Every interpolated-bound consumer must read endpoint bounded-operator rows through chapter 1644 and the strip estimate through chapter 3893 before the $\mathsf{Real}^{\uparrow}$ norm-bound ledger is visible.

Definition 5725.1 (Riesz-Thorin interpolation carrier)**.** *A* $\mathsf{RieszThorinInterpolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B, H, C, P, N)$$

with the following displayed rows:

1. X_0, X_1, Y_0, Y_1 *are endpoint* $\mathsf{NormedSpace}^{\uparrow}$ *rows for the source and target normed spaces at the two endpoints.*
2. A_0, A_1 *are endpoint* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *rows, recording the same displayed operator action with endpoint norm bounds over the corresponding normed-space rows.*
3. E_0, E_1 *are endpoint exponent rows, storing the source and target exponent ledgers and their rational comparison data.*
4. S *is the* $\mathsf{HadamardThreeLines}^{\uparrow}$ *strip-estimate row used to compare the endpoint bounds along the displayed interpolation strip.*
5. Θ *is the interpolation-parameter row, storing the inspected parameter, its endpoint incidence, and the convex-weight ledger consumed by* S*.*
6. B *is the* $\mathsf{Real}^{\uparrow}$ *norm-bound ledger exporting the interpolated bound only after* $A_0, A_1, E_0, E_1, S, \Theta$ *have been displayed.*

7. *H records componentwise* hsame *transport for endpoint normed spaces, bounded operators, exponent rows, strip estimate, interpolation parameter, norm-bound ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an interpolated-bound request through $X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B$*
9. *P is the* Pkg *provenance over* $\mathsf{RieszThorinInterpolation}^{\uparrow}$, $\mathsf{HadamardThreeLines}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Interpolation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows. It has no coordinate for a host interpolation space, quotient equality of operators, selected extremal analytic family, non-displayed exponent completion, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5725.2 (Riesz-Thorin interpolation NameCert obligations)**.** *For every accepted* $\mathsf{RieszThorinInterpolation}^{\uparrow}$ *carrier*

$$T = (X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}$ *surface consists exactly of endpoint normed-space admission through X_0, X_1, Y_0, Y_1, bounded-operator endpoint admission through A_0, A_1, endpoint exponent admission through E_0, E_1, Hadamard three-lines strip-estimate compatibility through S, interpolation-parameter admission through Θ, interpolated* $\mathsf{Real}^{\uparrow}$ *norm-bound export through B, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5725.1. The rows X_0, X_1, Y_0, Y_1 provide the endpoint normed-space surfaces, and A_0, A_1 are the only bounded-operator coordinates available to the classifier.

The exponent and strip data are then forced by row order. The endpoint exponent rows E_0, E_1 and the interpolation parameter Θ determine the displayed convex weights, while the $\mathsf{HadamardThreeLines}^{\uparrow}$ row S is the sole strip-estimate route that can compare endpoint bounds.

The bound row B reads only after those endpoint and strip rows are displayed. It exports the interpolated $\mathsf{Real}^{\uparrow}$ norm-bound ledger, not a selected analytic family or a host interpolation space.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since every excluded host object lacks a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 5725.3 (Riesz-Thorin horizontal dependency route)**.** *Every accepted interpolated-bound read for a* $\mathsf{RieszThorinInterpolation}^{\uparrow}$ *packet exposes the Hadamard three-lines strip row, endpoint* $\mathsf{NormedSpace}^{\uparrow}$ *rows, endpoint* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *rows, interpolation-parameter row, and terminal* $\mathsf{Real}^{\uparrow}$ *bound row before the interpolated estimate is visible. Equivalently, every consumer route factors through the displayed dependency lattice*

$$X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B, H, C, P, N$$

and through the sibling certificate surfaces of chapter 3893, chapter 1950, chapter 1644, chapter 224, and chapter 38.

Proof. Project the carrier $T = (X_0, X_1, Y_0, Y_1, A_0, A_1, E_0, E_1, S, \Theta, B, H, C, P, N)$ of Definition 5725.1. The rows X_0, X_1, Y_0, Y_1 are exactly the endpoint normed-space rows, and A_0, A_1 are exactly the endpoint bounded-operator rows over those spaces.

The rows E_0, E_1, Θ record the endpoint exponent and interpolation-parameter data consumed by the strip comparison. The only strip-estimate coordinate is S, so the interpolated estimate cannot be read before the Hadamard three-lines surface named in chapter 3893 is displayed.

The terminal bound row B is downstream of the endpoint, operator, exponent, strip, and interpolation-parameter rows. The structural rows H, C, P, N transport, replay, package, and name that same dependency lattice, and they introduce no bypass around the sibling NormedSpace, BoundedLinearOperator, Interpolation, HadamardThreeLines, or Real surfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}$.

Constructive story: A $\mathsf{RieszThorinInterpolation}^{\uparrow}$ packet is generated from endpoint NormedSpace rows, endpoint BoundedLinearOperator rows, endpoint exponent rows, a HadamardThreeLines strip-estimate row, an interpolation-parameter row, a RealUp norm-bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5725.1, Definition 5725.2, and Definition 5725.3 seed the finite Riesz-Thorin interpolation carrier over endpoint normed spaces, bounded operators, exponent rows, strip estimates, interpolation parameters, norm-bound ledgers, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RieszThorinInterpolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host interpolation spaces, quotient operator equality, selected extremal analytic families, non-displayed exponent completion, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint normed-space admission, bounded-operator admission, endpoint exponent compatibility, HadamardThreeLines strip-estimate compatibility, interpolation-parameter admission, RealUp norm-bound export, transport, replay, provenance, and local naming for BEDC.Derived.RieszThorinInterpolationUp.

The top-level $\mathsf{RieszThorinInterpolation}^{\uparrow}$ route records the sibling lattice that every interpolated norm-bound read must traverse. The proof surface is anchored in the three-lines estimate of chapter 3893, the normed source and target rows of chapter 1950, the operator-action rows of chapter 1644, the interpolation-family carrier of chapter 224, and the scalar seal of chapter 38.

Lemma 5725.4 (Riesz–Thorin sibling lattice route)**.** *Every accepted* $\mathsf{RieszThorinInterpolation}^{\uparrow}$ *consumer reads its endpoint bounds, analytic-strip comparison, interpolation parameter, bounded-linear-operator action, norm rows, and terminal* $\mathsf{Real}^{\uparrow}$ *scalar estimate through the displayed sibling lattice before the interpolated bound is public. The route exports no host complex interpolation theorem, quotient operator equality, selected analytic family, or ambient completeness coordinate beyond those sibling rows.*

Chapter 5726

A Concrete Naming Certificate for $\mathsf{HoeffdingFiniteSum}^{\uparrow}$

Following Hoeffding's finite bounded-sum inequality, the $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ packet records the finite concentration route by which independent bounded random variables yield an exponential tail estimate. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the law and range summaries of chapter 186, the independence ledger of chapter 187, the dyadic exponential-bound arithmetic of chapter 291, the terminal seal of chapter 38, and the finite-average probability route of chapter 4373. The packet names a bounded finite-sum concentration certificate; it is not a martingale inequality, a Chernoff optimization principle, an almost-sure convergence theorem, a host measure-theoretic limit, or an ambient $\mathsf{Real}^{\uparrow}$ completeness result.

Definition 5726.1 (Hoeffding finite-sum carrier)**.** *A* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, V, I, B, S, D, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row V is the finite family of* $\mathsf{RandomVar}^{\uparrow}$ *entries read over P. The row I is the* $\mathsf{Independence}^{\uparrow}$ *ledger certifying that the displayed family is independent in the finite index range under inspection. The row B is the bounded-range ledger: for each displayed variable it records lower and upper* $\mathsf{Real}^{\uparrow}$ *seals and the corresponding* $\mathsf{Distribution}^{\uparrow}$ *range summary. The row S records the centered finite-sum expression and the positive deviation request. The row D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *exponential-bound row naming the finite dyadic numerator, denominator, square, range-width sum, and slack comparison used by the displayed Hoeffding bound. The row E is the terminal* $\mathsf{Real}^{\uparrow}$ *tail seal naming the probability estimate for the exceptional event. The row H records componentwise* hsame *transport, C records* Cont *replay of the finite concentration route, Q records* Pkg *provenance over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Independence}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$, *and N is the local* $\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these eleven rows.*

Lean4 ✓ `BEDC.Derived.HoeffdingFiniteSumUp.HoeffdingFiniteSumTasteGate single carrier alignment`

Theorem 5726.2 (Hoeffding finite-sum NameCert obligations)**.** *For every accepted* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *carrier $(P, V, I, B, S, D, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 5726.1. Carrier admission displays the probability source, finite random-variable family, independence ledger, bounded-range ledger, finite-sum row, dyadic*

exponential-bound row, $\mathsf{Real}^{\uparrow}$ *tail seal, transport, replay, provenance, and local naming row. The certificate imports no host concentration theorem, martingale filtration, Chernoff variational optimizer, countable-choice schedule, external probability-limit operation, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Read the carrier rows in order. The source row P supplies the event classifier and normalization, while V exposes only a finite family of random variables over that same probability source.

The independence row I and bounded-range row B are then finite ledgers. They state exactly which variables are independent and which displayed lower and upper seals bound each variable before any exponential estimate is available.

The finite-sum row S fixes the centered sum and requested deviation. The dyadic row D records the arithmetic denominator, squared deviation, accumulated range-width budget, and slack comparison used by the exponential estimate, and the $\mathsf{Real}^{\uparrow}$ row E seals the resulting tail bound.

Finally H, C, Q, N transport, replay, source, and name the same route. Since the carrier has no coordinate for a host concentration theorem, variational optimizer, infinite limit, or completeness principle, these displayed rows exhaust the local certificate surface. □

Theorem 5726.3 (Hoeffding finite tail-bound route)**.** *Every accepted* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *tail-bound read factors through the route*

$$\mathsf{ProbSpace}^{\uparrow},\ \mathsf{RandomVar}^{\uparrow},\ \mathsf{Independence}^{\uparrow},\ \mathsf{Distribution}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by the carrier rows $P, V, I, B, S, D, E, H, C, Q, N$*. A probability-bound consumer can inspect the exceptional-event estimate only after the finite probability source, random-variable family, independence ledger, bounded-range ledger, centered-sum row, dyadic exponential-bound row, terminal real seal, transport, replay, provenance, and local naming row have been displayed.*

Proof. Start with an accepted carrier and project the source rows. The probability source P and finite random-variable family V provide the only measurable data available to the tail-bound request.

Next read I and B. The independence ledger is the only route by which the product-event step enters the packet, and the bounded-range ledger is the only route by which distributional lower and upper seals enter the range-width budget.

The centered-sum row S then determines the finite event being bounded. The dyadic row D supplies the exponential-bound arithmetic for that event, and the $\mathsf{Real}^{\uparrow}$ seal E is downstream from the same displayed dyadic comparison.

The structural rows H, C, Q, N preserve that route under classifier replacement and local naming. Therefore every tail-bound read is the finite Hoeffding handoff itself, not a hidden appeal to an external concentration theorem or ambient real-completeness principle. □

Theorem 5726.4 (Hoeffding finite-sum nonescape)**.** *For every accepted* $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ *packet, every concentration-facing read remains inside the displayed rows* $P, V, I, B, S, D, E, H, C, Q, N$*. In particular, the packet exports no martingale filtration, Chernoff optimizer, almost-sure convergence claim, host probability-limit operator, countable-choice selection, quotient equality of real names, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. The carrier of Definition 5726.1 has no coordinate beyond the eleven displayed rows. Thus a concentration-facing request can only project the probability source, finite variables, independence

ledger, range ledger, sum row, dyadic estimate, real tail seal, transport, replay, provenance, and local name.

The analytic content of the request is concentrated in I, B, S, D, E. Independence, bounded ranges, the finite centered sum, dyadic exponential arithmetic, and the terminal tail seal appear as explicit rows, so no further theorem object can be read from the packet.

The remaining rows H, C, Q, N are structural. They preserve displayed histories, replay the finite route, record package provenance, and attach the local certificate. Hence the accepted packet cannot export any of the excluded limit, optimizer, quotient, choice, or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}$.

Constructive story: A $\mathsf{HoeffdingFiniteSum}^{\uparrow}$ packet is generated from a probability source row, finite random-variable family, independence ledger, bounded-range ledger, centered finite-sum row, dyadic exponential-bound row, RealUp tail seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5726.1, Definition 5726.2, Definition 5726.3, and Definition 5726.4 seed the bounded finite-sum concentration route through ProbSpace, RandomVar, Independence, Distribution, DyadicRatCore, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HoeffdingFiniteSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close martingale inequalities, Chernoff optimization, almost-sure convergence, host probability limits, countable-choice selection, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite independence routing, bounded-range stability, dyadic exponential-bound handoff, tail-seal nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.HoeffdingFiniteSumUp.

Chapter 5727

A Concrete Naming Certificate for RegularCauchyLatticeOperations$^{\uparrow}$

Following Bishop and Bridges, the RegularCauchyLatticeOperations$^{\uparrow}$ packet records the finite constructive lattice-operation surface for regular Cauchy real names. It reads the regular rational route of chapter 301, the terminal real-name seal of chapter 38, the dyadic arithmetic surface of chapter 291, the lower-member packet of chapter 1832, and the upper-member packet of chapter 1833. The certificate gives downstream Real$^{\uparrow}$ consumers one finite min/max interface without importing trichotomy, quotient real equality, selected limits, countable choice, host order completeness, or ambient Real$^{\uparrow}$ completeness.

Definition 5727.1 (Regular Cauchy lattice operations carrier)**.** *A* RegularCauchyLatticeOperations$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, Y, T, D, M, A, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two accepted* Real$^{\uparrow}$ *rows presented by regular Cauchy names, exposing only their finite* RegSeqRat$^{\uparrow}$ *readbacks and terminal real seals.*
2. *T is the shared tolerance row used to align the lower-member and upper-member requests.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *ledger for the displayed comparison scale, branch budgets, and readback arithmetic consumed by both operation rows.*
4. *M is the* RegularCauchyMinimum$^{\uparrow}$ *lower-member row.*
5. *A is the* RegularCauchyMaximum$^{\uparrow}$ *upper-member row.*
6. *R is the paired regular rational readback row for the two operation outputs.*
7. *E is the paired* Real$^{\uparrow}$ *seal row, reached only after M, A, R have been displayed.*
8. *H records componentwise* hsame *transport for the two input names, tolerance, dyadic arithmetic, minimum row, maximum row, readback, seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from a lattice-operation request through $X, Y, T, D, M, A, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* RegularCauchyLatticeOperations$^{\uparrow}$*,* RegularCauchyMinimum$^{\uparrow}$*,* RegularCauchyMaximu RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, T, D, M, A, R, E, H, C, P, N$. The carrier has no coordinate for trichotomy, quotient real equality, host order completeness, selected limits, countable choice, a host lattice structure, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularCauchyLatticeOperationsUp.RegularCauchyLatticeOperationsTasteGate`
`single carrier alignment`

Theorem 5727.2 (Regular Cauchy lattice operations NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ *carrier*

$$L = (X, Y, T, D, M, A, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two regular Cauchy real rows, shared tolerance row, dyadic arithmetic ledger, minimum row, maximum row, paired readback, paired seal, transport, replay, provenance, and local name;*
2. *shared-scale exposure, requiring T and D to be displayed before either M or A may be consumed;*
3. *lower-member routing, requiring the minimum output to be read through the* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *row M;*
4. *upper-member routing, requiring the maximum output to be read through the* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *row A;*
5. *readback and seal ordering, requiring R to expose the paired regular rational outputs before E exposes the paired* $\mathsf{Real}^{\uparrow}$ *seals;*
6. *classifier stability, requiring componentwise* hsame *transport of $X, Y, T, D, M, A, R, E, C, P, N$ to preserve the accepted operation route;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no trichotomy, quotient real equality, host order completeness, selected limit, countable choice, host lattice structure, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5727.1. Its displayed rows are exactly the two regular Cauchy real inputs, the shared tolerance row, the dyadic ledger, the two operation rows, the paired readback and seal rows, and the structural rows.

Shared-scale exposure follows because M and A have no independent tolerance coordinate inside this packet. Both operation rows read the same T, D surface before any output row can be consumed.

The lower-member and upper-member obligations are inherited as named rows, not as host operations. The packet can read the lower member only through M and the upper member only through A.

Readback and seal ordering is forced by R, E. The real-facing consumer first receives the paired regular rational readback and only then the paired $\mathsf{Real}^{\uparrow}$ seal. Transport, replay, provenance, and local naming are exhausted by H, C, P, N, so no excluded host or quotient object is available. □

Theorem 5727.3 (Regular Cauchy lattice operations min-max readback)**.** *Let* $L = (X, Y, T, D, M, A, R, E, H, C, P$ *be an accepted* $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the lattice-operation output factors through the finite route*

$$X, Y, T, D \longmapsto M, A \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the packet exports the lower and upper regular Cauchy operation outputs only as paired $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *and* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *readbacks over the same dyadic scale. It exports no trichotomy, quotient real equality, host order completeness, selected limit, countable choice, or host lattice operation.*

Proof. Start with a real-facing read of the carrier. The only input rows are X, Y, and the only scale rows are T, D, so the consumer must read those coordinates before either operation row is available.

The operation rows are M and A. By Definition 5727.1, M names the lower-member route and A names the upper-member route; neither row carries a separate host order principle.

After the operation rows are displayed, the readback row R exposes the paired regular rational outputs and the seal row E exposes the paired $\mathsf{Real}^{\uparrow}$ boundary. The structural rows H, C, P, N preserve and name this route without adding any coordinate beyond it. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5727.1, Definition 5727.2, and Definition 5727.3 seed a finite min/max operation route for two regular Cauchy real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, host order completeness, selected limits, countable choice, host lattice operations, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-scale exposure, lower-member routing, upper-member routing, readback ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLatticeOperationsUp.

Constructive story: A $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ packet is generated from two regular Cauchy Real rows, a shared dyadic tolerance surface, RegularCauchyMinimum and RegularCauchyMaximum rows, paired regular rational readback, a paired RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5728

A Concrete Naming Certificate for $\mathsf{CauchyModulusBridge}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyModulusBridge}^{\uparrow}$ packet records the finite handoff by which a displayed Cauchy-criterion request becomes an explicit modulus schedule before any regular-rational readback or real-name seal is consumed. It sits after the effective criterion packet of chapter 3695, the modulus schedule surface of chapter 292, the regular rational readback of chapter 301, the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the L10 bridge from criterion-facing reads to explicit schedules as finite NameCert data; it is not quotient stream equality, a selected host limit, countable choice, trichotomy, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5728.1 (Cauchy modulus bridge carrier)**.** *A* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, M, E, S, D, R, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyCriterion}^{\uparrow}$ *request row naming the late-pair comparison surface to be served by the bridge.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row assigning the displayed precision request to a finite tail threshold.*
3. *E is the* $\mathsf{EffectiveCauchyCriterion}^{\uparrow}$ *row tying the same criterion request and modulus schedule to a finite effective handoff.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the criterion request and scheduled by the modulus row.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the radius, tail comparison, and endpoint budget used by the request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row available only after Q, M, E, S, D have been displayed.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the criterion, modulus, effective handoff, window, tolerance, and regular-rational rows have been read.*
8. *H records componentwise* hsame *transport for the criterion, modulus, effective handoff, stream-window, dyadic, regular-rational, real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a Cauchy-criterion request through $Q, M, E, S, D, R, L, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusBridge}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, EffectiveCauchyCriterio StreamName$^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, M, E, S, D, R, L, H, C, P, N$. It has no coordinate for quotient streams, selected limits, host sequence equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusBridgeUp.CauchyModulusBridgeTasteGate single carrier alignment`

Theorem 5728.2 (Cauchy modulus bridge NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *carrier $B = (Q, M, E, S, D, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed criterion row Q, modulus schedule M, effective criterion handoff E, finite stream window S, dyadic tolerance ledger D, regular-rational readback R, terminal real seal L, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 5728.1. The analytic rows visible to a consumer are exactly the criterion request Q, modulus schedule M, effective handoff E, finite window S, dyadic tolerance ledger D, regular-rational readback R, and terminal real seal L.

The bridge obligation is the ordering of those rows. A Cauchy-criterion request first exposes Q and then reads the displayed threshold in M through the effective handoff E; only after that handoff are the stream window S and dyadic tolerance ledger D available for regular readback.

The downstream rows are forced by the same carrier projection. The row R is the $\mathsf{RegSeqRat}^{\uparrow}$ readback obtained from the displayed window and tolerance data, and L is the $\mathsf{Real}^{\uparrow}$ seal reached only through that readback.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5728.3 (Cauchy modulus bridge effective-criterion handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CauchyCriterion}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{EffectiveCauchyCriterion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Re}$$

The handoff exposes only the displayed criterion request, explicit modulus schedule, effective criterion row, finite stream window, dyadic tolerance ledger, regular rational readback, terminal real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. It exports no quotient stream equality, selected host limit, hidden modulus oracle, countable-choice schedule, trichotomy split, host sequence equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with Definition 5728.2. It places every consumer read behind the criterion row, the explicit modulus row, and the effective criterion handoff.

Next open the finite observation route. The stream-window row S and dyadic tolerance row D are downstream of Q, M, E, so the regular-rational row R is a displayed readback from the same request rather than a detached sequence or selected limit.

The terminal seal is last. The $\mathsf{Real}^{\uparrow}$ row L is consumed only after R has been displayed, while H, C, P, N preserve the same dependency order under transport, replay, provenance, and local naming.

Thus any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer sees exactly the route stated in the theorem and cannot bypass it through a hidden analytic object. □

Theorem 5728.4 (Cauchy modulus bridge choice-free schedule)**.** *Let*

$$B = (Q, M, E, S, D, R, L, H, C, P, N) \quad \textit{and} \quad B' = (Q', M', E', S', D', R', L', H', C', P', N')$$

be accepted $\mathsf{CauchyModulusBridge}^{\uparrow}$ *carriers. If they agree componentwise on the displayed rows* $Q, M, E, S, D, R, L, H, C, P, N$*, then they determine the same modulus schedule and the same* $\mathsf{Real}^{\uparrow}$ *seal. No consumer of either packet can insert a countable-choice schedule, hidden modulus oracle, selected host limit, or extra selector coordinate between the criterion request and the terminal seal.*

Proof. Project both carriers through Definition 5728.1. The hypothesis identifies every displayed coordinate of B and B', so the criterion requests, explicit modulus rows, effective handoff rows, stream windows, dyadic ledgers, regular readbacks, Real seals, transport, replay, provenance, and local names are the same.

Use Definition 5728.2 to read the NameCert surface. Its obligation list has no row outside $Q, M, E, S, D, R, L, H, C, P, N$, so there is no remaining coordinate in which a second schedule or selector could differ.

Apply Definition 5728.3. The consumer order is forced as Q then M then E then S then D then R then L, and the terminal $\mathsf{Real}^{\uparrow}$ seal is downstream from the same regular-rational readback.

Thus the two accepted packets determine the same choice-free schedule and the same Real seal. The excluded choice and selector objects cannot be inserted because the carrier and its NameCert obligations expose no such coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyModulusBridge}^{\uparrow}$ packet is generated from a CauchyCriterion request row, a CauchyModulus schedule, an effective Cauchy criterion handoff, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5728.1, Definition 5728.2, Definition 5728.3, and Definition 5728.4 seed the finite bridge from Cauchy-criterion requests to explicit modulus schedules before RegSeqRat and Real consumers read the route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyModulusBridgeUp.CauchyModulusBridgeTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, hidden modulus oracles, countable choice, trichotomy, host sequence equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion-to-modulus exactness, effective handoff ordering, StreamName and DyadicRatCore readback, RegSeqRat handoff, RealUp seal confinement, transport stability, continuation replay, and provenance nonescape for BEDC.Derived.CauchyModulusBridgeUp.

Chapter 5729

A Concrete Naming Certificate for $\mathsf{MyhillNerode}^{\uparrow}$

Following Myhill and Nerode, the $\mathsf{MyhillNerode}^{\uparrow}$ packet records the finite right-congruence classifier behind regular languages and minimal finite automata as displayed BEDC data. It consumes accepted-word rows from chapter 351, presentation rows from chapter 2364, finite carrier rows from chapter 112, and word-spine rows from chapter 36. The packet does not import an external quotient of all languages; it names the finite distinguishability ledger that a minimization consumer can audit.

