval.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It records exactly the finite name coordinates inspected when an interval point, endpoint, or mesh point is read by a downstream consumer.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records regular rational approximations for the endpoints and mesh witnesses at the displayed tolerance requests.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row. It exposes only the terminal real-name seals obtained from S and Q.*
6. *T records componentwise* hsame *transport for the endpoint row, dyadic mesh row, StreamName windows, RegSeqRat readbacks, Real seals, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay of the finite route*

$$E, D \longmapsto S, Q \longmapsto R, T, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalChoiceFree}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalChoiceFree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, D, S, Q, R, T, C, P, N$. It has no coordinate for arbitrary open covers, selected limit points, quotient streams, trichotomy on host reals, countable choice, or a standard bridge.

Lean4 ✓ `BEDC.Derived.CompactIntervalChoiceFreeUp.TasteGate.CompactIntervalChoiceFreeTasteGate single carrier alignment`

Theorem 5208.2 (Compact interval choice-free finite-net obligations)**.** *For every accepted* CompactIntervalChoiceFr *carrier*

$$K = (E, D, S, Q, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactIntervalChoiceFree}^{\uparrow}}$ *surface consists exactly of carrier admission for located endpoints, the dyadic finite mesh, StreamName windows, RegSeqRat readback, Real seals, componentwise transport, displayed replay, provenance, and local naming. The finite mesh row must witness dyadic coverage of the displayed endpoint interval, endpoint transport must preserve the inspected located rows, and every Real-facing read must pass through the displayed StreamName and RegSeqRat rows before the Real seal is inspected.*

Proof. Project the accepted carrier in Definition 5208.1. Carrier admission is the assertion that the rows $E, D, S, Q, R, T, C, P, N$ are the only rows exposed by the packet.

The dyadic finite-net obligation is read from D. Its endpoint brackets, mesh radius, and predecessor-successor checks give the finite coverage witnesses needed by a compact interval consumer without appealing to an arbitrary open cover.

Endpoint transport is read from T and replayed by C. The componentwise hsame rows identify the displayed located endpoints, mesh data, StreamName windows, RegSeqRat readbacks, and Real seals before any consumer may compare packet outputs.

The ledger is therefore nonescaping. Since the carrier has no coordinate for open-cover compactness, selected limits, quotient streams, trichotomy, countable choice, or bridge data, the listed rows exhaust the local finite-net obligation surface. □

Theorem 5208.3 (Compact interval choice-free Real-completion boundary)**.** *Every Real and Completion consumer of an accepted* $\mathsf{CompactIntervalChoiceFree}^{\uparrow}$ *carrier factors through the dyadic finite mesh row D, the finite StreamName window row S, the regular rational readback row Q, and the terminal Real seal row R. The exported boundary supplies only finite mesh coverage, finite windows, regular readback, and Real seals; it exports no open-cover compactness, selected limit, quotient stream, trichotomy, countable choice, host real equality, or bridge claim.*

Proof. Project the consumer route through the carrier rows of Definition 5208.1. A completion-facing read can inspect endpoint and mesh data only through E and D, and any name coordinate needed for that read must pass through S.

The regular rational interpretation is then supplied by Q, and the terminal real-name boundary is supplied by R. Thus the Real-facing surface is reached by the finite route

$$D, S, Q, R$$

rather than by a quotient stream or a selected completed point.

The structural rows T, C, P, N transport, replay, source, and name this route only. Because no row stores open-cover compactness, countable choice, trichotomy, host equality, or bridge data, the consumer receives exactly the finite Real-completion boundary stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalChoiceFree}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalChoiceFree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5208.1, Definition 5208.2, and Definition 5208.3 seed the finite compact-interval carrier over located endpoints, dyadic mesh data, finite StreamName windows, RegSeqRat readback, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalChoiceFree}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CompactIntervalChoiceFreeUp.TasteGate.CompactIntervalChoiceFreeTasteGate\_single\_carri`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limits, quotient streams, trichotomy, countable choice, host real equality, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic finite-net coverage, endpoint transport, Real-completion boundary routing, provenance, and local naming for BEDC.Derived.CompactIntervalChoiceFreeUp.

Constructive story: A $\mathsf{CompactIntervalChoiceFree}^{\uparrow}$ packet is generated from LocatedInterval, DyadicRatCore, StreamName, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Chapter 5209

A Concrete Naming Certificate for $\mathsf{FiniteMetricEntropy}^{\uparrow}$

Following Kolmogorov and Tikhomirov on metric entropy, and Bishop-style finite nets, the $\mathsf{FiniteMetricEntropy}^{\uparrow}$ packet records a constructive quantitative compactness budget as finite BEDC data. It sits beside the metric source of chapter 57, the finite net surface of chapter 1767, the covering-number row of chapter 2187, the packing-number row of chapter 3761, the rational tolerance row of chapter 37, and the dyadic tolerance ledger of chapter 291. The packet binds covering and packing data to a visible entropy ledger without importing host cardinality, open-cover compactness, selected centers outside the displayed net, or ambient completeness.

Definition 5209.1 (Finite metric entropy carrier)**.** *A* $\mathsf{FiniteMetricEntropy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, \varepsilon, C, Pk, L, H, Cn, Q, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row, naming the carrier, distance classifier, and finite metric observations consumed by the entropy packet.*
2. *ε is a positive* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the radius at which the budget is read.*
3. *C is the finite* $\mathsf{MetricCoveringNumber}^{\uparrow}$ *row, exposing the displayed cover centers and the covering-number upper bound at tolerance ε.*
4. *Pk is the* $\mathsf{PackingNumber}^{\uparrow}$ *lower-bound row, exposing separated witnesses that can be read against the same metric and tolerance data.*
5. *L is the logarithmic or unary entropy-budget ledger, recording the finite budget associated to the covering row and the comparison against the packing row.*
6. *H records componentwise* hsame *transport for the metric source, tolerance, covering, packing, ledger, replay, provenance, and local naming rows.*
7. *Cn records displayed* Cont *replay from a metric-entropy request through $X, \varepsilon, C, Pk, L, H$.*
8. *Q is the* Pkg *provenance over* $\mathsf{FiniteMetricEntropy}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{MetricCoveringNumber}^{\uparrow}$, $\mathsf{PackingNumber}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricEntropy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host cardinality, an infinite open cover, a selected compactness witness, quotient point equality, countable choice, or ambient metric completeness.

Lean4 ✓ `BEDC.Derived.FiniteMetricEntropyUp.FiniteMetricEntropyTasteGate single carrier alignment`

Theorem 5209.2 (Finite metric entropy NameCert obligations)**.** *For every accepted* $\mathsf{FiniteMetricEntropy}^{\uparrow}$ *carrier*

$$M = (X, \varepsilon, C, Pk, L, H, Cn, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteMetricEntropy}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed metric source, positive tolerance, covering-number row, packing-number row, entropy ledger, transport, replay, provenance, and local naming rows;*
2. *tolerance visibility, requiring every covering or packing read to inspect the same positive* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* ε*;*
3. *covering exactness, requiring the covering budget* C *to be read through finite* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *centers and the* $\mathsf{MetricCoveringNumber}^{\uparrow}$ *row before the ledger* L *is consumed;*
4. *packing lower-bound visibility, requiring* Pk *to expose only displayed separated witnesses over* X *and* ε*;*
5. *entropy-ledger nonescape, requiring every logarithmic or unary budget read to pass through* C, Pk, L, H, Cn, Q, N *and to avoid host cardinality or compactness.*

No finite metric-entropy obligation is stored outside $X, \varepsilon, C, Pk, L, H, Cn, Q, N$*.*

Proof. Carrier admission is projection from Definition 5209.1. The accepted packet displays the metric source, positive tolerance, covering-number row, packing-number row, entropy ledger, transport, replay, provenance, and local naming rows.

The tolerance and covering obligations follow from the row order. A covering read has no access to centers or a budget until it has inspected X and ε, and the finite net surface is the only route from those rows to C.

The packing and ledger obligations are downstream. The row Pk supplies only displayed separated witnesses over the same metric and tolerance data, while L records the finite budget read from C and compared with Pk.

Finally, H, Cn, Q, N transport, replay, source, and name the same finite route. Since the carrier contains no host-cardinality, open-cover compactness, selected-center, quotient-equality, countable-choice, or ambient-completeness coordinate, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{FiniteMetricEntropy}^{\uparrow}$ consumer that reads an entropy budget without first displaying the metric row, positive tolerance, covering-number row, packing-number row, and ledger rows refutes the carrier surface.

Independence witness: metric, finite-epsilon-net, metric-covering-number, packing-number, rat, dyadicratcore: no listed sibling is bijective with $\mathsf{FiniteMetricEntropy}^{\uparrow}$ because this packet jointly carries metric source data, a positive tolerance row, covering and packing bounds, an entropy-budget ledger, transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMetricEntropy}^{\uparrow}}$**.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteMetricEntropy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5209.1 and Definition 5209.2 seed the finite entropy-budget route through metric source data, positive tolerance rows, covering numbers, packing lower bounds, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteMetricEntropy}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host cardinality, open-cover compactness, selected centers outside the displayed net, quotient point equality, countable choice, Lean verification, bridge checking, or ambient metric completeness.

Upgrade path: Obligation closure requires checked carrier admission, tolerance visibility, covering exactness, packing lower-bound visibility, and entropy-ledger nonescape for BEDC.Derived.FiniteMetricEntropyUp.

Constructive story: A FiniteMetricEntropy$^{\uparrow}$ packet is generated from MetricUp source data, a positive RatUp or DyadicRatCoreUp tolerance row, finite covering-number data, packing lower-bound data, an entropy-budget ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5210

A Concrete Naming Certificate for MetaCICCandidateNormalizationRouter$^{\uparrow}$

The MetaCICCandidateNormalizationRouter$^{\uparrow}$ packet realizes the candidate-mediated public route of chapter 9383 as finite closed-term routing data. It sits beside the candidate socket of chapter 3566, the redex frontier of chapter 1008, the bounded normal-equality checker of chapter 752, and the critical-path packet of chapter 765. The packet preserves candidate evidence as a visible row before any strong-normalization or no-infinite-reduction read is allowed.

Definition 5210.1 (MetaCIC candidate normalization router carrier)**.** *A* MetaCICCandidateNormalizationRouter$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, A, W, S, M, U, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed typed term row, recording the empty-context typing and closedness data consumed by the public normalization read.*
2. *A is the candidate-evidence row, naming the supplied reducibility candidate, closed-candidate wrapper, or candidate-set membership witness.*
3. *W is the closed-candidate wrapper row, displaying the closedness side conditions that keep the candidate evidence attached to T.*
4. *S is the candidate-set membership row, used when the route is mediated by a finite candidate-set package rather than a single candidate witness.*
5. *M is the application and Pi adequacy handoff row, recording which adequacy lemma may be consumed before an application or Pi-shaped read reaches normalization evidence.*
6. *U is the closed-candidate strong-normalization and no-infinite-reduction readback row reached only after T, A, W, S, M have been displayed.*
7. *O is the obstruction row refusing any closed-term strong-normalization read that bypasses candidate evidence.*
8. *H records componentwise* hsame *transport for the term, candidate, wrapper, membership, adequacy, readback, obstruction, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the audit-map request through T, A, W, S, M, U, O, H.*

10. *P is the* Pkg *provenance over* $\mathsf{MetaCICCandidateNormalizationRouter}^{\uparrow}$*, chapter 9383,* BHist*,* hsame*,* Cont*, and* NameCert*.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICCandidateNormalizationRouter}^{\uparrow}}$ *row.*

The classifier compares accepted router packets only through these rows. It has no coordinate for evidence-free strong normalization, an unconditional closed-term theorem, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, or completed closed consistency.

Theorem 5210.2 (MetaCIC candidate normalization router obligations)**.** *For every accepted* $\mathsf{MetaCICCandidateNormalizationRouter}^{\uparrow}$ *carrier*

$$R = (T, A, W, S, M, U, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICCandidateNormalizationRouter}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the closed typed term, candidate evidence, closed-candidate wrapper, candidate-set membership, adequacy handoff, readback, obstruction, transport, replay, provenance, and local naming rows;*
2. *candidate visibility, requiring every strong-normalization or no-infinite-reduction read to inspect A and the relevant wrapper row W or membership row S;*
3. *adequacy handoff exactness, requiring application and Pi consumers to pass through M before using candidate evidence to route a closed term;*
4. *obstruction exactness, requiring O to reject any route from T to U that bypasses candidate, wrapper, membership, or adequacy evidence;*
5. *transport and replay closure, requiring H, C, P, N to preserve the same candidate-mediated route.*

No router obligation is stored outside $T, A, W, S, M, U, O, H, C, P, N$.

Proof. Carrier admission is projection from Definition 5210.1. The accepted packet exposes exactly the closed typed term, candidate, wrapper, membership, adequacy, readback, obstruction, transport, replay, provenance, and local naming rows.

Candidate visibility follows from the audit-map route. The public closed-term read reaches U only through the candidate evidence A together with the displayed closed-candidate wrapper W or candidate-set membership row S.

Application and Pi reads are handled by M. That row records the adequacy handoff before the router treats candidate evidence as applicable to the closed term under inspection.

The obstruction row O records the negative boundary. Since no carrier coordinate supplies evidence-free strong normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, or completed closed consistency, O rejects exactly the bypasses named in the statement.

Finally, H, C, P, N transport, replay, source, and name the same route, so the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Any $\mathsf{MetaCICCandidateNormalizationRouter}^{\uparrow}$ strong-normalization read that reaches a closed typed term without candidate evidence, a closed-candidate wrapper or candidate-set membership row, and the relevant adequacy handoff refutes the packet.

Independence witness: normalization-candidate-socket, metacicredexfrontier, bounded-normal-equality-checker, metaciccriticalpath: no listed sibling is bijective with $\mathsf{MetaCICCandidateNormalizationRouter}^{\uparrow}$ because this packet jointly carries closed typed term data, candidate evidence, closed-candidate or candidate-set routing, adequacy handoff, obstruction, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICCandidateNormalizationRouter}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICCandidateNormalizationRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5210.1 and Definition 5210.2 seed the candidate-mediated closed-term normalization route through candidate evidence, closed-candidate wrappers, candidate-set membership, adequacy handoff, obstruction, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICCandidateNormalizationRouter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close evidence-free strong normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, completed closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate visibility, adequacy handoff exactness, obstruction exactness, and transport-replay closure for BEDC.Derived.MetaCICCandidateNormalizationRouterUp.

Constructive story: A $\mathsf{MetaCICCandidateNormalizationRouter}^{\uparrow}$ packet is generated from a closed typed term row, candidate-evidence row, closed-candidate wrapper, candidate-set membership row, application and Pi adequacy handoff, readback row, obstruction row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5211

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet records the separated completion boundary needed by the L10 Real and Completion route as finite BEDC data. It sits after the separation predicate of chapter 1925, the separated-completion carrier of chapter 1612, the metric completion route of chapter 1506, the finite stream interface of chapter 126, the dyadic tolerance core of chapter 291, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the envelope through displayed rows only; it does not quotient filters, select representatives, identify host equalities, invoke countable choice, or import ambient completeness.

Definition 5211.1 (Hausdorff completion envelope carrier)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (H, S, M, W, D, R, L, T, K, P, N)$$

where H *is the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$ *separation row,* S *is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* L *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal,* T *is componentwise* $\mathsf{BHist}/\mathsf{hsame}$ *transport,* K *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *row. A consumer of* E *receives a separated completion boundary only through these coordinates.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeTasteGate single carrier alignment`

Theorem 5211.2 (Hausdorff completion envelope obligations)**.** *Every accepted* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *read must expose the carrier of Definition 5789.1 in the order*

$$H, S, M, W, D, R, L, T, K, P, N.$$

The separation row H *and separated-completion row* S *are available before metric completion, stream observation, dyadic tolerance, regular readback, and real-seal rows are consumed; the transport, replay, provenance, and naming rows preserve the same displayed packet.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeNameCertObligations`

Proof. Project the carrier of Definition 5789.1. The packet has no completion-facing coordinates except $H, S, M, W, D, R, L, T, K, P, N$.

The Hausdorff and separated-completion rows are the first boundary data in the packet. Thus a consumer cannot inspect the metric completion route, finite stream windows, dyadic tolerances, regular readback, or terminal real seal without first reading the displayed separation surface.

Finally, the structural rows T, K, P, N only transport, replay, source, and name the same finite packet. They do not create quotient filters, selected representatives, host equality, choice-selected routes, or ambient completeness. □

Theorem 5211.3 (Hausdorff completion separated metric route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier factors through the separated route*

$$H, S \longmapsto M \longmapsto W, D, R, L.$$

The route records a separated metric-completion boundary for the L10 Real and Completion interface, not a quotient completion, a host equality theorem, a choice-selected representative, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier separated metric route`

Proof. Start from Definition 5789.2. It places the Hausdorff row H and separated-completion row S before the metric completion row M and before the stream, dyadic, regular-rational, and real-seal rows.

Read the metric completion route through M. Since M is downstream of H, S, every completion-facing use of M carries the displayed separated boundary with it.

The final Real-facing read is the finite route W, D, R, L. Because these rows are still coordinates of the same carrier, the route cannot be replaced by quotient representatives, host equality, countable choice, or ambient completeness. □

Theorem 5211.4 (Hausdorff completion envelope sibling route)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *consumer may hand its separated boundary to* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *only through the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$*,* $\mathsf{SeparatedCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows of*

$$E = (H, S, M, W, D, R, L, T, K, P, N).$$

The handoff contains no quotient-filter coordinate, representative-selection coordinate, host-equality coordinate, or ambient-completeness coordinate.

Proof. Apply Definition 5789.2. It places the Hausdorff row H, separated-completion row S, metric-completion row M, stream row W, dyadic row D, regular-rational row R, and terminal Real row L inside one displayed packet.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

The sibling $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ consumer therefore reads the same separated boundary as its input surface rather than receiving a separate primitive. Since the carrier only has the displayed rows and the structural rows T, K, P, N, quotient filters, selected representatives, host equality, and ambient completeness remain outside the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier sibling route`

Theorem 5211.5 (Hausdorff completion envelope Cauchy-net consumer link)**.** *Every* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier must read the same* $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before its directed-net completion route is consumed. The downstream sibling is chapter 3794, and the handoff is the displayed route*

$$H, S, M, W, D, R, L \longmapsto \mathsf{CauchyNetCompletion}^{\uparrow}.$$

It exports no quotient net, selected representative, host equality, countable-choice schedule, or ambient completeness coordinate.

Proof. Project the carrier $E = (H, S, M, W, D, R, L, T, K, P, N)$ of Definition 5789.1. The only completion-facing rows available to a consumer are the Hausdorff row H, separated-completion row S, metric-completion route M, finite stream row W, dyadic tolerance row D, regular readback row R, and terminal Real row L.

Apply Definition 5789.2. It places H, S, M, W, D, R, L inside one displayed packet before the structural rows T, K, P, N are used for transport, replay, provenance, and local naming.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

Therefore a downstream $\mathsf{CauchyNetCompletion}^{\uparrow}$ read can only consume the envelope through the same separated metric route before its directed-net completion surface is inspected. Since the packet has no quotient-net, selected-representative, host-equality, countable-choice, or ambient-completeness row, none of those objects can enter the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeForwardLink`

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5789.1, Definition 5789.2, and Definition 5789.3 name the separated completion envelope surface for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, host equality, choice-selected representatives, or ambient completeness.

Upgrade path: Obligation closure requires the carrier route to be tied to the sibling completion obligation theorems and then exposed as a public chapter surface.

Constructive story: A $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet is generated from Hausdorff separation, separated-completion boundary, metric-completion route, finite stream windows, dyadic tolerance, regular-rational readback, Real seal, transport, replay, provenance, and local NameCert rows.

Chapter 5212

A Concrete Naming Certificate for $\mathsf{BoundedLinearFunctional}^{\uparrow}$

Following Banach and Bourbaki functional analysis, the $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet records the scalar-valued bounded-linear-operator row that duality and weak-star consumers inspect before any host dual space is available. It sits over the linear-map route of chapter 48, the bounded-linear-operator surface of chapter 1644, the scalar-bound neighbour chapter 3603, the Banach-dual row of chapter 2265, the finite weak-star window of chapter 3420, the scalar endpoint seal of chapter 38, and the normed source surface of chapter 1950. The chapter names only displayed scalar-functional data: source rows, linearity rows, scalar target readback, norm-bound evidence, transport, replay, provenance, and local naming.

Definition 5212.1 (Bounded linear functional carrier)**.** *For a displayed* $\mathsf{NormedSpace}^{\uparrow}$ *source row* E *over the scalar endpoint surface of* $\mathsf{Real}^{\uparrow}$*, a* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E)$ *carrier is a finite* BHist *packet*

$$\Lambda = (E, L, T, K, O, H, C, P, N)$$

with the following displayed rows:

1. *E is the source normed-space row, including its carrier endpoints, scalar action, additive row, norm row, and classifier.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row from E to the scalar* $\mathsf{Real}^{\uparrow}$ *target.*
3. *T is the scalar-valued* $\mathsf{BoundedLinearOperator}^{\uparrow}(E, \mathsf{Real}^{\uparrow})$ *row carrying the same endpoint action as L.*
4. *K is the* $\mathsf{Real}^{\uparrow}$ *nonnegative bound endpoint for the functional.*
5. *O is the* $\mathsf{OperatorNorm}^{\uparrow}$ *handoff row exposing where the bound K is used.*
6. *H records componentwise* hsame *transport for the source, linear-map row, bounded-operator row, scalar bound, operator-norm handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a scalar-functional request through E, L, T, K, O, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedLinearFunctional}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{BanachDual}^{\uparrow}$, $\mathsf{BanachAlaoglu}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed source classifier, scalar endpoint transport, bounded-operator transport, bound transport, norm-bound ledger transport, replay, provenance, and local naming rows. It has no coordinate for a host dual space, quotient equality of functions, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BoundedLinearFunctionalUp.BoundedLinearFunctionalTasteGate single carrier alignment`

Theorem 5212.2 (Bounded linear functional NameCert obligations)**.** *For every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *carrier* $\Lambda = (E, L, T, K, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *surface consists exactly of source normed-space admission, linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from host dual objects. A consumer may inspect* $E, L, T, K, O, H, C, P, N$*, but it receives no ambient function space, quotient operator equality, selected representative, Hahn–Banach witness, unrestricted weak-star compactness theorem, or bridge data.*

Proof. Project the carrier rows. The analytic coordinates are exactly the source normed-space row E, the linear-map row L, the scalar-valued bounded-operator row T, the RealUp bound endpoint K, and the operator-norm handoff O.

The linearity obligation is read through $\mathsf{LinMap}^{\uparrow}$, while boundedness is read through $\mathsf{BoundedLinearOperator}^{\uparrow}(E,$ The scalar target is already the displayed $\mathsf{Real}^{\uparrow}$ endpoint surface, so the functional row never becomes a host-level function.

The bound exactness is the shared route through K and O. The operator-norm handoff records where the scalar bound is used, and componentwise hsame transport moves the source, action, bound, ledger, replay, provenance, and local naming rows together.

No remaining coordinate can manufacture a dual-space quotient, selected representative, Hahn–Banach witness, unrestricted compactness theorem, or bridge check. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 5212.3 (Bounded linear functional operator-norm handoff)**.** *Every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E$ *packet exports the finite route*

$$\mathsf{LinMap}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{OperatorNorm}^{\uparrow} \longmapsto \mathsf{BoundedLinearFunctional}^{\uparrow}$$

to functional-analysis consumers. The route first exposes the carried scalar-valued linear action, then the bounded-operator row, then the RealUp bound endpoint and operator-norm ledger; it does not expose a host supremum, quotient equality of functionals, selected norm-attaining vector, or hidden Banach completeness.

Proof. Begin with an accepted packet $\Lambda = (E, L, T, K, O, H, C, P, N)$. The read of L supplies only the displayed linear-map action from the source row to the scalar target.

The read of T then packages the same action as a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row. Its target row is $\mathsf{Real}^{\uparrow}$, and its bound endpoint is the displayed scalar K.

Finally the operator-norm handoff O records the norm-bound ledger that downstream consumers may inspect. Because no host norm function, quotient functional equality, selected vector, or hidden completion row is present, the exported handoff is exactly the displayed scalar-bound route. □

Theorem 5212.4 (Bounded linear functional dual-row nonescape)**.** *Any read of a* $\mathsf{BanachDual}^{\uparrow}$ *or* $\mathsf{BanachAlaoglu}^{\uparrow}$ *consumer that uses a* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *row factors through the same source normed-space row, scalar-valued bounded-operator row, RealUp bound endpoint, operator-norm handoff, componentwise transport, replay, provenance, and local naming rows of Definition 5790.1. The duality consumer receives a finite scalar-functional row, not a host dual space, a quotient function class, an unrestricted weak-star compactness theorem, or a selected cluster point.*

Proof. Read the duality consumer first. A $\mathsf{BanachDual}^{\uparrow}$ request needs a scalar-functional row over a displayed source, while a $\mathsf{BanachAlaoglu}^{\uparrow}$ request needs a finite family of such scalar-functional observations.

In either case the only scalar-functional packet available here is Λ. Its source row, bounded-operator row, bound endpoint, operator-norm handoff, and structural rows are projected in the order displayed by Definition 5790.1.

The downstream dual chapters may reuse those rows, but they cannot add coordinates that are absent from the packet. Thus quotient dual objects, host function classes, unrestricted weak-star compactness, selected cluster points, and bridge checks remain outside the read. □

Falsifiable prediction: Every accepted $\mathsf{BoundedLinearFunctional}^{\uparrow}$ scalar-functional read factors through a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ action row, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, and the local hsame, Cont, Pkg, and NameCert rows.

Independence witness: linearmap, boundedlinearoperator, operatornorm, banachdual, banachalaoglu, real, and normedspace: no listed sibling is bijective to $\mathsf{BoundedLinearFunctional}^{\uparrow}$ because this packet stores the scalar target restriction, the dual-facing provenance row, the operator-norm handoff, transport, replay, and local naming together as one finite scalar-functional surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet is generated from a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ scalar action, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5790.1, Definition 5790.2, Definition 5790.3, and Definition 5790.4 seed the scalar-functional row consumed by BanachDualUp and BanachAlaogluUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host dual spaces, quotient equality of functionals, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, scalar linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm handoff exactness, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BoundedLinearFunctionalUp.

Chapter 5213

A Concrete Naming Certificate for $\mathsf{CompletionModulusCategory}^{\uparrow}$

Following Bishop and Bridges on constructive completion and the functorial treatment of completions, the $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet records the finite category surface whose arrows preserve displayed completion moduli. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the completion functor of chapter 426, and the Cauchy completion functor of chapter 423. The packet names modulus-preserving completion morphisms as BEDC rows; it does not export quotient completions, selected representatives, host continuous maps, countable choice, or ambient completeness.

Definition 5213.1 (CompletionModulusCategory carrier)**.** *A* $\mathsf{CompletionModulusCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, A, S, R, D, E, F, H, C, P, N)$$

with the following displayed rows:

1. *O is the object ledger. Each object row records a completion-facing source, its displayed Cauchy-modulus discipline, and the local completion target read through the surrounding completion chapters.*
2. *A is the arrow ledger. Each arrow row records a finite morphism request together with the modulus transformation that sends source tolerances to target tolerances.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source and target names of an arrow.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the stream windows have been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare source and target moduli.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row read only after S, R, D have supplied the displayed tolerance route.*
7. *F records identity and composition rows for the completion functoriality surface, with identity arrows preserving the same modulus and composite arrows composing the displayed modulus transformations.*
8. *H records componentwise* hsame *transport for object rows, arrow rows, stream windows, regular readback, dyadic tolerances, Real seals, functoriality rows, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an arrow request through $O, A, S, R, D, E, F, H, P, N$.*
10. *P is the* Pkg *provenance over* CompletionModulusCategory$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, CauchyCompletionFunctor$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{CompletionModulusCategory}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite category packet for modulus-preserving completion morphisms. It has no coordinate for quotient completion points, selected representatives, host functions, global choice schedules, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryTasteGate single carrier alignment`

Theorem 5213.2 (CompletionModulusCategory NameCert obligations)**.** *For every accepted* CompletionModulusCa *carrier $M = (O, A, S, R, D, E, F, H, C, P, N)$, the local* NameCert$_{\text{CompletionModulusCategory}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed object ledger, arrow ledger, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, identity and composition rows, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface additionally requires each arrow row in A to expose its source modulus, target modulus, and modulus transformation before any Real$^{\uparrow}$*-facing read is accepted; each identity row in F to preserve the displayed modulus without adding a choice coordinate; and each composition row in F to compose the two displayed modulus transformations before the downstream seal is visible.*

Proof. Project the accepted carrier. The packet contains only the rows $O, A, S, R, D, E, F, H, C, P, N$, so carrier admission and ledger exhaustion are componentwise.

An arrow-facing request first reads the object and arrow ledgers O, A. The source and target names are then inspected through the finite stream windows S, regular rational readback R, and dyadic tolerance ledger D.

The functoriality rows F are local to the same displayed moduli. Identity preserves the stored modulus transformation, and composition combines the two stored transformations before the terminal seal E can be read.

Finally H, C, P, N transport, replay, source, and name this same finite route. Since quotient completions, selected representatives, host functions, global choice schedules, and ambient completeness are not carrier coordinates, they cannot be exported by the local NameCert. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryNameCertObligations`

Theorem 5213.3 (CompletionModulusCategory modulus functoriality)**.** *Every completion-facing consumer of an accepted* CompletionModulusCategory$^{\uparrow}$ *packet reads a modulus-preserving morphism through the finite route*

$$O, A, S, R, D, F, E, H, C, P, N.$$

Thus identity and composition of completion morphisms preserve the displayed modulus data before any Real$^{\uparrow}$ *seal or completion-functor read is exposed. The route factors through* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, *and* CauchyCompletionFunctor$^{\uparrow}$ *rather than through quotient completion equality, selected representatives, host continuous maps, countable choice, or ambient completeness.*

Proof. Start with a completion-facing morphism request. The object ledger O fixes the source and target completion rows, and the arrow ledger A fixes the modulus transformation to be checked.

The readback rows S, R, D display the inspected stream windows, regular rational observations, and dyadic tolerance comparisons. These rows are the only route by which the requested modulus can face the terminal Real seal.

The functoriality row F then supplies the identity or composition clause. In the identity case the same displayed modulus is replayed. In the composition case the two displayed modulus transformations are composed as finite rows before the result is handed to E.

The structural rows H, C, P, N preserve and name the same route. Therefore every completion-functor consumer receives finite modulus preservation data and no excluded quotient, selection, host-map, choice, or ambient-completeness surface. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryModulusFunctoriality`

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}$.

Constructive story: A $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet is generated from completion object rows, modulus-preserving arrow rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, RealUp seals, identity and composition rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5791.1, Definition 5791.2, and Definition 5791.3 seed the finite category surface for modulus-preserving completion morphisms.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host continuous maps, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-preserving arrow exactness, identity and composition rows, tolerance readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionModulusCategoryUp.

Chapter 5214

A Concrete Naming Certificate for $\mathsf{MarkovTriggerDynamics}^{\uparrow}$

The $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet realizes the finite rank-trigger dynamics of Definition 9462.1541, Definition 9462.1542, and Definition 9462.1546 as BEDC NameCert data. It records the state, support-rank, transition-count, drift, trigger-time, classifier, continuation, provenance, and naming rows needed by a downstream finite-dynamics consumer. The packet is a finite BHist surface for trigger-time readback; it is not a stochastic process on an ambient probability space, not an infinite sample path, not a hidden field model, and not a host Markov-chain object.

Definition 5214.1 (MarkovTriggerDynamics carrier)**.** *A* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, K, A, D, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite state row. It records the consumed external-codon count m and the covered support rank r for the current trigger state.*
2. *K is the support-rank row. It records the finite support coordinates currently covered by the observed codon rows and the rank read from that support.*
3. *A is the transition-count row. It stores the finite count of rank-preserving and rank-increasing next draws available from the current state.*
4. *D is the drift row. It records the displayed one-step rank drift computed from the same transition counts.*
5. *G is the trigger-time row. It records the finite recursion for the time to reach full rank and the deterministic threshold row consumed by trigger-time readers.*
6. *H records componentwise* hsame *transport for state, support-rank, transition-count, drift, trigger-time, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a state read through S, K, A, D, G, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$, BHist, hsame, Cont, *finite rank-trigger rows, finite transition-count rows, finite trigger-time rows, and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient probability space, hidden generator field, infinite sample path, external random oracle, host Markov-chain semantics, or unstated independence assumption.

Lean4 ✓ `BEDC.Derived.MarkovTriggerDynamicsUp.MarkovTriggerDynamicsTasteGate single carrier alignment`

Theorem 5214.2 (MarkovTriggerDynamics NameCert obligations)**.** *For every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier* $T = (S, K, A, D, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed state row, support-rank row, transition-count row, drift row, trigger-time row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface requires the transition-count row A *to be computed from the finite support-rank row* K*, the drift row* D *to read only the transition counts in* A*, and the trigger-time row* G *to replay the finite recursion from the displayed state row* S *without adding an external probability carrier.*

Proof. Project the accepted carrier. The packet exposes only $S, K, A, D, G, H, C, P, N$, so every NameCert obligation is a componentwise obligation on those rows.

The state and support rows S, K determine the finite rank-trigger situation. The transition-count row A counts rank-preserving and rank-increasing next draws from that finite support surface.

The drift row D is downstream of A, and the trigger-time row G is downstream of the same state and transition-count data. Thus the trigger-time read is a finite recursion over displayed rows, not an imported Markov-chain object.

Transport, replay, provenance, and local naming preserve the same coordinates. Since the excluded ambient and hidden objects are not coordinates of T, no consumer can read them from the packet. □

Theorem 5214.3 (MarkovTriggerDynamics finite trigger readback)**.** *Every trigger-time consumer of an accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *packet reads the finite route*

$$S, K, A, D, G, H, C, P, N.$$

Consequently the transition law, drift, and trigger-time rows are all determined by finite BHist transition-count data. No trigger-time read exports an infinite sample path, host Markov process, hidden field, or unstated independence source.

Proof. Start with the state row S and support-rank row K. They display the finite input state and the rank information that determines which next-draw counts are available.

The transition-count row A is the only row from which the drift row D may be read. The trigger-time row G then replays the finite recursion from those same transition counts.

Finally H, C, P, N transport, replay, source, and name the finite trigger route. Because no other row exists in the carrier, the stated nonescape clauses follow. □

Falsifiable prediction: Every $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ trigger-time read factors through finite state, support-rank, transition-count, drift, trigger-time, hsame, Cont, Pkg, and NameCert rows.

Independence witness: dna-boundary-tile, rank-trigger, finite-markov-transition: $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries state rows, support-rank rows, transition-count rows, drift rows, trigger-time rows, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Theorem 5214.4 (MarkovTriggerDynamics sibling dependency route)**.** *Every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *trigger-time read routes its finite state and transition-count rows through chapter 189 or chapter 4074 when the carrier is read as a Markov surface, through chapter 195 when it is read as finite transition evolution, and through chapter 3508 for the DNA boundary-trigger consumer.*

Proof. Project the existing carrier rows $S, K, A, D, G, H, C, P, N$. The state row S, support-rank row K, and transition-count row A provide exactly the finite Markov read, so a Markov-surface consumer reaches this packet through the Markov-chain or finite Markov-partition certificates.

The same rows, together with drift row D and trigger-time row G, form the finite transition-evolution route consumed by the dynamical-system certificate. The structural rows H, C, P, N then transport, replay, source, and name that route for the DNA boundary-trigger consumer.

This is a dependency route only. It does not add an ambient probability space, infinite sample path, unstated independence source, or host Markov-chain object to the carrier. □

Nontrivial TasteGate and FieldFaithful instances remain required before this finite trigger surface can be read as a checked biological field-faithfulness claim.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet is generated from finite state rows, support-rank rows, transition-count rows, drift rows, trigger-time recursion rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5792.1, Definition 5792.2, and Definition 5792.3 seed the finite rank-trigger Markov readback surface for DNA boundary-tile dynamics.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient probability spaces, infinite sample paths, hidden field models, host Markov-chain semantics, biological field-faithfulness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-count exactness, drift readback, trigger-time recursion, nontrivial TasteGate coverage, FieldFaithful evidence, transport, replay, provenance, and local naming for BEDC.Derived.MarkovTriggerDynamicsUp.

Chapter 5215

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet records the finite constructive route from regular Cauchy rational names to located completion data and then to the terminal $\mathsf{Real}^{\uparrow}$ seal. It reads the dyadic arithmetic surface of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the completion service exposed by chapter 128, and the real-name boundary of chapter 38. The packet supplies a located completion neighbour for the regular-Cauchy real route without asserting quotient completion equality, selected representatives, host order completeness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5215.1 (Regular Cauchy located completion carrier)**.** *A* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, Q, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the Cauchy name is inspected at requested precision scales.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for tolerance comparison, shrinkage, and rational distance estimates.*
4. *Q is the located completion row, recording the displayed located-distance and approximation data extracted from S, R, D.*
5. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row used only as a finite completion handoff for the displayed located data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback and located completion rows have been displayed.*
7. *H records componentwise* hsame *transport for stream windows, regular rational readbacks, dyadic arithmetic, located completion data, completion service, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a located-completion request through $S, R, D, Q, K, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, K, E, H, C, P, N$. The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host order completeness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedCompletionUp.RegularCauchyLocatedCompletionTasteGate single carrier alignment`

Theorem 5215.2 (Regular Cauchy located completion obligations)**.** *For every accepted* RegularCauchyLocatedCom *carrier*

$$L = (S, R, D, Q, K, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream-window row, regular rational readback row, dyadic arithmetic ledger, located completion row, complete-metric handoff, real seal, transport, replay, provenance, and local name;*
2. *window-readback coherence, requiring S to expose the finite inspection windows before R may be consumed as a regular rational name;*
3. *dyadic locatedness, requiring D to supply the tolerance comparisons and distance estimates used by the located completion row Q;*
4. *completion handoff ordering, requiring Q to be displayed before the* $\mathsf{CompleteMetric}^{\uparrow}$ *row K is exposed;*
5. *real-seal ordering, requiring E to be read only after S, R, D, Q, K have been displayed;*
6. *classifier stability, requiring componentwise* hsame *transport and displayed* Cont *replay to preserve all visible rows;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no quotient completion equality, selected representative, countable choice, host order completeness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5793.1. Its rows list the finite stream windows, regular rational readback, dyadic arithmetic ledger, located completion data, complete-metric handoff, real seal, and the structural rows.

Window-readback coherence follows because R has no independent observation coordinate in this packet. The regular rational read must pass through S, and the tolerance computations used by that read are then checked against the dyadic row D.

The located completion row Q is the only row that records located-distance data. The completion handoff K consumes that displayed row, and the real seal E is exposed only after the handoff has been displayed.

Transport, replay, provenance, and local naming are exhausted by H, C, P, N. Since quotient completion equality, selected representatives, countable choice, host order completeness, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier, no NameCert obligation can export them. □

Theorem 5215.3 (Regular Cauchy located completion Real seal route)**.** *Let* $L = (S, R, D, Q, K, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the located completion read factors through the finite route*

$$S, R, D \longmapsto Q \longmapsto K \longmapsto E \longmapsto H, C, P, N.$$

Thus the packet reaches the real-name boundary only through displayed $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic, located completion data, and the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff. It does not export quotient completion equality, selected representatives, countable choice, host order completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing read of the packet. The only observable name data are the stream windows S and the regular rational readback R, so any request for a real seal must first inspect those rows.

The dyadic row D supplies the tolerance and distance comparisons used by the located completion data Q. The complete-metric handoff K is then read as a service row for that displayed located data, not as an ambient completeness theorem.

Finally the seal row E exposes the $\mathsf{Real}^{\uparrow}$ boundary, and H, C, P, N transport, replay, source, and name the same displayed route. No remaining carrier coordinate can provide quotient completion equality, selected representatives, choice data, host order completeness, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5793.1, Definition 5793.2, and Definition 5793.3 seed a finite route from regular Cauchy names through located completion data to the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host order completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback coherence, dyadic locatedness, completion handoff ordering, real-seal ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLocatedCompletionU

Constructive story: A $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore arithmetic, located completion data, a CompleteMetric handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5216

A Concrete Naming Certificate for $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$

Following Banach, Picard, and Bishop–Bridges constructive analysis, the $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet records the finite handoff from an explicit contraction estimate to the Cauchy threshold consumed by the regular-rational and real endpoint routes. It sits between the Banach fixed-point modulus packet of chapter 4188, the Picard iteration and error-estimate packets of chapter 2359 and chapter 2233, and the regular Cauchy completion boundary of chapter 5793. The packet gives the endpoint route a single displayed Cauchy-threshold surface without selecting a fixed point, quotienting completion names, or importing ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5216.1 (Picard threshold Cauchy handoff carrier)**.** *A* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, I, E, M, R, K, S, T, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BanachFixedPointModulus}^{\uparrow}$ *source row whose contraction-rate route has already exposed the rational Lipschitz and finite Picard ledgers.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *ledger of adjacent iterate windows and replay order.*
3. *E is the* $\mathsf{PicardErrorEstimate}^{\uparrow}$ *row, carrying the residual-and-ratio estimate used to bound the Picard tail.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row produced from B, I, E for each requested dyadic or rational tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row made available only after the threshold row M has been displayed.*
6. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row consumed at the handoff boundary, not an ambient completeness theorem.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, R, K have been read.*
8. *T stores componentwise* hsame *transports for the Banach-modulus, Picard-iteration, error-estimate, Cauchy-threshold, regular-rational, complete-metric, real-seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from the contraction-rate request through $B, I, E, M, R, K, S, T, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$, $\mathsf{BanachFixedPointModulus}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{PicardErrorEstimate}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, I, E, M, R, K, S, T, C, P, N$. It has no coordinate for a selected fixed point, host fixed-point equality, quotient completion equality, detached Cauchy selector, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.PicardThresholdCauchyHandoffUp.PicardThresholdCauchyHandoffTasteGate`
`single carrier alignment`

Theorem 5216.2 (Picard threshold Cauchy handoff NameCert obligations)**.** *For every accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier $H = (B, I, E, M, R, K, S, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyH}}$ *surface consists exactly of carrier admission for the displayed rows; Banach-modulus source visibility through B; Picard-iteration visibility through I; error-estimate visibility through E; Cauchy-threshold construction through M; regular-rational readback through R; complete-metric service access through K; real seal access through S; classifier stability through T and C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 5794.1. The accepted packet exposes exactly the Banach-modulus source row, the Picard-iteration ledger, the error-estimate row, the Cauchy-threshold row, the regular-rational readback, the complete-metric service, the real seal, and the structural rows.

The threshold rows are ordered. The rows B, I, E must be displayed before M can answer a tolerance request, since M is the only coordinate that records the finite Cauchy threshold.

The endpoint rows are downstream. The row R reads the threshold as regular rational data, K is the visible complete-metric service row, and S is exposed only after those rows have been displayed. Transport, replay, provenance, and local naming are exhausted by T, C, P, N, so no further NameCert obligation is present. □

Theorem 5216.3 (Picard threshold Cauchy handoff Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing endpoint read of an accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{BanachFixedPointModulus}^{\uparrow},\ \mathsf{PicardIteration}^{\uparrow},\ \mathsf{PicardErrorEstimate}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Complete}$$

Thus the real seal is reached only after the explicit Picard threshold has been displayed as a $\mathsf{CauchyModulus}^{\uparrow}$ *row and repacked through the regular-rational and complete-metric handoff rows. The route exports no selected fixed point, quotient completion equality, detached Cauchy selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing endpoint request. The only contraction-rate source row is B, and its Picard data are refined in the visible rows I and E, so the request first reads those rows.

The threshold stage is forced by M. Apply the Banach fixed-point modulus route of Definition 4188.3 together with the Picard iteration surface of chapter 2359 and the error-estimate surface of chapter 2233. These sources supply the displayed threshold row without adding a selected endpoint.

After M is fixed, the readback and completion rows R and K expose the regular-rational and complete-metric boundary used by chapter 301 and chapter 128. The seal row S is then the only $\mathsf{Real}^{\uparrow}$ coordinate, and the structural rows T, C, P, N preserve the same route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5794.1, Definition 5794.2, and Definition 5794.3 seed the finite Picard-threshold handoff from BanachFixedPointModulus, PicardIteration, and PicardErrorEstimate rows to CauchyModulus, RegSeqRat, CompleteMetric, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, host fixed-point equality, quotient completion equality, detached Cauchy selectors, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard-threshold construction, regular-rational readback, complete-metric service access, real-seal ordering, classifier stability, provenance, and local naming for BEDC.Derived.PicardThreshol

Constructive story: A $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet is generated from a BanachFixedPointModulus source row, PicardIteration ledger, PicardErrorEstimate row, CauchyModulus threshold, RegSeqRat readback, CompleteMetric service row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5217

A Concrete Naming Certificate for $\mathsf{DiniUniformLimitModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the classical Dini theorem, the $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet extracts the finite uniform-modulus ledger visible in compact-metric monotone convergence data. It sits over chapter 2196, chapter 1436, chapter 129, chapter 130, chapter 463, chapter 369, chapter 301, and chapter 38. The packet names the finite net, rational tolerance budget, and extracted modulus route; it does not import open-cover compactness, chosen limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5217.1 (Dini uniform-limit modulus carrier)**.** *A* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row naming the compact-metric finite-source observations consumed by the extraction.*
2. *F is the monotone* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, recording the displayed continuous approximants and their pointwise monotone order.*
3. *W is the pointwise window row supplied by the Dini-continuity and Dini-uniform-convergence routes.*
4. *E is the finite net row over K, naming the finite mesh on which pointwise windows are inspected.*
5. *Q is the rational tolerance-budget row, storing the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerances assigned to the finite net and to the later readback.*
6. *U is the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row, obtained from E, Q, W and the monotone continuous family row F.*
7. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row, exposing only the modulus-controlled limit route supplied by U.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance transport.*
9. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row, naming the real-valued read without adding ambient real completeness.*
10. *H records componentwise* hsame *transport for compact-metric source, monotone family, pointwise window, finite net, rational tolerance, extracted modulus, uniform-limit handoff, rational readback, real seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the compact-metric source and monotone family through the finite net, tolerance budget, extracted modulus, and uniform-limit handoff.*
12. *P is the* Pkg *provenance over* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$, $\mathsf{DiniContinuity}^{\uparrow}$, $\mathsf{DiniUniformConvergence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, W, E, Q, U, L, R, S, H, C, P, N$. It has no coordinate for open-cover compactness, selected limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

`single carrier alignment`

Theorem 5217.2 (Dini uniform-limit modulus NameCert obligations)**.** *For every accepted* DiniUniformLimitModulu *carrier*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact-metric source, monotone continuous family, pointwise window, finite net, rational tolerance budget, extracted uniform modulus, UniformLimit handoff, RegSeqRat readback, Real seal, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires monotone-window visibility through F and W, finite-net extraction through E and Q, modulus handoff through U and L, Real-seal nonescape through S, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses open-cover compactness, selected limiting values, quotient function equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only computational rows are the compact-metric source K, monotone family F, pointwise windows W, finite net E, rational budget Q, extracted modulus U, uniform-limit handoff L, rational readback R, and real seal S.

The monotone-window step is local to F and W. The finite-net step is local to E and Q, so the modulus row U is extracted from displayed finite data rather than from an open cover or a choice of limiting values.

The handoff to $\mathsf{UniformLimit}^{\uparrow}$ passes only through U and L. The rational and real readback rows R and S name the downstream values without adding quotient function equality or ambient completeness.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded objects are not coordinates of D, no NameCert consumer can read them from this carrier. □

Falsifiable prediction: Every accepted $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ read must expose compact-metric source rows, monotone continuous-family rows, pointwise window rows, a finite net, a rational tolerance budget, an extracted uniform modulus, a UniformLimit handoff, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dini-continuity, diniuniformconvergence, compactmetric, continuousmap, uniformlimit, uniformmodulus, regseqrat, real: $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ is not bijective to any

listed sibling because it binds the finite net and rational tolerance budget to an extracted uniform-modulus handoff before UniformLimit and Real consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5795.1 and Definition 5795.2 seed the finite uniform-modulus ledger extracted from compact-metric monotone convergence data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limiting values, quotient function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window visibility, finite-net extraction, modulus handoff, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniUniformLimitModulusUp.

Constructive story: A $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet is generated from compact-metric source rows, monotone continuous-family rows, pointwise windows, finite net rows, rational tolerance-budget rows, extracted uniform-modulus rows, UniformLimit handoff rows, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5218

A Concrete Naming Certificate for $\mathsf{SummationByParts}^{\uparrow}$

Following Abel and Dirichlet, the $\mathsf{SummationByParts}^{\uparrow}$ packet records the finite identity surface by which displayed partial sums, coefficient windows, adjacent differences, and endpoint terms are bound into one NameCert row. It sits beside the Abel-summation route of chapter 1763, the Abel-test consumer of chapter 1496, and the Dirichlet-test consumer of chapter 1497. Its source rows use the finite series carrier of chapter 121; its regular readback, dyadic tolerance, and endpoint seal use chapter 301, chapter 291, and chapter 38. The packet names a finite algebraic identity for downstream convergence tests; it does not import infinite sums, quotient series equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5218.1 (Summation by parts carrier)**.** *A* $\mathsf{SummationByParts}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Series}^{\uparrow}$ *source row, exposing only the inspected finite term window and its displayed partial sums.*
2. *A is the coefficient-window row, naming the coefficient entries read over the same finite interval.*
3. *Δ is the adjacent-difference row, recording the displayed values $a_k - a_{k+1}$ used by the identity.*
4. *P is the partial-sum-window row, naming the cumulative sums paired with A and Δ.*
5. *B is the boundary-term row, displaying the endpoint products and the finite interior products determined by S, A, Δ, P.*
6. *T is the convergence-test handoff row consumed by* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$.
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed finite identity data.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the finite additions, subtractions, products, and endpoint comparisons used by B.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after $S, A, \Delta, P, B, T, R, D$ have been displayed.*
10. *H records componentwise* hsame *transport for the source, coefficient, difference, partial-sum, boundary, handoff, readback, dyadic, endpoint, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the route*

$$S, A, \Delta, P, B, T, R, D \longmapsto E.$$

12. *Q is the* Pkg *provenance over* $\mathsf{SummationByParts}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$. It has no coordinate for an infinite sum, quotient series equality, selected convergence witness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SummationByPartsUp.SummationByPartsTasteGate single carrier alignment`

Theorem 5218.2 (Summation by parts NameCert obligations)**.** *For every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *carrier*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet; source and partial-sum exposure through S and P; coefficient-window and adjacent-difference exposure through A and Δ; boundary-term exactness through B; convergence-test handoff through T; regular readback, dyadic accounting, and endpoint sealing through R, D, E; and transport, replay, provenance, and local naming through H, C, Q, N.*

Proof. Project the accepted carrier. The projection exposes exactly the rows $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$, so every naming obligation must be read from one of those displayed coordinates.

The identity rows are finite. The source row S and partial-sum row P display the inspected cumulative sums, the coefficient row A displays the paired coefficients, and Δ displays the adjacent differences used by the interior terms. The boundary row B records only the endpoint products and interior products determined by those rows.

The consumer handoff is downstream of the identity. A convergence-test consumer first reads T, and the regular and real-facing route then passes through R, D, E. These rows can transport the displayed finite calculation, but they do not introduce an independent summation principle.

Finally H, C, Q, N preserve, replay, source, and name the same route. Because the carrier has no coordinate for infinite sums, quotient series equality, selected convergence witnesses, countable choice, trichotomy, or ambient real completeness, the stated rows exhaust the local NameCert surface. □

Theorem 5218.3 (Summation by parts Cauchy-series handoff)**.** *Every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *packet that is consumed by an* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$ *route hands off only the finite identity chain*

$$\mathsf{Series}^{\uparrow} \longmapsto S, A, \Delta, P, B, T \longmapsto R, D, E, H, C, Q, N.$$

Thus a Cauchy-series or real-seal consumer may read the summation-by-parts row only after the series window, coefficient window, adjacent-difference ledger, partial-sum window, boundary ledger, and test handoff have been displayed. The handoff supplies no infinite sum, quotient series equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a convergence-test read. Carrier admission exposes the source row S and the finite identity rows A, Δ, P, B before the handoff row T is available.

The downstream chapters may add their own test-specific rows. The $\mathsf{AbelSummation}^{\uparrow}$ consumer reads the displayed finite identity as its transform row, the $\mathsf{AbelTest}^{\uparrow}$ consumer combines it with a monotone null coefficient ledger, and the $\mathsf{DirichletTest}^{\uparrow}$ consumer combines it with bounded partial sums and a null-tail schedule. In each case the summation-by-parts contribution remains the same displayed finite packet.

The Cauchy-facing route is therefore forced through R and D before E can seal the endpoint. Transport, replay, provenance, and local naming preserve that same route, so no excluded summation or completeness datum can be read from the packet. □

Falsifiable prediction: An accepted $\mathsf{SummationByParts}^{\uparrow}$ consumer that reaches an $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without reading the displayed source, coefficient, adjacent-difference, partial-sum, boundary-term, and handoff rows refutes the carrier surface.

Independence witness: abel-summation, abel-test, dirichlet-test, series, regseqrat, dyadicratcore, real: no listed sibling supplies the whole thirteen-row packet $K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$, because each sibling contributes only a transform consumer, convergence-test consumer, source series, regular readback, dyadic ledger, or endpoint seal while this chapter binds the finite identity itself.

Closure status for $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$.

Constructive story: A $\mathsf{SummationByParts}^{\uparrow}$ packet is generated from a SeriesUp finite source row, coefficient windows, adjacent-difference rows, partial-sum windows, boundary-term ledgers, AbelSummation/AbelTest/DirichletTest handoff rows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$, seed)

Scope closed: Definition 5796.1, Definition 5796.2, and Definition 5796.3 seed the finite summation-by-parts identity packet over $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite summation, quotient series equality, selected convergence witnesses, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite identity exactness, convergence-test handoff, Cauchy-series readback, dyadic accounting, endpoint sealing, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.SummationByPartsUp.

Chapter 5219

A Concrete Naming Certificate for $\mathsf{RealLineOrder}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealLineOrder}^{\uparrow}$ packet records the constructive real-line order and apartness boundary visible to finite BEDC NameCert consumers. It sits over the dyadic tolerance ledger of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the rational Cauchy completion route of chapter 3670, and the Bishop regular Cauchy limit seal of chapter 1821. The packet gives L10 consumers a located comparison interface before any real-order algebra can read it; it does not import trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5219.1 (Real line order carrier)**.** *A* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D, S, R, L, A, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the positive dyadic radius used by every finite comparison request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing only the finite stream observations inspected at that tolerance.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream windows into regular rational comparison data.*
4. *L is the located comparison row, recording the finite verdict surface for $x < y$ as a witnessed positive gap at the displayed tolerance, an unresolved window requiring a smaller displayed tolerance, or a symmetric failure of the current request.*
5. *A is the apartness row, recording positive-gap readback for $x \# y$ only through D, S, R, L.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same displayed stream and regular-rational data, not from host real equality.*
7. *H records componentwise* hsame *transport for dyadic tolerance, stream windows, regular-rational readback, located comparison, apartness, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite order request through $D, S, R, L, A, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, L, A, E, H, C, P, N$. It has no coordinate for trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderTasteGate single carrier alignment`

Theorem 5219.2 (Real line order NameCert obligations)**.** *For every accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier*

$$O = (D, S, R, L, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance row, stream-window row, regular-rational readback row, located comparison row, apartness row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise transport row, replay row, provenance row, and local naming row.*

The obligation surface requires finite tolerance visibility through D, window visibility through S, regular-rational comparison readback through R, located order exposure through L, apartness exposure through A, real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier of Definition 5797.1. The only analytic rows are the dyadic tolerance D, the finite stream windows S, the regular-rational readback R, the located comparison row L, the apartness row A, and the terminal real seal E.

The comparison step is located rather than trichotomic. A finite request may display a positive gap, request a smaller displayed tolerance, or fail symmetrically at the current window; none of these outcomes supplies a global three-way case split.

The equality-sensitive routes are absent. The readback row R is regular-rational data over the displayed windows, and the seal row E is reached only after D, S, R, L, A have been inspected. Thus the packet refuses quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded principles are not coordinates of O, no local NameCert obligation can demand them. □

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderNameCertObligations`

Theorem 5219.3 (Real line order apartness readback)**.** *Every apartness read exported by an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The apartness row A may expose only a positive-gap witness already visible through D, S, R, L. It exports no trichotomy datum, quotient equality, selected representative, host real equality, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Proof. Start with an apartness request. The request must first choose a displayed positive dyadic tolerance in D and inspect the finite windows in S.

The regular-rational readback R is then the only comparison source. The located comparison row L reads this finite data and either displays a positive gap at the requested tolerance or leaves the request unresolved for a smaller displayed tolerance.

The apartness row A can cite only the positive-gap branch already exposed by L. It refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$ because those objects are not carrier rows.

The terminal seal E preserves the same finite route into $\mathsf{Real}^{\uparrow}$. Transport and replay through H and C keep the route stable, while P and N only record provenance and local naming. □

Theorem 5219.4 (Real line order L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier must read the dyadic tolerance, stream-window, regular-rational readback, located comparison, apartness, and* $\mathsf{Real}^{\uparrow}$ *seal rows in the order*

$$D, S, R, L, A, E.$$

Consequently the handoff supplies a finite non-quotient comparison boundary for later real algebra and order packets, while refusing trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. An L10 order request begins with finite tolerance data. The row D fixes the displayed dyadic radius, and S opens only the stream windows inspected at that radius.

The row R repacks those windows as regular-rational readback. The located comparison row L can then answer only with the finite comparison surface generated from D, S, R.

Apartness is downstream of located comparison. The row A may expose a positive gap only when L has already displayed one, and E seals the same finite route as a $\mathsf{Real}^{\uparrow}$-facing endpoint.

Because no earlier or later row stores trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$, the L10 handoff cannot export those principles to later consumers. □

Falsifiable prediction: Every accepted $\mathsf{RealLineOrder}^{\uparrow}$ read must expose dyadic tolerance, StreamName windows, RegSeqRat readback, located comparison, apartness, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before an L10 order consumer can read a comparison boundary.

Independence witness: dyadicratcore, streamname, regseqrat, real, rational-cauchy-completion, bishop-regular-cauchy-limit-seal: $\mathsf{RealLineOrder}^{\uparrow}$ is not bijective to any listed sibling because it binds located comparison and apartness rows to the finite readback route before the RealUp seal is available.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5797.1, Definition 5797.2, Definition 5797.3, and Definition 5797.4 seed the finite non-quotient order and apartness boundary for displayed RealUp names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient equality, selected representatives, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite tolerance visibility, stream-window visibility, regular-rational readback, located comparison, apartness readback, RealUp seal handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.RealLineOrderUp.

Constructive story: A $\mathsf{RealLineOrder}^{\uparrow}$ packet is generated from a DyadicRatCoreUp tolerance row, StreamName finite windows, RegSeqRat readback, located comparison, apartness, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5220

A Concrete Naming Certificate for $\mathsf{SchwartzKernel}^{\uparrow}$

Following Schwartz and Gelfand–Shilov, the $\mathsf{SchwartzKernel}^{\uparrow}$ packet records the finite NameCert route by which a distribution kernel is read as a bilinear action between Schwartz test probes and tempered-distribution endpoints. It sits over the Schwartz-function carrier of chapter 3399, the tempered-distribution endpoint of chapter 2310, the nuclear factorization row of chapter 215, the projective tensor norm route of chapter 4088, the tensor-product source of chapter 87, and the real seal of chapter 38. The chapter exposes the kernel theorem as finite action, tensor, nuclearity, bound, transport, replay, provenance, and local naming rows; it does not import a host distribution space, quotient test-function equality, selected representatives, or an unrestricted topological-vector-space oracle.

Definition 5220.1 (Schwartz kernel carrier)**.** *A* $\mathsf{SchwartzKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, U, J, B, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SchwartzFunction}^{\uparrow}$ *test-probe row naming the finite seminorm windows inspected on the source side.*
2. *T is the* $\mathsf{TemperedDistribution}^{\uparrow}$ *endpoint row naming the distributional action read after the test windows are displayed.*
3. *U is the* $\mathsf{TensorProduct}^{\uparrow}$ *row naming the finite tensor source on which the two test-probe sides are paired.*
4. *J is the* ***??*** *row recording the projective-tensor bound used to compare the paired test windows.*
5. *B is the* $\mathsf{Nuclear}^{\uparrow}$ *factorization row, exposing the finite nuclear decomposition route by which the kernel action is read.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed scalar bounds and kernel-action readbacks.*
7. *H records componentwise* hsame *transport for test probes, tempered endpoint, tensor source, projective bound, nuclear factorization, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite kernel request through $S, T, U, J, B, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SchwartzKernel}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{Nuclear}^{\uparrow}$, ***??***, $\mathsf{TensorProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $S, T, U, J, B, R, H, C, P, N$. It has no coordinate for a host distribution space, quotient equality of test functions, selected representatives, ambient bornological completeness, or a topological-vector-space theorem outside the displayed rows.

Lean4 ✓ `BEDC.Derived.SchwartzKernelUp.SchwartzKernelTasteGate single carrier alignment`

Theorem 5220.2 (Schwartz kernel NameCert obligations)**.** *For every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *carrier*

$$K = (S, T, U, J, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *surface consists exactly of Schwartz test-probe admission through S, tempered-distribution endpoint admission through T, tensor-source admission through U, projective-bound exposure through J, nuclear-factorization exposure through B, scalar RealUp sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every kernel consumer must read the distributional action through these ten rows. No consumer may replace them by an ambient kernel theorem, quotient test-function equality, selected representative, hidden topological vector space, or host nuclear-space completion.

Proof. Project the accepted carrier of Definition 5798.1. The analytic rows are the Schwartz test row S, the tempered-distribution endpoint T, the tensor source U, the projective bound J, the nuclear factorization B, and the RealUp seal R.

The action route is finite. The tensor row U supplies the paired test-probe source, J records the displayed projective bound, and B records the nuclear factorization by which the kernel action becomes readable by a finite consumer.

Transport and replay do not create new analytic structure. The rows H and C preserve the displayed packet componentwise and replay only the same kernel request. The provenance and naming rows P, N package the route without adding host quotient equality or a hidden completion theorem.

Thus the listed rows are exactly the local NameCert obligations for $\mathsf{SchwartzKernel}^\uparrow$. □

Theorem 5220.3 (Schwartz kernel nuclear factorization boundary)**.** *Every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *read factors through the finite route*

$$\mathsf{SchwartzFunction}^\uparrow,\ \mathsf{TensorProduct}^\uparrow,\ ??,\ \mathsf{Nuclear}^\uparrow \longmapsto \mathsf{TemperedDistribution}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The nuclear row may expose only the displayed factorization and bound data already routed through S, U, J. It exports no host theorem identifying all kernels with all continuous bilinear forms, no quotient equality of test probes, no selected representative of a distribution, and no ambient completeness claim for the surrounding function spaces.

Proof. Start with a kernel read. The request first displays the finite Schwartz windows in S and the tensor source U on which the two test-probe sides are paired.

The projective tensor bound J is the only bound row available to the consumer. The nuclear factorization row B can cite only this displayed tensor-bound route, so its readback is a finite factorization certificate rather than an ambient nuclear-space theorem.

The tempered-distribution endpoint T then reads the resulting action, and R seals the scalar outputs as RealUp data. Transport through H and replay through C keep the same row order, while P and N record source and local naming.

Since no carrier coordinate stores host quotient equality, selected representatives, or ambient completeness, those principles cannot be exported by the factorization boundary. □

Falsifiable prediction: Every accepted $\mathsf{SchwartzKernel}^{\uparrow}$ packet must expose SchwartzFunctionUp test probes, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, TemperedDistributionUp endpoint action, RealUp scalar sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a kernel consumer can read the action.

Independence witness: schwartz-function, tempered-distribution, nuclear, projective-tensor-norm, tensorproduct, real: $\mathsf{SchwartzKernel}^{\uparrow}$ is not bijective to any listed sibling because it binds the test-probe tensor route, nuclear factorization boundary, distribution endpoint, and scalar seal as one finite kernel-action packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{SchwartzKernel}^{\uparrow}$ packet is generated from SchwartzFunctionUp test probes, a TemperedDistributionUp endpoint, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, RealUp scalar seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5798.1, Definition 5798.2, Definition 5798.3, the falsifiable prediction, and the independence witness seed the finite kernel-action route over Schwartz, tempered-distribution, tensor, nuclear, bound, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host distribution-space semantics, quotient equality of test functions, selected distribution representatives, ambient nuclear-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, test-probe visibility, tensor-source admission, projective-bound exactness, nuclear-factorization exposure, tempered-endpoint action, RealUp scalar sealing, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SchwartzKernelUp.

Chapter 5221

A Concrete Naming Certificate for $\mathsf{SynonymousTransition}^{\uparrow}$

The $\mathsf{SynonymousTransition}^{\uparrow}$ packet realizes the finite synonymous-transition geometry of Definition 9462.1186 as BEDC NameCert data. It sits beside the six-bit codon-window carrier of chapter 2234, the codon transition matrix of chapter 2245, the DNA boundary-tile packet of chapter 3393, the window-coverage trigger algebra of chapter 3478, and the DNA-window trigger threshold of chapter 4217. The packet names finite codon-window, class-adjacency, boundary-spectrum, threshold, transport, replay, provenance, and local naming rows; it is not a biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Definition 5221.1 (Synonymous transition carrier)**.** *A* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (W, M, A, B, T, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *row naming the finite Q_6 codon-window surface.*
2. *M is the* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *row naming one-bit codon transitions inspected by the packet.*
3. *A is the class-adjacency row recording the displayed synonymous and cross-class adjacency counts, including the largest weights of Definition 9462.1186.*
4. *B is the boundary-spectrum row recording internal edge counts, external boundary degrees, and the control-pair corner-contact data.*
5. *T is the* $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$ *row naming the finite threshold at which an adjacency or boundary-spectrum read may trigger a downstream tile consumer.*
6. *H records componentwise* hsame *transport for codon windows, transition matrix, class adjacency, boundary spectrum, trigger threshold, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite synonymous-transition request through W, M, A, B, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{SynonymousTransition}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{CodonTransitionMatrix}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, M, A, B, T, H, C, P, N$. It has no coordinate for biological mechanism, stochastic fitness, quotient codon equality, hidden enumeration, or an ambient graph-theory oracle outside the displayed finite rows.

Theorem 5221.2 (Synonymous transition NameCert obligations)**.** *For every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier*

$$G = (W, M, A, B, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *surface consists exactly of codon-window admission through W, transition-matrix admission through M, class-adjacency exposure through A, boundary-spectrum exposure through B, trigger-threshold exposure through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every downstream synonymous-transition consumer must read the graph through these nine rows. It cannot replace them by biological causation, stochastic selection, quotient codon semantics, an unrecorded enumeration, or a hidden graph oracle.

Proof. Project the accepted carrier of Definition 5799.1. The finite codon surface is W, the one-bit transition source is M, and the named graph data are the class-adjacency row A and boundary-spectrum row B.

The trigger row T records when the displayed adjacency or boundary-spectrum data may be read by a downstream tile or trigger consumer. It does not add a biological mechanism or a stochastic model; it only names the finite threshold over the same graph rows.

Transport and replay are componentwise. The rows H and C preserve and replay W, M, A, B, T with the same finite endpoints, while P and N record provenance and local naming.

Since the carrier has no coordinate for quotient codon equality, hidden enumeration, biological causation, or ambient graph semantics, the listed rows exhaust the local NameCert obligations. □

Theorem 5221.3 (Synonymous transition boundary-spectrum handoff)**.** *Every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *read factors through the finite route*

$$\mathsf{CodonSixBitWindow}^{\uparrow},\ \mathsf{CodonTransitionMatrix}^{\uparrow} \longmapsto \mathsf{SynonymousTransition}^{\uparrow} \longmapsto \mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{Wind}$$

The handoff exposes class-adjacency weights, internal-edge counts, external boundary degrees, and control-pair corner contacts only as finite packet rows. It exports no biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Proof. Start with the codon-window row W and the one-bit transition matrix row M. These rows supply the finite Q_6 source and the adjacency relation inspected by the packet.

The class-adjacency row A records the largest displayed weights, and B records the boundary-spectrum data. The downstream boundary-tile and trigger-algebra consumers therefore receive a finite graph packet rather than a biological or stochastic explanation.

The threshold row T names when the finite rows can be consumed by the trigger route. Transport through H and replay through C keep the same graph rows visible, while P and N only package their provenance and local name.

Thus every public read of the synonymous-transition geometry remains inside the finite codon-window, transition, adjacency, boundary-spectrum, threshold, transport, replay, provenance, and naming surface. □

Falsifiable prediction: Every accepted $\mathsf{SynonymousTransition}^{\uparrow}$ packet must expose CodonSixBitWindowUp, CodonTransitionMatrixUp, class-adjacency, boundary-spectrum, DNAWindowSixTriggerThresholdUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ rows before a downstream tile or trigger consumer can read the synonymous-transition graph.

Independence witness: codon-six-bit-window, codon-transition-matrix, dna-window-six-boundary-tile, window-coverage-trigger-algebra, dna-window-six-trigger-threshold: $\mathsf{SynonymousTransition}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries class-adjacency weights, boundary-spectrum rows, and trigger-threshold handoff over the finite codon-window graph.

Closure status for $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$.

Constructive story: A $\mathsf{SynonymousTransition}^{\uparrow}$ packet is generated from a CodonSixBitWindowUp source, a CodonTransitionMatrixUp one-bit transition row, class-adjacency counts, boundary-spectrum data, DNAWindowSixTriggerThresholdUp rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5799.1, Definition 5799.2, Definition 5799.3, the falsifiable prediction, and the independence witness seed the finite synonymous-transition packet over codon-window, transition, adjacency, boundary-spectrum, threshold, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic fitness, quotient codon semantics, hidden enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, codon-window visibility, transition-matrix exactness, class-adjacency exposure, boundary-spectrum exposure, trigger-threshold handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SynonymousTransitionUp.

Chapter 5222

A Concrete Naming Certificate for $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$

Following Feller and Billingsley on finite-sum normal approximation, the $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet records the finite BEDC surface by which an iid random-variable window is centered, scaled, read as a distribution row, and handed to a real-normal comparison seal. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the law readback of chapter 186, the regular rational window of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite central-limit-facing certificate; it is not an asymptotic central limit theorem, a characteristic-function convergence theorem, a host probability-limit operator, countable choice, quotient distribution equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5222.1 (Central-limit finite-window carrier)**.** *A* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, V, S, K, D, R, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row V is the displayed iid* $\mathsf{RandomVar}^{\uparrow}$ *window over P, including the finite index range and the shared law token read by the window. The row S is the finite partial-sum ledger naming the displayed sum, the sample count, and the centered numerator. The row K is the centering and scaling row, recording the finite mean token, variance or spread token, positive scale request, and normalized finite-sum expression. The row D is the* $\mathsf{Distribution}^{\uparrow}$ *readback for the normalized finite sum and its comparison request. The row R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *window that presents rational test intervals, tolerances, and finite comparison samples for the distribution read. The row E is the* $\mathsf{Real}^{\uparrow}$ *normal-window seal naming the terminal real comparison against the displayed normal row at the requested finite window. The row H records componentwise* hsame *transport for the probability source, iid window, partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat window, Real normal-window seal, continuation, provenance, and local naming rows. The row C records* Cont *replay from a normal-facing read through P, V, S, K, D, R, E and then through the structural rows. The row Q is the* Pkg *provenance over* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert. *The row N is the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these eleven rows.*

Lean4 ✓ `BEDC.Derived.CentralLimitFiniteWindowUp.TasteGate.CentralLimitFiniteWindowTasteGate single carrier alignment`

Theorem 5222.2 (Central-limit finite-window NameCert obligations)**.** *For every accepted* CentralLimitFiniteWindo *carrier* $(P, V, S, K, D, R, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 5800.1. Carrier admission displays the probability source, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, transport, replay, provenance, and local naming row. The certificate imports no host asymptotic central limit theorem, characteristic-function limit, Lindeberg replacement principle, countable-choice schedule, quotient distribution equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Project the carrier rows in order. The probability source P and iid random-variable window V are the only stochastic data exposed to the certificate, and the partial-sum ledger S fixes the finite sum before any normal-facing read is visible.

The centering and scaling row K then determines the normalized finite expression. The distribution row D and RegSeqRat window R provide the only comparison surface through which a finite law read can reach the terminal $\mathsf{Real}^{\uparrow}$ normal-window seal E.

Finally H, C, Q, N transport, replay, source, and name the same displayed route. Since the carrier has no coordinate for an asymptotic theorem, characteristic-function limit, quotient law equality, countable choice, or ambient completeness, the listed rows exhaust the local finite NameCert surface. □

Theorem 5222.3 (Central-limit finite-window normal handoff)**.** *Every normal-facing read of an accepted* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier factors through the finite route*

$$P \longmapsto V \longmapsto S \longmapsto K \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, Q, N$$

before any consumer receives a normal-window comparison. Thus the read is the displayed iid finite-sum, normalization, distribution, RegSeqRat, and RealUp handoff itself; it exports no host asymptotic CLT, countable choice, quotient distribution equality, characteristic-function convergence principle, or ambient real completeness.

Proof. Begin with a normal-facing request. The only probability data available are the source row P and the finite iid window V, so the request must first read the displayed sample range and shared law token.

The partial-sum row S and normalization row K are then forced. They provide the finite sum, centering token, scaling token, and normalized expression that the downstream distribution read consumes.

The request can reach a normal-window comparison only through D, R, E. The distribution row D names the finite law read, the RegSeqRat row R exposes rational windows and tolerances, and the RealUp row E seals the displayed normal comparison. The structural rows H, C, Q, N preserve that route without adding analytic content.

Therefore every accepted read factors through the finite iid-sum, normalization, distribution, RegSeqRat, and RealUp rows. The excluded asymptotic, choice, quotient, characteristic-function, and completeness principles cannot be inserted into the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet is generated from a probability source row, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5800.1, Definition 5800.2, and Definition 5800.3 seed the finite central-limit-facing handoff through ProbSpace, RandomVar, Distribution, RegSeqRat, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CentralLimitFiniteWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the asymptotic central limit theorem, characteristic-function convergence, Lindeberg replacement, countable-choice schedules, quotient distribution equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, iid-window routing, partial-sum ledger exactness, normalization stability, distribution-to-RegSeqRat handoff, RealUp normal-window nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.CentralLimitFiniteWindowUp.

Chapter 5223

A Concrete Naming Certificate for $\mathsf{LipschitzRealMap}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LipschitzRealMap}^{\uparrow}$ packet records a constructive real-map certificate whose continuity is controlled by a displayed dyadic Lipschitz constant and finite regular-rational windows. It sits after the dyadic tolerance ledger of chapter 291, the countable-name window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the located order and apartness neighbour of chapter 5797. The packet names the finite L10 route by which later continuous-map and metric-uniform-continuity consumers may read a real-valued map without importing host function extensionality, quotient representatives, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5223.1 (Lipschitz real-map carrier)**.** *A* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, K, W, R, M, H, C, P, N)$$

with the following rows:

1. *S is the source* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real input surface through displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
2. *T is the target* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real output surface through the same kind of finite readback.*
3. *K is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *Lipschitz constant row, including the positive dyadic bound and the displayed tolerance ledger used by every modulus request.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the source and target names inspected by the request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the displayed source and target windows into rational comparison data.*
6. *M is the modulus-inequality row, recording that every accepted finite pair of source reads with displayed apartness or distance bound is sent to a target read whose displayed difference is bounded by the dyadic constant in K times the source bound, up to the requested displayed tolerance.*
7. *H records componentwise* hsame *transport for source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a finite map request through $S, T, K, W, R, M, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LipschitzRealMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, T, K, W, R, M, H, C, P, N$. It has no coordinate for host function equality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LipschitzRealMapUp.LipschitzRealMapTasteGate single carrier alignment`

Theorem 5223.2 (Lipschitz real-map NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier*

$$F = (S, T, K, W, R, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* $\mathsf{Real}^{\uparrow}$ *seal, target* $\mathsf{Real}^{\uparrow}$ *seal, dyadic Lipschitz constant, finite StreamName windows, RegSeqRat readback, modulus inequality, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires finite source and target visibility through S and T, dyadic bound visibility through K, finite window visibility through W, rational readback through R, modulus-inequality exposure through M, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses host function extensionality, quotient equality of real presentations, selected representatives, global uniform-continuity principles, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5801.1. The source and target real seals are the only real-name endpoints, and both are read through finite StreamName and RegSeqRat windows rather than through host real equality.

The Lipschitz datum is the dyadic row K. A map request can inspect only the finite windows W and their rational readback R before the modulus row M exposes the displayed inequality for the requested tolerance.

The structural rows do not add analytic content. The transport row H preserves the already displayed source, target, constant, window, readback, and modulus rows componentwise, while C replays the same route and P, N record provenance and local naming.

Since no carrier coordinate stores host function equality, quotient real equality, selected representatives, global uniform continuity, or ambient completeness, no local NameCert obligation can require those objects. □

Theorem 5223.3 (Lipschitz real-map modulus stability)**.** *Let F_0 and F_1 be accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carriers whose source seals, target seals, dyadic Lipschitz constant rows, finite StreamName windows, and RegSeqRat readback rows are componentwise* hsame*-transported. Then every displayed modulus-inequality read exported by F_0 transports to the corresponding displayed modulus-inequality read exported by F_1.*

The stability claim is confined to the finite rows $S, T, K, W, R, M, H, C, P, N$. It does not identify host functions, quotient real presentations, selected Cauchy names, or ambient complete metric structures.

Proof. Start with a displayed modulus request for F_0. Its source and target real seals are read only through the finite StreamName windows and RegSeqRat readback rows named by S, T, W, R.

Use the componentwise hsame hypotheses. They transport the dyadic constant row K and the finite window/readback rows into the corresponding rows of F_1, so the same displayed source tolerance and target tolerance are available after transport.

The modulus row M is a row of the carrier rather than a host theorem about all representatives. Therefore the transported request reads the F_1 modulus row with the same displayed dyadic bound and the transported finite readback data.

Finally C, P, N replay, source, and name the transported route. No quotient equality, host function equality, selected representative, or ambient completeness principle is introduced by this transport. □

Theorem 5223.4 (Lipschitz real-map L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier must read the route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{LipschitzRealMap}^{\uparrow}$$

through the finite source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, transport, replay, provenance, and local NameCert rows. The handoff supplies a finite Lipschitz-control surface for later continuous-map and metric-uniform-continuity packets, while refusing host function extensionality, quotient equality, selected representatives, global uniform-continuity principles, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. An L10 map request begins with source and target real-name seals. By the carrier definition, these seals are visible only through the finite StreamName windows and RegSeqRat readback rows used by S, T, W, R.

The request then reads the dyadic constant row K and the located comparison surface supplied by the real-line order neighbour. These rows provide the displayed source difference and target tolerance against which the modulus inequality is checked.

The modulus row M is the only analytic output of the packet. It hands a consumer a finite inequality route, not a host-level function theorem.

The rows H, C, P, N transport, replay, source, and name the same route. Thus later continuous-map and metric-uniform-continuity packets can consume the finite Lipschitz surface without receiving quotient equality, selected representatives, host function extensionality, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzRealMap}^{\uparrow}$ packet is generated from source and target RealUp seal rows, a DyadicRatCore Lipschitz constant, finite StreamName windows, RegSeqRat readback, a displayed modulus-inequality row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, seed)

Scope closed: Definition 5801.1, Definition 5801.2, Definition 5801.3, and Definition 5801.4 seed the finite Lipschitz real-map surface over the current L10 real and completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and target RealUp sealing, dyadic constant visibility, finite window readback, modulus-inequality stability, transport, replay, provenance, and local naming for future BEDC.Derived.LipschitzRealMapUp.

Chapter 5224

A Concrete Naming Certificate for HyperbolicQuasiGeodesicShadow$^{\uparrow}$

The HyperbolicQuasiGeodesicShadow$^{\uparrow}$ packet realizes the observer-expansion shadow route of section 9463.4 as finite quasi-geodesic, boundary, visual-metric, Busemann, and lamination-compatible rows. It sits after disk readout through chapter 377, the metric surface of chapter 3474, the visual-metric packet of chapter 3866, the Busemann cocycle route of chapter 4134, the geodesic-lamination packet of chapter 4203, and the observer-expansion packet of chapter 4167. The packet names a finite shadow tied to a displayed quasi-geodesic route; it does not complete the boundary, choose a global geodesic representative, identify quotient ideal points, or import host hyperbolic geometry.

Definition 5224.1 (Hyperbolic quasi-geodesic shadow carrier)**.** *A* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, G, E, V, B, L, H, C, P, A, N)$$

with the following rows:

1. *D is the disk readout row, exposing only displayed* UnitDisk$^{\uparrow}$ *coordinates and the associated* HyperbolicMetric$^{\uparrow}$ *metric-read data.*
2. *G is the quasi-geodesic route row, recording the finite path samples, distortion budget, endpoint-facing direction, and local route ledger inspected by the shadow request.*
3. *E is the boundary endpoint row named by the displayed route, not by a completed ideal-boundary quotient.*
4. *V is the visual-metric shadow row, recording the finite shadow window read through* HyperbolicVisualMetric$^{\uparrow}$ *and the boundary endpoint E.*
5. *B is the Busemann cocycle tolerance row, recording the displayed additive tolerance used to compare the route and the shadow window.*
6. *L is the geodesic-lamination compatibility row, recording whether the displayed route is compatible with the finite noncrossing leaf data consumed by* HyperbolicGeodesicLamination$^{\uparrow}$.
7. *H records componentwise* hsame *transport for disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, replay, provenance, refusal, and local naming rows.*
8. *C records displayed* Cont *replay from an observer-expansion shadow request through $D, G, E, V, B, L, H, P, A, N$.*

9. *P is the* Pkg *provenance over* HyperbolicQuasiGeodesicShadow$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HyperbolicGeodesicLamination$^{\uparrow}$, HyperbolicObserverExpar BHist, hsame, Cont, *and* NameCert.
10. *A is the refusal row excluding completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, and host curvature semantics.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, G, E, V, B, L, H, C, P, A, N$.

Theorem 5224.2 (Hyperbolic quasi-geodesic shadow NameCert obligations)**.** *For every accepted* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier*

$$Q = (D, G, E, V, B, L, H, C, P, A, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *surface consists exactly of disk-readout visibility, quasi-geodesic route visibility, boundary endpoint exposure, visual-metric shadow-window exposure, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise transport, replay, provenance, refusal, and local naming rows.*

The packet exports no completed ideal boundary, quotient boundary equality, selected global geodesic, ambient hyperbolic compactification, physical observer trajectory, host curvature theorem, or global field semantics.

Proof. Project the carrier rows in order. The disk readout D supplies the only coordinate and metric source, while G supplies the displayed route samples and distortion budget inspected by the request.

The endpoint and shadow rows are downstream of that route. The endpoint row E names only the boundary read visible from G, and the visual row V records the finite shadow window tied to that endpoint.

The comparison rows B and L keep the shadow route finite. The Busemann tolerance is a displayed cocycle budget, and lamination compatibility is a finite noncrossing-leaf check, not a global geodesic-foliation theorem.

Finally H, C, P, A, N transport, replay, source, refuse, and name the same packet. Since the excluded host objects are not carrier rows, they cannot appear as NameCert obligations. □

Theorem 5224.3 (Hyperbolic quasi-geodesic shadow stability)**.** *Let Q_0 and Q_1 be accepted* HyperbolicQuasiGeodesi *carriers whose disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow window, Busemann tolerance, lamination compatibility, refusal, provenance, and local naming rows are componentwise* hsame*-transported. Then every observer-expansion consumer reads the same finite shadow surface through Q_0 and Q_1.*

The stability claim is confined to the finite rows $D, G, E, V, B, L, H, C, P, A, N$. It does not identify completed boundaries, quotient ideal points, selected geodesics, ambient compactifications, physical observer trajectories, host curvature data, or global fields.

Proof. Start with an observer-expansion shadow request for Q_0. The request must read disk coordinates and metric data through D and then the finite route samples and distortion budget through G.

Use the componentwise hsame transport. It carries the endpoint E, visual shadow window V, Busemann tolerance B, and lamination compatibility row L to the corresponding rows of Q_1.

The refusal row is transported with the same packet. Therefore the transported consumer sees the same excluded host objects and cannot insert completed boundary quotients, selected global geodesics, ambient compactifications, physical trajectories, curvature theorems, or global fields.

The replay row C and the provenance and naming rows P, N then present the transported shadow as the same finite observer-expansion surface. □

Theorem 5224.4 (Hyperbolic quasi-geodesic shadow vision handoff)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ *carrier must read the route*

$$\mathsf{UnitDisk}^{\uparrow},\ \mathsf{HyperbolicMetric}^{\uparrow},\ \mathsf{HyperbolicVisualMetric}^{\uparrow},\ \mathsf{HyperbolicBusemannCocycle}^{\uparrow},\ \mathsf{HyperbolicGeodesicLaminatio}$$

through disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, transport, replay, provenance, refusal, and local NameCert rows. The handoff realizes the vision-level shadow route as finite NameCert data without turning observer expansion into physical cosmology or a host hyperbolic-boundary theorem.

Proof. The vision handoff begins with disk and metric data. Rows D and G ensure that the consumer reads only displayed disk observations, metric readouts, finite route samples, and a distortion budget.

The endpoint and shadow window are then forced. Rows E and V bind the boundary endpoint and visual-metric shadow to the same route, while B records the Busemann tolerance needed to compare route and shadow.

Lamination compatibility is read through L. This makes the packet consumable by geodesic-lamination and observer-expansion rows without selecting a global geodesic representative or completing the boundary.

The rows H, C, P, A, N transport, replay, source, refuse, and name the handoff. Thus the vision-level quasi-geodesic shadow is realized as finite NameCert data and not as ambient hyperbolic geometry. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ read must expose a boundary endpoint, visual-metric shadow window, Busemann cocycle tolerance, quasi-geodesic route, transport row, provenance row, refusal row, and local NameCert before any observer-expansion consumer may read the shadow.

Independence witness: hyperbolic-visual-metric, hyperbolic-busemann-cocycle, hyperbolic-geodesic-lamination, hyperbolic-observer-expansion: $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ is not bijective to these siblings because it binds the quasi-geodesic route and shadow window together before the observer-expansion packet may consume the boundary read.

The Lean TasteGate for this packet must later provide $\mathsf{Nontrivial}\ \mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ in `lean4/BEDC/Derived/HyperbolicQuasiGeodesicShadowUp/` Those instances must keep $D, G, E, V, B, L, H, C, P, A, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ packet is generated from disk readout rows, a quasi-geodesic route, a boundary endpoint, a visual-metric shadow window, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, refusal, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5802.1, Definition 5802.2, Definition 5802.3, and Definition 5802.4 seed the finite quasi-geodesic shadow route for observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, host curvature semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk readout, quasi-geodesic route admission, endpoint exposure, visual-metric shadow windows, Busemann tolerance, lamination compatibility, TasteGate nontriviality, field faithfulness, refusal exactness, transport, replay, provenance, and local naming for future BEDC.Derived.HyperbolicQuasiGeodesicShadowUp.

Chapter 5225

A Concrete Naming Certificate for $\mathsf{Dendrite}^{\uparrow}$

Following Nadler and Kuratowski on continuum theory, the $\mathsf{Dendrite}^{\uparrow}$ packet records the finite BEDC surface for a locally connected compact metric continuum whose tree-like form is read through unique arcs and cutpoint separation. It sits over the compact metric carrier of chapter 129, the locally connected surface of chapter 5809, the Peano continuum boundary of chapter 2160, and the tree certificate of chapter 119. The packet names displayed endpoint, unique-arc, and cutpoint-separation rows; it does not import host continua, arbitrary path spaces, open-cover compactness, or quotient equality of arcs.

Definition 5225.1 (Dendrite carrier)**.** *A* $\mathsf{Dendrite}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric distance rows, finite ProbeBundle-net rows, complete-limit witness rows, and rational tolerance comparisons already certified by the compact-metric chapter.*
2. *L is the* $\mathsf{LocallyConnected}^{\uparrow}$ *row, recording the displayed connected neighbourhood refinements through which local arc and cutpoint requests are inspected.*
3. *P is the* $\mathsf{PeanoContinuum}^{\uparrow}$ *row, binding the compact metric and locally connected continuum surfaces before any dendrite consumer reads an arc boundary.*
4. *T is the* $\mathsf{Tree}^{\uparrow}$ *row, recording the finite tree-like separation surface used to rule out cycle-shaped routes.*
5. *E is the endpoint ledger, listing endpoint rows and their neighbourhood-read witnesses.*
6. *A is the unique-arc ledger, recording for every displayed endpoint or carried point pair the finite arc row, its endpoint membership rows, and its non-branching comparison rows.*
7. *C is the cutpoint-separation ledger, recording the displayed separation rows used when removing a carried point disconnects the relevant finite tree-like boundary.*
8. *H records componentwise* hsame *transport for compact metric data, local connectedness data, Peano-continuum data, tree data, endpoint rows, unique-arc rows, cutpoint-separation rows, replay, provenance, and local naming.*

9. *R records displayed* Cont *replay from a dendrite request through $K, L, P, T, E, A, C, H, G, Q, N$.*
10. *G is the* Pkg *provenance over* $\mathsf{Dendrite}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{PeanoContinuum}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *Q records the local source and consumer provenance for endpoint, unique-arc, and cutpoint-separation reads.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host continuum, arbitrary path selection, open-cover compactness, cycle elimination by excluded middle, or quotient equality of arcs.

Lean4 ✓ `BEDC.Derived.DendriteUp.DendriteTasteGate single carrier alignment`

Theorem 5225.2 (Dendrite NameCert obligations)**.** *For every accepted* $\mathsf{Dendrite}^{\uparrow}$ *carrier*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source, locally connected row, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming;*
2. *compact-continuum visibility, requiring every dendrite consumer to read compact metric and local connectedness data through K, L, P before reading endpoint or arc rows;*
3. *tree-like exactness, requiring the non-cycle and separation information to pass through T and the cutpoint-separation ledger C;*
4. *unique-arc exactness, requiring every arc-facing read to use the displayed ledger A with its endpoint membership and non-branching comparison rows;*
5. *endpoint exactness, requiring endpoint reads to use only the displayed endpoint ledger E and not a host boundary predicate;*
6. hsame, Cont, *and* Pkg *stability, requiring componentwise transport, displayed replay, and provenance to preserve precisely the listed rows;*
7. *non-escape, excluding host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, and quotient equality of arcs.*

No dendrite obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5803.1. The accepted tuple displays exactly the compact metric source, local connectedness, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming.

The compact-continuum route is K, L, P. The compact metric source supplies distance, finite-net, complete-limit, and tolerance-comparison rows; the locally connected row supplies connected neighbourhood refinements; and the Peano-continuum row binds those surfaces before endpoint or arc data are exposed.

The tree-like route is T, E, A, C. The tree row supplies the finite non-cycle surface, the endpoint ledger records boundary reads, the unique-arc ledger records the displayed arc row between

carried point pairs, and the cutpoint-separation ledger records the separation witnesses used by downstream consumers.

Finally, H, R, G, Q, N transport, replay, source, and name the same finite packet. Since the carrier has no row for a host continuum, arbitrary path space, open-cover compactness principle, selected arc representative, or quotient equality of arcs, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$ surface. □

Theorem 5225.3 (Dendrite unique-arc handoff)**.** *Every unique-arc or cutpoint-facing consumer of an accepted* $\mathsf{Dendrite}^\uparrow$ *carrier must read the finite route*

$$\mathsf{CompactMetric}^\uparrow,\ \mathsf{LocallyConnected}^\uparrow,\ \mathsf{PeanoContinuum}^\uparrow,\ \mathsf{Tree}^\uparrow \longmapsto E, A, C, H, R, G, Q, N.$$

The handoff exposes endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It does not expose arbitrary host paths, open-cover compactness, selected arc representatives, quotient equality of arcs, or a continuum object outside the displayed packet.*

Proof. Start with the compact-continuum source. The rows K, L, P force a consumer to read the compact metric, locally connected, and Peano-continuum surfaces before any arc-facing data can be inspected.

Next read the tree row T. This is the only row carrying the tree-like non-cycle surface, so a later cutpoint or arc argument cannot replace it by a host graph or a classical continuum theorem.

The endpoint and arc data are then E, A, C. Endpoint reads pass through E, unique-arc reads pass through A, and cutpoint-separation reads pass through C; the three ledgers remain tied to the same compact-continuum and tree source rows.

The structural rows H, R, G, Q, N preserve this route under transport, replay, provenance, and local naming. Because no excluded host-side row appears in the carrier, the consumer receives exactly the displayed unique-arc handoff and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{Dendrite}^\uparrow$ read must expose CompactMetric, LocallyConnected, PeanoContinuum, Tree, endpoint, unique-arc, cutpoint-separation, componentwise hsame, displayed Cont, Pkg, source provenance, and local NameCert rows before a continuum or arc consumer can inspect the dendrite boundary.

Independence witness: compactmetric, locally-connected, peano-continuum, tree: $\mathsf{Dendrite}^\uparrow$ is not bijective to any listed sibling because it binds endpoint, unique-arc, and cutpoint-separation ledgers over their common compact-continuum and tree-like source.

Closure status for $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$**.**

Constructive story: A $\mathsf{Dendrite}^\uparrow$ packet is generated from CompactMetricUp, LocallyConnectedUp, PeanoContinuumUp, TreeUp, endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, source provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, seed)

Scope closed: Definition 5803.1, Definition 5803.2, and Definition 5803.3 seed the finite dendrite certificate over compact metric, locally connected, Peano-continuum, tree, endpoint, unique-arc, cutpoint-separation, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, quotient equality of arcs, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-continuum visibility, tree-like exactness, endpoint exactness, unique-arc exactness, cutpoint-separation exactness, transport, replay, provenance, and local naming for BEDC.Derived.DendriteUp.

Chapter 5226

A Concrete Naming Certificate for $\mathsf{YoungIntegration}^{\uparrow}$

Following Young's integration theorem and Bishop–Bridges constructive analysis, the $\mathsf{YoungIntegration}^{\uparrow}$ packet records the finite dyadic route for integrating one Holder-controlled path against another. It sits beside the Holder-continuity surface of chapter 1766, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the tagged-mesh Riemann integral boundary of chapter 1526. The chapter names only a finite partition-and-error certificate; it does not import host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5226.1 (Young integration finite partition carrier)**.** *A* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the integrand path row, read through a* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
2. *G is the integrator path row, read through a second* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its own source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
3. *A and B are the two Holder exponent ledgers. They include the finite comparison row witnessing that the displayed exponents have a Young margin for the dyadic partition family.*
4. *W is the dyadic partition-window row. It lists the inspected endpoints, dyadic mesh refinements, cell order, adjacent-cell handoffs, and the finite cells on which the integration read is allowed to form sums.*
5. *V is the cross-variation tolerance ledger. It records the cellwise oscillation products, Holder-bound products, Young-margin comparisons, and finite sum-difference tolerances consumed by the route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for endpoint radii, mesh widths, exponent-comparison margins, oscillation products, and final error bounds.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational trace of dyadic Young sums.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the integral value, reached only after the two Holder rows, dyadic windows, cross-variation ledger, dyadic tolerances, and regular readback have been displayed.*
9. *H records componentwise* hsame *transport for the two Holder paths, exponent ledgers, partition windows, cross-variation ledger, dyadic ledger, readback, Real seal, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from a Young-integration request through Holder admission, dyadic partition windows, cross-variation tolerances, regular rational readback, and the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{YoungIntegration}^{\uparrow}$, $\mathsf{HolderContinuity}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, G, A, B, W, V, D, R, E, H, C, P, N$. It has no coordinate for an ambient path space, quotient equality of functions, a selected sequence of partitions, a hidden limiting argument, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.YoungIntegrationUp.YoungIntegrationTasteGate single carrier alignment`

Theorem 5226.2 (Young integration NameCert obligations)**.** *For every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier $Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *surface is exhausted by admission of two* $\mathsf{HolderContinuity}^{\uparrow}$ *path rows, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting,* $\mathsf{DyadicRatCore}^{\uparrow}$ *exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No accepted consumer may replace these rows by host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5804.1. The rows F and G expose the two Holder-controlled paths, and A, B expose only the finite exponent and Young-margin comparisons attached to those rows.

The partition and tolerance data are then forced. The row W lists the dyadic windows available to the route, while V records the cross-variation products and sum-difference tolerances over exactly those windows.

The terminal read is D, R, E. Dyadic exactness is read through D, the regular rational trace through R, and the Real integral seal through E only after the preceding rows have been consumed.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5226.3 (Young integration dyadic error budget)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *read that reaches the* $\mathsf{Real}^{\uparrow}$ *seal factors through the finite dyadic budget*

$$\mathsf{HolderContinuity}^{\uparrow}, \mathsf{HolderContinuity}^{\uparrow} \longmapsto \mathsf{DyadicPartition}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The row V must display the cross-variation tolerance consumed between the partition windows and the rational readback. Therefore the exported integral value is a finite dyadic Young-sum seal, not a Riemann-integral replacement, a measure-completion integral, a quotient path equality, a selected limiting partition, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the two Holder rows. Their displayed exponents and constants are read through F, G, A, B, so the route has only the finite power-law data needed to bound oscillations on dyadic cells.

Next read the dyadic partition windows. The row W fixes the cells, endpoints, mesh refinements, and adjacent-cell handoffs before any sum-difference comparison is requested.

The error budget is the pair V, D. The cross-variation ledger V records the oscillation products and Young-margin comparisons, and the dyadic ledger D records the exact rational tolerances used to compare any two displayed sums.

The readback and seal are downstream. The regular sequence row R is the only rational trace exported from the finite budgets, and E is the only Real seal. Thus the consumer cannot obtain any of the excluded host-level or choice-level objects from the packet. □

Theorem 5226.4 (Young integration Riemann boundary)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet reads it only as a finite tagged-mesh boundary: two Holder path rows, a dyadic partition-window row, a cross-variation tolerance ledger, dyadic exactness, regular rational readback, Real sealing, transport, replay, provenance, and local naming. The consumer receives no independent Riemann-integral certificate, no Darboux gap claim, no quotient equality of integrands, no measure-completion object, and no selected mesh-limit principle.*

Proof. The only Riemann-facing data in the carrier are the displayed dyadic windows and finite sum budgets. The two Holder path rows provide values to be sampled, while W supplies the finite tagged-mesh boundary.

The cross-variation ledger is not a Darboux or measure-theoretic claim. It records only the tolerance comparisons needed for the Young-sum route before the regular rational readback is sealed as a Real value.

The provenance row may name $\mathsf{RiemannIntegral}^{\uparrow}$ as a consumer boundary, but the local certificate remains $F, G, A, B, W, V, D, R, E, H, C, P, N$. Therefore a Riemann-integral consumer receives a finite boundary row rather than any independent integral theorem or hidden limiting principle. □

Theorem 5226.5 (Young integration Cauchy-modulus consumer)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet whose cross-variation ledger* V *requests a tail precision must consume the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route before* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *sealing. The route remains finite: it exports the displayed Young partition windows, dyadic error budget, explicit Cauchy-modulus handoff, regular rational readback, and terminal Real seal, but it exports no selected limiting partition, countable-choice schedule, hidden modulus oracle, or ambient completion theorem.*

Proof. Project the carrier of Definition 5804.1. The rows W, V, D, R, E expose the partition windows, cross-variation tolerance ledger, dyadic error budget, regular rational readback, and terminal Real seal.

Use Definition 5804.3. The row V is the place where sum-difference tolerances and tail precision demands are recorded, and D is the dyadic ledger that makes those demands finite.

When such a tail precision is requested, apply the effective handoff of Definition 5728.3 and the schedule determinacy of Definition 5728.4. They force the precision request through an explicit $\mathsf{CauchyModulusBridge}^{\uparrow}$ schedule before R can be read and before E can seal the result.

The remaining rows H, C, P, N transport, replay, source, and name the same finite route. Since neither the Young carrier nor the bridge carrier contains a selected limiting partition, countable-choice schedule, hidden oracle, or ambient completion coordinate, no such object is exported. □

Falsifiable prediction: An accepted $\mathsf{YoungIntegration}^{\uparrow}$ packet is refuted if a consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting either $\mathsf{HolderContinuity}^{\uparrow}$ path row, the dyadic partition-window row W, the cross-variation ledger V, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: HolderContinuity, DyadicPartition, DyadicRatCore, RegSeqRat, Real, RiemannIntegral: none is bijective with $\mathsf{YoungIntegration}^{\uparrow}$ because the packet jointly carries two Holder paths, Young-margin exponent rows, dyadic partition windows, cross-variation tolerances, dyadic exactness, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$.

Constructive story: A $\mathsf{YoungIntegration}^{\uparrow}$ packet is generated from two HolderContinuityUp path rows, exponent-margin ledgers, dyadic partition windows, cross-variation tolerance accounting, DyadicRatCore exactness, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5804.1, Definition 5804.2, Definition 5804.3, Definition 5804.4, and Definition 5804.5 seed the finite dyadic Young-integration route over HolderContinuityUp, DyadicPartitionUp, DyadicRatCoreUp, CauchyModulusBridgeUp, RegSeqRatUp, RealUp, and RiemannIntegralUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked two-path admission, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting, dyadic exactness, regular rational readback, Real-seal nonescape, and structural transport for BEDC.Derived.YoungIntegrationUp.

Chapter 5227

A Concrete Naming Certificate for $\mathsf{VariationDiminishing}^{\uparrow}$

Following Schoenberg and Karlin, the $\mathsf{VariationDiminishing}^{\uparrow}$ packet records a finite analysis row for transformations that do not increase displayed sign variation. It consumes the total-variation function surface of chapter 2257, the bounded-variation real-function carrier of chapter 3654, the regulated-function source of chapter 1554, and the tagged integration boundary of chapter 1526. The packet names the finite comparison by which a kernel or transformation row is read as variation-diminishing without importing a host operator algebra, total-positivity theorem, selected partitions, quotient functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5227.1 (Variation-diminishing carrier)**.** *A* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (B, T, R, I, K, M, H, C, P, N)$$

with the following rows:

1. *B is the* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *source row naming the accepted bounded-variation input surface.*
2. *T is the* $\mathsf{TotalVariationFunction}^{\uparrow}$ *row naming the displayed total-variation ledger used to count variation before and after the transformation.*
3. *R is the* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *row naming the regulated readback through which input and output functions are compared by finite step windows.*
4. *I is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *row naming the finite tagged-mesh integration boundary used when the transformation is read by kernel action or integral averaging.*
5. *K is the kernel or transformation row, including its displayed positivity-order or sign-regularity window.*
6. *M is the variation comparison row recording that each accepted finite sign-change ledger for the output is routed to a no-larger sign-change ledger for the input.*
7. *H records componentwise* hsame *transport for bounded-variation source, total-variation ledger, regulated readback, integral boundary, kernel row, comparison row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite transformation request through $B, T, R, I, K, M, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{VariationDiminishing}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RegulatedRealFunction}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and sibling* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, T, R, I, K, M, H, C, P, N$. It has no coordinate for host function equality, quotient representatives, selected limiting partitions, a global total-positivity theorem, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.VariationDiminishingUp.VariationDiminishingTasteGate single carrier alignment`

Theorem 5227.2 (Variation-diminishing NameCert obligations)**.** *For every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier*

$$V = (B, T, R, I, K, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded-variation source row B, total-variation ledger T, regulated-function readback R, Riemann-integral boundary I, kernel or transformation row K, variation comparison row M, componentwise transport H, displayed replay C, provenance P, and local naming N.*

The obligation surface requires every output variation read to pass through the displayed comparison row M after B, T, R, I, K have been projected. It refuses host operator equality, quotient equality of functions, selected partitions, unrestricted total positivity, measure-theoretic kernels, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5805.1. The source row B supplies the bounded-variation input, while T supplies the total-variation ledger on which finite sign-change comparisons can be read.

The rows R and I keep the analytic route finite. Regulated readback gives step-window access to input and output functions, and the Riemann-integral boundary records only the tagged-mesh action needed by a kernel or averaging read.

The row K names the transformation window, and M is the only row that compares variation before and after the transformation. Thus the NameCert consumer obtains a variation-diminishing assertion only through the displayed comparison row, not through a host theorem about all kernels.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores quotient functions, selected limiting partitions, unrestricted total positivity, measure completion, or ambient real completeness, no local obligation can require them. □

Theorem 5227.3 (Variation-diminishing total-variation route)**.** *Every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *consumer read factors through the route*

$$\mathsf{BoundedVariationRealFunction}^{\uparrow},\ \mathsf{TotalVariationFunction}^{\uparrow},\ \mathsf{RegulatedRealFunction}^{\uparrow},\ \mathsf{RiemannIntegral}^{\uparrow} \longmapsto \mathsf{VariationD}$$

The output variation ledger is accepted only after the bounded-variation input, cumulative total-variation ledger, regulated readback, tagged integration boundary, kernel row, and comparison row have been displayed. The route exports no selected limit, quotient function equality, global total-positivity principle, measure-completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. A variation-diminishing request first projects B and T. These rows bind the input function to the bounded-variation and total-variation sibling surfaces, so the requested comparison starts from finite variation data rather than from a host function space.

Next project R and I. The regulated row supplies finite step-window readback, while the integral boundary supplies the tagged-mesh route through which a kernel or averaging transformation can be inspected.

The transformation row K and comparison row M then give the only accepted variation comparison. They state that the displayed output sign-change ledger routes to a no-larger input ledger in the same finite packet.

Finally H, C, P, N preserve the route under transport, replay, provenance, and local naming. Hence every public read of $\mathsf{VariationDiminishing}^{\uparrow}$ passes through the four cited sibling anchors and does not acquire the excluded host-level principles. □

Falsifiable prediction: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet whose output variation read bypasses the displayed total-variation ledger or the regulated readback row is not accepted by the local NameCert.

Independence witness: total-variation-function, bounded-variation-real-function, regulatedrealfunction, riemannintegral: $\mathsf{VariationDiminishing}^{\uparrow}$ is not bijective to any listed sibling because it binds the source variation ledger, regulated readback, tagged integration boundary, transformation row, and no-increase comparison as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet is generated from bounded-variation source data, a total-variation ledger, regulated readback, Riemann tagged-mesh boundary, a kernel or transformation row, a variation comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5805.1, Definition 5805.2, Definition 5805.3, the falsifiable prediction, and the independence witness seed the finite variation-diminishing route over the current analysis rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host operator equality, quotient equality of functions, selected limiting partitions, unrestricted total positivity, measure completion, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation source visibility, total-variation ledger exactness, regulated readback, tagged integration boundary, transformation-row exposure, comparison-row stability, transport, replay, provenance, and local naming for future BEDC.Derived.VariationDiminishingUp.

$\mathsf{FrobeniusReciprocity}^{\uparrow}$ routes induction–restriction comparison through chapter 247, chapter 246, and chapter 245 before the child file states the local certificate.

Chapter 5228

A Concrete Naming Certificate for $\mathsf{FrobeniusReciprocity}^{\uparrow}$

Following Frobenius on induced characters, Serre's finite-group representation theory, and the induction–restriction formulation used by Fulton–Harris, the $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet records the finite comparison row between induction from a subgroup and restriction to that subgroup. It consumes the action rows of chapter 3662, the subgroup source of chapter 80, the representation-ring ledger of chapter 246, the induction–restriction packet of chapter 247, and the character-pairing surface of chapter 245. The packet names only finite source rows, adjunction ledgers, character-pairing boundaries, transport, replay, provenance, and downstream handoff rows; it does not assert a host category of representations, a functor equality, semisimplicity, Schur orthogonality, or a completed character table.

Theorem 5228.1 (FrobeniusReciprocityUp source obligations)**.** *For every accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet, the source surface is the displayed finite tuple*

$$\mathcal{F} = (G, H, R, I, Q, \Phi, \eta, \epsilon, \chi, \lambda, C, P, N),$$

where G is the consumed $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *action row, H is the consumed* $\mathsf{Subgroup}^{\uparrow}$ *row, R is the consumed* $\mathsf{RepresentationRing}^{\uparrow}$ *ledger, I is the consumed* $\mathsf{InducedRep}^{\uparrow}$ *induction–restriction row, Q is the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *pairing row, Φ is the Frobenius comparison row, η, ϵ are the displayed unit and counit rows, χ is the character-pairing boundary, λ is the finite ledger of visible source and endpoint reads, C is componentwise* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *row. No source obligation is imported from a host representation category, quotient carrier, functor category, or external adjunction object.*

Proof. Project the accepted packet. The source rows are precisely G, H, R, I, Q together with the local comparison rows $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

The consumed rows are already finite BEDC certificates. The finite-group representation row supplies the action display, the subgroup row supplies the inclusion boundary, the representation-ring row supplies the Grothendieck ledger, the induced-representation row supplies the induction–restriction endpoints, and the character-theory row supplies the pairing surface.

Since the tuple has no coordinate for a host representation category, quotient carrier, functor category, or external adjunction object, the listed rows exhaust the source obligations. □

Theorem 5228.2 (FrobeniusReciprocityUp adjunction ledger)**.** *The adjunction data of an accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet are exactly the finite rows $\Phi, \eta, \epsilon, \lambda$ over the consumed sources*

H, R, I. The row Φ compares the displayed induction endpoint with the displayed restriction endpoint, η and ϵ record the unit and counit witnesses as BHist *rows, and λ records the visible continuations among source, endpoint, and Frobenius reads. The ledger exports no host naturality square, functor equality, adjunction object, or semisimple decomposition.*

Proof. Begin with the induction–restriction source. The packet consumes the $\mathsf{InducedRep}^{\uparrow}$ row I, so the available endpoints are the displayed induction and restriction rows already carried by that certificate.

The Frobenius comparison is read through Φ. The unit and counit witnesses are read through η and ϵ, and every visible path among source and endpoint reads is recorded by the finite ledger λ.

Exactness is projection from the tuple. Any row outside $\Phi, \eta, \epsilon, \lambda$ is not part of the adjunction ledger, and no host naturality square or functor equality can be recovered from a coordinate that the packet does not carry. □

Theorem 5228.3 (FrobeniusReciprocityUp character-pairing boundary)**.** *Every character-pairing read of a* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet factors through the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *row Q, the representation-ring source R, the induction–restriction source I, and the displayed pairing boundary χ before it can inspect Φ, η, ϵ or λ. The boundary supplies only the finite character-pairing comparison needed for reciprocity and does not export Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra.*

Proof. Read the character side first. The only character-theory coordinate is Q, and the only representation-ring coordinate feeding it is R.

The induction and restriction endpoints enter through I. The displayed pairing boundary χ then names the finite comparison used by the Frobenius row before the ledger reads $\Phi, \eta, \epsilon, \lambda$.

Because the tuple has no coordinate for Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra, every character-pairing read remains inside the stated finite boundary. □

Theorem 5228.4 (FrobeniusReciprocityUp NameCert surface)**.** *The* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *obligation surface is the conjunction of the source obligations of Definition 5806.1, the adjunction ledger of Definition 5806.2, the character-pairing boundary of Definition 5806.3, componentwise* hsame *transport on all displayed source and ledger rows, finite* Cont *replay through C, and* Pkg *provenance through P. The surface exports no obligation outside the displayed tuple $\mathcal{F}$.*

Proof. First combine the source obligations with the adjunction ledger. The source theorem identifies the consumed BEDC certificates, and the ledger theorem identifies the only Frobenius comparison, unit, counit, and continuation rows.

Next add the character-pairing boundary. It places every character read behind Q, R, I, χ before the Frobenius ledger can be inspected.

Finally apply componentwise transport and replay. The rows C and P preserve exactly the displayed tuple, and the local row N names the resulting certificate. Since no obligation outside $\mathcal{F}$ is available, these clauses give the stated NameCert surface. □

Theorem 5228.5 (FrobeniusReciprocityUp consumer handoff)**.** *A downstream consumer of* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *may read exactly the consumed finite-group action row G, subgroup row H, representation-ring row R, induced-representation row I, character-theory row Q, Frobenius rows Φ, η, ϵ, character-pairing boundary χ, visible ledger λ, replay row C, provenance row P, and local name row N. Any consumer handoff to* $\mathsf{InducedRep}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, *or* $\mathsf{CharacterTheory}^{\uparrow}$ *factors through those*

rows and cannot bypass them through a host category, functor equality, semisimplicity theorem, or character-table computation.

Proof. Start with a downstream read. The only visible source coordinates are G, H, R, I, Q, and the only local Frobenius coordinates are $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

For an $\mathsf{InducedRep}^{\uparrow}$ consumer, the handoff is through I together with the Frobenius rows. For a $\mathsf{RepresentationRing}^{\uparrow}$ consumer, the handoff is through R and the source ledger. For a $\mathsf{CharacterTheory}^{\uparrow}$ consumer, the handoff is through Q and the pairing boundary χ.

The replay and provenance rows preserve the same finite route. Thus a consumer cannot bypass the displayed packet through a host category, functor equality, semisimplicity theorem, or character-table computation. □

Theorem 5228.6 (FrobeniusReciprocityUp sibling lattice)**.** *The* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet is a finite comparison consumer of the sibling carriers in chapter 3662, chapter 80, chapter 246, chapter 247, and chapter 245. Its local rows compare induction and restriction after those carriers are visible; they do not form an isolated kernel row and do not replace the representation, subgroup, ring, induced-representation, or character-theory certificates.*

Proof. Read the source tuple of Definition 5806.1. The rows G, H, R, I, Q are precisely the five sibling certificates named in the statement.

The consumer handoff of Definition 5806.5 permits downstream reads only through those rows together with the Frobenius comparison, unit, counit, pairing boundary, ledger, replay, provenance, and local name rows.

Therefore the packet sits inside the displayed representation-theory lattice. It is a comparison consumer over the sibling carriers, not a standalone kernel surface from which the sibling certificates can be reconstructed. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5806.1, Definition 5806.2, Definition 5806.3, Definition 5806.4, Definition 5806.5, and Definition 5806.6 seed the finite Frobenius reciprocity certificate over displayed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, semisimplicity, Schur orthogonality, irreducible decomposition, character-table computation, functor-category equality, or a host adjunction theorem.

Upgrade path: Obligation closure requires checked carrier admission, adjunction-ledger exactness, character-pairing boundary, NameCert surface, and downstream handoff for the same finite packet.

Constructive story: A $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet is generated from consumed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows, then records a finite Frobenius comparison, unit and counit rows, character-pairing boundary, visible continuation ledger, package provenance, and local NameCert evidence.

Chapter 5229

A Concrete Naming Certificate for $\mathsf{NormalOperator}^{\uparrow}$

Following Reed and Simon, the $\mathsf{NormalOperator}^{\uparrow}$ packet records the standard normal-operator surface as finite NameCert data over displayed Hilbert and inner-product candidates. It consumes the inner-product carrier of chapter 86, the Hilbert carrier of chapter 91, the linear-map rows of chapter 48, the operator-norm boundary of chapter 3603, and the downstream spectral-theorem consumer of chapter 214. The packet exposes only a bounded linear operator, its displayed adjoint-action row, the norm ledger, and the normality commutator row; it does not claim spectral measure existence, functional calculus, diagonalization, projection-valued measures, or a host operator algebra.

Definition 5229.1 (NormalOperator carrier)**.** *For a displayed* $\mathsf{Hilbert}^{\uparrow}$ *candidate* H *with* $\mathsf{InnerProduct}^{\uparrow}$ *row* I*, a* $\mathsf{NormalOperator}^{\uparrow}(H)$ *carrier is a finite* BHist *packet*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N)$$

with the following ten displayed fields:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *carrier row and I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row over the same point-history carrier.*
2. *T is a bounded* $\mathsf{LinMap}^{\uparrow}$ *endpoint action on the carried Hilbert endpoints.*
3. *T^* is the displayed adjoint-action row, certified by the finite inner-product comparison*

   $$\langle Tx, y\rangle_I \ \mathsf{hsame}\ \langle x, T^*y\rangle_I$$

   for the vector histories inspected by the packet.
4. *A is the adjoint-domain ledger, recording that the adjoint row is read over the same Hilbert, inner-product, linear-map, and boundedness surfaces as T.*
5. *K is the* $\mathsf{OperatorNorm}^{\uparrow}$ *bound row for T and for the displayed adjoint action T^*.*
6. *Q is the normality commutator row*

   $$T^*T \ \mathsf{hsame}\ TT^*$$

   read only on certified vector histories.
7. *L is the operator graph ledger: it stores inspected input histories, output histories, linearity rows, adjoint rows, norm-bound rows, and the commutator row.*

8. *H_T records componentwise* hsame *transport for the Hilbert source, inner-product row, endpoint actions, adjoint row, norm row, commutator row, and ledger.*
9. *C records displayed* Cont *replay for endpoint action requests, adjoint-action requests, norm-bound requests, and commutator inspections.*
10. *P, N are the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *naming rows.*

The classifier compares accepted carriers by action agreement on certified vector histories, adjoint-action agreement on the same inspected histories, transport of the operator-norm row, and transport of the graph, adjoint, normality, continuation, provenance, and local-name ledgers. It has no coordinate for host operator equality, quotient completion, spectral measures, eigenvector bases, or external functional calculus.

Lean4 ✓ `BEDC.Derived.NormalOperatorUp.NormalOperatorTasteGate single carrier alignment`

Theorem 5229.2 (NormalOperator NameCert obligations)**.** *For every accepted* $\mathsf{NormalOperator}^\uparrow$ *carrier*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the common* $\mathsf{Hilbert}^\uparrow$ *and* $\mathsf{InnerProduct}^\uparrow$ *rows;*
2. *bounded* $\mathsf{LinMap}^\uparrow$ *action for T on certified vector histories;*
3. *adjoint-action agreement for T^* against the displayed inner product;*
4. $\mathsf{OperatorNorm}^\uparrow$ *bound rows for the operator action and adjoint action;*
5. *normality commutator exactness through the displayed row Q;*
6. *graph-ledger exactness for input histories, output histories, linearity rows, adjoint rows, norm rows, and commutator rows;*
7. *classifier transport by action agreement, adjoint-action agreement, norm-row agreement, and componentwise ledger transport;*
8. Cont *replay,* Pkg *provenance, and local naming for exactly the displayed packet;*
9. *refusal of spectral measure existence, diagonalization, projection-valued measures, host operator quotients, and unrecorded functional calculus.*

Proof. Project the carrier of Definition 5807.1. The Hilbert and inner-product source rows, endpoint action, adjoint-action row, adjoint-domain ledger, norm row, commutator row, graph ledger, transport row, continuation row, provenance row, and local name are the full displayed inventory.

The adjoint and boundedness obligations are read before any spectral consumer appears. The adjoint row is the finite inner-product comparison for certified vector histories, and the norm row is the displayed $\mathsf{OperatorNorm}^\uparrow$ bound attached to both endpoint actions.

Normality is exactly the commutator row Q. Because Q compares T^*T and TT^* only through inspected vector histories and their graph ledger, the packet does not appeal to host equality of operators.

Finally H_T, C, P, N transport, replay, source, and name those rows. Since the carrier has no spectral-measure, diagonalization, projection-valued-measure, quotient, or functional-calculus coordinate, the listed rows exhaust the local normal-operator NameCert obligations. □

Theorem 5229.3 (NormalOperator InnerProduct spectral anchor)**.** *Every downstream spectral read of an accepted* $\mathsf{NormalOperator}^{\uparrow}$ *packet factors through the common Hilbert and inner-product rows, the bounded linear action, the displayed adjoint-action row, the operator-norm bound, and the normality commutator ledger before it can be consumed by the* $\mathsf{SpectralTheorem}^{\uparrow}$ *surface. The route is*

$$(H, I) \longmapsto (T, T^*, A, K, Q, L) \longmapsto (H_T, C, P, N),$$

and it exports no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality.

Proof. Expose the accepted packet by Definition 5807.1. The only analytic source rows are the Hilbert carrier, inner-product comparison row, endpoint action, displayed adjoint action, norm bound, and normality commutator.

Apply Definition 5807.2. The graph ledger forces the operator action, adjoint action, boundedness evidence, and commutator evidence to be read from one finite packet, and classifier transport keeps the operator and adjoint rows over the same certified vector histories.

It remains to hand the packet to spectral consumers. The $\mathsf{SpectralTheorem}^{\uparrow}$ chapter may consume the normality anchor only through the displayed rows already named here. Because no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality is a field of the carrier, the anchor supplies a pre-spectral normal-operator surface rather than a spectral theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5807.1, Definition 5807.2, and Definition 5807.3 seed the normal-operator surface over Hilbert, inner-product, bounded linear-map, adjoint-action, operator-norm, and commutator rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim spectral measures, spectral projections, diagonalization, eigenbasis construction, Borel functional calculus, host operator quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, adjoint-action agreement, norm-bound stability, normality commutator exactness, classifier transport, graph-ledger exactness, spectral-consumer nonescape, and bridge data for BEDC.Derived.NormalOperatorUp.

Constructive story: A $\mathsf{NormalOperator}^{\uparrow}$ packet is generated from a Hilbert source, an inner-product row, a bounded linear endpoint action, a displayed adjoint action, operator-norm bounds, a normality commutator row, graph and transport ledgers, continuation replay, provenance, and a local NameCert row.

Chapter 5230

A Concrete Naming Certificate for $\mathsf{HausdorffMeasure}^{\uparrow}$

Following Hausdorff and Federer's metric measure theory, the $\mathsf{HausdorffMeasure}^{\uparrow}$ packet records the finite dyadic-cover surface through which Hausdorff content and scale-stable measure reads become visible inside BEDC. It sits over the metric carrier of chapter 57, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the cover-valued outer-measure boundary of chapter 3385, and the finite scale-cover comparison surface of chapter 3877. The packet names only displayed dyadic cover packets, diameter budgets, weighted cover sums, scale comparison, transport, replay, provenance, and local naming; it is not a quotient cover family, not a selected infimum, not countable choice over covers, and not an ambient measure primitive.

Definition 5230.1 (Hausdorff measure dyadic-cover carrier)**.** *A* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (M, D, R, O, B, C, S, T, E, K, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the finite point classifier and distance comparisons used to bound cover diameters.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row, naming the dyadic radius budget and dyadic exponent used by the cover packet.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *value-seal row for diameter powers and finite cover sums.*
4. *O is the* $\mathsf{OuterMeasure}^{\uparrow}$ *handoff row, read only as a finite cover-valued boundary and not as a completed measure primitive.*
5. *B is the* $\mathsf{BoxDimension}^{\uparrow}$ *comparison row, exposing finite scale-cover counts against the same dyadic scale.*
6. *C is the finite dyadic cover packet, listing the displayed cover cells, their metric diameter witnesses, and their membership reads.*
7. *S is the cover-sum ledger, recording the finite Real-sealed sum of dyadic diameter weights.*
8. *T is the scale-stability ledger, recording that dyadic refinement reads the same metric source, outer-measure boundary, and box-dimension comparison rows.*
9. *E records componentwise* hsame *transport for metric, dyadic scale, Real seal, outer-measure handoff, box-dimension comparison, cover packet, cover sum, and stability rows.*

10. *K records displayed* Cont *replay from a metric source and dyadic scale through C, S, T, E, P, N.*
11. *P is the* Pkg *provenance over* $\mathsf{HausdorffMeasure}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{OuterMeasure}^{\uparrow}$, $\mathsf{BoxDimension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D, R, O, B, C, S, T, E, K, P, N$. It has no coordinate for quotient cover families, selected infima, countable-choice schedules over covers, host sigma-algebras, or ambient measure primitives.

Lean4 ✓ `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate single carrier alignment`

Theorem 5230.2 (Hausdorff measure NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier $H = (M, D, R, O, B, C, S, T, E, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *surface consists exactly of metric source admission, dyadic scale exposure, Real value sealing, finite outer-measure handoff, box-dimension scale comparison, finite dyadic cover admission, cover-sum exactness, scale-stability replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every measure-facing or dimension-facing consumer must read the displayed route*

$$\mathsf{Met}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto C, S, T \longmapsto \mathsf{OuterMeasure}^{\uparrow}, \mathsf{BoxDimension}^{\uparrow} \longmapsto E, K, P, N$$

before treating the packet as a Hausdorff-measure read.

Proof. Project the carrier of Definition 5808.1. The metric row M, dyadic row D, and Real seal row R are the only sources for distances, scales, and finite value readback.

The cover packet C and cover-sum ledger S are finite rows. They record displayed cover cells and dyadic diameter weights, so no step selects a minimizing cover family or takes an external infimum.

The outer-measure and box-dimension rows O, B are downstream comparison boundaries. They can read the same finite cover data, but they do not add a completed host measure, a quotient of covers, or countable choice over refinements.

Finally T, E, K, P, N transport, replay, source, and name the same finite route. Since every exported obligation is one of the listed rows, the local classifier cannot expose an ambient measure primitive or any detached cover selector. □

Theorem 5230.3 (Hausdorff measure dyadic-cover stability)**.** *Let $H = (M, D, R, O, B, C, S, T, E, K, P, N)$ be an accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier. For any displayed dyadic refinement of the scale row D, the scale-stability ledger T forces the refined read to reuse the same* $\mathsf{Met}^{\uparrow}$ *source, the same* $\mathsf{Real}^{\uparrow}$ *value-seal route, the same finite* $\mathsf{OuterMeasure}^{\uparrow}$ *cover boundary, and the same* $\mathsf{BoxDimension}^{\uparrow}$ *scale-count comparison before any consumer reads a Hausdorff-measure claim. The stable route is*

$$M, D, R, C, S, T \longmapsto O, B \longmapsto E, K, P, N.$$

It exports no quotient cover family, selected infimum, countable-choice cover schedule, host sigma-algebra closure, or ambient measure primitive.

Proof. Read the carrier of Definition 5808.1. A dyadic refinement changes only the displayed scale request inside D and the finite cover packet admitted by C.

Use the stability ledger T. It records that the refined cover is replayed against the same metric source and that its finite cover sum is sealed through the same Real row, so the refinement cannot introduce a detached minimizing cover or a host infimum.

The comparison rows O and B then read the refined packet as finite outer-measure and box-dimension boundary data. Componentwise transport and displayed replay through E, K, P, N preserve that route, while quotient covers, countable choice, host sigma-algebras, and ambient measure primitives remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HausdorffMeasure}^{\uparrow}$ consumer that reaches a Hausdorff-measure read without first exposing a MetricUp source row, a DyadicRatCore scale row, a RealUp value seal, a finite dyadic cover packet, a finite cover-sum ledger, an OuterMeasureUp handoff, a BoxDimensionUp comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row refutes the carrier surface.

Independence witness: metric, dyadicratcore, real, outermeasure, boxdimension: $\mathsf{HausdorffMeasure}^{\uparrow}$ is not bijective to any listed sibling because it binds metric diameter data, dyadic scales, Real-sealed finite cover sums, outer-measure cover boundaries, and box-dimension scale counts into one finite cover-stability NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffMeasure}^{\uparrow}$ packet is generated from a MetricUp source row, DyadicRatCore scale row, RealUp value-seal row, finite OuterMeasureUp handoff, BoxDimensionUp comparison row, finite dyadic cover packet, cover-sum ledger, scale-stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5808.1, Definition 5808.2, and Definition 5808.3 seed the finite dyadic-cover Hausdorff-measure interface over MetricUp, DyadicRatCoreUp, RealUp, OuterMeasureUp, and BoxDimensionUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient cover families, selected infima, countable choice over covers, host sigma-algebra completion, ambient measure primitives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic scale exposure, finite cover admission, cover-sum exactness, scale-stability replay, outer-measure handoff, box-dimension comparison, transport, provenance, and no-escape for BEDC.Derived.HausdorffMeasureUp.

Chapter 5231

A Concrete Naming Certificate for $\mathsf{LocallyConnected}^{\uparrow}$

Following Kelley and Bourbaki on local connectedness, the $\mathsf{LocallyConnected}^{\uparrow}$ packet records finite neighbourhood-component data rather than a selected basis of connected open sets. It sits beside the global connectedness carrier of chapter 2353, the compact metric source discipline of chapter 129, the metric ball rows of chapter 57, and the open-neighbourhood ledger of chapter 88. The packet exposes the local component route needed by compact-metric and connected-space consumers without importing path selection, arc connectedness, open-cover compactness, or a host topological basis.

Definition 5231.1 (Locally connected carrier)**.** *A* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, M, G, K, B, C, H, R, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-neighbourhood row whose entries name the ambient open requests.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *ball-observation row used when the local request is metric.*
3. *G is the* $\mathsf{ConnectedSpace}^{\uparrow}$ *global component row available to consumers that compare local and global connectedness.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-source row available to compact-metric consumers.*
5. *B is the finite neighbourhood-refinement row: each displayed point and open request has a named smaller neighbourhood row.*
6. *C is the local connected-component row attached to the refinement in B.*
7. *H records componentwise* hsame *transport for the topology, metric, connectedness, compact-metric, refinement, component, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from an ambient open request through metric ball observations when present, the finite refinement row, and the local component row.*
9. *P is the* Pkg *provenance over* $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConnectedSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, M, G, K, B, C, H, R, P, N$. It has no coordinate for selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, or a host basis of connected neighbourhoods.

Lean4 ✓ `BEDC.Derived.LocallyConnectedUp.TasteGate.LocallyConnectedTasteGate single carrier alignment`

Theorem 5231.2 (Locally connected NameCert obligations)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier* $L = (T, M, G, K, B, C, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *surface consists exactly of carrier admission for the topology, metric, connected-space, compact-metric, finite neighbourhood-refinement, local component, transport, replay, provenance, and naming rows; neighbourhood refinement from T through B; component exposure through C; metric compatibility through M when the request is ball-based; compact-metric compatibility through K for compact finite-source consumers; connected-space comparison through G; and non-escape from selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice.*

Proof. Project the carrier of Definition 5809.1. The projection exposes exactly the rows $T, M, G, K, B, C, H, R, P, N$ so every local naming obligation must be read from those coordinates.

The neighbourhood part is finite. An ambient open request is first read in T, then refined by the displayed row B, and only then receives the local component row C.

The metric and compact-metric rows are compatibility rows rather than extra selectors. A ball-based request may inspect M, and a compact-metric consumer may inspect K, but both routes still pass through the same B and C rows before local connectedness is exported.

Finally, H and R transport and replay the displayed route, while P and N source and name it. Since paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice are not rows of the carrier, the NameCert surface cannot export them. □

Theorem 5231.3 (Locally connected neighbourhood component route)**.** *Every connected-space or compact-metric consumer of an accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *packet reaches local connectedness through*

$$\mathsf{Topology}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{ConnectedSpace}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The finite route reads an ambient neighbourhood, optionally reads metric ball observations, refines to a displayed smaller neighbourhood, and then reads the named local connected component. It does not select a path, an arc, a subcover, a quotient component representative, or a host connected-neighbourhood basis.

Proof. Start with a consumer that asks for local connectedness around a displayed point. Carrier admission gives the consumer the topology row T, the metric row M when a ball observation is part of the request, the global connectedness row G, and the compact-metric row K.

The route then passes through B and C. The row B supplies the finite neighbourhood refinement, and C supplies the local component attached to that refinement.

The structural rows H, R, P, N do not add a hidden selector. They transport, replay, source, and name the same finite route, so no path, arc, arbitrary subcover, quotient representative, or host basis can replace the displayed neighbourhood-component data. □

Theorem 5231.4 (Locally connected obligation closure surface)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier* $L = (T, M, G, K, B, C, H, R, P, N)$*, the obligation-closure surface is exhausted by the displayed finite topology, metric, connected-space, compact-metric, neighbourhood-refinement, local-component, transport, replay, provenance, and naming rows. The row T supplies the open-neighbourhood*

source, M supplies metric-ball observations, G supplies connected-space comparison, K supplies compact-metric finite-source compatibility, B, C supply the local refinement and component rows, and H, R, P, N supply transport, replay, provenance, and local naming.

The local component route therefore consumes the connected-space carrier of chapter 2353, the compact-metric finite neighbourhood discipline of chapter 129, the metric-ball rows of chapter 57, and the topology neighbourhood ledger of chapter 88 before a local component can be named.

Proof. Apply Definition 5809.2 to the accepted carrier. It identifies the complete NameCert surface with the rows $T, M, G, K, B, C, H, R, P, N$.

Apply Definition 5809.3. The route from an open request to a local component passes through topology, optional metric-ball observations, connected-space comparison, compact-metric compatibility, finite refinement, and component rows before the structural rows transport and name the result.

The sibling lattice is read in that order: topology supplies the neighbourhood ledger, metric supplies ball observations, connected-space supplies the comparison carrier, and compact metric supplies the finite neighbourhood discipline. The local refinement and component rows then bind those sibling contributions into the $\mathsf{LocallyConnected}^{\uparrow}$ packet.

Thus the obligation surface is the stated finite route. Path or arc selection, open-cover compactness, quotient components, and a host basis are refused because none of them is a carrier coordinate or a row used by the two preceding theorems. □

Falsifiable prediction: Every accepted $\mathsf{LocallyConnected}^{\uparrow}$ read must expose a $\mathsf{Topology}^{\uparrow}$ open-neighbourhood row, optional $\mathsf{Met}^{\uparrow}$ ball observations, the $\mathsf{ConnectedSpace}^{\uparrow}$ comparison row when a global consumer is present, the $\mathsf{CompactMetric}^{\uparrow}$ finite-source row when a compact-metric consumer is present, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: topology, metric, connected-space, compactmetric: $\mathsf{LocallyConnected}^{\uparrow}$ is not bijective to any listed sibling because it binds a local neighbourhood-refinement row to a local component row before connected-space or compact-metric consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5809.1, Definition 5809.2, and Definition 5809.3 seed the finite local neighbourhood-component route over topology, metric, connected-space, and compact-metric rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close path connectedness, arc connectedness, arbitrary open-cover compactness, quotient component spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, neighbourhood refinement, local component exposure, connected-space comparison, compact-metric compatibility, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.LocallyConnectedUp.