Definition 5729.1 (Myhill–Nerode carrier)**.** *A* $\mathsf{MyhillNerode}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (\Sigma, W, L, E, C, D, Q, \delta, q_0, F, \mu, H, R, P, N)$$

with the following displayed rows:

1. Σ *is the finite alphabet row, read through* $\mathsf{FinSet}^{\uparrow}$*.*
2. W *is the finite word-window row, read through* $\mathsf{List}^{\uparrow}$ *over* Σ*.*
3. L *is the accepted-word observation ledger supplied by a* $\mathsf{RegularLanguage}^{\uparrow}$ *packet.*
4. E *is the finite right-congruence table on the displayed word window.*
5. C *is the context-extension row recording that suffix extension by displayed words preserves the table.*
6. D *is the distinguishability row naming a displayed suffix witness whenever two table rows are separated.*
7. Q *is the finite state row whose states are the displayed equivalence classes of* E*.*
8. δ *is the transition row induced by appending one alphabet symbol to a class representative.*
9. q_0 *is the start class of the empty word.*
10. F *is the accepting-class row, determined by membership in the accepted-word ledger.*
11. μ *is the minimization handoff row from the right-congruence table to the finite automaton presentation.*
12. H *stores componentwise* hsame *transport for alphabet, word-window, language, congruence, suffix, state, transition, accepting, and minimization rows.*

13. *R stores* Cont *replay from a regular-language query through the displayed right-congruence table.*
14. *P stores* Pkg *provenance over* $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{FiniteAutomaton}^{\uparrow}$, $\mathsf{FinSet}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
15. *N is the local* $\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Sigma, W, L, E, C, D, Q, \delta, q_0, F, \mu, H, R, P, N$. It has no coordinate for an infinite language quotient, a nondeterministic presentation, a regular-expression conversion, or a proof that an arbitrary external automaton has already been minimized.

Lean4 ✓ `BEDC.Derived.MyhillNerodeUp.MyhillNerodeTasteGate single carrier alignment`

Theorem 5729.2 (Myhill–Nerode NameCert obligations)**.** *For every accepted* $\mathsf{MyhillNerode}^{\uparrow}$ *carrier*

$$M = (\Sigma, W, L, E, C, D, Q, \delta, q_0, F, \mu, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}$ *surface consists exactly of finite alphabet exposure, word-window exposure, accepted-word observation, right-congruence tabulation, suffix-stability replay, distinguishability witnesses, quotient-state construction, induced transition replay, start-class selection, accepting-class selection, minimization handoff, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5729.1. The rows Σ, W, L, E, C, D expose the finite observation table and the suffix-stability checks used to read right congruence.

The rows Q, δ, q_0, F then repackage the table as a deterministic finite automaton presentation. Since Q is built from the displayed classes of E, the transition row is read by extending a representative by one displayed alphabet symbol and returning to the corresponding class.

The rows μ, H, R, P, N keep the minimization handoff, transport, replay, provenance, and local name attached to the same packet. No omitted coordinate can supply an external quotient, nondeterministic branch, or regular-expression conversion, so the listed rows exhaust the NameCert obligations. □

Theorem 5729.3 (Myhill–Nerode DFA minimization handoff)**.** *Every* $\mathsf{RegularLanguage}^{\uparrow}$ *consumer that claims a minimal deterministic finite automaton through a* $\mathsf{MyhillNerode}^{\uparrow}$ *packet must expose the finite right-congruence row E, the suffix-stability row C, the distinguishability row D, the quotient-state row Q, the induced transition row δ, the accepting-class row F, and the minimization handoff row μ. The handoff may feed a* $\mathsf{FiniteAutomaton}^{\uparrow}$ *presentation with those rows, but it does not identify arbitrary automaton presentations, choose a nondeterministic branch, or translate the packet into a regular-expression proof.*

Proof. Begin with the obligation theorem Definition 5729.2. It forces every minimization read through the displayed right-congruence table, suffix-stability replay, and distinguishability witnesses before any quotient-state row is consumed.

The quotient construction then uses the finite rows Q, δ, q_0, F to build a deterministic presentation. This presentation is compatible with the finite automaton carrier of chapter 2364 because it exposes finite states, a finite alphabet, a transition table, a start state, accepting states, and replay rows.

The minimization handoff remains bounded by the displayed table. It proves only the certificate route from regular-language observations to the minimal finite presentation named by the packet; stronger equivalence claims are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}$.

Constructive story: A $\mathsf{MyhillNerode}^{\uparrow}$ packet is generated from a finite alphabet row, word-window row, accepted-word observation ledger, right-congruence table, suffix-stability row, distinguishability witnesses, quotient-state row, induced transition row, start class, accepting classes, minimization handoff, componentwise transport, continuation replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5729.1, Definition 5729.2, and Definition 5729.3 seed the finite right-congruence certificate and its deterministic-minimization handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary automaton equivalence, nondeterministic minimization, regular-expression conversion, host-language quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, right-congruence stability, distinguishability coverage, quotient-state exactness, induced-transition replay, minimization handoff, TasteGate coverage, transport, replay, provenance, and local naming for BEDC.Derived.MyhillNerodeUp.

Chapter 5730

A Concrete Naming Certificate for $\mathsf{VariationSeminorm}^{\uparrow}$

Following Bishop–Bridges bounded-variation analysis and the Bourbaki treatment of seminormed structures, the $\mathsf{VariationSeminorm}^{\uparrow}$ packet records the finite seminorm-budget surface attached to displayed partition variation data. It sits between the bounded-variation carrier of chapter 398, the bounded-variation real-function row of chapter 3654, the variation-norm consumer of chapter 3804, the Jordan route of chapter 2069, the total-variation function surface of chapter 2257, the regular rational readback of chapter 301, and the terminal real endpoint seal of chapter 38. The packet names displayed partition-variation budgets and seminorm comparison rows without selecting a host supremum over all partitions, a quotient class of functions, or a completed bounded-variation space.

Definition 5730.1 (VariationSeminorm carrier)**.** *A* $\mathsf{VariationSeminorm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, F, J, T, R, Q, A, L, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{BoundedVariation}^{\uparrow}$ *packet, including its displayed partition ledger, endpoint rows, adjacent-edge observations, finite variation sum, and common-refinement data.*
2. *F is the* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *read tying the partition ledger to a displayed real-valued function row over the inspected interval.*
3. *J is the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *handoff row, exposing only the finite positive- and negative-variation ledgers available from the same partition data.*
4. *T is the* $\mathsf{TotalVariationFunction}^{\uparrow}$ *observation row for the displayed partition windows inspected by the packet.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal for all scalar values and variation budgets that the packet compares.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used when scalar budgets and endpoint values are inspected through regular rational names.*
7. *A is the displayed variation-seminorm row. It records the null-row witness for constant differences, finite additivity over displayed concatenations, scalar budget transport, and monotone comparison of partition refinements.*

8. *L is the seminorm ledger, listing the partition windows, budget rows, finite variation sums, constant-row witnesses, and refinement comparisons used by A.*
9. *H records componentwise* hsame *transport for the bounded-variation source, real-function row, Jordan route, total-variation observation, Real seal, regular-name readback, seminorm row, ledger, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a seminorm-budget request through $B, F, J, T, R, Q, A, L, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{VariationSeminorm}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{VariationNorm}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed source packet, real-function row, Jordan route, total-variation observation, Real and RegSeqRat scalar reads, seminorm ledger, componentwise transport, replay, provenance, and local name. It has no coordinate for a host supremum, quotient equality of functions, a completed seminormed space, a measure-theoretic variation object, or bridge checking.

Lean4 ✓ `BEDC.Derived.VariationSeminormUp.VariationSeminormTasteGate single carrier alignment`

Theorem 5730.2 (VariationSeminorm NameCert obligations)**.** *For every accepted* $\mathsf{VariationSeminorm}^{\uparrow}$ *carrier $S = (B, F, J, T, R, Q, A, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}$ *surface consists exactly of bounded-variation source admission, bounded-variation real-function readback, Jordan-route availability, total-variation observation, Real endpoint sealing, RegSeqRat scalar readback, displayed seminorm-row formation, ledger exactness, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming through the displayed rows.*

Proof. Project the finite carrier of Definition 5730.1. The analytic data available to the packet are the bounded-variation source B, the real-function row F, the Jordan handoff J, the total-variation observation T, the Real seal R, and the regular-name readback Q.

The seminorm row A is then formed from the displayed budget comparisons in those rows. Its null-row, finite-additivity, scalar-transport, and refinement-monotonicity clauses are recorded in the ledger L, so each seminorm request is tied to inspected partition windows rather than to a hidden family of all partitions.

Finally H, C, P, N transport, replay, source, and name exactly the same finite surface. Since the carrier has no host-supremum, quotient-function, completed-space, variation-measure, or bridge coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 5730.3 (VariationSeminorm refinement budget route)**.** *Every accepted* $\mathsf{VariationSeminorm}^{\uparrow}$ *packet exports the finite route*

$$\mathsf{BoundedVariation}^{\uparrow}, \mathsf{BoundedVariationRealFunction}^{\uparrow} \longrightarrow \mathsf{JordanVariationDecomposition}^{\uparrow}, \mathsf{TotalVariationFunction}^{\uparrow} \longrightarrow$$

to bounded-variation completion and regulated-integration consumers. The route transports displayed partition-variation budgets and seminorm comparison rows, but it exports no host supremum over all partitions, quotient equality of functions, selected Jordan decomposition, completed bounded-variation Banach space, or bridge data.

Proof. Begin with an accepted packet $S = (B, F, J, T, R, Q, A, L, H, C, P, N)$. A consumer first reads the bounded-variation source and real-function rows, so every endpoint value and edge variation remains tied to the finite partition windows in B and F.

The Jordan and total-variation rows are then read only as displayed handoffs. They expose finite positive- and negative-variation ledgers and total-variation observations attached to the same partition windows.

The scalar budget route is sealed by Q and R. The seminorm ledger L records the null, additivity, scalar-transport, and refinement-comparison rows used by A, while H, C, P, N transport, replay, source, and name the packet. No remaining coordinate can supply the excluded host objects, so the exported route is exactly the displayed finite seminorm-budget route. □

Falsifiable prediction: Every accepted $\mathsf{VariationSeminorm}^{\uparrow}$ read factors through a displayed $\mathsf{BoundedVariation}^{\uparrow}$ source, a $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ row, $\mathsf{JordanVariationDecomposition}^{\uparrow}$ and $\mathsf{TotalVariationFunction}^{\uparrow}$ handoff rows, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ scalar reads, and the local seminorm ledger, transport, replay, provenance, and naming rows.

Independence witness: boundedvariation, bounded-variation-real-function, variation-norm, jordan-variation-decomposition, total-variation-function, regseqrat, and real: no listed sibling is bijective to $\mathsf{VariationSeminorm}^{\uparrow}$ because this packet stores the seminorm-specific null, finite-additivity, scalar-transport, refinement-budget, ledger, replay, provenance, and local naming rows together as one finite surface.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationSeminorm}^{\uparrow}$ packet is generated from a BoundedVariation source, a BoundedVariationRealFunction read, JordanVariationDecomposition and TotalVariationFunction handoff rows, RegSeqRat and Real scalar reads, a displayed seminorm row, a finite budget ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5730.1, Definition 5730.2, and Definition 5730.3 seed the finite variation-seminorm carrier, obligation surface, and refinement-budget route over displayed bounded-variation and scalar-readback rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.VariationSeminormUp.VariationSeminormTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host suprema over all partitions, quotient equality of functions, selected Jordan decompositions, completed bounded-variation Banach spaces, variation measures, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, real-function readback, Jordan and total-variation handoff availability, Real and RegSeqRat scalar exactness, seminorm ledger exactness, classifier transport, replay, provenance, local naming, and nonescape for BEDC.Derived.VariationSeminormUp.

Chapter 5731

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet records the separated completion boundary needed by the L10 Real and Completion route as finite BEDC data. It sits after the separation predicate of chapter 1925, the separated-completion carrier of chapter 1612, the metric completion route of chapter 1506, the finite stream interface of chapter 126, the dyadic tolerance core of chapter 291, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the envelope through displayed rows only; it does not quotient filters, select representatives, identify host equalities, invoke countable choice, or import ambient completeness.

Definition 5731.1 (Hausdorff completion envelope carrier)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (H, S, M, W, D, R, L, T, K, P, N)$$

where H *is the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$ *separation row,* S *is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* L *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal,* T *is componentwise* $\mathsf{BHist/hsame}$ *transport,* K *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *row. A consumer of* E *receives a separated completion boundary only through these coordinates.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeTasteGate single carrier alignment`

Theorem 5731.2 (Hausdorff completion envelope obligations)**.** *Every accepted* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *read must expose the carrier of Definition 5789.1 in the order*

$$H, S, M, W, D, R, L, T, K, P, N.$$

The separation row H *and separated-completion row* S *are available before metric completion, stream observation, dyadic tolerance, regular readback, and real-seal rows are consumed; the transport, replay, provenance, and naming rows preserve the same displayed packet.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeNameCertObligations`

Proof. Project the carrier of Definition 5789.1. The packet has no completion-facing coordinates except $H, S, M, W, D, R, L, T, K, P, N$.

The Hausdorff and separated-completion rows are the first boundary data in the packet. Thus a consumer cannot inspect the metric completion route, finite stream windows, dyadic tolerances, regular readback, or terminal real seal without first reading the displayed separation surface.

Finally, the structural rows T, K, P, N only transport, replay, source, and name the same finite packet. They do not create quotient filters, selected representatives, host equality, choice-selected routes, or ambient completeness. □

Theorem 5731.3 (Hausdorff completion separated metric route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier factors through the separated route*

$$H, S \longmapsto M \longmapsto W, D, R, L.$$

The route records a separated metric-completion boundary for the L10 Real and Completion interface, not a quotient completion, a host equality theorem, a choice-selected representative, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier separated metric route`

Proof. Start from Definition 5789.2. It places the Hausdorff row H and separated-completion row S before the metric completion row M and before the stream, dyadic, regular-rational, and real-seal rows.

Read the metric completion route through M. Since M is downstream of H, S, every completion-facing use of M carries the displayed separated boundary with it.

The final Real-facing read is the finite route W, D, R, L. Because these rows are still coordinates of the same carrier, the route cannot be replaced by quotient representatives, host equality, countable choice, or ambient completeness. □

Theorem 5731.4 (Hausdorff completion envelope sibling route)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *consumer may hand its separated boundary to* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *only through the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$*,* $\mathsf{SeparatedCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows of*

$$E = (H, S, M, W, D, R, L, T, K, P, N).$$

The handoff contains no quotient-filter coordinate, representative-selection coordinate, host-equality coordinate, or ambient-completeness coordinate.

Proof. Apply Definition 5789.2. It places the Hausdorff row H, separated-completion row S, metric-completion row M, stream row W, dyadic row D, regular-rational row R, and terminal Real row L inside one displayed packet.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

The sibling $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ consumer therefore reads the same separated boundary as its input surface rather than receiving a separate primitive. Since the carrier only has the displayed rows and the structural rows T, K, P, N, quotient filters, selected representatives, host equality, and ambient completeness remain outside the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier sibling route`

Theorem 5731.5 (Hausdorff completion envelope Cauchy-net consumer link)**.** *Every* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier must read the same* $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before its directed-net completion route is consumed. The downstream sibling is chapter 3794, and the handoff is the displayed route*

$$H, S, M, W, D, R, L \longmapsto \mathsf{CauchyNetCompletion}^{\uparrow}.$$

It exports no quotient net, selected representative, host equality, countable-choice schedule, or ambient completeness coordinate.

Proof. Project the carrier $E = (H, S, M, W, D, R, L, T, K, P, N)$ of Definition 5789.1. The only completion-facing rows available to a consumer are the Hausdorff row H, separated-completion row S, metric-completion route M, finite stream row W, dyadic tolerance row D, regular readback row R, and terminal Real row L.

Apply Definition 5789.2. It places H, S, M, W, D, R, L inside one displayed packet before the structural rows T, K, P, N are used for transport, replay, provenance, and local naming.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

Therefore a downstream $\mathsf{CauchyNetCompletion}^{\uparrow}$ read can only consume the envelope through the same separated metric route before its directed-net completion surface is inspected. Since the packet has no quotient-net, selected-representative, host-equality, countable-choice, or ambient-completeness row, none of those objects can enter the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeForwardLink`

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5789.1, Definition 5789.2, and Definition 5789.3 name the separated completion envelope surface for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, host equality, choice-selected representatives, or ambient completeness.

Upgrade path: Obligation closure requires the carrier route to be tied to the sibling completion obligation theorems and then exposed as a public chapter surface.

Constructive story: A $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet is generated from Hausdorff separation, separated-completion boundary, metric-completion route, finite stream windows, dyadic tolerance, regular-rational readback, Real seal, transport, replay, provenance, and local NameCert rows.

Chapter 5732

A Concrete Naming Certificate for $\mathsf{BoundedLinearFunctional}^{\uparrow}$

Following Banach and Bourbaki functional analysis, the $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet records the scalar-valued bounded-linear-operator row that duality and weak-star consumers inspect before any host dual space is available. It sits over the linear-map route of chapter 48, the bounded-linear-operator surface of chapter 1644, the scalar-bound neighbour chapter 3603, the Banach-dual row of chapter 2265, the finite weak-star window of chapter 3420, the scalar endpoint seal of chapter 38, and the normed source surface of chapter 1950. The chapter names only displayed scalar-functional data: source rows, linearity rows, scalar target readback, norm-bound evidence, transport, replay, provenance, and local naming.

Definition 5732.1 (Bounded linear functional carrier)**.** *For a displayed* $\mathsf{NormedSpace}^{\uparrow}$ *source row* E *over the scalar endpoint surface of* $\mathsf{Real}^{\uparrow}$*, a* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E)$ *carrier is a finite* BHist *packet*

$$\Lambda = (E, L, T, K, O, H, C, P, N)$$

with the following displayed rows:

1. *E is the source normed-space row, including its carrier endpoints, scalar action, additive row, norm row, and classifier.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row from E to the scalar* $\mathsf{Real}^{\uparrow}$ *target.*
3. *T is the scalar-valued* $\mathsf{BoundedLinearOperator}^{\uparrow}(E, \mathsf{Real}^{\uparrow})$ *row carrying the same endpoint action as L.*
4. *K is the* $\mathsf{Real}^{\uparrow}$ *nonnegative bound endpoint for the functional.*
5. *O is the* $\mathsf{OperatorNorm}^{\uparrow}$ *handoff row exposing where the bound K is used.*
6. *H records componentwise* hsame *transport for the source, linear-map row, bounded-operator row, scalar bound, operator-norm handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a scalar-functional request through E, L, T, K, O, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedLinearFunctional}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{BanachDual}^{\uparrow}$, $\mathsf{BanachAlaoglu}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed source classifier, scalar endpoint transport, bounded-operator transport, bound transport, norm-bound ledger transport, replay, provenance, and local naming rows. It has no coordinate for a host dual space, quotient equality of functions, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BoundedLinearFunctionalUp.BoundedLinearFunctionalTasteGate single carrier alignment`

Theorem 5732.2 (Bounded linear functional NameCert obligations)**.** *For every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *carrier* $\Lambda = (E, L, T, K, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *surface consists exactly of source normed-space admission, linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from host dual objects. A consumer may inspect* $E, L, T, K, O, H, C, P, N$*, but it receives no ambient function space, quotient operator equality, selected representative, Hahn–Banach witness, unrestricted weak-star compactness theorem, or bridge data.*

Proof. Project the carrier rows. The analytic coordinates are exactly the source normed-space row E, the linear-map row L, the scalar-valued bounded-operator row T, the RealUp bound endpoint K, and the operator-norm handoff O.

The linearity obligation is read through $\mathsf{LinMap}^{\uparrow}$, while boundedness is read through $\mathsf{BoundedLinearOperator}^{\uparrow}(E,$ The scalar target is already the displayed $\mathsf{Real}^{\uparrow}$ endpoint surface, so the functional row never becomes a host-level function.

The bound exactness is the shared route through K and O. The operator-norm handoff records where the scalar bound is used, and componentwise hsame transport moves the source, action, bound, ledger, replay, provenance, and local naming rows together.

No remaining coordinate can manufacture a dual-space quotient, selected representative, Hahn–Banach witness, unrestricted compactness theorem, or bridge check. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 5732.3 (Bounded linear functional operator-norm handoff)**.** *Every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E$ *packet exports the finite route*

$$\mathsf{LinMap}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{OperatorNorm}^{\uparrow} \longmapsto \mathsf{BoundedLinearFunctional}^{\uparrow}$$

to functional-analysis consumers. The route first exposes the carried scalar-valued linear action, then the bounded-operator row, then the RealUp bound endpoint and operator-norm ledger; it does not expose a host supremum, quotient equality of functionals, selected norm-attaining vector, or hidden Banach completeness.

Proof. Begin with an accepted packet $\Lambda = (E, L, T, K, O, H, C, P, N)$. The read of L supplies only the displayed linear-map action from the source row to the scalar target.

The read of T then packages the same action as a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row. Its target row is $\mathsf{Real}^{\uparrow}$, and its bound endpoint is the displayed scalar K.

Finally the operator-norm handoff O records the norm-bound ledger that downstream consumers may inspect. Because no host norm function, quotient functional equality, selected vector, or hidden completion row is present, the exported handoff is exactly the displayed scalar-bound route. □

Theorem 5732.4 (Bounded linear functional dual-row nonescape)**.** *Any read of a* $\mathsf{BanachDual}^{\uparrow}$ *or* $\mathsf{BanachAlaoglu}^{\uparrow}$ *consumer that uses a* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *row factors through the same source normed-space row, scalar-valued bounded-operator row, RealUp bound endpoint, operator-norm handoff, componentwise transport, replay, provenance, and local naming rows of Definition 5790.1. The duality consumer receives a finite scalar-functional row, not a host dual space, a quotient function class, an unrestricted weak-star compactness theorem, or a selected cluster point.*

Proof. Read the duality consumer first. A $\mathsf{BanachDual}^{\uparrow}$ request needs a scalar-functional row over a displayed source, while a $\mathsf{BanachAlaoglu}^{\uparrow}$ request needs a finite family of such scalar-functional observations.

In either case the only scalar-functional packet available here is Λ. Its source row, bounded-operator row, bound endpoint, operator-norm handoff, and structural rows are projected in the order displayed by Definition 5790.1.

The downstream dual chapters may reuse those rows, but they cannot add coordinates that are absent from the packet. Thus quotient dual objects, host function classes, unrestricted weak-star compactness, selected cluster points, and bridge checks remain outside the read. □

Falsifiable prediction: Every accepted $\mathsf{BoundedLinearFunctional}^{\uparrow}$ scalar-functional read factors through a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ action row, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, and the local hsame, Cont, Pkg, and NameCert rows.

Independence witness: linearmap, boundedlinearoperator, operatornorm, banachdual, banachalaoglu, real, and normedspace: no listed sibling is bijective to $\mathsf{BoundedLinearFunctional}^{\uparrow}$ because this packet stores the scalar target restriction, the dual-facing provenance row, the operator-norm handoff, transport, replay, and local naming together as one finite scalar-functional surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet is generated from a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ scalar action, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5790.1, Definition 5790.2, Definition 5790.3, and Definition 5790.4 seed the scalar-functional row consumed by BanachDualUp and BanachAlaogluUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host dual spaces, quotient equality of functionals, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, scalar linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm handoff exactness, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BoundedLinearFunctionalUp.

Chapter 5733

A Concrete Naming Certificate for $\mathsf{CompletionModulusCategory}^{\uparrow}$

Following Bishop and Bridges on constructive completion and the functorial treatment of completions, the $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet records the finite category surface whose arrows preserve displayed completion moduli. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the completion functor of chapter 426, and the Cauchy completion functor of chapter 423. The packet names modulus-preserving completion morphisms as BEDC rows; it does not export quotient completions, selected representatives, host continuous maps, countable choice, or ambient completeness.

Definition 5733.1 (CompletionModulusCategory carrier)**.** *A* $\mathsf{CompletionModulusCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, A, S, R, D, E, F, H, C, P, N)$$

with the following displayed rows:

1. *O is the object ledger. Each object row records a completion-facing source, its displayed Cauchy-modulus discipline, and the local completion target read through the surrounding completion chapters.*
2. *A is the arrow ledger. Each arrow row records a finite morphism request together with the modulus transformation that sends source tolerances to target tolerances.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source and target names of an arrow.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the stream windows have been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare source and target moduli.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row read only after S, R, D have supplied the displayed tolerance route.*
7. *F records identity and composition rows for the completion functoriality surface, with identity arrows preserving the same modulus and composite arrows composing the displayed modulus transformations.*
8. *H records componentwise* hsame *transport for object rows, arrow rows, stream windows, regular readback, dyadic tolerances, Real seals, functoriality rows, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an arrow request through $O, A, S, R, D, E, F, H, P, N$.*
10. *P is the* Pkg *provenance over* CompletionModulusCategory$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, CauchyCompletionFunctor$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{CompletionModulusCategory}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite category packet for modulus-preserving completion morphisms. It has no coordinate for quotient completion points, selected representatives, host functions, global choice schedules, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryTasteGate single carrier alignment`

Theorem 5733.2 (CompletionModulusCategory NameCert obligations)**.** *For every accepted* CompletionModulusCa *carrier $M = (O, A, S, R, D, E, F, H, C, P, N)$, the local* NameCert$_{\text{CompletionModulusCategory}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed object ledger, arrow ledger, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, identity and composition rows, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface additionally requires each arrow row in A to expose its source modulus, target modulus, and modulus transformation before any Real$^{\uparrow}$*-facing read is accepted; each identity row in F to preserve the displayed modulus without adding a choice coordinate; and each composition row in F to compose the two displayed modulus transformations before the downstream seal is visible.*

Proof. Project the accepted carrier. The packet contains only the rows $O, A, S, R, D, E, F, H, C, P, N$, so carrier admission and ledger exhaustion are componentwise.