Constructive story: A $\mathsf{LocallyConnected}^{\uparrow}$ packet is generated from an open-neighbourhood row, optional metric ball observations, connected-space and compact-metric compatibility rows, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5232

A Concrete Naming Certificate for $\mathsf{BishopCauchyMean}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{BishopCauchyMean}^{\uparrow}$ packet records the finite averaging step used when a Cauchy source is read through displayed rational windows and sealed as a Real-facing name. It sits after the $\mathsf{Cauchy}^{\uparrow}$ source route of chapter 3413, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names finite averages of observed Cauchy data; it does not assert a selected limit, quotient stream equality, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5232.1 (Bishop Cauchy mean carrier)**.** *A* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Cauchy}^{\uparrow}$ *source row naming the Cauchy data whose finite observations are being averaged.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested dyadic radius, denominator budget, and comparison scale for the average.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the source entries inspected at tolerance D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream window into regular rational data.*
5. *A is the finite averaging ledger: it lists the inspected rational entries, their displayed weights, the denominator row, the partial-sum row, and the final mean row consumed by the certificate.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, W, R, A have been displayed.*
7. *H records componentwise* hsame *transport for the source, tolerance, window, readback, averaging ledger, Real seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a finite mean request through $S, D, W, R, A, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyMean}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^\uparrow}$ *row.*
The classifier compares accepted carriers only through $S, D, W, R, A, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness of $\mathsf{Real}^\uparrow$*, or an infinite averaging oracle.*

Lean4 ✓ `BEDC.Derived.BishopCauchyMeanUp.BishopCauchyMeanTasteGate single carrier alignment`

Theorem 5232.2 (Bishop Cauchy mean NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyMean}^\uparrow$ *carrier*

$$M = (S, D, W, R, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^\uparrow}$ *surface consists exactly of carrier admission for the Cauchy source row, dyadic tolerance row, finite stream window, regular rational readback, finite averaging ledger, terminal Real seal, componentwise transport row, displayed continuation replay, package provenance, and local naming row.*

The obligation surface requires Cauchy-source visibility through S, tolerance accounting through D, finite-window visibility through W, regular rational readback through R, average-ledger exactness through A, Real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It refuses selected limits, quotient stream equality, host real equality, countable choice, and ambient completeness of $\mathsf{Real}^\uparrow$*.*

Proof. Project the accepted carrier of Definition 5810.1. The only analytic rows are the Cauchy source S, the dyadic tolerance D, the finite window W, the regular rational readback R, the averaging ledger A, and the terminal Real seal E.

The averaging step is finite. The ledger A displays the inspected rational entries, their weights, the denominator row, the partial sums, and the final mean; no later consumer can ask for an average outside this listed window.

The terminal seal is downstream of the displayed route. Since the carrier has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness, or an infinite averaging oracle, those objects cannot enter the local NameCert surface.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. They preserve the displayed rows and do not add analytic content. □

Theorem 5232.3 (Bishop Cauchy mean finite-average stability)**.** *Let*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

be an accepted $\mathsf{BishopCauchyMean}^\uparrow$ *carrier. Every accepted consumer read of the mean row factors through the finite route*

$$\mathsf{Cauchy}^\uparrow(S),\ \mathsf{DyadicRatCore}^\uparrow(D),\ \mathsf{StreamName}^\uparrow(W),\ \mathsf{RegSeqRat}^\uparrow(R),\ A,\ \mathsf{Real}^\uparrow(E).$$

If the source row, tolerance row, finite window, readback row, and averaging ledger are transported componentwise by the displayed hsame *rows in H and replayed through C, then the consumer-visible mean row is unchanged as a* $\mathsf{BishopCauchyMean}^\uparrow$ *read. No quotient stream equality, selected limit, host real equality, countable choice, or ambient* $\mathsf{Real}^\uparrow$ *completeness row participates in the stability claim.*

Proof. Start with the consumer route. By the carrier definition, a mean read must first inspect the Cauchy source S, choose the displayed dyadic tolerance D, open the finite window W, and read the regular rational row R.

The average itself is then the ledger row A. Its entries, weights, denominator, partial sums, and final mean are finite displayed data, so componentwise hsame transport preserves exactly the rows that the consumer can inspect.

Replay through C exposes the transported packet with the same provenance and local naming rows P, N. The terminal Real seal E is reached from that transported finite route, not from a quotient stream or selected limit.

Thus any consumer-visible equality of mean reads is exhausted by $S, D, W, R, A, E, H, C, P, N$. The excluded rows are absent from the carrier and cannot affect the stability conclusion. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ read must expose a Cauchy source, dyadic tolerance, StreamName window, RegSeqRat readback, finite averaging ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a Real or Completion consumer can read the mean boundary.

Independence witness: cauchy, dyadicratcore, streamname, regseqrat, real: $\mathsf{BishopCauchyMean}^{\uparrow}$ is not bijective to any listed sibling because it binds a finite averaging ledger between regular rational readback and the Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyMean}^{\uparrow}$ packet is generated from a Cauchy source row, DyadicRatCore tolerance row, StreamName finite window, RegSeqRat readback, finite averaging ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5810.1, Definition 5810.2, and Definition 5810.3 seed the finite Cauchy-mean certificate over Cauchy, DyadicRatCore, StreamName, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite average ledger exactness, tolerance-window readback, regular rational handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyMeanUp.

Chapter 5233

A Concrete Naming Certificate for $\mathsf{BishopFixedPointInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet records the constructive interval fixed-point route as finite NameCert data. It sits after the located interval source of chapter 394, the bisection discipline of chapter 1465, the finite Cauchy-modulus rows used by chapter 292, the regular rational readback of chapter 301, the finite name windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the fixed-point certificate for a displayed interval self-map; it does not import a host compactness theorem, quotient real equality, choice-selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5233.1 (Bishop fixed-point interval carrier)**.** *A* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, T, M, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the closed located interval, its endpoint reads, and its dyadic radius ledger.*
2. *T is the contraction self-map row over I, recording that every admitted interval point is sent back into the same located interval.*
3. *M is an explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *or Lipschitz modulus row that turns each tolerance request into a finite contraction budget.*
4. *B is the* $\mathsf{IntervalBisection}^{\uparrow}$ *or nested located interval row that records the displayed shrinking interval chain.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the rational midpoint, endpoint, and radius observations.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *fixed-point seal reached only after the interval, contraction, modulus, bisection, and readback rows have been exposed.*
7. *H records componentwise* hsame *transport for I, T, M, B, R, E and for the structural rows.*
8. *C records displayed* Cont *replay for interval requests, contraction reads, modulus reads, nested interval reads, rational readback, and real-seal requests.*

9. *P is the* Pkg *provenance over* BishopFixedPointInterval$^{\uparrow}$, LocatedInterval$^{\uparrow}$, IntervalBisection$^{\uparrow}$, CauchyModulus$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{BishopFixedPointInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, T, M, B, R, E, H, C, P, N$. It has no coordinate for a host fixed-point theorem, quotient completion, selected limit, trichotomy, countable choice, or ambient compactness principle.

Lean4 ✓ `BEDC.Derived.BishopFixedPointIntervalUp.BishopFixedPointIntervalTasteGate single carrier alignment`

Theorem 5233.2 (Bishop fixed-point interval NameCert obligations)**.** *For every accepted* BishopFixedPointInterval$^{\uparrow}$ *carrier*

$$F = (I, T, M, B, R, E, H, C, P, N),$$

the local NameCert$_{\text{BishopFixedPointInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the located interval row I, contraction self-map row T, explicit modulus row M, nested bisection row B, regular rational readback row R, terminal real seal E, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N. Every fixed-point consumer must read these rows in the displayed order and cannot replace them by host interval compactness, quotient real equality, a selected limit, or an unrecorded convergence principle.*

Proof. Carrier admission is the finite packet of Definition 5811.1. The rows $I, T, M, B, R, E, H, C, P, N$ are the only coordinates available to the local certificate.

The positive interval route is then forced. The interval source is I, the self-map evidence is T, the contraction budget is M, and the nested interval chain is B; each row is compared only through the componentwise transport row H and replayed only through C.

The readback and seal are downstream. Rational observations pass through R and the dyadic and stream-name data named in P before the terminal Real$^{\uparrow}$ row E is exposed. Since no host compactness, quotient equality, selected limit, or external convergence coordinate occurs in the carrier, the listed rows exhaust the NameCert surface. □

Theorem 5233.3 (Bishop fixed-point interval Cauchy-modulus route)**.** *Let $F = (I, T, M, B, R, E, H, C, P, N)$ be an accepted* BishopFixedPointInterval$^{\uparrow}$ *packet. Each tolerance request for the fixed-point name is answered by first reading the* LocatedInterval$^{\uparrow}$ *row I, then the contraction self-map row T, then the explicit* CauchyModulus$^{\uparrow}$ *or Lipschitz row M, and only then the* IntervalBisection$^{\uparrow}$ *or nested located interval row B. The resulting finite observations are read through* StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* RegSeqRat$^{\uparrow}$ *as recorded by P, so no consumer can infer convergence from an unbounded host iteration or a choice-selected subsequence.*

Proof. Start with a tolerance request. The packet has no direct convergence row, so the request must project I to know the interval source and T to know that the displayed map remains inside the interval.

Next read the modulus row M. This row converts the tolerance into a finite contraction or Lipschitz budget. The nested row B can then expose only the finite bisection or located-interval observations licensed by that budget.

Finally use the readback rows listed in P. Stream windows, dyadic tolerances, and regular rational observations feed R, and H, C, N transport and name the same route. Thus the Cauchy route is explicit and finite, with no unbounded host iteration or selected subsequence. □

Theorem 5233.4 (Bishop fixed-point interval real-seal nonescape)**.** *For every accepted* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *packet, the terminal row* E *is exposed only as the* $\mathsf{Real}^{\uparrow}$ *seal of the displayed nested interval and Cauchy-modulus route*

$$I, T, M, B, R \longmapsto E \longmapsto H, C, P, N.$$

The seal may be consumed as the named fixed-point endpoint of the packet, but it cannot escape as quotient real equality, a proof of ambient $\mathsf{Real}^{\uparrow}$ *completeness, a host fixed-point theorem, an unrestricted interval compactness principle, or a selected representative outside the displayed rows.*

Proof. Read E from the carrier. It is terminal in the packet: the interval, self-map, modulus, nested interval, and rational readback rows precede it, and the structural rows only transport, replay, source, and name the resulting read.

Apply Definition 5811.3. Every tolerance request reaching E has already passed through the finite interval, contraction, modulus, bisection, stream, dyadic, and regular rational observations recorded by I, T, M, B, R, P.

It remains to rule out escape. The carrier has no coordinate for quotient real equality, ambient completeness, a host fixed-point theorem, unrestricted compactness, or selected representatives. Therefore E seals only the displayed fixed-point name of this packet. □

Falsifiable prediction: An accepted $\mathsf{BishopFixedPointInterval}^{\uparrow}$ consumer that reaches the terminal $\mathsf{Real}^{\uparrow}$ row E without first reading $I, T, M, B, R, H, C, P, N$ refutes the carrier surface.

Independence witness: locatedinterval, intervalbisection, cauchymodulus, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the full interval self-map packet $F = (I, T, M, B, R, E, H, C, P, N$ because each sibling contributes only a located interval source, a bisection route, a modulus row, a readback row, a finite name window, a dyadic ledger, or a terminal real seal while this chapter binds them into one fixed-point NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet is generated from a located interval row, contraction self-map row, explicit Cauchy or Lipschitz modulus row, nested bisection row, regular rational readback row, terminal Real seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5811.1, Definition 5811.2, Definition 5811.3, and Definition 5811.4 seed the finite constructive interval fixed-point route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point compactness, quotient real equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction self-map admission, explicit modulus routing, nested interval readback, terminal Real seal nonescape, and a Lean carrier/obligation formalization for BEDC.Derived.BishopFixedPointIntervalUp.

Chapter 5234

A Concrete Naming Certificate for $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$

The $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet realizes the private-coordinate minimal-cover theorem of Definition 9462.1678 as finite NameCert data. It records a trigger-coordinate carrier, a support-family cover ledger, and one private-coordinate witness row for each displayed support before any minimal-trigger criterion may be consumed. The packet keeps the enumeration theorem auditable without identifying it with a generic finite set, word list, Boolean classifier, regular-language recognizer, or finite automaton presentation.

Falsifiable prediction: Every accepted $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ consumer must display a cover row and one private-coordinate witness row for each support before using the minimal-trigger criterion.

Independence witness: finset, list, bool, regularlanguage, finite-automaton: $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ is not bijective to these siblings because it carries a support-family cover ledger plus a private-coordinate witness for every support row.

Definition 5234.1 (Private-coordinate trigger carrier)**.** *A* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the finite trigger-coordinate row.*
2. A *is the finite support-family row whose entries are displayed subsets of* Ω*.*
3. U *is the cover ledger asserting that the displayed supports cover every coordinate of* Ω*.*
4. V *is the private-coordinate witness ledger, with one row for each support in* A*.*
5. π *maps each support row to its selected private coordinate and records membership in that support.*
6. E *records exclusion from every other support row for the selected private coordinate.*
7. K *is the minimal-cover criterion row, readable only after* U, V, π, E *have been displayed.*
8. H *stores componentwise* hsame *transport for coordinate, support, cover, witness, exclusion, and criterion rows.*

9. *C stores* Cont *replay from a trigger query through the cover ledger and the private-coordinate witness rows.*
10. *P stores* Pkg *provenance over* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Omega, A, U, V, \pi, E, K, H, C, P, N$. It has no coordinate for a bare finite set, unordered list, Boolean truth table, regular-language recognizer, finite automaton run, or support family without displayed private witnesses.

Theorem 5234.2 (Private-coordinate trigger NameCert obligations)**.** *For every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *surface consists exactly of coordinate exposure, support-family exposure, cover-ledger replay, one private-coordinate witness row for each support, membership and exclusion checks for the selected witnesses, minimal-cover criterion exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5812.1. The rows Ω, A, U display the finite coordinate space, the support family, and the fact that the supports cover the full coordinate row.

The rows V, π, E attach a private coordinate to each support. Membership is recorded by π, and exclusion from every other support is recorded by E, so deleting the support removes at least one displayed coordinate from the cover.

The criterion row K is therefore readable only after the cover and private-witness rows have been exposed. The remaining rows H, C, P, N preserve transport, replay, provenance, and local naming for the same finite packet, and no omitted sibling surface supplies the private-coordinate ledger. □

Theorem 5234.3 (Private-coordinate minimal-cover criterion)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier exposes a minimal full trigger exactly through the displayed cover row U together with the private-coordinate witness rows V, π, E. A consumer may use the criterion row K only after reading a cover of Ω and one witness coordinate for every support row in A that belongs to that support and belongs to no other displayed support. The packet does not turn the support family into a regular language, finite automaton, Boolean table, or list quotient.*

Proof. The forward read uses the cover ledger U and the private-coordinate witness rows. If a support row is removed, its selected witness coordinate remains outside all other displayed supports by E, so the remaining family no longer covers Ω.

For the reverse read, the cover row already gives full coverage. The witness rows ensure that every support has a coordinate lost by deleting that support, so no displayed support is redundant.

Thus the criterion row K is exactly the finite private-coordinate minimal-cover test. The transport, replay, provenance, and local naming rows carry this test without converting it into any sibling classifier. □

Theorem 5234.4 (Private-coordinate trigger finite-set cover route)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *packet reads its support-family row as a finite-set-indexed cover through chapter 112. The exclusions from regular-language and automaton presentations are bounded by chapter 351 and chapter 2364: the private-coordinate carrier may display finite support rows, recognizer-like acceptance tests, or transition-like exclusion checks, but it exports the minimal-cover criterion only through the rows $\Omega, A, U, V, \pi, E, K, H, C, P, N$.*

Proof. Project the accepted carrier

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N).$$

The row Ω is the displayed coordinate object, and A is read as a finite family of supports indexed by the finite-set surface. The cover ledger U then witnesses coverage of every coordinate in Ω by those displayed supports.

The rows V, π, E are the extra private-coordinate ledger. They attach one witness coordinate to each support, record membership in that support, and record exclusion from every other displayed support. These rows are not supplied by the finite-set sibling, nor by the regular-language or finite-automaton presentations.

Consequently K is a private-coordinate minimal-cover read rather than a bare finite-set cover, a regular-language recognizer, or an automaton acceptance predicate. The structural rows H, C, P, N transport and replay only this displayed packet, so the sibling route records the finite-combinatorial surface without replacing the private-coordinate data. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$.

Constructive story: A $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet is generated from a finite trigger-coordinate row, support-family row, cover ledger, per-support private-coordinate witness ledger, membership and exclusion rows, minimal-cover criterion row, componentwise transport, continuation replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5812.1, Definition 5812.2, Definition 5812.3, and Definition 5812.4 seed the finite NameCert packet for private-coordinate minimal-cover witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, regular-language recognition, finite-automaton minimization, Boolean classifier completeness, or enumeration beyond the displayed private-coordinate criterion.

Upgrade path: Obligation closure requires checked carrier admission, cover-ledger replay, private-coordinate witness coverage, exclusion exactness, minimal-cover criterion replay, TasteGate nontriviality, FieldFaithful projection, transport, replay, provenance, and local naming for BEDC.Derived.PrivateCoordinateTriggerUp.

Chapter 5235

A Concrete Naming Certificate for $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet records the finite modulus by which a located real comparison request is read through displayed apartness or equality evidence, dyadic tolerances, explicit Cauchy-modulus schedules, regular rational readback, and the terminal real-name seal. It sits after the comparison surface of chapter 1730, the tail envelope of chapter 1769, the Cauchy-modulus bridge of chapter 5728, the rational readback of chapter 301, and the public real route of chapter 38. The packet names a finite comparison-schedule carrier; it is not trichotomy, quotient real equality, a selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5235.1 (Located real comparison modulus carrier)**.** *A* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, A, D, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{LocatedRealComparison}^{\uparrow}$ *request row for the two located real endpoints and the comparison direction being inspected.*
2. *A is the located evidence row. It records the displayed positive apartness witness when the request separates the endpoints, or the displayed equality-facing refusal row when the request reaches only an overlap tolerance.*
3. *D is the dyadic tolerance schedule. It lists the requested precision, comparison slack, endpoint radii, and finite tolerance refinements consumed by the comparison read.*
4. *B is the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route connecting the comparison request to an explicit Cauchy-modulus schedule before regular rational readback is allowed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected rational tails exposed by B and bounded by D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the comparison-facing read, available only after Q, A, D, B, R have been displayed.*
7. *H records componentwise* hsame *transport for the comparison request, evidence row, dyadic tolerance schedule, bridge route, readback, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from the comparison request through located evidence, dyadic scheduling, Cauchy-modulus bridging, regular rational readback, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, LocatedRealTailEnvelop $\mathsf{CauchyModulusBridge}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, A, D, B, R, E, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, a hidden selector, countable choice, a host comparison oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedRealComparisonModulusUp.LocatedRealComparisonModulusTasteGate`
`single carrier alignment`

Theorem 5235.2 (Located real comparison modulus obligations)**.** *For every accepted* LocatedRealComparisonModu *carrier*

$$M = (Q, A, D, B, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *surface consists exactly of comparison-request admission, located apartness-or-equality evidence, dyadic tolerance scheduling,* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *routing,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer of the comparison schedule must read those rows in the displayed order and receives no trichotomy split, quotient real equality, hidden selector, countable-choice schedule, host comparison oracle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 5813.1. The comparison request is Q, and the only evidence row attached to it is A.

The schedule is then forced through D and B. The dyadic row D records the finite tolerances to be inspected, while the $\mathsf{CauchyModulusBridge}^{\uparrow}$ row B turns those tolerance requests into explicit tail thresholds before any rational readback is exposed.

The terminal read is downstream. The regular rational row R reads only the displayed tails opened by B, and the $\mathsf{Real}^{\uparrow}$ seal E is available only after that readback.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for the excluded host-level or choice-level objects, the listed rows exhaust the local NameCert surface. □

Theorem 5235.3 (Located real comparison modulus nontrichotomy boundary)**.** *Every accepted* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *packet exports a positive schedule for comparison reads without exporting trichotomy. If the evidence row A records positive apartness, a downstream consumer may read that apartness only through Q, D, B, R, E; if A records only an equality-facing overlap tolerance, the consumer receives the displayed tolerance route and no forced left-or-right order verdict.*

Proof. Read the evidence row A together with the comparison request Q. The carrier does not contain a three-way order coordinate, so the two possible reads are positive displayed apartness or finite overlap tolerance.

For the positive branch, the dyadic tolerance row D and bridge row B determine which tails are inspected before R and E can be consumed. The apartness read is therefore a finite schedule read, not a global order split.

For the overlap branch, the same schedule exposes only the inspected tolerance data. Since no trichotomy coordinate or hidden selector appears in $M = (Q, A, D, B, R, E, H, C, P, N)$, the packet refuses any forced left-or-right verdict not displayed by the rows. □

Falsifiable prediction: An accepted $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is refuted if a comparison consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting the $\mathsf{LocatedRealComparison}^{\uparrow}$ request row Q, the evidence row A, the dyadic tolerance schedule D, the $\mathsf{CauchyModulusBridge}^{\uparrow}$ route B, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: LocatedRealComparison, LocatedRealTailEnvelope, CauchyModulusBridge, RegSeqRat, Real: none is bijective with $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ because the packet jointly carries a comparison request, apartness-or-equality evidence, dyadic tolerance scheduling, explicit Cauchy-modulus bridging, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is generated from a LocatedRealComparison request row, located apartness-or-equality evidence, a dyadic tolerance schedule, a CauchyModulusBridge route, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5813.1, Definition 5813.2, and Definition 5813.3 seed the finite comparison-modulus route over LocatedRealComparisonUp, LocatedRealTailEnvelopeUp, CauchyModulusBridgeUp, RegSeqRatUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, host comparison oracles, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, evidence-row exactness, dyadic schedule determinacy, Cauchy-modulus bridge routing, regular rational readback, Real-seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealComparisonModulusUp.

Chapter 5236

A Concrete Naming Certificate for $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$

The $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet realizes the boundary-shadow and observer-expansion route of chapter 9463 as finite cocycle-level NameCert data. It sits after the boundary-shadow route of chapter 3813, the observer-shadow metric of chapter 4154, the Busemann cocycle of chapter 4134, the horosphere-flow ledger of chapter 4051, and the observer-expansion packet of chapter 4167. The chapter names a finite expansion cocycle over displayed boundary and horosphere rows; it is not a completed hyperbolic boundary, quotient geodesic ray space, physical observer dynamics, selected ideal point, or ambient manifold theorem.

Definition 5236.1 (Boundary-shadow expansion cocycle carrier)**.** *A* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, O, B, F, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row recording the visible boundary shadow through which the cocycle is read.*
2. *O is the* $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ *row recording the observer-facing shadow metric comparison for the same boundary read.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row recording the additive Busemann comparison consumed by the expansion read.*
4. *F is the* $\mathsf{HorosphereFlowLedger}^{\uparrow}$ *row recording the horosphere-flow level through which boundary and Busemann rows are replayed.*
5. *E is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *row recording the displayed observer-expansion magnitude or direction attached to S, O, B, F.*
6. *H records componentwise* hsame *transport for boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow ledger, observer expansion, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, and observer-expansion read.*

8. *P is the* Pkg *provenance over* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HorosphereFlowLedger}^{\uparrow}$, HyperbolicObserverExp BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, O, B, F, E, H, C, P, N$. It has no coordinate for completed boundary points, quotient geodesic rays, a hidden expansion selector, physical observer dynamics, selected ideal endpoints, or ambient hyperbolic manifold data.

Theorem 5236.2 (Boundary-shadow expansion cocycle NameCert obligations)**.** *For every accepted* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ *carrier*

$$X = (S, O, B, F, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *surface consists exactly of boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, observer-expansion read, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any accepted expansion read that omits either the boundary-shadow row S or the Busemann cocycle row B is outside the packet.*

Proof. Project the carrier of Definition 5814.1. The boundary-facing rows are S and O, while the cocycle and horosphere-flow rows are B and F.

The expansion row E is downstream from those four rows. It can be read only after the visible boundary shadow, observer-shadow metric, Busemann cocycle, and horosphere-flow ledger have all been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for completed boundary data, quotient geodesic rays, hidden selectors, physical observer dynamics, selected endpoints, or ambient manifold structure, the listed rows exhaust the local NameCert surface. □

Theorem 5236.3 (Boundary-shadow expansion cocycle dependency route)**.** *Every accepted* BoundaryShadowExpan *read factors through*

$\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, HorosphereFlowLed

before a consumer may inspect the expansion cocycle as a local NameCert row. The route is finite and preserves the boundary-shadow row and Busemann cocycle row as separate coordinates.

Proof. Use Definition 5814.2. It places the boundary-shadow row, observer-shadow metric row, Busemann cocycle row, and horosphere-flow ledger before the expansion row.

The cocycle dependency is not reducible to one sibling. The boundary-shadow row supplies the boundary face, the observer-shadow metric supplies the observer-facing comparison, the Busemann row supplies the additive cocycle read, and the horosphere-flow row supplies the level ledger.

Only after those rows are present can E, H, C, P, N expose the expansion cocycle as a local packet. Therefore a consumer cannot collapse the route to a single hyperbolic object or bypass the separate boundary-shadow and Busemann coordinates. □

Falsifiable prediction: Any accepted $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet is refuted if the expansion read omits either the boundary-shadow row S or the Busemann cocycle row B.

Independence witness: hyperbolic_boundary_shadow, hyperbolic_observer_shadow_metric, hyperbolic_busemann_cocycle, horosphere_flow_ledger, hyperbolic_observer_expansion: none

is bijective with $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ because the packet jointly carries boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow level, observer expansion, transport, replay, provenance, and local naming.

The Lean TasteGate route for this packet must provide `Nontrivial BoundaryShadowExpansionCocycleUp` and `FieldFaithful BoundaryShadowExpansionCocycleUp` instances in `lean4/BEDC/Derived/BoundaryShadowE` Those instances must preserve $S, O, B, F, E, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet is generated from HyperbolicBoundaryShadow rows, HyperbolicObserverShadowMetric rows, HyperbolicBusemannCocycle rows, HorosphereFlowLedger rows, HyperbolicObserverExpansion rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5814.1, Definition 5814.2, and Definition 5814.3 seed the finite boundary-shadow expansion cocycle route over boundary, observer-shadow, Busemann, horosphere-flow, expansion, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic boundaries, quotient geodesic ray spaces, physical observer dynamics, selected ideal endpoints, ambient manifold theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow exactness, observer-shadow metric readback, Busemann cocycle separation, horosphere-flow routing, observer-expansion exposure, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.BoundaryShadowExpansionCocycleUp.

The $\mathsf{HellyBraySelection}^{\uparrow}$ hub routes bounded-variation selection through chapter 398, chapter 2069, chapter 301, chapter 126, and chapter 38 before the child files expose the finite selection packet.

Chapter 5237

A Concrete Naming Certificate for $\mathsf{HellyBraySelection}^{\uparrow}$

Following Helly and Bray, the $\mathsf{HellyBraySelection}^{\uparrow}$ packet records the finite selection surface by which bounded-variation source data are read through Jordan signed-variation rows, finite stream windows, regular rational readback, and terminal real seals before a downstream selection consumer may use the packet. It sits after the bounded-variation carrier of chapter 398, the Jordan variation decomposition rows of chapter 2069, the regular rational readback route of chapter 301, the finite observation windows of chapter 126, and the terminal real-name boundary of chapter 38. Helly–Bray selection also feeds distribution-facing compactness through chapter 186, chapter 92, and chapter 4008 when the bounded-variation read is consumed as a tight probability-family route. The chapter names a finite BEDC selection packet, not host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5237.1 (Helly–Bray selection carrier)**.** *A* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, J, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, carrying the bounded-variation object, finite variation ledger, and endpoint budget exposed to the selection request.*
2. *J is the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *row, displaying the signed-variation split and the positive and negative variation rows read from B.*
3. *S is the family of* $\mathsf{StreamName}^{\uparrow}$ *finite windows opened by the inspected variation rows and by the downstream Real-facing request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, recording the rational comparisons used before any Real seal is visible.*
5. *E is the finite family of* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after B, J, S, R have been displayed.*
6. *T records componentwise* hsame *transport for the bounded-variation source, Jordan rows, finite windows, readbacks, Real seals, continuation, provenance, and local naming.*
7. *C records displayed* Cont *replay from bounded-variation data through Jordan signed-variation rows, finite windows, regular rational readback, Real seals, transport, provenance, and local naming.*

8. *P is the* Pkg *provenance over* $\mathsf{HellyBraySelection}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, J, S, R, E, T, C, P, N$. The carrier has no coordinate for host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5237.2 (Helly–Bray selection NameCert obligations)**.** *For every accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier*

$$H = (B, J, S, R, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded-variation source row, Jordan signed-variation decomposition row, StreamName finite windows, RegSeqRat readback row, Real seal rows, transport, replay, provenance, and local naming;*
2. *variation-source exposure, requiring every selection-facing read to begin with B and then pass through the signed-variation rows J rather than through a host weak-convergence theorem;*
3. *finite-window locality, requiring S to list the exact stream windows opened by the variation rows and the Real-facing request;*
4. *readback ordering, requiring R to consume the displayed windows in S before any row of E is exposed;*
5. *componentwise transport, displayed replay, provenance, and local naming for the same rows through T, C, P, N;*
6. *nonescape, excluding host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Helly–Bray selection obligation is stored outside these rows.

Proof. Project the accepted carrier. The only source coordinate is the bounded-variation row B, and the only signed-variation coordinate is the Jordan row J.

The finite observation surface is then forced by row order. The StreamName windows S are opened from the displayed variation rows, the RegSeqRat readback R reads only those windows, and the Real seals E appear only after that readback has been displayed.

Transport and replay preserve the same route componentwise through T and C. Provenance P and local naming N record that route as the local certificate surface.

Since none of the excluded objects occurs as a carrier coordinate, a consumer cannot add weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient Real completeness to the local NameCert obligations. □

Theorem 5237.3 (Helly–Bray selection finite-window route)**.** *Every Real-facing or variation-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier factors its read through*

$$\mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{JordanVariationDecomposition}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto T, C, P, N$$

Thus the consumer receives bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise transport, continuation replay, provenance, and local naming. The route supplies no host weak convergence, measure completion, quotient function equality, selected subsequence, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier $H = (B, J, S, R, E, T, C, P, N)$. The first projection gives the bounded-variation source row B, and the next projection gives the Jordan signed-variation row J over that source.

The finite-window part is local. The windows S are the only observation rows available to the packet, and R is the only regular rational readback attached to those windows.

The Real-facing boundary is reached only at E. The remaining rows T, C, P, N transport, replay, source, and name the same finite route; they do not add a new selection principle.

Because the carrier omits host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient Real completeness, every accepted consumer read is exhausted by the displayed finite-window route. □

Theorem 5237.4 (Helly–Bray distribution forward link)**.** *Every* $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, *or* $\mathsf{ProkhorovTightProbabi}$ *consumer that cites an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier must first read the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *signed-variation row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows of Definition 5815.1. The downstream route to chapter 186, chapter 92, and chapter 4008 therefore receives only bounded-variation source data, Jordan variation data, displayed windows, rational readback, Real seals, componentwise transport, replay, provenance, and local naming. It receives no host weak convergence theorem, measure completion, quotient equality, selected subsequence, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $H = (B, J, S, R, E, T, C, P, N)$. The only distribution-facing source row is B, and the only signed-measure decomposition row available to the packet is J.

Use the finite-window route of Definition 5815.3. It forces every Real-facing and variation-facing read through S, R, E before the transport, replay, provenance, and local naming rows can be consumed.

Now attach a downstream distribution, measure, or tight-probability request. Since those consumers cite the Helly–Bray packet only through the displayed route, the request reaches chapter 186, chapter 92, or chapter 4008 after $B, J, S, R, E, T, C, P, N$ have already been displayed.

The excluded objects are not carrier coordinates. Thus the forward link cannot export host weak convergence, measure completion, quotient equality, selected subsequences, countable choice, or ambient Real completeness to any distribution-facing consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5815.1, Definition 5815.2, Definition 5815.3, and Definition 5815.4 seed the finite Helly–Bray selection route over bounded-variation data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, transport, replay, provenance, local naming, and distribution-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, variation-source exposure, finite-window locality, readback ordering, transport, replay, provenance, local naming, and finite-window routing for BEDC.Derived.HellyBraySelectionUp.

Constructive story: A $\mathsf{HellyBraySelection}^{\uparrow}$ packet is generated from bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

The Helly–Bray route is a distribution-facing read of the finite selection surface already named by chapter 1732; its bounded real sequence and compactness rows are supplied through chapter 1415 before the distribution consumer is allowed to inspect the signed-variation packet.

Theorem 5237.5 (Helly–Bray Helly-selection dependency route)**.** *Every* $\mathsf{Distribution}^{\uparrow}$ *or compactness-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *packet must first expose the finite* $\mathsf{HellySelection}^{\uparrow}$ *selection surface of chapter 1732 together with the bounded real sequence route of chapter 1415. In carrier notation, the read passes through the bounded-variation source row, Jordan signed-variation row, finite window rows, regular rational readback, terminal Real seals, componentwise transport, replay, provenance, and local naming rows before the distribution-facing route of Definition 5815.4 is public. It is therefore not a free weak-convergence theorem, measure-completion theorem, quotient-function equality, choice-selected subsequence, or ambient compactness principle.*

Proof. Start with the carrier of Definition 5815.1. Its only sequence-facing data are the bounded-variation row, Jordan signed-variation row, finite windows, regular rational readback, and terminal Real seals.

Read those rows through the finite-window route of Definition 5815.3. The same bounded source discipline is the one exported by the $\mathsf{HellySelection}^{\uparrow}$ packet, and the bounded real sequence route supplies the finite window and bound rows before any compactness-facing consumer can inspect them.

Finally attach the distribution forward link. Since Definition 5815.4 exposes distribution consumers only after the Helly–Bray carrier rows have been displayed, the downstream route receives the Helly-selection and bounded-sequence surfaces as dependencies rather than as hidden host compactness or choice principles. □

Chapter 5238

A Concrete Naming Certificate for $\mathsf{DiniFiniteMinimumBudget}^{\uparrow}$

Following Dini's theorem and Bishop–Bridges constructive compactness, the $\mathsf{DiniFiniteMinimumBudget}^{\uparrow}$ packet records the finite extraction row that turns a monotone compact-window Dini certificate into one displayed tolerance budget. It consumes the $\mathsf{CompactMetric}^{\uparrow}$ source, monotone $\mathsf{ContinuousMap}^{\uparrow}$ family rows, the $\mathsf{DiniTheorem}^{\uparrow}$ compact-window route, $\mathsf{UniformModulus}^{\uparrow}$ handoff data, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance cells, the terminal $\mathsf{Real}^{\uparrow}$ seal, BHist history rows, hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ data. The packet names only the finite minimum-budget route; it is not host supremum selection, a selected minimum outside the carrier, open-cover compactness, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

The dependency surface is horizontal: chapter 1387 supplies the compact-window Dini route, chapter 129 supplies the inspected compact carrier, chapter 130 supplies the monotone continuous-family rows, and chapter 369 receives the extracted budget. Thus the minimum-budget row is a downstream finite extraction from those sibling carriers, not an isolated tolerance selector.

Definition 5238.1 (Dini finite-minimum budget carrier)**.** *A* $\mathsf{DiniFiniteMinimumBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, D, U, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row naming the finite compact-metric windows inspected by the extraction.*
2. *F is the monotone* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, including the displayed pointwise comparison ledger used by the Dini route.*
3. *D is the* $\mathsf{DiniTheorem}^{\uparrow}$ *row that supplies the monotone uniform-window certificate over K and F.*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row consumed by uniform-limit and compact-uniform-modulus readers.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, listing the candidate dyadic budgets and their finite comparison cells.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by every displayed tolerance and value comparison.*
7. *H records componentwise* hsame *transport for $K, F, D, U, Q, E, C, P, N$.*

8. *C records displayed* Cont *replay from compact windows and monotone family rows through the Dini row, the finite dyadic budget comparisons, the uniform-modulus handoff, and the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{DiniFiniteMinimumBudget}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DiniTheorem}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniFiniteMinimumBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for an ambient supremum, an externally selected minimum, open-cover compactness, quotient equality of real names, countable choice, or host Real completeness.

Lean4 ✓ `BEDC.Derived.DiniFiniteMinimumBudgetUp.DiniFiniteMinimumBudgetTasteGate single carrier alignment`

Theorem 5238.2 (Dini compact finite-minimum budget)**.** *For every accepted* $\mathsf{DiniFiniteMinimumBudget}^{\uparrow}$ *carrier*

$$B = (K, F, D, U, Q, E, H, C, P, N),$$

the finite probe cover displayed by K, F, D and the dyadic tolerance cells displayed by Q determine one displayed minimum tolerance budget before the uniform-modulus handoff U is exported. The extraction route is

$$K, F, D, Q, E, H, C, P, N \longrightarrow U.$$

Thus a $\mathsf{UniformLimit}^{\uparrow}$ *or compact-uniform-modulus consumer receives a finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget sealed by* $\mathsf{Real}^{\uparrow}$ *and transported by* hsame *and* Cont*, without host supremum, selected minimum outside the carrier, open-cover compactness, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted packet. The compact source row K, monotone family row F, and Dini row D are the only rows that can name the finite probe cover for the tolerance request.

The dyadic row Q lists the candidate tolerance cells. Since the carrier is finite, the budget comparison is a displayed finite comparison among the cells in Q, with every real-valued read sealed through E before the handoff row is exposed.

The route to U is then replayed by C and transported componentwise by H. The provenance and naming rows P, N record the same finite route as the local certificate surface.

No excluded object is a coordinate of B. Consequently the exported budget is the displayed finite minimum-budget row inside the carrier, not an ambient supremum, external selector, open-cover argument, quotient equality, choice schedule, or completeness argument. □

Falsifiable prediction: Every accepted $\mathsf{DiniFiniteMinimumBudget}^{\uparrow}$ consumer that exports a $\mathsf{UniformModulus}^{\uparrow}$ handoff must first expose the compact-metric windows, monotone continuous-family rows, DiniTheorem route, finite $\mathsf{DyadicRatCore}^{\uparrow}$ budget cells, $\mathsf{Real}^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: dini-theorem, compactmetric, continuousmap, uniformmodulus, dyadicratcore, real: $\mathsf{DiniFiniteMinimumBudget}^{\uparrow}$ is not bijective to any listed sibling because it binds the finite Dini probe cover to one displayed dyadic minimum-budget handoff before uniform-limit or compact-uniform-modulus consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniFiniteMinimumBudget}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniFiniteMinimumBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5816.1 and Definition 5816.2 seed the finite minimum-budget extraction route from compact Dini data to a uniform-modulus-facing handoff.

Formal verification: FormalStatus(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host supremum selection, selected minima outside the carrier, open-cover compactness, quotient equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite probe-cover exposure, dyadic minimum-budget extraction, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniFiniteMinimumBudgetUp.

Constructive story: A DiniFiniteMinimumBudget$^{\uparrow}$ packet is generated from compact-metric source rows, monotone ContinuousMap family rows, a DiniTheorem compact-window route, UniformModulus handoff rows, DyadicRatCore tolerance cells, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5239

A Concrete Naming Certificate for $\mathsf{FiniteCauchyFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet records the finite directed-tail surface used when a completion consumer asks for Cauchy-filter evidence before reading a regular rational name or a terminal real-name seal. It sits beside the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite filter basis for tail requests; it is not a quotient filter, a selected limit, countable choice, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5239.1 (Finite Cauchy filter carrier)**.** *A* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (W, T, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the filter request.*
2. T *is the directed-tail request row, naming the finite family of later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii and comparison budgets used by the directed tails.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and tolerance ledger.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, T, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the stream windows, tail requests, dyadic ledgers, regular readback, and real seal.*
7. C *records displayed* Cont *replay of the same finite filter route.*
8. P *records* Pkg *provenance over* $\mathsf{FiniteCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, T, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.FiniteCauchyFilterUp.FiniteCauchyFilterTasteGate single carrier alignment`

Theorem 5239.2 (Finite Cauchy filter NameCert obligations)**.** *For the carrier of Definition 5817.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail request visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-ledger preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal access, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $F = (W, T, D, R, E, H, C, P, N)$. The rows W, T, D expose the finite source windows, directed tail requests, and dyadic tolerance budgets before any regular-rational or real-facing read is admitted.

The readback row R is then determined by the displayed windows and tolerance ledger. Since the carrier stores no second regular-rational coordinate, every $\mathsf{RegSeqRat}^{\uparrow}$ consumer reads the same finite route.

The seal row E is downstream of W, T, D, R. The transport row H, continuation row C, package provenance row P, and local naming row N preserve exactly that route and provide no coordinate for quotient filters, selected limits, countable choice, host stream equality, host real equality, or ambient completeness. □

Theorem 5239.3 (Finite Cauchy filter Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier factors through the finite route*

$$W, T, D, R, E, H, C, P, N.$$

In particular, the consumer must first read $\mathsf{StreamName}^{\uparrow}$ *windows, directed tail requests,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Start with the carrier definition. The only real-facing row is E, and it is displayed after the stream windows, directed-tail row, dyadic ledger, and regular readback row.

Apply Definition 5817.2. The local NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Thus any Real-facing consumer receives the finite packet $W, T, D, R, E, H, C, P, N$ and no quotient-filter, selected-limit, countable-choice, host-equality, or ambient-completeness substitute. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet is generated from finite StreamName windows, directed tail requests, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 5817.1, Definition 5817.2, and Definition 5817.3 specify the finite directed-tail filter carrier and its Real-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filter construction, selected limits, countable choice, host stream equality, host real equality, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for directed-tail visibility, tolerance-ledger preservation, readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 5240

A Concrete Naming Certificate for DNAWindowSixTranslationBoundary$^{\uparrow}$

The DNAWindowSixTranslationBoundary$^{\uparrow}$ packet realizes the local translation-boundary branch of subsection 9462.28.21 as finite NameCert data. It consumes the codon-window and stop-tile boundary analysis in the source vision, the curated code-boundary ledger of **??**, and the trigger-threshold surface of chapter 4217. The packet names only a finite window-six translation-boundary carrier; biological translation realization, universality, protein function, and evolutionary mechanism remain outside the BEDC kernel packet.

Definition 5240.1 (DNA window-six translation-boundary carrier)**.** *A* DNAWindowSixTranslationBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, S, T, L, R, V, H, C, P, N)$$

with the following displayed rows:

1. *Q is the codon Q_6 window row recording the six-bit coordinate readback for the inspected codon window.*
2. *S is the stop-tile boundary row recording the local halt boundary and continuation-corner split from the source vision.*
3. *T is the translation-classifier row supplied by external biological bridge data.*
4. *L is the curated code-boundary ledger row inherited from* BioRealityQSixLeaveOneCodeBoundaryLedger$^{\uparrow}$*.*
5. *R is the release-factor or release-mechanism row that records which external recognition boundary is being tested.*
6. *V is the finite validation row recording which observed table, organismal code row, or assay class is used for the test.*
7. *H records componentwise* hsame *transport for the window, tile, classifier, ledger, release, and validation rows.*
8. *C records displayed* Cont *replay of the boundary read through those rows.*
9. *P records* Pkg *provenance over the source vision, the bio-reality ledger sibling,* DNAWindowSixTriggerThreshold$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and local naming rows.*
10. *N is the local* NameCert$_{\text{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for biological necessity, global identification of the genetic code with the window-six fold, protein-folding realization, universal stop assignment, hidden BEDC channel tokens, or untested mechanism.

Theorem 5240.2 (DNA window-six translation-boundary obligations)**.** *For the carrier of Definition 5818.1, the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *surface consists exactly of codon-window exposure, stop-tile boundary visibility, external translation-classifier disclosure, curated code-ledger preservation, release-boundary test exposure, finite validation-row visibility, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $B = (Q, S, T, L, R, V, H, C, P, N)$. The rows Q, S, T expose the finite codon window, the local translation boundary, and the external classifier before any biological reading is admitted.

The ledger and release rows L, R keep the packet anchored to the bio-reality boundary sibling and to a displayed recognition test. The validation row V records the observed table or assay class being tested, so the packet has a falsifiable contact surface rather than a kernel claim of biological necessity.

The structural rows H, C, P, N transport, replay, source, and name exactly the displayed boundary route. Since no further coordinate is present, the carrier cannot export global window-six identity, universal stop assignment, protein-folding realization, hidden channel tokens, or untested mechanism. □

Theorem 5240.3 (DNA window-six translation-boundary sibling handoff)**.** *Every accepted* DNAWindowSixTranslat *read that reaches a translation-boundary consumer must first expose the source-vision stop-tile row of subsection 9462.28.21, the curated code-boundary ledger row of* **??**, *and the finite trigger-threshold row of chapter 4217. The handoff is therefore a concrete finite boundary-tile NameCert route, not a narrative-only direction.*

Proof. Use Definition 5818.1. The source-vision row is carried by S, the code-boundary ledger is carried by L, and the trigger-facing finite boundary read is recorded in the same package provenance P.

Now apply Definition 5818.2. The local NameCert requires those rows before the translation-boundary consumer can read N. Hence the consumer sees the source vision, the bio-reality ledger sibling, and the trigger-threshold sibling as displayed packet data rather than as detached prose. □

Falsifiable prediction: An accepted $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet must expose a finite validation row naming the observed code table, organismal code row, or release-factor assay class before it can export a translation-boundary reading.

Independence witness: bioreality-q-six-leave-one-code-boundary-ledger, dna-window-six-trigger-threshold, synonymous-transition: the $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is not bijective to any listed sibling because it jointly carries codon-window, stop-tile, external translation-classifier, curated code-ledger, release-boundary, validation, transport, replay, provenance, and local naming rows.

The Lean follow-up must provide $\mathsf{Nontrivial}\ \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{DNAWindowSi}$ TasteGate instances before this packet can move beyond seed closure.

Closure status for $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is generated from codon Q-six window rows, stop-tile boundary rows, external translation-classifier rows, curated code-boundary ledgers, release-boundary tests, finite validation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, seed)

Scope closed: Definition 5818.1, Definition 5818.2, and Definition 5818.3 specify the finite translation-boundary carrier and sibling route.

Formal verification: FormalStatus(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim biological-code necessity, global window-six identity, universal stop assignment, protein-folding realization, hidden BEDC channel tokens, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding, TasteGate nontriviality, field faithfulness, validation-row exactness, sibling-route preservation, transport, replay, provenance, and local naming.

Chapter 5241

A Concrete Naming Certificate for $\mathsf{RegulatedConvergence}^{\uparrow}$

Following Bishop and Bridges on regulated functions and uniform convergence, the $\mathsf{RegulatedConvergence}^{\uparrow}$ packet records the finite route by which a displayed sequence of regulated real functions converges uniformly to a regulated endpoint. It sits after the regulated-function carrier of chapter 1906, the regulated-integral consumer boundary of chapter 1557, the uniform-convergence ledger of chapter 3417, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite convergence-and-handoff surface; it does not import measure completion, quotient equality of functions, selected host limits, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5241.1 (Regulated convergence carrier)**.** *A* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

with the following displayed rows:

1. *F is the source row naming the regulated-function family through* $\mathsf{RegulatedFunction}^{\uparrow}$ *data, including the displayed interval, step-window, endpoint, and oscillation ledgers available to each inspected member.*
2. *U is the* $\mathsf{UniformConvergence}^{\uparrow}$ *tail row, recording one shared tolerance schedule for the whole regulated family rather than pointwise schedules chosen separately at each argument.*
3. *W is the finite window row exposing exactly the function indices, domain windows, and endpoint reads used by the shared tail schedule.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the real-valued observations in those windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after F, U, W, R have been displayed.*
6. *I is the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *handoff row; it records that integral-facing consumers may read the regulated endpoint only through the same finite regulated-function, uniform-tail, window, readback, and Real-seal route.*
7. *H records componentwise* hsame *transport for F, U, W, R, E, I and for the structural rows.*
8. *C records displayed* Cont *replay for regulated-function reads, uniform-tail requests, finite window reads, regular rational readback, Real-seal requests, and integral handoff requests.*

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedConvergence}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, U, W, R, E, I, H, C, P, N$. It has no coordinate for a host function quotient, selected limiting function, measure completion, pointwise-only convergence, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceTasteGate single carrier alignment`

Theorem 5241.2 (Regulated convergence NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier*

$$G = (F, U, W, R, E, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the regulated-function family row F, uniform-convergence tail row U, finite window row W, regular rational readback row R, terminal Real seal E, regulated-integral handoff row I, componentwise transport row H, displayed replay row C, package provenance row P, and local naming row N. Every endpoint-facing or integral-facing consumer must read these rows in the displayed route and cannot replace them by pointwise convergence, a selected host limit, quotient equality of functions, measure completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 5819.1. The only analytic rows are the regulated-function family F, the shared uniform tail ledger U, the finite window row W, the regular rational readback R, the terminal Real seal E, and the integral handoff I.

The convergence route is uniform. A consumer must read the single tail schedule U before it can inspect the windows W and the regular readback R, so pointwise-only schedules and externally selected host limits are not part of the packet.

The endpoint and integral rows are downstream. The seal E is exposed only after F, U, W, R, and the integral-facing row I reads that same route rather than a separate measure-completion or function-quotient object.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded row occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 5241.3 (Regulated convergence integral handoff)**.** *Let*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

be an accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier. Every* $\mathsf{RegulatedIntegral}^{\uparrow}$ *consumer read of the limiting regulated function factors through the finite route*

$$\mathsf{RegulatedFunction}^{\uparrow}(F),\ \mathsf{UniformConvergence}^{\uparrow}(U),\ W,\ \mathsf{RegSeqRat}^{\uparrow}(R),\ \mathsf{Real}^{\uparrow}(E),\ \mathsf{RegulatedIntegral}^{\uparrow}(I).$$

Thus the handoff to integration uses the same regulated-family rows, shared uniform-tail ledger, finite windows, regular rational readback, and Real seal as the convergence certificate. It supplies no measure completion, quotient function equality, selected limiting function, open-cover compactness, or ambient real-completeness principle.

Proof. Start with an integral-facing request. By the carrier definition, the only integral row is I, and its replay route in C passes through the same regulated-family and convergence rows used by endpoint-facing consumers.

Read the regulated source through F and the uniform tail through U. The finite windows W then expose the inspected function indices and domain reads, and the regular rational row R records the real-valued observations visible at those windows.

Only after this route is displayed can the terminal seal E be consumed and handed to I. Componentwise transport in H and replay in C preserve the same rows, while P and N record their provenance and local naming.

The carrier has no coordinate for measure completion, quotient function equality, selected limits, open-cover compactness, or ambient real completeness. Therefore every regulated-integral handoff is confined to the finite route displayed in the statement. □

Falsifiable prediction: An accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ consumer that reaches a $\mathsf{RegulatedIntegral}^{\uparrow}$ handoff without first reading $F, U, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: regulated-function, regulated-integral, uniform-convergence, regseqrat, real: none is bijective to $\mathsf{RegulatedConvergence}^{\uparrow}$ because this packet jointly binds a regulated-function family, a shared uniform tail ledger, finite windows, regular rational readback, terminal Real seal, integral handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedConvergence}^{\uparrow}$ packet is generated from a regulated-function family row, UniformConvergence tail row, finite window row, RegSeqRat readback, terminal Real seal, RegulatedIntegral handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5819.1, Definition 5819.2, and Definition 5819.3 seed the finite regulated-convergence route over regulated functions, uniform convergence, regular rational readback, Real seals, and regulated-integral consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, quotient function equality, selected host limits, pointwise-only convergence, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated-family visibility, uniform-tail exactness, finite window readback, Real-seal nonescape, regulated-integral handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedConvergenceUp.

Chapter 5242

A Concrete Naming Certificate for $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$

Following Cantor and Bishop–Bridges, the $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet records the finite located nested-interval route by which displayed interval windows become a regular rational Cauchy name and then a terminal real seal. It refines the nested dyadic Cauchy route of chapter 1811, reads endpoint and radius rows through chapter 291, schedules finite observations through chapter 126, hands the scheduled rows to chapter 301, and reaches only the seal boundary of chapter 38. The chapter isolates the located interval-to-name handoff; it does not claim a host intersection point, quotient stream equality, selected limit, countable choice, or ambient completeness.

Definition 5242.1 (Located nested-interval limit carrier)**.** *A* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite nested located-interval window. It records the inspected interval chain, endpoint rows, located containment witnesses, and the finite separation reads available at each displayed stage.*
2. *D is the dyadic shrink ledger. It records the dyadic endpoint comparisons, width bounds, and tolerance requests read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It names exactly the finite endpoint, midpoint, and shrink-ledger observations that may be queried before regular rational readback.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the scheduled located-interval observations and the dyadic shrink ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after I, D, S, R have been displayed.*
6. *H records componentwise* hsame *transport for interval windows, shrink ledgers, stream schedules, regular rational handoffs, real seals, replay rows, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located nested-interval request through I, D, S, R, E and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$*,* $\mathsf{NestedDyadicCauchy}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, R, E, H, C, P, N$. It has no coordinate for completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.LocatedNestedIntervalLimitUp.LocatedNestedIntervalLimitTasteGate single carrier alignment`

Theorem 5242.2 (Located nested-interval limit NameCert obligations)**.** *For every accepted* LocatedNestedIntervalL *carrier*

$$L = (I, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite located interval window, dyadic shrink ledger, StreamName schedule, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming row;*
2. *located nesting exposure, requiring every interval read to be one of the displayed rows of I together with its displayed containment and located separation witnesses;*
3. *dyadic shrink exactness, requiring every tolerance request to be discharged by a visible width or endpoint comparison stored in D and read through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
4. *schedule compatibility, requiring S to expose only the finite interval, endpoint, midpoint, and ledger observations used by D and R;*
5. *RegSeqRat handoff exactness, requiring R to be formed only after the interval window, shrink ledger, and schedule rows have been projected;*
6. *Real-seal nonescape, requiring E to be consumed only after I, D, S, R and the structural rows H, C, P, N have been displayed.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5820.1. The projection exposes one finite located nested-interval window, one dyadic shrink ledger, one StreamName schedule, one RegSeqRat handoff, one Real seal, and the transport, replay, provenance, and naming rows.

Located nesting exposure is forced by I. A consumer may inspect only interval rows already present in the finite window, and each such row carries its displayed containment and located separation witnesses.

Dyadic shrink exactness is forced by D. Each tolerance request is answered by a displayed dyadic width or endpoint comparison, so no host intersection or selected limit is needed to choose a tail.

The schedule and handoff rows are downstream. The row S records the finite observations that may be opened, and R repacks exactly those observations under the shrink ledger as a regular rational Cauchy surface.

Finally E, H, C, P, N close the route. The Real seal is reachable only after the regular handoff has been displayed, while the structural rows only transport, replay, source, and name the same finite data. Therefore no completed intersection, quotient stream equality, host real equality, countable choice, ambient completeness, Lean verification, or bridge-checking coordinate is present. □

Theorem 5242.3 (Located nested-interval RegSeqRat handoff)**.** *Let* $L = (I, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read exported by* L *factors through the displayed route*

$$I \longmapsto D \longmapsto S \longmapsto R \longmapsto H, C, P, N.$$

The route reads a finite located nested-interval window, a dyadic shrink ledger, and the scheduled endpoint observations before it exports the regular rational Cauchy row. The terminal $\mathsf{Real}^{\uparrow}$ *seal* E *is available only after this handoff has been displayed.*

Proof. Start with the displayed located interval window I. Its rows give the only endpoint, midpoint, containment, and located separation data available to a regular rational consumer.

Use the dyadic shrink ledger D to answer the displayed tolerance request. The chosen comparison is part of the same finite packet and is read through $\mathsf{DyadicRatCore}^{\uparrow}$, so there is no external modulus, choice-selected tail, or host interval intersection.

The schedule row S then fixes which interval observations are opened. The handoff row R is obtained by reading those scheduled observations under the shrink discipline and repacking them as the $\mathsf{RegSeqRat}^{\uparrow}$ surface.

The rows H, C, P, N transport, replay, source, and name that handoff, and the seal row E remains downstream of it. Since the carrier has no quotient-stream, host-real, selected-limit, choice, or completeness coordinate, every regular rational read factors through the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5820.1, Definition 5820.2, and Definition 5820.3 seed the finite located nested-interval route from displayed interval windows and dyadic shrink ledgers to a RegSeqRat handoff and terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located nesting exposure, dyadic shrink exactness, schedule compatibility, RegSeqRat handoff exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedNestedIntervalLimitUp.

Constructive story: A $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet is generated from a finite nested located-interval window, a dyadic shrink ledger, a StreamName schedule, a RegSeqRat handoff row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5243

A Concrete Naming Certificate for $\mathsf{CauchyTailRequest}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailRequest}^{\uparrow}$ packet isolates the finite directed-tail request that a Cauchy or completion consumer must expose before it can read a regular rational name or a terminal real-name seal. It sits beside the finite window carrier of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal seal of chapter 38, and the finite filter surface of chapter 5817. The packet names the request row consumed by those sibling routes; it is not a quotient filter, a selected limit, a countable-choice schedule, host stream equality, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5243.1 (Cauchy tail request carrier)**.** *A* $\mathsf{CauchyTailRequest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, Q, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the request.*
2. Q *is the directed tail request row, naming the finite later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the directed tail request.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and tolerances.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, Q, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the window, request, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay of the same finite directed-tail route.*
8. P *records* Pkg *provenance over* $\mathsf{CauchyTailRequest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteCauchyFilter}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, Q, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 (definition) `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestUp`

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestTasteGate single carrier alignment`

Theorem 5243.2 (Cauchy tail request NameCert obligations)**.** *For the carrier of Definition 5821.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *consumer that reads a directed-tail row receives it through this displayed request surface.*

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestCarrier namecert obligations`

Proof. Project the accepted packet $T = (W, Q, D, R, E, H, C, P, N)$. The rows W, Q, D expose the finite windows, directed tail request, and dyadic tolerance ledger before any regular-rational or real-facing read is admitted.

The readback row R is downstream of those displayed rows. It therefore records only the $\mathsf{RegSeqRat}^{\uparrow}$ observation generated from the named windows and tolerance ledger, not an external sequence or choice schedule.

The seal row E is terminal for the request route. Transport through H and replay through C preserve exactly the displayed route, while P and N record provenance and local naming.

Finally compare the route with Definition 5817.2. The finite filter packet consumes its directed-tail row as a request coordinate, and the rows above are precisely the admitted request surface available to that consumer. Since no remaining coordinate exists, quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, and bridge checking are outside the chapter claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyTailRequest}^{\uparrow}$ packet is generated from finite StreamName windows, a directed tail request row, DyadicRatCore tolerance data, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, seed)

Scope closed: Definition 5821.1 and Definition 5821.2 specify the finite directed-tail request carrier and its filter-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for tail visibility, tolerance preservation, readback, seal routing, transport, replay, provenance, and local naming.

Chapter 5244

A Concrete Naming Certificate for $\mathsf{QuotientLeakageMarkov}^{\uparrow}$

The $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet realizes the quotient leakage transition matrix of Definition 9462.1376 as finite NameCert data. It consumes the DNA window-six boundary-tile source of subsection 9462.28.21, the codon-window carrier of chapter 2234, the boundary-tile packet of chapter 3393, the six-boundary coverage route of chapter 3470, and the translation-boundary packet of chapter 5818. The packet names a finite six-state Markov ledger only; it is not a biological stochastic model, empirical evolutionary claim, host quotient-codon semantics, or unrestricted state-space enumeration.

Definition 5244.1 (QuotientLeakageMarkov carrier)**.** *A* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, T, O, E, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the six-state orbit row listing* AGR*,* Anchor_6*,* $\mathrm{StopStart}_6$*,* UUR*,* CUR*, and* CUY*.*
2. *T is the transient transition-matrix row of Definition 9462.1376, with entries read as exact rational finite counts.*
3. *O is the outside-probability row recording* $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ *for the six displayed states.*
4. *E is the expected-exit ledger row recording the rational exit values of Definition 9462.1380.*
5. *W is the finite window-six source row tying the orbit states to the codon-window and boundary-tile siblings.*
6. *H records componentwise* hsame *transport for the state, transition, outside-probability, exit-ledger, source, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite Markov read through* S, T, O, E, W, H, P, N*.*
8. *P is the* Pkg *provenance over* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$*,* $\mathsf{CodonSixBitWindow}^{\uparrow}$*,* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$*, the source vision of subsection 9462.28.21,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, O, E, W, H, C, P, N$*. It has no coordinate for biological transition realization, hidden codon quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process.*

Theorem 5244.2 (QuotientLeakageMarkov NameCert obligations)**.** *For the carrier of Definition 5822.1, the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *surface consists exactly of six-state exposure, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, window-six sibling routing, componentwise transport, displayed replay, provenance, and local naming. Every accepted read preserves the outside probabilities displayed in Definition 9462.1378.*

Proof. Project the accepted carrier $Q = (S, T, O, E, W, H, C, P, N)$. The state row S fixes the six orbit states, and the transition row T is the only source of one-bit flip probabilities.

The outside-probability row O is read from the outside column of T and matches the finite rational list in Definition 9462.1378. Thus an accepted packet cannot alter leakage rates without changing a displayed row.

The expected-exit row E is downstream of the same finite matrix and records the rational ledger of Definition 9462.1380. The source row W ties these finite state rows back to the codon-window, boundary-tile, coverage, and translation-boundary siblings.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since no other coordinate is present, the NameCert surface cannot export biological mechanism, hidden quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process. □

Theorem 5244.3 (QuotientLeakageMarkov sibling dependency route)**.** *Every accepted* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *consumer first reads the finite codon-window source, boundary-tile classifier, six-boundary coverage route, and translation-boundary packet before it consumes the transition row* T*, outside row* O*, or expected-exit row* E*. The dependency route is*

$$\mathsf{CodonSixBitWindow}^{\uparrow}, \mathsf{DnaWindowSixBoundaryTile}^{\uparrow}, \mathsf{SixBoundaryTileCoverage}^{\uparrow}, \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$$

Proof. Use the provenance row P and source row W of Definition 5822.1. These rows name the finite codon-window and boundary-tile sources before the Markov matrix is admitted.

The transition row T then reads the six-state quotient matrix of Definition 9462.1376. The outside-probability row O and expected-exit row E are downstream ledger rows, so they cannot be consumed before the sibling source route has been displayed.

Transport and replay by H and C preserve this order, while N names it locally. Hence the consumer receives a concrete dependency route rather than a detached numerical table. □

Falsifiable prediction: Every accepted $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ read preserves the displayed outside probabilities $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ for AGR, Anchor_6, StopStart_6, UUR, CUR, and CUY.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, six-boundary-tile-coverage, dna-window-six-translation-boundary: $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries six orbit states, a rational transition matrix, outside probabilities, expected-exit ledgers, window-source routing, transport, replay, provenance, and local naming.

The Lean follow-up must provide explicit $\mathsf{Nontrivial}\ \mathsf{QuotientLeakageMarkov}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{QuotientLeakageM}$ TasteGate instances preserving $S, T, O, E, W, H, C, P, N$ as distinct displayed rows.

Closure status for $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$**.**

Constructive story: A $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet is generated from six orbit states, a rational transition matrix, outside-probability rows, expected-exit ledgers, a finite window-six source row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5822.1, Definition 5822.2, and Definition 5822.3 specify the finite quotient-leakage Markov carrier and sibling dependency route.

Formal verification: FormalStatus(NameCert$_{\text{QuotientLeakageMarkov}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological transition realization, empirical evolutionary mechanism, hidden codon quotient semantics, unbounded simulation, completed stochastic processes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, sibling routing, transport, replay, provenance, and local naming for BEDC.Derived.QuotientLeakage

Chapter 5245

A Concrete Naming Certificate for $\mathsf{CauchyCriterionUniform}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet records the uniform Cauchy criterion route used when a Real and Completion consumer asks for one displayed threshold discipline across a finite family of stream windows. It sits beside the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Cauchy hub of chapter 3413. The packet names a uniform criterion surface; it is not a quotient Cauchy class, selected limit, host equality theorem, countable-choice schedule, trichotomy principle, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5245.1 (Cauchy criterion uniform carrier)**.** *A* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *S records the* $\mathsf{StreamName}^{\uparrow}$ *window family inspected by the uniform criterion request.*
2. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the dyadic radii and comparison budgets shared by the family.*
3. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and dyadic tolerances.*
4. *E records the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, available only after S, D, R, M have been exposed.*
5. *M records the uniform modulus row, naming the common threshold discipline for all displayed windows in the family.*
6. *H records componentwise* hsame *transport for the stream windows, dyadic tolerances, regular readback, Real seal, uniform modulus, replay route, provenance, and local name.*
7. *C records displayed* Cont *replay of the same finite route.*
8. *P records* Pkg *provenance over* $\mathsf{CauchyCriterionUniform}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N records the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, R, E, M, H, C, P, N$. It has no coordinate for a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUniformUp.CauchyCriterionUniformTasteGate single carrier alignment`

Theorem 5245.2 (Cauchy criterion uniform NameCert obligations)**.** *For the carrier of Definition 5823.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the finite packet* $U = (S, D, R, E, M, H, C, P, N)$*;*
2. *uniform window exposure through the* $\mathsf{StreamName}^{\uparrow}$ *row* S *and the common modulus row* M*;*
3. *dyadic tolerance exactness through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*;*
4. *regular readback through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*;*
5. *ledger non-escape through* H, C, P, N*.*

Proof. Project the accepted packet $U = (S, D, R, E, M, H, C, P, N)$. Carrier admission is exactly the admission of this finite tuple, so a consumer can inspect only the displayed coordinates.

The uniform window obligation reads S together with the common threshold discipline M. The dyadic tolerance obligation reads D, and the regular readback obligation reads R before any terminal seal row E is available.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since the carrier has no remaining coordinate, the ledger cannot export a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient completeness claim. □

Theorem 5245.3 (Cauchy criterion uniform Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier factors through the finite route*

$$S, D, R, M \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer must read stream windows, dyadic tolerances, regular readback, and the uniform modulus before the terminal real seal is exposed. The route exports no quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 5823.1. The only terminal real-facing coordinate is E, and the definition places it downstream of the finite stream-window, dyadic-tolerance, regular-readback, and uniform-modulus rows.

Apply Definition 5823.2. The NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Therefore any Real-facing consumer receives exactly the finite packet route displayed above. No quotient Cauchy class, selected limit, host equality, countable-choice schedule, trichotomy row, or ambient-completeness coordinate supplies another path to the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet is generated from finite StreamName windows, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, a uniform modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, seed)

Scope closed: Definition 5823.1, Definition 5823.2, and Definition 5823.3 specify the finite uniform Cauchy criterion carrier and its Real-facing seal route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy classes, selected limits, host equality, countable choice, trichotomy, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for uniform window exposure, dyadic tolerance exactness, regular readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 5246

A Concrete Naming Certificate for CauchyProductCompletionProjection$^{\uparrow}$

Following Bishop and Bridges on constructive products of Cauchy completions and Kelley on product uniformities, the CauchyProductCompletionProjection$^{\uparrow}$ packet records the coordinate projection surface for an accepted product-completion read. It sits downstream of the product packet of chapter 3797 and the completion-product route of chapter 1540, while every coordinate read still passes through the StreamName$^{\uparrow}$ windows of chapter 126, the RegSeqRat$^{\uparrow}$ readbacks of chapter 301, the DyadicRatCore$^{\uparrow}$ budgets of chapter 291, and the terminal Real$^{\uparrow}$ seal of chapter 38.