An arrow-facing request first reads the object and arrow ledgers O, A. The source and target names are then inspected through the finite stream windows S, regular rational readback R, and dyadic tolerance ledger D.

The functoriality rows F are local to the same displayed moduli. Identity preserves the stored modulus transformation, and composition combines the two stored transformations before the terminal seal E can be read.

Finally H, C, P, N transport, replay, source, and name this same finite route. Since quotient completions, selected representatives, host functions, global choice schedules, and ambient completeness are not carrier coordinates, they cannot be exported by the local NameCert. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryNameCertObligations`

Theorem 5733.3 (CompletionModulusCategory modulus functoriality)**.** *Every completion-facing consumer of an accepted* CompletionModulusCategory$^{\uparrow}$ *packet reads a modulus-preserving morphism through the finite route*

$$O, A, S, R, D, F, E, H, C, P, N.$$

Thus identity and composition of completion morphisms preserve the displayed modulus data before any Real$^{\uparrow}$ *seal or completion-functor read is exposed. The route factors through* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, *and* CauchyCompletionFunctor$^{\uparrow}$ *rather than through quotient completion equality, selected representatives, host continuous maps, countable choice, or ambient completeness.*

Proof. Start with a completion-facing morphism request. The object ledger O fixes the source and target completion rows, and the arrow ledger A fixes the modulus transformation to be checked.

The readback rows S, R, D display the inspected stream windows, regular rational observations, and dyadic tolerance comparisons. These rows are the only route by which the requested modulus can face the terminal Real seal.

The functoriality row F then supplies the identity or composition clause. In the identity case the same displayed modulus is replayed. In the composition case the two displayed modulus transformations are composed as finite rows before the result is handed to E.

The structural rows H, C, P, N preserve and name the same route. Therefore every completion-functor consumer receives finite modulus preservation data and no excluded quotient, selection, host-map, choice, or ambient-completeness surface. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryModulusFunctoriality`

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}$.

Constructive story: A $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet is generated from completion object rows, modulus-preserving arrow rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, RealUp seals, identity and composition rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5791.1, Definition 5791.2, and Definition 5791.3 seed the finite category surface for modulus-preserving completion morphisms.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host continuous maps, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-preserving arrow exactness, identity and composition rows, tolerance readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionModulusCategoryUp.

Chapter 5734

A Concrete Naming Certificate for $\mathsf{MarkovTriggerDynamics}^{\uparrow}$

The $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet realizes the finite rank-trigger dynamics of Definition 9462.1541, Definition 9462.1542, and Definition 9462.1546 as BEDC NameCert data. It records the state, support-rank, transition-count, drift, trigger-time, classifier, continuation, provenance, and naming rows needed by a downstream finite-dynamics consumer. The packet is a finite BHist surface for trigger-time readback; it is not a stochastic process on an ambient probability space, not an infinite sample path, not a hidden field model, and not a host Markov-chain object.

Definition 5734.1 (MarkovTriggerDynamics carrier)**.** *A* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, K, A, D, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite state row. It records the consumed external-codon count m and the covered support rank r for the current trigger state.*
2. *K is the support-rank row. It records the finite support coordinates currently covered by the observed codon rows and the rank read from that support.*
3. *A is the transition-count row. It stores the finite count of rank-preserving and rank-increasing next draws available from the current state.*
4. *D is the drift row. It records the displayed one-step rank drift computed from the same transition counts.*
5. *G is the trigger-time row. It records the finite recursion for the time to reach full rank and the deterministic threshold row consumed by trigger-time readers.*
6. *H records componentwise* hsame *transport for state, support-rank, transition-count, drift, trigger-time, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a state read through S, K, A, D, G, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$, BHist, hsame, Cont, *finite rank-trigger rows, finite transition-count rows, finite trigger-time rows, and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient probability space, hidden generator field, infinite sample path, external random oracle, host Markov-chain semantics, or unstated independence assumption.

Lean4 ✓ `BEDC.Derived.MarkovTriggerDynamicsUp.MarkovTriggerDynamicsTasteGate single carrier alignment`

Theorem 5734.2 (MarkovTriggerDynamics NameCert obligations)**.** *For every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier* $T = (S, K, A, D, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed state row, support-rank row, transition-count row, drift row, trigger-time row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface requires the transition-count row A *to be computed from the finite support-rank row* K*, the drift row* D *to read only the transition counts in* A*, and the trigger-time row* G *to replay the finite recursion from the displayed state row* S *without adding an external probability carrier.*

Proof. Project the accepted carrier. The packet exposes only $S, K, A, D, G, H, C, P, N$, so every NameCert obligation is a componentwise obligation on those rows.

The state and support rows S, K determine the finite rank-trigger situation. The transition-count row A counts rank-preserving and rank-increasing next draws from that finite support surface.

The drift row D is downstream of A, and the trigger-time row G is downstream of the same state and transition-count data. Thus the trigger-time read is a finite recursion over displayed rows, not an imported Markov-chain object.

Transport, replay, provenance, and local naming preserve the same coordinates. Since the excluded ambient and hidden objects are not coordinates of T, no consumer can read them from the packet. □

Theorem 5734.3 (MarkovTriggerDynamics finite trigger readback)**.** *Every trigger-time consumer of an accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *packet reads the finite route*

$$S, K, A, D, G, H, C, P, N.$$

Consequently the transition law, drift, and trigger-time rows are all determined by finite BHist transition-count data. No trigger-time read exports an infinite sample path, host Markov process, hidden field, or unstated independence source.

Proof. Start with the state row S and support-rank row K. They display the finite input state and the rank information that determines which next-draw counts are available.

The transition-count row A is the only row from which the drift row D may be read. The trigger-time row G then replays the finite recursion from those same transition counts.

Finally H, C, P, N transport, replay, source, and name the finite trigger route. Because no other row exists in the carrier, the stated nonescape clauses follow. □

Falsifiable prediction: Every $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ trigger-time read factors through finite state, support-rank, transition-count, drift, trigger-time, hsame, Cont, Pkg, and NameCert rows.

Independence witness: dna-boundary-tile, rank-trigger, finite-markov-transition: $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries state rows, support-rank rows, transition-count rows, drift rows, trigger-time rows, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Theorem 5734.4 (MarkovTriggerDynamics sibling dependency route)**.** *Every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *trigger-time read routes its finite state and transition-count rows through chapter 189 or chapter 4074 when the carrier is read as a Markov surface, through chapter 195 when it is read as finite transition evolution, and through chapter 3508 for the DNA boundary-trigger consumer.*

Proof. Project the existing carrier rows $S, K, A, D, G, H, C, P, N$. The state row S, support-rank row K, and transition-count row A provide exactly the finite Markov read, so a Markov-surface consumer reaches this packet through the Markov-chain or finite Markov-partition certificates.

The same rows, together with drift row D and trigger-time row G, form the finite transition-evolution route consumed by the dynamical-system certificate. The structural rows H, C, P, N then transport, replay, source, and name that route for the DNA boundary-trigger consumer.

This is a dependency route only. It does not add an ambient probability space, infinite sample path, unstated independence source, or host Markov-chain object to the carrier. □

Nontrivial TasteGate and FieldFaithful instances remain required before this finite trigger surface can be read as a checked biological field-faithfulness claim.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet is generated from finite state rows, support-rank rows, transition-count rows, drift rows, trigger-time recursion rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5792.1, Definition 5792.2, and Definition 5792.3 seed the finite rank-trigger Markov readback surface for DNA boundary-tile dynamics.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient probability spaces, infinite sample paths, hidden field models, host Markov-chain semantics, biological field-faithfulness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-count exactness, drift readback, trigger-time recursion, nontrivial TasteGate coverage, FieldFaithful evidence, transport, replay, provenance, and local naming for BEDC.Derived.MarkovTriggerDynamicsUp.

Chapter 5735

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet records the finite constructive route from regular Cauchy rational names to located completion data and then to the terminal $\mathsf{Real}^{\uparrow}$ seal. It reads the dyadic arithmetic surface of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the completion service exposed by chapter 128, and the real-name boundary of chapter 38. The packet supplies a located completion neighbour for the regular-Cauchy real route without asserting quotient completion equality, selected representatives, host order completeness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5735.1 (Regular Cauchy located completion carrier)**.** *A* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, Q, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the Cauchy name is inspected at requested precision scales.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for tolerance comparison, shrinkage, and rational distance estimates.*
4. *Q is the located completion row, recording the displayed located-distance and approximation data extracted from S, R, D.*
5. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row used only as a finite completion handoff for the displayed located data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback and located completion rows have been displayed.*
7. *H records componentwise* hsame *transport for stream windows, regular rational readbacks, dyadic arithmetic, located completion data, completion service, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a located-completion request through $S, R, D, Q, K, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, K, E, H, C, P, N$. The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host order completeness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedCompletionUp.RegularCauchyLocatedCompletionTasteGate single carrier alignment`

Theorem 5735.2 (Regular Cauchy located completion obligations)**.** *For every accepted* RegularCauchyLocatedCom *carrier*

$$L = (S, R, D, Q, K, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream-window row, regular rational readback row, dyadic arithmetic ledger, located completion row, complete-metric handoff, real seal, transport, replay, provenance, and local name;*
2. *window-readback coherence, requiring S to expose the finite inspection windows before R may be consumed as a regular rational name;*
3. *dyadic locatedness, requiring D to supply the tolerance comparisons and distance estimates used by the located completion row Q;*
4. *completion handoff ordering, requiring Q to be displayed before the* $\mathsf{CompleteMetric}^{\uparrow}$ *row K is exposed;*
5. *real-seal ordering, requiring E to be read only after S, R, D, Q, K have been displayed;*
6. *classifier stability, requiring componentwise* hsame *transport and displayed* Cont *replay to preserve all visible rows;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no quotient completion equality, selected representative, countable choice, host order completeness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5793.1. Its rows list the finite stream windows, regular rational readback, dyadic arithmetic ledger, located completion data, complete-metric handoff, real seal, and the structural rows.

Window-readback coherence follows because R has no independent observation coordinate in this packet. The regular rational read must pass through S, and the tolerance computations used by that read are then checked against the dyadic row D.

The located completion row Q is the only row that records located-distance data. The completion handoff K consumes that displayed row, and the real seal E is exposed only after the handoff has been displayed.

Transport, replay, provenance, and local naming are exhausted by H, C, P, N. Since quotient completion equality, selected representatives, countable choice, host order completeness, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier, no NameCert obligation can export them. □

Theorem 5735.3 (Regular Cauchy located completion Real seal route)**.** *Let* $L = (S, R, D, Q, K, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the located completion read factors through the finite route*

$$S, R, D \longmapsto Q \longmapsto K \longmapsto E \longmapsto H, C, P, N.$$

Thus the packet reaches the real-name boundary only through displayed $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic, located completion data, and the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff. It does not export quotient completion equality, selected representatives, countable choice, host order completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing read of the packet. The only observable name data are the stream windows S and the regular rational readback R, so any request for a real seal must first inspect those rows.

The dyadic row D supplies the tolerance and distance comparisons used by the located completion data Q. The complete-metric handoff K is then read as a service row for that displayed located data, not as an ambient completeness theorem.

Finally the seal row E exposes the $\mathsf{Real}^{\uparrow}$ boundary, and H, C, P, N transport, replay, source, and name the same displayed route. No remaining carrier coordinate can provide quotient completion equality, selected representatives, choice data, host order completeness, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5793.1, Definition 5793.2, and Definition 5793.3 seed a finite route from regular Cauchy names through located completion data to the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host order completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback coherence, dyadic locatedness, completion handoff ordering, real-seal ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLocatedCompletionU

Constructive story: A $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore arithmetic, located completion data, a CompleteMetric handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5736

A Concrete Naming Certificate for $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$

Following Banach, Picard, and Bishop–Bridges constructive analysis, the $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet records the finite handoff from an explicit contraction estimate to the Cauchy threshold consumed by the regular-rational and real endpoint routes. It sits between the Banach fixed-point modulus packet of chapter 4188, the Picard iteration and error-estimate packets of chapter 2359 and chapter 2233, and the regular Cauchy completion boundary of chapter 5793. The packet gives the endpoint route a single displayed Cauchy-threshold surface without selecting a fixed point, quotienting completion names, or importing ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5736.1 (Picard threshold Cauchy handoff carrier)**.** *A* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, I, E, M, R, K, S, T, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BanachFixedPointModulus}^{\uparrow}$ *source row whose contraction-rate route has already exposed the rational Lipschitz and finite Picard ledgers.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *ledger of adjacent iterate windows and replay order.*
3. *E is the* $\mathsf{PicardErrorEstimate}^{\uparrow}$ *row, carrying the residual-and-ratio estimate used to bound the Picard tail.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row produced from B, I, E for each requested dyadic or rational tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row made available only after the threshold row M has been displayed.*
6. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row consumed at the handoff boundary, not an ambient completeness theorem.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, R, K have been read.*
8. *T stores componentwise* hsame *transports for the Banach-modulus, Picard-iteration, error-estimate, Cauchy-threshold, regular-rational, complete-metric, real-seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from the contraction-rate request through $B, I, E, M, R, K, S, T, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$, $\mathsf{BanachFixedPointModulus}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{PicardErrorEstimate}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, I, E, M, R, K, S, T, C, P, N$. It has no coordinate for a selected fixed point, host fixed-point equality, quotient completion equality, detached Cauchy selector, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.PicardThresholdCauchyHandoffUp.PicardThresholdCauchyHandoffTasteGate`
`single carrier alignment`

Theorem 5736.2 (Picard threshold Cauchy handoff NameCert obligations)**.** *For every accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier $H = (B, I, E, M, R, K, S, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyH}}$ *surface consists exactly of carrier admission for the displayed rows; Banach-modulus source visibility through B; Picard-iteration visibility through I; error-estimate visibility through E; Cauchy-threshold construction through M; regular-rational readback through R; complete-metric service access through K; real seal access through S; classifier stability through T and C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 5794.1. The accepted packet exposes exactly the Banach-modulus source row, the Picard-iteration ledger, the error-estimate row, the Cauchy-threshold row, the regular-rational readback, the complete-metric service, the real seal, and the structural rows.

The threshold rows are ordered. The rows B, I, E must be displayed before M can answer a tolerance request, since M is the only coordinate that records the finite Cauchy threshold.

The endpoint rows are downstream. The row R reads the threshold as regular rational data, K is the visible complete-metric service row, and S is exposed only after those rows have been displayed. Transport, replay, provenance, and local naming are exhausted by T, C, P, N, so no further NameCert obligation is present. □

Theorem 5736.3 (Picard threshold Cauchy handoff Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing endpoint read of an accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{BanachFixedPointModulus}^{\uparrow},\ \mathsf{PicardIteration}^{\uparrow},\ \mathsf{PicardErrorEstimate}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Complete}$$

Thus the real seal is reached only after the explicit Picard threshold has been displayed as a $\mathsf{CauchyModulus}^{\uparrow}$ *row and repacked through the regular-rational and complete-metric handoff rows. The route exports no selected fixed point, quotient completion equality, detached Cauchy selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing endpoint request. The only contraction-rate source row is B, and its Picard data are refined in the visible rows I and E, so the request first reads those rows.

The threshold stage is forced by M. Apply the Banach fixed-point modulus route of Definition 4188.3 together with the Picard iteration surface of chapter 2359 and the error-estimate surface of chapter 2233. These sources supply the displayed threshold row without adding a selected endpoint.

After M is fixed, the readback and completion rows R and K expose the regular-rational and complete-metric boundary used by chapter 301 and chapter 128. The seal row S is then the only $\mathsf{Real}^{\uparrow}$ coordinate, and the structural rows T, C, P, N preserve the same route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5794.1, Definition 5794.2, and Definition 5794.3 seed the finite Picard-threshold handoff from BanachFixedPointModulus, PicardIteration, and PicardErrorEstimate rows to CauchyModulus, RegSeqRat, CompleteMetric, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, host fixed-point equality, quotient completion equality, detached Cauchy selectors, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard-threshold construction, regular-rational readback, complete-metric service access, real-seal ordering, classifier stability, provenance, and local naming for BEDC.Derived.PicardThreshol

Constructive story: A $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet is generated from a BanachFixedPointModulus source row, PicardIteration ledger, PicardErrorEstimate row, CauchyModulus threshold, RegSeqRat readback, CompleteMetric service row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5737

A Concrete Naming Certificate for $\mathsf{DiniUniformLimitModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the classical Dini theorem, the $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet extracts the finite uniform-modulus ledger visible in compact-metric monotone convergence data. It sits over chapter 2196, chapter 1436, chapter 129, chapter 130, chapter 463, chapter 369, chapter 301, and chapter 38. The packet names the finite net, rational tolerance budget, and extracted modulus route; it does not import open-cover compactness, chosen limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5737.1 (Dini uniform-limit modulus carrier)**.** *A* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row naming the compact-metric finite-source observations consumed by the extraction.*
2. *F is the monotone* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, recording the displayed continuous approximants and their pointwise monotone order.*
3. *W is the pointwise window row supplied by the Dini-continuity and Dini-uniform-convergence routes.*
4. *E is the finite net row over K, naming the finite mesh on which pointwise windows are inspected.*
5. *Q is the rational tolerance-budget row, storing the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerances assigned to the finite net and to the later readback.*
6. *U is the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row, obtained from E, Q, W and the monotone continuous family row F.*
7. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row, exposing only the modulus-controlled limit route supplied by U.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance transport.*
9. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row, naming the real-valued read without adding ambient real completeness.*
10. *H records componentwise* hsame *transport for compact-metric source, monotone family, pointwise window, finite net, rational tolerance, extracted modulus, uniform-limit handoff, rational readback, real seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the compact-metric source and monotone family through the finite net, tolerance budget, extracted modulus, and uniform-limit handoff.*
12. *P is the* Pkg *provenance over* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$, $\mathsf{DiniContinuity}^{\uparrow}$, $\mathsf{DiniUniformConvergence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, W, E, Q, U, L, R, S, H, C, P, N$. It has no coordinate for open-cover compactness, selected limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiniUniformLimitModulusUp.TasteGate.DiniUniformLimitModulusTasteGate`
`single carrier alignment`

Theorem 5737.2 (Dini uniform-limit modulus NameCert obligations)**.** *For every accepted* DiniUniformLimitModulu *carrier*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact-metric source, monotone continuous family, pointwise window, finite net, rational tolerance budget, extracted uniform modulus, UniformLimit handoff, RegSeqRat readback, Real seal, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires monotone-window visibility through F and W, finite-net extraction through E and Q, modulus handoff through U and L, Real-seal nonescape through S, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses open-cover compactness, selected limiting values, quotient function equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only computational rows are the compact-metric source K, monotone family F, pointwise windows W, finite net E, rational budget Q, extracted modulus U, uniform-limit handoff L, rational readback R, and real seal S.

The monotone-window step is local to F and W. The finite-net step is local to E and Q, so the modulus row U is extracted from displayed finite data rather than from an open cover or a choice of limiting values.

The handoff to $\mathsf{UniformLimit}^{\uparrow}$ passes only through U and L. The rational and real readback rows R and S name the downstream values without adding quotient function equality or ambient completeness.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded objects are not coordinates of D, no NameCert consumer can read them from this carrier. □

Falsifiable prediction: Every accepted $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ read must expose compact-metric source rows, monotone continuous-family rows, pointwise window rows, a finite net, a rational tolerance budget, an extracted uniform modulus, a UniformLimit handoff, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dini-continuity, diniuniformconvergence, compactmetric, continuousmap, uniformlimit, uniformmodulus, regseqrat, real: $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ is not bijective to any

listed sibling because it binds the finite net and rational tolerance budget to an extracted uniform-modulus handoff before UniformLimit and Real consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5795.1 and Definition 5795.2 seed the finite uniform-modulus ledger extracted from compact-metric monotone convergence data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limiting values, quotient function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window visibility, finite-net extraction, modulus handoff, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniUniformLimitModulusUp.

Constructive story: A $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet is generated from compact-metric source rows, monotone continuous-family rows, pointwise windows, finite net rows, rational tolerance-budget rows, extracted uniform-modulus rows, UniformLimit handoff rows, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5738

A Concrete Naming Certificate for $\mathsf{SummationByParts}^{\uparrow}$

Following Abel and Dirichlet, the $\mathsf{SummationByParts}^{\uparrow}$ packet records the finite identity surface by which displayed partial sums, coefficient windows, adjacent differences, and endpoint terms are bound into one NameCert row. It sits beside the Abel-summation route of chapter 1763, the Abel-test consumer of chapter 1496, and the Dirichlet-test consumer of chapter 1497. Its source rows use the finite series carrier of chapter 121; its regular readback, dyadic tolerance, and endpoint seal use chapter 301, chapter 291, and chapter 38. The packet names a finite algebraic identity for downstream convergence tests; it does not import infinite sums, quotient series equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5738.1 (Summation by parts carrier)**.** *A* $\mathsf{SummationByParts}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Series}^{\uparrow}$ *source row, exposing only the inspected finite term window and its displayed partial sums.*
2. *A is the coefficient-window row, naming the coefficient entries read over the same finite interval.*
3. *Δ is the adjacent-difference row, recording the displayed values $a_k - a_{k+1}$ used by the identity.*
4. *P is the partial-sum-window row, naming the cumulative sums paired with A and Δ.*
5. *B is the boundary-term row, displaying the endpoint products and the finite interior products determined by S, A, Δ, P.*
6. *T is the convergence-test handoff row consumed by* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$.
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed finite identity data.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the finite additions, subtractions, products, and endpoint comparisons used by B.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after $S, A, \Delta, P, B, T, R, D$ have been displayed.*
10. *H records componentwise* hsame *transport for the source, coefficient, difference, partial-sum, boundary, handoff, readback, dyadic, endpoint, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the route*

$$S, A, \Delta, P, B, T, R, D \longmapsto E.$$

12. *Q is the* Pkg *provenance over* $\mathsf{SummationByParts}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$. It has no coordinate for an infinite sum, quotient series equality, selected convergence witness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SummationByPartsUp.SummationByPartsTasteGate single carrier alignment`

Theorem 5738.2 (Summation by parts NameCert obligations)**.** *For every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *carrier*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet; source and partial-sum exposure through S and P; coefficient-window and adjacent-difference exposure through A and Δ; boundary-term exactness through B; convergence-test handoff through T; regular readback, dyadic accounting, and endpoint sealing through R, D, E; and transport, replay, provenance, and local naming through H, C, Q, N.*

Proof. Project the accepted carrier. The projection exposes exactly the rows $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$, so every naming obligation must be read from one of those displayed coordinates.

The identity rows are finite. The source row S and partial-sum row P display the inspected cumulative sums, the coefficient row A displays the paired coefficients, and Δ displays the adjacent differences used by the interior terms. The boundary row B records only the endpoint products and interior products determined by those rows.

The consumer handoff is downstream of the identity. A convergence-test consumer first reads T, and the regular and real-facing route then passes through R, D, E. These rows can transport the displayed finite calculation, but they do not introduce an independent summation principle.

Finally H, C, Q, N preserve, replay, source, and name the same route. Because the carrier has no coordinate for infinite sums, quotient series equality, selected convergence witnesses, countable choice, trichotomy, or ambient real completeness, the stated rows exhaust the local NameCert surface. □

Theorem 5738.3 (Summation by parts Cauchy-series handoff)**.** *Every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *packet that is consumed by an* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$ *route hands off only the finite identity chain*

$$\mathsf{Series}^{\uparrow} \longmapsto S, A, \Delta, P, B, T \longmapsto R, D, E, H, C, Q, N.$$

Thus a Cauchy-series or real-seal consumer may read the summation-by-parts row only after the series window, coefficient window, adjacent-difference ledger, partial-sum window, boundary ledger, and test handoff have been displayed. The handoff supplies no infinite sum, quotient series equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a convergence-test read. Carrier admission exposes the source row S and the finite identity rows A, Δ, P, B before the handoff row T is available.

The downstream chapters may add their own test-specific rows. The $\mathsf{AbelSummation}^{\uparrow}$ consumer reads the displayed finite identity as its transform row, the $\mathsf{AbelTest}^{\uparrow}$ consumer combines it with a monotone null coefficient ledger, and the $\mathsf{DirichletTest}^{\uparrow}$ consumer combines it with bounded partial sums and a null-tail schedule. In each case the summation-by-parts contribution remains the same displayed finite packet.

The Cauchy-facing route is therefore forced through R and D before E can seal the endpoint. Transport, replay, provenance, and local naming preserve that same route, so no excluded summation or completeness datum can be read from the packet. □

Falsifiable prediction: An accepted $\mathsf{SummationByParts}^{\uparrow}$ consumer that reaches an $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without reading the displayed source, coefficient, adjacent-difference, partial-sum, boundary-term, and handoff rows refutes the carrier surface.

Independence witness: abel-summation, abel-test, dirichlet-test, series, regseqrat, dyadicratcore, real: no listed sibling supplies the whole thirteen-row packet $K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$, because each sibling contributes only a transform consumer, convergence-test consumer, source series, regular readback, dyadic ledger, or endpoint seal while this chapter binds the finite identity itself.