Definition 5246.1 (CauchyProductCompletionProjection carrier)**.** *A* CauchyProductCompletionProjection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* CauchyProductCompletion$^{\uparrow}$ *product-completion packet whose coordinate route is being inspected.*
2. *π_0, π_1 are the left and right projection selector rows, each naming which displayed coordinate window is exposed.*
3. *S_0, S_1 are the coordinate* StreamName$^{\uparrow}$ *windows opened by the two projection selectors.*
4. *D_0, D_1 are the* DyadicRatCore$^{\uparrow}$ *budget rows attached to the finite coordinate observations read from those windows.*
5. *R_0, R_1 are the* RegSeqRat$^{\uparrow}$ *readback rows obtained from the same coordinate windows and dyadic budgets.*
6. *L_0, L_1 are the coordinate completion-seal rows witnessing that each projected read remains inside the product-completion packet.*
7. *H records componentwise* hsame *transport for the product packet, selectors, stream windows, dyadic budgets, regular readbacks, and coordinate completion seals.*
8. *C records the* Cont *replay from the product-completion packet through the selected coordinate window, dyadic budget, regular readback, and completion seal.*
9. *P is the* Pkg *provenance over* CauchyProductCompletionProjection$^{\uparrow}$, CauchyProductCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *row.*
The carrier compares accepted projections only through $Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, host product equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CauchyProductCompletionProjectionUp.CauchyProductCompletionProjectionTasteGate`
`single carrier alignment`

Theorem 5246.2 (CauchyProductCompletionProjection NameCert obligations)**.** *For an accepted packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *surface consists exactly of product-packet admission, selector exposure, coordinate stream-window exposure, dyadic-budget accounting, regular readback, coordinate completion-seal nonescape, componentwise transport, replay, provenance, and local naming for the displayed rows.*

Proof. Project the carrier of Definition 5824.1. The row Q supplies the already displayed product-completion packet, while π_0, π_1 determine which coordinate route is being opened.

For each selector, the corresponding stream window is read before any dyadic budget or regular readback is available. Thus S_0, S_1 precede D_0, D_1, and the regular rows R_0, R_1 are exposed only through those windows and budgets.

The completion-seal rows L_0, L_1 bind the coordinate read back to Q. The transport table H and replay table C preserve the same product packet, selector, window, budget, readback, and seal rows, while P and N record provenance and local naming.

Since these are the only carrier coordinates, the NameCert surface has no route to quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5246.3 (CauchyProductCompletionProjection route)**.** *Every coordinate read exported by an accepted* $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ *carrier factors through*

$\mathsf{CauchyProductCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameC

The left and right selectors expose only the displayed coordinate windows and their completion seals; they do not turn the product-completion packet into a host tuple, a quotient-completion equality, or a chosen representative.

Proof. Start with an accepted carrier J. The selector rows π_0, π_1 are not host projections; they are displayed BEDC rows attached to the product-completion packet Q.

Reading either selector first opens the matching $\mathsf{StreamName}^{\uparrow}$ window. The dyadic budget row is then inspected, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback is obtained from the same finite coordinate window.

The coordinate completion seal is the last coordinate-facing row before export. It keeps the read inside the product-completion packet named by Q, and the structural rows H, C, P, N attach transport, replay, provenance, and local naming to the same route.

Thus every projection read remains a finite NameCert route through the displayed rows. No coordinate of J supplies quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ packet is generated from an accepted CauchyProductCompletion packet, left and right projection selector rows, coordinate StreamName windows, DyadicRatCore budgets, RegSeqRat readbacks, coordinate completion seals, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5824.1, Definition 5824.2, and Definition 5824.3 seed the finite coordinate-projection route for product completions.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host product equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, selector exposure, coordinate window accounting, regular readback, completion-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductCompletionPro

Chapter 5247

A Concrete Naming Certificate for $\mathsf{CauchyModulusSubsequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet records the finite route by which a bounded regular Cauchy source exposes a modulus-indexed subsequence schedule without exporting an infinite selector. It sits between the bounded subsequence envelope of chapter 1698, the regular subsequence route of chapter 381, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a constructive completion-facing certificate: it supplies a monotone cofinal schedule, finite windows, tolerance accounting, and a Real seal, but not countable choice, quotient stream equality, a selected infinite subsequence, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5247.1 (Cauchy modulus subsequence carrier)**.** *A* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, M, T, W, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$ *source row whose bounded regular Cauchy data are available before any subsequence-modulus request is read.*
2. *M is the modulus row. It records the requested Cauchy tolerance discipline and the finite comparison budget used by the subsequence schedule.*
3. *T is the monotone cofinal schedule row. It records the finite evidence that requested indices are sent to later source windows and that the schedule is cofinal in the displayed source.*
4. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows selected by the schedule row T at the requested modulus levels.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed windows and dyadic tolerances.*
7. *R is the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff row reached from B, M, T, W, D, Q.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the bounded source, modulus, schedule, windows, tolerance ledger, regular readback, and regular subsequence handoff have been displayed.*

9. *H records componentwise* hsame *transport for the bounded source, modulus, cofinal schedule, windows, dyadic ledger, regular readback, regular subsequence handoff, terminal seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a subsequence-modulus request through $B, M, T, W, D, Q, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$, $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, M, T, W, D, Q, R, E, H, C, P, N$. It has no coordinate for a selected infinite subsequence, quotient stream equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusSubsequenceUp.CauchyModulusSubsequenceTasteGate single carrier alignment`

Theorem 5247.2 (Cauchy modulus subsequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier $S = (B, M, T, W, D, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequ}}$ *surface consists exactly of carrier admission, bounded-source admission through B, modulus monotonicity through M, monotone cofinal schedule admission through T, finite-window determinacy through W, dyadic tolerance accounting through D, regular rational readback through Q,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff through R, Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5825.1. Its analytic coordinates are exactly the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular readback Q, regular subsequence handoff R, and terminal Real seal E.

The modulus and schedule obligations are displayed before any support row is inspected. The row M supplies the tolerance discipline, while T records monotonicity and cofinality for the finite requested indices. The window row W and tolerance row D then determine which $\mathsf{StreamName}^{\uparrow}$ windows and dyadic bounds are visible at those requests.

The readback and seal obligations remain downstream. The row Q reads the visible windows as $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the $\mathsf{RegularCauchySubsequence}^{\uparrow}$ handoff, and E is reachable only after the preceding rows have been displayed. Rows H, C, P, N transport, replay, source, and name that same finite route, so no further NameCert obligation remains outside the listed coordinates. □

Theorem 5247.3 (Cauchy modulus subsequence window determinacy)**.** *Every consumer admitted by an accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier must read the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular rational readback Q, regular subsequence handoff R, and terminal Real seal E before reading the transport, replay, provenance, or local naming rows. The packet exports no selected infinite subsequence, quotient stream equality, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer read. By Definition 5825.1, the only consumer-facing route before the support rows is the ordered list B, M, T, W, D, Q, R, E.

The rows B, M, T fix the source, tolerance request, and monotone cofinal schedule. The row W then supplies only the finite windows named by that schedule, and D supplies the dyadic tolerance ledger attached to those windows. Thus the visible subsequence data are determined by displayed finite requests, not by an externally selected infinite object.

The remaining analytic rows are also fixed by the displayed windows. The readback row Q converts those windows into $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the regular subsequence handoff, and E is the terminal Real seal for that route. Since the carrier contains no coordinate for quotient stream equality, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the support rows H, C, P, N can only preserve the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet is generated from a bounded regular Cauchy source, a modulus row, a monotone cofinal schedule, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RegularCauchySubsequence handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5825.1, Definition 5825.2, and Definition 5825.3 seed the constructive subsequence-modulus route over bounded regular Cauchy data, finite windows, dyadic tolerances, regular readback, regular subsequence handoff, Real sealing, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, quotient stream equality, countable choice, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Lean verification requires carrier admission, modulus monotonicity, cofinal schedule admission, finite-window determinacy, dyadic tolerance accounting, RegSeqRat readback, RegularCauchySubsequence handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusSubsequenceUp.

Chapter 5248

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$

Following Mac Lane on monads and Eilenberg–Moore comparison, together with Bishop–Bridges constructive completion, the $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet records the finite BEDC surface where the L10 completion monad, its algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared as one NameCert boundary. The packet reads chapter 378, chapter 1845, chapter 1981, chapter 397, chapter 3351, chapter 126, chapter 301, chapter 291, and chapter 38. It names the comparison surface only; it does not assert quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5248.1 (CauchyCompletionMonadicity carrier)**.** *A* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion-monad row, displaying the unit and bind schedule before any algebra or comparison read is consumed.*
2. *A is the* $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ *action row, recording the Eilenberg–Moore algebra action over the displayed completion route.*
3. *K is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *row, exposing the unit, bind, and reassociated-bind consumer route.*
4. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row, carrying the extension and uniqueness ledger used by comparison consumers.*
5. *D is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *unit route, displaying the dense source-to-completion image before the algebra or universal-property read is exported.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row used by the monad, algebra, Kleisli, universal-property, and dense-embedding rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the same finite windows.*
8. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare completion-facing reads at the same finite precision.*

9. *E is the terminal* Real$^{\uparrow}$ *readback seal reached only after W, R, Q have all been displayed.*
10. *H records componentwise* hsame *transport for the monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from comparison requests through $T, A, K, U, D, W, R, Q, E, H, P, N$.*
12. *P is the* Pkg *provenance over* CauchyCompletionMonadicity$^{\uparrow}$, CauchyCompletionMonad$^{\uparrow}$, CauchyCompletionAlgebr CauchyCompletionKleisli$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, MetricCompletionDenseEmbedding$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{CauchyCompletionMonadicity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, A, K, U, D, W, R, Q, E, H, C, P, N$. The carrier has no coordinate for quotient completion classes, selected limit representatives, host equality of completed objects, countable-choice schedules, ambient completeness, full Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 5248.2 (CauchyCompletionMonadicity NameCert obligations)**.** *For every accepted* CauchyCompletionM *carrier*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N),$$

the local NameCert$_{\text{CauchyCompletionMonadicity}^{\uparrow}}$ *surface consists exactly of carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, StreamName–RegSeqRat–DyadicRatCore–Real readback discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No local obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5827.1. The displayed tuple lists every row available to the classifier, so local comparison can inspect only the completion monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, transport, replay, provenance, and local naming.

The monadicity-facing rows are read in order. The monad row T displays the unit and bind schedule, the algebra row A records the Eilenberg–Moore action over that schedule, and the Kleisli row K keeps unit, bind, and reassociated-bind consumers on the same finite route.

The universal and dense rows then bind the comparison surface. The row U supplies extension and uniqueness data, while D supplies the dense source-to-completion unit route used before the comparison is exported.

Finally the readback and structural rows close the NameCert surface. The rows W, R, Q, E give finite windows, regular rational readback, dyadic tolerances, and the terminal Real seal; the rows H, C, P, N transport, replay, source, and name exactly that packet. Since no excluded coordinate occurs, no additional local obligation is available. □

Theorem 5248.3 (CauchyCompletionMonadicity comparison surface)**.** *Every comparison consumer of an accepted* CauchyCompletionMonadicity$^{\uparrow}$ *carrier factors through the finite route*

$$T, A, K, U, D \longmapsto W \longmapsto R \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the completion-monad route, the algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared only after the StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$,

$\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback surface has been displayed. The comparison exports no quotient completion equality, selected limit, host equality of completed objects, countable choice, ambient completeness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the monad and algebra rows. The row T supplies the displayed completion transformer, and A reads its algebra action only as a row over that transformer.

Next attach the Kleisli and universal-property rows. The row K exposes the unit, bind, and reassociated-bind route, while U records the extension and uniqueness ledger for completion-facing consumers.

Now read the dense-embedding unit route D. It displays the source-to-completion image before the comparison reaches any terminal seal, so the route is a visible unit comparison rather than a selected representative.

Finally consume the readback and structural rows. The finite window W, regular readback R, dyadic tolerance ledger Q, and Real seal E precede transport, replay, provenance, and naming through H, C, P, N. Since the carrier contains no coordinate for the excluded objects, the comparison surface cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet is generated from a CauchyCompletionMonad route, CauchyCompletionAlgebra action row, CauchyCompletionKleisli route, CompletionUniversalProperty row, MetricCompletionDenseEmbedding unit route, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5827.1, Definition 5827.2, and Definition 5827.3 seed the finite monadicity comparison boundary for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, readback discipline, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionMonadicityUp.

Chapter 5249

A Concrete Naming Certificate for $\mathsf{BorsukUlam}^{\uparrow}$

Following Borsuk and Ulam, the $\mathsf{BorsukUlam}^{\uparrow}$ packet records the antipodal obstruction theorem as finite BEDC NameCert data rather than as a host topological principle. It sits after the degree surface of chapter 3745, the continuous-map rows of chapter 130, the real-name seal of chapter 38, the compact metric source of chapter 129, and the circle boundary model of chapter 58. The packet names the displayed antipodal route consumed by obstruction and degree-facing chapters; it does not select antipodal points, import unrestricted classical degree theory, identify quotient spheres, choose representatives, or appeal to ambient completeness.

Definition 5249.1 (Borsuk-Ulam carrier)**.** *A* $\mathsf{BorsukUlam}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, A, F, D, C, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the compact metric sphere row read through the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *surface and the* $\mathsf{S}^{1\uparrow}$ *boundary model.*
2. *A is the antipodal-pair ledger, exposing only named paired source rows and the finite equality-refusal data attached to them.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the map whose antipodal comparison is being inspected.*
4. *D is the* $\mathsf{BrouwerDegree}^{\uparrow}$ *obstruction row, read only through the displayed degree certificate and never through unrestricted host degree theory.*
5. *C is the* $\mathsf{Real}^{\uparrow}$ *comparison-seal row for the coordinate difference or collapsed real-valued comparison consumed by the obstruction route.*
6. *R is the refusal row excluding selected antipodal points, quotient equality of sphere points, choice, unrestricted classical degree theory, and ambient completeness.*
7. *H records componentwise* hsame *transport for the compact source, antipodal ledger, continuous-map row, degree row, real comparison seal, refusal row, provenance, and local naming.*
8. *K records displayed* Cont *replay from the compact metric source through the antipodal ledger, continuous-map row, degree obstruction, real comparison seal, and refusal row.*
9. *P is the* Pkg *provenance over* $\mathsf{BorsukUlam}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{BrouwerDegree}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *row.*

The classifier compares accepted packets only through $S, A, F, D, C, R, H, K, P, N$. It has no coordinate for a chosen antipodal pair, quotient equality on the sphere, unrestricted classical degree theory, countable choice, or ambient Real completeness.

Lean4 (definition) `BEDC.Derived.BorsukUlamUp.BorsukUlamUp`
Lean4 ✓ `BEDC.Derived.BorsukUlamUp.BorsukUlamTasteGate single carrier alignment`

Theorem 5249.2 (Borsuk-Ulam NameCert obligations)**.** *For every accepted* $\mathsf{BorsukUlam}^\uparrow$ *carrier* $U = (S, A, F, D, C, R, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *surface consists exactly of compact metric sphere admission, antipodal-pair ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, refusal of host and quotient shortcuts, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obstruction-facing consumer must read*

$$S, A, F \longmapsto D, C \longmapsto R, H, K, P, N$$

before treating the packet as a Borsuk-Ulam certificate.

Proof. Project the carrier of Definition 5828.1. The compact source row S, antipodal ledger A, and continuous-map row F are the only rows available before the obstruction is read.

The degree and real-comparison rows D, C are downstream of that source route. The degree row is the displayed $\mathsf{BrouwerDegree}^\uparrow$ certificate, and the real row is the displayed $\mathsf{Real}^\uparrow$ seal for the comparison consumed by the obstruction.

Finally R, H, K, P, N refuse shortcuts, transport the same rows, replay the finite route, source it, and name it locally. Since the carrier has no coordinate for selected antipodal points, quotient equality, unrestricted host degree theory, countable choice, or ambient Real completeness, no consumer can export those objects from the certificate. □

Theorem 5249.3 (Borsuk-Ulam antipodal route)**.** *Every accepted* $\mathsf{BorsukUlam}^\uparrow$ *antipodal-obstruction read factors through the displayed compact metric sphere row, the* $\mathsf{S}^{1\uparrow}$ *boundary model, the antipodal-pair ledger, the* $\mathsf{ContinuousMap}^\uparrow$ *row, the* $\mathsf{BrouwerDegree}^\uparrow$ *obstruction row, the terminal* $\mathsf{Real}^\uparrow$ *comparison seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert*. The route exports no selected antipodal point, unrestricted classical degree theorem, quotient equality of sphere points, choice principle, ambient completeness, Lean verification, or bridge-checked surface.*

Proof. Start with an accepted carrier $U = (S, A, F, D, C, R, H, K, P, N)$. The source read begins at S and A, so the antipodal data is visible only as a finite paired ledger over the displayed compact metric and circle rows.

Read the map through F and then the obstruction through D, C. The $\mathsf{ContinuousMap}^\uparrow$ row supplies the function-facing data, the $\mathsf{BrouwerDegree}^\uparrow$ row supplies the obstruction route, and the $\mathsf{Real}^\uparrow$ row supplies only the comparison seal reached from those displayed rows.

The refusal and structural rows close the route. The row R blocks selected points, quotient equality, unrestricted degree theory, choice, and ambient completeness, while H, K, P, N preserve the same finite certificate under transport, replay, provenance, and local naming. □

Falsifiable prediction: Every accepted $\mathsf{BorsukUlam}^\uparrow$ consumer reads compact metric sphere data, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a Real

comparison seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before it treats the packet as an antipodal obstruction certificate.

Independence witness: brouwer-degree, continuousmap, real, compactmetric, s1: $\mathsf{BorsukUlam}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact sphere data, antipodal pairing, continuous-map readback, degree obstruction, real comparison sealing, refusal, transport, replay, provenance, and local naming into one obstruction-facing certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}$.

Constructive story: A $\mathsf{BorsukUlam}^{\uparrow}$ packet is generated from a compact metric sphere row, an S1 boundary model, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a RealUp comparison seal, shortcut refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5828.1, Definition 5828.2, and Definition 5828.3 seed the finite antipodal obstruction route over compact metric, circle, continuous-map, degree, real-seal, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected antipodal points, unrestricted classical degree theory, quotient equality, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, antipodal ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, transport, replay, provenance, and local naming for BEDC.Derived.BorsukUlamUp.

Chapter 5250

A Concrete Naming Certificate for $\mathsf{DenjoyYoungSaks}^{\uparrow}$

Following Saks and Bishop–Bridges constructive real analysis, the $\mathsf{DenjoyYoungSaks}^{\uparrow}$ packet records the finite boundary at which a real-valued interval map can expose upper and lower Dini-derivative rows without importing the classical almost-everywhere Denjoy–Young–Saks theorem. It sits next to the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation window of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet is a finite classification boundary for displayed Dini rows, oscillation windows, regular-rational readback, and terminal Real seals; it is not a measure theorem, an almost-everywhere classifier, or a host-real differentiability principle.

Definition 5250.1 (Denjoy–Young–Saks finite Dini carrier)**.** *A* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the inspected interval row, listing the finitely presented source intervals and endpoint cells on which the local boundary is read.*
2. *F is the function-observation row, recording the finite source and target windows used to compare difference quotients.*
3. *U is the upper Dini row, storing the displayed upper right, upper left, and two-sided upper derivative bounds visible at the inspected windows.*
4. *L is the lower Dini row, storing the corresponding lower right, lower left, and two-sided lower derivative bounds.*
5. *O is the oscillation-window row, recording the finite alternation and stabilization tests used to classify a displayed window as one of the Dini-boundary cases.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by I, F, O and no hidden stream coordinates.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data extracted from the finite stream windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger supporting the difference-quotient comparisons and oscillation bounds.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the interval, function-observation, Dini, oscillation, stream, readback, and dyadic rows have been exposed.*

10. *H records componentwise* hsame *transport for intervals, function observations, Dini rows, oscillation windows, stream schedules, regular readbacks, dyadic ledgers, Real seals, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the inspected interval and function rows through U, L, O, S, R, D and into the Real seal E.*

12. *P is the* Pkg *provenance over* $\mathsf{DenjoyYoungSaks}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, U, L, O, S, R, D, E, H, C, P, N$. It has no coordinate for measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, host real order trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.DenjoyYoungSaksUp.DenjoyYoungSaksTasteGate single carrier alignment`

Theorem 5250.2 (Denjoy–Young–Saks finite boundary obligations)**.** *For every accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier $Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the inspected interval, function-observation, upper Dini, lower Dini, oscillation-window, stream-schedule, regular-readback, dyadic-ledger, Real-seal, transport, replay, provenance, and local naming rows;*

2. *interval and observation exactness, requiring every Dini comparison to read its source cell from I and its finite function window from F before any derivative row is accepted;*

3. *upper and lower Dini-row exactness, requiring U and L to store only the finite upper and lower derivative bounds justified by the displayed difference-quotient windows;*

4. *oscillation-window classification, requiring O to record the finite alternation, stabilization, and gap tests that separate the visible Dini-boundary cases;*

5. *stream, readback, and dyadic exactness, requiring S, R, D to expose only the finite observations, regular rational readbacks, and dyadic tolerance rows demanded by I, F, U, L, O;*

6. *Real seal nonescape, requiring E to remain downstream of I, F, U, L, O, S, R, D and never to serve as a selected derivative, a host real equality witness, or an almost-everywhere theorem;*

7. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve exactly the displayed finite route.*

No $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *obligation is stored outside these rows, and the packet makes no claim that the classical Denjoy–Young–Saks alternatives hold almost everywhere.*

Proof. Carrier admission is projection from Definition 5829.1. The accepted packet displays exactly the inspected interval row I, function-observation row F, upper and lower Dini rows U, L, oscillation row O, stream schedule S, regular readback R, dyadic ledger D, Real seal E, and structural rows H, C, P, N.

Interval and observation exactness follow from the row order. A Dini comparison first reads the source cell in I and the finite function-observation window in F; only then may it inspect the upper row U, lower row L, or oscillation row O attached to that window.

The stream, regular-readback, and dyadic rows are downstream of the same finite windows. The schedule S opens only the observations demanded by I, F, O, the row R records the resulting regular rational readback, and D stores the tolerance comparisons needed for the displayed difference-quotient bounds.

Finally, the Real seal E is terminal for this finite boundary route. The transport row H, replay row C, provenance row P, and local naming row N preserve the same packet, so measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness cannot become local obligations. □

Theorem 5250.3 (Denjoy–Young–Saks Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{StreamName}^{\uparrow}$ *consumer of an accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier reads the displayed route*

$$I, F, U, L, O, S, R, D, E, H, C, P, N.$$

Consequently the consumer may inspect finite interval cells, function observations, upper and lower Dini rows, oscillation windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal Real seal, componentwise transport, replay, provenance, and local naming. It cannot read a measure structure, an almost-everywhere assertion, a selected derivative, quotient real equality, host real trichotomy, countable choice, or ambient completeness from the packet.

Proof. Project the accepted carrier through Definition 5829.1. Its Real-facing and readback-facing rows are exactly S, R, D, E together with the preceding interval, function, Dini, and oscillation rows I, F, U, L, O and the structural rows H, C, P, N.

The route reaches E only after the finite Dini and oscillation boundary has been displayed. Thus any consumer that asks for a Real seal or regular rational readback must already have passed through the interval cells, function observations, upper and lower Dini rows, oscillation windows, stream schedule, and dyadic tolerance ledger.

Since the carrier has no row for measure, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, or ambient completeness, none of those objects can be read by a downstream consumer. □

Theorem 5250.4 (Denjoy–Young–Saks oscillation-window induction)**.** *For an accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier* $Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$*, induction over the finite oscillation-window row* O *preserves the separation between the upper Dini row* U *and the lower Dini row* L*. At every displayed stage the packet remains a finite boundary classifier over the rows of Definition 5829.1; the induction cannot promote the packet to an almost-everywhere measure theorem, cannot select a derivative, and cannot export a host-real differentiability principle.*

Proof. Induct over the displayed list of oscillation windows in O. The empty row has no Dini comparison to transport, so the upper and lower rows remain separated by the carrier projection.

For the step, assume the previously displayed windows preserve the separation of U and L. The next window is admitted only through the oscillation-window classification row in Definition 5829.2, so it may inspect the finite alternation, stabilization, and gap tests attached to that window but cannot rewrite the carrier outside $I, F, U, L, O, S, R, D, E, H, C, P, N$.

The Real-seal nonescape theorem Definition 5829.3 keeps every downstream read behind the same finite route. Thus adjoining the next oscillation window preserves the visible upper/lower Dini separation and leaves measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness outside the packet. □

Falsifiable prediction: Every $\mathsf{DenjoyYoungSaks}^{\uparrow}$ Real-facing or readback-facing read factors through finite interval cells, function-observation windows, upper and lower Dini rows, oscillation windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{DenjoyYoungSaks}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries upper and lower Dini rows, oscillation-window classification, regular-rational readback, dyadic tolerance data, and a terminal Real seal in one finite boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$.

Constructive story: A $\mathsf{DenjoyYoungSaks}^{\uparrow}$ packet is generated from inspected interval cells, function-observation windows, upper and lower Dini rows, oscillation-window classifications, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5829.1, Definition 5829.2, and Definition 5829.3 seed the finite Denjoy–Young–Saks boundary route over Dini rows, oscillation windows, regular-rational readback, dyadic tolerance rows, and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DenjoyYoungSaksUp.DenjoyYoungSaksTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close the classical almost-everywhere Denjoy–Young–Saks theorem, measure-null exceptional sets, selected derivatives, quotient real equality, trichotomy, countable choice, ambient completeness, or bridge checking beyond the carrier-alignment Lean target.

Upgrade path: Obligation closure requires checked carrier admission, Dini-row exactness, oscillation-window classification, stream-readback-dyadic exactness, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.DenjoyYoungSaksUp.

Chapter 5251

A Concrete Naming Certificate for $\mathsf{UniformlyConvexSpace}^{\uparrow}$

Following Clarkson's uniformly convex Banach-space reading and Bishop–Bridges constructive normed-space practice, the $\mathsf{UniformlyConvexSpace}^{\uparrow}$ packet records a finite modulus-of-convexity surface over the normed-space carrier of chapter 1950. It consumes the $\mathsf{NormedSpace}^{\uparrow}$ row, the real-valued norm and midpoint reads through chapter 38, the metric handoff of chapter 57, and the completion-facing route of chapter 95 and chapter 3413. The packet gives Banach, Hilbert, fixed-point, and convexity consumers a named uniform-convexity certificate without importing host Banach-space equality, selected minimizers, quotient completions, or choice.

Definition 5251.1 (UniformlyConvexSpace carrier)**.** *A* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (N, R, A, M, \Delta, Q, H, T, P, C)$$

with the following displayed rows:

1. *N is the* $\mathsf{NormedSpace}^{\uparrow}$ *row, exposing vector operations, the norm read, and the induced metric only through the normed-space NameCert surface.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by norm values, radius comparisons, midpoint estimates, and positive modulus outputs.*
3. *A is the midpoint row, reading $(x + y)/2$ through the vector addition, scalar action, and real scalar rows already visible in N and R.*
4. *M is the metric handoff row, routing distance and unit-ball comparisons through the* $\mathsf{Met}^{\uparrow}$ *read induced by N.*
5. *Δ is the convexity-modulus row: for each displayed positive separation request it supplies a positive real margin forcing the midpoint norm below the unit bound whenever the two admitted unit vectors are separated by that request.*
6. *Q is the completion-facing row, allowing Cauchy and completion consumers to read the same norm, metric, midpoint, and modulus data without selecting a completed point.*
7. *H records componentwise* hsame *transport for N, R, A, M, Δ, Q and for the local structural rows.*
8. *T records displayed* Cont *replay from a uniform-convexity request through $N, R, A, M, \Delta, Q, H, P, C$.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformlyConvexSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *C is the local* $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for host Banach-space equality, strict-convexity as a pointwise substitute, quotient completion, selected closest points, compactness, reflexivity, or a choice principle.

Theorem 5251.2 (UniformlyConvexSpace NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *carrier* $U = (N, R, A, M, \Delta, Q, H, T, P, C)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, normed-space visibility, real-valued norm and midpoint readback, metric separation handoff, positive modulus admission, midpoint contraction under the displayed separation request, completion-facing nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside* $N, R, A, M, \Delta, Q, H, T, P, C$*.*

Lean4 ✓ `BEDC.Derived.UniformlyConvexSpaceUp.UniformlyConvexSpaceTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 5831.1. The rows $N, R, A, M, \Delta, Q, H, T, P, C$ are the whole accepted packet.

The normed-space, Real, midpoint, and metric obligations are read first. The row N supplies the normed vector carrier, R supplies real-valued comparisons, A supplies midpoint formation, and M supplies the induced metric separation route.

The uniform-convexity content is isolated in Δ. For a displayed positive separation request, Δ supplies a positive margin and forces the midpoint norm read through A, N, R below the unit bound. Since Q, H, T, P, C only hand off, transport, replay, source, and name the same route, no host Banach-space equality, quotient completion, selected point, compactness, reflexivity, or choice coordinate can enter. □

Theorem 5251.3 (UniformlyConvexSpace modulus convexity route)**.** *Every accepted* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *consumer that asks for uniform convexity factors through*

$$\mathsf{NormedSpace}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{Completion}^{\uparrow}, \mathsf{Cauchy}^{\uparrow} \longmapsto H, T, P, C.$$

The modulus row Δ may be read only after the normed-space carrier, real norm values, midpoint operation, and metric separation row have been displayed. The route exports a finite modulus-of-convexity NameCert surface, not host strict convexity, a selected minimizer, quotient completion equality, compactness, reflexivity, or countable choice.

Proof. Begin with a uniform-convexity request. The normed-space row N supplies the only vector and norm data, while R supplies the real-valued unit-ball and positivity comparisons.

Read midpoint and separation next. The midpoint row A is formed from the displayed operations of N and R, and the metric handoff M reads separation through the induced metric of the same normed-space packet.

Only then can the modulus row Δ answer the request. Its output is tied to the displayed positive separation and midpoint norm route, and the completion-facing row Q sends Cauchy or completion consumers through the same route rather than through a selected completed point.

Finally H, T, P, C transport, replay, source, and name the packet. The excluded host strict-convexity, selected-minimizer, quotient-completion, compactness, reflexivity, and choice objects are absent from the carrier, so the finite modulus route is the whole exported surface. □

Falsifiable prediction: An accepted $\mathsf{UniformlyConvexSpace}^{\uparrow}$ read is refuted if a consumer obtains a uniform-convexity margin without first displaying the $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, midpoint, $\mathsf{Met}^{\uparrow}$, completion-facing, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: normedspace, real, metric, completion, cauchy: no listed sibling is bijective to $\mathsf{UniformlyConvexSpace}^{\uparrow}$ because the packet jointly carries normed-space data, real norm comparisons, midpoint formation, metric separation, a positive convexity modulus, completion-facing handoff, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformlyConvexSpace}^{\uparrow}$ packet is generated from a NormedSpace row, Real norm-comparison rows, a midpoint row, an induced Metric separation row, a convexity-modulus row, a Completion and Cauchy handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5831.1, Definition 5831.2, and Definition 5831.3 seed the finite modulus-of-convexity route over normed-space, real, metric, completion, and Cauchy rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.UniformlyConvexSpaceUp.UniformlyConvexSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host Banach-space equality, strict-convexity substitution, selected minimizers, quotient completions, compactness, reflexivity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, midpoint formation, metric separation, positive modulus exactness, completion-facing nonescape, and local naming for BEDC.Derived.UniformlyConvexSpaceUp.

Chapter 5252

A Concrete Naming Certificate for $\mathsf{HyperbolicTranslationLength}^{\uparrow}$

Following the classical translation length of a hyperbolic isometry, the $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ packet records the finite invariant-length route visible to the hyperbolic phase geometry of chapter 9463. It consumes the metric-read surface of chapter 3474, the routed geodesic-flow surface of chapter 3856, the additive Busemann cocycle route of chapter 4134, the four-boundary-point comparison of chapter 3948, and the terminal real seal of chapter 38. The packet names stable displacement growth as finite BEDC data; it does not import a host hyperbolic manifold, quotient ideal boundary, selected axis, spectral radius, or global curvature theorem.

Definition 5252.1 (HyperbolicTranslationLength carrier)**.** *A* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, F, B, X, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row, exposing displacement reads for the source and its iterated image.*
2. *F is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row, recording the finite routed-flow data used to compare iterates along the same visible geodesic route.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row, supplying additive boundary-cocycle comparisons for the same displayed endpoints.*
4. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *row, recording the four-boundary-point invariant used to stabilize the length read.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by displacement values, additive cocycle values, cross-ratio reads, and the final nonnegative length seal.*
6. *D is the displacement-growth row, comparing the displayed iterate window through M, F, B, X, R without selecting an infinite orbit or an axis.*
7. *E is the endpoint-stability row, stating that the same boundary data are replayed by the metric, flow, Busemann, and cross-ratio rows.*
8. *H records componentwise* hsame *transport for M, F, B, X, R, D, E and for the local structural rows.*

9. *C records displayed* Cont *replay from a translation-length request through $M, F, B, X, R, D, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host isometry group, selected invariant axis, quotient boundary equality, spectral radius, completed hyperbolic manifold, or physical expansion law.

Lean4 ✓ `BEDC.Derived.HyperbolicTranslationLengthUp.HyperbolicTranslationLengthTasteGate single carrier alignment`

Theorem 5252.2 (HyperbolicTranslationLength NameCert obligations)**.** *For every accepted* HyperbolicTranslation *carrier $L = (M, F, B, X, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$ *surface consists exactly of metric displacement visibility, geodesic-flow routing, Busemann additivity, cross-ratio stabilization, real-valued length sealing, displacement-growth comparison, endpoint stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside $M, F, B, X, R, D, E, H, C, P, N$.*

Proof. Project the carrier of Definition 5832.1. The rows $M, F, B, X, R, D, E, H, C, P, N$ are the whole visible packet.

The geometric route is read first. Metric displacement comes from M, routed iteration from F, additive boundary comparison from B, and four-boundary-point stabilization from X.

The Real and displacement rows then seal the length read. The row R supplies the real-valued comparison surface, while D and E ensure that the same endpoint data are used by the metric, flow, Busemann, and cross-ratio reads.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate names a host isometry group, selected invariant axis, quotient boundary equality, spectral radius, completed manifold, or physical expansion law, the listed obligations exhaust the local surface. □

Theorem 5252.3 (HyperbolicTranslationLength invariant route)**.** *Every accepted* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *read factors through*

$$\mathsf{HyperbolicMetric}^{\uparrow}, \mathsf{HyperbolicGeodesicFlow}^{\uparrow}, \mathsf{HyperbolicBusemannCocycle}^{\uparrow}, \mathsf{HyperbolicCrossRatio}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto H, C, P$$

The finite route records displacement growth and boundary stabilization as a real-sealed invariant length, and it exports no host hyperbolic isometry, selected axis, quotient ideal-boundary equality, spectral radius, completed hyperbolic manifold, or cosmological expansion claim.

Proof. Begin with the displacement request. The metric row M supplies finite distance reads, and the geodesic-flow row F keeps the iterated comparison on the same displayed route.

Read boundary stabilization next. The Busemann cocycle row B supplies additive endpoint comparison, while the cross-ratio row X records the four-boundary-point invariant. The endpoint-stability row E requires these boundary reads to describe the same displayed data.

The Real row R and displacement-growth row D seal the invariant length as a finite real-valued read. The structural rows H, C, P, N preserve, replay, source, and name that route, while the excluded host and quotient objects remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ consumer is refuted if it obtains an invariant length without displaying the $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}$ $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, displacement-growth, endpoint-stability, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: hyperbolicmetric, hyperbolic-geodesic-flow, hyperbolic-busemann-cocycle, hyperbolic-cross-ratio, real: no listed sibling is bijective to $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ because the packet jointly carries metric displacement, routed flow, additive boundary cocycle, cross-ratio stabilization, Real sealing, displacement-growth comparison, endpoint stability, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ packet is generated from HyperbolicMetric displacement rows, HyperbolicGeodesicFlow routing rows, HyperbolicBusemannCocycle additive boundary rows, HyperbolicCrossRatio stabilization rows, Real sealing rows, displacement-growth and endpoint-stability rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5832.1, Definition 5832.2, and Definition 5832.3 seed the finite invariant-length packet over metric, flow, Busemann, cross-ratio, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host hyperbolic isometries, selected axes, quotient ideal-boundary equality, spectral radii, completed hyperbolic manifolds, physical expansion laws, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, displacement visibility, flow routing, Busemann additivity, cross-ratio stabilization, Real length sealing, endpoint stability, and local naming for BEDC.Derived.HyperbolicTranslationLengthUp.

Chapter 5253

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ packet records the finite envelope that carries a regular Cauchy rational readback into the terminal Real naming seal. It sits after the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational sequence interface of chapter 301, the terminal real-name packet of chapter 38, and the completion route of chapter 1506. The packet is a finite NameCert envelope for the handoff itself; it does not assert that the host real line is complete.

Definition 5253.1 (Regular Cauchy completion envelope carrier)**.** *A* $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (W, D, R, E_R, M, T, C, P, N)$$

where W *is the displayed* $\mathsf{StreamName}^{\uparrow}$ *window row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row,* E_R *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* T *records componentwise* $\mathsf{BHist}/\mathsf{hsame}$ *transport,* C *records displayed* Cont *replay,* P *is* Pkg *provenance over the displayed rows, and* N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}$ *row. A consumer of the carrier receives the completion handoff only through these nine coordinates.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionEnvelopeUp.RegularCauchyCompletionEnvelopeTasteGate`
`single carrier alignment`

Theorem 5253.2 (Regular Cauchy completion envelope obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletion}$ *carrier*

$$E = (W, D, R, E_R, M, T, C, P, N),$$

the local NameCert surface consists exactly of window admission, tolerance admission, regular readback admission, terminal Real-seal admission, metric-completion route admission, transport stability, continuation replay, provenance preservation, and local naming preservation for the displayed packet. No quotient stream equality, selected representative, countable choice schedule, host completeness principle, or $\mathsf{Real}^{\uparrow}$ *completeness theorem is a coordinate of this surface.*

Proof. Project the carrier of Definition 5833.1. Its only data rows are $W, D, R, E_R, M, T, C, P, N$, so the local NameCert can inspect exactly those displayed coordinates.

The first four rows bind the finite observation, dyadic tolerance, regular rational readback, and terminal Real seal. The metric-completion row M is therefore read as a route row over those data, not as an ambient completeness object.

The structural rows T, C, P, N preserve the same packet under componentwise transport, continuation replay, provenance, and local naming. Since the carrier has no slot for quotient stream equality, selected representatives, countable choice, host completeness, or Real completeness, none of those objects can be exported by the obligation surface. □

Theorem 5253.3 (Regular Cauchy completion envelope Real handoff)**.** *Every Real-facing completion consumer of an accepted* $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ *carrier reads the terminal handoff through the ordered finite route*

$$W, D, R, E_R, M, T, C, P, N.$$

In particular, the consumer reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal only after the* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed inside the same envelope.*

Proof. Start from Definition 5833.2. It makes $W, D, R, E_R, M, T, C, P, N$ the entire accepted surface of the envelope.

Read the Real-facing route through W, D, R, E_R. The StreamName windows expose the finite observations, the dyadic ledger records the tolerance budget, the regular-rational row gives the readback, and the terminal row gives the Real seal inside the same packet.

The completion route M and the structural rows T, C, P, N only replay and name that displayed handoff. Thus the consumer cannot replace the handoff by quotient stream equality, a chosen representative, countable choice, host completeness, or a completeness theorem for $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5833.1, Definition 5833.2, and Definition 5833.3 seed the finite regular-Cauchy-to-Real completion envelope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyCompletionEnvelopeUp.RegularCauchyCompletionEnvelopeTasteGate\_single\_car`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host completeness, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, row order, Real handoff, transport stability, replay stability, provenance preservation, and local NameCert preservation for BEDC.Derived.RegularCauchyCompletionEnvelopeUp.

Constructive story: A $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore tolerance, RegSeqRat readback, terminal Real seal, metric-completion routing, transport, replay, provenance, and local NameCert rows.

Chapter 5254

A Concrete Naming Certificate for $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$

Following Bishop–Bridges constructive locatedness, the $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ packet records the finite interval-selection surface that can be read by Cauchy and Real interval consumers without selecting an endpoint or importing compactness. It sits over the located interval carrier of chapter 394, the rational cell ledger of chapter 354, the optional dyadic refinement rows of chapter 306, the endpoint observation windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal Real seal of chapter 38. The packet names a finite route through displayed interval data; it does not assert endpoint choice, Heine–Borel compactness, trichotomy, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5254.1 (WeaklyLocatedIntervalSelection carrier)**.** *A* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, Q, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the source interval and its locatedness probes.*
2. *Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger listing the rational subinterval cells visible to the selection route.*
3. *D is an optional* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row; when present, it refines cells already displayed by Q and adds no independent selector.*
4. *W is the paired* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window row through which finite endpoint observations are read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same endpoint windows and rational cells.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by any Real-facing endpoint or interval consumer.*
7. *H records componentwise* hsame *transport for $L, Q, D, W, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from located interval probes through rational cells, optional dyadic refinements, endpoint windows, regular readbacks, and the Real seal.*
9. *P is* Pkg *provenance over* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$*,* $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets componentwise through these ten rows. There is no coordinate for an endpoint selector, an open-cover compactness argument, a trichotomy oracle, quotient equality of Real names, or host Real completeness.

Lean4 ✓ `BEDC.Derived.WeaklyLocatedIntervalSelectionUp.WeaklyLocatedIntervalSelectionTasteGate`
`single carrier alignment`

Theorem 5254.2 (WeaklyLocatedIntervalSelection NameCert obligations)**.** *For every accepted* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *carrier*

$$S = (L, Q, D, W, R, E, H, C, P, N),$$

the local NameCert surface consists exactly of the following obligations:

1. *carrier admission for the finite* BHist *packet S and its displayed rows;*
2. *located-cell visibility from the* $\mathsf{LocatedInterval}^{\uparrow}$ *row L into the* $\mathsf{RationalInterval}^{\uparrow}$ *ledger Q;*
3. *finite selection-route exactness through the visible rational cells and any displayed* $\mathsf{DyadicInterval}^{\uparrow}$ *refinements D;*
4. *endpoint-window transport from Q, D into the* $\mathsf{StreamName}^{\uparrow}$ *windows W and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R;*
5. *Real-seal nonescape, requiring every Real-facing read to pass through the displayed* $\mathsf{Real}^{\uparrow}$ *row E;*
6. *componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance preservation, and local* NameCert *preservation through H, C, P, N.*

No endpoint choice principle, Heine–Borel theorem, trichotomy principle, quotient equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem is an obligation or an output of this surface.*

Theorem 5254.3 (Weakly located interval selection route exhaustion)**.** *For every accepted* WeaklyLocatedIntervalSe
carrier

$$S = (L, Q, D, W, R, E, H, C, P, N),$$

every endpoint, interval, or Real-facing consumer factors through the displayed rows $L, Q, D, W, R, E, H, C, P, N$. Such a consumer cannot read endpoint choice, Heine–Borel compactness, trichotomy, quotient equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows of Definition 5834.1. The located interval source is L, the rational cell ledger is Q, and the optional dyadic refinement row is D.

Located-cell visibility therefore passes through L, Q, D. Endpoint or interval reads have no route around these rows because the packet stores no detached endpoint selector or host interval object.

The endpoint windows and regular rational readbacks are then W and R. A Real-facing consumer reaches the seal row E only after those finite windows and readbacks are visible.

Finally H, C, P, N transport, replay, source, and name the same route. Since endpoint choice, Heine–Borel compactness, trichotomy, quotient equality, and ambient completeness are absent from the tuple, the displayed rows exhaust every admitted consumer read. □

Closure status for $\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$ **·**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5834.1, Definition 5834.2, and Definition 5834.3 seed the finite weakly located interval-selection route over chapter 394, chapter 354, chapter 306, chapter 126, chapter 301, and chapter 38.

Formal verification: FormalStatus(NameCert$_{\text{WeaklyLocatedIntervalSelection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close endpoint choice, Heine–Borel compactness, trichotomy, quotient real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-cell visibility, finite selection-route exactness, endpoint-window transport, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.WeaklyLocatedIntervalSelectionUp.

Constructive story: A WeaklyLocatedIntervalSelection$^{\uparrow}$ packet is generated from LocatedInterval rows, RationalInterval cell ledgers, optional DyadicInterval refinements, StreamName endpoint windows, RegSeqRat readbacks, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5255

A Concrete Naming Certificate for $\mathsf{UniformInverseModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UniformInverseModulus}^{\uparrow}$ packet records compact inverse-modulus extraction from uniform homeomorphism data as finite NameCert data. It reads the homeomorphism and inverse-graph surface of chapter 1815, the compact finite-net rows of chapter 129, the graph and pointwise continuity rows of chapter 130, the exported modulus interface of chapter 369, the metric-source and metric-target rows of chapter 4230, and the terminal real-name seal of chapter 38. The chapter names the finite compact route that turns displayed inverse radii into a uniform inverse modulus; it is not a selected inverse function, host function equality, quotient real equality, open-cover compactness, or ambient completeness principle.

Definition 5255.1 (Uniform inverse modulus carrier)**.** *A* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A)$$

with the following displayed rows:

1. *X is the compact source row, exposing the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net data used to cover the compact domain of the homeomorphism.*
2. *Y is the target metric row, including the distance ledger into which the inverse-modulus estimate is reported.*
3. *F is the* $\mathsf{UniformHomeomorphism}^{\uparrow}$ *graph row from X to Y, carrying the forward graph and the homeomorphism naming data.*
4. *G is the inverse graph row displayed by the same homeomorphism packet.*
5. *E is the positive precision row, read through* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint histories when the consumer presents a real tolerance.*
6. *N is the finite net row of the compact source at the scale needed for the inverse-modulus extraction.*
7. *R lists the pointwise inverse radius rows attached to the centers named by N.*
8. *M is the finite radius-fold row, obtained only by folding the finite family R over the index list of N.*
9. *T is the target estimate row, combining inverse-graph exactness, finite-net coverage, the folded radius row, and the target metric triangle ledger.*

10. *H records componentwise* hsame *transport for the compact source, target metric, homeomorphism graph, inverse graph, precision, finite-net, inverse-radius, radius-fold, and estimate rows.*
11. *C records the displayed* Cont *replay route from compact homeomorphism data and pointwise inverse radii to the* $\mathsf{UniformModulus}^{\uparrow}$ *export.*
12. *P records* Pkg *provenance over* $\mathsf{UniformInverseModulus}^{\uparrow}$, $\mathsf{UniformHomeomorphism}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, RegSeqRat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *A is the local* $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$ *row.*

The carrier exposes only displayed compact finite nets, graph rows, inverse-graph rows, endpoint readbacks, finite radius rows, componentwise transport, replay, provenance, and local naming. It has no coordinate for a host inverse function, selected inverse choice, host function equality, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformInverseModulusUp.UniformInverseModulusTasteGate single carrier alignment`

Theorem 5255.2 (Uniform inverse modulus obligations)**.** *For every accepted* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the compact source, target metric, homeomorphism graph, inverse graph, precision, finite-net, inverse-radius, radius-fold, target-estimate, transport, replay, provenance, and local naming rows;*
2. *inverse-graph exactness, requiring every inverse read to pass through the displayed row G attached to the homeomorphism row F;*
3. *compact finite-net handoff, requiring the compact source row X and precision row E to determine the finite row N before any inverse radius is folded;*
4. *finite radius fold, requiring M to be obtained only by folding the pointwise inverse radius rows R over the finite indices of N;*
5. *target estimate, requiring T to combine compact-net coverage, inverse-graph exactness, folded-radius data, and the target metric ledger;*
6. *transport, replay, and provenance, requiring H, C, P, A to source the same displayed route componentwise;*
7. *nonescape, requiring the packet to export no host inverse function, selected inverse choice, host function equality, quotient real equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 5835.1. The projection exposes exactly the rows $X, Y, F, G, E, N, R, M, T, H$ so carrier admission and row inventory are finite.

The inverse read is confined to G. Since G is listed as a row of the same homeomorphism packet that supplies F, inverse-graph exactness is consumed as displayed graph data rather than as host function equality or selected inverse choice.

The compact handoff reads X and E before radius data. These rows determine the finite net N, and the pointwise inverse radii in R are indexed only by the centers listed by N.

Fold R over that finite index list to obtain M. The target estimate row T then combines the compact-net coverage, inverse-graph exactness, folded radius, and target metric triangle route. Finally H, C, P, A transport, replay, source, and name the same route, so no excluded equality, choice, open-cover, trichotomy, or completeness coordinate is introduced. □

Theorem 5255.3 (Uniform inverse modulus compact handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *export from an accepted* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A)$$

factors through the displayed finite route

$$X, F, G, E \longmapsto N, R \longmapsto M, T \longmapsto H, C, P, A.$$

Thus the inverse-modulus export is a compact finite-net and radius-fold handoff. It exports no host function equality, selected inverse choice, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from a $\mathsf{UniformModulus}^{\uparrow}$ consumer of I. By Definition 5835.2, the consumer must read the compact source, homeomorphism graph, inverse graph, and precision rows before the finite-net row is available.

The only finite-net row is N, and the only pointwise inverse-radius inventory is R. Hence the consumer reaches the exported modulus row M only after the finite fold over R indexed by N.

The target estimate T is downstream of that fold. It cannot be read as a host inverse function or as quotient equality of inverse values, because the carrier contains only displayed graph and metric-ledger rows.

Finally the structural rows H, C, P, A transport, replay, source, and name the same compact route. Since the carrier contains no coordinate for selected inverse choice, trichotomy, open-cover compactness, or ambient completeness, the export factors through exactly the displayed finite-net and radius-fold handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformInverseModulus}^{\uparrow}$ packet is generated from UniformHomeomorphism graph and inverse-graph rows, CompactMetric finite-net rows, ContinuousMap pointwise inverse-radius rows, UniformModulus export rows, MetricSpace distance ledgers, RealUp and RegSeqRat endpoint readbacks, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$, seed)

Scope closed: Definition 5835.1, Definition 5835.2, and Definition 5835.3 seed the finite compact route from displayed inverse radii to a UniformModulus consumer.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient completeness, host inverse functions, selected inverse choice, quotient real equality, trichotomy, open-cover compactness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inverse-graph exactness, compact finite-net handoff, finite radius fold, target estimate, transport, replay, provenance, and local naming for BEDC.Derived.UniformInverseModulusUp.

Chapter 5256

A Concrete Naming Certificate for $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$

Following Bishop and Bridges on constructive real intervals, the $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ packet records a bounded interval together with the finite nested-window route used by Real and completion consumers. It sits over the dyadic rational arithmetic of chapter 291, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names a bounded interval principle for displayed nested windows; it does not assert open-cover compactness, a global supremum operator, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5256.1 (BoundedCompleteRealInterval carrier)**.** *A* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded interval row. It records the inspected lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, the boundedness witness visible to the packet, and the local containment predicate for interval windows.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger. It records the dyadic rational cuts used to compare successive windows and to certify the displayed diameter bound.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It lists exactly the finite endpoint and interval observations that may be inspected by the nested-window route.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same dyadic cuts and stream windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by every Real-facing extraction from B, D, W, R.*
6. *H records componentwise* hsame *transport for bounded interval rows, dyadic ledgers, stream windows, regular rational readbacks, Real seals, replay, provenance, and the local name.*
7. *C records displayed* Cont *replay from a nested-window request through B, D, W, R, E.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, D, W, R, E, H, C, P, N$. There is no coordinate for open-cover compactness, a selected supremum, host interval equality, quotient equality of Real names, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedCompleteRealIntervalUp.TasteGate.BoundedCompleteRealIntervalTasteGate single carrier alignment`

Theorem 5256.2 (BoundedCompleteRealInterval NameCert obligations)**.** *For every accepted* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier*

$$I = (B, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded interval row, dyadic endpoint ledger, stream windows, regular rational readback, Real seal, componentwise transport, continuation replay, package provenance, and local naming row;*
2. *bounded-window visibility, requiring every interval read to pass through the displayed lower-upper row B and its local containment predicate;*
3. *dyadic diameter discipline, requiring D to witness the inspected endpoint comparisons and the shrinking-width estimates used by the extraction route;*
4. *stream-readback exactness, requiring W and R to reuse the same finite endpoint observations and dyadic cuts rather than selecting a second Real representative;*
5. *Real-seal nonescape, requiring every Real-facing output to pass through E after B, D, W, R have all been projected;*
6. *structural preservation through H, C, P, N, with no exported row for open-cover compactness, selected suprema, host interval equality, quotient Real equality, countable choice, trichotomy, or ambient Real completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5836.1. The accepted packet displays exactly the bounded interval row, dyadic endpoint ledger, stream windows, regular rational readback, Real seal, and the structural rows.

Bounded-window visibility is forced by B. A consumer can inspect only the finite lower-upper interval data and the local containment predicate already present in the carrier.

Dyadic diameter discipline is forced by D. The endpoint comparisons and shrinking-width estimates used by the packet are the only numerical rows available to the later stream and readback rows.

The rows W and R are downstream of the same dyadic ledger. They schedule finite observations and repack them as regular rational readback without replacing the bounded interval by a second Real representative.

Finally, E, H, C, P, N close the route. The Real seal is reached only after B, D, W, R, while transport, replay, provenance, and naming preserve the same displayed data. Since no excluded coordinate occurs in the carrier, the local NameCert surface has exactly the listed obligations. □

Theorem 5256.3 (BoundedCompleteRealInterval nested-interval extraction)**.** *Let $I = (B, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier. Every nested-window extraction exported by I factors through the finite route*

$$B \longmapsto D \longmapsto W \longmapsto R \longmapsto E$$

before it can inspect transport, replay, provenance, or local naming rows. The extracted Real-facing read is therefore determined by the bounded interval row, the dyadic diameter ledger, the stream windows, and the regular rational readback visible in the packet.

Proof. Begin with a nested-window extraction from I. The carrier gives no source row before the bounded interval row B, so the lower-upper interval data and local containment predicate are inspected first.

The extraction then projects the dyadic ledger D. This fixes the endpoint comparisons and diameter estimates available to the finite window schedule.

Next the extraction passes through W and R. The stream row exposes only the finite endpoint observations allowed by B, D, and the regular rational row repacks those same observations as the readback consumed by the Real seal.

Only after this route has been displayed can the extraction reach E. The remaining rows H, C, P, N preserve, replay, source, and name the same route, so the exported extraction is exhausted by the displayed bounded-window data. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5836.1, Definition 5836.2, and Definition 5836.3 seed the bounded real interval packet over dyadic endpoint ledgers, StreamName windows, RegSeqRat readbacks, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, a global supremum operator, host interval equality, quotient real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-window visibility, dyadic diameter discipline, stream-readback exactness, Real-seal nonescape, structural preservation, and nested-window extraction for BEDC.Derived.BoundedCompleteRealIntervalUp.

Constructive story: A $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ packet is generated from a bounded Real interval row, a DyadicRatCore endpoint ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5257

A Concrete Naming Certificate for $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Mac Lane on functoriality, the $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ packet records the finite BEDC surface where a displayed real-completion request is read functorially through bounded windows rather than through a quotient completion object. It sits over the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the completion-map discipline of chapter 1937. The packet gives downstream completion consumers one named window-functor route before any quotient stream, selected limit, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle is available.

Definition 5257.1 (RealCompletionWindowFunctor carrier)**.** *A* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (W, D, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row naming the source and target observation windows used by the completion request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the source and target windows at the requested precision.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and tolerances.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, D, R have all been displayed.*
5. *F is the functorial map row, read through* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$*, recording how the displayed source window is transported to the displayed target window.*
6. *H records componentwise* hsame *transport for W, D, R, E, F, C, P, N.*
7. *C records displayed* Cont *replay from a completion-window request through W, D, R, E, F, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the nine displayed rows. It has no coordinate for quotient completion classes, selected representatives, host real equality, countable-choice schedules, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealCompletionWindowFunctorUp.RealCompletionWindowFunctorTasteGate single carrier alignment`

Theorem 5257.2 (RealCompletionWindowFunctor NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *carrier*

$$Q = (W, D, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed finite packet* Q*;*
2. *analytic readback order* $W \longmapsto D \longmapsto R \longmapsto E$*;*
3. *functorial map exposure through the row* F *over the same windows and tolerances;*
4. *structural stability through* hsame *transport and displayed* Cont *replay;*
5. *provenance and local naming through* P *and* N*.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5777.1. The accepted packet displays exactly $W, D, R, E, F, H, C, P, N$, so every local NameCert read must be a read of one of those coordinates.

The analytic route is ordered by the displayed rows. The finite StreamName windows W are inspected before the dyadic tolerance ledger D, the regular rational readback R, and the terminal Real seal E.

The functorial row F is attached to the same window and tolerance ledger through $\mathsf{CauchyCompletionFunctoriality}$ Thus a completion consumer receives only the displayed map action on the finite route, not a quotient completion map or a selected representative.

Finally the rows H, C, P, N transport, replay, source, and name the same packet. Since no excluded object occurs as a carrier coordinate, no additional local obligation is available. □

Theorem 5257.3 (RealCompletionWindowFunctor finite route)**.** *Every completion-facing read exported by an accepted* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *carrier factors through the finite route*

$$W \longmapsto D \longmapsto R \longmapsto E \longmapsto F \longmapsto H, C, P, N.$$

Consequently the functorial completion-map row is consumed only after the StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, and Real seal boundary have been displayed inside the same packet.

Proof. Apply Definition 5777.2. Its obligation surface exposes exactly carrier admission, analytic readback order, functorial map exposure, structural stability, provenance, and local naming.

Read the analytic side first. The rows W, D, R, E display the finite observation windows, dyadic tolerance ledger, regular rational readback, and terminal Real seal.

Then read the functorial side through F and the structural rows. The rows H, C, P, N keep that map action attached to the same finite packet. Therefore the completion consumer cannot detach the functorial map from the displayed window route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5777.1, Definition 5777.2, and Definition 5777.3 seed the finite completion-window functor route over StreamName, DyadicRatCore, RegSeqRat, Real, CauchyCompletionFunctoriality, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, full functor laws for all completion objects, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window order, tolerance readback, Real-seal routing, functorial-map exposure, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionWindowFunctorUp.

Constructive story: A $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a terminal Real seal, a CauchyCompletionFunctoriality map row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5258

A Concrete Naming Certificate for $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$

The $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ packet realizes the Real and Completion route of chapter 9238 as finite window-functor data before any completion consumer reads a limit-facing object. It binds the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the displayed completion functor row of chapter 5777. The packet names a finite completion-window functor surface for the Real completeness spine; it does not assert quotient completion equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5258.1 (RealCompletenessWindowFunctor carrier)**.** *A* $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (V, W, D, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *V is the originating Real-completeness request row read from chapter 9238.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row exposed before any regular-rational or Real-seal read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same window request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that consumes W and D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, D, R have been displayed.*
6. *F is the* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *row that packages the finite functorial completion handoff.*
7. *H records componentwise* hsame *transport for $V, W, D, R, E, F, C, P, N$.*
8. *C records displayed* Cont *replay from a Real-completeness request through $V, W, D, R, E, F, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$, $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten rows. It has no coordinate for quotient completion classes, selected representatives, countable-choice schedules, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 5258.2 (RealCompletenessWindowFunctor NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ *carrier*

$$Q = (V, W, D, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission, originating Real-completeness request exposure, StreamName window exposure, DyadicRatCore tolerance exposure, RegSeqRat readback exposure, Real seal exposure, finite completion-window functor exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Carrier admission is projection from Definition 5778.1. The tuple displays exactly $V, W, D, R, E, F, H, C, P, N$ so the local NameCert can inspect only those rows.

The Real-completeness request row V is read before the finite analytic route. The rows W, D, R, E then display StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and the terminal Real seal.

The functorial row F is the only completion-window handoff. It packages the Real-completion functorial read after the displayed analytic route rather than replacing it by a quotient completion object.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded coordinate occurs, no additional local obligation is available. □

Falsifiable prediction: Every accepted $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ read displays $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ seal rows before any completion consumer reads the packet.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchycompletionfunctoriality: $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ is not bijective to any listed sibling because it jointly retains the originating Real-completeness request, finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, Real seal, completion-window functor row, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5778.1 and Definition 5778.2 seed the finite Real-completeness completion-window functor route over StreamName, DyadicRatCore, RegSeqRat, Real, RealCompletionWindowFunctor, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, full Real-completeness proof, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request exposure, finite-window exposure, tolerance exposure, regular readback, Real-seal exposure, completion-window functor exposure, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletenessWindowFunctorUp.

Constructive story: A $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ packet is generated from a Real-completeness request row, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, a RealCompletionWindowFunctor row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5259

A Concrete Naming Certificate for $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ packet records the explicit modulus route by which a bounded compact-real sequence yields inspected subsequence windows before any downstream consumer reads a real cluster seal. It sits over the constructive subsequence packet of chapter 5830, the sibling Bolzano–Weierstrass route of chapter 1254, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite subsequence-modulus carrier for compact-real consumers; it is not an open-cover compactness theorem, not an arbitrary-choice selector, not quotient real equality, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5259.1 (Compact real subsequence modulus carrier)**.** *A* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, S, B, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact real source row, exposing the bounded* $\mathsf{Real}^{\uparrow}$ *sequence request and the compact-metric inspection data visible to the packet.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing exactly the finite source windows inspected by the modulus.*
3. *B is the* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ *and* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *route row, carrying the interval-refinement and subsequence scheduling surface without adding a host compactness principle.*
4. *W is the subsequence-modulus row, recording selected indices, monotonicity, cofinal scheduling, and the finite window assignment for each requested precision.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording radius requests, split budgets, comparison windows, and common-scale data used by the selected windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same selected windows and tolerance ledger.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *cluster seal, visible only after K, S, B, W, D, R have been displayed.*
8. *H records componentwise* hsame *transport for the source, stream windows, route, modulus, tolerance, readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a compact-real subsequence request through source inspection, stream windows, route selection, modulus scheduling, dyadic tolerance accounting, regular rational readback, and the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$, $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, S, B, W, D, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, arbitrary choice, quotient real equality, selected least cluster points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactRealSubsequenceModulusUp.TasteGate.CompactRealSubsequenceModulusTasteGate single carrier alignment`

Theorem 5259.2 (Compact real subsequence modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ *carrier*

$$M = (K, S, B, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}$ *surface consists exactly of compact real source exposure through K, finite stream-window exposure through S, constructive Bolzano–Weierstrass route exposure through B, subsequence-modulus scheduling through W, dyadic tolerance accounting through D, regular rational readback through R, terminal real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5779.1. Its analytic rows are the compact real source K, stream windows S, constructive route B, subsequence modulus W, tolerance ledger D, regular readback R, and real seal E.

The modulus obligation is finite because W records selected indices, monotonicity, cofinal scheduling, and selected windows as packet data. The route row B imports the displayed ConstructiveBolzanoWeierst and $\mathsf{BolzanoWeierstrass}^{\uparrow}$ subsequence construction rather than an ambient compactness theorem.

The readback obligation then passes through D and R. The same selected windows receive the dyadic tolerance budget before they can be read as a $\mathsf{RegSeqRat}^{\uparrow}$ sequence.

Finally E, H, C, P, N seal, transport, replay, source, and name only those rows. Since the carrier contains no open-cover, arbitrary-choice, quotient-equality, selected-least-cluster, or ambient-completeness coordinate, the listed rows exhaust the local certificate surface. □

Theorem 5259.3 (Constructive Bolzano–Weierstrass modulus route)**.** *Every* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ *consumer that reads a compact real subsequence route from an accepted carrier must factor through*

$$\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow},\quad \mathsf{BolzanoWeierstrass}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

The factorization exposes finite source windows, a displayed subsequence-modulus row, dyadic tolerance accounting, regular rational readback, and a terminal real seal; it exports no open-cover compactness, arbitrary-choice selector, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Apply Definition 5779.2. It places the constructive and sibling Bolzano–Weierstrass route row before the modulus row and before any regular rational readback.

The finite windows are exactly the row S, and the selected windows are exactly the row W. Thus any consumer that changes the source window or selected window must leave the displayed carrier.

The dyadic tolerance ledger D is read before R, and R is read before the terminal real seal E. This orders the packet through the stated route and prevents the excluded host principles from entering the subsequence-modulus handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5779.1, Definition 5779.2, and Definition 5779.3 seed the explicit compact-real subsequence-modulus route through finite windows, dyadic tolerances, regular readback, and real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, arbitrary choice, quotient real equality, selected least cluster points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exactness, constructive Bolzano–Weierstrass route exposure, subsequence-modulus scheduling, dyadic tolerance accounting, RegSeqRat readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactRealSubsequenceModulusUp.

Constructive story: A $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ packet is generated from compact real source data, finite StreamName windows, ConstructiveBolzanoWeierstrass and BolzanoWeierstrass route data, subsequence-modulus scheduling, DyadicRatCore tolerance accounting, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Chapter 5260

A Concrete Naming Certificate for MetaCICNormalEndpointComparator$^{\uparrow}$

The MetaCICNormalEndpointComparator$^{\uparrow}$ packet realizes the bounded-conversion endpoint bridge named by the MetaCIC decidability audit map of chapter 9379. It sits between the bounded normal conversion bridge of chapter 3439, the decidable conversion frontier of chapter 4097, the normalization frontier of chapter 892, the normal-form consistency seal of chapter 740, and the critical-path packet of chapter 765. The packet is a finite comparator for finished bounded normal endpoints; it is not a global beta-conversion decider, not a strong-normalization theorem, and not a host equality oracle.

Definition 5260.1 (MetaCIC normal endpoint comparator carrier)**.** *A* MetaCICNormalEndpointComparator$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, L, R, B, F, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed closed-term pair row supplied by the decidable conversion frontier.*
2. *L and R are the left and right bounded-normal computation traces, each carrying fuel, output syntax, and finished-endpoint evidence.*
3. *B is the* BoundedNormalConversionBridge$^{\uparrow}$ *row, exposing the bounded comparison result and its soundness route.*
4. *F is the* MetaCICNormalizationFrontier$^{\uparrow}$ *row, recording that both bounded traces have reached named normal endpoints at the comparator fuel.*
5. *S is the* NormalFormConsistencySeal$^{\uparrow}$ *row, checking that the two endpoint witnesses are read through the same normal-form consistency surface.*
6. *Q is the* MetaCICCriticalPath$^{\uparrow}$ *row that keeps the comparator tied to the decidability and normalization critical path rather than to an unrestricted conversion oracle.*
7. *H records componentwise* hsame *transport for the term pair, endpoint traces, bridge, frontier, seal, critical-path, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a bounded conversion request through endpoint computation, finished-normal evidence, endpoint comparison, consistency sealing, and critical-path accounting.*

9. *P is the* Pkg *provenance over* MetaCICNormalEndpointComparator$^{\uparrow}$, MetaCICDecidableConversionFrontier$^{\uparrow}$, BoundedNormalConversionBridge$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, NormalFormConsistencySeal$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, L, R, B, F, S, Q, H, C, P, N$. It has no coordinate for unrestricted conversion decidability, fuel-erased normalization, strong normalization, proof irrelevance, quotienting of syntax, or host equality.

Theorem 5260.2 (MetaCIC normal endpoint comparator NameCert obligations)**.** *For every accepted* MetaCICNormalEndpointComparator$^{\uparrow}$ *carrier*

$$E = (T, L, R, B, F, S, Q, H, C, P, N),$$

the local NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$ *surface consists exactly of typed closed-term pair admission through T, left and right bounded endpoint traces through L, R, bounded conversion bridge exposure through B, normalization-frontier endpoint evidence through F, normal-form consistency sealing through S, critical-path accounting through Q, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5780.1. The computational rows are exactly the term pair T, the endpoint traces L, R, the bounded conversion bridge B, the normalization frontier F, the consistency seal S, and the critical-path row Q.

The endpoint evidence is finite because L and R carry bounded traces at a displayed fuel. The row F records that those traces have reached finished normal endpoints before the comparator is consumed.

The comparison then passes through B and S. The bridge supplies the bounded conversion handoff, and the seal checks that the endpoint witnesses are compared through the same normal-form consistency surface.

Finally Q, H, C, P, N keep the packet on the MetaCIC critical path, transport it componentwise, replay it, source it, and name it. Since the carrier contains no unrestricted conversion, fuel-erased normalization, strong-normalization, proof-irrelevance, syntax-quotient, or host-equality coordinate, the listed rows exhaust the local certificate surface. □

Theorem 5260.3 (Bounded conversion endpoint handoff)**.** *Every* MetaCICNormalEndpointComparator$^{\uparrow}$ *consumer that promotes bounded conversion evidence to a finished endpoint comparison must factor through*

MetaCICDecidableConversionFrontier$^{\uparrow}$, BoundedNormalConversionBridge$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, No

The handoff supplies only typed closed-term pair data, bounded traces, finished endpoint evidence, endpoint consistency, critical-path accounting, transport, replay, provenance, and local naming.

Proof. Use Definition 5780.2. The typed closed-term pair is read first through T, while L and R record the bounded normal computations to be compared.

The row F is the endpoint boundary: it must be displayed before a bounded comparison can be read as a finished normal-form comparison. The bridge row B and seal row S then compare those endpoints through the bounded-conversion and normal-form consistency surfaces.

The critical-path row Q prevents the handoff from being read as a global conversion theorem. The structural rows H, C, P, N preserve and name only this finite route, so the consumer receives no unrestricted conversion decider or host equality oracle. □

Theorem 5260.4 (Closed-normal comparator vision obligations)**.** *The* MetaCICNormalEndpointComparator$^{\uparrow}$ *packet exposes exactly the finite comparator surface consumed by chapter 9376: closed normal endpoint rows, false-endpoint exclusion rows, and comparator determinacy rows are read through the displayed term pair T, bounded traces L, R, bounded conversion bridge B, normalization frontier F, normal-form consistency seal S, critical-path row Q, componentwise transport H, replay C, provenance P, and local naming N. No consumer of this surface receives unrestricted conversion decidability, fuel-erased normalization, proof irrelevance, syntax quotient equality, or host equality.*

Proof. Project the carrier of Definition 5780.1. The closed normal endpoint rows are precisely the finished bounded traces L, R read together with the normalization-frontier evidence F.

The false-endpoint exclusion row is read through the normal-form consistency seal S and the critical-path row Q. Those rows are the only coordinates tying the finished endpoint comparison to the closed-normal consistency boundary of chapter 9376.

Comparator determinacy is then read through the bounded conversion bridge B over the same typed pair T. The structural rows H, C, P, N transport, replay, source, and name this finite route.

Since the carrier contains no unrestricted conversion decider, fuel-erased normalizer, proof-irrelevance coordinate, syntax quotient, or host equality oracle, the listed rows are the complete comparator obligation surface consumed by the closed-normal consistency route. □

Falsifiable prediction: A MetaCIC conversion consumer that reads a finished endpoint comparison while omitting either bounded endpoint trace, the bounded-normal-conversion bridge, the normalization-frontier endpoint evidence, the normal-form consistency seal, the critical-path row, transport, replay, provenance, or local naming refutes MetaCICNormalEndpointComparator$^{\uparrow}$.

Independence witness: metacic-decidable-conversion-frontier, bounded-normal-conversion-bridge, metacicnormalizationfrontier, normal-form-consistency-seal, metaciccriticalpath: MetaCICNormalEndpointCompara is not bijective to any listed sibling because it jointly carries typed closed-term pair data, two bounded endpoint traces, bounded conversion bridge data, finished-normal endpoint evidence, consistency sealing, critical-path accounting, transport, replay, provenance, and local NameCert rows in one comparator packet.

The Lean follow-up must provide explicit Nontrivial MetaCICNormalEndpointComparator$^{\uparrow}$ and FieldFaithful MetaCICNormalEndpointComparator$^{\uparrow}$ instances in TasteGate.lean for the same finite carrier.

Closure status for NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$, seed)

Scope closed: Definition 5780.1, Definition 5780.2, and Definition 5780.3 seed the finite comparator that hands bounded conversion evidence to finished normal endpoints.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim unrestricted conversion decidability, fuel-erased normalization, strong normalization, proof irrelevance, quotient syntax equality, host equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint trace exactness, bounded bridge exposure, normalization-frontier endpoint evidence, normal-form consistency sealing, critical-path accounting, transport, replay, provenance, local naming, and TasteGate nontriviality with field faithfulness for BEDC.Derived.MetaCICNormalEndpointComparatorUp.

Constructive story: A MetaCICNormalEndpointComparator$^{\uparrow}$ packet is generated from typed closed-term pair data, two bounded endpoint traces, BoundedNormalConversionBridge data, MetaCICNormalizationFrontier endpoint evidence, NormalFormConsistencySeal data, MetaCICCriticalPath accounting, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Chapter 5261

A Concrete Naming Certificate for $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$

Following Riemann and Bishop–Bridges constructive integration, the $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ packet records the finite route by which a continuous function on a located closed real interval receives a Darboux/Riemann integrability certificate. It consumes the pointwise-modulus surface of chapter 59, the tag-bearing finite interval route of chapter 4296, the Darboux upper/lower boundary of chapter 1880, the integrability carrier of chapter 1960, the weak located interval selector of chapter 5834, and the real-name seal of chapter 38. The packet gives integration consumers a finite NameCert surface for continuous functions without importing measure integration, open-cover compactness, quotient equality of real names, selected limiting values, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5261.1 (Continuous Riemann integrability carrier)**.** *A* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, T, D, J, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Continuous}^{\uparrow}$ *row exposing the pointwise modulus and graph-stability data of the integrand over the displayed interval source.*
2. *T is the* $\mathsf{TaggedRealPartition}^{\uparrow}$ *row naming the finite partition cells, tag containment, window reads, regular readbacks, and terminal real seals used for integration.*
3. *D is the* $\mathsf{DarbouxSum}^{\uparrow}$ *row carrying lower and upper finite sums over the same displayed partition route.*
4. *J is the* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff row, read only after the Darboux gap row has been displayed.*
5. *W is the* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *row that exposes located cells and endpoint windows for the closed interval source.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened for interval endpoints, partition tags, and pointwise modulus reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family attached to the same finite windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, T, D, J, W, S, R have been displayed.*

9. *H records componentwise* hsame *transport for the continuous row, tagged partition, Darboux rows, integrability handoff, weak interval selector, window and readback rows, real seal, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from pointwise modulus requests through located cells, finite tagged partitions, Darboux lower/upper rows, the integrability handoff, and the terminal real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, T, D, J, W, S, R, E, H, C, P, N$. It has no coordinate for full integration theory, measure integration, open-cover compactness, quotient equality, selected limits, or ambient real completeness.

Theorem 5261.2 (Continuous Riemann integrability NameCert obligations)**.** *For every accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier*

$$I = (F, T, D, J, W, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the finite* BHist *packet and the displayed rows $F, T, D, J, W, S, R, E, H, C, P, N$;*

2. *interval-source visibility through the weakly located interval row W and its located cell, endpoint-window, and regular-readback route;*

3. *pointwise modulus exposure through the continuous-function row F, with every modulus read tied to displayed interval cells and finite windows;*

4. *finite tagged partition coverage through T, including cell containment, tag containment, and the same* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows;*

5. *Darboux gap control through D, read as finite lower and upper sums over the displayed tagged partition route;*

6. *integrability handoff through J, allowed only after the Darboux gap row and partition coverage rows are visible;*

7. *Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No full integration theory, measure integration, open-cover compactness, quotient equality of real names, selected limiting value, Lean verification, or bridge checking is an obligation or output of this packet.

Proof. Carrier admission is the projection of Definition 5838.1. The accepted packet displays the continuous row, tagged partition, Darboux row, integrability handoff, weak interval selector, window family, regular readback, real seal, transport, replay, provenance, and local name.

The interval and modulus rows are read first. The row W supplies located cells and endpoint windows, while F supplies pointwise modulus data only over those displayed cells and windows.

The finite partition route is then exposed by T. Tags and endpoints are read through S and R, so the integration-facing partition is a finite BEDC object rather than a host partition or a selected representative family.

The Darboux and integrability rows are downstream. The row D computes lower and upper finite sums over the displayed partition route, and J exports integrability evidence only after that gap control is visible.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no coordinate for the excluded analytic objects, the listed rows exhaust the local NameCert surface. □

Theorem 5261.3 (Continuous Riemann integrability Darboux handoff)**.** *Every integration-facing consumer of an accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier factors through the finite partition and Darboux rows*

$$W, F \longmapsto T, S, R \longmapsto D \longmapsto J \longmapsto E, H, C, P, N.$$

Consequently the consumer receives a finite located-cell, pointwise-modulus, tagged-partition, lower/upper Darboux, integrability-handoff, and Real-seal route rather than quotient reals, host equality, choice-selected witnesses, or ambient Real completeness.

Proof. Begin with an integration-facing read. The weak interval selector W and continuous row F force the request through located cells, endpoint windows, and pointwise modulus rows before any partition or sum row can be inspected.

Next read the tagged partition route T, S, R. The finite cells and tags are displayed together with their StreamName windows and RegSeqRat readbacks, so later rows cannot detach the partition from the interval source.

The Darboux row D is then read as lower and upper finite sums over those displayed cells and tags. The integrability row J is therefore a handoff from finite Darboux gap control, not from a quotient real or host equality judgment.

The terminal seal and structural rows E, H, C, P, N preserve that route. No excluded object is stored in the carrier, so every consumer factors through the displayed finite partition and Darboux rows. □

Theorem 5261.4 (Continuous Riemann integrability uniform-modulus handoff)**.** *Every accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier whose continuous row factors through a displayed uniform-modulus or composed-modulus route passes the Darboux gap and* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff through the finite chain*

$$\mathsf{Continuous}^{\uparrow},\ \mathsf{UniformContinuityComposition}^{\uparrow},\ \mathsf{TaggedRealPartition}^{\uparrow},\ \mathsf{DarbouxSum}^{\uparrow},\ \mathsf{RiemannIntegrable}^{\uparrow},\ \mathsf{StreamNar}$$

The handoff therefore reads composed modulus data before the Darboux row and exports no host integral selector, quotient function equality, open-cover compactness argument, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5838.1. The displayed rows are the continuous row F, tagged partition row T, Darboux row D, Riemann-integrable handoff J, weak interval selector W, StreamName windows S, RegSeqRat readbacks R, Real seal E, transport, replay, provenance, and local naming rows.

Use Definition 5838.2 for row exhaustion. When the continuous row is supplied by a uniform-modulus or composed-modulus route, the only admitted modulus source is the displayed $\mathsf{Continuous}^{\uparrow}$ row together with the $\mathsf{UniformContinuityComposition}^{\uparrow}$ composed-modulus handoff of chapter 3891.

Now apply Definition 5838.3. The tagged partition, Darboux lower and upper sums, and integrability row must be read after the same StreamName windows, RegSeqRat readbacks, and terminal Real seal, so the composed-modulus source cannot bypass the finite Darboux route.

Since the carrier stores no host integral selector, quotient function equality, open-cover compactness proof, or ambient completeness object, the listed finite rows are the whole uniform-modulus handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$.

Constructive story: A $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ packet is generated from a Continuous row, TaggedRealPartition row, DarbouxSum row, RiemannIntegrable handoff row, WeaklyLocatedIntervalSelection row, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5838.1, Definition 5838.2, Definition 5838.3, and Definition 5838.4 seed the finite Darboux/Riemann integrability route for continuous functions on located closed real intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full integration theory, measure integration, open-cover compactness, quotient equality, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source visibility, pointwise modulus exposure, finite tagged partition coverage, Darboux gap control, integrability handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ContinuousRiemannIntegrabilityUp.

Chapter 5262

A Concrete Naming Certificate for $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy approximations, the $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ packet binds Cauchy mesh refinement, cofinal dyadic mesh selection, and diagonal Real mesh budgets into one finite common-refinement route. It sits over the two-request refinement carrier of chapter 3832, the cofinal dyadic selector of chapter 2254, the diagonal mesh-budget surface of chapter 618, and the terminal real-name seal of chapter 38. The packet gives Real-completeness consumers a finite cofinal mesh handoff without quotient streams, selected limits, countable choice, host real equality, or ambient completeness as an extra row.

Definition 5262.1 (Regular Cauchy mesh cofinality carrier)**.** *A* $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, R, D, B, S, A, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyMeshRefinement}^{\uparrow}$ *row exposing source Cauchy requests, two displayed dyadic meshes, and their common finite refinement.*
2. *R is the* $\mathsf{CofinalDyadicMesh}^{\uparrow}$ *row refining the incoming observation request to a dyadic mesh window.*
3. *D is the* $\mathsf{RealDiagonalMeshBudget}^{\uparrow}$ *row listing the inspected diagonal indices, selected windows, dyadic tolerances, and aggregation ledger.*
4. *B is the shared budget row aligning the request precision of Q, the cofinal selector depth of R, and the diagonal finite mesh budget of D.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened by the shared budget.*
6. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family over the same windows, with all dyadic tolerances read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, R, D, B, S, A have been displayed.*
8. *H records componentwise* hsame *transport for the refinement row, cofinal selector row, diagonal budget row, shared budget, window and readback rows, seal row, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from an observation request through*

$$Q, R, D \longmapsto B \longmapsto S \longmapsto A \longmapsto E.$$

10. *P is the* Pkg *provenance over* RegularCauchyMeshCofinality$^{\uparrow}$, CauchyMeshRefinement$^{\uparrow}$, CofinalDyadicMesh$^{\uparrow}$, RealDiagonalMeshBudget$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{RegularCauchyMeshCofinality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, R, D, B, S, A, E, H, C, P, N$. It has no coordinate for quotient streams, hidden subnets, selected limits, countable-choice schedules, host real equality, trichotomy, or ambient Real completeness.

Theorem 5262.2 (Regular Cauchy mesh cofinality NameCert obligations)**.** *For every accepted* RegularCauchyMeshCofinality$^{\uparrow}$ *carrier*

$$K = (Q, R, D, B, S, A, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyMeshCofinality}^{\uparrow}}$ *surface consists exactly of carrier admission, Cauchy mesh-refinement exposure through Q, cofinal dyadic mesh exposure through R, Real diagonal mesh-budget exposure through D, shared precision and mesh-budget alignment through B, finite* StreamName$^{\uparrow}$ *window exposure through S,* RegSeqRat$^{\uparrow}$ *readback and* DyadicRatCore$^{\uparrow}$ *tolerance visibility through A, terminal* Real$^{\uparrow}$ *seal admission through E, componentwise transport through H, route replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 5839.1. The accepted packet displays exactly the Cauchy refinement, cofinal selector, diagonal budget, shared budget, windows, readbacks, seal, transports, replay, provenance, and local name.

The three mesh sources are read before any Real-facing seal. The row Q displays the common refinement of source Cauchy meshes, R displays the cofinal dyadic selector for the observation request, and D displays the finite diagonal mesh budget.

The shared row B aligns these sources. It is the only place where the precision request, cofinal selector depth, and diagonal inspected indices meet, so the window row S and regular readback row A inherit one finite route.

The seal and structural rows E, H, C, P, N preserve that route. Since the carrier has no coordinate for the excluded completion objects, the listed rows exhaust the local certificate surface. □

Theorem 5262.3 (Regular Cauchy mesh cofinality Real-completeness handoff)**.** *Every Real-completeness or diagonal-limit consumer of an accepted* RegularCauchyMeshCofinality$^{\uparrow}$ *carrier receives its seal-facing data only through the cofinal finite route*

$$Q, R, D \longmapsto B \longmapsto S \longmapsto A \longmapsto E, H, C, P, N.$$

Thus the consumer factors through Cauchy mesh refinement, cofinal dyadic mesh selection, Real diagonal mesh budgeting, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, and the RealUp seal before any completion-facing conclusion is exported.

Proof. Start from a Real-completeness consumer request. The packet first exposes Q, so the two source Cauchy requests and their common refinement are finite displayed data.

The request then passes through R and D. The cofinal dyadic selector supplies a finite mesh window, while the diagonal mesh-budget row supplies the finite inspected indices and dyadic tolerance ledger.

The budget row B is the common meeting point. It forces the StreamName windows S and RegSeqRat readbacks A to use the same finite refinement and the same dyadic tolerance rows.

Only after this route is displayed may the Real seal E be read. Transport, replay, provenance, and local naming preserve the route, and the excluded quotient or choice-based completion objects are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ packet is generated from CauchyMeshRefinement, CofinalDyadicMesh, RealDiagonalMeshBudget, a shared precision and mesh-budget row, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5839.1, Definition 5839.2, and Definition 5839.3 seed the finite cofinal common-refinement mesh route used by Real-completeness and diagonal-limit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, hidden subnets, selected limits, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy mesh-refinement exposure, cofinal dyadic mesh exposure, Real diagonal mesh-budget exposure, shared-budget alignment, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance visibility, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMeshCofinalityUp.

Chapter 5263

A Concrete Naming Certificate for $\mathsf{OneSidedLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{OneSidedLimit}^{\uparrow}$ packet records the left- and right-hand real-limit interface as finite BEDC data. It sits next to the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation schedule of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet names only displayed side-tagged approach windows, regular rational reads, dyadic tolerance rows, transport, replay, provenance, and a terminal Real seal; it does not import two-sided completeness, host real equality, quotient streams, trichotomy, or a selected limiting point.

Definition 5263.1 (One-sided limit carrier)**.** *A* $\mathsf{OneSidedLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, L, W, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the approach-anchor row, naming the source point or endpoint cell at which the one-sided read is taken.*
2. *L is the side classifier row, with each visible approach window tagged as left-hand or right-hand before any limiting seal is inspected.*
3. *W is the finite approach-window row, listing only windows compatible with the tag in L and the anchor in A.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by the side-tagged windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data observed on S.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the displayed one-sided comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from A, L, W, S, R, D.*
8. *H records componentwise* hsame *transport for the anchor, side classifier, windows, stream schedule, regular readback, dyadic ledger, Real seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from the side-tagged approach windows through the stream, readback, dyadic, and Real-seal rows.*
10. *P is the* Pkg *provenance over* $\mathsf{OneSidedLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $A, L, W, S, R, D, E, H, C, P, N$. It has no coordinate for a two-sided completion theorem, quotient real equality, host order trichotomy, countable choice, or a selected limit outside the named side-tagged windows.

Lean4 ✓ `BEDC.Derived.OneSidedLimitUp.OneSidedLimitTasteGate single carrier alignment`

Theorem 5263.2 (One-sided limit NameCert obligations)**.** *For every accepted* $\mathsf{OneSidedLimit}^{\uparrow}$ *carrier $K = (A, L, W, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the approach anchor, side classifier, approach windows, stream schedule, regular readback, dyadic ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *side classifier stability, requiring each transported window to retain its left-hand or right-hand tag before a readback row is consumed;*
3. *dyadic tolerance ledger exactness, requiring D to expose only the tolerance rows demanded by the side-tagged windows in W;*
4. $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring S and R to read only the finite observations selected by A, L, W;*
5. *Real seal nonescape, requiring E to remain downstream of A, L, W, S, R, D and never to serve as a two-sided completeness witness or host real equality row;*
6. *componentwise transport, replay, provenance, and local naming through H, C, P, N.*

No $\mathsf{OneSidedLimit}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5841.1. The accepted packet displays the approach anchor A, side classifier L, finite approach windows W, stream schedule S, regular readback R, dyadic ledger D, Real seal E, and structural rows H, C, P, N.

Side classifier stability is componentwise. A transported window may be read only with the left-hand or right-hand tag already recorded in L, and the replay row C keeps the same tag attached while the stream and regular-rational rows are inspected.

The tolerance and readback rows are downstream of the same finite windows. The ledger D records the dyadic comparisons demanded by W, the schedule S opens only those observations, and R records the regular rational readback.

Finally, the Real seal E is terminal for the route. Since the carrier contains no row for two-sided completeness, quotient real equality, host order trichotomy, countable choice, or a selected limit outside the displayed windows, those objects cannot become local obligations. □

Theorem 5263.3 (One-sided limit Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{OneSidedLimit}^{\uparrow}$ *packet reads the proposed one-sided limit only through the displayed finite route*

$$A, L, W, S, R, D, E, H, C, P, N.$$

Consequently the handoff to $\mathsf{Real}^{\uparrow}$ *is available only after the approach anchor, side classifier, finite approach windows, StreamName schedule, RegSeqRat readback, and DyadicRatCore tolerance ledger have been exposed. The handoff exports no two-sided completeness theorem, quotient stream equality, host real equality, order trichotomy, countable choice principle, or selected limiting point.*

Proof. Project the accepted carrier through Definition 5841.1. Its Real-facing row is the single terminal coordinate E, and the only route to E passes through A, L, W, S, R, D and the structural rows H, C, P, N.

The finite approach windows determine the side of approach before readback begins. Thus a consumer that asks for a Real seal must already have read the side classifier, the compatible windows, the stream schedule, the regular rational row, and the dyadic tolerance ledger.

The remaining coordinates transport and name the same route. Because no carrier row stores a two-sided completion principle, quotient equality, host equality, trichotomy, choice, or an independent selected limit, the Real-seal handoff cannot export any of those objects. □

Falsifiable prediction: Every $\mathsf{OneSidedLimit}^{\uparrow}$ Real-facing read factors through an approach anchor, a left/right side classifier, finite approach windows, a StreamName schedule, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{OneSidedLimit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a side classifier, finite approach windows, scheduled regular-rational readback, dyadic tolerance data, and a terminal Real seal in one one-sided packet.

Closure status for $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{OneSidedLimit}^{\uparrow}$ packet is generated from an approach anchor, a left/right side classifier, finite approach windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5841.1, Definition 5841.2, and Definition 5841.3 seed the finite one-sided real-limit route through side-tagged approach windows and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.OneSidedLimitUp.OneSidedLimitTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close two-sided real completeness, quotient stream equality, host real equality, trichotomy, countable choice, selected limits outside the displayed windows, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, side classifier stability, dyadic tolerance exactness, StreamName and RegSeqRat readback, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.OneSidedLimitUp.

Chapter 5264

A Concrete Naming Certificate for $\mathsf{BertrandSeriesTest}^{\uparrow}$

Following Bertrand's logarithmic refinement of ratio-type convergence tests and Bishop–Bridges constructive real-series practice, the $\mathsf{BertrandSeriesTest}^{\uparrow}$ packet records the finite second-order quotient-defect route that turns displayed positive-series tail data into a regular Cauchy comparison handoff. It sits beside the neighboring quotient-defect surfaces of chapter 1719, chapter 2113, and chapter 2130, refines the ratio and comparison routes of chapter 1461 and chapter 1459, and exports endpoints only through the dyadic, stream, regular-rational, and Real seals of chapter 291, chapter 126, chapter 301, and chapter 38. The packet names finite Bertrand-test evidence only through inspected source windows, adjacent quotient windows, a logarithmic defect ledger, dyadic domination, comparison-test routing, regular rational readback, and terminal Real sealing; it is not host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 5264.1 (Bertrand series test carrier)**.** *A* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Q, L, D, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source real-series row, exposing only positive-term windows, partial-sum windows, and tail-threshold requests used by the current convergence test.*
2. *Q is the adjacent quotient-window row, recording the inspected neighboring-term quotients on the same displayed tail window.*
3. *L is the logarithmic defect ledger, storing the finite index, logarithmic scale, rational margin, and second-order defect rows used by the Bertrand comparison.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *domination ledger, converting the displayed logarithmic defect and margin rows into a finite majorant or minorant comparison.*
5. *T is the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff row that consumes S, Q, L, D before any convergence conclusion is exposed.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the source, quotient, logarithmic defect, domination, and comparison rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after the comparison handoff and stream windows have been displayed.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint-facing consumers.*
9. *H stores componentwise* hsame *transport for the source, quotient, logarithmic defect, domination, comparison, window, readback, seal, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay from each tail request through Q, L, D, T, W, R, E.*
11. *P is the* Pkg *provenance over* $\mathsf{BertrandSeriesTest}^{\uparrow}$, $\mathsf{RaabeDuhamelTest}^{\uparrow}$, $\mathsf{KummerTest}^{\uparrow}$, $\mathsf{GaussTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, L, D, T, W, R, E, H, C, P, N$. It has no coordinate for host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BertrandSeriesTestUp.BertrandSeriesTestTasteGate single carrier alignment`

Theorem 5264.2 (Bertrand series test NameCert obligations)**.** *For every accepted* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier*

$$B = (S, Q, L, D, T, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source real-series windows, adjacent quotient windows, logarithmic defect ledger, dyadic domination ledger, comparison-test handoff, stream windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming row;*
2. *quotient-window exactness, requiring every quotient read used by the Bertrand defect to be read from the displayed neighboring positive-term windows in S and Q;*
3. *logarithmic-defect stability, requiring the finite index, logarithmic scale, rational margin, and second-order defect rows in L to remain attached to the accepted tail request;*
4. *dyadic domination routing, requiring D and W to convert the displayed logarithmic defect data into the same finite comparison windows consumed by T;*
5. *regular and Real handoff, requiring endpoint-facing data to pass through T, W, R, E in that order before a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives data;*
6. *ledger non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed rows and to exclude host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 5842.1. Carrier admission is exactly the inventory $S, Q, L, D, T, W, R, E, H, C$ so the local certificate has no detached row for an infinite sum, quotient series equality, selected sum, or ambient completeness theorem.

The quotient and logarithmic-defect clauses are read before the comparison handoff. The row S exposes only inspected positive-term and partial-sum windows, the row Q exposes only neighboring-term quotient windows, and L records the finite index, logarithmic scale, rational margin, and second-order defect attached to the current tail request.

The domination route is then forced through D, W, T. The dyadic ledger D converts the displayed logarithmic defect data into comparison evidence, the window row W fixes the finite stream windows, and the comparison-test row T is the only route that may export a regular Cauchy conclusion.

Finally, R and E supply the regular rational and Real-facing endpoint route. The structural rows H, C, P, N preserve, replay, source, and name the same route, so none of them can introduce host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge data. □

Theorem 5264.3 (Bertrand series test tail route)**.** *Every endpoint-facing read of an accepted* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier factors through*

$$\mathsf{RaabeDuhamelTest}^{\uparrow},\ \mathsf{KummerTest}^{\uparrow},\ \mathsf{GaussTest}^{\uparrow},\ \mathsf{RegularCauchyRatioTest}^{\uparrow},\ \mathsf{RegularCauchyComparisonTest}^{\uparrow},\ \mathsf{Dyadic}$$

Concretely, the read consumes source real-series windows and adjacent quotient rows, reads the logarithmic second-order defect ledger, converts that ledger into dyadic domination and stream-window evidence, enters the $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff, and reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *only through the displayed readback and seal rows.*

Proof. Begin with an endpoint-facing read of an accepted carrier. By Definition 5842.1, the only source data available before the defect estimate are the source windows in S and the adjacent quotient windows in Q.

The Bertrand-specific data are then read from L and D. The logarithmic ledger supplies the finite index, logarithmic scale, rational margin, and second-order defect, while the dyadic ledger turns those rows into the domination evidence needed for comparison.

The neighboring quotient-defect tests are reference faces in the same lattice. The Raabe–Duhamel, Kummer, and Gauss packets identify the adjacent first-order and auxiliary defect surfaces, while the ratio route supplies the shared adjacent-quotient discipline. The accepted $\mathsf{BertrandSeriesTest}^{\uparrow}$ endpoint route still has to enter the comparison handoff T.

After T is displayed, the route proceeds through the finite $\mathsf{StreamName}^{\uparrow}$ windows in W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E. The transport, replay, provenance, and naming rows keep the same route, so no host summability, quotient series equality, selected sums, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness can enter. □

Falsifiable prediction: Every accepted $\mathsf{BertrandSeriesTest}^{\uparrow}$ endpoint-facing read factors through source real-series windows, adjacent quotient rows, a logarithmic defect ledger, dyadic domination, a RegularCauchyComparisonTest handoff, StreamName windows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: raabeduhameltest, kummertest, gausstest, regularcauchyratiotest, regularcauchycomparisontest, dyadicratcore, streamname, regseqrat, real: $\mathsf{BertrandSeriesTest}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source series windows, adjacent quotient windows, a logarithmic second-order defect ledger, dyadic domination, comparison-test routing, regular rational readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BertrandSeriesTest}^{\uparrow}$ packet is generated from source real-series windows, adjacent quotient windows, a logarithmic second-order defect ledger, dyadic domination, a RegularCauchyComparisonTest handoff, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5842.1, Definition 5842.2, and Definition 5842.3 seed the finite Bertrand convergence-test boundary over displayed source series, quotient, logarithmic defect, comparison, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier admission, quotient-window exactness, logarithmic-defect stability, dyadic domination routing, regular and Real handoff, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.BertrandSeriesTestUp.

Chapter 5265

A Concrete Naming Certificate for $\mathsf{RationalCanonicalForm}^{\uparrow}$

Following Frobenius and standard linear algebra treatments of finite-dimensional operators, the $\mathsf{RationalCanonicalForm}^{\uparrow}$ packet records the rational canonical form of a displayed finite linear operator as BEDC NameCert data. It consumes the finite matrix rows of chapter 49, the linear-map surface of chapter 48, the polynomial source of chapter 50, the module and vector-space carriers of chapter 46 and chapter 47, and the invariant-factor route supplied by chapter 2262. The packet names only a finite certificate surface for companion-block assembly; it does not assert a host Jordan form theorem, algebraic closure, eigenvalue selection, basis choice outside the displayed rows, or a global classification oracle.

Definition 5265.1 (Rational canonical form carrier)**.** *A* $\mathsf{RationalCanonicalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (V, L, M, S, I, B, A, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *or* $\mathsf{Module}^{\uparrow}$ *source row naming the finite underlying carrier and its scalar action.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row naming the endomorphism whose canonical form is being read.*
3. *M is the* $\mathsf{Mat}^{\uparrow}$ *presentation row for the same endomorphism over the displayed finite basis data already carried by V and L.*
4. *S is the consumed* $\mathsf{SmithNormalForm}^{\uparrow}$ *dependency row applied to the polynomial matrix route attached to M.*
5. *I is the invariant-factor* $\mathsf{Poly}^{\uparrow}$ *row, listing monic polynomial factors with the divisibility ledger exposed by S.*
6. *B is the companion-block row, assembling one finite block for each invariant factor in I and recording the row and column positions used by the assembly.*
7. *A is the block-assembly exactness row, stating that the displayed* $\mathsf{Mat}^{\uparrow}$ *presentation is transported to the companion-block matrix through the same* $\mathsf{LinMap}^{\uparrow}$ *and* $\mathsf{Poly}^{\uparrow}$ *rows.*
8. *H stores componentwise* hsame *transport for the vector or module source, linear map, matrix presentation, Smith-normal dependency, invariant factors, companion blocks, assembly row, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from a canonical-form request through V, L, M, S, I, B, A and back to the same finite operator surface.*
10. *P is the* Pkg *provenance over* $\mathsf{RationalCanonicalForm}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{SmithNormalForm}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$ *row.*

The carrier has no coordinate for selected eigenvalues, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, or a detached canonical-form oracle.

Lean4 ✓ `BEDC.Derived.RationalCanonicalFormUp.TasteGate.RationalCanonicalFormTasteGate single carrier alignment`

Theorem 5265.2 (Rational canonical form NameCert obligations)**.** *For every accepted* $\mathsf{RationalCanonicalForm}^{\uparrow}$ *carrier*

$$F = (V, L, M, S, I, B, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$ *surface consists exactly of finite source admission for V, L, M, Smith-normal dependency routing through S, invariant-factor exposure through I, companion-block assembly through B, block-assembly exactness through A, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5843.1. The algebraic source rows are exactly the vector or module carrier V, the endomorphism row L, the finite matrix presentation M, the Smith-normal dependency row S, the invariant-factor row I, and the companion-block assembly rows B, A.

The invariant factors are not read from a host classification theorem. They are exposed as $\mathsf{Poly}^{\uparrow}$ rows whose divisibility and matrix-reduction dependency is routed through $\mathsf{SmithNormalForm}^{\uparrow}$ before any companion block is assembled.

The companion-block row B is finite because it is indexed by the displayed invariant-factor list I. The exactness row A then compares the assembled block matrix with the original $\mathsf{Mat}^{\uparrow}$ presentation through the same $\mathsf{LinMap}^{\uparrow}$ endpoint and componentwise hsame transport.

Finally H, C, P, N transport, replay, source, and name only this finite route. Since the carrier contains no coordinate for eigenvalue selection, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, or a detached canonical-form oracle, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: A $\mathsf{RationalCanonicalForm}^{\uparrow}$ consumer that exports a canonical-form matrix while omitting the Smith-normal dependency row, invariant-factor polynomial row, companion-block assembly row, componentwise hsame, displayed Cont, Pkg, or local NameCert rows refutes the carrier of Definition 5843.1.

Independence witness: matrix, linearmap, polynomial, module, vecspace, smith-normal-form: $\mathsf{RationalCanonicalForm}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite operator source, matrix presentation, invariant-factor polynomial ledger, Smith-normal dependency, companion-block assembly, exactness row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RationalCanonicalForm}^{\uparrow}$ packet is generated from VecSpaceUp or ModuleUp source data, a LinearMapUp endomorphism row, a MatrixUp presentation, a SmithNormalFormUp dependency route, invariant-factor PolynomialUp rows, companion-block assembly rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RationalCanonicalForm}\uparrow}$, seed)

Scope closed: Definition 5843.1 and Definition 5843.2 seed the finite rational-canonical-form packet over matrix, linear-map, polynomial, module, vector-space, and Smith-normal rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RationalCanonicalForm}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim eigenvalue selection, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, invariant-factor exposure, Smith-normal dependency routing, companion-block assembly, exactness, transport, replay, provenance, and local naming for BEDC.Derived.RationalCanonicalForn

Chapter 5266

A Concrete Naming Certificate for $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$

The $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ packet realizes the Rule 110 pattern-classifier branch of chapter 9390 as finite BEDC NameCert data. It consumes the cellular automaton carrier of chapter 934, the row-classifier surface of chapter 941, the pattern catalog of chapter 995, the local-stencil observation route of chapter 1036, and the Rule 110 glider catalog of chapter 1045. The packet names finite row windows, transition-table reads, orbit prefixes, pattern tags, transport, replay, provenance, and a local NameCert row; it is not a universality theorem, an infinite-orbit classifier, an undecidable continuation oracle, or a hidden substrate semantics.

Definition 5266.1 (Rule 110 pattern classifier carrier)**.** *A* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (W, T, O, G, K, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite row-window row, naming the inspected Rule 110 space-time rectangle and its boundary cells.*
2. *T is the transition-table row, exposing the eight local update cases used to advance the window.*
3. *O is the orbit-prefix row, recording the finite sequence of rows replayed from the initial window by T.*
4. *G is the glider and ether catalog row consumed from* $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$ *and* $\mathsf{CellularPatternCatalog}^{\uparrow}$*.*
5. *K is the classifier-tag row, assigning each inspected subwindow to a displayed ether, glider, collision, boundary, or unknown tag.*
6. *H stores componentwise* hsame *transport for windows, transition-table rows, orbit prefixes, tags, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a classifier request through W, T, O, G, K.*
8. *P is the* Pkg *provenance over* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$*,* $\mathsf{CellularAutomaton}^{\uparrow}$*,* $\mathsf{CellularRowClassifier}^{\uparrow}$*,* $\mathsf{CellularPatternCatalog}^{\uparrow}$*,* $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$*,* $\mathsf{LocalStencilObservation}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$ *row.*

The carrier has no coordinate for infinite continuation, termination of all continuations, host universality, unbounded pattern search, quotient orbit equality, or a substrate semantics outside the displayed rows.

Theorem 5266.2 (Rule 110 pattern classifier NameCert obligations)**.** *For every accepted* RuleOneTenPatternClassif *carrier*

$$R = (W, T, O, G, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$ *surface consists exactly of row-window admission through* W*, transition-table exposure through* T*, orbit-prefix replay through* O*, catalog lookup through* G*, classifier-tag exactness through* K*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier of Definition 5844.1. The finite cellular rows are exactly the inspected window W, transition table T, orbit prefix O, catalog row G, classifier row K, and the structural rows H, C, P, N.

The transition-table row is read before the orbit prefix, so every displayed successor row is justified by the same eight local Rule 110 cases. The classifier tag is then attached to a finite subwindow already present in O and compared against the catalog row G.

The transport and replay rows preserve that order. Since the carrier contains no infinite continuation coordinate, no all-continuations termination field, no unbounded pattern search, no quotient orbit equality, and no host universality proof, the local NameCert obligations are exhausted by the listed finite rows. □

Falsifiable prediction: A $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ classifier read that assigns a glider, ether, collision, boundary, or unknown tag without exposing the finite row window, transition-table row, orbit-prefix row, catalog row, componentwise hsame, displayed Cont, Pkg, and local NameCert rows refutes the carrier of Definition 5844.1.

Independence witness: continuationautomaton, finiteprefixautomaton, continuationtermination, typecheckingmembershiptrace, classifiermorphism: $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Rule 110 row windows, the transition table, orbit prefixes, catalog tags, classifier transport, replay, provenance, and local NameCert rows.

The Lean TasteGate file for this packet must provide Nontrivial $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ and FieldFaithful $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ instances for the displayed rows $W, T, O, G, K, H, C, P, N$ before the classifier can serve as a verified taste-gate consumer.

Closure status for $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ packet is generated from a finite Rule 110 row window, transition table, orbit prefix, pattern catalog, classifier tags, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$, seed)

Scope closed: Definition 5844.1 and Definition 5844.2 seed the finite Rule 110 pattern-classifier packet over row-window, transition-table, orbit-prefix, catalog, tag, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a universality theorem, infinite-orbit classification, continuation termination, unbounded pattern search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked row-window admission, transition-table exposure, orbit-prefix replay, catalog lookup, classifier-tag exactness, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.RuleOneTenPatternClassifierUp.

Chapter 5267

A Concrete Naming Certificate for $\mathsf{ObservabilityGramian}^{\uparrow}$

The $\mathsf{ObservabilityGramian}^{\uparrow}$ interface records the finite observability Gramian packet of a finite-dimensional linear control system. Its textbook source is the finite-horizon observability Gramian in Kalman's control-theoretic duality and the matrix-ledger presentation used by Kailath, Sayed, and Hassibi for linear estimation. The BEDC packet is the finite dual certificate read beside $\mathsf{ReachabilityGramian}^{\uparrow}$ in chapter 455; it is not an ambient analytic observability theorem.

The dependency anchors are the finite observation surface of chapter 294, the reachability dual surface of chapter 297, the matrix rows of chapter 49, the vector-space rows of chapter 47, and the linear-map rows of chapter 48. These anchors force the Gramian to be read as displayed $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{LinMap}^{\uparrow}$ data before a control consumer can compare it with the reachability Gramian.

5267.1 Carrier definition

Definition 5267.1 (ObservabilityGramianUp finite carrier)**.** *An* $\mathsf{ObservabilityGramian}^{\uparrow}$ *carrier is a finite* BHist *packet with rows*

$$(A, C, n, W, L, R, P, N).$$

Here A is the displayed transition-matrix row, C is the displayed output-matrix row, n is a unary finite-horizon row, W is the displayed finite Gramian-sum ledger with summand rows

$$C^{\mathsf{T}}C, \quad A^{\mathsf{T}}C^{\mathsf{T}}CA, \quad (A^{\mathsf{T}})^2C^{\mathsf{T}}CA^2, \quad \ldots, \quad (A^{\mathsf{T}})^{n-1}C^{\mathsf{T}}CA^{n-1},$$

L is the componentwise hsame *transport ledger for the transition, output, horizon, summand, and Gramian endpoint rows, R is the finite dual-readback row comparing W with the observation-matrix rows $C, CA, \ldots, CA^{n-1}$ of* $\mathsf{ControlObservability}^{\uparrow}$*, P is the* Pkg *provenance over* $\mathsf{ObservabilityGramian}^{\uparrow}$*,* $\mathsf{ControlObservability}^{\uparrow}$*,* $\mathsf{ControlControllability}^{\uparrow}$*,* $\mathsf{ReachabilityGramian}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*, and N is the local* $\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by componentwise hsame *transport of the A, C, n, W, L, R, P, N rows. It does not quotient by a host unobservable subspace, analytic trajectory family, Riccati equation, spectral factorization, infinite-horizon Gramian, or external estimator object.*

Lean4 ✓ `BEDC.Derived.ObservabilityGramianUp.ObservabilityGramianTasteGate single carrier alignment`

5267.2 Certificate surface

Theorem 5267.2 (ObservabilityGramianUp NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}$ *obligation surface has exactly five finite rows:*

1. *carrier admission for the displayed* A, C, n, W, L, R, P, N *packet of Definition 5787.1;*
2. *classifier transport under componentwise* hsame *of the transition, output, horizon, Gramian, summand-ledger, dual-readback, package, and local certificate rows;*
3. *finite sum ledger exactness, saying that the Gramian endpoint inside* W *is read only as the finite sum of the displayed adjoint-output summands inside* W*;*
4. *observability handoff, saying that the observation-matrix surface of* $\mathsf{ControlObservability}^{\uparrow}$ *can consume* A*,* C*,* n*,* W*,* L*, and* R *only through the displayed* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* Cont*, and* Pkg *rows;*
5. *dual non-escape, saying that no accepted route exports a host unobservable subspace, analytic output trajectory, Riccati solution, spectral factorization, infinite-horizon Gramian, covariance process, or external estimator.*

Proof. The carrier row is Definition 5787.1. It displays the transition row, output row, unary horizon, Gramian endpoint, summand ledger, transport ledger, dual-readback row, package provenance, and local naming row as finite BHist coordinates.

Classifier transport is componentwise. Replacing each displayed coordinate by an hsame-matched coordinate leaves the same finite packet shape, so the transported packet is again admitted by the carrier.

For finite sum exactness, inspect W. Each summand is a displayed matrix product formed from A, C, and transposes, and the Gramian endpoint is the finite fold of precisely those rows. The readback row R ties that ledger to the observation rows without introducing a host observability theorem.

The observability handoff is a projection to the shared A, C, and n rows, to the finite observation rows of $\mathsf{ControlObservability}^{\uparrow}$, and to the Gramian sum named by W. Because those rows are already packaged with $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{LinMap}^{\uparrow}$ provenance, a downstream observability certificate can read them without importing analytic control-system semantics.

Dual non-escape follows from constructor inspection of the carrier. The packet has no coordinate for a host unobservable subspace, analytic output trajectory, Riccati solution, spectral factorization, infinite-horizon Gramian, covariance process, or external estimator, so none of those objects can be projected by a consumer route. □

Theorem 5267.3 (ObservabilityGramianUp finite dual handoff)**.** *Every* $\mathsf{ControlObservability}^{\uparrow}$*,* $\mathsf{ControlControllability}^{\uparrow}$*, or* $\mathsf{ReachabilityGramian}^{\uparrow}$ *consumer of an accepted* $\mathsf{ObservabilityGramian}^{\uparrow}$ *packet can read only the displayed* A *row,* C *row, unary horizon row* n*, finite Gramian-summand and endpoint row* W*,* hsame *transport ledger* L*, dual-readback row* R*,* Pkg *provenance, and local* NameCert *row of Definition 5787.1. The handoff supplies the finite dual route from observation rows to the reachability-side Gramian ledger, but it supplies no host Kalman decomposition, no analytic trajectory semantics, and no infinite-horizon duality theorem.*

Proof. Project the accepted packet to the rows A, C, n, W, L, R, P, N. The first three rows are the finite control-system coordinates shared with $\mathsf{ControlObservability}^{\uparrow}$, while W records the finite adjoint-output Gramian ledger and L records componentwise transport over those same coordinates.

The dual-readback row R ties the summands in W to the observation rows $C, CA, \ldots, CA^{n-1}$. Thus a $\mathsf{ControlObservability}^{\uparrow}$ consumer reads the packet through the observation matrix surface, and a $\mathsf{ControlControllability}^{\uparrow}$ or $\mathsf{ReachabilityGramian}^{\uparrow}$ consumer reads only the dual comparison route named by the shared package provenance.

The carrier contains no row for a host Kalman decomposition, analytic trajectory semantics, or infinite-horizon duality theorem. Therefore the handoff is exactly the finite BEDC packet projection and does not add a control-theory semantic bridge. □

Theorem 5267.4 (ObservabilityGramianUp ledger non-escape)**.** *Every exported route from an accepted* $\mathsf{ObservabilityGramian}^{\uparrow}$ *packet factors through the finite rows* A, C, n, W, L, R, P, N *of Definition 5787.1. In particular, the packet exports no ambient unobservable subspace, no analytic output trajectory family, no Riccati solution, no spectral factorization, no stochastic covariance process, no infinite-horizon Gramian, and no external numerical estimator.*

Proof. Take an exported consumer route and project the carrier. The available coordinates are exactly the transition row, output row, horizon row, finite Gramian-summand and endpoint row, transport ledger, dual-readback row, package provenance, and local certificate row.

The NameCert obligations account for carrier admission, classifier transport, finite sum exactness, observability handoff, and dual non-escape. Each obligation is stated over those displayed coordinates and is preserved by the stored hsame, Cont, and Pkg rows.

Thus every export factors through the listed finite coordinates. Since the carrier contains no ambient unobservable subspace, analytic output trajectory family, Riccati solution, spectral factorization, stochastic covariance process, infinite-horizon Gramian, or external numerical estimator, no accepted route can supply one downstream. □

Closure status for $\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}$.

Constructive story: An $\mathsf{ObservabilityGramian}^{\uparrow}$ packet is generated from displayed transition and output matrix rows, a unary finite horizon, the finite adjoint-output Gramian summand and endpoint row, componentwise hsame transport ledger, a dual-readback row to the observation-matrix surface, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5787.1, Definition 5787.2, Definition 5787.3, and Definition 5787.4 bind the finite carrier, five-row NameCert surface, dual handoff, and non-escape boundary for observability Gramian packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host unobservable-subspace semantics, analytic output trajectories, Riccati theory, spectral factorization, stochastic covariance, infinite-horizon Gramians, numerical estimators, or a checked Lean certificate.

Upgrade path: Obligation closure requires a Lean carrier encoding and checked finite-ledger theorems for finite sum exactness, dual handoff, and non-escape.

Chapter 5268

A Concrete Naming Certificate for $\mathsf{HelmholtzDecomposition}^{\uparrow}$

Following Helmholtz and Hodge-style decomposition theory, the $\mathsf{HelmholtzDecomposition}^{\uparrow}$ packet records the finite BEDC surface by which a displayed vector-field row is read as the sum of a gradient-potential row and a divergence-free row over a Hilbert source. It consumes the Hilbert carrier of chapter 91, the vector-space operations of chapter 47, the linear-map rows of chapter 48, and the projection-theorem surface of chapter 2374. The packet names only the displayed analytic decomposition route; it does not assert PDE solvability, global boundary regularity, unique gauges, Sobolev completeness, or a host Hodge theorem.

Definition 5268.1 (Helmholtz decomposition carrier)**.** *A* $\mathsf{HelmholtzDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (H, V, G, D, O, B, T, C, P, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row. It supplies the ambient inner-product and norm-facing carrier on which the vector field and both components are read.*
2. *V is the vector-field row. It records the admitted field endpoint together with the* $\mathsf{VecSpace}^{\uparrow}$ *addition, subtraction, and scalar rows used to state the splitting.*
3. *G is the gradient-potential row. It names a potential window and the displayed* $\mathsf{LinMap}^{\uparrow}$ *route that reads its gradient as a vector-field component.*
4. *D is the divergence-free row. It records the classifier saying that the second component lies in the displayed kernel row selected by the divergence operator.*
5. *O is the orthogonal-projection row. It reads the gradient component and the divergence-free component through the projection-theorem surface of chapter 2374.*
6. *B is the boundary ledger. It records exactly which boundary observations are available before a projection or divergence-free read is exposed.*
7. *T records componentwise* hsame *transport for the Hilbert source, vector field, gradient-potential row, divergence-free row, projection row, boundary ledger, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a Helmholtz-decomposition request through $H, V, G, D, O, B, T, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{HelmholtzDecomposition}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, OrthogonalProjectionThec BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $H, V, G, D, O, B, T, C, P, N$. It has no coordinate for a host PDE solution operator, selected gauge, ambient Sobolev space, hidden boundary regularity theorem, quotient vector-field equality, or unrestricted Hodge decomposition.

Lean4 ✓ `BEDC.Derived.HelmholtzDecompositionUp.HelmholtzDecompositionTasteGate single carrier alignment`

Theorem 5268.2 (Helmholtz decomposition NameCert obligations)**.** *For every accepted* $\mathsf{HelmholtzDecomposition}^{\uparrow}$ *carrier $K = (H, V, G, D, O, B, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}^{\uparrow}}$ *surface consists exactly of the following finite obligation families:*

1. *Hilbert-source admission for the displayed* $\mathsf{Hilbert}^{\uparrow}$ *row H;*
2. *vector-field admission for the field endpoint and* $\mathsf{VecSpace}^{\uparrow}$ *operations stored in V;*
3. *gradient-potential admission for the potential window and* $\mathsf{LinMap}^{\uparrow}$ *gradient route stored in G;*
4. *divergence-free admission for the kernel classifier stored in D;*
5. *orthogonal-projection admission for the projection row O over the gradient and divergence-free components;*
6. *boundary-ledger admission for the displayed boundary observations stored in B;*
7. *componentwise transport, displayed replay, provenance, and local naming through T, C, P, N.*

Consequently a downstream PDE, variational, or Hodge-facing consumer may read Helmholtz data only through the displayed Hilbert, vector-space, linear-map, projection, boundary, transport, replay, provenance, and local naming rows. The packet exports no host PDE solver, gauge selector, Sobolev-completion theorem, quotient vector-field equality, or unrestricted Hodge decomposition.

Proof. Project the carrier of Definition 5788.1. The visible analytic rows are the Hilbert source H, the vector-field row V, the gradient-potential row G, the divergence-free row D, the orthogonal-projection row O, and the boundary ledger B.

The source and algebraic rows are read first. The Hilbert row comes from chapter 91, while V supplies the vector operations inherited from chapter 47. Thus the decomposition statement is formed only inside a displayed carrier.

Next the two component rows are exposed. The gradient-potential row G factors its gradient read through the linear-map surface of chapter 48, and the divergence-free row D supplies the displayed kernel classifier before any splitting conclusion is available.

The projection and boundary rows then bind the route. The row O reads the orthogonal splitting discipline through chapter 2374, while B restricts the boundary observations available to that read.

Finally T, C, P, N transport, replay, source, and name the same displayed rows. Since no excluded analytic object is a coordinate of K, the listed obligation families exhaust the local NameCert surface. □

Theorem 5268.3 (Helmholtz decomposition orthogonal splitting route)**.** *Every splitting read accepted from a* $\mathsf{HelmholtzDecomposition}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Hilbert}^{\uparrow} \longmapsto \mathsf{VecSpace}^{\uparrow} \longmapsto \mathsf{LinMap}^{\uparrow} \longmapsto \mathsf{OrthogonalProjectionTheorem}^{\uparrow} \longmapsto \mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}^{\uparrow}}.$$

The exported surface is a displayed field row together with a gradient-potential component, a divergence-free component, an orthogonal projection ledger, and a boundary ledger. It does not provide a global PDE solution operator, a selected gauge, Sobolev regularity, quotient equality of vector fields, or the full Hodge decomposition theorem.

Proof. Start from an accepted packet $K = (H, V, G, D, O, B, T, C, P, N)$. A consumer first opens the Hilbert row H, so every norm, orthogonality, and projection read remains attached to the same displayed source.

The vector-space row V then supplies the algebra needed to read the field as the sum of two displayed components. This step uses only the finite operations exposed by chapter 47.

The gradient-potential component is read through G and the linear-map surface of chapter 48. The divergence-free component is read through D, whose kernel classifier is already part of the packet.

The orthogonal splitting claim is finally routed through O and the projection-theorem packet of chapter 2374. The boundary ledger B records the available boundary observations before the local name N is exposed.

Transport and replay through T and C preserve this order, while P records the provenance of the same finite route. No host solver, gauge selector, Sobolev regularity theorem, quotient equality, or unrestricted Hodge theorem is introduced. □

Closure status for $\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5788.1, Definition 5788.2, and Definition 5788.3 seed the finite Helmholtz decomposition packet over Hilbert, vector-space, linear-map, projection, boundary, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HelmholtzDecompositionUp.HelmholtzDecompositionTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim PDE solvability, global gauges, Sobolev regularity, quotient vector-field equality, unrestricted Hodge decomposition, or bridge checking.

Upgrade path: Obligation closure asks for checked Hilbert-source admission, vector-field admission, gradient-potential admission, divergence-free admission, orthogonal-projection admission, boundary-ledger admission, transport, replay, provenance, and local naming for BEDC.Derived.HelmholtzDecompositionUp.

Constructive story: A $\mathsf{HelmholtzDecomposition}^{\uparrow}$ packet is generated from a displayed Hilbert source, a vector-field row, a gradient-potential row read through LinearMapUp, a divergence-free kernel row, an orthogonal-projection row, a boundary ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5269

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet records the separated completion boundary needed by the L10 Real and Completion route as finite BEDC data. It sits after the separation predicate of chapter 1925, the separated-completion carrier of chapter 1612, the metric completion route of chapter 1506, the finite stream interface of chapter 126, the dyadic tolerance core of chapter 291, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the envelope through displayed rows only; it does not quotient filters, select representatives, identify host equalities, invoke countable choice, or import ambient completeness.

Definition 5269.1 (Hausdorff completion envelope carrier)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (H, S, M, W, D, R, L, T, K, P, N)$$

where H *is the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$ *separation row,* S *is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* L *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal,* T *is componentwise* $\mathsf{BHist/hsame}$ *transport,* K *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *row. A consumer of* E *receives a separated completion boundary only through these coordinates.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeTasteGate single carrier alignment`

Theorem 5269.2 (Hausdorff completion envelope obligations)**.** *Every accepted* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *read must expose the carrier of Definition 5789.1 in the order*

$$H, S, M, W, D, R, L, T, K, P, N.$$

The separation row H *and separated-completion row* S *are available before metric completion, stream observation, dyadic tolerance, regular readback, and real-seal rows are consumed; the transport, replay, provenance, and naming rows preserve the same displayed packet.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeNameCertObligations`

Proof. Project the carrier of Definition 5789.1. The packet has no completion-facing coordinates except $H, S, M, W, D, R, L, T, K, P, N$.

The Hausdorff and separated-completion rows are the first boundary data in the packet. Thus a consumer cannot inspect the metric completion route, finite stream windows, dyadic tolerances, regular readback, or terminal real seal without first reading the displayed separation surface.

Finally, the structural rows T, K, P, N only transport, replay, source, and name the same finite packet. They do not create quotient filters, selected representatives, host equality, choice-selected routes, or ambient completeness. □

Theorem 5269.3 (Hausdorff completion separated metric route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier factors through the separated route*

$$H, S \longmapsto M \longmapsto W, D, R, L.$$

The route records a separated metric-completion boundary for the L10 Real and Completion interface, not a quotient completion, a host equality theorem, a choice-selected representative, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier separated metric route`

Proof. Start from Definition 5789.2. It places the Hausdorff row H and separated-completion row S before the metric completion row M and before the stream, dyadic, regular-rational, and real-seal rows.

Read the metric completion route through M. Since M is downstream of H, S, every completion-facing use of M carries the displayed separated boundary with it.

The final Real-facing read is the finite route W, D, R, L. Because these rows are still coordinates of the same carrier, the route cannot be replaced by quotient representatives, host equality, countable choice, or ambient completeness. □

Theorem 5269.4 (Hausdorff completion envelope sibling route)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *consumer may hand its separated boundary to* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *only through the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$*,* $\mathsf{SeparatedCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows of*

$$E = (H, S, M, W, D, R, L, T, K, P, N).$$

The handoff contains no quotient-filter coordinate, representative-selection coordinate, host-equality coordinate, or ambient-completeness coordinate.

Proof. Apply Definition 5789.2. It places the Hausdorff row H, separated-completion row S, metric-completion row M, stream row W, dyadic row D, regular-rational row R, and terminal Real row L inside one displayed packet.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

The sibling $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ consumer therefore reads the same separated boundary as its input surface rather than receiving a separate primitive. Since the carrier only has the displayed rows and the structural rows T, K, P, N, quotient filters, selected representatives, host equality, and ambient completeness remain outside the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier sibling route`

Theorem 5269.5 (Hausdorff completion envelope Cauchy-net consumer link)**.** *Every* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier must read the same* $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before its directed-net completion route is consumed. The downstream sibling is chapter 3794, and the handoff is the displayed route*

$$H, S, M, W, D, R, L \longmapsto \mathsf{CauchyNetCompletion}^{\uparrow}.$$

It exports no quotient net, selected representative, host equality, countable-choice schedule, or ambient completeness coordinate.

Proof. Project the carrier $E = (H, S, M, W, D, R, L, T, K, P, N)$ of Definition 5789.1. The only completion-facing rows available to a consumer are the Hausdorff row H, separated-completion row S, metric-completion route M, finite stream row W, dyadic tolerance row D, regular readback row R, and terminal Real row L.

Apply Definition 5789.2. It places H, S, M, W, D, R, L inside one displayed packet before the structural rows T, K, P, N are used for transport, replay, provenance, and local naming.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

Therefore a downstream $\mathsf{CauchyNetCompletion}^{\uparrow}$ read can only consume the envelope through the same separated metric route before its directed-net completion surface is inspected. Since the packet has no quotient-net, selected-representative, host-equality, countable-choice, or ambient-completeness row, none of those objects can enter the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeForwardLink`

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5789.1, Definition 5789.2, and Definition 5789.3 name the separated completion envelope surface for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, host equality, choice-selected representatives, or ambient completeness.

Upgrade path: Obligation closure requires the carrier route to be tied to the sibling completion obligation theorems and then exposed as a public chapter surface.

Constructive story: A $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet is generated from Hausdorff separation, separated-completion boundary, metric-completion route, finite stream windows, dyadic tolerance, regular-rational readback, Real seal, transport, replay, provenance, and local NameCert rows.

Chapter 5270

A Concrete Naming Certificate for $\mathsf{BoundedLinearFunctional}^{\uparrow}$

Following Banach and Bourbaki functional analysis, the $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet records the scalar-valued bounded-linear-operator row that duality and weak-star consumers inspect before any host dual space is available. It sits over the linear-map route of chapter 48, the bounded-linear-operator surface of chapter 1644, the scalar-bound neighbour chapter 3603, the Banach-dual row of chapter 2265, the finite weak-star window of chapter 3420, the scalar endpoint seal of chapter 38, and the normed source surface of chapter 1950. The chapter names only displayed scalar-functional data: source rows, linearity rows, scalar target readback, norm-bound evidence, transport, replay, provenance, and local naming.

Definition 5270.1 (Bounded linear functional carrier)**.** *For a displayed* $\mathsf{NormedSpace}^{\uparrow}$ *source row* E *over the scalar endpoint surface of* $\mathsf{Real}^{\uparrow}$*, a* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E)$ *carrier is a finite* BHist *packet*

$$\Lambda = (E, L, T, K, O, H, C, P, N)$$

with the following displayed rows:

1. *E is the source normed-space row, including its carrier endpoints, scalar action, additive row, norm row, and classifier.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row from E to the scalar* $\mathsf{Real}^{\uparrow}$ *target.*
3. *T is the scalar-valued* $\mathsf{BoundedLinearOperator}^{\uparrow}(E, \mathsf{Real}^{\uparrow})$ *row carrying the same endpoint action as L.*
4. *K is the* $\mathsf{Real}^{\uparrow}$ *nonnegative bound endpoint for the functional.*
5. *O is the* $\mathsf{OperatorNorm}^{\uparrow}$ *handoff row exposing where the bound K is used.*
6. *H records componentwise* hsame *transport for the source, linear-map row, bounded-operator row, scalar bound, operator-norm handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a scalar-functional request through E, L, T, K, O, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedLinearFunctional}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{BanachDual}^{\uparrow}$, $\mathsf{BanachAlaoglu}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed source classifier, scalar endpoint transport, bounded-operator transport, bound transport, norm-bound ledger transport, replay, provenance, and local naming rows. It has no coordinate for a host dual space, quotient equality of functions, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BoundedLinearFunctionalUp.BoundedLinearFunctionalTasteGate single carrier alignment`

Theorem 5270.2 (Bounded linear functional NameCert obligations)**.** *For every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *carrier* $\Lambda = (E, L, T, K, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *surface consists exactly of source normed-space admission, linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from host dual objects. A consumer may inspect* $E, L, T, K, O, H, C, P, N$*, but it receives no ambient function space, quotient operator equality, selected representative, Hahn–Banach witness, unrestricted weak-star compactness theorem, or bridge data.*

Proof. Project the carrier rows. The analytic coordinates are exactly the source normed-space row E, the linear-map row L, the scalar-valued bounded-operator row T, the RealUp bound endpoint K, and the operator-norm handoff O.

The linearity obligation is read through $\mathsf{LinMap}^{\uparrow}$, while boundedness is read through $\mathsf{BoundedLinearOperator}^{\uparrow}(E,$ The scalar target is already the displayed $\mathsf{Real}^{\uparrow}$ endpoint surface, so the functional row never becomes a host-level function.

The bound exactness is the shared route through K and O. The operator-norm handoff records where the scalar bound is used, and componentwise hsame transport moves the source, action, bound, ledger, replay, provenance, and local naming rows together.

No remaining coordinate can manufacture a dual-space quotient, selected representative, Hahn–Banach witness, unrestricted compactness theorem, or bridge check. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 5270.3 (Bounded linear functional operator-norm handoff)**.** *Every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E$ *packet exports the finite route*

$$\mathsf{LinMap}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{OperatorNorm}^{\uparrow} \longmapsto \mathsf{BoundedLinearFunctional}^{\uparrow}$$

to functional-analysis consumers. The route first exposes the carried scalar-valued linear action, then the bounded-operator row, then the RealUp bound endpoint and operator-norm ledger; it does not expose a host supremum, quotient equality of functionals, selected norm-attaining vector, or hidden Banach completeness.

Proof. Begin with an accepted packet $\Lambda = (E, L, T, K, O, H, C, P, N)$. The read of L supplies only the displayed linear-map action from the source row to the scalar target.

The read of T then packages the same action as a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row. Its target row is $\mathsf{Real}^{\uparrow}$, and its bound endpoint is the displayed scalar K.

Finally the operator-norm handoff O records the norm-bound ledger that downstream consumers may inspect. Because no host norm function, quotient functional equality, selected vector, or hidden completion row is present, the exported handoff is exactly the displayed scalar-bound route. □

Theorem 5270.4 (Bounded linear functional dual-row nonescape)**.** *Any read of a* $\mathsf{BanachDual}^{\uparrow}$ *or* $\mathsf{BanachAlaoglu}^{\uparrow}$ *consumer that uses a* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *row factors through the same source normed-space row, scalar-valued bounded-operator row, RealUp bound endpoint, operator-norm handoff, componentwise transport, replay, provenance, and local naming rows of Definition 5790.1. The duality consumer receives a finite scalar-functional row, not a host dual space, a quotient function class, an unrestricted weak-star compactness theorem, or a selected cluster point.*

Proof. Read the duality consumer first. A $\mathsf{BanachDual}^{\uparrow}$ request needs a scalar-functional row over a displayed source, while a $\mathsf{BanachAlaoglu}^{\uparrow}$ request needs a finite family of such scalar-functional observations.

In either case the only scalar-functional packet available here is Λ. Its source row, bounded-operator row, bound endpoint, operator-norm handoff, and structural rows are projected in the order displayed by Definition 5790.1.

The downstream dual chapters may reuse those rows, but they cannot add coordinates that are absent from the packet. Thus quotient dual objects, host function classes, unrestricted weak-star compactness, selected cluster points, and bridge checks remain outside the read. □

Falsifiable prediction: Every accepted $\mathsf{BoundedLinearFunctional}^{\uparrow}$ scalar-functional read factors through a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ action row, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, and the local hsame, Cont, Pkg, and NameCert rows.

Independence witness: linearmap, boundedlinearoperator, operatornorm, banachdual, banachalaoglu, real, and normedspace: no listed sibling is bijective to $\mathsf{BoundedLinearFunctional}^{\uparrow}$ because this packet stores the scalar target restriction, the dual-facing provenance row, the operator-norm handoff, transport, replay, and local naming together as one finite scalar-functional surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet is generated from a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ scalar action, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5790.1, Definition 5790.2, Definition 5790.3, and Definition 5790.4 seed the scalar-functional row consumed by BanachDualUp and BanachAlaogluUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host dual spaces, quotient equality of functionals, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, scalar linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm handoff exactness, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BoundedLinearFunctionalUp.

Chapter 5271

A Concrete Naming Certificate for $\mathsf{CompletionModulusCategory}^{\uparrow}$

Following Bishop and Bridges on constructive completion and the functorial treatment of completions, the $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet records the finite category surface whose arrows preserve displayed completion moduli. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the completion functor of chapter 426, and the Cauchy completion functor of chapter 423. The packet names modulus-preserving completion morphisms as BEDC rows; it does not export quotient completions, selected representatives, host continuous maps, countable choice, or ambient completeness.

Definition 5271.1 (CompletionModulusCategory carrier)**.** *A* $\mathsf{CompletionModulusCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, A, S, R, D, E, F, H, C, P, N)$$

with the following displayed rows:

1. *O is the object ledger. Each object row records a completion-facing source, its displayed Cauchy-modulus discipline, and the local completion target read through the surrounding completion chapters.*
2. *A is the arrow ledger. Each arrow row records a finite morphism request together with the modulus transformation that sends source tolerances to target tolerances.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source and target names of an arrow.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the stream windows have been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare source and target moduli.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row read only after S, R, D have supplied the displayed tolerance route.*
7. *F records identity and composition rows for the completion functoriality surface, with identity arrows preserving the same modulus and composite arrows composing the displayed modulus transformations.*
8. *H records componentwise* hsame *transport for object rows, arrow rows, stream windows, regular readback, dyadic tolerances, Real seals, functoriality rows, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an arrow request through $O, A, S, R, D, E, F, H, P, N$.*
10. *P is the* Pkg *provenance over* CompletionModulusCategory$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, CauchyCompletionFunctor$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{CompletionModulusCategory}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite category packet for modulus-preserving completion morphisms. It has no coordinate for quotient completion points, selected representatives, host functions, global choice schedules, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryTasteGate single carrier alignment`

Theorem 5271.2 (CompletionModulusCategory NameCert obligations)**.** *For every accepted* CompletionModulusCa *carrier $M = (O, A, S, R, D, E, F, H, C, P, N)$, the local* NameCert$_{\text{CompletionModulusCategory}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed object ledger, arrow ledger, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, identity and composition rows, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface additionally requires each arrow row in A to expose its source modulus, target modulus, and modulus transformation before any Real$^{\uparrow}$*-facing read is accepted; each identity row in F to preserve the displayed modulus without adding a choice coordinate; and each composition row in F to compose the two displayed modulus transformations before the downstream seal is visible.*

Proof. Project the accepted carrier. The packet contains only the rows $O, A, S, R, D, E, F, H, C, P, N$, so carrier admission and ledger exhaustion are componentwise.