Closure status for $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$.

Constructive story: A $\mathsf{SummationByParts}^{\uparrow}$ packet is generated from a SeriesUp finite source row, coefficient windows, adjacent-difference rows, partial-sum windows, boundary-term ledgers, AbelSummation/AbelTest/DirichletTest handoff rows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5796.1, Definition 5796.2, and Definition 5796.3 seed the finite summation-by-parts identity packet over $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite summation, quotient series equality, selected convergence witnesses, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite identity exactness, convergence-test handoff, Cauchy-series readback, dyadic accounting, endpoint sealing, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.SummationByPartsUp.

Chapter 5739

A Concrete Naming Certificate for $\mathsf{RealLineOrder}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealLineOrder}^{\uparrow}$ packet records the constructive real-line order and apartness boundary visible to finite BEDC NameCert consumers. It sits over the dyadic tolerance ledger of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the rational Cauchy completion route of chapter 3670, and the Bishop regular Cauchy limit seal of chapter 1821. The packet gives L10 consumers a located comparison interface before any real-order algebra can read it; it does not import trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5739.1 (Real line order carrier)**.** *A* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D, S, R, L, A, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the positive dyadic radius used by every finite comparison request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing only the finite stream observations inspected at that tolerance.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream windows into regular rational comparison data.*
4. *L is the located comparison row, recording the finite verdict surface for $x < y$ as a witnessed positive gap at the displayed tolerance, an unresolved window requiring a smaller displayed tolerance, or a symmetric failure of the current request.*
5. *A is the apartness row, recording positive-gap readback for $x \# y$ only through D, S, R, L.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same displayed stream and regular-rational data, not from host real equality.*
7. *H records componentwise* hsame *transport for dyadic tolerance, stream windows, regular-rational readback, located comparison, apartness, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite order request through $D, S, R, L, A, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, L, A, E, H, C, P, N$. It has no coordinate for trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderTasteGate single carrier alignment`

Theorem 5739.2 (Real line order NameCert obligations)**.** *For every accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier*

$$O = (D, S, R, L, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance row, stream-window row, regular-rational readback row, located comparison row, apartness row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise transport row, replay row, provenance row, and local naming row.*

The obligation surface requires finite tolerance visibility through D, window visibility through S, regular-rational comparison readback through R, located order exposure through L, apartness exposure through A, real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier of Definition 5797.1. The only analytic rows are the dyadic tolerance D, the finite stream windows S, the regular-rational readback R, the located comparison row L, the apartness row A, and the terminal real seal E.

The comparison step is located rather than trichotomic. A finite request may display a positive gap, request a smaller displayed tolerance, or fail symmetrically at the current window; none of these outcomes supplies a global three-way case split.

The equality-sensitive routes are absent. The readback row R is regular-rational data over the displayed windows, and the seal row E is reached only after D, S, R, L, A have been inspected. Thus the packet refuses quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded principles are not coordinates of O, no local NameCert obligation can demand them. □

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderNameCertObligations`

Theorem 5739.3 (Real line order apartness readback)**.** *Every apartness read exported by an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The apartness row A may expose only a positive-gap witness already visible through D, S, R, L. It exports no trichotomy datum, quotient equality, selected representative, host real equality, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Proof. Start with an apartness request. The request must first choose a displayed positive dyadic tolerance in D and inspect the finite windows in S.

The regular-rational readback R is then the only comparison source. The located comparison row L reads this finite data and either displays a positive gap at the requested tolerance or leaves the request unresolved for a smaller displayed tolerance.

The apartness row A can cite only the positive-gap branch already exposed by L. It refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$ because those objects are not carrier rows.

The terminal seal E preserves the same finite route into $\mathsf{Real}^{\uparrow}$. Transport and replay through H and C keep the route stable, while P and N only record provenance and local naming. □

Theorem 5739.4 (Real line order L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier must read the dyadic tolerance, stream-window, regular-rational readback, located comparison, apartness, and* $\mathsf{Real}^{\uparrow}$ *seal rows in the order*

$$D, S, R, L, A, E.$$

Consequently the handoff supplies a finite non-quotient comparison boundary for later real algebra and order packets, while refusing trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. An L10 order request begins with finite tolerance data. The row D fixes the displayed dyadic radius, and S opens only the stream windows inspected at that radius.

The row R repacks those windows as regular-rational readback. The located comparison row L can then answer only with the finite comparison surface generated from D, S, R.

Apartness is downstream of located comparison. The row A may expose a positive gap only when L has already displayed one, and E seals the same finite route as a $\mathsf{Real}^{\uparrow}$-facing endpoint.

Because no earlier or later row stores trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$, the L10 handoff cannot export those principles to later consumers. □

Falsifiable prediction: Every accepted $\mathsf{RealLineOrder}^{\uparrow}$ read must expose dyadic tolerance, StreamName windows, RegSeqRat readback, located comparison, apartness, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before an L10 order consumer can read a comparison boundary.

Independence witness: dyadicratcore, streamname, regseqrat, real, rational-cauchy-completion, bishop-regular-cauchy-limit-seal: $\mathsf{RealLineOrder}^{\uparrow}$ is not bijective to any listed sibling because it binds located comparison and apartness rows to the finite readback route before the RealUp seal is available.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5797.1, Definition 5797.2, Definition 5797.3, and Definition 5797.4 seed the finite non-quotient order and apartness boundary for displayed RealUp names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient equality, selected representatives, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite tolerance visibility, stream-window visibility, regular-rational readback, located comparison, apartness readback, RealUp seal handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.RealLineOrderUp.

Constructive story: A $\mathsf{RealLineOrder}^{\uparrow}$ packet is generated from a DyadicRatCoreUp tolerance row, StreamName finite windows, RegSeqRat readback, located comparison, apartness, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5740

A Concrete Naming Certificate for $\mathsf{SchwartzKernel}^{\uparrow}$

Following Schwartz and Gelfand–Shilov, the $\mathsf{SchwartzKernel}^{\uparrow}$ packet records the finite NameCert route by which a distribution kernel is read as a bilinear action between Schwartz test probes and tempered-distribution endpoints. It sits over the Schwartz-function carrier of chapter 3399, the tempered-distribution endpoint of chapter 2310, the nuclear factorization row of chapter 215, the projective tensor norm route of chapter 4088, the tensor-product source of chapter 87, and the real seal of chapter 38. The chapter exposes the kernel theorem as finite action, tensor, nuclearity, bound, transport, replay, provenance, and local naming rows; it does not import a host distribution space, quotient test-function equality, selected representatives, or an unrestricted topological-vector-space oracle.

Definition 5740.1 (Schwartz kernel carrier)**.** *A* $\mathsf{SchwartzKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, U, J, B, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SchwartzFunction}^{\uparrow}$ *test-probe row naming the finite seminorm windows inspected on the source side.*
2. *T is the* $\mathsf{TemperedDistribution}^{\uparrow}$ *endpoint row naming the distributional action read after the test windows are displayed.*
3. *U is the* $\mathsf{TensorProduct}^{\uparrow}$ *row naming the finite tensor source on which the two test-probe sides are paired.*
4. *J is the* ***??*** *row recording the projective-tensor bound used to compare the paired test windows.*
5. *B is the* $\mathsf{Nuclear}^{\uparrow}$ *factorization row, exposing the finite nuclear decomposition route by which the kernel action is read.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed scalar bounds and kernel-action readbacks.*
7. *H records componentwise* hsame *transport for test probes, tempered endpoint, tensor source, projective bound, nuclear factorization, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite kernel request through $S, T, U, J, B, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SchwartzKernel}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{Nuclear}^{\uparrow}$, ***??***, $\mathsf{TensorProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $S, T, U, J, B, R, H, C, P, N$. It has no coordinate for a host distribution space, quotient equality of test functions, selected representatives, ambient bornological completeness, or a topological-vector-space theorem outside the displayed rows.

Lean4 ✓ `BEDC.Derived.SchwartzKernelUp.SchwartzKernelTasteGate single carrier alignment`

Theorem 5740.2 (Schwartz kernel NameCert obligations)**.** *For every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *carrier*

$$K = (S, T, U, J, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *surface consists exactly of Schwartz test-probe admission through S, tempered-distribution endpoint admission through T, tensor-source admission through U, projective-bound exposure through J, nuclear-factorization exposure through B, scalar RealUp sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every kernel consumer must read the distributional action through these ten rows. No consumer may replace them by an ambient kernel theorem, quotient test-function equality, selected representative, hidden topological vector space, or host nuclear-space completion.

Proof. Project the accepted carrier of Definition 5798.1. The analytic rows are the Schwartz test row S, the tempered-distribution endpoint T, the tensor source U, the projective bound J, the nuclear factorization B, and the RealUp seal R.

The action route is finite. The tensor row U supplies the paired test-probe source, J records the displayed projective bound, and B records the nuclear factorization by which the kernel action becomes readable by a finite consumer.

Transport and replay do not create new analytic structure. The rows H and C preserve the displayed packet componentwise and replay only the same kernel request. The provenance and naming rows P, N package the route without adding host quotient equality or a hidden completion theorem.

Thus the listed rows are exactly the local NameCert obligations for $\mathsf{SchwartzKernel}^\uparrow$. □

Theorem 5740.3 (Schwartz kernel nuclear factorization boundary)**.** *Every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *read factors through the finite route*

$$\mathsf{SchwartzFunction}^\uparrow,\ \mathsf{TensorProduct}^\uparrow,\ ??,\ \mathsf{Nuclear}^\uparrow \longmapsto \mathsf{TemperedDistribution}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The nuclear row may expose only the displayed factorization and bound data already routed through S, U, J. It exports no host theorem identifying all kernels with all continuous bilinear forms, no quotient equality of test probes, no selected representative of a distribution, and no ambient completeness claim for the surrounding function spaces.

Proof. Start with a kernel read. The request first displays the finite Schwartz windows in S and the tensor source U on which the two test-probe sides are paired.

The projective tensor bound J is the only bound row available to the consumer. The nuclear factorization row B can cite only this displayed tensor-bound route, so its readback is a finite factorization certificate rather than an ambient nuclear-space theorem.

The tempered-distribution endpoint T then reads the resulting action, and R seals the scalar outputs as RealUp data. Transport through H and replay through C keep the same row order, while P and N record source and local naming.

Since no carrier coordinate stores host quotient equality, selected representatives, or ambient completeness, those principles cannot be exported by the factorization boundary. □

Falsifiable prediction: Every accepted $\mathsf{SchwartzKernel}^{\uparrow}$ packet must expose SchwartzFunctionUp test probes, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, TemperedDistributionUp endpoint action, RealUp scalar sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a kernel consumer can read the action.

Independence witness: schwartz-function, tempered-distribution, nuclear, projective-tensor-norm, tensorproduct, real: $\mathsf{SchwartzKernel}^{\uparrow}$ is not bijective to any listed sibling because it binds the test-probe tensor route, nuclear factorization boundary, distribution endpoint, and scalar seal as one finite kernel-action packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{SchwartzKernel}^{\uparrow}$ packet is generated from SchwartzFunctionUp test probes, a TemperedDistributionUp endpoint, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, RealUp scalar seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5798.1, Definition 5798.2, Definition 5798.3, the falsifiable prediction, and the independence witness seed the finite kernel-action route over Schwartz, tempered-distribution, tensor, nuclear, bound, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host distribution-space semantics, quotient equality of test functions, selected distribution representatives, ambient nuclear-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, test-probe visibility, tensor-source admission, projective-bound exactness, nuclear-factorization exposure, tempered-endpoint action, RealUp scalar sealing, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SchwartzKernelUp.

Chapter 5741

A Concrete Naming Certificate for $\mathsf{SynonymousTransition}^{\uparrow}$

The $\mathsf{SynonymousTransition}^{\uparrow}$ packet realizes the finite synonymous-transition geometry of Definition 9462.1186 as BEDC NameCert data. It sits beside the six-bit codon-window carrier of chapter 2234, the codon transition matrix of chapter 2245, the DNA boundary-tile packet of chapter 3393, the window-coverage trigger algebra of chapter 3478, and the DNA-window trigger threshold of chapter 4217. The packet names finite codon-window, class-adjacency, boundary-spectrum, threshold, transport, replay, provenance, and local naming rows; it is not a biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Definition 5741.1 (Synonymous transition carrier)**.** *A* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (W, M, A, B, T, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *row naming the finite Q_6 codon-window surface.*
2. *M is the* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *row naming one-bit codon transitions inspected by the packet.*
3. *A is the class-adjacency row recording the displayed synonymous and cross-class adjacency counts, including the largest weights of Definition 9462.1186.*
4. *B is the boundary-spectrum row recording internal edge counts, external boundary degrees, and the control-pair corner-contact data.*
5. *T is the* $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$ *row naming the finite threshold at which an adjacency or boundary-spectrum read may trigger a downstream tile consumer.*
6. *H records componentwise* hsame *transport for codon windows, transition matrix, class adjacency, boundary spectrum, trigger threshold, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite synonymous-transition request through W, M, A, B, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{SynonymousTransition}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{CodonTransitionMatrix}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, M, A, B, T, H, C, P, N$. It has no coordinate for biological mechanism, stochastic fitness, quotient codon equality, hidden enumeration, or an ambient graph-theory oracle outside the displayed finite rows.

Theorem 5741.2 (Synonymous transition NameCert obligations)**.** *For every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier*

$$G = (W, M, A, B, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *surface consists exactly of codon-window admission through W, transition-matrix admission through M, class-adjacency exposure through A, boundary-spectrum exposure through B, trigger-threshold exposure through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every downstream synonymous-transition consumer must read the graph through these nine rows. It cannot replace them by biological causation, stochastic selection, quotient codon semantics, an unrecorded enumeration, or a hidden graph oracle.

Proof. Project the accepted carrier of Definition 5799.1. The finite codon surface is W, the one-bit transition source is M, and the named graph data are the class-adjacency row A and boundary-spectrum row B.

The trigger row T records when the displayed adjacency or boundary-spectrum data may be read by a downstream tile or trigger consumer. It does not add a biological mechanism or a stochastic model; it only names the finite threshold over the same graph rows.

Transport and replay are componentwise. The rows H and C preserve and replay W, M, A, B, T with the same finite endpoints, while P and N record provenance and local naming.

Since the carrier has no coordinate for quotient codon equality, hidden enumeration, biological causation, or ambient graph semantics, the listed rows exhaust the local NameCert obligations. □

Theorem 5741.3 (Synonymous transition boundary-spectrum handoff)**.** *Every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *read factors through the finite route*

$$\mathsf{CodonSixBitWindow}^{\uparrow},\ \mathsf{CodonTransitionMatrix}^{\uparrow} \longmapsto \mathsf{SynonymousTransition}^{\uparrow} \longmapsto \mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{Windo}$$

The handoff exposes class-adjacency weights, internal-edge counts, external boundary degrees, and control-pair corner contacts only as finite packet rows. It exports no biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Proof. Start with the codon-window row W and the one-bit transition matrix row M. These rows supply the finite Q_6 source and the adjacency relation inspected by the packet.

The class-adjacency row A records the largest displayed weights, and B records the boundary-spectrum data. The downstream boundary-tile and trigger-algebra consumers therefore receive a finite graph packet rather than a biological or stochastic explanation.

The threshold row T names when the finite rows can be consumed by the trigger route. Transport through H and replay through C keep the same graph rows visible, while P and N only package their provenance and local name.

Thus every public read of the synonymous-transition geometry remains inside the finite codon-window, transition, adjacency, boundary-spectrum, threshold, transport, replay, provenance, and naming surface. □

Falsifiable prediction: Every accepted $\mathsf{SynonymousTransition}^{\uparrow}$ packet must expose CodonSixBitWindowUp, CodonTransitionMatrixUp, class-adjacency, boundary-spectrum, DNAWindowSixTriggerThresholdUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ rows before a downstream tile or trigger consumer can read the synonymous-transition graph.

Independence witness: codon-six-bit-window, codon-transition-matrix, dna-window-six-boundary-tile, window-coverage-trigger-algebra, dna-window-six-trigger-threshold: $\mathsf{SynonymousTransition}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries class-adjacency weights, boundary-spectrum rows, and trigger-threshold handoff over the finite codon-window graph.

Closure status for $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$.

Constructive story: A $\mathsf{SynonymousTransition}^{\uparrow}$ packet is generated from a CodonSixBitWindowUp source, a CodonTransitionMatrixUp one-bit transition row, class-adjacency counts, boundary-spectrum data, DNAWindowSixTriggerThresholdUp rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5799.1, Definition 5799.2, Definition 5799.3, the falsifiable prediction, and the independence witness seed the finite synonymous-transition packet over codon-window, transition, adjacency, boundary-spectrum, threshold, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic fitness, quotient codon semantics, hidden enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, codon-window visibility, transition-matrix exactness, class-adjacency exposure, boundary-spectrum exposure, trigger-threshold handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SynonymousTransitionUp.

Chapter 5742

A Concrete Naming Certificate for $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$

Following Feller and Billingsley on finite-sum normal approximation, the $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet records the finite BEDC surface by which an iid random-variable window is centered, scaled, read as a distribution row, and handed to a real-normal comparison seal. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the law readback of chapter 186, the regular rational window of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite central-limit-facing certificate; it is not an asymptotic central limit theorem, a characteristic-function convergence theorem, a host probability-limit operator, countable choice, quotient distribution equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5742.1 (Central-limit finite-window carrier)**.** *A* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, V, S, K, D, R, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row V is the displayed iid* $\mathsf{RandomVar}^{\uparrow}$ *window over P, including the finite index range and the shared law token read by the window. The row S is the finite partial-sum ledger naming the displayed sum, the sample count, and the centered numerator. The row K is the centering and scaling row, recording the finite mean token, variance or spread token, positive scale request, and normalized finite-sum expression. The row D is the* $\mathsf{Distribution}^{\uparrow}$ *readback for the normalized finite sum and its comparison request. The row R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *window that presents rational test intervals, tolerances, and finite comparison samples for the distribution read. The row E is the* $\mathsf{Real}^{\uparrow}$ *normal-window seal naming the terminal real comparison against the displayed normal row at the requested finite window. The row H records componentwise* hsame *transport for the probability source, iid window, partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat window, Real normal-window seal, continuation, provenance, and local naming rows. The row C records* Cont *replay from a normal-facing read through P, V, S, K, D, R, E and then through the structural rows. The row Q is the* Pkg *provenance over* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert. *The row N is the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these eleven rows.*

Lean4 ✓ `BEDC.Derived.CentralLimitFiniteWindowUp.TasteGate.CentralLimitFiniteWindowTasteGate single carrier alignment`

Theorem 5742.2 (Central-limit finite-window NameCert obligations)**.** *For every accepted* CentralLimitFiniteWindo *carrier* $(P, V, S, K, D, R, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 5800.1. Carrier admission displays the probability source, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, transport, replay, provenance, and local naming row. The certificate imports no host asymptotic central limit theorem, characteristic-function limit, Lindeberg replacement principle, countable-choice schedule, quotient distribution equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Project the carrier rows in order. The probability source P and iid random-variable window V are the only stochastic data exposed to the certificate, and the partial-sum ledger S fixes the finite sum before any normal-facing read is visible.

The centering and scaling row K then determines the normalized finite expression. The distribution row D and RegSeqRat window R provide the only comparison surface through which a finite law read can reach the terminal $\mathsf{Real}^{\uparrow}$ normal-window seal E.

Finally H, C, Q, N transport, replay, source, and name the same displayed route. Since the carrier has no coordinate for an asymptotic theorem, characteristic-function limit, quotient law equality, countable choice, or ambient completeness, the listed rows exhaust the local finite NameCert surface. □

Theorem 5742.3 (Central-limit finite-window normal handoff)**.** *Every normal-facing read of an accepted* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier factors through the finite route*

$$P \longmapsto V \longmapsto S \longmapsto K \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, Q, N$$

before any consumer receives a normal-window comparison. Thus the read is the displayed iid finite-sum, normalization, distribution, RegSeqRat, and RealUp handoff itself; it exports no host asymptotic CLT, countable choice, quotient distribution equality, characteristic-function convergence principle, or ambient real completeness.

Proof. Begin with a normal-facing request. The only probability data available are the source row P and the finite iid window V, so the request must first read the displayed sample range and shared law token.

The partial-sum row S and normalization row K are then forced. They provide the finite sum, centering token, scaling token, and normalized expression that the downstream distribution read consumes.

The request can reach a normal-window comparison only through D, R, E. The distribution row D names the finite law read, the RegSeqRat row R exposes rational windows and tolerances, and the RealUp row E seals the displayed normal comparison. The structural rows H, C, Q, N preserve that route without adding analytic content.

Therefore every accepted read factors through the finite iid-sum, normalization, distribution, RegSeqRat, and RealUp rows. The excluded asymptotic, choice, quotient, characteristic-function, and completeness principles cannot be inserted into the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet is generated from a probability source row, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5800.1, Definition 5800.2, and Definition 5800.3 seed the finite central-limit-facing handoff through ProbSpace, RandomVar, Distribution, RegSeqRat, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CentralLimitFiniteWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the asymptotic central limit theorem, characteristic-function convergence, Lindeberg replacement, countable-choice schedules, quotient distribution equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, iid-window routing, partial-sum ledger exactness, normalization stability, distribution-to-RegSeqRat handoff, RealUp normal-window nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.CentralLimitFiniteWindowUp.

Chapter 5743

A Concrete Naming Certificate for $\mathsf{LipschitzRealMap}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LipschitzRealMap}^{\uparrow}$ packet records a constructive real-map certificate whose continuity is controlled by a displayed dyadic Lipschitz constant and finite regular-rational windows. It sits after the dyadic tolerance ledger of chapter 291, the countable-name window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the located order and apartness neighbour of chapter 5797. The packet names the finite L10 route by which later continuous-map and metric-uniform-continuity consumers may read a real-valued map without importing host function extensionality, quotient representatives, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5743.1 (Lipschitz real-map carrier)**.** *A* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, K, W, R, M, H, C, P, N)$$

with the following rows:

1. *S is the source* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real input surface through displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
2. *T is the target* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real output surface through the same kind of finite readback.*
3. *K is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *Lipschitz constant row, including the positive dyadic bound and the displayed tolerance ledger used by every modulus request.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the source and target names inspected by the request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the displayed source and target windows into rational comparison data.*
6. *M is the modulus-inequality row, recording that every accepted finite pair of source reads with displayed apartness or distance bound is sent to a target read whose displayed difference is bounded by the dyadic constant in K times the source bound, up to the requested displayed tolerance.*
7. *H records componentwise* hsame *transport for source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a finite map request through $S, T, K, W, R, M, H, P, N$.*
9. *P is the* Pkg *provenance over* LipschitzRealMap$^{\uparrow}$, Real$^{\uparrow}$, RealLineOrder$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{LipschitzRealMap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, T, K, W, R, M, H, C, P, N$. It has no coordinate for host function equality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, or ambient completeness of Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LipschitzRealMapUp.LipschitzRealMapTasteGate single carrier alignment`

Theorem 5743.2 (Lipschitz real-map NameCert obligations)**.** *For every accepted* LipschitzRealMap$^{\uparrow}$ *carrier*

$$F = (S, T, K, W, R, M, H, C, P, N),$$

the local NameCert$_{\text{LipschitzRealMap}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* Real$^{\uparrow}$ *seal, target* Real$^{\uparrow}$ *seal, dyadic Lipschitz constant, finite StreamName windows, RegSeqRat readback, modulus inequality, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires finite source and target visibility through S and T, dyadic bound visibility through K, finite window visibility through W, rational readback through R, modulus-inequality exposure through M, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses host function extensionality, quotient equality of real presentations, selected representatives, global uniform-continuity principles, and ambient completeness of Real$^{\uparrow}$.

Proof. Project the carrier of Definition 5801.1. The source and target real seals are the only real-name endpoints, and both are read through finite StreamName and RegSeqRat windows rather than through host real equality.

The Lipschitz datum is the dyadic row K. A map request can inspect only the finite windows W and their rational readback R before the modulus row M exposes the displayed inequality for the requested tolerance.

The structural rows do not add analytic content. The transport row H preserves the already displayed source, target, constant, window, readback, and modulus rows componentwise, while C replays the same route and P, N record provenance and local naming.

Since no carrier coordinate stores host function equality, quotient real equality, selected representatives, global uniform continuity, or ambient completeness, no local NameCert obligation can require those objects. □

Theorem 5743.3 (Lipschitz real-map modulus stability)**.** *Let F_0 and F_1 be accepted* LipschitzRealMap$^{\uparrow}$ *carriers whose source seals, target seals, dyadic Lipschitz constant rows, finite StreamName windows, and RegSeqRat readback rows are componentwise* hsame*-transported. Then every displayed modulus-inequality read exported by F_0 transports to the corresponding displayed modulus-inequality read exported by F_1.*

The stability claim is confined to the finite rows $S, T, K, W, R, M, H, C, P, N$. It does not identify host functions, quotient real presentations, selected Cauchy names, or ambient complete metric structures.