An arrow-facing request first reads the object and arrow ledgers O, A. The source and target names are then inspected through the finite stream windows S, regular rational readback R, and dyadic tolerance ledger D.

The functoriality rows F are local to the same displayed moduli. Identity preserves the stored modulus transformation, and composition combines the two stored transformations before the terminal seal E can be read.

Finally H, C, P, N transport, replay, source, and name this same finite route. Since quotient completions, selected representatives, host functions, global choice schedules, and ambient completeness are not carrier coordinates, they cannot be exported by the local NameCert. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryNameCertObligations`

Theorem 5271.3 (CompletionModulusCategory modulus functoriality)**.** *Every completion-facing consumer of an accepted* CompletionModulusCategory$^{\uparrow}$ *packet reads a modulus-preserving morphism through the finite route*

$$O, A, S, R, D, F, E, H, C, P, N.$$

Thus identity and composition of completion morphisms preserve the displayed modulus data before any Real$^{\uparrow}$ *seal or completion-functor read is exposed. The route factors through* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, *and* CauchyCompletionFunctor$^{\uparrow}$ *rather than through quotient completion equality, selected representatives, host continuous maps, countable choice, or ambient completeness.*

Proof. Start with a completion-facing morphism request. The object ledger O fixes the source and target completion rows, and the arrow ledger A fixes the modulus transformation to be checked.

The readback rows S, R, D display the inspected stream windows, regular rational observations, and dyadic tolerance comparisons. These rows are the only route by which the requested modulus can face the terminal Real seal.

The functoriality row F then supplies the identity or composition clause. In the identity case the same displayed modulus is replayed. In the composition case the two displayed modulus transformations are composed as finite rows before the result is handed to E.

The structural rows H, C, P, N preserve and name the same route. Therefore every completion-functor consumer receives finite modulus preservation data and no excluded quotient, selection, host-map, choice, or ambient-completeness surface. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryModulusFunctoriality`

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}$.

Constructive story: A $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet is generated from completion object rows, modulus-preserving arrow rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, RealUp seals, identity and composition rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5791.1, Definition 5791.2, and Definition 5791.3 seed the finite category surface for modulus-preserving completion morphisms.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host continuous maps, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-preserving arrow exactness, identity and composition rows, tolerance readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionModulusCategoryUp.

Chapter 5272

A Concrete Naming Certificate for $\mathsf{MarkovTriggerDynamics}^{\uparrow}$

The $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet realizes the finite rank-trigger dynamics of Definition 9462.1541, Definition 9462.1542, and Definition 9462.1546 as BEDC NameCert data. It records the state, support-rank, transition-count, drift, trigger-time, classifier, continuation, provenance, and naming rows needed by a downstream finite-dynamics consumer. The packet is a finite BHist surface for trigger-time readback; it is not a stochastic process on an ambient probability space, not an infinite sample path, not a hidden field model, and not a host Markov-chain object.

Definition 5272.1 (MarkovTriggerDynamics carrier)**.** *A* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, K, A, D, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite state row. It records the consumed external-codon count m and the covered support rank r for the current trigger state.*
2. *K is the support-rank row. It records the finite support coordinates currently covered by the observed codon rows and the rank read from that support.*
3. *A is the transition-count row. It stores the finite count of rank-preserving and rank-increasing next draws available from the current state.*
4. *D is the drift row. It records the displayed one-step rank drift computed from the same transition counts.*
5. *G is the trigger-time row. It records the finite recursion for the time to reach full rank and the deterministic threshold row consumed by trigger-time readers.*
6. *H records componentwise* hsame *transport for state, support-rank, transition-count, drift, trigger-time, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a state read through S, K, A, D, G, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$, BHist, hsame, Cont, *finite rank-trigger rows, finite transition-count rows, finite trigger-time rows, and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient probability space, hidden generator field, infinite sample path, external random oracle, host Markov-chain semantics, or unstated independence assumption.

Lean4 ✓ `BEDC.Derived.MarkovTriggerDynamicsUp.MarkovTriggerDynamicsTasteGate single carrier alignment`

Theorem 5272.2 (MarkovTriggerDynamics NameCert obligations)**.** *For every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier* $T = (S, K, A, D, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed state row, support-rank row, transition-count row, drift row, trigger-time row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface requires the transition-count row A *to be computed from the finite support-rank row* K*, the drift row* D *to read only the transition counts in* A*, and the trigger-time row* G *to replay the finite recursion from the displayed state row* S *without adding an external probability carrier.*

Proof. Project the accepted carrier. The packet exposes only $S, K, A, D, G, H, C, P, N$, so every NameCert obligation is a componentwise obligation on those rows.

The state and support rows S, K determine the finite rank-trigger situation. The transition-count row A counts rank-preserving and rank-increasing next draws from that finite support surface.

The drift row D is downstream of A, and the trigger-time row G is downstream of the same state and transition-count data. Thus the trigger-time read is a finite recursion over displayed rows, not an imported Markov-chain object.

Transport, replay, provenance, and local naming preserve the same coordinates. Since the excluded ambient and hidden objects are not coordinates of T, no consumer can read them from the packet. □

Theorem 5272.3 (MarkovTriggerDynamics finite trigger readback)**.** *Every trigger-time consumer of an accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *packet reads the finite route*

$$S, K, A, D, G, H, C, P, N.$$

Consequently the transition law, drift, and trigger-time rows are all determined by finite BHist transition-count data. No trigger-time read exports an infinite sample path, host Markov process, hidden field, or unstated independence source.

Proof. Start with the state row S and support-rank row K. They display the finite input state and the rank information that determines which next-draw counts are available.

The transition-count row A is the only row from which the drift row D may be read. The trigger-time row G then replays the finite recursion from those same transition counts.

Finally H, C, P, N transport, replay, source, and name the finite trigger route. Because no other row exists in the carrier, the stated nonescape clauses follow. □

Falsifiable prediction: Every $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ trigger-time read factors through finite state, support-rank, transition-count, drift, trigger-time, hsame, Cont, Pkg, and NameCert rows.

Independence witness: dna-boundary-tile, rank-trigger, finite-markov-transition: $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries state rows, support-rank rows, transition-count rows, drift rows, trigger-time rows, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Theorem 5272.4 (MarkovTriggerDynamics sibling dependency route)**.** *Every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *trigger-time read routes its finite state and transition-count rows through chapter 189 or chapter 4074 when the carrier is read as a Markov surface, through chapter 195 when it is read as finite transition evolution, and through chapter 3508 for the DNA boundary-trigger consumer.*

Proof. Project the existing carrier rows $S, K, A, D, G, H, C, P, N$. The state row S, support-rank row K, and transition-count row A provide exactly the finite Markov read, so a Markov-surface consumer reaches this packet through the Markov-chain or finite Markov-partition certificates.

The same rows, together with drift row D and trigger-time row G, form the finite transition-evolution route consumed by the dynamical-system certificate. The structural rows H, C, P, N then transport, replay, source, and name that route for the DNA boundary-trigger consumer.

This is a dependency route only. It does not add an ambient probability space, infinite sample path, unstated independence source, or host Markov-chain object to the carrier. □

Nontrivial TasteGate and FieldFaithful instances remain required before this finite trigger surface can be read as a checked biological field-faithfulness claim.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet is generated from finite state rows, support-rank rows, transition-count rows, drift rows, trigger-time recursion rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5792.1, Definition 5792.2, and Definition 5792.3 seed the finite rank-trigger Markov readback surface for DNA boundary-tile dynamics.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient probability spaces, infinite sample paths, hidden field models, host Markov-chain semantics, biological field-faithfulness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-count exactness, drift readback, trigger-time recursion, nontrivial TasteGate coverage, FieldFaithful evidence, transport, replay, provenance, and local naming for BEDC.Derived.MarkovTriggerDynamicsUp.

Chapter 5273

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet records the finite constructive route from regular Cauchy rational names to located completion data and then to the terminal $\mathsf{Real}^{\uparrow}$ seal. It reads the dyadic arithmetic surface of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the completion service exposed by chapter 128, and the real-name boundary of chapter 38. The packet supplies a located completion neighbour for the regular-Cauchy real route without asserting quotient completion equality, selected representatives, host order completeness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5273.1 (Regular Cauchy located completion carrier)**.** *A* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, Q, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the Cauchy name is inspected at requested precision scales.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for tolerance comparison, shrinkage, and rational distance estimates.*
4. *Q is the located completion row, recording the displayed located-distance and approximation data extracted from S, R, D.*
5. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row used only as a finite completion handoff for the displayed located data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback and located completion rows have been displayed.*
7. *H records componentwise* hsame *transport for stream windows, regular rational readbacks, dyadic arithmetic, located completion data, completion service, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a located-completion request through $S, R, D, Q, K, E, H, P, N$.*

9. *P is the* Pkg *provenance over* RegularCauchyLocatedCompletion$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RegularCauchyLocatedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, K, E, H, C, P, N$. The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host order completeness, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedCompletionUp.RegularCauchyLocatedCompletionTasteGate single carrier alignment`

Theorem 5273.2 (Regular Cauchy located completion obligations)**.** *For every accepted* RegularCauchyLocatedCom *carrier*

$$L = (S, R, D, Q, K, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyLocatedCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream-window row, regular rational readback row, dyadic arithmetic ledger, located completion row, complete-metric handoff, real seal, transport, replay, provenance, and local name;*
2. *window-readback coherence, requiring S to expose the finite inspection windows before R may be consumed as a regular rational name;*
3. *dyadic locatedness, requiring D to supply the tolerance comparisons and distance estimates used by the located completion row Q;*
4. *completion handoff ordering, requiring Q to be displayed before the* CompleteMetric$^{\uparrow}$ *row K is exposed;*
5. *real-seal ordering, requiring E to be read only after S, R, D, Q, K have been displayed;*
6. *classifier stability, requiring componentwise* hsame *transport and displayed* Cont *replay to preserve all visible rows;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no quotient completion equality, selected representative, countable choice, host order completeness, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5793.1. Its rows list the finite stream windows, regular rational readback, dyadic arithmetic ledger, located completion data, complete-metric handoff, real seal, and the structural rows.

Window-readback coherence follows because R has no independent observation coordinate in this packet. The regular rational read must pass through S, and the tolerance computations used by that read are then checked against the dyadic row D.

The located completion row Q is the only row that records located-distance data. The completion handoff K consumes that displayed row, and the real seal E is exposed only after the handoff has been displayed.

Transport, replay, provenance, and local naming are exhausted by H, C, P, N. Since quotient completion equality, selected representatives, countable choice, host order completeness, and ambient Real$^{\uparrow}$ completeness are absent from the carrier, no NameCert obligation can export them. □

Theorem 5273.3 (Regular Cauchy located completion Real seal route)**.** *Let* $L = (S, R, D, Q, K, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the located completion read factors through the finite route*

$$S, R, D \longmapsto Q \longmapsto K \longmapsto E \longmapsto H, C, P, N.$$

Thus the packet reaches the real-name boundary only through displayed $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic, located completion data, and the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff. It does not export quotient completion equality, selected representatives, countable choice, host order completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing read of the packet. The only observable name data are the stream windows S and the regular rational readback R, so any request for a real seal must first inspect those rows.

The dyadic row D supplies the tolerance and distance comparisons used by the located completion data Q. The complete-metric handoff K is then read as a service row for that displayed located data, not as an ambient completeness theorem.

Finally the seal row E exposes the $\mathsf{Real}^{\uparrow}$ boundary, and H, C, P, N transport, replay, source, and name the same displayed route. No remaining carrier coordinate can provide quotient completion equality, selected representatives, choice data, host order completeness, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5793.1, Definition 5793.2, and Definition 5793.3 seed a finite route from regular Cauchy names through located completion data to the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host order completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback coherence, dyadic locatedness, completion handoff ordering, real-seal ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLocatedCompletionU

Constructive story: A $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore arithmetic, located completion data, a CompleteMetric handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5274

A Concrete Naming Certificate for $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$

Following Banach, Picard, and Bishop–Bridges constructive analysis, the $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet records the finite handoff from an explicit contraction estimate to the Cauchy threshold consumed by the regular-rational and real endpoint routes. It sits between the Banach fixed-point modulus packet of chapter 4188, the Picard iteration and error-estimate packets of chapter 2359 and chapter 2233, and the regular Cauchy completion boundary of chapter 5793. The packet gives the endpoint route a single displayed Cauchy-threshold surface without selecting a fixed point, quotienting completion names, or importing ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5274.1 (Picard threshold Cauchy handoff carrier)**.** *A* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, I, E, M, R, K, S, T, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BanachFixedPointModulus}^{\uparrow}$ *source row whose contraction-rate route has already exposed the rational Lipschitz and finite Picard ledgers.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *ledger of adjacent iterate windows and replay order.*
3. *E is the* $\mathsf{PicardErrorEstimate}^{\uparrow}$ *row, carrying the residual-and-ratio estimate used to bound the Picard tail.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row produced from B, I, E for each requested dyadic or rational tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row made available only after the threshold row M has been displayed.*
6. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row consumed at the handoff boundary, not an ambient completeness theorem.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, R, K have been read.*
8. *T stores componentwise* hsame *transports for the Banach-modulus, Picard-iteration, error-estimate, Cauchy-threshold, regular-rational, complete-metric, real-seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from the contraction-rate request through $B, I, E, M, R, K, S, T, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$, $\mathsf{BanachFixedPointModulus}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{PicardErrorEstimate}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, I, E, M, R, K, S, T, C, P, N$. It has no coordinate for a selected fixed point, host fixed-point equality, quotient completion equality, detached Cauchy selector, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.PicardThresholdCauchyHandoffUp.PicardThresholdCauchyHandoffTasteGate`
`single carrier alignment`

Theorem 5274.2 (Picard threshold Cauchy handoff NameCert obligations)**.** *For every accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier $H = (B, I, E, M, R, K, S, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyH}}$ *surface consists exactly of carrier admission for the displayed rows; Banach-modulus source visibility through B; Picard-iteration visibility through I; error-estimate visibility through E; Cauchy-threshold construction through M; regular-rational readback through R; complete-metric service access through K; real seal access through S; classifier stability through T and C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 5794.1. The accepted packet exposes exactly the Banach-modulus source row, the Picard-iteration ledger, the error-estimate row, the Cauchy-threshold row, the regular-rational readback, the complete-metric service, the real seal, and the structural rows.

The threshold rows are ordered. The rows B, I, E must be displayed before M can answer a tolerance request, since M is the only coordinate that records the finite Cauchy threshold.

The endpoint rows are downstream. The row R reads the threshold as regular rational data, K is the visible complete-metric service row, and S is exposed only after those rows have been displayed. Transport, replay, provenance, and local naming are exhausted by T, C, P, N, so no further NameCert obligation is present. □

Theorem 5274.3 (Picard threshold Cauchy handoff Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing endpoint read of an accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{BanachFixedPointModulus}^{\uparrow},\ \mathsf{PicardIteration}^{\uparrow},\ \mathsf{PicardErrorEstimate}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Complete}$$

Thus the real seal is reached only after the explicit Picard threshold has been displayed as a $\mathsf{CauchyModulus}^{\uparrow}$ *row and repacked through the regular-rational and complete-metric handoff rows. The route exports no selected fixed point, quotient completion equality, detached Cauchy selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing endpoint request. The only contraction-rate source row is B, and its Picard data are refined in the visible rows I and E, so the request first reads those rows.

The threshold stage is forced by M. Apply the Banach fixed-point modulus route of Definition 4188.3 together with the Picard iteration surface of chapter 2359 and the error-estimate surface of chapter 2233. These sources supply the displayed threshold row without adding a selected endpoint.

After M is fixed, the readback and completion rows R and K expose the regular-rational and complete-metric boundary used by chapter 301 and chapter 128. The seal row S is then the only $\mathsf{Real}^{\uparrow}$ coordinate, and the structural rows T, C, P, N preserve the same route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5794.1, Definition 5794.2, and Definition 5794.3 seed the finite Picard-threshold handoff from BanachFixedPointModulus, PicardIteration, and PicardErrorEstimate rows to CauchyModulus, RegSeqRat, CompleteMetric, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, host fixed-point equality, quotient completion equality, detached Cauchy selectors, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard-threshold construction, regular-rational readback, complete-metric service access, real-seal ordering, classifier stability, provenance, and local naming for BEDC.Derived.PicardThreshol

Constructive story: A $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet is generated from a BanachFixedPointModulus source row, PicardIteration ledger, PicardErrorEstimate row, CauchyModulus threshold, RegSeqRat readback, CompleteMetric service row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5275

A Concrete Naming Certificate for $\mathsf{DiniUniformLimitModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the classical Dini theorem, the $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet extracts the finite uniform-modulus ledger visible in compact-metric monotone convergence data. It sits over chapter 2196, chapter 1436, chapter 129, chapter 130, chapter 463, chapter 369, chapter 301, and chapter 38. The packet names the finite net, rational tolerance budget, and extracted modulus route; it does not import open-cover compactness, chosen limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5275.1 (Dini uniform-limit modulus carrier)**.** *A* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row naming the compact-metric finite-source observations consumed by the extraction.*
2. *F is the monotone* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, recording the displayed continuous approximants and their pointwise monotone order.*
3. *W is the pointwise window row supplied by the Dini-continuity and Dini-uniform-convergence routes.*
4. *E is the finite net row over K, naming the finite mesh on which pointwise windows are inspected.*
5. *Q is the rational tolerance-budget row, storing the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerances assigned to the finite net and to the later readback.*
6. *U is the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row, obtained from E, Q, W and the monotone continuous family row F.*
7. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row, exposing only the modulus-controlled limit route supplied by U.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance transport.*
9. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row, naming the real-valued read without adding ambient real completeness.*
10. *H records componentwise* hsame *transport for compact-metric source, monotone family, pointwise window, finite net, rational tolerance, extracted modulus, uniform-limit handoff, rational readback, real seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the compact-metric source and monotone family through the finite net, tolerance budget, extracted modulus, and uniform-limit handoff.*
12. *P is the* Pkg *provenance over* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$, $\mathsf{DiniContinuity}^{\uparrow}$, $\mathsf{DiniUniformConvergence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, W, E, Q, U, L, R, S, H, C, P, N$. It has no coordinate for open-cover compactness, selected limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiniUniformLimitModulusUp.TasteGate.DiniUniformLimitModulusTasteGate`
`single carrier alignment`

Theorem 5275.2 (Dini uniform-limit modulus NameCert obligations)**.** *For every accepted* DiniUniformLimitModulu *carrier*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact-metric source, monotone continuous family, pointwise window, finite net, rational tolerance budget, extracted uniform modulus, UniformLimit handoff, RegSeqRat readback, Real seal, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires monotone-window visibility through F and W, finite-net extraction through E and Q, modulus handoff through U and L, Real-seal nonescape through S, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses open-cover compactness, selected limiting values, quotient function equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only computational rows are the compact-metric source K, monotone family F, pointwise windows W, finite net E, rational budget Q, extracted modulus U, uniform-limit handoff L, rational readback R, and real seal S.

The monotone-window step is local to F and W. The finite-net step is local to E and Q, so the modulus row U is extracted from displayed finite data rather than from an open cover or a choice of limiting values.

The handoff to $\mathsf{UniformLimit}^{\uparrow}$ passes only through U and L. The rational and real readback rows R and S name the downstream values without adding quotient function equality or ambient completeness.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded objects are not coordinates of D, no NameCert consumer can read them from this carrier. □

Falsifiable prediction: Every accepted $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ read must expose compact-metric source rows, monotone continuous-family rows, pointwise window rows, a finite net, a rational tolerance budget, an extracted uniform modulus, a UniformLimit handoff, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dini-continuity, diniuniformconvergence, compactmetric, continuousmap, uniformlimit, uniformmodulus, regseqrat, real: $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ is not bijective to any

listed sibling because it binds the finite net and rational tolerance budget to an extracted uniform-modulus handoff before UniformLimit and Real consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5795.1 and Definition 5795.2 seed the finite uniform-modulus ledger extracted from compact-metric monotone convergence data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limiting values, quotient function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window visibility, finite-net extraction, modulus handoff, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniUniformLimitModulusUp.

Constructive story: A $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet is generated from compact-metric source rows, monotone continuous-family rows, pointwise windows, finite net rows, rational tolerance-budget rows, extracted uniform-modulus rows, UniformLimit handoff rows, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5276

A Concrete Naming Certificate for $\mathsf{SummationByParts}^{\uparrow}$

Following Abel and Dirichlet, the $\mathsf{SummationByParts}^{\uparrow}$ packet records the finite identity surface by which displayed partial sums, coefficient windows, adjacent differences, and endpoint terms are bound into one NameCert row. It sits beside the Abel-summation route of chapter 1763, the Abel-test consumer of chapter 1496, and the Dirichlet-test consumer of chapter 1497. Its source rows use the finite series carrier of chapter 121; its regular readback, dyadic tolerance, and endpoint seal use chapter 301, chapter 291, and chapter 38. The packet names a finite algebraic identity for downstream convergence tests; it does not import infinite sums, quotient series equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5276.1 (Summation by parts carrier)**.** *A* $\mathsf{SummationByParts}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Series}^{\uparrow}$ *source row, exposing only the inspected finite term window and its displayed partial sums.*
2. *A is the coefficient-window row, naming the coefficient entries read over the same finite interval.*
3. *Δ is the adjacent-difference row, recording the displayed values $a_k - a_{k+1}$ used by the identity.*
4. *P is the partial-sum-window row, naming the cumulative sums paired with A and Δ.*
5. *B is the boundary-term row, displaying the endpoint products and the finite interior products determined by S, A, Δ, P.*
6. *T is the convergence-test handoff row consumed by* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$.
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed finite identity data.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the finite additions, subtractions, products, and endpoint comparisons used by B.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after $S, A, \Delta, P, B, T, R, D$ have been displayed.*
10. *H records componentwise* hsame *transport for the source, coefficient, difference, partial-sum, boundary, handoff, readback, dyadic, endpoint, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the route*

$$S, A, \Delta, P, B, T, R, D \longmapsto E.$$

12. *Q is the* Pkg *provenance over* $\mathsf{SummationByParts}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$. It has no coordinate for an infinite sum, quotient series equality, selected convergence witness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SummationByPartsUp.SummationByPartsTasteGate single carrier alignment`

Theorem 5276.2 (Summation by parts NameCert obligations)**.** *For every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *carrier*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet; source and partial-sum exposure through S and P; coefficient-window and adjacent-difference exposure through A and Δ; boundary-term exactness through B; convergence-test handoff through T; regular readback, dyadic accounting, and endpoint sealing through R, D, E; and transport, replay, provenance, and local naming through H, C, Q, N.*

Proof. Project the accepted carrier. The projection exposes exactly the rows $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$, so every naming obligation must be read from one of those displayed coordinates.

The identity rows are finite. The source row S and partial-sum row P display the inspected cumulative sums, the coefficient row A displays the paired coefficients, and Δ displays the adjacent differences used by the interior terms. The boundary row B records only the endpoint products and interior products determined by those rows.

The consumer handoff is downstream of the identity. A convergence-test consumer first reads T, and the regular and real-facing route then passes through R, D, E. These rows can transport the displayed finite calculation, but they do not introduce an independent summation principle.

Finally H, C, Q, N preserve, replay, source, and name the same route. Because the carrier has no coordinate for infinite sums, quotient series equality, selected convergence witnesses, countable choice, trichotomy, or ambient real completeness, the stated rows exhaust the local NameCert surface. □

Theorem 5276.3 (Summation by parts Cauchy-series handoff)**.** *Every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *packet that is consumed by an* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$ *route hands off only the finite identity chain*

$$\mathsf{Series}^{\uparrow} \longmapsto S, A, \Delta, P, B, T \longmapsto R, D, E, H, C, Q, N.$$

Thus a Cauchy-series or real-seal consumer may read the summation-by-parts row only after the series window, coefficient window, adjacent-difference ledger, partial-sum window, boundary ledger, and test handoff have been displayed. The handoff supplies no infinite sum, quotient series equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a convergence-test read. Carrier admission exposes the source row S and the finite identity rows A, Δ, P, B before the handoff row T is available.

The downstream chapters may add their own test-specific rows. The $\mathsf{AbelSummation}^{\uparrow}$ consumer reads the displayed finite identity as its transform row, the $\mathsf{AbelTest}^{\uparrow}$ consumer combines it with a monotone null coefficient ledger, and the $\mathsf{DirichletTest}^{\uparrow}$ consumer combines it with bounded partial sums and a null-tail schedule. In each case the summation-by-parts contribution remains the same displayed finite packet.

The Cauchy-facing route is therefore forced through R and D before E can seal the endpoint. Transport, replay, provenance, and local naming preserve that same route, so no excluded summation or completeness datum can be read from the packet. □

Falsifiable prediction: An accepted $\mathsf{SummationByParts}^{\uparrow}$ consumer that reaches an $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without reading the displayed source, coefficient, adjacent-difference, partial-sum, boundary-term, and handoff rows refutes the carrier surface.

Independence witness: abel-summation, abel-test, dirichlet-test, series, regseqrat, dyadicratcore, real: no listed sibling supplies the whole thirteen-row packet $K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$, because each sibling contributes only a transform consumer, convergence-test consumer, source series, regular readback, dyadic ledger, or endpoint seal while this chapter binds the finite identity itself.

Closure status for $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$.

Constructive story: A $\mathsf{SummationByParts}^{\uparrow}$ packet is generated from a SeriesUp finite source row, coefficient windows, adjacent-difference rows, partial-sum windows, boundary-term ledgers, AbelSummation/AbelTest/DirichletTest handoff rows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5796.1, Definition 5796.2, and Definition 5796.3 seed the finite summation-by-parts identity packet over $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite summation, quotient series equality, selected convergence witnesses, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite identity exactness, convergence-test handoff, Cauchy-series readback, dyadic accounting, endpoint sealing, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.SummationByPartsUp.

Chapter 5277

A Concrete Naming Certificate for $\mathsf{RealLineOrder}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealLineOrder}^{\uparrow}$ packet records the constructive real-line order and apartness boundary visible to finite BEDC NameCert consumers. It sits over the dyadic tolerance ledger of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the rational Cauchy completion route of chapter 3670, and the Bishop regular Cauchy limit seal of chapter 1821. The packet gives L10 consumers a located comparison interface before any real-order algebra can read it; it does not import trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5277.1 (Real line order carrier)**.** *A* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D, S, R, L, A, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the positive dyadic radius used by every finite comparison request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing only the finite stream observations inspected at that tolerance.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream windows into regular rational comparison data.*
4. *L is the located comparison row, recording the finite verdict surface for $x < y$ as a witnessed positive gap at the displayed tolerance, an unresolved window requiring a smaller displayed tolerance, or a symmetric failure of the current request.*
5. *A is the apartness row, recording positive-gap readback for $x \# y$ only through D, S, R, L.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same displayed stream and regular-rational data, not from host real equality.*
7. *H records componentwise* hsame *transport for dyadic tolerance, stream windows, regular-rational readback, located comparison, apartness, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite order request through $D, S, R, L, A, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, L, A, E, H, C, P, N$. It has no coordinate for trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderTasteGate single carrier alignment`

Theorem 5277.2 (Real line order NameCert obligations)**.** *For every accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier*

$$O = (D, S, R, L, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance row, stream-window row, regular-rational readback row, located comparison row, apartness row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise transport row, replay row, provenance row, and local naming row.*

The obligation surface requires finite tolerance visibility through D, window visibility through S, regular-rational comparison readback through R, located order exposure through L, apartness exposure through A, real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier of Definition 5797.1. The only analytic rows are the dyadic tolerance D, the finite stream windows S, the regular-rational readback R, the located comparison row L, the apartness row A, and the terminal real seal E.

The comparison step is located rather than trichotomic. A finite request may display a positive gap, request a smaller displayed tolerance, or fail symmetrically at the current window; none of these outcomes supplies a global three-way case split.

The equality-sensitive routes are absent. The readback row R is regular-rational data over the displayed windows, and the seal row E is reached only after D, S, R, L, A have been inspected. Thus the packet refuses quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded principles are not coordinates of O, no local NameCert obligation can demand them. □

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderNameCertObligations`

Theorem 5277.3 (Real line order apartness readback)**.** *Every apartness read exported by an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The apartness row A may expose only a positive-gap witness already visible through D, S, R, L. It exports no trichotomy datum, quotient equality, selected representative, host real equality, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Proof. Start with an apartness request. The request must first choose a displayed positive dyadic tolerance in D and inspect the finite windows in S.

The regular-rational readback R is then the only comparison source. The located comparison row L reads this finite data and either displays a positive gap at the requested tolerance or leaves the request unresolved for a smaller displayed tolerance.

The apartness row A can cite only the positive-gap branch already exposed by L. It refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$ because those objects are not carrier rows.

The terminal seal E preserves the same finite route into $\mathsf{Real}^{\uparrow}$. Transport and replay through H and C keep the route stable, while P and N only record provenance and local naming. □

Theorem 5277.4 (Real line order L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier must read the dyadic tolerance, stream-window, regular-rational readback, located comparison, apartness, and* $\mathsf{Real}^{\uparrow}$ *seal rows in the order*

$$D, S, R, L, A, E.$$

Consequently the handoff supplies a finite non-quotient comparison boundary for later real algebra and order packets, while refusing trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. An L10 order request begins with finite tolerance data. The row D fixes the displayed dyadic radius, and S opens only the stream windows inspected at that radius.

The row R repacks those windows as regular-rational readback. The located comparison row L can then answer only with the finite comparison surface generated from D, S, R.

Apartness is downstream of located comparison. The row A may expose a positive gap only when L has already displayed one, and E seals the same finite route as a $\mathsf{Real}^{\uparrow}$-facing endpoint.

Because no earlier or later row stores trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$, the L10 handoff cannot export those principles to later consumers. □

Falsifiable prediction: Every accepted $\mathsf{RealLineOrder}^{\uparrow}$ read must expose dyadic tolerance, StreamName windows, RegSeqRat readback, located comparison, apartness, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before an L10 order consumer can read a comparison boundary.

Independence witness: dyadicratcore, streamname, regseqrat, real, rational-cauchy-completion, bishop-regular-cauchy-limit-seal: $\mathsf{RealLineOrder}^{\uparrow}$ is not bijective to any listed sibling because it binds located comparison and apartness rows to the finite readback route before the RealUp seal is available.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5797.1, Definition 5797.2, Definition 5797.3, and Definition 5797.4 seed the finite non-quotient order and apartness boundary for displayed RealUp names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient equality, selected representatives, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite tolerance visibility, stream-window visibility, regular-rational readback, located comparison, apartness readback, RealUp seal handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.RealLineOrderUp.

Constructive story: A $\mathsf{RealLineOrder}^{\uparrow}$ packet is generated from a DyadicRatCoreUp tolerance row, StreamName finite windows, RegSeqRat readback, located comparison, apartness, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5278

A Concrete Naming Certificate for $\mathsf{SchwartzKernel}^{\uparrow}$

Following Schwartz and Gelfand–Shilov, the $\mathsf{SchwartzKernel}^{\uparrow}$ packet records the finite NameCert route by which a distribution kernel is read as a bilinear action between Schwartz test probes and tempered-distribution endpoints. It sits over the Schwartz-function carrier of chapter 3399, the tempered-distribution endpoint of chapter 2310, the nuclear factorization row of chapter 215, the projective tensor norm route of chapter 4088, the tensor-product source of chapter 87, and the real seal of chapter 38. The chapter exposes the kernel theorem as finite action, tensor, nuclearity, bound, transport, replay, provenance, and local naming rows; it does not import a host distribution space, quotient test-function equality, selected representatives, or an unrestricted topological-vector-space oracle.

Definition 5278.1 (Schwartz kernel carrier)**.** *A* $\mathsf{SchwartzKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, U, J, B, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SchwartzFunction}^{\uparrow}$ *test-probe row naming the finite seminorm windows inspected on the source side.*
2. *T is the* $\mathsf{TemperedDistribution}^{\uparrow}$ *endpoint row naming the distributional action read after the test windows are displayed.*
3. *U is the* $\mathsf{TensorProduct}^{\uparrow}$ *row naming the finite tensor source on which the two test-probe sides are paired.*
4. *J is the* ***??*** *row recording the projective-tensor bound used to compare the paired test windows.*
5. *B is the* $\mathsf{Nuclear}^{\uparrow}$ *factorization row, exposing the finite nuclear decomposition route by which the kernel action is read.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed scalar bounds and kernel-action readbacks.*
7. *H records componentwise* hsame *transport for test probes, tempered endpoint, tensor source, projective bound, nuclear factorization, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite kernel request through $S, T, U, J, B, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SchwartzKernel}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{Nuclear}^{\uparrow}$, ***??***, $\mathsf{TensorProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $S, T, U, J, B, R, H, C, P, N$. It has no coordinate for a host distribution space, quotient equality of test functions, selected representatives, ambient bornological completeness, or a topological-vector-space theorem outside the displayed rows.

Lean4 ✓ `BEDC.Derived.SchwartzKernelUp.SchwartzKernelTasteGate single carrier alignment`

Theorem 5278.2 (Schwartz kernel NameCert obligations)**.** *For every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *carrier*

$$K = (S, T, U, J, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *surface consists exactly of Schwartz test-probe admission through S, tempered-distribution endpoint admission through T, tensor-source admission through U, projective-bound exposure through J, nuclear-factorization exposure through B, scalar RealUp sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every kernel consumer must read the distributional action through these ten rows. No consumer may replace them by an ambient kernel theorem, quotient test-function equality, selected representative, hidden topological vector space, or host nuclear-space completion.

Proof. Project the accepted carrier of Definition 5798.1. The analytic rows are the Schwartz test row S, the tempered-distribution endpoint T, the tensor source U, the projective bound J, the nuclear factorization B, and the RealUp seal R.

The action route is finite. The tensor row U supplies the paired test-probe source, J records the displayed projective bound, and B records the nuclear factorization by which the kernel action becomes readable by a finite consumer.

Transport and replay do not create new analytic structure. The rows H and C preserve the displayed packet componentwise and replay only the same kernel request. The provenance and naming rows P, N package the route without adding host quotient equality or a hidden completion theorem.

Thus the listed rows are exactly the local NameCert obligations for $\mathsf{SchwartzKernel}^\uparrow$. □

Theorem 5278.3 (Schwartz kernel nuclear factorization boundary)**.** *Every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *read factors through the finite route*

$$\mathsf{SchwartzFunction}^\uparrow,\ \mathsf{TensorProduct}^\uparrow,\ ??,\ \mathsf{Nuclear}^\uparrow \longmapsto \mathsf{TemperedDistribution}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The nuclear row may expose only the displayed factorization and bound data already routed through S, U, J. It exports no host theorem identifying all kernels with all continuous bilinear forms, no quotient equality of test probes, no selected representative of a distribution, and no ambient completeness claim for the surrounding function spaces.

Proof. Start with a kernel read. The request first displays the finite Schwartz windows in S and the tensor source U on which the two test-probe sides are paired.

The projective tensor bound J is the only bound row available to the consumer. The nuclear factorization row B can cite only this displayed tensor-bound route, so its readback is a finite factorization certificate rather than an ambient nuclear-space theorem.

The tempered-distribution endpoint T then reads the resulting action, and R seals the scalar outputs as RealUp data. Transport through H and replay through C keep the same row order, while P and N record source and local naming.

Since no carrier coordinate stores host quotient equality, selected representatives, or ambient completeness, those principles cannot be exported by the factorization boundary. □

Falsifiable prediction: Every accepted $\mathsf{SchwartzKernel}^{\uparrow}$ packet must expose SchwartzFunctionUp test probes, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, TemperedDistributionUp endpoint action, RealUp scalar sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a kernel consumer can read the action.

Independence witness: schwartz-function, tempered-distribution, nuclear, projective-tensor-norm, tensorproduct, real: $\mathsf{SchwartzKernel}^{\uparrow}$ is not bijective to any listed sibling because it binds the test-probe tensor route, nuclear factorization boundary, distribution endpoint, and scalar seal as one finite kernel-action packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{SchwartzKernel}^{\uparrow}$ packet is generated from SchwartzFunctionUp test probes, a TemperedDistributionUp endpoint, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, RealUp scalar seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5798.1, Definition 5798.2, Definition 5798.3, the falsifiable prediction, and the independence witness seed the finite kernel-action route over Schwartz, tempered-distribution, tensor, nuclear, bound, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host distribution-space semantics, quotient equality of test functions, selected distribution representatives, ambient nuclear-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, test-probe visibility, tensor-source admission, projective-bound exactness, nuclear-factorization exposure, tempered-endpoint action, RealUp scalar sealing, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SchwartzKernelUp.

Chapter 5279

A Concrete Naming Certificate for $\mathsf{SynonymousTransition}^{\uparrow}$

The $\mathsf{SynonymousTransition}^{\uparrow}$ packet realizes the finite synonymous-transition geometry of Definition 9462.1186 as BEDC NameCert data. It sits beside the six-bit codon-window carrier of chapter 2234, the codon transition matrix of chapter 2245, the DNA boundary-tile packet of chapter 3393, the window-coverage trigger algebra of chapter 3478, and the DNA-window trigger threshold of chapter 4217. The packet names finite codon-window, class-adjacency, boundary-spectrum, threshold, transport, replay, provenance, and local naming rows; it is not a biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Definition 5279.1 (Synonymous transition carrier)**.** *A* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (W, M, A, B, T, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *row naming the finite Q_6 codon-window surface.*
2. *M is the* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *row naming one-bit codon transitions inspected by the packet.*
3. *A is the class-adjacency row recording the displayed synonymous and cross-class adjacency counts, including the largest weights of Definition 9462.1186.*
4. *B is the boundary-spectrum row recording internal edge counts, external boundary degrees, and the control-pair corner-contact data.*
5. *T is the* $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$ *row naming the finite threshold at which an adjacency or boundary-spectrum read may trigger a downstream tile consumer.*
6. *H records componentwise* hsame *transport for codon windows, transition matrix, class adjacency, boundary spectrum, trigger threshold, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite synonymous-transition request through W, M, A, B, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{SynonymousTransition}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{CodonTransitionMatrix}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, M, A, B, T, H, C, P, N$. It has no coordinate for biological mechanism, stochastic fitness, quotient codon equality, hidden enumeration, or an ambient graph-theory oracle outside the displayed finite rows.

Theorem 5279.2 (Synonymous transition NameCert obligations)**.** *For every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier*

$$G = (W, M, A, B, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *surface consists exactly of codon-window admission through W, transition-matrix admission through M, class-adjacency exposure through A, boundary-spectrum exposure through B, trigger-threshold exposure through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every downstream synonymous-transition consumer must read the graph through these nine rows. It cannot replace them by biological causation, stochastic selection, quotient codon semantics, an unrecorded enumeration, or a hidden graph oracle.

Proof. Project the accepted carrier of Definition 5799.1. The finite codon surface is W, the one-bit transition source is M, and the named graph data are the class-adjacency row A and boundary-spectrum row B.

The trigger row T records when the displayed adjacency or boundary-spectrum data may be read by a downstream tile or trigger consumer. It does not add a biological mechanism or a stochastic model; it only names the finite threshold over the same graph rows.

Transport and replay are componentwise. The rows H and C preserve and replay W, M, A, B, T with the same finite endpoints, while P and N record provenance and local naming.

Since the carrier has no coordinate for quotient codon equality, hidden enumeration, biological causation, or ambient graph semantics, the listed rows exhaust the local NameCert obligations. □

Theorem 5279.3 (Synonymous transition boundary-spectrum handoff)**.** *Every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *read factors through the finite route*

$$\mathsf{CodonSixBitWindow}^{\uparrow},\ \mathsf{CodonTransitionMatrix}^{\uparrow} \longmapsto \mathsf{SynonymousTransition}^{\uparrow} \longmapsto \mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{Windo}$$

The handoff exposes class-adjacency weights, internal-edge counts, external boundary degrees, and control-pair corner contacts only as finite packet rows. It exports no biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Proof. Start with the codon-window row W and the one-bit transition matrix row M. These rows supply the finite Q_6 source and the adjacency relation inspected by the packet.

The class-adjacency row A records the largest displayed weights, and B records the boundary-spectrum data. The downstream boundary-tile and trigger-algebra consumers therefore receive a finite graph packet rather than a biological or stochastic explanation.

The threshold row T names when the finite rows can be consumed by the trigger route. Transport through H and replay through C keep the same graph rows visible, while P and N only package their provenance and local name.

Thus every public read of the synonymous-transition geometry remains inside the finite codon-window, transition, adjacency, boundary-spectrum, threshold, transport, replay, provenance, and naming surface. □

Falsifiable prediction: Every accepted $\mathsf{SynonymousTransition}^{\uparrow}$ packet must expose CodonSixBitWindowUp, CodonTransitionMatrixUp, class-adjacency, boundary-spectrum, DNAWindowSixTriggerThresholdUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ rows before a downstream tile or trigger consumer can read the synonymous-transition graph.

Independence witness: codon-six-bit-window, codon-transition-matrix, dna-window-six-boundary-tile, window-coverage-trigger-algebra, dna-window-six-trigger-threshold: $\mathsf{SynonymousTransition}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries class-adjacency weights, boundary-spectrum rows, and trigger-threshold handoff over the finite codon-window graph.

Closure status for $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$.

Constructive story: A $\mathsf{SynonymousTransition}^{\uparrow}$ packet is generated from a CodonSixBitWindowUp source, a CodonTransitionMatrixUp one-bit transition row, class-adjacency counts, boundary-spectrum data, DNAWindowSixTriggerThresholdUp rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5799.1, Definition 5799.2, Definition 5799.3, the falsifiable prediction, and the independence witness seed the finite synonymous-transition packet over codon-window, transition, adjacency, boundary-spectrum, threshold, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic fitness, quotient codon semantics, hidden enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, codon-window visibility, transition-matrix exactness, class-adjacency exposure, boundary-spectrum exposure, trigger-threshold handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SynonymousTransitionUp.

Chapter 5280

A Concrete Naming Certificate for $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$

Following Feller and Billingsley on finite-sum normal approximation, the $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet records the finite BEDC surface by which an iid random-variable window is centered, scaled, read as a distribution row, and handed to a real-normal comparison seal. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the law readback of chapter 186, the regular rational window of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite central-limit-facing certificate; it is not an asymptotic central limit theorem, a characteristic-function convergence theorem, a host probability-limit operator, countable choice, quotient distribution equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5280.1 (Central-limit finite-window carrier)**.** *A* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, V, S, K, D, R, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row V is the displayed iid* $\mathsf{RandomVar}^{\uparrow}$ *window over P, including the finite index range and the shared law token read by the window. The row S is the finite partial-sum ledger naming the displayed sum, the sample count, and the centered numerator. The row K is the centering and scaling row, recording the finite mean token, variance or spread token, positive scale request, and normalized finite-sum expression. The row D is the* $\mathsf{Distribution}^{\uparrow}$ *readback for the normalized finite sum and its comparison request. The row R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *window that presents rational test intervals, tolerances, and finite comparison samples for the distribution read. The row E is the* $\mathsf{Real}^{\uparrow}$ *normal-window seal naming the terminal real comparison against the displayed normal row at the requested finite window. The row H records componentwise* hsame *transport for the probability source, iid window, partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat window, Real normal-window seal, continuation, provenance, and local naming rows. The row C records* Cont *replay from a normal-facing read through P, V, S, K, D, R, E and then through the structural rows. The row Q is the* Pkg *provenance over* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert. *The row N is the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these eleven rows.*

Lean4 ✓ `BEDC.Derived.CentralLimitFiniteWindowUp.TasteGate.CentralLimitFiniteWindowTasteGate single carrier alignment`

Theorem 5280.2 (Central-limit finite-window NameCert obligations)**.** *For every accepted* CentralLimitFiniteWindo *carrier* $(P, V, S, K, D, R, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 5800.1. Carrier admission displays the probability source, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, transport, replay, provenance, and local naming row. The certificate imports no host asymptotic central limit theorem, characteristic-function limit, Lindeberg replacement principle, countable-choice schedule, quotient distribution equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Project the carrier rows in order. The probability source P and iid random-variable window V are the only stochastic data exposed to the certificate, and the partial-sum ledger S fixes the finite sum before any normal-facing read is visible.

The centering and scaling row K then determines the normalized finite expression. The distribution row D and RegSeqRat window R provide the only comparison surface through which a finite law read can reach the terminal $\mathsf{Real}^{\uparrow}$ normal-window seal E.

Finally H, C, Q, N transport, replay, source, and name the same displayed route. Since the carrier has no coordinate for an asymptotic theorem, characteristic-function limit, quotient law equality, countable choice, or ambient completeness, the listed rows exhaust the local finite NameCert surface. □

Theorem 5280.3 (Central-limit finite-window normal handoff)**.** *Every normal-facing read of an accepted* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier factors through the finite route*

$$P \longmapsto V \longmapsto S \longmapsto K \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, Q, N$$

before any consumer receives a normal-window comparison. Thus the read is the displayed iid finite-sum, normalization, distribution, RegSeqRat, and RealUp handoff itself; it exports no host asymptotic CLT, countable choice, quotient distribution equality, characteristic-function convergence principle, or ambient real completeness.

Proof. Begin with a normal-facing request. The only probability data available are the source row P and the finite iid window V, so the request must first read the displayed sample range and shared law token.

The partial-sum row S and normalization row K are then forced. They provide the finite sum, centering token, scaling token, and normalized expression that the downstream distribution read consumes.

The request can reach a normal-window comparison only through D, R, E. The distribution row D names the finite law read, the RegSeqRat row R exposes rational windows and tolerances, and the RealUp row E seals the displayed normal comparison. The structural rows H, C, Q, N preserve that route without adding analytic content.

Therefore every accepted read factors through the finite iid-sum, normalization, distribution, RegSeqRat, and RealUp rows. The excluded asymptotic, choice, quotient, characteristic-function, and completeness principles cannot be inserted into the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet is generated from a probability source row, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5800.1, Definition 5800.2, and Definition 5800.3 seed the finite central-limit-facing handoff through ProbSpace, RandomVar, Distribution, RegSeqRat, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CentralLimitFiniteWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the asymptotic central limit theorem, characteristic-function convergence, Lindeberg replacement, countable-choice schedules, quotient distribution equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, iid-window routing, partial-sum ledger exactness, normalization stability, distribution-to-RegSeqRat handoff, RealUp normal-window nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.CentralLimitFiniteWindowUp.

Chapter 5281

A Concrete Naming Certificate for $\mathsf{LipschitzRealMap}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LipschitzRealMap}^{\uparrow}$ packet records a constructive real-map certificate whose continuity is controlled by a displayed dyadic Lipschitz constant and finite regular-rational windows. It sits after the dyadic tolerance ledger of chapter 291, the countable-name window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the located order and apartness neighbour of chapter 5797. The packet names the finite L10 route by which later continuous-map and metric-uniform-continuity consumers may read a real-valued map without importing host function extensionality, quotient representatives, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5281.1 (Lipschitz real-map carrier)**.** *A* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, K, W, R, M, H, C, P, N)$$

with the following rows:

1. *S is the source* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real input surface through displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
2. *T is the target* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real output surface through the same kind of finite readback.*
3. *K is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *Lipschitz constant row, including the positive dyadic bound and the displayed tolerance ledger used by every modulus request.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the source and target names inspected by the request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the displayed source and target windows into rational comparison data.*
6. *M is the modulus-inequality row, recording that every accepted finite pair of source reads with displayed apartness or distance bound is sent to a target read whose displayed difference is bounded by the dyadic constant in K times the source bound, up to the requested displayed tolerance.*
7. *H records componentwise* hsame *transport for source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a finite map request through $S, T, K, W, R, M, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LipschitzRealMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, T, K, W, R, M, H, C, P, N$. It has no coordinate for host function equality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LipschitzRealMapUp.LipschitzRealMapTasteGate single carrier alignment`

Theorem 5281.2 (Lipschitz real-map NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier*

$$F = (S, T, K, W, R, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* $\mathsf{Real}^{\uparrow}$ *seal, target* $\mathsf{Real}^{\uparrow}$ *seal, dyadic Lipschitz constant, finite StreamName windows, RegSeqRat readback, modulus inequality, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires finite source and target visibility through S and T, dyadic bound visibility through K, finite window visibility through W, rational readback through R, modulus-inequality exposure through M, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses host function extensionality, quotient equality of real presentations, selected representatives, global uniform-continuity principles, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5801.1. The source and target real seals are the only real-name endpoints, and both are read through finite StreamName and RegSeqRat windows rather than through host real equality.

The Lipschitz datum is the dyadic row K. A map request can inspect only the finite windows W and their rational readback R before the modulus row M exposes the displayed inequality for the requested tolerance.

The structural rows do not add analytic content. The transport row H preserves the already displayed source, target, constant, window, readback, and modulus rows componentwise, while C replays the same route and P, N record provenance and local naming.

Since no carrier coordinate stores host function equality, quotient real equality, selected representatives, global uniform continuity, or ambient completeness, no local NameCert obligation can require those objects. □

Theorem 5281.3 (Lipschitz real-map modulus stability)**.** *Let F_0 and F_1 be accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carriers whose source seals, target seals, dyadic Lipschitz constant rows, finite StreamName windows, and RegSeqRat readback rows are componentwise* hsame*-transported. Then every displayed modulus-inequality read exported by F_0 transports to the corresponding displayed modulus-inequality read exported by F_1.*

The stability claim is confined to the finite rows $S, T, K, W, R, M, H, C, P, N$. It does not identify host functions, quotient real presentations, selected Cauchy names, or ambient complete metric structures.

Proof. Start with a displayed modulus request for F_0. Its source and target real seals are read only through the finite StreamName windows and RegSeqRat readback rows named by S, T, W, R.

Use the componentwise hsame hypotheses. They transport the dyadic constant row K and the finite window/readback rows into the corresponding rows of F_1, so the same displayed source tolerance and target tolerance are available after transport.

The modulus row M is a row of the carrier rather than a host theorem about all representatives. Therefore the transported request reads the F_1 modulus row with the same displayed dyadic bound and the transported finite readback data.

Finally C, P, N replay, source, and name the transported route. No quotient equality, host function equality, selected representative, or ambient completeness principle is introduced by this transport. □

Theorem 5281.4 (Lipschitz real-map L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier must read the route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{LipschitzRealMap}^{\uparrow}$$

through the finite source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, transport, replay, provenance, and local NameCert rows. The handoff supplies a finite Lipschitz-control surface for later continuous-map and metric-uniform-continuity packets, while refusing host function extensionality, quotient equality, selected representatives, global uniform-continuity principles, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. An L10 map request begins with source and target real-name seals. By the carrier definition, these seals are visible only through the finite StreamName windows and RegSeqRat readback rows used by S, T, W, R.

The request then reads the dyadic constant row K and the located comparison surface supplied by the real-line order neighbour. These rows provide the displayed source difference and target tolerance against which the modulus inequality is checked.

The modulus row M is the only analytic output of the packet. It hands a consumer a finite inequality route, not a host-level function theorem.

The rows H, C, P, N transport, replay, source, and name the same route. Thus later continuous-map and metric-uniform-continuity packets can consume the finite Lipschitz surface without receiving quotient equality, selected representatives, host function extensionality, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzRealMap}^{\uparrow}$ packet is generated from source and target RealUp seal rows, a DyadicRatCore Lipschitz constant, finite StreamName windows, RegSeqRat readback, a displayed modulus-inequality row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, seed)

Scope closed: Definition 5801.1, Definition 5801.2, Definition 5801.3, and Definition 5801.4 seed the finite Lipschitz real-map surface over the current L10 real and completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and target RealUp sealing, dyadic constant visibility, finite window readback, modulus-inequality stability, transport, replay, provenance, and local naming for future BEDC.Derived.LipschitzRealMapUp.

Chapter 5282

A Concrete Naming Certificate for HyperbolicQuasiGeodesicShadow$^{\uparrow}$

The HyperbolicQuasiGeodesicShadow$^{\uparrow}$ packet realizes the observer-expansion shadow route of section 9463.4 as finite quasi-geodesic, boundary, visual-metric, Busemann, and lamination-compatible rows. It sits after disk readout through chapter 377, the metric surface of chapter 3474, the visual-metric packet of chapter 3866, the Busemann cocycle route of chapter 4134, the geodesic-lamination packet of chapter 4203, and the observer-expansion packet of chapter 4167. The packet names a finite shadow tied to a displayed quasi-geodesic route; it does not complete the boundary, choose a global geodesic representative, identify quotient ideal points, or import host hyperbolic geometry.

Definition 5282.1 (Hyperbolic quasi-geodesic shadow carrier)**.** *A* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, G, E, V, B, L, H, C, P, A, N)$$

with the following rows:

1. *D is the disk readout row, exposing only displayed* UnitDisk$^{\uparrow}$ *coordinates and the associated* HyperbolicMetric$^{\uparrow}$ *metric-read data.*
2. *G is the quasi-geodesic route row, recording the finite path samples, distortion budget, endpoint-facing direction, and local route ledger inspected by the shadow request.*
3. *E is the boundary endpoint row named by the displayed route, not by a completed ideal-boundary quotient.*
4. *V is the visual-metric shadow row, recording the finite shadow window read through* HyperbolicVisualMetric$^{\uparrow}$ *and the boundary endpoint E.*
5. *B is the Busemann cocycle tolerance row, recording the displayed additive tolerance used to compare the route and the shadow window.*
6. *L is the geodesic-lamination compatibility row, recording whether the displayed route is compatible with the finite noncrossing leaf data consumed by* HyperbolicGeodesicLamination$^{\uparrow}$.
7. *H records componentwise* hsame *transport for disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, replay, provenance, refusal, and local naming rows.*
8. *C records displayed* Cont *replay from an observer-expansion shadow request through $D, G, E, V, B, L, H, P, A, N$.*

9. *P is the* Pkg *provenance over* HyperbolicQuasiGeodesicShadow$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HyperbolicGeodesicLamination$^{\uparrow}$, HyperbolicObserverExpar BHist, hsame, Cont, *and* NameCert.
10. *A is the refusal row excluding completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, and host curvature semantics.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, G, E, V, B, L, H, C, P, A, N$.

Theorem 5282.2 (Hyperbolic quasi-geodesic shadow NameCert obligations)**.** *For every accepted* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier*

$$Q = (D, G, E, V, B, L, H, C, P, A, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *surface consists exactly of disk-readout visibility, quasi-geodesic route visibility, boundary endpoint exposure, visual-metric shadow-window exposure, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise transport, replay, provenance, refusal, and local naming rows.*

The packet exports no completed ideal boundary, quotient boundary equality, selected global geodesic, ambient hyperbolic compactification, physical observer trajectory, host curvature theorem, or global field semantics.

Proof. Project the carrier rows in order. The disk readout D supplies the only coordinate and metric source, while G supplies the displayed route samples and distortion budget inspected by the request.

The endpoint and shadow rows are downstream of that route. The endpoint row E names only the boundary read visible from G, and the visual row V records the finite shadow window tied to that endpoint.

The comparison rows B and L keep the shadow route finite. The Busemann tolerance is a displayed cocycle budget, and lamination compatibility is a finite noncrossing-leaf check, not a global geodesic-foliation theorem.

Finally H, C, P, A, N transport, replay, source, refuse, and name the same packet. Since the excluded host objects are not carrier rows, they cannot appear as NameCert obligations. □

Theorem 5282.3 (Hyperbolic quasi-geodesic shadow stability)**.** *Let Q_0 and Q_1 be accepted* HyperbolicQuasiGeodesi *carriers whose disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow window, Busemann tolerance, lamination compatibility, refusal, provenance, and local naming rows are componentwise* hsame*-transported. Then every observer-expansion consumer reads the same finite shadow surface through Q_0 and Q_1.*

The stability claim is confined to the finite rows $D, G, E, V, B, L, H, C, P, A, N$. It does not identify completed boundaries, quotient ideal points, selected geodesics, ambient compactifications, physical observer trajectories, host curvature data, or global fields.

Proof. Start with an observer-expansion shadow request for Q_0. The request must read disk coordinates and metric data through D and then the finite route samples and distortion budget through G.

Use the componentwise hsame transport. It carries the endpoint E, visual shadow window V, Busemann tolerance B, and lamination compatibility row L to the corresponding rows of Q_1.

The refusal row is transported with the same packet. Therefore the transported consumer sees the same excluded host objects and cannot insert completed boundary quotients, selected global geodesics, ambient compactifications, physical trajectories, curvature theorems, or global fields.

The replay row C and the provenance and naming rows P, N then present the transported shadow as the same finite observer-expansion surface. □

Theorem 5282.4 (Hyperbolic quasi-geodesic shadow vision handoff)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ *carrier must read the route*

$\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicGeodesicLaminatio}$

through disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, transport, replay, provenance, refusal, and local NameCert rows. The handoff realizes the vision-level shadow route as finite NameCert data without turning observer expansion into physical cosmology or a host hyperbolic-boundary theorem.

Proof. The vision handoff begins with disk and metric data. Rows D and G ensure that the consumer reads only displayed disk observations, metric readouts, finite route samples, and a distortion budget.

The endpoint and shadow window are then forced. Rows E and V bind the boundary endpoint and visual-metric shadow to the same route, while B records the Busemann tolerance needed to compare route and shadow.

Lamination compatibility is read through L. This makes the packet consumable by geodesic-lamination and observer-expansion rows without selecting a global geodesic representative or completing the boundary.

The rows H, C, P, A, N transport, replay, source, refuse, and name the handoff. Thus the vision-level quasi-geodesic shadow is realized as finite NameCert data and not as ambient hyperbolic geometry. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ read must expose a boundary endpoint, visual-metric shadow window, Busemann cocycle tolerance, quasi-geodesic route, transport row, provenance row, refusal row, and local NameCert before any observer-expansion consumer may read the shadow.

Independence witness: hyperbolic-visual-metric, hyperbolic-busemann-cocycle, hyperbolic-geodesic-lamination, hyperbolic-observer-expansion: $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ is not bijective to these siblings because it binds the quasi-geodesic route and shadow window together before the observer-expansion packet may consume the boundary read.

The Lean TasteGate for this packet must later provide $\mathsf{Nontrivial}\ \mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ in `lean4/BEDC/Derived/HyperbolicQuasiGeodesicShadowUp/` Those instances must keep $D, G, E, V, B, L, H, C, P, A, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ packet is generated from disk readout rows, a quasi-geodesic route, a boundary endpoint, a visual-metric shadow window, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, refusal, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5802.1, Definition 5802.2, Definition 5802.3, and Definition 5802.4 seed the finite quasi-geodesic shadow route for observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, host curvature semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk readout, quasi-geodesic route admission, endpoint exposure, visual-metric shadow windows, Busemann tolerance, lamination compatibility, TasteGate nontriviality, field faithfulness, refusal exactness, transport, replay, provenance, and local naming for future BEDC.Derived.HyperbolicQuasiGeodesicShadowUp.

Chapter 5283

A Concrete Naming Certificate for $\mathsf{Dendrite}^{\uparrow}$

Following Nadler and Kuratowski on continuum theory, the $\mathsf{Dendrite}^{\uparrow}$ packet records the finite BEDC surface for a locally connected compact metric continuum whose tree-like form is read through unique arcs and cutpoint separation. It sits over the compact metric carrier of chapter 129, the locally connected surface of chapter 5809, the Peano continuum boundary of chapter 2160, and the tree certificate of chapter 119. The packet names displayed endpoint, unique-arc, and cutpoint-separation rows; it does not import host continua, arbitrary path spaces, open-cover compactness, or quotient equality of arcs.

Definition 5283.1 (Dendrite carrier)**.** *A* $\mathsf{Dendrite}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric distance rows, finite ProbeBundle-net rows, complete-limit witness rows, and rational tolerance comparisons already certified by the compact-metric chapter.*
2. *L is the* $\mathsf{LocallyConnected}^{\uparrow}$ *row, recording the displayed connected neighbourhood refinements through which local arc and cutpoint requests are inspected.*
3. *P is the* $\mathsf{PeanoContinuum}^{\uparrow}$ *row, binding the compact metric and locally connected continuum surfaces before any dendrite consumer reads an arc boundary.*
4. *T is the* $\mathsf{Tree}^{\uparrow}$ *row, recording the finite tree-like separation surface used to rule out cycle-shaped routes.*
5. *E is the endpoint ledger, listing endpoint rows and their neighbourhood-read witnesses.*
6. *A is the unique-arc ledger, recording for every displayed endpoint or carried point pair the finite arc row, its endpoint membership rows, and its non-branching comparison rows.*
7. *C is the cutpoint-separation ledger, recording the displayed separation rows used when removing a carried point disconnects the relevant finite tree-like boundary.*
8. *H records componentwise* hsame *transport for compact metric data, local connectedness data, Peano-continuum data, tree data, endpoint rows, unique-arc rows, cutpoint-separation rows, replay, provenance, and local naming.*

9. *R records displayed* Cont *replay from a dendrite request through $K, L, P, T, E, A, C, H, G, Q, N$.*
10. *G is the* Pkg *provenance over* $\mathsf{Dendrite}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{PeanoContinuum}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *Q records the local source and consumer provenance for endpoint, unique-arc, and cutpoint-separation reads.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host continuum, arbitrary path selection, open-cover compactness, cycle elimination by excluded middle, or quotient equality of arcs.

Lean4 ✓ `BEDC.Derived.DendriteUp.DendriteTasteGate single carrier alignment`

Theorem 5283.2 (Dendrite NameCert obligations)**.** *For every accepted* $\mathsf{Dendrite}^{\uparrow}$ *carrier*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source, locally connected row, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming;*
2. *compact-continuum visibility, requiring every dendrite consumer to read compact metric and local connectedness data through K, L, P before reading endpoint or arc rows;*
3. *tree-like exactness, requiring the non-cycle and separation information to pass through T and the cutpoint-separation ledger C;*
4. *unique-arc exactness, requiring every arc-facing read to use the displayed ledger A with its endpoint membership and non-branching comparison rows;*
5. *endpoint exactness, requiring endpoint reads to use only the displayed endpoint ledger E and not a host boundary predicate;*
6. hsame, Cont, *and* Pkg *stability, requiring componentwise transport, displayed replay, and provenance to preserve precisely the listed rows;*
7. *non-escape, excluding host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, and quotient equality of arcs.*

No dendrite obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5803.1. The accepted tuple displays exactly the compact metric source, local connectedness, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming.

The compact-continuum route is K, L, P. The compact metric source supplies distance, finite-net, complete-limit, and tolerance-comparison rows; the locally connected row supplies connected neighbourhood refinements; and the Peano-continuum row binds those surfaces before endpoint or arc data are exposed.

The tree-like route is T, E, A, C. The tree row supplies the finite non-cycle surface, the endpoint ledger records boundary reads, the unique-arc ledger records the displayed arc row between

carried point pairs, and the cutpoint-separation ledger records the separation witnesses used by downstream consumers.

Finally, H, R, G, Q, N transport, replay, source, and name the same finite packet. Since the carrier has no row for a host continuum, arbitrary path space, open-cover compactness principle, selected arc representative, or quotient equality of arcs, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$ surface. □

Theorem 5283.3 (Dendrite unique-arc handoff)**.** *Every unique-arc or cutpoint-facing consumer of an accepted* $\mathsf{Dendrite}^\uparrow$ *carrier must read the finite route*

$$\mathsf{CompactMetric}^\uparrow,\ \mathsf{LocallyConnected}^\uparrow,\ \mathsf{PeanoContinuum}^\uparrow,\ \mathsf{Tree}^\uparrow \longmapsto E, A, C, H, R, G, Q, N.$$

The handoff exposes endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It does not expose arbitrary host paths, open-cover compactness, selected arc representatives, quotient equality of arcs, or a continuum object outside the displayed packet.*

Proof. Start with the compact-continuum source. The rows K, L, P force a consumer to read the compact metric, locally connected, and Peano-continuum surfaces before any arc-facing data can be inspected.

Next read the tree row T. This is the only row carrying the tree-like non-cycle surface, so a later cutpoint or arc argument cannot replace it by a host graph or a classical continuum theorem.

The endpoint and arc data are then E, A, C. Endpoint reads pass through E, unique-arc reads pass through A, and cutpoint-separation reads pass through C; the three ledgers remain tied to the same compact-continuum and tree source rows.

The structural rows H, R, G, Q, N preserve this route under transport, replay, provenance, and local naming. Because no excluded host-side row appears in the carrier, the consumer receives exactly the displayed unique-arc handoff and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{Dendrite}^\uparrow$ read must expose CompactMetric, LocallyConnected, PeanoContinuum, Tree, endpoint, unique-arc, cutpoint-separation, componentwise hsame, displayed Cont, Pkg, source provenance, and local NameCert rows before a continuum or arc consumer can inspect the dendrite boundary.

Independence witness: compactmetric, locally-connected, peano-continuum, tree: $\mathsf{Dendrite}^\uparrow$ is not bijective to any listed sibling because it binds endpoint, unique-arc, and cutpoint-separation ledgers over their common compact-continuum and tree-like source.

Closure status for $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$**.**

Constructive story: A $\mathsf{Dendrite}^\uparrow$ packet is generated from CompactMetricUp, LocallyConnectedUp, PeanoContinuumUp, TreeUp, endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, source provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, seed)

Scope closed: Definition 5803.1, Definition 5803.2, and Definition 5803.3 seed the finite dendrite certificate over compact metric, locally connected, Peano-continuum, tree, endpoint, unique-arc, cutpoint-separation, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, quotient equality of arcs, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-continuum visibility, tree-like exactness, endpoint exactness, unique-arc exactness, cutpoint-separation exactness, transport, replay, provenance, and local naming for BEDC.Derived.DendriteUp.

Chapter 5284

A Concrete Naming Certificate for $\mathsf{YoungIntegration}^{\uparrow}$

Following Young's integration theorem and Bishop–Bridges constructive analysis, the $\mathsf{YoungIntegration}^{\uparrow}$ packet records the finite dyadic route for integrating one Holder-controlled path against another. It sits beside the Holder-continuity surface of chapter 1766, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the tagged-mesh Riemann integral boundary of chapter 1526. The chapter names only a finite partition-and-error certificate; it does not import host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5284.1 (Young integration finite partition carrier)**.** *A* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the integrand path row, read through a* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
2. *G is the integrator path row, read through a second* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its own source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
3. *A and B are the two Holder exponent ledgers. They include the finite comparison row witnessing that the displayed exponents have a Young margin for the dyadic partition family.*
4. *W is the dyadic partition-window row. It lists the inspected endpoints, dyadic mesh refinements, cell order, adjacent-cell handoffs, and the finite cells on which the integration read is allowed to form sums.*
5. *V is the cross-variation tolerance ledger. It records the cellwise oscillation products, Holder-bound products, Young-margin comparisons, and finite sum-difference tolerances consumed by the route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for endpoint radii, mesh widths, exponent-comparison margins, oscillation products, and final error bounds.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational trace of dyadic Young sums.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the integral value, reached only after the two Holder rows, dyadic windows, cross-variation ledger, dyadic tolerances, and regular readback have been displayed.*
9. *H records componentwise* hsame *transport for the two Holder paths, exponent ledgers, partition windows, cross-variation ledger, dyadic ledger, readback, Real seal, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from a Young-integration request through Holder admission, dyadic partition windows, cross-variation tolerances, regular rational readback, and the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{YoungIntegration}^{\uparrow}$, $\mathsf{HolderContinuity}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, G, A, B, W, V, D, R, E, H, C, P, N$. It has no coordinate for an ambient path space, quotient equality of functions, a selected sequence of partitions, a hidden limiting argument, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.YoungIntegrationUp.YoungIntegrationTasteGate single carrier alignment`

Theorem 5284.2 (Young integration NameCert obligations)**.** *For every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier $Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *surface is exhausted by admission of two* $\mathsf{HolderContinuity}^{\uparrow}$ *path rows, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting,* $\mathsf{DyadicRatCore}^{\uparrow}$ *exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No accepted consumer may replace these rows by host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5804.1. The rows F and G expose the two Holder-controlled paths, and A, B expose only the finite exponent and Young-margin comparisons attached to those rows.

The partition and tolerance data are then forced. The row W lists the dyadic windows available to the route, while V records the cross-variation products and sum-difference tolerances over exactly those windows.

The terminal read is D, R, E. Dyadic exactness is read through D, the regular rational trace through R, and the Real integral seal through E only after the preceding rows have been consumed.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5284.3 (Young integration dyadic error budget)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *read that reaches the* $\mathsf{Real}^{\uparrow}$ *seal factors through the finite dyadic budget*

$$\mathsf{HolderContinuity}^{\uparrow}, \mathsf{HolderContinuity}^{\uparrow} \longmapsto \mathsf{DyadicPartition}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The row V must display the cross-variation tolerance consumed between the partition windows and the rational readback. Therefore the exported integral value is a finite dyadic Young-sum seal, not a Riemann-integral replacement, a measure-completion integral, a quotient path equality, a selected limiting partition, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the two Holder rows. Their displayed exponents and constants are read through F, G, A, B, so the route has only the finite power-law data needed to bound oscillations on dyadic cells.

Next read the dyadic partition windows. The row W fixes the cells, endpoints, mesh refinements, and adjacent-cell handoffs before any sum-difference comparison is requested.

The error budget is the pair V, D. The cross-variation ledger V records the oscillation products and Young-margin comparisons, and the dyadic ledger D records the exact rational tolerances used to compare any two displayed sums.

The readback and seal are downstream. The regular sequence row R is the only rational trace exported from the finite budgets, and E is the only Real seal. Thus the consumer cannot obtain any of the excluded host-level or choice-level objects from the packet. □

Theorem 5284.4 (Young integration Riemann boundary)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet reads it only as a finite tagged-mesh boundary: two Holder path rows, a dyadic partition-window row, a cross-variation tolerance ledger, dyadic exactness, regular rational readback, Real sealing, transport, replay, provenance, and local naming. The consumer receives no independent Riemann-integral certificate, no Darboux gap claim, no quotient equality of integrands, no measure-completion object, and no selected mesh-limit principle.*

Proof. The only Riemann-facing data in the carrier are the displayed dyadic windows and finite sum budgets. The two Holder path rows provide values to be sampled, while W supplies the finite tagged-mesh boundary.

The cross-variation ledger is not a Darboux or measure-theoretic claim. It records only the tolerance comparisons needed for the Young-sum route before the regular rational readback is sealed as a Real value.

The provenance row may name $\mathsf{RiemannIntegral}^{\uparrow}$ as a consumer boundary, but the local certificate remains $F, G, A, B, W, V, D, R, E, H, C, P, N$. Therefore a Riemann-integral consumer receives a finite boundary row rather than any independent integral theorem or hidden limiting principle. □

Theorem 5284.5 (Young integration Cauchy-modulus consumer)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet whose cross-variation ledger* V *requests a tail precision must consume the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route before* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *sealing. The route remains finite: it exports the displayed Young partition windows, dyadic error budget, explicit Cauchy-modulus handoff, regular rational readback, and terminal Real seal, but it exports no selected limiting partition, countable-choice schedule, hidden modulus oracle, or ambient completion theorem.*

Proof. Project the carrier of Definition 5804.1. The rows W, V, D, R, E expose the partition windows, cross-variation tolerance ledger, dyadic error budget, regular rational readback, and terminal Real seal.

Use Definition 5804.3. The row V is the place where sum-difference tolerances and tail precision demands are recorded, and D is the dyadic ledger that makes those demands finite.

When such a tail precision is requested, apply the effective handoff of Definition 5728.3 and the schedule determinacy of Definition 5728.4. They force the precision request through an explicit $\mathsf{CauchyModulusBridge}^{\uparrow}$ schedule before R can be read and before E can seal the result.

The remaining rows H, C, P, N transport, replay, source, and name the same finite route. Since neither the Young carrier nor the bridge carrier contains a selected limiting partition, countable-choice schedule, hidden oracle, or ambient completion coordinate, no such object is exported. □

Falsifiable prediction: An accepted $\mathsf{YoungIntegration}^{\uparrow}$ packet is refuted if a consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting either $\mathsf{HolderContinuity}^{\uparrow}$ path row, the dyadic partition-window row W, the cross-variation ledger V, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: HolderContinuity, DyadicPartition, DyadicRatCore, RegSeqRat, Real, RiemannIntegral: none is bijective with $\mathsf{YoungIntegration}^{\uparrow}$ because the packet jointly carries two Holder paths, Young-margin exponent rows, dyadic partition windows, cross-variation tolerances, dyadic exactness, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$.

Constructive story: A $\mathsf{YoungIntegration}^{\uparrow}$ packet is generated from two HolderContinuityUp path rows, exponent-margin ledgers, dyadic partition windows, cross-variation tolerance accounting, DyadicRatCore exactness, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5804.1, Definition 5804.2, Definition 5804.3, Definition 5804.4, and Definition 5804.5 seed the finite dyadic Young-integration route over HolderContinuityUp, DyadicPartitionUp, DyadicRatCoreUp, CauchyModulusBridgeUp, RegSeqRatUp, RealUp, and RiemannIntegralUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked two-path admission, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting, dyadic exactness, regular rational readback, Real-seal nonescape, and structural transport for BEDC.Derived.YoungIntegrationUp.

Chapter 5285

A Concrete Naming Certificate for $\mathsf{VariationDiminishing}^{\uparrow}$

Following Schoenberg and Karlin, the $\mathsf{VariationDiminishing}^{\uparrow}$ packet records a finite analysis row for transformations that do not increase displayed sign variation. It consumes the total-variation function surface of chapter 2257, the bounded-variation real-function carrier of chapter 3654, the regulated-function source of chapter 1554, and the tagged integration boundary of chapter 1526. The packet names the finite comparison by which a kernel or transformation row is read as variation-diminishing without importing a host operator algebra, total-positivity theorem, selected partitions, quotient functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5285.1 (Variation-diminishing carrier)**.** *A* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (B, T, R, I, K, M, H, C, P, N)$$

with the following rows:

1. *B is the* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *source row naming the accepted bounded-variation input surface.*
2. *T is the* $\mathsf{TotalVariationFunction}^{\uparrow}$ *row naming the displayed total-variation ledger used to count variation before and after the transformation.*
3. *R is the* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *row naming the regulated readback through which input and output functions are compared by finite step windows.*
4. *I is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *row naming the finite tagged-mesh integration boundary used when the transformation is read by kernel action or integral averaging.*
5. *K is the kernel or transformation row, including its displayed positivity-order or sign-regularity window.*
6. *M is the variation comparison row recording that each accepted finite sign-change ledger for the output is routed to a no-larger sign-change ledger for the input.*
7. *H records componentwise* hsame *transport for bounded-variation source, total-variation ledger, regulated readback, integral boundary, kernel row, comparison row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite transformation request through $B, T, R, I, K, M, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{VariationDiminishing}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RegulatedRealFunction}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and sibling* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, T, R, I, K, M, H, C, P, N$. It has no coordinate for host function equality, quotient representatives, selected limiting partitions, a global total-positivity theorem, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.VariationDiminishingUp.VariationDiminishingTasteGate single carrier alignment`

Theorem 5285.2 (Variation-diminishing NameCert obligations)**.** *For every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier*

$$V = (B, T, R, I, K, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded-variation source row B, total-variation ledger T, regulated-function readback R, Riemann-integral boundary I, kernel or transformation row K, variation comparison row M, componentwise transport H, displayed replay C, provenance P, and local naming N.*

The obligation surface requires every output variation read to pass through the displayed comparison row M after B, T, R, I, K have been projected. It refuses host operator equality, quotient equality of functions, selected partitions, unrestricted total positivity, measure-theoretic kernels, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5805.1. The source row B supplies the bounded-variation input, while T supplies the total-variation ledger on which finite sign-change comparisons can be read.

The rows R and I keep the analytic route finite. Regulated readback gives step-window access to input and output functions, and the Riemann-integral boundary records only the tagged-mesh action needed by a kernel or averaging read.

The row K names the transformation window, and M is the only row that compares variation before and after the transformation. Thus the NameCert consumer obtains a variation-diminishing assertion only through the displayed comparison row, not through a host theorem about all kernels.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores quotient functions, selected limiting partitions, unrestricted total positivity, measure completion, or ambient real completeness, no local obligation can require them. □

Theorem 5285.3 (Variation-diminishing total-variation route)**.** *Every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *consumer read factors through the route*

$$\mathsf{BoundedVariationRealFunction}^{\uparrow},\ \mathsf{TotalVariationFunction}^{\uparrow},\ \mathsf{RegulatedRealFunction}^{\uparrow},\ \mathsf{RiemannIntegral}^{\uparrow} \longmapsto \mathsf{VariationD}$$

The output variation ledger is accepted only after the bounded-variation input, cumulative total-variation ledger, regulated readback, tagged integration boundary, kernel row, and comparison row have been displayed. The route exports no selected limit, quotient function equality, global total-positivity principle, measure-completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. A variation-diminishing request first projects B and T. These rows bind the input function to the bounded-variation and total-variation sibling surfaces, so the requested comparison starts from finite variation data rather than from a host function space.

Next project R and I. The regulated row supplies finite step-window readback, while the integral boundary supplies the tagged-mesh route through which a kernel or averaging transformation can be inspected.

The transformation row K and comparison row M then give the only accepted variation comparison. They state that the displayed output sign-change ledger routes to a no-larger input ledger in the same finite packet.

Finally H, C, P, N preserve the route under transport, replay, provenance, and local naming. Hence every public read of $\mathsf{VariationDiminishing}^{\uparrow}$ passes through the four cited sibling anchors and does not acquire the excluded host-level principles. □

Falsifiable prediction: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet whose output variation read bypasses the displayed total-variation ledger or the regulated readback row is not accepted by the local NameCert.

Independence witness: total-variation-function, bounded-variation-real-function, regulatedrealfunction, riemannintegral: $\mathsf{VariationDiminishing}^{\uparrow}$ is not bijective to any listed sibling because it binds the source variation ledger, regulated readback, tagged integration boundary, transformation row, and no-increase comparison as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet is generated from bounded-variation source data, a total-variation ledger, regulated readback, Riemann tagged-mesh boundary, a kernel or transformation row, a variation comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5805.1, Definition 5805.2, Definition 5805.3, the falsifiable prediction, and the independence witness seed the finite variation-diminishing route over the current analysis rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host operator equality, quotient equality of functions, selected limiting partitions, unrestricted total positivity, measure completion, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation source visibility, total-variation ledger exactness, regulated readback, tagged integration boundary, transformation-row exposure, comparison-row stability, transport, replay, provenance, and local naming for future BEDC.Derived.VariationDiminishingUp.

$\mathsf{FrobeniusReciprocity}^{\uparrow}$ routes induction–restriction comparison through chapter 247, chapter 246, and chapter 245 before the child file states the local certificate.

Chapter 5286

A Concrete Naming Certificate for $\mathsf{FrobeniusReciprocity}^{\uparrow}$

Following Frobenius on induced characters, Serre's finite-group representation theory, and the induction–restriction formulation used by Fulton–Harris, the $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet records the finite comparison row between induction from a subgroup and restriction to that subgroup. It consumes the action rows of chapter 3662, the subgroup source of chapter 80, the representation-ring ledger of chapter 246, the induction–restriction packet of chapter 247, and the character-pairing surface of chapter 245. The packet names only finite source rows, adjunction ledgers, character-pairing boundaries, transport, replay, provenance, and downstream handoff rows; it does not assert a host category of representations, a functor equality, semisimplicity, Schur orthogonality, or a completed character table.

Theorem 5286.1 (FrobeniusReciprocityUp source obligations)**.** *For every accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet, the source surface is the displayed finite tuple*

$$\mathcal{F} = (G, H, R, I, Q, \Phi, \eta, \epsilon, \chi, \lambda, C, P, N),$$

where G is the consumed $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *action row, H is the consumed* $\mathsf{Subgroup}^{\uparrow}$ *row, R is the consumed* $\mathsf{RepresentationRing}^{\uparrow}$ *ledger, I is the consumed* $\mathsf{InducedRep}^{\uparrow}$ *induction–restriction row, Q is the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *pairing row, Φ is the Frobenius comparison row, η, ϵ are the displayed unit and counit rows, χ is the character-pairing boundary, λ is the finite ledger of visible source and endpoint reads, C is componentwise* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *row. No source obligation is imported from a host representation category, quotient carrier, functor category, or external adjunction object.*

Proof. Project the accepted packet. The source rows are precisely G, H, R, I, Q together with the local comparison rows $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

The consumed rows are already finite BEDC certificates. The finite-group representation row supplies the action display, the subgroup row supplies the inclusion boundary, the representation-ring row supplies the Grothendieck ledger, the induced-representation row supplies the induction–restriction endpoints, and the character-theory row supplies the pairing surface.

Since the tuple has no coordinate for a host representation category, quotient carrier, functor category, or external adjunction object, the listed rows exhaust the source obligations. □

Theorem 5286.2 (FrobeniusReciprocityUp adjunction ledger)**.** *The adjunction data of an accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet are exactly the finite rows $\Phi, \eta, \epsilon, \lambda$ over the consumed sources*

H, R, I. The row Φ compares the displayed induction endpoint with the displayed restriction endpoint, η and ϵ record the unit and counit witnesses as BHist *rows, and λ records the visible continuations among source, endpoint, and Frobenius reads. The ledger exports no host naturality square, functor equality, adjunction object, or semisimple decomposition.*

Proof. Begin with the induction–restriction source. The packet consumes the $\mathsf{InducedRep}^{\uparrow}$ row I, so the available endpoints are the displayed induction and restriction rows already carried by that certificate.

The Frobenius comparison is read through Φ. The unit and counit witnesses are read through η and ϵ, and every visible path among source and endpoint reads is recorded by the finite ledger λ.

Exactness is projection from the tuple. Any row outside $\Phi, \eta, \epsilon, \lambda$ is not part of the adjunction ledger, and no host naturality square or functor equality can be recovered from a coordinate that the packet does not carry. □

Theorem 5286.3 (FrobeniusReciprocityUp character-pairing boundary)**.** *Every character-pairing read of a* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet factors through the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *row Q, the representation-ring source R, the induction–restriction source I, and the displayed pairing boundary χ before it can inspect Φ, η, ϵ or λ. The boundary supplies only the finite character-pairing comparison needed for reciprocity and does not export Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra.*

Proof. Read the character side first. The only character-theory coordinate is Q, and the only representation-ring coordinate feeding it is R.

The induction and restriction endpoints enter through I. The displayed pairing boundary χ then names the finite comparison used by the Frobenius row before the ledger reads $\Phi, \eta, \epsilon, \lambda$.

Because the tuple has no coordinate for Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra, every character-pairing read remains inside the stated finite boundary. □

Theorem 5286.4 (FrobeniusReciprocityUp NameCert surface)**.** *The* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *obligation surface is the conjunction of the source obligations of Definition 5806.1, the adjunction ledger of Definition 5806.2, the character-pairing boundary of Definition 5806.3, componentwise* hsame *transport on all displayed source and ledger rows, finite* Cont *replay through C, and* Pkg *provenance through P. The surface exports no obligation outside the displayed tuple $\mathcal{F}$.*

Proof. First combine the source obligations with the adjunction ledger. The source theorem identifies the consumed BEDC certificates, and the ledger theorem identifies the only Frobenius comparison, unit, counit, and continuation rows.

Next add the character-pairing boundary. It places every character read behind Q, R, I, χ before the Frobenius ledger can be inspected.

Finally apply componentwise transport and replay. The rows C and P preserve exactly the displayed tuple, and the local row N names the resulting certificate. Since no obligation outside $\mathcal{F}$ is available, these clauses give the stated NameCert surface. □

Theorem 5286.5 (FrobeniusReciprocityUp consumer handoff)**.** *A downstream consumer of* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *may read exactly the consumed finite-group action row G, subgroup row H, representation-ring row R, induced-representation row I, character-theory row Q, Frobenius rows Φ, η, ϵ, character-pairing boundary χ, visible ledger λ, replay row C, provenance row P, and local name row N. Any consumer handoff to* $\mathsf{InducedRep}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, *or* $\mathsf{CharacterTheory}^{\uparrow}$ *factors through those*

rows and cannot bypass them through a host category, functor equality, semisimplicity theorem, or character-table computation.

Proof. Start with a downstream read. The only visible source coordinates are G, H, R, I, Q, and the only local Frobenius coordinates are $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

For an $\mathsf{InducedRep}^{\uparrow}$ consumer, the handoff is through I together with the Frobenius rows. For a $\mathsf{RepresentationRing}^{\uparrow}$ consumer, the handoff is through R and the source ledger. For a $\mathsf{CharacterTheory}^{\uparrow}$ consumer, the handoff is through Q and the pairing boundary χ.

The replay and provenance rows preserve the same finite route. Thus a consumer cannot bypass the displayed packet through a host category, functor equality, semisimplicity theorem, or character-table computation. □

Theorem 5286.6 (FrobeniusReciprocityUp sibling lattice)**.** *The* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet is a finite comparison consumer of the sibling carriers in chapter 3662, chapter 80, chapter 246, chapter 247, and chapter 245. Its local rows compare induction and restriction after those carriers are visible; they do not form an isolated kernel row and do not replace the representation, subgroup, ring, induced-representation, or character-theory certificates.*

Proof. Read the source tuple of Definition 5806.1. The rows G, H, R, I, Q are precisely the five sibling certificates named in the statement.

The consumer handoff of Definition 5806.5 permits downstream reads only through those rows together with the Frobenius comparison, unit, counit, pairing boundary, ledger, replay, provenance, and local name rows.

Therefore the packet sits inside the displayed representation-theory lattice. It is a comparison consumer over the sibling carriers, not a standalone kernel surface from which the sibling certificates can be reconstructed. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5806.1, Definition 5806.2, Definition 5806.3, Definition 5806.4, Definition 5806.5, and Definition 5806.6 seed the finite Frobenius reciprocity certificate over displayed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, semisimplicity, Schur orthogonality, irreducible decomposition, character-table computation, functor-category equality, or a host adjunction theorem.

Upgrade path: Obligation closure requires checked carrier admission, adjunction-ledger exactness, character-pairing boundary, NameCert surface, and downstream handoff for the same finite packet.

Constructive story: A $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet is generated from consumed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows, then records a finite Frobenius comparison, unit and counit rows, character-pairing boundary, visible continuation ledger, package provenance, and local NameCert evidence.

Chapter 5287

A Concrete Naming Certificate for $\mathsf{NormalOperator}^{\uparrow}$

Following Reed and Simon, the $\mathsf{NormalOperator}^{\uparrow}$ packet records the standard normal-operator surface as finite NameCert data over displayed Hilbert and inner-product candidates. It consumes the inner-product carrier of chapter 86, the Hilbert carrier of chapter 91, the linear-map rows of chapter 48, the operator-norm boundary of chapter 3603, and the downstream spectral-theorem consumer of chapter 214. The packet exposes only a bounded linear operator, its displayed adjoint-action row, the norm ledger, and the normality commutator row; it does not claim spectral measure existence, functional calculus, diagonalization, projection-valued measures, or a host operator algebra.

Definition 5287.1 (NormalOperator carrier)**.** *For a displayed* $\mathsf{Hilbert}^{\uparrow}$ *candidate* H *with* $\mathsf{InnerProduct}^{\uparrow}$ *row* I*, a* $\mathsf{NormalOperator}^{\uparrow}(H)$ *carrier is a finite* BHist *packet*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N)$$

with the following ten displayed fields:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *carrier row and I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row over the same point-history carrier.*
2. *T is a bounded* $\mathsf{LinMap}^{\uparrow}$ *endpoint action on the carried Hilbert endpoints.*
3. *T^* is the displayed adjoint-action row, certified by the finite inner-product comparison*

   $$\langle Tx, y\rangle_I \ \mathsf{hsame}\ \langle x, T^*y\rangle_I$$

   for the vector histories inspected by the packet.
4. *A is the adjoint-domain ledger, recording that the adjoint row is read over the same Hilbert, inner-product, linear-map, and boundedness surfaces as T.*
5. *K is the* $\mathsf{OperatorNorm}^{\uparrow}$ *bound row for T and for the displayed adjoint action T^*.*
6. *Q is the normality commutator row*

   $$T^*T \ \mathsf{hsame}\ TT^*$$

   read only on certified vector histories.
7. *L is the operator graph ledger: it stores inspected input histories, output histories, linearity rows, adjoint rows, norm-bound rows, and the commutator row.*

8. *H_T records componentwise* hsame *transport for the Hilbert source, inner-product row, endpoint actions, adjoint row, norm row, commutator row, and ledger.*
9. *C records displayed* Cont *replay for endpoint action requests, adjoint-action requests, norm-bound requests, and commutator inspections.*
10. *P, N are the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *naming rows.*

The classifier compares accepted carriers by action agreement on certified vector histories, adjoint-action agreement on the same inspected histories, transport of the operator-norm row, and transport of the graph, adjoint, normality, continuation, provenance, and local-name ledgers. It has no coordinate for host operator equality, quotient completion, spectral measures, eigenvector bases, or external functional calculus.

Lean4 ✓ `BEDC.Derived.NormalOperatorUp.NormalOperatorTasteGate single carrier alignment`

Theorem 5287.2 (NormalOperator NameCert obligations)**.** *For every accepted* $\mathsf{NormalOperator}^\uparrow$ *carrier*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the common* $\mathsf{Hilbert}^\uparrow$ *and* $\mathsf{InnerProduct}^\uparrow$ *rows;*
2. *bounded* $\mathsf{LinMap}^\uparrow$ *action for T on certified vector histories;*
3. *adjoint-action agreement for T^* against the displayed inner product;*
4. $\mathsf{OperatorNorm}^\uparrow$ *bound rows for the operator action and adjoint action;*
5. *normality commutator exactness through the displayed row Q;*
6. *graph-ledger exactness for input histories, output histories, linearity rows, adjoint rows, norm rows, and commutator rows;*
7. *classifier transport by action agreement, adjoint-action agreement, norm-row agreement, and componentwise ledger transport;*
8. Cont *replay,* Pkg *provenance, and local naming for exactly the displayed packet;*
9. *refusal of spectral measure existence, diagonalization, projection-valued measures, host operator quotients, and unrecorded functional calculus.*

Proof. Project the carrier of Definition 5807.1. The Hilbert and inner-product source rows, endpoint action, adjoint-action row, adjoint-domain ledger, norm row, commutator row, graph ledger, transport row, continuation row, provenance row, and local name are the full displayed inventory.

The adjoint and boundedness obligations are read before any spectral consumer appears. The adjoint row is the finite inner-product comparison for certified vector histories, and the norm row is the displayed $\mathsf{OperatorNorm}^\uparrow$ bound attached to both endpoint actions.

Normality is exactly the commutator row Q. Because Q compares T^*T and TT^* only through inspected vector histories and their graph ledger, the packet does not appeal to host equality of operators.

Finally H_T, C, P, N transport, replay, source, and name those rows. Since the carrier has no spectral-measure, diagonalization, projection-valued-measure, quotient, or functional-calculus coordinate, the listed rows exhaust the local normal-operator NameCert obligations. □

Theorem 5287.3 (NormalOperator InnerProduct spectral anchor)**.** *Every downstream spectral read of an accepted* $\mathsf{NormalOperator}^{\uparrow}$ *packet factors through the common Hilbert and inner-product rows, the bounded linear action, the displayed adjoint-action row, the operator-norm bound, and the normality commutator ledger before it can be consumed by the* $\mathsf{SpectralTheorem}^{\uparrow}$ *surface. The route is*

$$(H, I) \longmapsto (T, T^*, A, K, Q, L) \longmapsto (H_T, C, P, N),$$

and it exports no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality.

Proof. Expose the accepted packet by Definition 5807.1. The only analytic source rows are the Hilbert carrier, inner-product comparison row, endpoint action, displayed adjoint action, norm bound, and normality commutator.

Apply Definition 5807.2. The graph ledger forces the operator action, adjoint action, boundedness evidence, and commutator evidence to be read from one finite packet, and classifier transport keeps the operator and adjoint rows over the same certified vector histories.

It remains to hand the packet to spectral consumers. The $\mathsf{SpectralTheorem}^{\uparrow}$ chapter may consume the normality anchor only through the displayed rows already named here. Because no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality is a field of the carrier, the anchor supplies a pre-spectral normal-operator surface rather than a spectral theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5807.1, Definition 5807.2, and Definition 5807.3 seed the normal-operator surface over Hilbert, inner-product, bounded linear-map, adjoint-action, operator-norm, and commutator rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim spectral measures, spectral projections, diagonalization, eigenbasis construction, Borel functional calculus, host operator quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, adjoint-action agreement, norm-bound stability, normality commutator exactness, classifier transport, graph-ledger exactness, spectral-consumer nonescape, and bridge data for BEDC.Derived.NormalOperatorUp.

Constructive story: A $\mathsf{NormalOperator}^{\uparrow}$ packet is generated from a Hilbert source, an inner-product row, a bounded linear endpoint action, a displayed adjoint action, operator-norm bounds, a normality commutator row, graph and transport ledgers, continuation replay, provenance, and a local NameCert row.

Chapter 5288

A Concrete Naming Certificate for $\mathsf{HausdorffMeasure}^{\uparrow}$

Following Hausdorff and Federer's metric measure theory, the $\mathsf{HausdorffMeasure}^{\uparrow}$ packet records the finite dyadic-cover surface through which Hausdorff content and scale-stable measure reads become visible inside BEDC. It sits over the metric carrier of chapter 57, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the cover-valued outer-measure boundary of chapter 3385, and the finite scale-cover comparison surface of chapter 3877. The packet names only displayed dyadic cover packets, diameter budgets, weighted cover sums, scale comparison, transport, replay, provenance, and local naming; it is not a quotient cover family, not a selected infimum, not countable choice over covers, and not an ambient measure primitive.

Definition 5288.1 (Hausdorff measure dyadic-cover carrier)**.** *A* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (M, D, R, O, B, C, S, T, E, K, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the finite point classifier and distance comparisons used to bound cover diameters.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row, naming the dyadic radius budget and dyadic exponent used by the cover packet.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *value-seal row for diameter powers and finite cover sums.*
4. *O is the* $\mathsf{OuterMeasure}^{\uparrow}$ *handoff row, read only as a finite cover-valued boundary and not as a completed measure primitive.*
5. *B is the* $\mathsf{BoxDimension}^{\uparrow}$ *comparison row, exposing finite scale-cover counts against the same dyadic scale.*
6. *C is the finite dyadic cover packet, listing the displayed cover cells, their metric diameter witnesses, and their membership reads.*
7. *S is the cover-sum ledger, recording the finite Real-sealed sum of dyadic diameter weights.*
8. *T is the scale-stability ledger, recording that dyadic refinement reads the same metric source, outer-measure boundary, and box-dimension comparison rows.*
9. *E records componentwise* hsame *transport for metric, dyadic scale, Real seal, outer-measure handoff, box-dimension comparison, cover packet, cover sum, and stability rows.*

10. *K records displayed* Cont *replay from a metric source and dyadic scale through C, S, T, E, P, N.*
11. *P is the* Pkg *provenance over* $\mathsf{HausdorffMeasure}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{OuterMeasure}^{\uparrow}$, $\mathsf{BoxDimension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D, R, O, B, C, S, T, E, K, P, N$. It has no coordinate for quotient cover families, selected infima, countable-choice schedules over covers, host sigma-algebras, or ambient measure primitives.

Lean4 ✓ `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate single carrier alignment`

Theorem 5288.2 (Hausdorff measure NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier $H = (M, D, R, O, B, C, S, T, E, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *surface consists exactly of metric source admission, dyadic scale exposure, Real value sealing, finite outer-measure handoff, box-dimension scale comparison, finite dyadic cover admission, cover-sum exactness, scale-stability replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every measure-facing or dimension-facing consumer must read the displayed route*

$$\mathsf{Met}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto C, S, T \longmapsto \mathsf{OuterMeasure}^{\uparrow}, \mathsf{BoxDimension}^{\uparrow} \longmapsto E, K, P, N$$

before treating the packet as a Hausdorff-measure read.

Proof. Project the carrier of Definition 5808.1. The metric row M, dyadic row D, and Real seal row R are the only sources for distances, scales, and finite value readback.

The cover packet C and cover-sum ledger S are finite rows. They record displayed cover cells and dyadic diameter weights, so no step selects a minimizing cover family or takes an external infimum.

The outer-measure and box-dimension rows O, B are downstream comparison boundaries. They can read the same finite cover data, but they do not add a completed host measure, a quotient of covers, or countable choice over refinements.

Finally T, E, K, P, N transport, replay, source, and name the same finite route. Since every exported obligation is one of the listed rows, the local classifier cannot expose an ambient measure primitive or any detached cover selector. □

Theorem 5288.3 (Hausdorff measure dyadic-cover stability)**.** *Let $H = (M, D, R, O, B, C, S, T, E, K, P, N)$ be an accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier. For any displayed dyadic refinement of the scale row D, the scale-stability ledger T forces the refined read to reuse the same* $\mathsf{Met}^{\uparrow}$ *source, the same* $\mathsf{Real}^{\uparrow}$ *value-seal route, the same finite* $\mathsf{OuterMeasure}^{\uparrow}$ *cover boundary, and the same* $\mathsf{BoxDimension}^{\uparrow}$ *scale-count comparison before any consumer reads a Hausdorff-measure claim. The stable route is*

$$M, D, R, C, S, T \longmapsto O, B \longmapsto E, K, P, N.$$

It exports no quotient cover family, selected infimum, countable-choice cover schedule, host sigma-algebra closure, or ambient measure primitive.

Proof. Read the carrier of Definition 5808.1. A dyadic refinement changes only the displayed scale request inside D and the finite cover packet admitted by C.

Use the stability ledger T. It records that the refined cover is replayed against the same metric source and that its finite cover sum is sealed through the same Real row, so the refinement cannot introduce a detached minimizing cover or a host infimum.

The comparison rows O and B then read the refined packet as finite outer-measure and box-dimension boundary data. Componentwise transport and displayed replay through E, K, P, N preserve that route, while quotient covers, countable choice, host sigma-algebras, and ambient measure primitives remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HausdorffMeasure}^{\uparrow}$ consumer that reaches a Hausdorff-measure read without first exposing a MetricUp source row, a DyadicRatCore scale row, a RealUp value seal, a finite dyadic cover packet, a finite cover-sum ledger, an OuterMeasureUp handoff, a BoxDimensionUp comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row refutes the carrier surface.

Independence witness: metric, dyadicratcore, real, outermeasure, boxdimension: $\mathsf{HausdorffMeasure}^{\uparrow}$ is not bijective to any listed sibling because it binds metric diameter data, dyadic scales, Real-sealed finite cover sums, outer-measure cover boundaries, and box-dimension scale counts into one finite cover-stability NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffMeasure}^{\uparrow}$ packet is generated from a MetricUp source row, DyadicRatCore scale row, RealUp value-seal row, finite OuterMeasureUp handoff, BoxDimensionUp comparison row, finite dyadic cover packet, cover-sum ledger, scale-stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5808.1, Definition 5808.2, and Definition 5808.3 seed the finite dyadic-cover Hausdorff-measure interface over MetricUp, DyadicRatCoreUp, RealUp, OuterMeasureUp, and BoxDimensionUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient cover families, selected infima, countable choice over covers, host sigma-algebra completion, ambient measure primitives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic scale exposure, finite cover admission, cover-sum exactness, scale-stability replay, outer-measure handoff, box-dimension comparison, transport, provenance, and no-escape for BEDC.Derived.HausdorffMeasureUp.

Chapter 5289

A Concrete Naming Certificate for $\mathsf{LocallyConnected}^{\uparrow}$

Following Kelley and Bourbaki on local connectedness, the $\mathsf{LocallyConnected}^{\uparrow}$ packet records finite neighbourhood-component data rather than a selected basis of connected open sets. It sits beside the global connectedness carrier of chapter 2353, the compact metric source discipline of chapter 129, the metric ball rows of chapter 57, and the open-neighbourhood ledger of chapter 88. The packet exposes the local component route needed by compact-metric and connected-space consumers without importing path selection, arc connectedness, open-cover compactness, or a host topological basis.

Definition 5289.1 (Locally connected carrier)**.** *A* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, M, G, K, B, C, H, R, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-neighbourhood row whose entries name the ambient open requests.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *ball-observation row used when the local request is metric.*
3. *G is the* $\mathsf{ConnectedSpace}^{\uparrow}$ *global component row available to consumers that compare local and global connectedness.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-source row available to compact-metric consumers.*
5. *B is the finite neighbourhood-refinement row: each displayed point and open request has a named smaller neighbourhood row.*
6. *C is the local connected-component row attached to the refinement in B.*
7. *H records componentwise* hsame *transport for the topology, metric, connectedness, compact-metric, refinement, component, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from an ambient open request through metric ball observations when present, the finite refinement row, and the local component row.*
9. *P is the* Pkg *provenance over* $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConnectedSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, M, G, K, B, C, H, R, P, N$. It has no coordinate for selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, or a host basis of connected neighbourhoods.

Lean4 ✓ `BEDC.Derived.LocallyConnectedUp.TasteGate.LocallyConnectedTasteGate single carrier alignment`

Theorem 5289.2 (Locally connected NameCert obligations)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier* $L = (T, M, G, K, B, C, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *surface consists exactly of carrier admission for the topology, metric, connected-space, compact-metric, finite neighbourhood-refinement, local component, transport, replay, provenance, and naming rows; neighbourhood refinement from T through B; component exposure through C; metric compatibility through M when the request is ball-based; compact-metric compatibility through K for compact finite-source consumers; connected-space comparison through G; and non-escape from selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice.*

Proof. Project the carrier of Definition 5809.1. The projection exposes exactly the rows $T, M, G, K, B, C, H, R, P, N$ so every local naming obligation must be read from those coordinates.

The neighbourhood part is finite. An ambient open request is first read in T, then refined by the displayed row B, and only then receives the local component row C.

The metric and compact-metric rows are compatibility rows rather than extra selectors. A ball-based request may inspect M, and a compact-metric consumer may inspect K, but both routes still pass through the same B and C rows before local connectedness is exported.

Finally, H and R transport and replay the displayed route, while P and N source and name it. Since paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice are not rows of the carrier, the NameCert surface cannot export them. □

Theorem 5289.3 (Locally connected neighbourhood component route)**.** *Every connected-space or compact-metric consumer of an accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *packet reaches local connectedness through*

$$\mathsf{Topology}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{ConnectedSpace}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The finite route reads an ambient neighbourhood, optionally reads metric ball observations, refines to a displayed smaller neighbourhood, and then reads the named local connected component. It does not select a path, an arc, a subcover, a quotient component representative, or a host connected-neighbourhood basis.

Proof. Start with a consumer that asks for local connectedness around a displayed point. Carrier admission gives the consumer the topology row T, the metric row M when a ball observation is part of the request, the global connectedness row G, and the compact-metric row K.

The route then passes through B and C. The row B supplies the finite neighbourhood refinement, and C supplies the local component attached to that refinement.

The structural rows H, R, P, N do not add a hidden selector. They transport, replay, source, and name the same finite route, so no path, arc, arbitrary subcover, quotient representative, or host basis can replace the displayed neighbourhood-component data. □

Theorem 5289.4 (Locally connected obligation closure surface)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier* $L = (T, M, G, K, B, C, H, R, P, N)$*, the obligation-closure surface is exhausted by the displayed finite topology, metric, connected-space, compact-metric, neighbourhood-refinement, local-component, transport, replay, provenance, and naming rows. The row T supplies the open-neighbourhood*

source, M supplies metric-ball observations, G supplies connected-space comparison, K supplies compact-metric finite-source compatibility, B, C supply the local refinement and component rows, and H, R, P, N supply transport, replay, provenance, and local naming.

The local component route therefore consumes the connected-space carrier of chapter 2353, the compact-metric finite neighbourhood discipline of chapter 129, the metric-ball rows of chapter 57, and the topology neighbourhood ledger of chapter 88 before a local component can be named.

Proof. Apply Definition 5809.2 to the accepted carrier. It identifies the complete NameCert surface with the rows $T, M, G, K, B, C, H, R, P, N$.

Apply Definition 5809.3. The route from an open request to a local component passes through topology, optional metric-ball observations, connected-space comparison, compact-metric compatibility, finite refinement, and component rows before the structural rows transport and name the result.

The sibling lattice is read in that order: topology supplies the neighbourhood ledger, metric supplies ball observations, connected-space supplies the comparison carrier, and compact metric supplies the finite neighbourhood discipline. The local refinement and component rows then bind those sibling contributions into the $\mathsf{LocallyConnected}^{\uparrow}$ packet.

Thus the obligation surface is the stated finite route. Path or arc selection, open-cover compactness, quotient components, and a host basis are refused because none of them is a carrier coordinate or a row used by the two preceding theorems. □

Falsifiable prediction: Every accepted $\mathsf{LocallyConnected}^{\uparrow}$ read must expose a $\mathsf{Topology}^{\uparrow}$ open-neighbourhood row, optional $\mathsf{Met}^{\uparrow}$ ball observations, the $\mathsf{ConnectedSpace}^{\uparrow}$ comparison row when a global consumer is present, the $\mathsf{CompactMetric}^{\uparrow}$ finite-source row when a compact-metric consumer is present, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: topology, metric, connected-space, compactmetric: $\mathsf{LocallyConnected}^{\uparrow}$ is not bijective to any listed sibling because it binds a local neighbourhood-refinement row to a local component row before connected-space or compact-metric consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5809.1, Definition 5809.2, and Definition 5809.3 seed the finite local neighbourhood-component route over topology, metric, connected-space, and compact-metric rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close path connectedness, arc connectedness, arbitrary open-cover compactness, quotient component spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, neighbourhood refinement, local component exposure, connected-space comparison, compact-metric compatibility, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.LocallyConnectedUp.

Constructive story: A $\mathsf{LocallyConnected}^{\uparrow}$ packet is generated from an open-neighbourhood row, optional metric ball observations, connected-space and compact-metric compatibility rows, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5290

A Concrete Naming Certificate for $\mathsf{BishopCauchyMean}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{BishopCauchyMean}^{\uparrow}$ packet records the finite averaging step used when a Cauchy source is read through displayed rational windows and sealed as a Real-facing name. It sits after the $\mathsf{Cauchy}^{\uparrow}$ source route of chapter 3413, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names finite averages of observed Cauchy data; it does not assert a selected limit, quotient stream equality, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5290.1 (Bishop Cauchy mean carrier)**.** *A* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Cauchy}^{\uparrow}$ *source row naming the Cauchy data whose finite observations are being averaged.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested dyadic radius, denominator budget, and comparison scale for the average.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the source entries inspected at tolerance D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream window into regular rational data.*
5. *A is the finite averaging ledger: it lists the inspected rational entries, their displayed weights, the denominator row, the partial-sum row, and the final mean row consumed by the certificate.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, W, R, A have been displayed.*
7. *H records componentwise* hsame *transport for the source, tolerance, window, readback, averaging ledger, Real seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a finite mean request through $S, D, W, R, A, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyMean}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, D, W, R, A, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness of $\mathsf{Real}^{\uparrow}$*, or an infinite averaging oracle.*

Lean4 ✓ `BEDC.Derived.BishopCauchyMeanUp.BishopCauchyMeanTasteGate single carrier alignment`

Theorem 5290.2 (Bishop Cauchy mean NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier*

$$M = (S, D, W, R, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cauchy source row, dyadic tolerance row, finite stream window, regular rational readback, finite averaging ledger, terminal Real seal, componentwise transport row, displayed continuation replay, package provenance, and local naming row.*

The obligation surface requires Cauchy-source visibility through S, tolerance accounting through D, finite-window visibility through W, regular rational readback through R, average-ledger exactness through A, Real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It refuses selected limits, quotient stream equality, host real equality, countable choice, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the accepted carrier of Definition 5810.1. The only analytic rows are the Cauchy source S, the dyadic tolerance D, the finite window W, the regular rational readback R, the averaging ledger A, and the terminal Real seal E.

The averaging step is finite. The ledger A displays the inspected rational entries, their weights, the denominator row, the partial sums, and the final mean; no later consumer can ask for an average outside this listed window.

The terminal seal is downstream of the displayed route. Since the carrier has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness, or an infinite averaging oracle, those objects cannot enter the local NameCert surface.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. They preserve the displayed rows and do not add analytic content. □

Theorem 5290.3 (Bishop Cauchy mean finite-average stability)**.** *Let*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

be an accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier. Every accepted consumer read of the mean row factors through the finite route*

$$\mathsf{Cauchy}^{\uparrow}(S),\ \mathsf{DyadicRatCore}^{\uparrow}(D),\ \mathsf{StreamName}^{\uparrow}(W),\ \mathsf{RegSeqRat}^{\uparrow}(R),\ A,\ \mathsf{Real}^{\uparrow}(E).$$

If the source row, tolerance row, finite window, readback row, and averaging ledger are transported componentwise by the displayed hsame *rows in H and replayed through C, then the consumer-visible mean row is unchanged as a* $\mathsf{BishopCauchyMean}^{\uparrow}$ *read. No quotient stream equality, selected limit, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row participates in the stability claim.*

Proof. Start with the consumer route. By the carrier definition, a mean read must first inspect the Cauchy source S, choose the displayed dyadic tolerance D, open the finite window W, and read the regular rational row R.

The average itself is then the ledger row A. Its entries, weights, denominator, partial sums, and final mean are finite displayed data, so componentwise hsame transport preserves exactly the rows that the consumer can inspect.

Replay through C exposes the transported packet with the same provenance and local naming rows P, N. The terminal Real seal E is reached from that transported finite route, not from a quotient stream or selected limit.

Thus any consumer-visible equality of mean reads is exhausted by $S, D, W, R, A, E, H, C, P, N$. The excluded rows are absent from the carrier and cannot affect the stability conclusion. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ read must expose a Cauchy source, dyadic tolerance, StreamName window, RegSeqRat readback, finite averaging ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a Real or Completion consumer can read the mean boundary.

Independence witness: cauchy, dyadicratcore, streamname, regseqrat, real: $\mathsf{BishopCauchyMean}^{\uparrow}$ is not bijective to any listed sibling because it binds a finite averaging ledger between regular rational readback and the Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyMean}^{\uparrow}$ packet is generated from a Cauchy source row, DyadicRatCore tolerance row, StreamName finite window, RegSeqRat readback, finite averaging ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5810.1, Definition 5810.2, and Definition 5810.3 seed the finite Cauchy-mean certificate over Cauchy, DyadicRatCore, StreamName, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite average ledger exactness, tolerance-window readback, regular rational handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyMeanUp.

Chapter 5291

A Concrete Naming Certificate for $\mathsf{BishopFixedPointInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet records the constructive interval fixed-point route as finite NameCert data. It sits after the located interval source of chapter 394, the bisection discipline of chapter 1465, the finite Cauchy-modulus rows used by chapter 292, the regular rational readback of chapter 301, the finite name windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the fixed-point certificate for a displayed interval self-map; it does not import a host compactness theorem, quotient real equality, choice-selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5291.1 (Bishop fixed-point interval carrier)**.** *A* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, T, M, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the closed located interval, its endpoint reads, and its dyadic radius ledger.*
2. *T is the contraction self-map row over I, recording that every admitted interval point is sent back into the same located interval.*
3. *M is an explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *or Lipschitz modulus row that turns each tolerance request into a finite contraction budget.*
4. *B is the* $\mathsf{IntervalBisection}^{\uparrow}$ *or nested located interval row that records the displayed shrinking interval chain.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the rational midpoint, endpoint, and radius observations.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *fixed-point seal reached only after the interval, contraction, modulus, bisection, and readback rows have been exposed.*
7. *H records componentwise* hsame *transport for I, T, M, B, R, E and for the structural rows.*
8. *C records displayed* Cont *replay for interval requests, contraction reads, modulus reads, nested interval reads, rational readback, and real-seal requests.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopFixedPointInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{IntervalBisection}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, T, M, B, R, E, H, C, P, N$. It has no coordinate for a host fixed-point theorem, quotient completion, selected limit, trichotomy, countable choice, or ambient compactness principle.

Lean4 ✓ `BEDC.Derived.BishopFixedPointIntervalUp.BishopFixedPointIntervalTasteGate single carrier alignment`

Theorem 5291.2 (Bishop fixed-point interval NameCert obligations)**.** *For every accepted* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *carrier*

$$F = (I, T, M, B, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the located interval row I, contraction self-map row T, explicit modulus row M, nested bisection row B, regular rational readback row R, terminal real seal E, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N. Every fixed-point consumer must read these rows in the displayed order and cannot replace them by host interval compactness, quotient real equality, a selected limit, or an unrecorded convergence principle.*

Proof. Carrier admission is the finite packet of Definition 5811.1. The rows $I, T, M, B, R, E, H, C, P, N$ are the only coordinates available to the local certificate.

The positive interval route is then forced. The interval source is I, the self-map evidence is T, the contraction budget is M, and the nested interval chain is B; each row is compared only through the componentwise transport row H and replayed only through C.

The readback and seal are downstream. Rational observations pass through R and the dyadic and stream-name data named in P before the terminal $\mathsf{Real}^{\uparrow}$ row E is exposed. Since no host compactness, quotient equality, selected limit, or external convergence coordinate occurs in the carrier, the listed rows exhaust the NameCert surface. □

Theorem 5291.3 (Bishop fixed-point interval Cauchy-modulus route)**.** *Let $F = (I, T, M, B, R, E, H, C, P, N)$ be an accepted* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *packet. Each tolerance request for the fixed-point name is answered by first reading the* $\mathsf{LocatedInterval}^{\uparrow}$ *row I, then the contraction self-map row T, then the explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *or Lipschitz row M, and only then the* $\mathsf{IntervalBisection}^{\uparrow}$ *or nested located interval row B. The resulting finite observations are read through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *as recorded by P, so no consumer can infer convergence from an unbounded host iteration or a choice-selected subsequence.*

Proof. Start with a tolerance request. The packet has no direct convergence row, so the request must project I to know the interval source and T to know that the displayed map remains inside the interval.

Next read the modulus row M. This row converts the tolerance into a finite contraction or Lipschitz budget. The nested row B can then expose only the finite bisection or located-interval observations licensed by that budget.

Finally use the readback rows listed in P. Stream windows, dyadic tolerances, and regular rational observations feed R, and H, C, N transport and name the same route. Thus the Cauchy route is explicit and finite, with no unbounded host iteration or selected subsequence. □

Theorem 5291.4 (Bishop fixed-point interval real-seal nonescape)**.** *For every accepted* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *packet, the terminal row* E *is exposed only as the* $\mathsf{Real}^{\uparrow}$ *seal of the displayed nested interval and Cauchy-modulus route*

$$I, T, M, B, R \longmapsto E \longmapsto H, C, P, N.$$

The seal may be consumed as the named fixed-point endpoint of the packet, but it cannot escape as quotient real equality, a proof of ambient $\mathsf{Real}^{\uparrow}$ *completeness, a host fixed-point theorem, an unrestricted interval compactness principle, or a selected representative outside the displayed rows.*

Proof. Read E from the carrier. It is terminal in the packet: the interval, self-map, modulus, nested interval, and rational readback rows precede it, and the structural rows only transport, replay, source, and name the resulting read.

Apply Definition 5811.3. Every tolerance request reaching E has already passed through the finite interval, contraction, modulus, bisection, stream, dyadic, and regular rational observations recorded by I, T, M, B, R, P.

It remains to rule out escape. The carrier has no coordinate for quotient real equality, ambient completeness, a host fixed-point theorem, unrestricted compactness, or selected representatives. Therefore E seals only the displayed fixed-point name of this packet. □

Falsifiable prediction: An accepted $\mathsf{BishopFixedPointInterval}^{\uparrow}$ consumer that reaches the terminal $\mathsf{Real}^{\uparrow}$ row E without first reading $I, T, M, B, R, H, C, P, N$ refutes the carrier surface.

Independence witness: locatedinterval, intervalbisection, cauchymodulus, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the full interval self-map packet $F = (I, T, M, B, R, E, H, C, P, N$ because each sibling contributes only a located interval source, a bisection route, a modulus row, a readback row, a finite name window, a dyadic ledger, or a terminal real seal while this chapter binds them into one fixed-point NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet is generated from a located interval row, contraction self-map row, explicit Cauchy or Lipschitz modulus row, nested bisection row, regular rational readback row, terminal Real seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5811.1, Definition 5811.2, Definition 5811.3, and Definition 5811.4 seed the finite constructive interval fixed-point route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point compactness, quotient real equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction self-map admission, explicit modulus routing, nested interval readback, terminal Real seal nonescape, and a Lean carrier/obligation formalization for BEDC.Derived.BishopFixedPointIntervalUp.

Chapter 5292

A Concrete Naming Certificate for $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$

The $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet realizes the private-coordinate minimal-cover theorem of Definition 9462.1678 as finite NameCert data. It records a trigger-coordinate carrier, a support-family cover ledger, and one private-coordinate witness row for each displayed support before any minimal-trigger criterion may be consumed. The packet keeps the enumeration theorem auditable without identifying it with a generic finite set, word list, Boolean classifier, regular-language recognizer, or finite automaton presentation.

Falsifiable prediction: Every accepted $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ consumer must display a cover row and one private-coordinate witness row for each support before using the minimal-trigger criterion.

Independence witness: finset, list, bool, regularlanguage, finite-automaton: $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ is not bijective to these siblings because it carries a support-family cover ledger plus a private-coordinate witness for every support row.

Definition 5292.1 (Private-coordinate trigger carrier)**.** *A* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the finite trigger-coordinate row.*
2. A *is the finite support-family row whose entries are displayed subsets of* Ω*.*
3. U *is the cover ledger asserting that the displayed supports cover every coordinate of* Ω*.*
4. V *is the private-coordinate witness ledger, with one row for each support in* A*.*
5. π *maps each support row to its selected private coordinate and records membership in that support.*
6. E *records exclusion from every other support row for the selected private coordinate.*
7. K *is the minimal-cover criterion row, readable only after* U, V, π, E *have been displayed.*
8. H *stores componentwise* hsame *transport for coordinate, support, cover, witness, exclusion, and criterion rows.*

9. *C stores* Cont *replay from a trigger query through the cover ledger and the private-coordinate witness rows.*
10. *P stores* Pkg *provenance over* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Omega, A, U, V, \pi, E, K, H, C, P, N$. It has no coordinate for a bare finite set, unordered list, Boolean truth table, regular-language recognizer, finite automaton run, or support family without displayed private witnesses.

Theorem 5292.2 (Private-coordinate trigger NameCert obligations)**.** *For every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *surface consists exactly of coordinate exposure, support-family exposure, cover-ledger replay, one private-coordinate witness row for each support, membership and exclusion checks for the selected witnesses, minimal-cover criterion exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5812.1. The rows Ω, A, U display the finite coordinate space, the support family, and the fact that the supports cover the full coordinate row.

The rows V, π, E attach a private coordinate to each support. Membership is recorded by π, and exclusion from every other support is recorded by E, so deleting the support removes at least one displayed coordinate from the cover.

The criterion row K is therefore readable only after the cover and private-witness rows have been exposed. The remaining rows H, C, P, N preserve transport, replay, provenance, and local naming for the same finite packet, and no omitted sibling surface supplies the private-coordinate ledger. □

Theorem 5292.3 (Private-coordinate minimal-cover criterion)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier exposes a minimal full trigger exactly through the displayed cover row U together with the private-coordinate witness rows V, π, E. A consumer may use the criterion row K only after reading a cover of Ω and one witness coordinate for every support row in A that belongs to that support and belongs to no other displayed support. The packet does not turn the support family into a regular language, finite automaton, Boolean table, or list quotient.*

Proof. The forward read uses the cover ledger U and the private-coordinate witness rows. If a support row is removed, its selected witness coordinate remains outside all other displayed supports by E, so the remaining family no longer covers Ω.

For the reverse read, the cover row already gives full coverage. The witness rows ensure that every support has a coordinate lost by deleting that support, so no displayed support is redundant.

Thus the criterion row K is exactly the finite private-coordinate minimal-cover test. The transport, replay, provenance, and local naming rows carry this test without converting it into any sibling classifier. □

Theorem 5292.4 (Private-coordinate trigger finite-set cover route)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *packet reads its support-family row as a finite-set-indexed cover through chapter 112. The exclusions from regular-language and automaton presentations are bounded by chapter 351 and chapter 2364: the private-coordinate carrier may display finite support rows, recognizer-like acceptance tests, or transition-like exclusion checks, but it exports the minimal-cover criterion only through the rows $\Omega, A, U, V, \pi, E, K, H, C, P, N$.*

Proof. Project the accepted carrier

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N).$$

The row Ω is the displayed coordinate object, and A is read as a finite family of supports indexed by the finite-set surface. The cover ledger U then witnesses coverage of every coordinate in Ω by those displayed supports.

The rows V, π, E are the extra private-coordinate ledger. They attach one witness coordinate to each support, record membership in that support, and record exclusion from every other displayed support. These rows are not supplied by the finite-set sibling, nor by the regular-language or finite-automaton presentations.

Consequently K is a private-coordinate minimal-cover read rather than a bare finite-set cover, a regular-language recognizer, or an automaton acceptance predicate. The structural rows H, C, P, N transport and replay only this displayed packet, so the sibling route records the finite-combinatorial surface without replacing the private-coordinate data. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$.

Constructive story: A $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet is generated from a finite trigger-coordinate row, support-family row, cover ledger, per-support private-coordinate witness ledger, membership and exclusion rows, minimal-cover criterion row, componentwise transport, continuation replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5812.1, Definition 5812.2, Definition 5812.3, and Definition 5812.4 seed the finite NameCert packet for private-coordinate minimal-cover witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, regular-language recognition, finite-automaton minimization, Boolean classifier completeness, or enumeration beyond the displayed private-coordinate criterion.

Upgrade path: Obligation closure requires checked carrier admission, cover-ledger replay, private-coordinate witness coverage, exclusion exactness, minimal-cover criterion replay, TasteGate nontriviality, FieldFaithful projection, transport, replay, provenance, and local naming for BEDC.Derived.PrivateCoordinateTriggerUp.

Chapter 5293

A Concrete Naming Certificate for $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet records the finite modulus by which a located real comparison request is read through displayed apartness or equality evidence, dyadic tolerances, explicit Cauchy-modulus schedules, regular rational readback, and the terminal real-name seal. It sits after the comparison surface of chapter 1730, the tail envelope of chapter 1769, the Cauchy-modulus bridge of chapter 5728, the rational readback of chapter 301, and the public real route of chapter 38. The packet names a finite comparison-schedule carrier; it is not trichotomy, quotient real equality, a selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5293.1 (Located real comparison modulus carrier)**.** *A* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, A, D, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{LocatedRealComparison}^{\uparrow}$ *request row for the two located real endpoints and the comparison direction being inspected.*
2. *A is the located evidence row. It records the displayed positive apartness witness when the request separates the endpoints, or the displayed equality-facing refusal row when the request reaches only an overlap tolerance.*
3. *D is the dyadic tolerance schedule. It lists the requested precision, comparison slack, endpoint radii, and finite tolerance refinements consumed by the comparison read.*
4. *B is the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route connecting the comparison request to an explicit Cauchy-modulus schedule before regular rational readback is allowed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected rational tails exposed by B and bounded by D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the comparison-facing read, available only after Q, A, D, B, R have been displayed.*
7. *H records componentwise* hsame *transport for the comparison request, evidence row, dyadic tolerance schedule, bridge route, readback, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from the comparison request through located evidence, dyadic scheduling, Cauchy-modulus bridging, regular rational readback, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, LocatedRealTailEnvelop $\mathsf{CauchyModulusBridge}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, A, D, B, R, E, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, a hidden selector, countable choice, a host comparison oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedRealComparisonModulusUp.LocatedRealComparisonModulusTasteGate`
`single carrier alignment`

Theorem 5293.2 (Located real comparison modulus obligations)**.** *For every accepted* LocatedRealComparisonModu *carrier*

$$M = (Q, A, D, B, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *surface consists exactly of comparison-request admission, located apartness-or-equality evidence, dyadic tolerance scheduling,* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *routing,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer of the comparison schedule must read those rows in the displayed order and receives no trichotomy split, quotient real equality, hidden selector, countable-choice schedule, host comparison oracle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 5813.1. The comparison request is Q, and the only evidence row attached to it is A.

The schedule is then forced through D and B. The dyadic row D records the finite tolerances to be inspected, while the $\mathsf{CauchyModulusBridge}^{\uparrow}$ row B turns those tolerance requests into explicit tail thresholds before any rational readback is exposed.

The terminal read is downstream. The regular rational row R reads only the displayed tails opened by B, and the $\mathsf{Real}^{\uparrow}$ seal E is available only after that readback.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for the excluded host-level or choice-level objects, the listed rows exhaust the local NameCert surface. □

Theorem 5293.3 (Located real comparison modulus nontrichotomy boundary)**.** *Every accepted* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *packet exports a positive schedule for comparison reads without exporting trichotomy. If the evidence row A records positive apartness, a downstream consumer may read that apartness only through Q, D, B, R, E; if A records only an equality-facing overlap tolerance, the consumer receives the displayed tolerance route and no forced left-or-right order verdict.*

Proof. Read the evidence row A together with the comparison request Q. The carrier does not contain a three-way order coordinate, so the two possible reads are positive displayed apartness or finite overlap tolerance.

For the positive branch, the dyadic tolerance row D and bridge row B determine which tails are inspected before R and E can be consumed. The apartness read is therefore a finite schedule read, not a global order split.

For the overlap branch, the same schedule exposes only the inspected tolerance data. Since no trichotomy coordinate or hidden selector appears in $M = (Q, A, D, B, R, E, H, C, P, N)$, the packet refuses any forced left-or-right verdict not displayed by the rows. □

Falsifiable prediction: An accepted $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is refuted if a comparison consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting the $\mathsf{LocatedRealComparison}^{\uparrow}$ request row Q, the evidence row A, the dyadic tolerance schedule D, the $\mathsf{CauchyModulusBridge}^{\uparrow}$ route B, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: LocatedRealComparison, LocatedRealTailEnvelope, CauchyModulusBridge, RegSeqRat, Real: none is bijective with $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ because the packet jointly carries a comparison request, apartness-or-equality evidence, dyadic tolerance scheduling, explicit Cauchy-modulus bridging, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is generated from a LocatedRealComparison request row, located apartness-or-equality evidence, a dyadic tolerance schedule, a CauchyModulusBridge route, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5813.1, Definition 5813.2, and Definition 5813.3 seed the finite comparison-modulus route over LocatedRealComparisonUp, LocatedRealTailEnvelopeUp, CauchyModulusBridgeUp, RegSeqRatUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, host comparison oracles, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, evidence-row exactness, dyadic schedule determinacy, Cauchy-modulus bridge routing, regular rational readback, Real-seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealComparisonModulusUp.

Chapter 5294

A Concrete Naming Certificate for $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$

The $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet realizes the boundary-shadow and observer-expansion route of chapter 9463 as finite cocycle-level NameCert data. It sits after the boundary-shadow route of chapter 3813, the observer-shadow metric of chapter 4154, the Busemann cocycle of chapter 4134, the horosphere-flow ledger of chapter 4051, and the observer-expansion packet of chapter 4167. The chapter names a finite expansion cocycle over displayed boundary and horosphere rows; it is not a completed hyperbolic boundary, quotient geodesic ray space, physical observer dynamics, selected ideal point, or ambient manifold theorem.

Definition 5294.1 (Boundary-shadow expansion cocycle carrier)**.** *A* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, O, B, F, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row recording the visible boundary shadow through which the cocycle is read.*
2. *O is the* $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ *row recording the observer-facing shadow metric comparison for the same boundary read.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row recording the additive Busemann comparison consumed by the expansion read.*
4. *F is the* $\mathsf{HorosphereFlowLedger}^{\uparrow}$ *row recording the horosphere-flow level through which boundary and Busemann rows are replayed.*
5. *E is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *row recording the displayed observer-expansion magnitude or direction attached to S, O, B, F.*
6. *H records componentwise* hsame *transport for boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow ledger, observer expansion, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, and observer-expansion read.*

8. *P is the* Pkg *provenance over* BoundaryShadowExpansionCocycle$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicObserverShadowMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HorosphereFlowLedger$^{\uparrow}$, HyperbolicObserverExp BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* NameCert$_{\text{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, O, B, F, E, H, C, P, N$. It has no coordinate for completed boundary points, quotient geodesic rays, a hidden expansion selector, physical observer dynamics, selected ideal endpoints, or ambient hyperbolic manifold data.

Theorem 5294.2 (Boundary-shadow expansion cocycle NameCert obligations)**.** *For every accepted* BoundaryShadowExpansionCocycle$^{\uparrow}$ *carrier*

$$X = (S, O, B, F, E, H, C, P, N),$$

the local NameCert$_{\text{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *surface consists exactly of boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, observer-expansion read, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any accepted expansion read that omits either the boundary-shadow row S or the Busemann cocycle row B is outside the packet.*

Proof. Project the carrier of Definition 5814.1. The boundary-facing rows are S and O, while the cocycle and horosphere-flow rows are B and F.

The expansion row E is downstream from those four rows. It can be read only after the visible boundary shadow, observer-shadow metric, Busemann cocycle, and horosphere-flow ledger have all been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for completed boundary data, quotient geodesic rays, hidden selectors, physical observer dynamics, selected endpoints, or ambient manifold structure, the listed rows exhaust the local NameCert surface. □

Theorem 5294.3 (Boundary-shadow expansion cocycle dependency route)**.** *Every accepted* BoundaryShadowExpan *read factors through*

HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicObserverShadowMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HorosphereFlowLed

before a consumer may inspect the expansion cocycle as a local NameCert row. The route is finite and preserves the boundary-shadow row and Busemann cocycle row as separate coordinates.

Proof. Use Definition 5814.2. It places the boundary-shadow row, observer-shadow metric row, Busemann cocycle row, and horosphere-flow ledger before the expansion row.

The cocycle dependency is not reducible to one sibling. The boundary-shadow row supplies the boundary face, the observer-shadow metric supplies the observer-facing comparison, the Busemann row supplies the additive cocycle read, and the horosphere-flow row supplies the level ledger.

Only after those rows are present can E, H, C, P, N expose the expansion cocycle as a local packet. Therefore a consumer cannot collapse the route to a single hyperbolic object or bypass the separate boundary-shadow and Busemann coordinates. □

Falsifiable prediction: Any accepted BoundaryShadowExpansionCocycle$^{\uparrow}$ packet is refuted if the expansion read omits either the boundary-shadow row S or the Busemann cocycle row B.

Independence witness: hyperbolic_boundary_shadow, hyperbolic_observer_shadow_metric, hyperbolic_busemann_cocycle, horosphere_flow_ledger, hyperbolic_observer_expansion: none

is bijective with $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ because the packet jointly carries boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow level, observer expansion, transport, replay, provenance, and local naming.

The Lean TasteGate route for this packet must provide `Nontrivial BoundaryShadowExpansionCocycleUp` and `FieldFaithful BoundaryShadowExpansionCocycleUp` instances in `lean4/BEDC/Derived/BoundaryShadowE` Those instances must preserve $S, O, B, F, E, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet is generated from HyperbolicBoundaryShadow rows, HyperbolicObserverShadowMetric rows, HyperbolicBusemannCocycle rows, HorosphereFlowLedger rows, HyperbolicObserverExpansion rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5814.1, Definition 5814.2, and Definition 5814.3 seed the finite boundary-shadow expansion cocycle route over boundary, observer-shadow, Busemann, horosphere-flow, expansion, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic boundaries, quotient geodesic ray spaces, physical observer dynamics, selected ideal endpoints, ambient manifold theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow exactness, observer-shadow metric readback, Busemann cocycle separation, horosphere-flow routing, observer-expansion exposure, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.BoundaryShadowExpansionCocycleUp.

The $\mathsf{HellyBraySelection}^{\uparrow}$ hub routes bounded-variation selection through chapter 398, chapter 2069, chapter 301, chapter 126, and chapter 38 before the child files expose the finite selection packet.

Chapter 5295

A Concrete Naming Certificate for $\mathsf{HellyBraySelection}^{\uparrow}$

Following Helly and Bray, the $\mathsf{HellyBraySelection}^{\uparrow}$ packet records the finite selection surface by which bounded-variation source data are read through Jordan signed-variation rows, finite stream windows, regular rational readback, and terminal real seals before a downstream selection consumer may use the packet. It sits after the bounded-variation carrier of chapter 398, the Jordan variation decomposition rows of chapter 2069, the regular rational readback route of chapter 301, the finite observation windows of chapter 126, and the terminal real-name boundary of chapter 38. Helly–Bray selection also feeds distribution-facing compactness through chapter 186, chapter 92, and chapter 4008 when the bounded-variation read is consumed as a tight probability-family route. The chapter names a finite BEDC selection packet, not host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5295.1 (Helly–Bray selection carrier)**.** *A* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, J, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, carrying the bounded-variation object, finite variation ledger, and endpoint budget exposed to the selection request.*
2. *J is the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *row, displaying the signed-variation split and the positive and negative variation rows read from B.*
3. *S is the family of* $\mathsf{StreamName}^{\uparrow}$ *finite windows opened by the inspected variation rows and by the downstream Real-facing request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, recording the rational comparisons used before any Real seal is visible.*
5. *E is the finite family of* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after B, J, S, R have been displayed.*
6. *T records componentwise* hsame *transport for the bounded-variation source, Jordan rows, finite windows, readbacks, Real seals, continuation, provenance, and local naming.*
7. *C records displayed* Cont *replay from bounded-variation data through Jordan signed-variation rows, finite windows, regular rational readback, Real seals, transport, provenance, and local naming.*

8. *P is the* Pkg *provenance over* $\mathsf{HellyBraySelection}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, J, S, R, E, T, C, P, N$. The carrier has no coordinate for host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5295.2 (Helly–Bray selection NameCert obligations)**.** *For every accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier*

$$H = (B, J, S, R, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded-variation source row, Jordan signed-variation decomposition row, StreamName finite windows, RegSeqRat readback row, Real seal rows, transport, replay, provenance, and local naming;*
2. *variation-source exposure, requiring every selection-facing read to begin with B and then pass through the signed-variation rows J rather than through a host weak-convergence theorem;*
3. *finite-window locality, requiring S to list the exact stream windows opened by the variation rows and the Real-facing request;*
4. *readback ordering, requiring R to consume the displayed windows in S before any row of E is exposed;*
5. *componentwise transport, displayed replay, provenance, and local naming for the same rows through T, C, P, N;*
6. *nonescape, excluding host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Helly–Bray selection obligation is stored outside these rows.