Proof. Start with a displayed modulus request for F_0. Its source and target real seals are read only through the finite StreamName windows and RegSeqRat readback rows named by S, T, W, R.

Use the componentwise hsame hypotheses. They transport the dyadic constant row K and the finite window/readback rows into the corresponding rows of F_1, so the same displayed source tolerance and target tolerance are available after transport.

The modulus row M is a row of the carrier rather than a host theorem about all representatives. Therefore the transported request reads the F_1 modulus row with the same displayed dyadic bound and the transported finite readback data.

Finally C, P, N replay, source, and name the transported route. No quotient equality, host function equality, selected representative, or ambient completeness principle is introduced by this transport. □

Theorem 5743.4 (Lipschitz real-map L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier must read the route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{LipschitzRealMap}^{\uparrow}$$

through the finite source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, transport, replay, provenance, and local NameCert rows. The handoff supplies a finite Lipschitz-control surface for later continuous-map and metric-uniform-continuity packets, while refusing host function extensionality, quotient equality, selected representatives, global uniform-continuity principles, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. An L10 map request begins with source and target real-name seals. By the carrier definition, these seals are visible only through the finite StreamName windows and RegSeqRat readback rows used by S, T, W, R.

The request then reads the dyadic constant row K and the located comparison surface supplied by the real-line order neighbour. These rows provide the displayed source difference and target tolerance against which the modulus inequality is checked.

The modulus row M is the only analytic output of the packet. It hands a consumer a finite inequality route, not a host-level function theorem.

The rows H, C, P, N transport, replay, source, and name the same route. Thus later continuous-map and metric-uniform-continuity packets can consume the finite Lipschitz surface without receiving quotient equality, selected representatives, host function extensionality, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzRealMap}^{\uparrow}$ packet is generated from source and target RealUp seal rows, a DyadicRatCore Lipschitz constant, finite StreamName windows, RegSeqRat readback, a displayed modulus-inequality row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, seed)

Scope closed: Definition 5801.1, Definition 5801.2, Definition 5801.3, and Definition 5801.4 seed the finite Lipschitz real-map surface over the current L10 real and completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and target RealUp sealing, dyadic constant visibility, finite window readback, modulus-inequality stability, transport, replay, provenance, and local naming for future BEDC.Derived.LipschitzRealMapUp.

Chapter 5744

A Concrete Naming Certificate for HyperbolicQuasiGeodesicShadow$^{\uparrow}$

The HyperbolicQuasiGeodesicShadow$^{\uparrow}$ packet realizes the observer-expansion shadow route of section 9463.4 as finite quasi-geodesic, boundary, visual-metric, Busemann, and lamination-compatible rows. It sits after disk readout through chapter 377, the metric surface of chapter 3474, the visual-metric packet of chapter 3866, the Busemann cocycle route of chapter 4134, the geodesic-lamination packet of chapter 4203, and the observer-expansion packet of chapter 4167. The packet names a finite shadow tied to a displayed quasi-geodesic route; it does not complete the boundary, choose a global geodesic representative, identify quotient ideal points, or import host hyperbolic geometry.

Definition 5744.1 (Hyperbolic quasi-geodesic shadow carrier)**.** *A* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, G, E, V, B, L, H, C, P, A, N)$$

with the following rows:

1. *D is the disk readout row, exposing only displayed* UnitDisk$^{\uparrow}$ *coordinates and the associated* HyperbolicMetric$^{\uparrow}$ *metric-read data.*
2. *G is the quasi-geodesic route row, recording the finite path samples, distortion budget, endpoint-facing direction, and local route ledger inspected by the shadow request.*
3. *E is the boundary endpoint row named by the displayed route, not by a completed ideal-boundary quotient.*
4. *V is the visual-metric shadow row, recording the finite shadow window read through* HyperbolicVisualMetric$^{\uparrow}$ *and the boundary endpoint E.*
5. *B is the Busemann cocycle tolerance row, recording the displayed additive tolerance used to compare the route and the shadow window.*
6. *L is the geodesic-lamination compatibility row, recording whether the displayed route is compatible with the finite noncrossing leaf data consumed by* HyperbolicGeodesicLamination$^{\uparrow}$.
7. *H records componentwise* hsame *transport for disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, replay, provenance, refusal, and local naming rows.*
8. *C records displayed* Cont *replay from an observer-expansion shadow request through $D, G, E, V, B, L, H, P, A, N$.*

9. *P is the* Pkg *provenance over* HyperbolicQuasiGeodesicShadow$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HyperbolicGeodesicLamination$^{\uparrow}$, HyperbolicObserverExpar BHist, hsame, Cont, *and* NameCert.
10. *A is the refusal row excluding completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, and host curvature semantics.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, G, E, V, B, L, H, C, P, A, N$.

Theorem 5744.2 (Hyperbolic quasi-geodesic shadow NameCert obligations)**.** *For every accepted* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier*

$$Q = (D, G, E, V, B, L, H, C, P, A, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *surface consists exactly of disk-readout visibility, quasi-geodesic route visibility, boundary endpoint exposure, visual-metric shadow-window exposure, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise transport, replay, provenance, refusal, and local naming rows.*

The packet exports no completed ideal boundary, quotient boundary equality, selected global geodesic, ambient hyperbolic compactification, physical observer trajectory, host curvature theorem, or global field semantics.

Proof. Project the carrier rows in order. The disk readout D supplies the only coordinate and metric source, while G supplies the displayed route samples and distortion budget inspected by the request.

The endpoint and shadow rows are downstream of that route. The endpoint row E names only the boundary read visible from G, and the visual row V records the finite shadow window tied to that endpoint.

The comparison rows B and L keep the shadow route finite. The Busemann tolerance is a displayed cocycle budget, and lamination compatibility is a finite noncrossing-leaf check, not a global geodesic-foliation theorem.

Finally H, C, P, A, N transport, replay, source, refuse, and name the same packet. Since the excluded host objects are not carrier rows, they cannot appear as NameCert obligations. □

Theorem 5744.3 (Hyperbolic quasi-geodesic shadow stability)**.** *Let Q_0 and Q_1 be accepted* HyperbolicQuasiGeodesi *carriers whose disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow window, Busemann tolerance, lamination compatibility, refusal, provenance, and local naming rows are componentwise* hsame*-transported. Then every observer-expansion consumer reads the same finite shadow surface through Q_0 and Q_1.*

The stability claim is confined to the finite rows $D, G, E, V, B, L, H, C, P, A, N$. It does not identify completed boundaries, quotient ideal points, selected geodesics, ambient compactifications, physical observer trajectories, host curvature data, or global fields.

Proof. Start with an observer-expansion shadow request for Q_0. The request must read disk coordinates and metric data through D and then the finite route samples and distortion budget through G.

Use the componentwise hsame transport. It carries the endpoint E, visual shadow window V, Busemann tolerance B, and lamination compatibility row L to the corresponding rows of Q_1.

The refusal row is transported with the same packet. Therefore the transported consumer sees the same excluded host objects and cannot insert completed boundary quotients, selected global geodesics, ambient compactifications, physical trajectories, curvature theorems, or global fields.

The replay row C and the provenance and naming rows P, N then present the transported shadow as the same finite observer-expansion surface. □

Theorem 5744.4 (Hyperbolic quasi-geodesic shadow vision handoff)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ *carrier must read the route*

$\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicGeodesicLaminatio}$

through disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, transport, replay, provenance, refusal, and local NameCert rows. The handoff realizes the vision-level shadow route as finite NameCert data without turning observer expansion into physical cosmology or a host hyperbolic-boundary theorem.

Proof. The vision handoff begins with disk and metric data. Rows D and G ensure that the consumer reads only displayed disk observations, metric readouts, finite route samples, and a distortion budget.

The endpoint and shadow window are then forced. Rows E and V bind the boundary endpoint and visual-metric shadow to the same route, while B records the Busemann tolerance needed to compare route and shadow.

Lamination compatibility is read through L. This makes the packet consumable by geodesic-lamination and observer-expansion rows without selecting a global geodesic representative or completing the boundary.

The rows H, C, P, A, N transport, replay, source, refuse, and name the handoff. Thus the vision-level quasi-geodesic shadow is realized as finite NameCert data and not as ambient hyperbolic geometry. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ read must expose a boundary endpoint, visual-metric shadow window, Busemann cocycle tolerance, quasi-geodesic route, transport row, provenance row, refusal row, and local NameCert before any observer-expansion consumer may read the shadow.

Independence witness: hyperbolic-visual-metric, hyperbolic-busemann-cocycle, hyperbolic-geodesic-lamination, hyperbolic-observer-expansion: $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ is not bijective to these siblings because it binds the quasi-geodesic route and shadow window together before the observer-expansion packet may consume the boundary read.

The Lean TasteGate for this packet must later provide Nontrivial $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ in `lean4/BEDC/Derived/HyperbolicQuasiGeodesicShadowUp/` Those instances must keep $D, G, E, V, B, L, H, C, P, A, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ packet is generated from disk readout rows, a quasi-geodesic route, a boundary endpoint, a visual-metric shadow window, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, refusal, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5802.1, Definition 5802.2, Definition 5802.3, and Definition 5802.4 seed the finite quasi-geodesic shadow route for observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, host curvature semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk readout, quasi-geodesic route admission, endpoint exposure, visual-metric shadow windows, Busemann tolerance, lamination compatibility, TasteGate nontriviality, field faithfulness, refusal exactness, transport, replay, provenance, and local naming for future BEDC.Derived.HyperbolicQuasiGeodesicShadowUp.

Chapter 5745

A Concrete Naming Certificate for $\mathsf{Dendrite}^{\uparrow}$

Following Nadler and Kuratowski on continuum theory, the $\mathsf{Dendrite}^{\uparrow}$ packet records the finite BEDC surface for a locally connected compact metric continuum whose tree-like form is read through unique arcs and cutpoint separation. It sits over the compact metric carrier of chapter 129, the locally connected surface of chapter 5809, the Peano continuum boundary of chapter 2160, and the tree certificate of chapter 119. The packet names displayed endpoint, unique-arc, and cutpoint-separation rows; it does not import host continua, arbitrary path spaces, open-cover compactness, or quotient equality of arcs.

Definition 5745.1 (Dendrite carrier)**.** *A* $\mathsf{Dendrite}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric distance rows, finite ProbeBundle-net rows, complete-limit witness rows, and rational tolerance comparisons already certified by the compact-metric chapter.*
2. *L is the* $\mathsf{LocallyConnected}^{\uparrow}$ *row, recording the displayed connected neighbourhood refinements through which local arc and cutpoint requests are inspected.*
3. *P is the* $\mathsf{PeanoContinuum}^{\uparrow}$ *row, binding the compact metric and locally connected continuum surfaces before any dendrite consumer reads an arc boundary.*
4. *T is the* $\mathsf{Tree}^{\uparrow}$ *row, recording the finite tree-like separation surface used to rule out cycle-shaped routes.*
5. *E is the endpoint ledger, listing endpoint rows and their neighbourhood-read witnesses.*
6. *A is the unique-arc ledger, recording for every displayed endpoint or carried point pair the finite arc row, its endpoint membership rows, and its non-branching comparison rows.*
7. *C is the cutpoint-separation ledger, recording the displayed separation rows used when removing a carried point disconnects the relevant finite tree-like boundary.*
8. *H records componentwise* hsame *transport for compact metric data, local connectedness data, Peano-continuum data, tree data, endpoint rows, unique-arc rows, cutpoint-separation rows, replay, provenance, and local naming.*

9. *R records displayed* Cont *replay from a dendrite request through* $K, L, P, T, E, A, C, H, G, Q, N$.
10. *G is the* Pkg *provenance over* $\mathsf{Dendrite}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{PeanoContinuum}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *Q records the local source and consumer provenance for endpoint, unique-arc, and cutpoint-separation reads.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host continuum, arbitrary path selection, open-cover compactness, cycle elimination by excluded middle, or quotient equality of arcs.

Lean4 ✓ `BEDC.Derived.DendriteUp.DendriteTasteGate single carrier alignment`

Theorem 5745.2 (Dendrite NameCert obligations)**.** *For every accepted* $\mathsf{Dendrite}^{\uparrow}$ *carrier*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source, locally connected row, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming;*
2. *compact-continuum visibility, requiring every dendrite consumer to read compact metric and local connectedness data through K, L, P before reading endpoint or arc rows;*
3. *tree-like exactness, requiring the non-cycle and separation information to pass through T and the cutpoint-separation ledger C;*
4. *unique-arc exactness, requiring every arc-facing read to use the displayed ledger A with its endpoint membership and non-branching comparison rows;*
5. *endpoint exactness, requiring endpoint reads to use only the displayed endpoint ledger E and not a host boundary predicate;*
6. hsame, Cont, *and* Pkg *stability, requiring componentwise transport, displayed replay, and provenance to preserve precisely the listed rows;*
7. *non-escape, excluding host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, and quotient equality of arcs.*

No dendrite obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5803.1. The accepted tuple displays exactly the compact metric source, local connectedness, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming.

The compact-continuum route is K, L, P. The compact metric source supplies distance, finite-net, complete-limit, and tolerance-comparison rows; the locally connected row supplies connected neighbourhood refinements; and the Peano-continuum row binds those surfaces before endpoint or arc data are exposed.

The tree-like route is T, E, A, C. The tree row supplies the finite non-cycle surface, the endpoint ledger records boundary reads, the unique-arc ledger records the displayed arc row between

carried point pairs, and the cutpoint-separation ledger records the separation witnesses used by downstream consumers.

Finally, H, R, G, Q, N transport, replay, source, and name the same finite packet. Since the carrier has no row for a host continuum, arbitrary path space, open-cover compactness principle, selected arc representative, or quotient equality of arcs, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$ surface. □

Theorem 5745.3 (Dendrite unique-arc handoff)**.** *Every unique-arc or cutpoint-facing consumer of an accepted* $\mathsf{Dendrite}^\uparrow$ *carrier must read the finite route*

$$\mathsf{CompactMetric}^\uparrow,\ \mathsf{LocallyConnected}^\uparrow,\ \mathsf{PeanoContinuum}^\uparrow,\ \mathsf{Tree}^\uparrow \longmapsto E, A, C, H, R, G, Q, N.$$

The handoff exposes endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It does not expose arbitrary host paths, open-cover compactness, selected arc representatives, quotient equality of arcs, or a continuum object outside the displayed packet.*

Proof. Start with the compact-continuum source. The rows K, L, P force a consumer to read the compact metric, locally connected, and Peano-continuum surfaces before any arc-facing data can be inspected.

Next read the tree row T. This is the only row carrying the tree-like non-cycle surface, so a later cutpoint or arc argument cannot replace it by a host graph or a classical continuum theorem.

The endpoint and arc data are then E, A, C. Endpoint reads pass through E, unique-arc reads pass through A, and cutpoint-separation reads pass through C; the three ledgers remain tied to the same compact-continuum and tree source rows.

The structural rows H, R, G, Q, N preserve this route under transport, replay, provenance, and local naming. Because no excluded host-side row appears in the carrier, the consumer receives exactly the displayed unique-arc handoff and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{Dendrite}^\uparrow$ read must expose CompactMetric, LocallyConnected, PeanoContinuum, Tree, endpoint, unique-arc, cutpoint-separation, componentwise hsame, displayed Cont, Pkg, source provenance, and local NameCert rows before a continuum or arc consumer can inspect the dendrite boundary.

Independence witness: compactmetric, locally-connected, peano-continuum, tree: $\mathsf{Dendrite}^\uparrow$ is not bijective to any listed sibling because it binds endpoint, unique-arc, and cutpoint-separation ledgers over their common compact-continuum and tree-like source.

Closure status for $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$**.**

Constructive story: A $\mathsf{Dendrite}^\uparrow$ packet is generated from CompactMetricUp, LocallyConnectedUp, PeanoContinuumUp, TreeUp, endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, source provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, seed)

Scope closed: Definition 5803.1, Definition 5803.2, and Definition 5803.3 seed the finite dendrite certificate over compact metric, locally connected, Peano-continuum, tree, endpoint, unique-arc, cutpoint-separation, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, quotient equality of arcs, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-continuum visibility, tree-like exactness, endpoint exactness, unique-arc exactness, cutpoint-separation exactness, transport, replay, provenance, and local naming for BEDC.Derived.DendriteUp.

Chapter 5746

A Concrete Naming Certificate for $\mathsf{YoungIntegration}^{\uparrow}$

Following Young's integration theorem and Bishop–Bridges constructive analysis, the $\mathsf{YoungIntegration}^{\uparrow}$ packet records the finite dyadic route for integrating one Holder-controlled path against another. It sits beside the Holder-continuity surface of chapter 1766, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the tagged-mesh Riemann integral boundary of chapter 1526. The chapter names only a finite partition-and-error certificate; it does not import host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5746.1 (Young integration finite partition carrier)**.** *A* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the integrand path row, read through a* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
2. *G is the integrator path row, read through a second* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its own source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
3. *A and B are the two Holder exponent ledgers. They include the finite comparison row witnessing that the displayed exponents have a Young margin for the dyadic partition family.*
4. *W is the dyadic partition-window row. It lists the inspected endpoints, dyadic mesh refinements, cell order, adjacent-cell handoffs, and the finite cells on which the integration read is allowed to form sums.*
5. *V is the cross-variation tolerance ledger. It records the cellwise oscillation products, Holder-bound products, Young-margin comparisons, and finite sum-difference tolerances consumed by the route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for endpoint radii, mesh widths, exponent-comparison margins, oscillation products, and final error bounds.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational trace of dyadic Young sums.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the integral value, reached only after the two Holder rows, dyadic windows, cross-variation ledger, dyadic tolerances, and regular readback have been displayed.*
9. *H records componentwise* hsame *transport for the two Holder paths, exponent ledgers, partition windows, cross-variation ledger, dyadic ledger, readback, Real seal, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from a Young-integration request through Holder admission, dyadic partition windows, cross-variation tolerances, regular rational readback, and the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{YoungIntegration}^{\uparrow}$, $\mathsf{HolderContinuity}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, G, A, B, W, V, D, R, E, H, C, P, N$. It has no coordinate for an ambient path space, quotient equality of functions, a selected sequence of partitions, a hidden limiting argument, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.YoungIntegrationUp.YoungIntegrationTasteGate single carrier alignment`

Theorem 5746.2 (Young integration NameCert obligations)**.** *For every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier $Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *surface is exhausted by admission of two* $\mathsf{HolderContinuity}^{\uparrow}$ *path rows, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting,* $\mathsf{DyadicRatCore}^{\uparrow}$ *exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No accepted consumer may replace these rows by host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5804.1. The rows F and G expose the two Holder-controlled paths, and A, B expose only the finite exponent and Young-margin comparisons attached to those rows.

The partition and tolerance data are then forced. The row W lists the dyadic windows available to the route, while V records the cross-variation products and sum-difference tolerances over exactly those windows.

The terminal read is D, R, E. Dyadic exactness is read through D, the regular rational trace through R, and the Real integral seal through E only after the preceding rows have been consumed.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5746.3 (Young integration dyadic error budget)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *read that reaches the* $\mathsf{Real}^{\uparrow}$ *seal factors through the finite dyadic budget*

$$\mathsf{HolderContinuity}^{\uparrow}, \mathsf{HolderContinuity}^{\uparrow} \longmapsto \mathsf{DyadicPartition}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The row V must display the cross-variation tolerance consumed between the partition windows and the rational readback. Therefore the exported integral value is a finite dyadic Young-sum seal, not a Riemann-integral replacement, a measure-completion integral, a quotient path equality, a selected limiting partition, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the two Holder rows. Their displayed exponents and constants are read through F, G, A, B, so the route has only the finite power-law data needed to bound oscillations on dyadic cells.

Next read the dyadic partition windows. The row W fixes the cells, endpoints, mesh refinements, and adjacent-cell handoffs before any sum-difference comparison is requested.

The error budget is the pair V, D. The cross-variation ledger V records the oscillation products and Young-margin comparisons, and the dyadic ledger D records the exact rational tolerances used to compare any two displayed sums.

The readback and seal are downstream. The regular sequence row R is the only rational trace exported from the finite budgets, and E is the only Real seal. Thus the consumer cannot obtain any of the excluded host-level or choice-level objects from the packet. □

Theorem 5746.4 (Young integration Riemann boundary)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet reads it only as a finite tagged-mesh boundary: two Holder path rows, a dyadic partition-window row, a cross-variation tolerance ledger, dyadic exactness, regular rational readback, Real sealing, transport, replay, provenance, and local naming. The consumer receives no independent Riemann-integral certificate, no Darboux gap claim, no quotient equality of integrands, no measure-completion object, and no selected mesh-limit principle.*

Proof. The only Riemann-facing data in the carrier are the displayed dyadic windows and finite sum budgets. The two Holder path rows provide values to be sampled, while W supplies the finite tagged-mesh boundary.

The cross-variation ledger is not a Darboux or measure-theoretic claim. It records only the tolerance comparisons needed for the Young-sum route before the regular rational readback is sealed as a Real value.

The provenance row may name $\mathsf{RiemannIntegral}^{\uparrow}$ as a consumer boundary, but the local certificate remains $F, G, A, B, W, V, D, R, E, H, C, P, N$. Therefore a Riemann-integral consumer receives a finite boundary row rather than any independent integral theorem or hidden limiting principle. □

Theorem 5746.5 (Young integration Cauchy-modulus consumer)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet whose cross-variation ledger* V *requests a tail precision must consume the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route before* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *sealing. The route remains finite: it exports the displayed Young partition windows, dyadic error budget, explicit Cauchy-modulus handoff, regular rational readback, and terminal Real seal, but it exports no selected limiting partition, countable-choice schedule, hidden modulus oracle, or ambient completion theorem.*

Proof. Project the carrier of Definition 5804.1. The rows W, V, D, R, E expose the partition windows, cross-variation tolerance ledger, dyadic error budget, regular rational readback, and terminal Real seal.

Use Definition 5804.3. The row V is the place where sum-difference tolerances and tail precision demands are recorded, and D is the dyadic ledger that makes those demands finite.

When such a tail precision is requested, apply the effective handoff of Definition 5728.3 and the schedule determinacy of Definition 5728.4. They force the precision request through an explicit $\mathsf{CauchyModulusBridge}^{\uparrow}$ schedule before R can be read and before E can seal the result.

The remaining rows H, C, P, N transport, replay, source, and name the same finite route. Since neither the Young carrier nor the bridge carrier contains a selected limiting partition, countable-choice schedule, hidden oracle, or ambient completion coordinate, no such object is exported. □

Falsifiable prediction: An accepted $\mathsf{YoungIntegration}^{\uparrow}$ packet is refuted if a consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting either $\mathsf{HolderContinuity}^{\uparrow}$ path row, the dyadic partition-window row W, the cross-variation ledger V, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: HolderContinuity, DyadicPartition, DyadicRatCore, RegSeqRat, Real, RiemannIntegral: none is bijective with $\mathsf{YoungIntegration}^{\uparrow}$ because the packet jointly carries two Holder paths, Young-margin exponent rows, dyadic partition windows, cross-variation tolerances, dyadic exactness, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$.

Constructive story: A $\mathsf{YoungIntegration}^{\uparrow}$ packet is generated from two HolderContinuityUp path rows, exponent-margin ledgers, dyadic partition windows, cross-variation tolerance accounting, DyadicRatCore exactness, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5804.1, Definition 5804.2, Definition 5804.3, Definition 5804.4, and Definition 5804.5 seed the finite dyadic Young-integration route over HolderContinuityUp, DyadicPartitionUp, DyadicRatCoreUp, CauchyModulusBridgeUp, RegSeqRatUp, RealUp, and RiemannIntegralUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked two-path admission, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting, dyadic exactness, regular rational readback, Real-seal nonescape, and structural transport for BEDC.Derived.YoungIntegrationUp.

Chapter 5747

A Concrete Naming Certificate for $\mathsf{VariationDiminishing}^{\uparrow}$

Following Schoenberg and Karlin, the $\mathsf{VariationDiminishing}^{\uparrow}$ packet records a finite analysis row for transformations that do not increase displayed sign variation. It consumes the total-variation function surface of chapter 2257, the bounded-variation real-function carrier of chapter 3654, the regulated-function source of chapter 1554, and the tagged integration boundary of chapter 1526. The packet names the finite comparison by which a kernel or transformation row is read as variation-diminishing without importing a host operator algebra, total-positivity theorem, selected partitions, quotient functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5747.1 (Variation-diminishing carrier)**.** *A* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (B, T, R, I, K, M, H, C, P, N)$$

with the following rows:

1. *B is the* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *source row naming the accepted bounded-variation input surface.*
2. *T is the* $\mathsf{TotalVariationFunction}^{\uparrow}$ *row naming the displayed total-variation ledger used to count variation before and after the transformation.*
3. *R is the* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *row naming the regulated readback through which input and output functions are compared by finite step windows.*
4. *I is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *row naming the finite tagged-mesh integration boundary used when the transformation is read by kernel action or integral averaging.*
5. *K is the kernel or transformation row, including its displayed positivity-order or sign-regularity window.*
6. *M is the variation comparison row recording that each accepted finite sign-change ledger for the output is routed to a no-larger sign-change ledger for the input.*
7. *H records componentwise* hsame *transport for bounded-variation source, total-variation ledger, regulated readback, integral boundary, kernel row, comparison row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite transformation request through $B, T, R, I, K, M, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{VariationDiminishing}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RegulatedRealFunction}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and sibling* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, T, R, I, K, M, H, C, P, N$. It has no coordinate for host function equality, quotient representatives, selected limiting partitions, a global total-positivity theorem, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.VariationDiminishingUp.VariationDiminishingTasteGate single carrier alignment`

Theorem 5747.2 (Variation-diminishing NameCert obligations)**.** *For every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier*

$$V = (B, T, R, I, K, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded-variation source row B, total-variation ledger T, regulated-function readback R, Riemann-integral boundary I, kernel or transformation row K, variation comparison row M, componentwise transport H, displayed replay C, provenance P, and local naming N.*

The obligation surface requires every output variation read to pass through the displayed comparison row M after B, T, R, I, K have been projected. It refuses host operator equality, quotient equality of functions, selected partitions, unrestricted total positivity, measure-theoretic kernels, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5805.1. The source row B supplies the bounded-variation input, while T supplies the total-variation ledger on which finite sign-change comparisons can be read.