Proof. Project the accepted carrier. The only source coordinate is the bounded-variation row B, and the only signed-variation coordinate is the Jordan row J.

The finite observation surface is then forced by row order. The StreamName windows S are opened from the displayed variation rows, the RegSeqRat readback R reads only those windows, and the Real seals E appear only after that readback has been displayed.

Transport and replay preserve the same route componentwise through T and C. Provenance P and local naming N record that route as the local certificate surface.

Since none of the excluded objects occurs as a carrier coordinate, a consumer cannot add weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient Real completeness to the local NameCert obligations. □

Theorem 5295.3 (Helly–Bray selection finite-window route)**.** *Every Real-facing or variation-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier factors its read through*

$$\mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{JordanVariationDecomposition}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto T, C, P, N$$

Thus the consumer receives bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise transport, continuation replay, provenance, and local naming. The route supplies no host weak convergence, measure completion, quotient function equality, selected subsequence, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier $H = (B, J, S, R, E, T, C, P, N)$. The first projection gives the bounded-variation source row B, and the next projection gives the Jordan signed-variation row J over that source.

The finite-window part is local. The windows S are the only observation rows available to the packet, and R is the only regular rational readback attached to those windows.

The Real-facing boundary is reached only at E. The remaining rows T, C, P, N transport, replay, source, and name the same finite route; they do not add a new selection principle.

Because the carrier omits host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient Real completeness, every accepted consumer read is exhausted by the displayed finite-window route. □

Theorem 5295.4 (Helly–Bray distribution forward link)**.** *Every* $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, *or* $\mathsf{ProkhorovTightProbabi}$ *consumer that cites an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier must first read the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *signed-variation row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows of Definition 5815.1. The downstream route to chapter 186, chapter 92, and chapter 4008 therefore receives only bounded-variation source data, Jordan variation data, displayed windows, rational readback, Real seals, componentwise transport, replay, provenance, and local naming. It receives no host weak convergence theorem, measure completion, quotient equality, selected subsequence, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $H = (B, J, S, R, E, T, C, P, N)$. The only distribution-facing source row is B, and the only signed-measure decomposition row available to the packet is J.

Use the finite-window route of Definition 5815.3. It forces every Real-facing and variation-facing read through S, R, E before the transport, replay, provenance, and local naming rows can be consumed.

Now attach a downstream distribution, measure, or tight-probability request. Since those consumers cite the Helly–Bray packet only through the displayed route, the request reaches chapter 186, chapter 92, or chapter 4008 after $B, J, S, R, E, T, C, P, N$ have already been displayed.

The excluded objects are not carrier coordinates. Thus the forward link cannot export host weak convergence, measure completion, quotient equality, selected subsequences, countable choice, or ambient Real completeness to any distribution-facing consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5815.1, Definition 5815.2, Definition 5815.3, and Definition 5815.4 seed the finite Helly–Bray selection route over bounded-variation data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, transport, replay, provenance, local naming, and distribution-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, variation-source exposure, finite-window locality, readback ordering, transport, replay, provenance, local naming, and finite-window routing for BEDC.Derived.HellyBraySelectionUp.

Constructive story: A $\mathsf{HellyBraySelection}^{\uparrow}$ packet is generated from bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

The Helly–Bray route is a distribution-facing read of the finite selection surface already named by chapter 1732; its bounded real sequence and compactness rows are supplied through chapter 1415 before the distribution consumer is allowed to inspect the signed-variation packet.

Theorem 5295.5 (Helly–Bray Helly-selection dependency route)**.** *Every* $\mathsf{Distribution}^{\uparrow}$ *or compactness-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *packet must first expose the finite* $\mathsf{HellySelection}^{\uparrow}$ *selection surface of chapter 1732 together with the bounded real sequence route of chapter 1415. In carrier notation, the read passes through the bounded-variation source row, Jordan signed-variation row, finite window rows, regular rational readback, terminal Real seals, componentwise transport, replay, provenance, and local naming rows before the distribution-facing route of Definition 5815.4 is public. It is therefore not a free weak-convergence theorem, measure-completion theorem, quotient-function equality, choice-selected subsequence, or ambient compactness principle.*

Proof. Start with the carrier of Definition 5815.1. Its only sequence-facing data are the bounded-variation row, Jordan signed-variation row, finite windows, regular rational readback, and terminal Real seals.

Read those rows through the finite-window route of Definition 5815.3. The same bounded source discipline is the one exported by the $\mathsf{HellySelection}^{\uparrow}$ packet, and the bounded real sequence route supplies the finite window and bound rows before any compactness-facing consumer can inspect them.

Finally attach the distribution forward link. Since Definition 5815.4 exposes distribution consumers only after the Helly–Bray carrier rows have been displayed, the downstream route receives the Helly-selection and bounded-sequence surfaces as dependencies rather than as hidden host compactness or choice principles. □

Chapter 5296

A Concrete Naming Certificate for DiniFiniteMinimumBudget$^{\uparrow}$

Following Dini's theorem and Bishop–Bridges constructive compactness, the DiniFiniteMinimumBudget$^{\uparrow}$ packet records the finite extraction row that turns a monotone compact-window Dini certificate into one displayed tolerance budget. It consumes the CompactMetric$^{\uparrow}$ source, monotone ContinuousMap$^{\uparrow}$ family rows, the DiniTheorem$^{\uparrow}$ compact-window route, UniformModulus$^{\uparrow}$ handoff data, DyadicRatCore$^{\uparrow}$ tolerance cells, the terminal Real$^{\uparrow}$ seal, BHist history rows, hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data. The packet names only the finite minimum-budget route; it is not host supremum selection, a selected minimum outside the carrier, open-cover compactness, quotient equality, or ambient Real$^{\uparrow}$ completeness.

The dependency surface is horizontal: chapter 1387 supplies the compact-window Dini route, chapter 129 supplies the inspected compact carrier, chapter 130 supplies the monotone continuous-family rows, and chapter 369 receives the extracted budget. Thus the minimum-budget row is a downstream finite extraction from those sibling carriers, not an isolated tolerance selector.

Definition 5296.1 (Dini finite-minimum budget carrier)**.** *A* DiniFiniteMinimumBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, D, U, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row naming the finite compact-metric windows inspected by the extraction.*
2. *F is the monotone* ContinuousMap$^{\uparrow}$ *family row, including the displayed pointwise comparison ledger used by the Dini route.*
3. *D is the* DiniTheorem$^{\uparrow}$ *row that supplies the monotone uniform-window certificate over K and F.*
4. *U is the* UniformModulus$^{\uparrow}$ *handoff row consumed by uniform-limit and compact-uniform-modulus readers.*
5. *Q is the* DyadicRatCore$^{\uparrow}$ *tolerance row, listing the candidate dyadic budgets and their finite comparison cells.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row reached by every displayed tolerance and value comparison.*
7. *H records componentwise* hsame *transport for $K, F, D, U, Q, E, C, P, N$.*

8. *C records displayed* Cont *replay from compact windows and monotone family rows through the Dini row, the finite dyadic budget comparisons, the uniform-modulus handoff, and the Real seal.*
9. *P is the* Pkg *provenance over* DiniFiniteMinimumBudget$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DiniTheorem$^{\uparrow}$, UniformModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for an ambient supremum, an externally selected minimum, open-cover compactness, quotient equality of real names, countable choice, or host Real completeness.

Lean4 ✓ `BEDC.Derived.DiniFiniteMinimumBudgetUp.DiniFiniteMinimumBudgetTasteGate single carrier alignment`

Theorem 5296.2 (Dini compact finite-minimum budget)**.** *For every accepted* DiniFiniteMinimumBudget$^{\uparrow}$ *carrier*

$$B = (K, F, D, U, Q, E, H, C, P, N),$$

the finite probe cover displayed by K, F, D and the dyadic tolerance cells displayed by Q determine one displayed minimum tolerance budget before the uniform-modulus handoff U is exported. The extraction route is

$$K, F, D, Q, E, H, C, P, N \longrightarrow U.$$

Thus a UniformLimit$^{\uparrow}$ *or compact-uniform-modulus consumer receives a finite* DyadicRatCore$^{\uparrow}$ *budget sealed by* Real$^{\uparrow}$ *and transported by* hsame *and* Cont*, without host supremum, selected minimum outside the carrier, open-cover compactness, quotient equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the accepted packet. The compact source row K, monotone family row F, and Dini row D are the only rows that can name the finite probe cover for the tolerance request.

The dyadic row Q lists the candidate tolerance cells. Since the carrier is finite, the budget comparison is a displayed finite comparison among the cells in Q, with every real-valued read sealed through E before the handoff row is exposed.

The route to U is then replayed by C and transported componentwise by H. The provenance and naming rows P, N record the same finite route as the local certificate surface.

No excluded object is a coordinate of B. Consequently the exported budget is the displayed finite minimum-budget row inside the carrier, not an ambient supremum, external selector, open-cover argument, quotient equality, choice schedule, or completeness argument. □

Falsifiable prediction: Every accepted DiniFiniteMinimumBudget$^{\uparrow}$ consumer that exports a UniformModulus$^{\uparrow}$ handoff must first expose the compact-metric windows, monotone continuous-family rows, DiniTheorem route, finite DyadicRatCore$^{\uparrow}$ budget cells, Real$^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: dini-theorem, compactmetric, continuousmap, uniformmodulus, dyadicratcore, real: DiniFiniteMinimumBudget$^{\uparrow}$ is not bijective to any listed sibling because it binds the finite Dini probe cover to one displayed dyadic minimum-budget handoff before uniform-limit or compact-uniform-modulus consumers may read the result.

Closure status for NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, seed)

Scope closed: Definition 5816.1 and Definition 5816.2 seed the finite minimum-budget extraction route from compact Dini data to a uniform-modulus-facing handoff.

Formal verification: FormalStatus(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host supremum selection, selected minima outside the carrier, open-cover compactness, quotient equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite probe-cover exposure, dyadic minimum-budget extraction, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniFiniteMinimumBudgetUp.

Constructive story: A DiniFiniteMinimumBudget$^{\uparrow}$ packet is generated from compact-metric source rows, monotone ContinuousMap family rows, a DiniTheorem compact-window route, UniformModulus handoff rows, DyadicRatCore tolerance cells, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5297

A Concrete Naming Certificate for $\mathsf{FiniteCauchyFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet records the finite directed-tail surface used when a completion consumer asks for Cauchy-filter evidence before reading a regular rational name or a terminal real-name seal. It sits beside the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite filter basis for tail requests; it is not a quotient filter, a selected limit, countable choice, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5297.1 (Finite Cauchy filter carrier)**.** *A* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (W, T, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the filter request.*
2. T *is the directed-tail request row, naming the finite family of later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii and comparison budgets used by the directed tails.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and tolerance ledger.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, T, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the stream windows, tail requests, dyadic ledgers, regular readback, and real seal.*
7. C *records displayed* Cont *replay of the same finite filter route.*
8. P *records* Pkg *provenance over* $\mathsf{FiniteCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, T, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.FiniteCauchyFilterUp.FiniteCauchyFilterTasteGate single carrier alignment`

Theorem 5297.2 (Finite Cauchy filter NameCert obligations)**.** *For the carrier of Definition 5817.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail request visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-ledger preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal access, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $F = (W, T, D, R, E, H, C, P, N)$. The rows W, T, D expose the finite source windows, directed tail requests, and dyadic tolerance budgets before any regular-rational or real-facing read is admitted.

The readback row R is then determined by the displayed windows and tolerance ledger. Since the carrier stores no second regular-rational coordinate, every $\mathsf{RegSeqRat}^{\uparrow}$ consumer reads the same finite route.

The seal row E is downstream of W, T, D, R. The transport row H, continuation row C, package provenance row P, and local naming row N preserve exactly that route and provide no coordinate for quotient filters, selected limits, countable choice, host stream equality, host real equality, or ambient completeness. □

Theorem 5297.3 (Finite Cauchy filter Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier factors through the finite route*

$$W, T, D, R, E, H, C, P, N.$$

In particular, the consumer must first read $\mathsf{StreamName}^{\uparrow}$ *windows, directed tail requests,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Start with the carrier definition. The only real-facing row is E, and it is displayed after the stream windows, directed-tail row, dyadic ledger, and regular readback row.

Apply Definition 5817.2. The local NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Thus any Real-facing consumer receives the finite packet $W, T, D, R, E, H, C, P, N$ and no quotient-filter, selected-limit, countable-choice, host-equality, or ambient-completeness substitute. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet is generated from finite StreamName windows, directed tail requests, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 5817.1, Definition 5817.2, and Definition 5817.3 specify the finite directed-tail filter carrier and its Real-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filter construction, selected limits, countable choice, host stream equality, host real equality, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for directed-tail visibility, tolerance-ledger preservation, readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 5298

A Concrete Naming Certificate for DNAWindowSixTranslationBoundary$^{\uparrow}$

The DNAWindowSixTranslationBoundary$^{\uparrow}$ packet realizes the local translation-boundary branch of subsection 9462.28.21 as finite NameCert data. It consumes the codon-window and stop-tile boundary analysis in the source vision, the curated code-boundary ledger of **??**, and the trigger-threshold surface of chapter 4217. The packet names only a finite window-six translation-boundary carrier; biological translation realization, universality, protein function, and evolutionary mechanism remain outside the BEDC kernel packet.

Definition 5298.1 (DNA window-six translation-boundary carrier)**.** *A* DNAWindowSixTranslationBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, S, T, L, R, V, H, C, P, N)$$

with the following displayed rows:

1. *Q is the codon Q_6 window row recording the six-bit coordinate readback for the inspected codon window.*
2. *S is the stop-tile boundary row recording the local halt boundary and continuation-corner split from the source vision.*
3. *T is the translation-classifier row supplied by external biological bridge data.*
4. *L is the curated code-boundary ledger row inherited from* BioRealityQSixLeaveOneCodeBoundaryLedger$^{\uparrow}$*.*
5. *R is the release-factor or release-mechanism row that records which external recognition boundary is being tested.*
6. *V is the finite validation row recording which observed table, organismal code row, or assay class is used for the test.*
7. *H records componentwise* hsame *transport for the window, tile, classifier, ledger, release, and validation rows.*
8. *C records displayed* Cont *replay of the boundary read through those rows.*
9. *P records* Pkg *provenance over the source vision, the bio-reality ledger sibling,* DNAWindowSixTriggerThreshold$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and local naming rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for biological necessity, global identification of the genetic code with the window-six fold, protein-folding realization, universal stop assignment, hidden BEDC channel tokens, or untested mechanism.

Theorem 5298.2 (DNA window-six translation-boundary obligations)**.** *For the carrier of Definition 5818.1, the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *surface consists exactly of codon-window exposure, stop-tile boundary visibility, external translation-classifier disclosure, curated code-ledger preservation, release-boundary test exposure, finite validation-row visibility, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $B = (Q, S, T, L, R, V, H, C, P, N)$. The rows Q, S, T expose the finite codon window, the local translation boundary, and the external classifier before any biological reading is admitted.

The ledger and release rows L, R keep the packet anchored to the bio-reality boundary sibling and to a displayed recognition test. The validation row V records the observed table or assay class being tested, so the packet has a falsifiable contact surface rather than a kernel claim of biological necessity.

The structural rows H, C, P, N transport, replay, source, and name exactly the displayed boundary route. Since no further coordinate is present, the carrier cannot export global window-six identity, universal stop assignment, protein-folding realization, hidden channel tokens, or untested mechanism. □

Theorem 5298.3 (DNA window-six translation-boundary sibling handoff)**.** *Every accepted* DNAWindowSixTranslat *read that reaches a translation-boundary consumer must first expose the source-vision stop-tile row of subsection 9462.28.21, the curated code-boundary ledger row of* **??***, and the finite trigger-threshold row of chapter 4217. The handoff is therefore a concrete finite boundary-tile NameCert route, not a narrative-only direction.*

Proof. Use Definition 5818.1. The source-vision row is carried by S, the code-boundary ledger is carried by L, and the trigger-facing finite boundary read is recorded in the same package provenance P.

Now apply Definition 5818.2. The local NameCert requires those rows before the translation-boundary consumer can read N. Hence the consumer sees the source vision, the bio-reality ledger sibling, and the trigger-threshold sibling as displayed packet data rather than as detached prose. □

Falsifiable prediction: An accepted $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet must expose a finite validation row naming the observed code table, organismal code row, or release-factor assay class before it can export a translation-boundary reading.

Independence witness: bioreality-q-six-leave-one-code-boundary-ledger, dna-window-six-trigger-threshold, synonymous-transition: the $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is not bijective to any listed sibling because it jointly carries codon-window, stop-tile, external translation-classifier, curated code-ledger, release-boundary, validation, transport, replay, provenance, and local naming rows.

The Lean follow-up must provide $\mathsf{Nontrivial}\ \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{DNAWindowSi}$ TasteGate instances before this packet can move beyond seed closure.

Closure status for $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is generated from codon Q-six window rows, stop-tile boundary rows, external translation-classifier rows, curated code-boundary ledgers, release-boundary tests, finite validation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, seed)

Scope closed: Definition 5818.1, Definition 5818.2, and Definition 5818.3 specify the finite translation-boundary carrier and sibling route.

Formal verification: FormalStatus(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim biological-code necessity, global window-six identity, universal stop assignment, protein-folding realization, hidden BEDC channel tokens, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding, TasteGate nontriviality, field faithfulness, validation-row exactness, sibling-route preservation, transport, replay, provenance, and local naming.

Chapter 5299

A Concrete Naming Certificate for $\mathsf{RegulatedConvergence}^{\uparrow}$

Following Bishop and Bridges on regulated functions and uniform convergence, the $\mathsf{RegulatedConvergence}^{\uparrow}$ packet records the finite route by which a displayed sequence of regulated real functions converges uniformly to a regulated endpoint. It sits after the regulated-function carrier of chapter 1906, the regulated-integral consumer boundary of chapter 1557, the uniform-convergence ledger of chapter 3417, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite convergence-and-handoff surface; it does not import measure completion, quotient equality of functions, selected host limits, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5299.1 (Regulated convergence carrier)**.** *A* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

with the following displayed rows:

1. *F is the source row naming the regulated-function family through* $\mathsf{RegulatedFunction}^{\uparrow}$ *data, including the displayed interval, step-window, endpoint, and oscillation ledgers available to each inspected member.*
2. *U is the* $\mathsf{UniformConvergence}^{\uparrow}$ *tail row, recording one shared tolerance schedule for the whole regulated family rather than pointwise schedules chosen separately at each argument.*
3. *W is the finite window row exposing exactly the function indices, domain windows, and endpoint reads used by the shared tail schedule.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the real-valued observations in those windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after F, U, W, R have been displayed.*
6. *I is the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *handoff row; it records that integral-facing consumers may read the regulated endpoint only through the same finite regulated-function, uniform-tail, window, readback, and Real-seal route.*
7. *H records componentwise* hsame *transport for F, U, W, R, E, I and for the structural rows.*
8. *C records displayed* Cont *replay for regulated-function reads, uniform-tail requests, finite window reads, regular rational readback, Real-seal requests, and integral handoff requests.*

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedConvergence}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, U, W, R, E, I, H, C, P, N$. It has no coordinate for a host function quotient, selected limiting function, measure completion, pointwise-only convergence, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceTasteGate single carrier alignment`

Theorem 5299.2 (Regulated convergence NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier*

$$G = (F, U, W, R, E, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the regulated-function family row F, uniform-convergence tail row U, finite window row W, regular rational readback row R, terminal Real seal E, regulated-integral handoff row I, componentwise transport row H, displayed replay row C, package provenance row P, and local naming row N. Every endpoint-facing or integral-facing consumer must read these rows in the displayed route and cannot replace them by pointwise convergence, a selected host limit, quotient equality of functions, measure completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 5819.1. The only analytic rows are the regulated-function family F, the shared uniform tail ledger U, the finite window row W, the regular rational readback R, the terminal Real seal E, and the integral handoff I.

The convergence route is uniform. A consumer must read the single tail schedule U before it can inspect the windows W and the regular readback R, so pointwise-only schedules and externally selected host limits are not part of the packet.

The endpoint and integral rows are downstream. The seal E is exposed only after F, U, W, R, and the integral-facing row I reads that same route rather than a separate measure-completion or function-quotient object.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded row occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 5299.3 (Regulated convergence integral handoff)**.** *Let*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

be an accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier. Every* $\mathsf{RegulatedIntegral}^{\uparrow}$ *consumer read of the limiting regulated function factors through the finite route*

$$\mathsf{RegulatedFunction}^{\uparrow}(F),\ \mathsf{UniformConvergence}^{\uparrow}(U),\ W,\ \mathsf{RegSeqRat}^{\uparrow}(R),\ \mathsf{Real}^{\uparrow}(E),\ \mathsf{RegulatedIntegral}^{\uparrow}(I).$$

Thus the handoff to integration uses the same regulated-family rows, shared uniform-tail ledger, finite windows, regular rational readback, and Real seal as the convergence certificate. It supplies no measure completion, quotient function equality, selected limiting function, open-cover compactness, or ambient real-completeness principle.

Proof. Start with an integral-facing request. By the carrier definition, the only integral row is I, and its replay route in C passes through the same regulated-family and convergence rows used by endpoint-facing consumers.

Read the regulated source through F and the uniform tail through U. The finite windows W then expose the inspected function indices and domain reads, and the regular rational row R records the real-valued observations visible at those windows.

Only after this route is displayed can the terminal seal E be consumed and handed to I. Componentwise transport in H and replay in C preserve the same rows, while P and N record their provenance and local naming.

The carrier has no coordinate for measure completion, quotient function equality, selected limits, open-cover compactness, or ambient real completeness. Therefore every regulated-integral handoff is confined to the finite route displayed in the statement. □

Falsifiable prediction: An accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ consumer that reaches a $\mathsf{RegulatedIntegral}^{\uparrow}$ handoff without first reading $F, U, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: regulated-function, regulated-integral, uniform-convergence, regseqrat, real: none is bijective to $\mathsf{RegulatedConvergence}^{\uparrow}$ because this packet jointly binds a regulated-function family, a shared uniform tail ledger, finite windows, regular rational readback, terminal Real seal, integral handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedConvergence}^{\uparrow}$ packet is generated from a regulated-function family row, UniformConvergence tail row, finite window row, RegSeqRat readback, terminal Real seal, RegulatedIntegral handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5819.1, Definition 5819.2, and Definition 5819.3 seed the finite regulated-convergence route over regulated functions, uniform convergence, regular rational readback, Real seals, and regulated-integral consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, quotient function equality, selected host limits, pointwise-only convergence, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated-family visibility, uniform-tail exactness, finite window readback, Real-seal nonescape, regulated-integral handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedConvergenceUp.

Chapter 5300

A Concrete Naming Certificate for $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$

Following Cantor and Bishop–Bridges, the $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet records the finite located nested-interval route by which displayed interval windows become a regular rational Cauchy name and then a terminal real seal. It refines the nested dyadic Cauchy route of chapter 1811, reads endpoint and radius rows through chapter 291, schedules finite observations through chapter 126, hands the scheduled rows to chapter 301, and reaches only the seal boundary of chapter 38. The chapter isolates the located interval-to-name handoff; it does not claim a host intersection point, quotient stream equality, selected limit, countable choice, or ambient completeness.

Definition 5300.1 (Located nested-interval limit carrier)**.** *A* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite nested located-interval window. It records the inspected interval chain, endpoint rows, located containment witnesses, and the finite separation reads available at each displayed stage.*
2. *D is the dyadic shrink ledger. It records the dyadic endpoint comparisons, width bounds, and tolerance requests read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It names exactly the finite endpoint, midpoint, and shrink-ledger observations that may be queried before regular rational readback.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the scheduled located-interval observations and the dyadic shrink ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after I, D, S, R have been displayed.*
6. *H records componentwise* hsame *transport for interval windows, shrink ledgers, stream schedules, regular rational handoffs, real seals, replay rows, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located nested-interval request through I, D, S, R, E and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$*,* $\mathsf{NestedDyadicCauchy}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, R, E, H, C, P, N$. It has no coordinate for completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.LocatedNestedIntervalLimitUp.LocatedNestedIntervalLimitTasteGate single carrier alignment`

Theorem 5300.2 (Located nested-interval limit NameCert obligations)**.** *For every accepted* LocatedNestedIntervalL *carrier*

$$L = (I, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite located interval window, dyadic shrink ledger, StreamName schedule, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming row;*
2. *located nesting exposure, requiring every interval read to be one of the displayed rows of I together with its displayed containment and located separation witnesses;*
3. *dyadic shrink exactness, requiring every tolerance request to be discharged by a visible width or endpoint comparison stored in D and read through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
4. *schedule compatibility, requiring S to expose only the finite interval, endpoint, midpoint, and ledger observations used by D and R;*
5. *RegSeqRat handoff exactness, requiring R to be formed only after the interval window, shrink ledger, and schedule rows have been projected;*
6. *Real-seal nonescape, requiring E to be consumed only after I, D, S, R and the structural rows H, C, P, N have been displayed.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5820.1. The projection exposes one finite located nested-interval window, one dyadic shrink ledger, one StreamName schedule, one RegSeqRat handoff, one Real seal, and the transport, replay, provenance, and naming rows.

Located nesting exposure is forced by I. A consumer may inspect only interval rows already present in the finite window, and each such row carries its displayed containment and located separation witnesses.

Dyadic shrink exactness is forced by D. Each tolerance request is answered by a displayed dyadic width or endpoint comparison, so no host intersection or selected limit is needed to choose a tail.

The schedule and handoff rows are downstream. The row S records the finite observations that may be opened, and R repacks exactly those observations under the shrink ledger as a regular rational Cauchy surface.

Finally E, H, C, P, N close the route. The Real seal is reachable only after the regular handoff has been displayed, while the structural rows only transport, replay, source, and name the same finite data. Therefore no completed intersection, quotient stream equality, host real equality, countable choice, ambient completeness, Lean verification, or bridge-checking coordinate is present. □

Theorem 5300.3 (Located nested-interval RegSeqRat handoff)**.** *Let* $L = (I, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read exported by* L *factors through the displayed route*

$$I \longmapsto D \longmapsto S \longmapsto R \longmapsto H, C, P, N.$$

The route reads a finite located nested-interval window, a dyadic shrink ledger, and the scheduled endpoint observations before it exports the regular rational Cauchy row. The terminal $\mathsf{Real}^{\uparrow}$ *seal* E *is available only after this handoff has been displayed.*

Proof. Start with the displayed located interval window I. Its rows give the only endpoint, midpoint, containment, and located separation data available to a regular rational consumer.

Use the dyadic shrink ledger D to answer the displayed tolerance request. The chosen comparison is part of the same finite packet and is read through $\mathsf{DyadicRatCore}^{\uparrow}$, so there is no external modulus, choice-selected tail, or host interval intersection.

The schedule row S then fixes which interval observations are opened. The handoff row R is obtained by reading those scheduled observations under the shrink discipline and repacking them as the $\mathsf{RegSeqRat}^{\uparrow}$ surface.

The rows H, C, P, N transport, replay, source, and name that handoff, and the seal row E remains downstream of it. Since the carrier has no quotient-stream, host-real, selected-limit, choice, or completeness coordinate, every regular rational read factors through the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5820.1, Definition 5820.2, and Definition 5820.3 seed the finite located nested-interval route from displayed interval windows and dyadic shrink ledgers to a RegSeqRat handoff and terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located nesting exposure, dyadic shrink exactness, schedule compatibility, RegSeqRat handoff exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedNestedIntervalLimitUp.

Constructive story: A $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet is generated from a finite nested located-interval window, a dyadic shrink ledger, a StreamName schedule, a RegSeqRat handoff row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5301

A Concrete Naming Certificate for $\mathsf{CauchyTailRequest}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailRequest}^{\uparrow}$ packet isolates the finite directed-tail request that a Cauchy or completion consumer must expose before it can read a regular rational name or a terminal real-name seal. It sits beside the finite window carrier of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal seal of chapter 38, and the finite filter surface of chapter 5817. The packet names the request row consumed by those sibling routes; it is not a quotient filter, a selected limit, a countable-choice schedule, host stream equality, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5301.1 (Cauchy tail request carrier)**.** *A* $\mathsf{CauchyTailRequest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, Q, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the request.*
2. Q *is the directed tail request row, naming the finite later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the directed tail request.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and tolerances.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, Q, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the window, request, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay of the same finite directed-tail route.*
8. P *records* Pkg *provenance over* $\mathsf{CauchyTailRequest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteCauchyFilter}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, Q, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 (definition) `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestUp`

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestTasteGate single carrier alignment`

Theorem 5301.2 (Cauchy tail request NameCert obligations)**.** *For the carrier of Definition 5821.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *consumer that reads a directed-tail row receives it through this displayed request surface.*

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestCarrier namecert obligations`

Proof. Project the accepted packet $T = (W, Q, D, R, E, H, C, P, N)$. The rows W, Q, D expose the finite windows, directed tail request, and dyadic tolerance ledger before any regular-rational or real-facing read is admitted.

The readback row R is downstream of those displayed rows. It therefore records only the $\mathsf{RegSeqRat}^{\uparrow}$ observation generated from the named windows and tolerance ledger, not an external sequence or choice schedule.

The seal row E is terminal for the request route. Transport through H and replay through C preserve exactly the displayed route, while P and N record provenance and local naming.

Finally compare the route with Definition 5817.2. The finite filter packet consumes its directed-tail row as a request coordinate, and the rows above are precisely the admitted request surface available to that consumer. Since no remaining coordinate exists, quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, and bridge checking are outside the chapter claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyTailRequest}^{\uparrow}$ packet is generated from finite StreamName windows, a directed tail request row, DyadicRatCore tolerance data, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, seed)

Scope closed: Definition 5821.1 and Definition 5821.2 specify the finite directed-tail request carrier and its filter-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for tail visibility, tolerance preservation, readback, seal routing, transport, replay, provenance, and local naming.

Chapter 5302

A Concrete Naming Certificate for $\mathsf{QuotientLeakageMarkov}^{\uparrow}$

The $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet realizes the quotient leakage transition matrix of Definition 9462.1376 as finite NameCert data. It consumes the DNA window-six boundary-tile source of subsection 9462.28.21, the codon-window carrier of chapter 2234, the boundary-tile packet of chapter 3393, the six-boundary coverage route of chapter 3470, and the translation-boundary packet of chapter 5818. The packet names a finite six-state Markov ledger only; it is not a biological stochastic model, empirical evolutionary claim, host quotient-codon semantics, or unrestricted state-space enumeration.

Definition 5302.1 (QuotientLeakageMarkov carrier)**.** *A* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, T, O, E, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the six-state orbit row listing* AGR*,* Anchor_6*,* $\mathrm{StopStart}_6$*,* UUR*,* CUR*, and* CUY*.*
2. *T is the transient transition-matrix row of Definition 9462.1376, with entries read as exact rational finite counts.*
3. *O is the outside-probability row recording* $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ *for the six displayed states.*
4. *E is the expected-exit ledger row recording the rational exit values of Definition 9462.1380.*
5. *W is the finite window-six source row tying the orbit states to the codon-window and boundary-tile siblings.*
6. *H records componentwise* hsame *transport for the state, transition, outside-probability, exit-ledger, source, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite Markov read through* S, T, O, E, W, H, P, N*.*
8. *P is the* Pkg *provenance over* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$*,* $\mathsf{CodonSixBitWindow}^{\uparrow}$*,* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$*, the source vision of subsection 9462.28.21,* BHist*,* hsame*,* Cont*, and* NameCert*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, O, E, W, H, C, P, N$*. It has no coordinate for biological transition realization, hidden codon quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process.*

Theorem 5302.2 (QuotientLeakageMarkov NameCert obligations)**.** *For the carrier of Definition 5822.1, the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *surface consists exactly of six-state exposure, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, window-six sibling routing, componentwise transport, displayed replay, provenance, and local naming. Every accepted read preserves the outside probabilities displayed in Definition 9462.1378.*

Proof. Project the accepted carrier $Q = (S, T, O, E, W, H, C, P, N)$. The state row S fixes the six orbit states, and the transition row T is the only source of one-bit flip probabilities.

The outside-probability row O is read from the outside column of T and matches the finite rational list in Definition 9462.1378. Thus an accepted packet cannot alter leakage rates without changing a displayed row.

The expected-exit row E is downstream of the same finite matrix and records the rational ledger of Definition 9462.1380. The source row W ties these finite state rows back to the codon-window, boundary-tile, coverage, and translation-boundary siblings.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since no other coordinate is present, the NameCert surface cannot export biological mechanism, hidden quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process. □

Theorem 5302.3 (QuotientLeakageMarkov sibling dependency route)**.** *Every accepted* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *consumer first reads the finite codon-window source, boundary-tile classifier, six-boundary coverage route, and translation-boundary packet before it consumes the transition row* T*, outside row* O*, or expected-exit row* E*. The dependency route is*

$$\mathsf{CodonSixBitWindow}^{\uparrow}, \mathsf{DnaWindowSixBoundaryTile}^{\uparrow}, \mathsf{SixBoundaryTileCoverage}^{\uparrow}, \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$$

Proof. Use the provenance row P and source row W of Definition 5822.1. These rows name the finite codon-window and boundary-tile sources before the Markov matrix is admitted.

The transition row T then reads the six-state quotient matrix of Definition 9462.1376. The outside-probability row O and expected-exit row E are downstream ledger rows, so they cannot be consumed before the sibling source route has been displayed.

Transport and replay by H and C preserve this order, while N names it locally. Hence the consumer receives a concrete dependency route rather than a detached numerical table. □

Falsifiable prediction: Every accepted $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ read preserves the displayed outside probabilities $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ for AGR, Anchor_6, StopStart_6, UUR, CUR, and CUY.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, six-boundary-tile-coverage, dna-window-six-translation-boundary: $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries six orbit states, a rational transition matrix, outside probabilities, expected-exit ledgers, window-source routing, transport, replay, provenance, and local naming.

The Lean follow-up must provide explicit $\mathsf{Nontrivial}\ \mathsf{QuotientLeakageMarkov}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{QuotientLeakageM}$ TasteGate instances preserving $S, T, O, E, W, H, C, P, N$ as distinct displayed rows.

Closure status for $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$**.**

Constructive story: A $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet is generated from six orbit states, a rational transition matrix, outside-probability rows, expected-exit ledgers, a finite window-six source row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5822.1, Definition 5822.2, and Definition 5822.3 specify the finite quotient-leakage Markov carrier and sibling dependency route.

Formal verification: FormalStatus(NameCert$_{\text{QuotientLeakageMarkov}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological transition realization, empirical evolutionary mechanism, hidden codon quotient semantics, unbounded simulation, completed stochastic processes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, sibling routing, transport, replay, provenance, and local naming for BEDC.Derived.QuotientLeakage

Chapter 5303

A Concrete Naming Certificate for $\mathsf{CauchyCriterionUniform}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet records the uniform Cauchy criterion route used when a Real and Completion consumer asks for one displayed threshold discipline across a finite family of stream windows. It sits beside the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Cauchy hub of chapter 3413. The packet names a uniform criterion surface; it is not a quotient Cauchy class, selected limit, host equality theorem, countable-choice schedule, trichotomy principle, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5303.1 (Cauchy criterion uniform carrier)**.** *A* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *S records the* $\mathsf{StreamName}^{\uparrow}$ *window family inspected by the uniform criterion request.*
2. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the dyadic radii and comparison budgets shared by the family.*
3. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and dyadic tolerances.*
4. *E records the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, available only after S, D, R, M have been exposed.*
5. *M records the uniform modulus row, naming the common threshold discipline for all displayed windows in the family.*
6. *H records componentwise* hsame *transport for the stream windows, dyadic tolerances, regular readback, Real seal, uniform modulus, replay route, provenance, and local name.*
7. *C records displayed* Cont *replay of the same finite route.*
8. *P records* Pkg *provenance over* $\mathsf{CauchyCriterionUniform}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N records the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, R, E, M, H, C, P, N$. It has no coordinate for a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUniformUp.CauchyCriterionUniformTasteGate single carrier alignment`

Theorem 5303.2 (Cauchy criterion uniform NameCert obligations)**.** *For the carrier of Definition 5823.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the finite packet* $U = (S, D, R, E, M, H, C, P, N)$*;*
2. *uniform window exposure through the* $\mathsf{StreamName}^{\uparrow}$ *row* S *and the common modulus row* M*;*
3. *dyadic tolerance exactness through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*;*
4. *regular readback through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*;*
5. *ledger non-escape through* H, C, P, N*.*

Proof. Project the accepted packet $U = (S, D, R, E, M, H, C, P, N)$. Carrier admission is exactly the admission of this finite tuple, so a consumer can inspect only the displayed coordinates.

The uniform window obligation reads S together with the common threshold discipline M. The dyadic tolerance obligation reads D, and the regular readback obligation reads R before any terminal seal row E is available.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since the carrier has no remaining coordinate, the ledger cannot export a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient completeness claim. □

Theorem 5303.3 (Cauchy criterion uniform Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier factors through the finite route*

$$S, D, R, M \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer must read stream windows, dyadic tolerances, regular readback, and the uniform modulus before the terminal real seal is exposed. The route exports no quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 5823.1. The only terminal real-facing coordinate is E, and the definition places it downstream of the finite stream-window, dyadic-tolerance, regular-readback, and uniform-modulus rows.

Apply Definition 5823.2. The NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Therefore any Real-facing consumer receives exactly the finite packet route displayed above. No quotient Cauchy class, selected limit, host equality, countable-choice schedule, trichotomy row, or ambient-completeness coordinate supplies another path to the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet is generated from finite StreamName windows, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, a uniform modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, seed)

Scope closed: Definition 5823.1, Definition 5823.2, and Definition 5823.3 specify the finite uniform Cauchy criterion carrier and its Real-facing seal route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy classes, selected limits, host equality, countable choice, trichotomy, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for uniform window exposure, dyadic tolerance exactness, regular readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 5304

A Concrete Naming Certificate for CauchyProductCompletionProjection$^{\uparrow}$

Following Bishop and Bridges on constructive products of Cauchy completions and Kelley on product uniformities, the CauchyProductCompletionProjection$^{\uparrow}$ packet records the coordinate projection surface for an accepted product-completion read. It sits downstream of the product packet of chapter 3797 and the completion-product route of chapter 1540, while every coordinate read still passes through the StreamName$^{\uparrow}$ windows of chapter 126, the RegSeqRat$^{\uparrow}$ readbacks of chapter 301, the DyadicRatCore$^{\uparrow}$ budgets of chapter 291, and the terminal Real$^{\uparrow}$ seal of chapter 38.

Definition 5304.1 (CauchyProductCompletionProjection carrier)**.** *A* CauchyProductCompletionProjection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* CauchyProductCompletion$^{\uparrow}$ *product-completion packet whose coordinate route is being inspected.*
2. *π_0, π_1 are the left and right projection selector rows, each naming which displayed coordinate window is exposed.*
3. *S_0, S_1 are the coordinate* StreamName$^{\uparrow}$ *windows opened by the two projection selectors.*
4. *D_0, D_1 are the* DyadicRatCore$^{\uparrow}$ *budget rows attached to the finite coordinate observations read from those windows.*
5. *R_0, R_1 are the* RegSeqRat$^{\uparrow}$ *readback rows obtained from the same coordinate windows and dyadic budgets.*
6. *L_0, L_1 are the coordinate completion-seal rows witnessing that each projected read remains inside the product-completion packet.*
7. *H records componentwise* hsame *transport for the product packet, selectors, stream windows, dyadic budgets, regular readbacks, and coordinate completion seals.*
8. *C records the* Cont *replay from the product-completion packet through the selected coordinate window, dyadic budget, regular readback, and completion seal.*
9. *P is the* Pkg *provenance over* CauchyProductCompletionProjection$^{\uparrow}$, CauchyProductCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *row.*
The carrier compares accepted projections only through $Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, host product equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CauchyProductCompletionProjectionUp.CauchyProductCompletionProjectionTasteGate`
`single carrier alignment`

Theorem 5304.2 (CauchyProductCompletionProjection NameCert obligations)**.** *For an accepted packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *surface consists exactly of product-packet admission, selector exposure, coordinate stream-window exposure, dyadic-budget accounting, regular readback, coordinate completion-seal nonescape, componentwise transport, replay, provenance, and local naming for the displayed rows.*

Proof. Project the carrier of Definition 5824.1. The row Q supplies the already displayed product-completion packet, while π_0, π_1 determine which coordinate route is being opened.

For each selector, the corresponding stream window is read before any dyadic budget or regular readback is available. Thus S_0, S_1 precede D_0, D_1, and the regular rows R_0, R_1 are exposed only through those windows and budgets.

The completion-seal rows L_0, L_1 bind the coordinate read back to Q. The transport table H and replay table C preserve the same product packet, selector, window, budget, readback, and seal rows, while P and N record provenance and local naming.

Since these are the only carrier coordinates, the NameCert surface has no route to quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5304.3 (CauchyProductCompletionProjection route)**.** *Every coordinate read exported by an accepted* $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ *carrier factors through*

$$\mathsf{CauchyProductCompletion}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameC}$$

The left and right selectors expose only the displayed coordinate windows and their completion seals; they do not turn the product-completion packet into a host tuple, a quotient-completion equality, or a chosen representative.

Proof. Start with an accepted carrier J. The selector rows π_0, π_1 are not host projections; they are displayed BEDC rows attached to the product-completion packet Q.

Reading either selector first opens the matching $\mathsf{StreamName}^{\uparrow}$ window. The dyadic budget row is then inspected, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback is obtained from the same finite coordinate window.

The coordinate completion seal is the last coordinate-facing row before export. It keeps the read inside the product-completion packet named by Q, and the structural rows H, C, P, N attach transport, replay, provenance, and local naming to the same route.

Thus every projection read remains a finite NameCert route through the displayed rows. No coordinate of J supplies quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ packet is generated from an accepted CauchyProductCompletion packet, left and right projection selector rows, coordinate StreamName windows, DyadicRatCore budgets, RegSeqRat readbacks, coordinate completion seals, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5824.1, Definition 5824.2, and Definition 5824.3 seed the finite coordinate-projection route for product completions.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host product equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, selector exposure, coordinate window accounting, regular readback, completion-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductCompletionPro

Chapter 5305

A Concrete Naming Certificate for $\mathsf{CauchyModulusSubsequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet records the finite route by which a bounded regular Cauchy source exposes a modulus-indexed subsequence schedule without exporting an infinite selector. It sits between the bounded subsequence envelope of chapter 1698, the regular subsequence route of chapter 381, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a constructive completion-facing certificate: it supplies a monotone cofinal schedule, finite windows, tolerance accounting, and a Real seal, but not countable choice, quotient stream equality, a selected infinite subsequence, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5305.1 (Cauchy modulus subsequence carrier)**.** *A* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, M, T, W, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$ *source row whose bounded regular Cauchy data are available before any subsequence-modulus request is read.*
2. *M is the modulus row. It records the requested Cauchy tolerance discipline and the finite comparison budget used by the subsequence schedule.*
3. *T is the monotone cofinal schedule row. It records the finite evidence that requested indices are sent to later source windows and that the schedule is cofinal in the displayed source.*
4. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows selected by the schedule row T at the requested modulus levels.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed windows and dyadic tolerances.*
7. *R is the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff row reached from B, M, T, W, D, Q.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the bounded source, modulus, schedule, windows, tolerance ledger, regular readback, and regular subsequence handoff have been displayed.*

9. *H records componentwise* hsame *transport for the bounded source, modulus, cofinal schedule, windows, dyadic ledger, regular readback, regular subsequence handoff, terminal seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a subsequence-modulus request through $B, M, T, W, D, Q, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$, $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, M, T, W, D, Q, R, E, H, C, P, N$. It has no coordinate for a selected infinite subsequence, quotient stream equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusSubsequenceUp.CauchyModulusSubsequenceTasteGate single carrier alignment`

Theorem 5305.2 (Cauchy modulus subsequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier $S = (B, M, T, W, D, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequ}}$ *surface consists exactly of carrier admission, bounded-source admission through B, modulus monotonicity through M, monotone cofinal schedule admission through T, finite-window determinacy through W, dyadic tolerance accounting through D, regular rational readback through Q,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff through R, Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5825.1. Its analytic coordinates are exactly the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular readback Q, regular subsequence handoff R, and terminal Real seal E.

The modulus and schedule obligations are displayed before any support row is inspected. The row M supplies the tolerance discipline, while T records monotonicity and cofinality for the finite requested indices. The window row W and tolerance row D then determine which $\mathsf{StreamName}^{\uparrow}$ windows and dyadic bounds are visible at those requests.

The readback and seal obligations remain downstream. The row Q reads the visible windows as $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the $\mathsf{RegularCauchySubsequence}^{\uparrow}$ handoff, and E is reachable only after the preceding rows have been displayed. Rows H, C, P, N transport, replay, source, and name that same finite route, so no further NameCert obligation remains outside the listed coordinates. □

Theorem 5305.3 (Cauchy modulus subsequence window determinacy)**.** *Every consumer admitted by an accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier must read the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular rational readback Q, regular subsequence handoff R, and terminal Real seal E before reading the transport, replay, provenance, or local naming rows. The packet exports no selected infinite subsequence, quotient stream equality, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer read. By Definition 5825.1, the only consumer-facing route before the support rows is the ordered list B, M, T, W, D, Q, R, E.

The rows B, M, T fix the source, tolerance request, and monotone cofinal schedule. The row W then supplies only the finite windows named by that schedule, and D supplies the dyadic tolerance ledger attached to those windows. Thus the visible subsequence data are determined by displayed finite requests, not by an externally selected infinite object.

The remaining analytic rows are also fixed by the displayed windows. The readback row Q converts those windows into $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the regular subsequence handoff, and E is the terminal Real seal for that route. Since the carrier contains no coordinate for quotient stream equality, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the support rows H, C, P, N can only preserve the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet is generated from a bounded regular Cauchy source, a modulus row, a monotone cofinal schedule, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RegularCauchySubsequence handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5825.1, Definition 5825.2, and Definition 5825.3 seed the constructive subsequence-modulus route over bounded regular Cauchy data, finite windows, dyadic tolerances, regular readback, regular subsequence handoff, Real sealing, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, quotient stream equality, countable choice, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Lean verification requires carrier admission, modulus monotonicity, cofinal schedule admission, finite-window determinacy, dyadic tolerance accounting, RegSeqRat readback, RegularCauchySubsequence handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusSubsequenceUp.

$\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ reads its comparison surface through chapter 126, chapter 301, chapter 291, chapter 1820, and chapter 38 before the child NameCert body is input.

Chapter 5306

A Concrete Naming Certificate for $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ packet records the finite comparison surface at which two regular Cauchy presentations can be inspected before a real-name or completion-facing consumer reads them. It sits on the finite observation windows of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the non-quotient classifier boundary of chapter 1820.

Falsifiable prediction: If a purported $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ consumer compares two regular Cauchy presentations without exposing finite StreamName windows, RegSeqRat readbacks, the DyadicRatCore tolerance ledger, the CauchyEquivalenceSetoid classifier, and the terminal Real seal, then the consumer has left the certificate.

Definition 5306.1 (Regular Cauchy sequence comparison carrier)**.** *A* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows available to the comparison request.*
2. R_0 *and* R_1 *are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, exposing regular rational values before any real-name seal is consumed.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the displayed precision cells and refinement rows used by the comparison.*
4. Q *is the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier row over* S_0, S_1, R_0, R_1, D.
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite windows, readbacks, tolerance ledger, and classifier row are visible.*
6. H *records componentwise* hsame *transport for the two stream rows, two readback rows, dyadic ledger, classifier, real seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from a comparison request through* $S_0, S_1, R_0, R_1, D, Q, E, H, P, N$.
8. P *is the* Pkg *provenance over* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}$ *row.*
The carrier compares accepted packets only through $S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, host real equality, choice of representatives, selected limits, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchySequenceComparisonUp.RegularCauchySequenceComparisonTasteGate`
`single carrier alignment`

Theorem 5306.2 (Regular Cauchy sequence comparison NameCert obligations)**.** *For the carrier of Definition 5826.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$K = (S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N),$$

finite StreamName window exposure through S_0, S_1, regular rational readback through R_0, R_1, dyadic tolerance accountability through D, Cauchy-equivalence classifier exposure through Q, Real seal nonescape through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.

Proof. Carrier admission is projection from Definition 5826.1. The projection exposes exactly the two StreamName windows, two RegSeqRat readbacks, DyadicRatCore tolerance ledger, CauchyEquivalenceSetoid classifier, Real seal, transport, replay, provenance, and local naming rows.

The comparison route reads those rows in order. The two finite windows are inspected before the regular rational readbacks, the readbacks feed the dyadic tolerance ledger, and the ledger feeds the classifier row Q.

The Real seal E is downstream of the displayed comparison surface. The rows H, C, P, N transport, replay, source, and name that same finite route; none of them adds quotient stream equality, selected representatives, host real equality, choice, or ambient completeness. □

Theorem 5306.3 (Regular Cauchy sequence comparison carrier transport)**.** *Let*

$$K = (S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N)$$

and

$$K' = (S'_0, S'_1, R'_0, R'_1, D', Q', E', H', C', P', N')$$

be $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *carrier packets. If the displayed row H supplies componentwise* hsame *transport from each row of K to the corresponding row of K', then carrier admission for K transports to carrier admission for K' along exactly the rows*

$$S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N.$$

The transported packet has no added coordinate for quotient stream equality, host real equality, selected representative, countable choice, selected limit, or ambient completeness.

Proof. Project the carrier tuple of Definition 5826.1. The only exposed coordinates are the two StreamName rows, two RegSeqRat readback rows, DyadicRatCore tolerance ledger, classifier, Real seal, transport, replay, provenance, and local naming rows.

Use the NameCert obligations of Definition 5826.2. They require componentwise transport to act row by row on the displayed packet rather than by replacing the packet with a host quotient or selected real representative.

The sibling routes keep each transported row inside its own finite surface: StreamName supplies finite windows, RegSeqRat supplies rational readbacks, DyadicRatCore supplies tolerance cells,

CauchyEquivalenceSetoid supplies the classifier boundary, and Real supplies only the terminal seal. Therefore the transported accepted packet is still read through the same carrier coordinates, and no excluded equality, choice, limit, or completeness datum is introduced. □

Theorem 5306.4 (Regular Cauchy sequence comparison classifier stability)**.** *For an accepted packet*

$$K = (S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N),$$

replace the finite StreamName windows, RegSeqRat readbacks, and DyadicRatCore tolerance rows by rows displayed in H as componentwise hsame*-stable. Then the CauchyEquivalenceSetoid classifier row Q remains the classifier row for the transported comparison route. In particular, classifier stability is witnessed before any Real seal is consumed and does not use quotient stream equality or host real equality.*

Proof. Start from the carrier projection in Definition 5826.1. The row Q is named there only over S_0, S_1, R_0, R_1, D, so its inputs are the finite StreamName windows, the RegSeqRat readbacks, and the DyadicRatCore tolerance ledger.

Apply the obligation surface of Definition 5826.2. It places componentwise transport in the displayed row H and keeps replay in C, so replacing the finite windows, readbacks, and tolerance rows by H-stable rows preserves the same inspected classifier boundary.

The chapter's sibling routes enforce the order of reading: finite windows first, regular rational readbacks next, dyadic tolerance accounting next, and only then the CauchyEquivalenceSetoid row. The Real seal E is downstream, so classifier stability is decided without a host quotient, host equality, selected representative, choice, selected limit, or ambient completeness row. □

Theorem 5306.5 (Regular Cauchy sequence comparison ledger exactness)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer of an accepted* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *comparison packet factors through exactly*

$$S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N.$$

The exported ledger gives the consumer finite StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, the CauchyEquivalenceSetoid classifier, the Real seal, componentwise transport, displayed replay, provenance, and local naming, and gives no selected representative, quotient equality, host real equality, countable choice, selected limit, or ambient completeness row.

Proof. Project the accepted carrier of Definition 5826.1. Its displayed coordinates are exactly $S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N$, and the definition explicitly leaves out representative selection, quotient equality, host equality, choice, selected limits, and ambient completeness.

Use Definition 5826.2 to read the ledger as a NameCert surface. Carrier admission exposes the finite windows, readbacks, tolerance ledger, classifier, Real seal, transport, replay, provenance, and local name as the complete comparison route.

The StreamName, RegSeqRat, DyadicRatCore, CauchyEquivalenceSetoid, and Real sibling chapters provide only their named local rows to this route. Hence any $\mathsf{Real}^{\uparrow}$ or completion-facing consumer receives precisely the displayed packet rows and cannot obtain any excluded external equality, selection, choice, limit, or completeness datum from the ledger. □

Theorem 5306.6 (Regular Cauchy sequence comparison transitive window)**.** *Let*

$$K_{01} = (S_0, S_1, R_0, R_1, D_{01}, Q_{01}, E_{01}, H_{01}, C_{01}, P_{01}, N_{01})$$

and

$$K_{12} = (S_1', S_2, R_1', R_2, D_{12}, Q_{12}, E_{12}, H_{12}, C_{12}, P_{12}, N_{12})$$

be accepted $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *packets. If the middle presentation rows* S_1, R_1 *and* S_1', R_1' *are linked by the displayed componentwise* hsame *transport, and the dyadic tolerance/readback rows* D_{01} *and* D_{12} *expose compatible comparison windows, then the composed comparison from the first presentation to the third is forced through the same finite route*

$$S_0, S_1, S_2, R_0, R_1, R_2, D_{01}, D_{12}, Q_{01}, Q_{12}, E_{01}, E_{12}, H_{01}, H_{12}, C_{01}, C_{12}, P_{01}, P_{12}, N_{01}, N_{12}.$$

In particular, a Real or Completion consumer of the composed read receives only finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows, and receives no quotient stream equality, selected representative, host real equality, countable choice, selected limit, or ambient completeness datum.*

Proof. Project the two accepted carriers. The first packet exposes the finite route from S_0, R_0 to S_1, R_1 through $D_{01}, Q_{01}, E_{01}, H_{01}, C_{01}, P_{01}, N_{01}$, and the second exposes the corresponding route from S_1', R_1' to S_2, R_2 through $D_{12}, Q_{12}, E_{12}, H_{12}, C_{12}, P_{12}, N_{12}$.

Use the displayed componentwise hsame data on the shared middle presentation. It identifies only the carried StreamName and RegSeqRat rows needed to splice the two finite comparison windows; it does not create a quotient equality of streams or a host equality of real names.

The compatible dyadic rows concatenate the displayed tolerance/readback windows. Therefore the composed read is still inspected through the listed StreamName, RegSeqRat, DyadicRatCore, classifier, Real seal, transport, replay, provenance, and local naming rows.

Since neither carrier has a coordinate for selected representatives, host real equality, selected limits, choice, or ambient completeness, the composed comparison has no such coordinate either. The transitive window is exactly the finite route displayed above. □

Theorem 5306.7 (Regular Cauchy sequence comparison RegSeqRat handoff)**.** *Every completion-facing or Real-facing consumer of an accepted* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *packet reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff before it reaches the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier or the* $\mathsf{Real}^{\uparrow}$ *seal. More precisely, every exported comparison factors through*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N$$

and no consumer receives quotient stream equality, host real equality, selected representatives, countable choice, or ambient completeness from the packet.

Proof. Project the carrier of Definition 5826.1. The only pre-classifier rows are the finite StreamName windows S_0, S_1, the RegSeqRat readbacks R_0, R_1, and the DyadicRatCore ledger D.

Apply the NameCert obligations of Definition 5826.2. They force the CauchyEquivalenceSetoid classifier row Q to be read through those finite windows, readbacks, and tolerance rows before the Real seal E is available.

Finally use the sibling routes named in the chapter introduction: StreamName supplies finite windows, RegSeqRat supplies regular rational readback, DyadicRatCore supplies tolerance cells, CauchyEquivalenceSetoid supplies the non-quotient classifier, and Real supplies the terminal seal. The carrier contains no row for any excluded equality or selection principle. □

Theorem 5306.8 (Regular Cauchy sequence comparison Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *packet reads comparison evidence only after passing through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *boundary. Thus equality or separation evidence is available only along the finite route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N,$$

and not through host quotient equality, a selected representative, countable choice, selected limits, or ambient completeness.

Proof. Start with the RegSeqRat handoff of Definition 5826.7. It already forces every completion-facing or Real-facing read through finite StreamName windows, RegSeqRat readbacks, and the DyadicRatCore ledger before the classifier row Q and Real seal E are available.

The classifier row Q is the Cauchy-equivalence boundary for the displayed rows S_0, S_1, R_0, R_1, D. Reading equality or separation evidence before Q would skip the boundary named by the carrier, while reading it after E without Q would replace the packet by a host quotient.

The structural rows H, C, P, N preserve and name the same route. This is therefore a substantive sibling dependency among StreamName, RegSeqRat, DyadicRatCore, CauchyEquivalenceSetoid, and Real, not a host quotient or a selected representative. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ packet is generated from two StreamName finite-window rows, two RegSeqRat readback rows, a DyadicRatCore tolerance ledger, a CauchyEquivalenceSetoid classifier row, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 5826.1, Definition 5826.2, Definition 5826.3, Definition 5826.4, Definition 5826.5, Definition 5826.6, and Definition 5826.7 bind the obligation surface for the finite comparison route of regular Cauchy presentations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected representatives, countable choice, selected limits, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires binding the displayed BHist, hsame, Cont, Pkg, NameCert, StreamName, RegSeqRat, DyadicRatCore, CauchyEquivalenceSetoid, and Real rows as the complete BEDC primitive scope for the same comparison packet.

Chapter 5307

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$

Following Mac Lane on monads and Eilenberg–Moore comparison, together with Bishop–Bridges constructive completion, the $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet records the finite BEDC surface where the L10 completion monad, its algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared as one NameCert boundary. The packet reads chapter 378, chapter 1845, chapter 1981, chapter 397, chapter 3351, chapter 126, chapter 301, chapter 291, and chapter 38. It names the comparison surface only; it does not assert quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5307.1 (CauchyCompletionMonadicity carrier)**.** *A* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion-monad row, displaying the unit and bind schedule before any algebra or comparison read is consumed.*
2. *A is the* $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ *action row, recording the Eilenberg–Moore algebra action over the displayed completion route.*
3. *K is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *row, exposing the unit, bind, and reassociated-bind consumer route.*
4. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row, carrying the extension and uniqueness ledger used by comparison consumers.*
5. *D is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *unit route, displaying the dense source-to-completion image before the algebra or universal-property read is exported.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row used by the monad, algebra, Kleisli, universal-property, and dense-embedding rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the same finite windows.*
8. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare completion-facing reads at the same finite precision.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *readback seal reached only after W, R, Q have all been displayed.*
10. *H records componentwise* hsame *transport for the monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from comparison requests through $T, A, K, U, D, W, R, Q, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, CauchyCompletionAlgebr $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, A, K, U, D, W, R, Q, E, H, C, P, N$. The carrier has no coordinate for quotient completion classes, selected limit representatives, host equality of completed objects, countable-choice schedules, ambient completeness, full $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 5307.2 (CauchyCompletionMonadicity NameCert obligations)**.** *For every accepted* CauchyCompletionM *carrier*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$ *surface consists exactly of carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, StreamName–RegSeqRat–DyadicRatCore–Real readback discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No local obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5827.1. The displayed tuple lists every row available to the classifier, so local comparison can inspect only the completion monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, transport, replay, provenance, and local naming.

The monadicity-facing rows are read in order. The monad row T displays the unit and bind schedule, the algebra row A records the Eilenberg–Moore action over that schedule, and the Kleisli row K keeps unit, bind, and reassociated-bind consumers on the same finite route.

The universal and dense rows then bind the comparison surface. The row U supplies extension and uniqueness data, while D supplies the dense source-to-completion unit route used before the comparison is exported.

Finally the readback and structural rows close the NameCert surface. The rows W, R, Q, E give finite windows, regular rational readback, dyadic tolerances, and the terminal Real seal; the rows H, C, P, N transport, replay, source, and name exactly that packet. Since no excluded coordinate occurs, no additional local obligation is available. □

Theorem 5307.3 (CauchyCompletionMonadicity comparison surface)**.** *Every comparison consumer of an accepted* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier factors through the finite route*

$$T, A, K, U, D \longmapsto W \longmapsto R \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the completion-monad route, the algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared only after the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$,

$\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback surface has been displayed. The comparison exports no quotient completion equality, selected limit, host equality of completed objects, countable choice, ambient completeness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the monad and algebra rows. The row T supplies the displayed completion transformer, and A reads its algebra action only as a row over that transformer.

Next attach the Kleisli and universal-property rows. The row K exposes the unit, bind, and reassociated-bind route, while U records the extension and uniqueness ledger for completion-facing consumers.

Now read the dense-embedding unit route D. It displays the source-to-completion image before the comparison reaches any terminal seal, so the route is a visible unit comparison rather than a selected representative.

Finally consume the readback and structural rows. The finite window W, regular readback R, dyadic tolerance ledger Q, and Real seal E precede transport, replay, provenance, and naming through H, C, P, N. Since the carrier contains no coordinate for the excluded objects, the comparison surface cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet is generated from a CauchyCompletionMonad route, CauchyCompletionAlgebra action row, CauchyCompletionKleisli route, CompletionUniversalProperty row, MetricCompletionDenseEmbedding unit route, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5827.1, Definition 5827.2, and Definition 5827.3 seed the finite monadicity comparison boundary for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, readback discipline, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionMonadicityUp.

Chapter 5308

A Concrete Naming Certificate for $\mathsf{BorsukUlam}^{\uparrow}$

Following Borsuk and Ulam, the $\mathsf{BorsukUlam}^{\uparrow}$ packet records the antipodal obstruction theorem as finite BEDC NameCert data rather than as a host topological principle. It sits after the degree surface of chapter 3745, the continuous-map rows of chapter 130, the real-name seal of chapter 38, the compact metric source of chapter 129, and the circle boundary model of chapter 58. The packet names the displayed antipodal route consumed by obstruction and degree-facing chapters; it does not select antipodal points, import unrestricted classical degree theory, identify quotient spheres, choose representatives, or appeal to ambient completeness.

Definition 5308.1 (Borsuk-Ulam carrier)**.** *A* $\mathsf{BorsukUlam}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, A, F, D, C, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the compact metric sphere row read through the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *surface and the* $\mathsf{S}^{1\uparrow}$ *boundary model.*
2. *A is the antipodal-pair ledger, exposing only named paired source rows and the finite equality-refusal data attached to them.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the map whose antipodal comparison is being inspected.*
4. *D is the* $\mathsf{BrouwerDegree}^{\uparrow}$ *obstruction row, read only through the displayed degree certificate and never through unrestricted host degree theory.*
5. *C is the* $\mathsf{Real}^{\uparrow}$ *comparison-seal row for the coordinate difference or collapsed real-valued comparison consumed by the obstruction route.*
6. *R is the refusal row excluding selected antipodal points, quotient equality of sphere points, choice, unrestricted classical degree theory, and ambient completeness.*
7. *H records componentwise* hsame *transport for the compact source, antipodal ledger, continuous-map row, degree row, real comparison seal, refusal row, provenance, and local naming.*
8. *K records displayed* Cont *replay from the compact metric source through the antipodal ledger, continuous-map row, degree obstruction, real comparison seal, and refusal row.*
9. *P is the* Pkg *provenance over* $\mathsf{BorsukUlam}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{BrouwerDegree}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *row.*

The classifier compares accepted packets only through $S, A, F, D, C, R, H, K, P, N$. It has no coordinate for a chosen antipodal pair, quotient equality on the sphere, unrestricted classical degree theory, countable choice, or ambient Real completeness.

Lean4 (definition) `BEDC.Derived.BorsukUlamUp.BorsukUlamUp`
Lean4 ✓ `BEDC.Derived.BorsukUlamUp.BorsukUlamTasteGate single carrier alignment`

Theorem 5308.2 (Borsuk-Ulam NameCert obligations)**.** *For every accepted* $\mathsf{BorsukUlam}^\uparrow$ *carrier* $U = (S, A, F, D, C, R, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *surface consists exactly of compact metric sphere admission, antipodal-pair ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, refusal of host and quotient shortcuts, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obstruction-facing consumer must read*

$$S, A, F \longmapsto D, C \longmapsto R, H, K, P, N$$

before treating the packet as a Borsuk-Ulam certificate.

Proof. Project the carrier of Definition 5828.1. The compact source row S, antipodal ledger A, and continuous-map row F are the only rows available before the obstruction is read.

The degree and real-comparison rows D, C are downstream of that source route. The degree row is the displayed $\mathsf{BrouwerDegree}^\uparrow$ certificate, and the real row is the displayed $\mathsf{Real}^\uparrow$ seal for the comparison consumed by the obstruction.

Finally R, H, K, P, N refuse shortcuts, transport the same rows, replay the finite route, source it, and name it locally. Since the carrier has no coordinate for selected antipodal points, quotient equality, unrestricted host degree theory, countable choice, or ambient Real completeness, no consumer can export those objects from the certificate. □

Theorem 5308.3 (Borsuk-Ulam antipodal route)**.** *Every accepted* $\mathsf{BorsukUlam}^\uparrow$ *antipodal-obstruction read factors through the displayed compact metric sphere row, the* $\mathsf{S}^{1\uparrow}$ *boundary model, the antipodal-pair ledger, the* $\mathsf{ContinuousMap}^\uparrow$ *row, the* $\mathsf{BrouwerDegree}^\uparrow$ *obstruction row, the terminal* $\mathsf{Real}^\uparrow$ *comparison seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert*. The route exports no selected antipodal point, unrestricted classical degree theorem, quotient equality of sphere points, choice principle, ambient completeness, Lean verification, or bridge-checked surface.*

Proof. Start with an accepted carrier $U = (S, A, F, D, C, R, H, K, P, N)$. The source read begins at S and A, so the antipodal data is visible only as a finite paired ledger over the displayed compact metric and circle rows.

Read the map through F and then the obstruction through D, C. The $\mathsf{ContinuousMap}^\uparrow$ row supplies the function-facing data, the $\mathsf{BrouwerDegree}^\uparrow$ row supplies the obstruction route, and the $\mathsf{Real}^\uparrow$ row supplies only the comparison seal reached from those displayed rows.

The refusal and structural rows close the route. The row R blocks selected points, quotient equality, unrestricted degree theory, choice, and ambient completeness, while H, K, P, N preserve the same finite certificate under transport, replay, provenance, and local naming. □

Falsifiable prediction: Every accepted $\mathsf{BorsukUlam}^\uparrow$ consumer reads compact metric sphere data, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a Real

comparison seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before it treats the packet as an antipodal obstruction certificate.