The rows R and I keep the analytic route finite. Regulated readback gives step-window access to input and output functions, and the Riemann-integral boundary records only the tagged-mesh action needed by a kernel or averaging read.

The row K names the transformation window, and M is the only row that compares variation before and after the transformation. Thus the NameCert consumer obtains a variation-diminishing assertion only through the displayed comparison row, not through a host theorem about all kernels.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores quotient functions, selected limiting partitions, unrestricted total positivity, measure completion, or ambient real completeness, no local obligation can require them. □

Theorem 5747.3 (Variation-diminishing total-variation route)**.** *Every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *consumer read factors through the route*

$$\mathsf{BoundedVariationRealFunction}^{\uparrow},\ \mathsf{TotalVariationFunction}^{\uparrow},\ \mathsf{RegulatedRealFunction}^{\uparrow},\ \mathsf{RiemannIntegral}^{\uparrow} \longmapsto \mathsf{VariationD}$$

The output variation ledger is accepted only after the bounded-variation input, cumulative total-variation ledger, regulated readback, tagged integration boundary, kernel row, and comparison row have been displayed. The route exports no selected limit, quotient function equality, global total-positivity principle, measure-completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. A variation-diminishing request first projects B and T. These rows bind the input function to the bounded-variation and total-variation sibling surfaces, so the requested comparison starts from finite variation data rather than from a host function space.

Next project R and I. The regulated row supplies finite step-window readback, while the integral boundary supplies the tagged-mesh route through which a kernel or averaging transformation can be inspected.

The transformation row K and comparison row M then give the only accepted variation comparison. They state that the displayed output sign-change ledger routes to a no-larger input ledger in the same finite packet.

Finally H, C, P, N preserve the route under transport, replay, provenance, and local naming. Hence every public read of $\mathsf{VariationDiminishing}^{\uparrow}$ passes through the four cited sibling anchors and does not acquire the excluded host-level principles. □

Falsifiable prediction: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet whose output variation read bypasses the displayed total-variation ledger or the regulated readback row is not accepted by the local NameCert.

Independence witness: total-variation-function, bounded-variation-real-function, regulatedrealfunction, riemannintegral: $\mathsf{VariationDiminishing}^{\uparrow}$ is not bijective to any listed sibling because it binds the source variation ledger, regulated readback, tagged integration boundary, transformation row, and no-increase comparison as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet is generated from bounded-variation source data, a total-variation ledger, regulated readback, Riemann tagged-mesh boundary, a kernel or transformation row, a variation comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5805.1, Definition 5805.2, Definition 5805.3, the falsifiable prediction, and the independence witness seed the finite variation-diminishing route over the current analysis rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host operator equality, quotient equality of functions, selected limiting partitions, unrestricted total positivity, measure completion, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation source visibility, total-variation ledger exactness, regulated readback, tagged integration boundary, transformation-row exposure, comparison-row stability, transport, replay, provenance, and local naming for future BEDC.Derived.VariationDiminishingUp.

$\mathsf{FrobeniusReciprocity}^{\uparrow}$ routes induction–restriction comparison through chapter 247, chapter 246, and chapter 245 before the child file states the local certificate.

Chapter 5748

A Concrete Naming Certificate for $\mathsf{FrobeniusReciprocity}^{\uparrow}$

Following Frobenius on induced characters, Serre's finite-group representation theory, and the induction–restriction formulation used by Fulton–Harris, the $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet records the finite comparison row between induction from a subgroup and restriction to that subgroup. It consumes the action rows of chapter 3662, the subgroup source of chapter 80, the representation-ring ledger of chapter 246, the induction–restriction packet of chapter 247, and the character-pairing surface of chapter 245. The packet names only finite source rows, adjunction ledgers, character-pairing boundaries, transport, replay, provenance, and downstream handoff rows; it does not assert a host category of representations, a functor equality, semisimplicity, Schur orthogonality, or a completed character table.

Theorem 5748.1 (FrobeniusReciprocityUp source obligations)**.** *For every accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet, the source surface is the displayed finite tuple*

$$\mathcal{F} = (G, H, R, I, Q, \Phi, \eta, \epsilon, \chi, \lambda, C, P, N),$$

where G is the consumed $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *action row, H is the consumed* $\mathsf{Subgroup}^{\uparrow}$ *row, R is the consumed* $\mathsf{RepresentationRing}^{\uparrow}$ *ledger, I is the consumed* $\mathsf{InducedRep}^{\uparrow}$ *induction–restriction row, Q is the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *pairing row, Φ is the Frobenius comparison row, η, ϵ are the displayed unit and counit rows, χ is the character-pairing boundary, λ is the finite ledger of visible source and endpoint reads, C is componentwise* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *row. No source obligation is imported from a host representation category, quotient carrier, functor category, or external adjunction object.*

Proof. Project the accepted packet. The source rows are precisely G, H, R, I, Q together with the local comparison rows $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

The consumed rows are already finite BEDC certificates. The finite-group representation row supplies the action display, the subgroup row supplies the inclusion boundary, the representation-ring row supplies the Grothendieck ledger, the induced-representation row supplies the induction–restriction endpoints, and the character-theory row supplies the pairing surface.

Since the tuple has no coordinate for a host representation category, quotient carrier, functor category, or external adjunction object, the listed rows exhaust the source obligations. □

Theorem 5748.2 (FrobeniusReciprocityUp adjunction ledger)**.** *The adjunction data of an accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet are exactly the finite rows $\Phi, \eta, \epsilon, \lambda$ over the consumed sources*

H, R, I. The row Φ compares the displayed induction endpoint with the displayed restriction endpoint, η and ϵ record the unit and counit witnesses as BHist *rows, and λ records the visible continuations among source, endpoint, and Frobenius reads. The ledger exports no host naturality square, functor equality, adjunction object, or semisimple decomposition.*

Proof. Begin with the induction–restriction source. The packet consumes the $\mathsf{InducedRep}^{\uparrow}$ row I, so the available endpoints are the displayed induction and restriction rows already carried by that certificate.

The Frobenius comparison is read through Φ. The unit and counit witnesses are read through η and ϵ, and every visible path among source and endpoint reads is recorded by the finite ledger λ.

Exactness is projection from the tuple. Any row outside $\Phi, \eta, \epsilon, \lambda$ is not part of the adjunction ledger, and no host naturality square or functor equality can be recovered from a coordinate that the packet does not carry. □

Theorem 5748.3 (FrobeniusReciprocityUp character-pairing boundary)**.** *Every character-pairing read of a* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet factors through the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *row Q, the representation-ring source R, the induction–restriction source I, and the displayed pairing boundary χ before it can inspect Φ, η, ϵ or λ. The boundary supplies only the finite character-pairing comparison needed for reciprocity and does not export Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra.*

Proof. Read the character side first. The only character-theory coordinate is Q, and the only representation-ring coordinate feeding it is R.

The induction and restriction endpoints enter through I. The displayed pairing boundary χ then names the finite comparison used by the Frobenius row before the ledger reads $\Phi, \eta, \epsilon, \lambda$.

Because the tuple has no coordinate for Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra, every character-pairing read remains inside the stated finite boundary. □

Theorem 5748.4 (FrobeniusReciprocityUp NameCert surface)**.** *The* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *obligation surface is the conjunction of the source obligations of Definition 5806.1, the adjunction ledger of Definition 5806.2, the character-pairing boundary of Definition 5806.3, componentwise* hsame *transport on all displayed source and ledger rows, finite* Cont *replay through C, and* Pkg *provenance through P. The surface exports no obligation outside the displayed tuple $\mathcal{F}$.*

Proof. First combine the source obligations with the adjunction ledger. The source theorem identifies the consumed BEDC certificates, and the ledger theorem identifies the only Frobenius comparison, unit, counit, and continuation rows.

Next add the character-pairing boundary. It places every character read behind Q, R, I, χ before the Frobenius ledger can be inspected.

Finally apply componentwise transport and replay. The rows C and P preserve exactly the displayed tuple, and the local row N names the resulting certificate. Since no obligation outside $\mathcal{F}$ is available, these clauses give the stated NameCert surface. □

Theorem 5748.5 (FrobeniusReciprocityUp consumer handoff)**.** *A downstream consumer of* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *may read exactly the consumed finite-group action row G, subgroup row H, representation-ring row R, induced-representation row I, character-theory row Q, Frobenius rows Φ, η, ϵ, character-pairing boundary χ, visible ledger λ, replay row C, provenance row P, and local name row N. Any consumer handoff to* $\mathsf{InducedRep}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, *or* $\mathsf{CharacterTheory}^{\uparrow}$ *factors through those*

rows and cannot bypass them through a host category, functor equality, semisimplicity theorem, or character-table computation.

Proof. Start with a downstream read. The only visible source coordinates are G, H, R, I, Q, and the only local Frobenius coordinates are $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

For an $\mathsf{InducedRep}^{\uparrow}$ consumer, the handoff is through I together with the Frobenius rows. For a $\mathsf{RepresentationRing}^{\uparrow}$ consumer, the handoff is through R and the source ledger. For a $\mathsf{CharacterTheory}^{\uparrow}$ consumer, the handoff is through Q and the pairing boundary χ.

The replay and provenance rows preserve the same finite route. Thus a consumer cannot bypass the displayed packet through a host category, functor equality, semisimplicity theorem, or character-table computation. □

Theorem 5748.6 (FrobeniusReciprocityUp sibling lattice)**.** *The* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet is a finite comparison consumer of the sibling carriers in chapter 3662, chapter 80, chapter 246, chapter 247, and chapter 245. Its local rows compare induction and restriction after those carriers are visible; they do not form an isolated kernel row and do not replace the representation, subgroup, ring, induced-representation, or character-theory certificates.*

Proof. Read the source tuple of Definition 5806.1. The rows G, H, R, I, Q are precisely the five sibling certificates named in the statement.

The consumer handoff of Definition 5806.5 permits downstream reads only through those rows together with the Frobenius comparison, unit, counit, pairing boundary, ledger, replay, provenance, and local name rows.

Therefore the packet sits inside the displayed representation-theory lattice. It is a comparison consumer over the sibling carriers, not a standalone kernel surface from which the sibling certificates can be reconstructed. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5806.1, Definition 5806.2, Definition 5806.3, Definition 5806.4, Definition 5806.5, and Definition 5806.6 seed the finite Frobenius reciprocity certificate over displayed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, semisimplicity, Schur orthogonality, irreducible decomposition, character-table computation, functor-category equality, or a host adjunction theorem.

Upgrade path: Obligation closure requires checked carrier admission, adjunction-ledger exactness, character-pairing boundary, NameCert surface, and downstream handoff for the same finite packet.

Constructive story: A $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet is generated from consumed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows, then records a finite Frobenius comparison, unit and counit rows, character-pairing boundary, visible continuation ledger, package provenance, and local NameCert evidence.

Chapter 5749

A Concrete Naming Certificate for $\mathsf{NormalOperator}^{\uparrow}$

Following Reed and Simon, the $\mathsf{NormalOperator}^{\uparrow}$ packet records the standard normal-operator surface as finite NameCert data over displayed Hilbert and inner-product candidates. It consumes the inner-product carrier of chapter 86, the Hilbert carrier of chapter 91, the linear-map rows of chapter 48, the operator-norm boundary of chapter 3603, and the downstream spectral-theorem consumer of chapter 214. The packet exposes only a bounded linear operator, its displayed adjoint-action row, the norm ledger, and the normality commutator row; it does not claim spectral measure existence, functional calculus, diagonalization, projection-valued measures, or a host operator algebra.

Definition 5749.1 (NormalOperator carrier)**.** *For a displayed* $\mathsf{Hilbert}^{\uparrow}$ *candidate* H *with* $\mathsf{InnerProduct}^{\uparrow}$ *row* I*, a* $\mathsf{NormalOperator}^{\uparrow}(H)$ *carrier is a finite* BHist *packet*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N)$$

with the following ten displayed fields:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *carrier row and I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row over the same point-history carrier.*
2. *T is a bounded* $\mathsf{LinMap}^{\uparrow}$ *endpoint action on the carried Hilbert endpoints.*
3. *T^* is the displayed adjoint-action row, certified by the finite inner-product comparison*

   $$\langle Tx, y\rangle_I \ \mathsf{hsame}\ \langle x, T^*y\rangle_I$$

   for the vector histories inspected by the packet.
4. *A is the adjoint-domain ledger, recording that the adjoint row is read over the same Hilbert, inner-product, linear-map, and boundedness surfaces as T.*
5. *K is the* $\mathsf{OperatorNorm}^{\uparrow}$ *bound row for T and for the displayed adjoint action T^*.*
6. *Q is the normality commutator row*

   $$T^*T \ \mathsf{hsame}\ TT^*$$

   read only on certified vector histories.
7. *L is the operator graph ledger: it stores inspected input histories, output histories, linearity rows, adjoint rows, norm-bound rows, and the commutator row.*

8. *H_T records componentwise* hsame *transport for the Hilbert source, inner-product row, endpoint actions, adjoint row, norm row, commutator row, and ledger.*
9. *C records displayed* Cont *replay for endpoint action requests, adjoint-action requests, norm-bound requests, and commutator inspections.*
10. *P, N are the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *naming rows.*

The classifier compares accepted carriers by action agreement on certified vector histories, adjoint-action agreement on the same inspected histories, transport of the operator-norm row, and transport of the graph, adjoint, normality, continuation, provenance, and local-name ledgers. It has no coordinate for host operator equality, quotient completion, spectral measures, eigenvector bases, or external functional calculus.

Lean4 ✓ `BEDC.Derived.NormalOperatorUp.NormalOperatorTasteGate single carrier alignment`

Theorem 5749.2 (NormalOperator NameCert obligations)**.** *For every accepted* $\mathsf{NormalOperator}^\uparrow$ *carrier*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the common* $\mathsf{Hilbert}^\uparrow$ *and* $\mathsf{InnerProduct}^\uparrow$ *rows;*
2. *bounded* $\mathsf{LinMap}^\uparrow$ *action for T on certified vector histories;*
3. *adjoint-action agreement for T^* against the displayed inner product;*
4. $\mathsf{OperatorNorm}^\uparrow$ *bound rows for the operator action and adjoint action;*
5. *normality commutator exactness through the displayed row Q;*
6. *graph-ledger exactness for input histories, output histories, linearity rows, adjoint rows, norm rows, and commutator rows;*
7. *classifier transport by action agreement, adjoint-action agreement, norm-row agreement, and componentwise ledger transport;*
8. Cont *replay,* Pkg *provenance, and local naming for exactly the displayed packet;*
9. *refusal of spectral measure existence, diagonalization, projection-valued measures, host operator quotients, and unrecorded functional calculus.*

Proof. Project the carrier of Definition 5807.1. The Hilbert and inner-product source rows, endpoint action, adjoint-action row, adjoint-domain ledger, norm row, commutator row, graph ledger, transport row, continuation row, provenance row, and local name are the full displayed inventory.

The adjoint and boundedness obligations are read before any spectral consumer appears. The adjoint row is the finite inner-product comparison for certified vector histories, and the norm row is the displayed $\mathsf{OperatorNorm}^\uparrow$ bound attached to both endpoint actions.

Normality is exactly the commutator row Q. Because Q compares T^*T and TT^* only through inspected vector histories and their graph ledger, the packet does not appeal to host equality of operators.

Finally H_T, C, P, N transport, replay, source, and name those rows. Since the carrier has no spectral-measure, diagonalization, projection-valued-measure, quotient, or functional-calculus coordinate, the listed rows exhaust the local normal-operator NameCert obligations. □

Theorem 5749.3 (NormalOperator InnerProduct spectral anchor)**.** *Every downstream spectral read of an accepted* $\mathsf{NormalOperator}^{\uparrow}$ *packet factors through the common Hilbert and inner-product rows, the bounded linear action, the displayed adjoint-action row, the operator-norm bound, and the normality commutator ledger before it can be consumed by the* $\mathsf{SpectralTheorem}^{\uparrow}$ *surface. The route is*

$$(H, I) \longmapsto (T, T^*, A, K, Q, L) \longmapsto (H_T, C, P, N),$$

and it exports no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality.

Proof. Expose the accepted packet by Definition 5807.1. The only analytic source rows are the Hilbert carrier, inner-product comparison row, endpoint action, displayed adjoint action, norm bound, and normality commutator.

Apply Definition 5807.2. The graph ledger forces the operator action, adjoint action, boundedness evidence, and commutator evidence to be read from one finite packet, and classifier transport keeps the operator and adjoint rows over the same certified vector histories.

It remains to hand the packet to spectral consumers. The $\mathsf{SpectralTheorem}^{\uparrow}$ chapter may consume the normality anchor only through the displayed rows already named here. Because no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality is a field of the carrier, the anchor supplies a pre-spectral normal-operator surface rather than a spectral theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5807.1, Definition 5807.2, and Definition 5807.3 seed the normal-operator surface over Hilbert, inner-product, bounded linear-map, adjoint-action, operator-norm, and commutator rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim spectral measures, spectral projections, diagonalization, eigenbasis construction, Borel functional calculus, host operator quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, adjoint-action agreement, norm-bound stability, normality commutator exactness, classifier transport, graph-ledger exactness, spectral-consumer nonescape, and bridge data for BEDC.Derived.NormalOperatorUp.

Constructive story: A $\mathsf{NormalOperator}^{\uparrow}$ packet is generated from a Hilbert source, an inner-product row, a bounded linear endpoint action, a displayed adjoint action, operator-norm bounds, a normality commutator row, graph and transport ledgers, continuation replay, provenance, and a local NameCert row.

Chapter 5750

A Concrete Naming Certificate for $\mathsf{HausdorffMeasure}^{\uparrow}$

Following Hausdorff and Federer's metric measure theory, the $\mathsf{HausdorffMeasure}^{\uparrow}$ packet records the finite dyadic-cover surface through which Hausdorff content and scale-stable measure reads become visible inside BEDC. It sits over the metric carrier of chapter 57, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the cover-valued outer-measure boundary of chapter 3385, and the finite scale-cover comparison surface of chapter 3877. The packet names only displayed dyadic cover packets, diameter budgets, weighted cover sums, scale comparison, transport, replay, provenance, and local naming; it is not a quotient cover family, not a selected infimum, not countable choice over covers, and not an ambient measure primitive.

Definition 5750.1 (Hausdorff measure dyadic-cover carrier)**.** *A* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (M, D, R, O, B, C, S, T, E, K, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the finite point classifier and distance comparisons used to bound cover diameters.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row, naming the dyadic radius budget and dyadic exponent used by the cover packet.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *value-seal row for diameter powers and finite cover sums.*
4. *O is the* $\mathsf{OuterMeasure}^{\uparrow}$ *handoff row, read only as a finite cover-valued boundary and not as a completed measure primitive.*
5. *B is the* $\mathsf{BoxDimension}^{\uparrow}$ *comparison row, exposing finite scale-cover counts against the same dyadic scale.*
6. *C is the finite dyadic cover packet, listing the displayed cover cells, their metric diameter witnesses, and their membership reads.*
7. *S is the cover-sum ledger, recording the finite Real-sealed sum of dyadic diameter weights.*
8. *T is the scale-stability ledger, recording that dyadic refinement reads the same metric source, outer-measure boundary, and box-dimension comparison rows.*
9. *E records componentwise* hsame *transport for metric, dyadic scale, Real seal, outer-measure handoff, box-dimension comparison, cover packet, cover sum, and stability rows.*

10. *K records displayed* Cont *replay from a metric source and dyadic scale through C, S, T, E, P, N.*
11. *P is the* Pkg *provenance over* $\mathsf{HausdorffMeasure}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{OuterMeasure}^{\uparrow}$, $\mathsf{BoxDimension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D, R, O, B, C, S, T, E, K, P, N$. It has no coordinate for quotient cover families, selected infima, countable-choice schedules over covers, host sigma-algebras, or ambient measure primitives.

Lean4 ✓ `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate single carrier alignment`

Theorem 5750.2 (Hausdorff measure NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier $H = (M, D, R, O, B, C, S, T, E, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *surface consists exactly of metric source admission, dyadic scale exposure, Real value sealing, finite outer-measure handoff, box-dimension scale comparison, finite dyadic cover admission, cover-sum exactness, scale-stability replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every measure-facing or dimension-facing consumer must read the displayed route*

$$\mathsf{Met}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto C, S, T \longmapsto \mathsf{OuterMeasure}^{\uparrow}, \mathsf{BoxDimension}^{\uparrow} \longmapsto E, K, P, N$$

before treating the packet as a Hausdorff-measure read.

Proof. Project the carrier of Definition 5808.1. The metric row M, dyadic row D, and Real seal row R are the only sources for distances, scales, and finite value readback.

The cover packet C and cover-sum ledger S are finite rows. They record displayed cover cells and dyadic diameter weights, so no step selects a minimizing cover family or takes an external infimum.

The outer-measure and box-dimension rows O, B are downstream comparison boundaries. They can read the same finite cover data, but they do not add a completed host measure, a quotient of covers, or countable choice over refinements.

Finally T, E, K, P, N transport, replay, source, and name the same finite route. Since every exported obligation is one of the listed rows, the local classifier cannot expose an ambient measure primitive or any detached cover selector. □

Theorem 5750.3 (Hausdorff measure dyadic-cover stability)**.** *Let $H = (M, D, R, O, B, C, S, T, E, K, P, N)$ be an accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier. For any displayed dyadic refinement of the scale row D, the scale-stability ledger T forces the refined read to reuse the same* $\mathsf{Met}^{\uparrow}$ *source, the same* $\mathsf{Real}^{\uparrow}$ *value-seal route, the same finite* $\mathsf{OuterMeasure}^{\uparrow}$ *cover boundary, and the same* $\mathsf{BoxDimension}^{\uparrow}$ *scale-count comparison before any consumer reads a Hausdorff-measure claim. The stable route is*

$$M, D, R, C, S, T \longmapsto O, B \longmapsto E, K, P, N.$$

It exports no quotient cover family, selected infimum, countable-choice cover schedule, host sigma-algebra closure, or ambient measure primitive.

Proof. Read the carrier of Definition 5808.1. A dyadic refinement changes only the displayed scale request inside D and the finite cover packet admitted by C.

Use the stability ledger T. It records that the refined cover is replayed against the same metric source and that its finite cover sum is sealed through the same Real row, so the refinement cannot introduce a detached minimizing cover or a host infimum.

The comparison rows O and B then read the refined packet as finite outer-measure and box-dimension boundary data. Componentwise transport and displayed replay through E, K, P, N preserve that route, while quotient covers, countable choice, host sigma-algebras, and ambient measure primitives remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HausdorffMeasure}^{\uparrow}$ consumer that reaches a Hausdorff-measure read without first exposing a MetricUp source row, a DyadicRatCore scale row, a RealUp value seal, a finite dyadic cover packet, a finite cover-sum ledger, an OuterMeasureUp handoff, a BoxDimensionUp comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row refutes the carrier surface.

Independence witness: metric, dyadicratcore, real, outermeasure, boxdimension: $\mathsf{HausdorffMeasure}^{\uparrow}$ is not bijective to any listed sibling because it binds metric diameter data, dyadic scales, Real-sealed finite cover sums, outer-measure cover boundaries, and box-dimension scale counts into one finite cover-stability NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffMeasure}^{\uparrow}$ packet is generated from a MetricUp source row, DyadicRatCore scale row, RealUp value-seal row, finite OuterMeasureUp handoff, BoxDimensionUp comparison row, finite dyadic cover packet, cover-sum ledger, scale-stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5808.1, Definition 5808.2, and Definition 5808.3 seed the finite dyadic-cover Hausdorff-measure interface over MetricUp, DyadicRatCoreUp, RealUp, OuterMeasureUp, and BoxDimensionUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient cover families, selected infima, countable choice over covers, host sigma-algebra completion, ambient measure primitives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic scale exposure, finite cover admission, cover-sum exactness, scale-stability replay, outer-measure handoff, box-dimension comparison, transport, provenance, and no-escape for BEDC.Derived.HausdorffMeasureUp.

Chapter 5751

A Concrete Naming Certificate for $\mathsf{LocallyConnected}^{\uparrow}$

Following Kelley and Bourbaki on local connectedness, the $\mathsf{LocallyConnected}^{\uparrow}$ packet records finite neighbourhood-component data rather than a selected basis of connected open sets. It sits beside the global connectedness carrier of chapter 2353, the compact metric source discipline of chapter 129, the metric ball rows of chapter 57, and the open-neighbourhood ledger of chapter 88. The packet exposes the local component route needed by compact-metric and connected-space consumers without importing path selection, arc connectedness, open-cover compactness, or a host topological basis.

Definition 5751.1 (Locally connected carrier)**.** *A* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, M, G, K, B, C, H, R, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-neighbourhood row whose entries name the ambient open requests.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *ball-observation row used when the local request is metric.*
3. *G is the* $\mathsf{ConnectedSpace}^{\uparrow}$ *global component row available to consumers that compare local and global connectedness.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-source row available to compact-metric consumers.*
5. *B is the finite neighbourhood-refinement row: each displayed point and open request has a named smaller neighbourhood row.*
6. *C is the local connected-component row attached to the refinement in B.*
7. *H records componentwise* hsame *transport for the topology, metric, connectedness, compact-metric, refinement, component, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from an ambient open request through metric ball observations when present, the finite refinement row, and the local component row.*
9. *P is the* Pkg *provenance over* $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConnectedSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, M, G, K, B, C, H, R, P, N$. It has no coordinate for selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, or a host basis of connected neighbourhoods.

Lean4 ✓ `BEDC.Derived.LocallyConnectedUp.TasteGate.LocallyConnectedTasteGate single carrier alignment`

Theorem 5751.2 (Locally connected NameCert obligations)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier* $L = (T, M, G, K, B, C, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *surface consists exactly of carrier admission for the topology, metric, connected-space, compact-metric, finite neighbourhood-refinement, local component, transport, replay, provenance, and naming rows; neighbourhood refinement from T through B; component exposure through C; metric compatibility through M when the request is ball-based; compact-metric compatibility through K for compact finite-source consumers; connected-space comparison through G; and non-escape from selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice.*

Proof. Project the carrier of Definition 5809.1. The projection exposes exactly the rows $T, M, G, K, B, C, H, R, P, N$ so every local naming obligation must be read from those coordinates.

The neighbourhood part is finite. An ambient open request is first read in T, then refined by the displayed row B, and only then receives the local component row C.

The metric and compact-metric rows are compatibility rows rather than extra selectors. A ball-based request may inspect M, and a compact-metric consumer may inspect K, but both routes still pass through the same B and C rows before local connectedness is exported.

Finally, H and R transport and replay the displayed route, while P and N source and name it. Since paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice are not rows of the carrier, the NameCert surface cannot export them. □

Theorem 5751.3 (Locally connected neighbourhood component route)**.** *Every connected-space or compact-metric consumer of an accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *packet reaches local connectedness through*

$$\mathsf{Topology}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{ConnectedSpace}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The finite route reads an ambient neighbourhood, optionally reads metric ball observations, refines to a displayed smaller neighbourhood, and then reads the named local connected component. It does not select a path, an arc, a subcover, a quotient component representative, or a host connected-neighbourhood basis.

Proof. Start with a consumer that asks for local connectedness around a displayed point. Carrier admission gives the consumer the topology row T, the metric row M when a ball observation is part of the request, the global connectedness row G, and the compact-metric row K.

The route then passes through B and C. The row B supplies the finite neighbourhood refinement, and C supplies the local component attached to that refinement.

The structural rows H, R, P, N do not add a hidden selector. They transport, replay, source, and name the same finite route, so no path, arc, arbitrary subcover, quotient representative, or host basis can replace the displayed neighbourhood-component data. □

Theorem 5751.4 (Locally connected obligation closure surface)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier* $L = (T, M, G, K, B, C, H, R, P, N)$*, the obligation-closure surface is exhausted by the displayed finite topology, metric, connected-space, compact-metric, neighbourhood-refinement, local-component, transport, replay, provenance, and naming rows. The row T supplies the open-neighbourhood*

source, M supplies metric-ball observations, G supplies connected-space comparison, K supplies compact-metric finite-source compatibility, B, C supply the local refinement and component rows, and H, R, P, N supply transport, replay, provenance, and local naming.

The local component route therefore consumes the connected-space carrier of chapter 2353, the compact-metric finite neighbourhood discipline of chapter 129, the metric-ball rows of chapter 57, and the topology neighbourhood ledger of chapter 88 before a local component can be named.

Proof. Apply Definition 5809.2 to the accepted carrier. It identifies the complete NameCert surface with the rows $T, M, G, K, B, C, H, R, P, N$.

Apply Definition 5809.3. The route from an open request to a local component passes through topology, optional metric-ball observations, connected-space comparison, compact-metric compatibility, finite refinement, and component rows before the structural rows transport and name the result.

The sibling lattice is read in that order: topology supplies the neighbourhood ledger, metric supplies ball observations, connected-space supplies the comparison carrier, and compact metric supplies the finite neighbourhood discipline. The local refinement and component rows then bind those sibling contributions into the $\mathsf{LocallyConnected}^{\uparrow}$ packet.

Thus the obligation surface is the stated finite route. Path or arc selection, open-cover compactness, quotient components, and a host basis are refused because none of them is a carrier coordinate or a row used by the two preceding theorems. □

Falsifiable prediction: Every accepted $\mathsf{LocallyConnected}^{\uparrow}$ read must expose a $\mathsf{Topology}^{\uparrow}$ open-neighbourhood row, optional $\mathsf{Met}^{\uparrow}$ ball observations, the $\mathsf{ConnectedSpace}^{\uparrow}$ comparison row when a global consumer is present, the $\mathsf{CompactMetric}^{\uparrow}$ finite-source row when a compact-metric consumer is present, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: topology, metric, connected-space, compactmetric: $\mathsf{LocallyConnected}^{\uparrow}$ is not bijective to any listed sibling because it binds a local neighbourhood-refinement row to a local component row before connected-space or compact-metric consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5809.1, Definition 5809.2, and Definition 5809.3 seed the finite local neighbourhood-component route over topology, metric, connected-space, and compact-metric rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close path connectedness, arc connectedness, arbitrary open-cover compactness, quotient component spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, neighbourhood refinement, local component exposure, connected-space comparison, compact-metric compatibility, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.LocallyConnectedUp.

Constructive story: A $\mathsf{LocallyConnected}^{\uparrow}$ packet is generated from an open-neighbourhood row, optional metric ball observations, connected-space and compact-metric compatibility rows, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5752

A Concrete Naming Certificate for $\mathsf{BishopCauchyMean}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{BishopCauchyMean}^{\uparrow}$ packet records the finite averaging step used when a Cauchy source is read through displayed rational windows and sealed as a Real-facing name. It sits after the $\mathsf{Cauchy}^{\uparrow}$ source route of chapter 3413, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names finite averages of observed Cauchy data; it does not assert a selected limit, quotient stream equality, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5752.1 (Bishop Cauchy mean carrier)**.** *A* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Cauchy}^{\uparrow}$ *source row naming the Cauchy data whose finite observations are being averaged.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested dyadic radius, denominator budget, and comparison scale for the average.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the source entries inspected at tolerance D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream window into regular rational data.*
5. *A is the finite averaging ledger: it lists the inspected rational entries, their displayed weights, the denominator row, the partial-sum row, and the final mean row consumed by the certificate.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, W, R, A have been displayed.*
7. *H records componentwise* hsame *transport for the source, tolerance, window, readback, averaging ledger, Real seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a finite mean request through $S, D, W, R, A, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyMean}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, D, W, R, A, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness of $\mathsf{Real}^{\uparrow}$*, or an infinite averaging oracle.*

Lean4 ✓ `BEDC.Derived.BishopCauchyMeanUp.BishopCauchyMeanTasteGate single carrier alignment`

Theorem 5752.2 (Bishop Cauchy mean NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier*

$$M = (S, D, W, R, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cauchy source row, dyadic tolerance row, finite stream window, regular rational readback, finite averaging ledger, terminal Real seal, componentwise transport row, displayed continuation replay, package provenance, and local naming row.*

The obligation surface requires Cauchy-source visibility through S, tolerance accounting through D, finite-window visibility through W, regular rational readback through R, average-ledger exactness through A, Real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It refuses selected limits, quotient stream equality, host real equality, countable choice, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the accepted carrier of Definition 5810.1. The only analytic rows are the Cauchy source S, the dyadic tolerance D, the finite window W, the regular rational readback R, the averaging ledger A, and the terminal Real seal E.

The averaging step is finite. The ledger A displays the inspected rational entries, their weights, the denominator row, the partial sums, and the final mean; no later consumer can ask for an average outside this listed window.

The terminal seal is downstream of the displayed route. Since the carrier has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness, or an infinite averaging oracle, those objects cannot enter the local NameCert surface.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. They preserve the displayed rows and do not add analytic content. □

Theorem 5752.3 (Bishop Cauchy mean finite-average stability)**.** *Let*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

be an accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier. Every accepted consumer read of the mean row factors through the finite route*

$$\mathsf{Cauchy}^{\uparrow}(S),\ \mathsf{DyadicRatCore}^{\uparrow}(D),\ \mathsf{StreamName}^{\uparrow}(W),\ \mathsf{RegSeqRat}^{\uparrow}(R),\ A,\ \mathsf{Real}^{\uparrow}(E).$$

If the source row, tolerance row, finite window, readback row, and averaging ledger are transported componentwise by the displayed hsame *rows in H and replayed through C, then the consumer-visible mean row is unchanged as a* $\mathsf{BishopCauchyMean}^{\uparrow}$ *read. No quotient stream equality, selected limit, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row participates in the stability claim.*

Proof. Start with the consumer route. By the carrier definition, a mean read must first inspect the Cauchy source S, choose the displayed dyadic tolerance D, open the finite window W, and read the regular rational row R.

The average itself is then the ledger row A. Its entries, weights, denominator, partial sums, and final mean are finite displayed data, so componentwise hsame transport preserves exactly the rows that the consumer can inspect.

Replay through C exposes the transported packet with the same provenance and local naming rows P, N. The terminal Real seal E is reached from that transported finite route, not from a quotient stream or selected limit.

Thus any consumer-visible equality of mean reads is exhausted by $S, D, W, R, A, E, H, C, P, N$. The excluded rows are absent from the carrier and cannot affect the stability conclusion. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ read must expose a Cauchy source, dyadic tolerance, StreamName window, RegSeqRat readback, finite averaging ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a Real or Completion consumer can read the mean boundary.

Independence witness: cauchy, dyadicratcore, streamname, regseqrat, real: $\mathsf{BishopCauchyMean}^{\uparrow}$ is not bijective to any listed sibling because it binds a finite averaging ledger between regular rational readback and the Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyMean}^{\uparrow}$ packet is generated from a Cauchy source row, DyadicRatCore tolerance row, StreamName finite window, RegSeqRat readback, finite averaging ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5810.1, Definition 5810.2, and Definition 5810.3 seed the finite Cauchy-mean certificate over Cauchy, DyadicRatCore, StreamName, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite average ledger exactness, tolerance-window readback, regular rational handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyMeanUp.

Chapter 5753

A Concrete Naming Certificate for $\mathsf{BishopFixedPointInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet records the constructive interval fixed-point route as finite NameCert data. It sits after the located interval source of chapter 394, the bisection discipline of chapter 1465, the finite Cauchy-modulus rows used by chapter 292, the regular rational readback of chapter 301, the finite name windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the fixed-point certificate for a displayed interval self-map; it does not import a host compactness theorem, quotient real equality, choice-selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5753.1 (Bishop fixed-point interval carrier)**.** *A* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, T, M, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the closed located interval, its endpoint reads, and its dyadic radius ledger.*
2. *T is the contraction self-map row over I, recording that every admitted interval point is sent back into the same located interval.*
3. *M is an explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *or Lipschitz modulus row that turns each tolerance request into a finite contraction budget.*
4. *B is the* $\mathsf{IntervalBisection}^{\uparrow}$ *or nested located interval row that records the displayed shrinking interval chain.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the rational midpoint, endpoint, and radius observations.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *fixed-point seal reached only after the interval, contraction, modulus, bisection, and readback rows have been exposed.*
7. *H records componentwise* hsame *transport for I, T, M, B, R, E and for the structural rows.*
8. *C records displayed* Cont *replay for interval requests, contraction reads, modulus reads, nested interval reads, rational readback, and real-seal requests.*

9. *P is the* Pkg *provenance over* BishopFixedPointInterval$^{\uparrow}$, LocatedInterval$^{\uparrow}$, IntervalBisection$^{\uparrow}$, CauchyModulus$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{BishopFixedPointInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, T, M, B, R, E, H, C, P, N$. It has no coordinate for a host fixed-point theorem, quotient completion, selected limit, trichotomy, countable choice, or ambient compactness principle.

Lean4 ✓ `BEDC.Derived.BishopFixedPointIntervalUp.BishopFixedPointIntervalTasteGate single carrier alignment`

Theorem 5753.2 (Bishop fixed-point interval NameCert obligations)**.** *For every accepted* BishopFixedPointInterval$^{\uparrow}$ *carrier*

$$F = (I, T, M, B, R, E, H, C, P, N),$$

the local NameCert$_{\text{BishopFixedPointInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the located interval row I, contraction self-map row T, explicit modulus row M, nested bisection row B, regular rational readback row R, terminal real seal E, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N. Every fixed-point consumer must read these rows in the displayed order and cannot replace them by host interval compactness, quotient real equality, a selected limit, or an unrecorded convergence principle.*

Proof. Carrier admission is the finite packet of Definition 5811.1. The rows $I, T, M, B, R, E, H, C, P, N$ are the only coordinates available to the local certificate.

The positive interval route is then forced. The interval source is I, the self-map evidence is T, the contraction budget is M, and the nested interval chain is B; each row is compared only through the componentwise transport row H and replayed only through C.

The readback and seal are downstream. Rational observations pass through R and the dyadic and stream-name data named in P before the terminal Real$^{\uparrow}$ row E is exposed. Since no host compactness, quotient equality, selected limit, or external convergence coordinate occurs in the carrier, the listed rows exhaust the NameCert surface. □

Theorem 5753.3 (Bishop fixed-point interval Cauchy-modulus route)**.** *Let $F = (I, T, M, B, R, E, H, C, P, N)$ be an accepted* BishopFixedPointInterval$^{\uparrow}$ *packet. Each tolerance request for the fixed-point name is answered by first reading the* LocatedInterval$^{\uparrow}$ *row I, then the contraction self-map row T, then the explicit* CauchyModulus$^{\uparrow}$ *or Lipschitz row M, and only then the* IntervalBisection$^{\uparrow}$ *or nested located interval row B. The resulting finite observations are read through* StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* RegSeqRat$^{\uparrow}$ *as recorded by P, so no consumer can infer convergence from an unbounded host iteration or a choice-selected subsequence.*

Proof. Start with a tolerance request. The packet has no direct convergence row, so the request must project I to know the interval source and T to know that the displayed map remains inside the interval.

Next read the modulus row M. This row converts the tolerance into a finite contraction or Lipschitz budget. The nested row B can then expose only the finite bisection or located-interval observations licensed by that budget.

Finally use the readback rows listed in P. Stream windows, dyadic tolerances, and regular rational observations feed R, and H, C, N transport and name the same route. Thus the Cauchy route is explicit and finite, with no unbounded host iteration or selected subsequence. □

Theorem 5753.4 (Bishop fixed-point interval real-seal nonescape)**.** *For every accepted* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *packet, the terminal row* E *is exposed only as the* $\mathsf{Real}^{\uparrow}$ *seal of the displayed nested interval and Cauchy-modulus route*

$$I, T, M, B, R \longmapsto E \longmapsto H, C, P, N.$$

The seal may be consumed as the named fixed-point endpoint of the packet, but it cannot escape as quotient real equality, a proof of ambient $\mathsf{Real}^{\uparrow}$ *completeness, a host fixed-point theorem, an unrestricted interval compactness principle, or a selected representative outside the displayed rows.*

Proof. Read E from the carrier. It is terminal in the packet: the interval, self-map, modulus, nested interval, and rational readback rows precede it, and the structural rows only transport, replay, source, and name the resulting read.

Apply Definition 5811.3. Every tolerance request reaching E has already passed through the finite interval, contraction, modulus, bisection, stream, dyadic, and regular rational observations recorded by I, T, M, B, R, P.

It remains to rule out escape. The carrier has no coordinate for quotient real equality, ambient completeness, a host fixed-point theorem, unrestricted compactness, or selected representatives. Therefore E seals only the displayed fixed-point name of this packet. □

Falsifiable prediction: An accepted $\mathsf{BishopFixedPointInterval}^{\uparrow}$ consumer that reaches the terminal $\mathsf{Real}^{\uparrow}$ row E without first reading $I, T, M, B, R, H, C, P, N$ refutes the carrier surface.

Independence witness: locatedinterval, intervalbisection, cauchymodulus, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the full interval self-map packet $F = (I, T, M, B, R, E, H, C, P, N$ because each sibling contributes only a located interval source, a bisection route, a modulus row, a readback row, a finite name window, a dyadic ledger, or a terminal real seal while this chapter binds them into one fixed-point NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet is generated from a located interval row, contraction self-map row, explicit Cauchy or Lipschitz modulus row, nested bisection row, regular rational readback row, terminal Real seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5811.1, Definition 5811.2, Definition 5811.3, and Definition 5811.4 seed the finite constructive interval fixed-point route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point compactness, quotient real equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction self-map admission, explicit modulus routing, nested interval readback, terminal Real seal nonescape, and a Lean carrier/obligation formalization for BEDC.Derived.BishopFixedPointIntervalUp.

Chapter 5754

A Concrete Naming Certificate for $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$

The $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet realizes the private-coordinate minimal-cover theorem of Definition 9462.1678 as finite NameCert data. It records a trigger-coordinate carrier, a support-family cover ledger, and one private-coordinate witness row for each displayed support before any minimal-trigger criterion may be consumed. The packet keeps the enumeration theorem auditable without identifying it with a generic finite set, word list, Boolean classifier, regular-language recognizer, or finite automaton presentation.

Falsifiable prediction: Every accepted $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ consumer must display a cover row and one private-coordinate witness row for each support before using the minimal-trigger criterion.

Independence witness: finset, list, bool, regularlanguage, finite-automaton: $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ is not bijective to these siblings because it carries a support-family cover ledger plus a private-coordinate witness for every support row.

Definition 5754.1 (Private-coordinate trigger carrier)**.** *A* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the finite trigger-coordinate row.*
2. A *is the finite support-family row whose entries are displayed subsets of* Ω*.*
3. U *is the cover ledger asserting that the displayed supports cover every coordinate of* Ω*.*
4. V *is the private-coordinate witness ledger, with one row for each support in* A*.*
5. π *maps each support row to its selected private coordinate and records membership in that support.*
6. E *records exclusion from every other support row for the selected private coordinate.*
7. K *is the minimal-cover criterion row, readable only after* U, V, π, E *have been displayed.*
8. H *stores componentwise* hsame *transport for coordinate, support, cover, witness, exclusion, and criterion rows.*

9. *C stores* Cont *replay from a trigger query through the cover ledger and the private-coordinate witness rows.*
10. *P stores* Pkg *provenance over* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Omega, A, U, V, \pi, E, K, H, C, P, N$. It has no coordinate for a bare finite set, unordered list, Boolean truth table, regular-language recognizer, finite automaton run, or support family without displayed private witnesses.

Theorem 5754.2 (Private-coordinate trigger NameCert obligations)**.** *For every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *surface consists exactly of coordinate exposure, support-family exposure, cover-ledger replay, one private-coordinate witness row for each support, membership and exclusion checks for the selected witnesses, minimal-cover criterion exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5812.1. The rows Ω, A, U display the finite coordinate space, the support family, and the fact that the supports cover the full coordinate row.

The rows V, π, E attach a private coordinate to each support. Membership is recorded by π, and exclusion from every other support is recorded by E, so deleting the support removes at least one displayed coordinate from the cover.

The criterion row K is therefore readable only after the cover and private-witness rows have been exposed. The remaining rows H, C, P, N preserve transport, replay, provenance, and local naming for the same finite packet, and no omitted sibling surface supplies the private-coordinate ledger. □

Theorem 5754.3 (Private-coordinate minimal-cover criterion)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier exposes a minimal full trigger exactly through the displayed cover row U together with the private-coordinate witness rows V, π, E. A consumer may use the criterion row K only after reading a cover of Ω and one witness coordinate for every support row in A that belongs to that support and belongs to no other displayed support. The packet does not turn the support family into a regular language, finite automaton, Boolean table, or list quotient.*

Proof. The forward read uses the cover ledger U and the private-coordinate witness rows. If a support row is removed, its selected witness coordinate remains outside all other displayed supports by E, so the remaining family no longer covers Ω.

For the reverse read, the cover row already gives full coverage. The witness rows ensure that every support has a coordinate lost by deleting that support, so no displayed support is redundant.

Thus the criterion row K is exactly the finite private-coordinate minimal-cover test. The transport, replay, provenance, and local naming rows carry this test without converting it into any sibling classifier. □

Theorem 5754.4 (Private-coordinate trigger finite-set cover route)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *packet reads its support-family row as a finite-set-indexed cover through chapter 112. The exclusions from regular-language and automaton presentations are bounded by chapter 351 and chapter 2364: the private-coordinate carrier may display finite support rows, recognizer-like acceptance tests, or transition-like exclusion checks, but it exports the minimal-cover criterion only through the rows $\Omega, A, U, V, \pi, E, K, H, C, P, N$.*

Proof. Project the accepted carrier

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N).$$

The row Ω is the displayed coordinate object, and A is read as a finite family of supports indexed by the finite-set surface. The cover ledger U then witnesses coverage of every coordinate in Ω by those displayed supports.

The rows V, π, E are the extra private-coordinate ledger. They attach one witness coordinate to each support, record membership in that support, and record exclusion from every other displayed support. These rows are not supplied by the finite-set sibling, nor by the regular-language or finite-automaton presentations.

Consequently K is a private-coordinate minimal-cover read rather than a bare finite-set cover, a regular-language recognizer, or an automaton acceptance predicate. The structural rows H, C, P, N transport and replay only this displayed packet, so the sibling route records the finite-combinatorial surface without replacing the private-coordinate data. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$.

Constructive story: A $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet is generated from a finite trigger-coordinate row, support-family row, cover ledger, per-support private-coordinate witness ledger, membership and exclusion rows, minimal-cover criterion row, componentwise transport, continuation replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5812.1, Definition 5812.2, Definition 5812.3, and Definition 5812.4 seed the finite NameCert packet for private-coordinate minimal-cover witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, regular-language recognition, finite-automaton minimization, Boolean classifier completeness, or enumeration beyond the displayed private-coordinate criterion.

Upgrade path: Obligation closure requires checked carrier admission, cover-ledger replay, private-coordinate witness coverage, exclusion exactness, minimal-cover criterion replay, TasteGate nontriviality, FieldFaithful projection, transport, replay, provenance, and local naming for BEDC.Derived.PrivateCoordinateTriggerUp.

Chapter 5755

A Concrete Naming Certificate for $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet records the finite modulus by which a located real comparison request is read through displayed apartness or equality evidence, dyadic tolerances, explicit Cauchy-modulus schedules, regular rational readback, and the terminal real-name seal. It sits after the comparison surface of chapter 1730, the tail envelope of chapter 1769, the Cauchy-modulus bridge of chapter 5728, the rational readback of chapter 301, and the public real route of chapter 38. The packet names a finite comparison-schedule carrier; it is not trichotomy, quotient real equality, a selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5755.1 (Located real comparison modulus carrier)**.** *A* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, A, D, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{LocatedRealComparison}^{\uparrow}$ *request row for the two located real endpoints and the comparison direction being inspected.*
2. *A is the located evidence row. It records the displayed positive apartness witness when the request separates the endpoints, or the displayed equality-facing refusal row when the request reaches only an overlap tolerance.*
3. *D is the dyadic tolerance schedule. It lists the requested precision, comparison slack, endpoint radii, and finite tolerance refinements consumed by the comparison read.*
4. *B is the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route connecting the comparison request to an explicit Cauchy-modulus schedule before regular rational readback is allowed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected rational tails exposed by B and bounded by D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the comparison-facing read, available only after Q, A, D, B, R have been displayed.*
7. *H records componentwise* hsame *transport for the comparison request, evidence row, dyadic tolerance schedule, bridge route, readback, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from the comparison request through located evidence, dyadic scheduling, Cauchy-modulus bridging, regular rational readback, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, LocatedRealTailEnvelop $\mathsf{CauchyModulusBridge}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, A, D, B, R, E, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, a hidden selector, countable choice, a host comparison oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedRealComparisonModulusUp.LocatedRealComparisonModulusTasteGate`
`single carrier alignment`

Theorem 5755.2 (Located real comparison modulus obligations)**.** *For every accepted* LocatedRealComparisonModu *carrier*

$$M = (Q, A, D, B, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *surface consists exactly of comparison-request admission, located apartness-or-equality evidence, dyadic tolerance scheduling,* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *routing,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer of the comparison schedule must read those rows in the displayed order and receives no trichotomy split, quotient real equality, hidden selector, countable-choice schedule, host comparison oracle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 5813.1. The comparison request is Q, and the only evidence row attached to it is A.

The schedule is then forced through D and B. The dyadic row D records the finite tolerances to be inspected, while the $\mathsf{CauchyModulusBridge}^{\uparrow}$ row B turns those tolerance requests into explicit tail thresholds before any rational readback is exposed.

The terminal read is downstream. The regular rational row R reads only the displayed tails opened by B, and the $\mathsf{Real}^{\uparrow}$ seal E is available only after that readback.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for the excluded host-level or choice-level objects, the listed rows exhaust the local NameCert surface. □

Theorem 5755.3 (Located real comparison modulus nontrichotomy boundary)**.** *Every accepted* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *packet exports a positive schedule for comparison reads without exporting trichotomy. If the evidence row A records positive apartness, a downstream consumer may read that apartness only through Q, D, B, R, E; if A records only an equality-facing overlap tolerance, the consumer receives the displayed tolerance route and no forced left-or-right order verdict.*

Proof. Read the evidence row A together with the comparison request Q. The carrier does not contain a three-way order coordinate, so the two possible reads are positive displayed apartness or finite overlap tolerance.

For the positive branch, the dyadic tolerance row D and bridge row B determine which tails are inspected before R and E can be consumed. The apartness read is therefore a finite schedule read, not a global order split.

For the overlap branch, the same schedule exposes only the inspected tolerance data. Since no trichotomy coordinate or hidden selector appears in $M = (Q, A, D, B, R, E, H, C, P, N)$, the packet refuses any forced left-or-right verdict not displayed by the rows. □

Falsifiable prediction: An accepted $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is refuted if a comparison consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting the $\mathsf{LocatedRealComparison}^{\uparrow}$ request row Q, the evidence row A, the dyadic tolerance schedule D, the $\mathsf{CauchyModulusBridge}^{\uparrow}$ route B, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: LocatedRealComparison, LocatedRealTailEnvelope, CauchyModulusBridge, RegSeqRat, Real: none is bijective with $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ because the packet jointly carries a comparison request, apartness-or-equality evidence, dyadic tolerance scheduling, explicit Cauchy-modulus bridging, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is generated from a LocatedRealComparison request row, located apartness-or-equality evidence, a dyadic tolerance schedule, a CauchyModulusBridge route, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5813.1, Definition 5813.2, and Definition 5813.3 seed the finite comparison-modulus route over LocatedRealComparisonUp, LocatedRealTailEnvelopeUp, CauchyModulusBridgeUp, RegSeqRatUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, host comparison oracles, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, evidence-row exactness, dyadic schedule determinacy, Cauchy-modulus bridge routing, regular rational readback, Real-seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealComparisonModulusUp.

Chapter 5756

A Concrete Naming Certificate for $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$

The $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet realizes the boundary-shadow and observer-expansion route of chapter 9463 as finite cocycle-level NameCert data. It sits after the boundary-shadow route of chapter 3813, the observer-shadow metric of chapter 4154, the Busemann cocycle of chapter 4134, the horosphere-flow ledger of chapter 4051, and the observer-expansion packet of chapter 4167. The chapter names a finite expansion cocycle over displayed boundary and horosphere rows; it is not a completed hyperbolic boundary, quotient geodesic ray space, physical observer dynamics, selected ideal point, or ambient manifold theorem.

Definition 5756.1 (Boundary-shadow expansion cocycle carrier)**.** *A* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, O, B, F, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row recording the visible boundary shadow through which the cocycle is read.*
2. *O is the* $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ *row recording the observer-facing shadow metric comparison for the same boundary read.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row recording the additive Busemann comparison consumed by the expansion read.*
4. *F is the* $\mathsf{HorosphereFlowLedger}^{\uparrow}$ *row recording the horosphere-flow level through which boundary and Busemann rows are replayed.*
5. *E is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *row recording the displayed observer-expansion magnitude or direction attached to S, O, B, F.*
6. *H records componentwise* hsame *transport for boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow ledger, observer expansion, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, and observer-expansion read.*

8. *P is the* Pkg *provenance over* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HorosphereFlowLedger}^{\uparrow}$, HyperbolicObserverExp BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, O, B, F, E, H, C, P, N$. It has no coordinate for completed boundary points, quotient geodesic rays, a hidden expansion selector, physical observer dynamics, selected ideal endpoints, or ambient hyperbolic manifold data.

Theorem 5756.2 (Boundary-shadow expansion cocycle NameCert obligations)**.** *For every accepted* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ *carrier*

$$X = (S, O, B, F, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *surface consists exactly of boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, observer-expansion read, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any accepted expansion read that omits either the boundary-shadow row S or the Busemann cocycle row B is outside the packet.*

Proof. Project the carrier of Definition 5814.1. The boundary-facing rows are S and O, while the cocycle and horosphere-flow rows are B and F.

The expansion row E is downstream from those four rows. It can be read only after the visible boundary shadow, observer-shadow metric, Busemann cocycle, and horosphere-flow ledger have all been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for completed boundary data, quotient geodesic rays, hidden selectors, physical observer dynamics, selected endpoints, or ambient manifold structure, the listed rows exhaust the local NameCert surface. □

Theorem 5756.3 (Boundary-shadow expansion cocycle dependency route)**.** *Every accepted* BoundaryShadowExpan *read factors through*

$\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, HorosphereFlowLed

before a consumer may inspect the expansion cocycle as a local NameCert row. The route is finite and preserves the boundary-shadow row and Busemann cocycle row as separate coordinates.

Proof. Use Definition 5814.2. It places the boundary-shadow row, observer-shadow metric row, Busemann cocycle row, and horosphere-flow ledger before the expansion row.

The cocycle dependency is not reducible to one sibling. The boundary-shadow row supplies the boundary face, the observer-shadow metric supplies the observer-facing comparison, the Busemann row supplies the additive cocycle read, and the horosphere-flow row supplies the level ledger.

Only after those rows are present can E, H, C, P, N expose the expansion cocycle as a local packet. Therefore a consumer cannot collapse the route to a single hyperbolic object or bypass the separate boundary-shadow and Busemann coordinates. □

Falsifiable prediction: Any accepted $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet is refuted if the expansion read omits either the boundary-shadow row S or the Busemann cocycle row B.

Independence witness: hyperbolic_boundary_shadow, hyperbolic_observer_shadow_metric, hyperbolic_busemann_cocycle, horosphere_flow_ledger, hyperbolic_observer_expansion: none

is bijective with $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ because the packet jointly carries boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow level, observer expansion, transport, replay, provenance, and local naming.

The Lean TasteGate route for this packet must provide `Nontrivial BoundaryShadowExpansionCocycleUp` and `FieldFaithful BoundaryShadowExpansionCocycleUp` instances in `lean4/BEDC/Derived/BoundaryShadowE` Those instances must preserve $S, O, B, F, E, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet is generated from HyperbolicBoundaryShadow rows, HyperbolicObserverShadowMetric rows, HyperbolicBusemannCocycle rows, HorosphereFlowLedger rows, HyperbolicObserverExpansion rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5814.1, Definition 5814.2, and Definition 5814.3 seed the finite boundary-shadow expansion cocycle route over boundary, observer-shadow, Busemann, horosphere-flow, expansion, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic boundaries, quotient geodesic ray spaces, physical observer dynamics, selected ideal endpoints, ambient manifold theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow exactness, observer-shadow metric readback, Busemann cocycle separation, horosphere-flow routing, observer-expansion exposure, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.BoundaryShadowExpansionCocycleUp.

The $\mathsf{HellyBraySelection}^{\uparrow}$ hub routes bounded-variation selection through chapter 398, chapter 2069, chapter 301, chapter 126, and chapter 38 before the child files expose the finite selection packet.

Chapter 5757

A Concrete Naming Certificate for $\mathsf{HellyBraySelection}^{\uparrow}$

Following Helly and Bray, the $\mathsf{HellyBraySelection}^{\uparrow}$ packet records the finite selection surface by which bounded-variation source data are read through Jordan signed-variation rows, finite stream windows, regular rational readback, and terminal real seals before a downstream selection consumer may use the packet. It sits after the bounded-variation carrier of chapter 398, the Jordan variation decomposition rows of chapter 2069, the regular rational readback route of chapter 301, the finite observation windows of chapter 126, and the terminal real-name boundary of chapter 38. Helly–Bray selection also feeds distribution-facing compactness through chapter 186, chapter 92, and chapter 4008 when the bounded-variation read is consumed as a tight probability-family route. The chapter names a finite BEDC selection packet, not host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5757.1 (Helly–Bray selection carrier)**.** *A* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, J, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, carrying the bounded-variation object, finite variation ledger, and endpoint budget exposed to the selection request.*
2. *J is the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *row, displaying the signed-variation split and the positive and negative variation rows read from B.*
3. *S is the family of* $\mathsf{StreamName}^{\uparrow}$ *finite windows opened by the inspected variation rows and by the downstream Real-facing request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, recording the rational comparisons used before any Real seal is visible.*
5. *E is the finite family of* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after B, J, S, R have been displayed.*
6. *T records componentwise* hsame *transport for the bounded-variation source, Jordan rows, finite windows, readbacks, Real seals, continuation, provenance, and local naming.*
7. *C records displayed* Cont *replay from bounded-variation data through Jordan signed-variation rows, finite windows, regular rational readback, Real seals, transport, provenance, and local naming.*

8. *P is the* Pkg *provenance over* $\mathsf{HellyBraySelection}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, J, S, R, E, T, C, P, N$. The carrier has no coordinate for host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5757.2 (Helly–Bray selection NameCert obligations)**.** *For every accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier*

$$H = (B, J, S, R, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded-variation source row, Jordan signed-variation decomposition row, StreamName finite windows, RegSeqRat readback row, Real seal rows, transport, replay, provenance, and local naming;*
2. *variation-source exposure, requiring every selection-facing read to begin with B and then pass through the signed-variation rows J rather than through a host weak-convergence theorem;*
3. *finite-window locality, requiring S to list the exact stream windows opened by the variation rows and the Real-facing request;*
4. *readback ordering, requiring R to consume the displayed windows in S before any row of E is exposed;*
5. *componentwise transport, displayed replay, provenance, and local naming for the same rows through T, C, P, N;*
6. *nonescape, excluding host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Helly–Bray selection obligation is stored outside these rows.

Proof. Project the accepted carrier. The only source coordinate is the bounded-variation row B, and the only signed-variation coordinate is the Jordan row J.

The finite observation surface is then forced by row order. The StreamName windows S are opened from the displayed variation rows, the RegSeqRat readback R reads only those windows, and the Real seals E appear only after that readback has been displayed.

Transport and replay preserve the same route componentwise through T and C. Provenance P and local naming N record that route as the local certificate surface.

Since none of the excluded objects occurs as a carrier coordinate, a consumer cannot add weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient Real completeness to the local NameCert obligations. □

Theorem 5757.3 (Helly–Bray selection finite-window route)**.** *Every Real-facing or variation-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier factors its read through*

$$\mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{JordanVariationDecomposition}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto T, C, P, N$$

Thus the consumer receives bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise transport, continuation replay, provenance, and local naming. The route supplies no host weak convergence, measure completion, quotient function equality, selected subsequence, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier $H = (B, J, S, R, E, T, C, P, N)$. The first projection gives the bounded-variation source row B, and the next projection gives the Jordan signed-variation row J over that source.

The finite-window part is local. The windows S are the only observation rows available to the packet, and R is the only regular rational readback attached to those windows.

The Real-facing boundary is reached only at E. The remaining rows T, C, P, N transport, replay, source, and name the same finite route; they do not add a new selection principle.

Because the carrier omits host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient Real completeness, every accepted consumer read is exhausted by the displayed finite-window route. □

Theorem 5757.4 (Helly–Bray distribution forward link)**.** *Every* $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, *or* $\mathsf{ProkhorovTightProbabi}$ *consumer that cites an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier must first read the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *signed-variation row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows of Definition 5815.1. The downstream route to chapter 186, chapter 92, and chapter 4008 therefore receives only bounded-variation source data, Jordan variation data, displayed windows, rational readback, Real seals, componentwise transport, replay, provenance, and local naming. It receives no host weak convergence theorem, measure completion, quotient equality, selected subsequence, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $H = (B, J, S, R, E, T, C, P, N)$. The only distribution-facing source row is B, and the only signed-measure decomposition row available to the packet is J.

Use the finite-window route of Definition 5815.3. It forces every Real-facing and variation-facing read through S, R, E before the transport, replay, provenance, and local naming rows can be consumed.

Now attach a downstream distribution, measure, or tight-probability request. Since those consumers cite the Helly–Bray packet only through the displayed route, the request reaches chapter 186, chapter 92, or chapter 4008 after $B, J, S, R, E, T, C, P, N$ have already been displayed.

The excluded objects are not carrier coordinates. Thus the forward link cannot export host weak convergence, measure completion, quotient equality, selected subsequences, countable choice, or ambient Real completeness to any distribution-facing consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5815.1, Definition 5815.2, Definition 5815.3, and Definition 5815.4 seed the finite Helly–Bray selection route over bounded-variation data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, transport, replay, provenance, local naming, and distribution-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, variation-source exposure, finite-window locality, readback ordering, transport, replay, provenance, local naming, and finite-window routing for BEDC.Derived.HellyBraySelectionUp.

Constructive story: A $\mathsf{HellyBraySelection}^{\uparrow}$ packet is generated from bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

The Helly–Bray route is a distribution-facing read of the finite selection surface already named by chapter 1732; its bounded real sequence and compactness rows are supplied through chapter 1415 before the distribution consumer is allowed to inspect the signed-variation packet.

Theorem 5757.5 (Helly–Bray Helly-selection dependency route)**.** *Every* $\mathsf{Distribution}^{\uparrow}$ *or compactness-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *packet must first expose the finite* $\mathsf{HellySelection}^{\uparrow}$ *selection surface of chapter 1732 together with the bounded real sequence route of chapter 1415. In carrier notation, the read passes through the bounded-variation source row, Jordan signed-variation row, finite window rows, regular rational readback, terminal Real seals, componentwise transport, replay, provenance, and local naming rows before the distribution-facing route of Definition 5815.4 is public. It is therefore not a free weak-convergence theorem, measure-completion theorem, quotient-function equality, choice-selected subsequence, or ambient compactness principle.*

Proof. Start with the carrier of Definition 5815.1. Its only sequence-facing data are the bounded-variation row, Jordan signed-variation row, finite windows, regular rational readback, and terminal Real seals.

Read those rows through the finite-window route of Definition 5815.3. The same bounded source discipline is the one exported by the $\mathsf{HellySelection}^{\uparrow}$ packet, and the bounded real sequence route supplies the finite window and bound rows before any compactness-facing consumer can inspect them.

Finally attach the distribution forward link. Since Definition 5815.4 exposes distribution consumers only after the Helly–Bray carrier rows have been displayed, the downstream route receives the Helly-selection and bounded-sequence surfaces as dependencies rather than as hidden host compactness or choice principles. □

Chapter 5758

A Concrete Naming Certificate for DiniFiniteMinimumBudget$^{\uparrow}$

Following Dini's theorem and Bishop–Bridges constructive compactness, the DiniFiniteMinimumBudget$^{\uparrow}$ packet records the finite extraction row that turns a monotone compact-window Dini certificate into one displayed tolerance budget. It consumes the CompactMetric$^{\uparrow}$ source, monotone ContinuousMap$^{\uparrow}$ family rows, the DiniTheorem$^{\uparrow}$ compact-window route, UniformModulus$^{\uparrow}$ handoff data, DyadicRatCore$^{\uparrow}$ tolerance cells, the terminal Real$^{\uparrow}$ seal, BHist history rows, hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data. The packet names only the finite minimum-budget route; it is not host supremum selection, a selected minimum outside the carrier, open-cover compactness, quotient equality, or ambient Real$^{\uparrow}$ completeness.

The dependency surface is horizontal: chapter 1387 supplies the compact-window Dini route, chapter 129 supplies the inspected compact carrier, chapter 130 supplies the monotone continuous-family rows, and chapter 369 receives the extracted budget. Thus the minimum-budget row is a downstream finite extraction from those sibling carriers, not an isolated tolerance selector.

Definition 5758.1 (Dini finite-minimum budget carrier)**.** *A* DiniFiniteMinimumBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, D, U, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row naming the finite compact-metric windows inspected by the extraction.*
2. *F is the monotone* ContinuousMap$^{\uparrow}$ *family row, including the displayed pointwise comparison ledger used by the Dini route.*
3. *D is the* DiniTheorem$^{\uparrow}$ *row that supplies the monotone uniform-window certificate over K and F.*
4. *U is the* UniformModulus$^{\uparrow}$ *handoff row consumed by uniform-limit and compact-uniform-modulus readers.*
5. *Q is the* DyadicRatCore$^{\uparrow}$ *tolerance row, listing the candidate dyadic budgets and their finite comparison cells.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row reached by every displayed tolerance and value comparison.*
7. *H records componentwise* hsame *transport for $K, F, D, U, Q, E, C, P, N$.*

8. *C records displayed* Cont *replay from compact windows and monotone family rows through the Dini row, the finite dyadic budget comparisons, the uniform-modulus handoff, and the Real seal.*
9. *P is the* Pkg *provenance over* DiniFiniteMinimumBudget$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DiniTheorem$^{\uparrow}$, UniformModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for an ambient supremum, an externally selected minimum, open-cover compactness, quotient equality of real names, countable choice, or host Real completeness.

Lean4 ✓ `BEDC.Derived.DiniFiniteMinimumBudgetUp.DiniFiniteMinimumBudgetTasteGate single carrier alignment`

Theorem 5758.2 (Dini compact finite-minimum budget)**.** *For every accepted* DiniFiniteMinimumBudget$^{\uparrow}$ *carrier*

$$B = (K, F, D, U, Q, E, H, C, P, N),$$

the finite probe cover displayed by K, F, D and the dyadic tolerance cells displayed by Q determine one displayed minimum tolerance budget before the uniform-modulus handoff U is exported. The extraction route is

$$K, F, D, Q, E, H, C, P, N \longrightarrow U.$$

Thus a UniformLimit$^{\uparrow}$ *or compact-uniform-modulus consumer receives a finite* DyadicRatCore$^{\uparrow}$ *budget sealed by* Real$^{\uparrow}$ *and transported by* hsame *and* Cont*, without host supremum, selected minimum outside the carrier, open-cover compactness, quotient equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the accepted packet. The compact source row K, monotone family row F, and Dini row D are the only rows that can name the finite probe cover for the tolerance request.

The dyadic row Q lists the candidate tolerance cells. Since the carrier is finite, the budget comparison is a displayed finite comparison among the cells in Q, with every real-valued read sealed through E before the handoff row is exposed.

The route to U is then replayed by C and transported componentwise by H. The provenance and naming rows P, N record the same finite route as the local certificate surface.

No excluded object is a coordinate of B. Consequently the exported budget is the displayed finite minimum-budget row inside the carrier, not an ambient supremum, external selector, open-cover argument, quotient equality, choice schedule, or completeness argument. □

Falsifiable prediction: Every accepted DiniFiniteMinimumBudget$^{\uparrow}$ consumer that exports a UniformModulus$^{\uparrow}$ handoff must first expose the compact-metric windows, monotone continuous-family rows, DiniTheorem route, finite DyadicRatCore$^{\uparrow}$ budget cells, Real$^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: dini-theorem, compactmetric, continuousmap, uniformmodulus, dyadicratcore, real: DiniFiniteMinimumBudget$^{\uparrow}$ is not bijective to any listed sibling because it binds the finite Dini probe cover to one displayed dyadic minimum-budget handoff before uniform-limit or compact-uniform-modulus consumers may read the result.

Closure status for NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, seed)

Scope closed: Definition 5816.1 and Definition 5816.2 seed the finite minimum-budget extraction route from compact Dini data to a uniform-modulus-facing handoff.

Formal verification: FormalStatus(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host supremum selection, selected minima outside the carrier, open-cover compactness, quotient equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite probe-cover exposure, dyadic minimum-budget extraction, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniFiniteMinimumBudgetUp.

Constructive story: A DiniFiniteMinimumBudget$^{\uparrow}$ packet is generated from compact-metric source rows, monotone ContinuousMap family rows, a DiniTheorem compact-window route, UniformModulus handoff rows, DyadicRatCore tolerance cells, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5759

A Concrete Naming Certificate for $\mathsf{FiniteCauchyFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet records the finite directed-tail surface used when a completion consumer asks for Cauchy-filter evidence before reading a regular rational name or a terminal real-name seal. It sits beside the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite filter basis for tail requests; it is not a quotient filter, a selected limit, countable choice, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5759.1 (Finite Cauchy filter carrier)**.** *A* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (W, T, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the filter request.*
2. T *is the directed-tail request row, naming the finite family of later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii and comparison budgets used by the directed tails.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and tolerance ledger.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, T, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the stream windows, tail requests, dyadic ledgers, regular readback, and real seal.*
7. C *records displayed* Cont *replay of the same finite filter route.*
8. P *records* Pkg *provenance over* $\mathsf{FiniteCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, T, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.FiniteCauchyFilterUp.FiniteCauchyFilterTasteGate single carrier alignment`

Theorem 5759.2 (Finite Cauchy filter NameCert obligations)**.** *For the carrier of Definition 5817.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail request visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-ledger preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal access, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $F = (W, T, D, R, E, H, C, P, N)$. The rows W, T, D expose the finite source windows, directed tail requests, and dyadic tolerance budgets before any regular-rational or real-facing read is admitted.

The readback row R is then determined by the displayed windows and tolerance ledger. Since the carrier stores no second regular-rational coordinate, every $\mathsf{RegSeqRat}^{\uparrow}$ consumer reads the same finite route.

The seal row E is downstream of W, T, D, R. The transport row H, continuation row C, package provenance row P, and local naming row N preserve exactly that route and provide no coordinate for quotient filters, selected limits, countable choice, host stream equality, host real equality, or ambient completeness. □

Theorem 5759.3 (Finite Cauchy filter Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier factors through the finite route*

$$W, T, D, R, E, H, C, P, N.$$

In particular, the consumer must first read $\mathsf{StreamName}^{\uparrow}$ *windows, directed tail requests,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Start with the carrier definition. The only real-facing row is E, and it is displayed after the stream windows, directed-tail row, dyadic ledger, and regular readback row.

Apply Definition 5817.2. The local NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Thus any Real-facing consumer receives the finite packet $W, T, D, R, E, H, C, P, N$ and no quotient-filter, selected-limit, countable-choice, host-equality, or ambient-completeness substitute. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet is generated from finite StreamName windows, directed tail requests, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 5817.1, Definition 5817.2, and Definition 5817.3 specify the finite directed-tail filter carrier and its Real-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filter construction, selected limits, countable choice, host stream equality, host real equality, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for directed-tail visibility, tolerance-ledger preservation, readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 5760

A Concrete Naming Certificate for DNAWindowSixTranslationBoundary$^{\uparrow}$

The DNAWindowSixTranslationBoundary$^{\uparrow}$ packet realizes the local translation-boundary branch of subsection 9462.28.21 as finite NameCert data. It consumes the codon-window and stop-tile boundary analysis in the source vision, the curated code-boundary ledger of **??**, and the trigger-threshold surface of chapter 4217. The packet names only a finite window-six translation-boundary carrier; biological translation realization, universality, protein function, and evolutionary mechanism remain outside the BEDC kernel packet.

Definition 5760.1 (DNA window-six translation-boundary carrier)**.** *A* DNAWindowSixTranslationBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, S, T, L, R, V, H, C, P, N)$$

with the following displayed rows:

1. *Q is the codon Q_6 window row recording the six-bit coordinate readback for the inspected codon window.*
2. *S is the stop-tile boundary row recording the local halt boundary and continuation-corner split from the source vision.*
3. *T is the translation-classifier row supplied by external biological bridge data.*
4. *L is the curated code-boundary ledger row inherited from* BioRealityQSixLeaveOneCodeBoundaryLedger$^{\uparrow}$*.*
5. *R is the release-factor or release-mechanism row that records which external recognition boundary is being tested.*
6. *V is the finite validation row recording which observed table, organismal code row, or assay class is used for the test.*
7. *H records componentwise* hsame *transport for the window, tile, classifier, ledger, release, and validation rows.*
8. *C records displayed* Cont *replay of the boundary read through those rows.*
9. *P records* Pkg *provenance over the source vision, the bio-reality ledger sibling,* DNAWindowSixTriggerThreshold$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and local naming rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for biological necessity, global identification of the genetic code with the window-six fold, protein-folding realization, universal stop assignment, hidden BEDC channel tokens, or untested mechanism.

Theorem 5760.2 (DNA window-six translation-boundary obligations)**.** *For the carrier of Definition 5818.1, the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *surface consists exactly of codon-window exposure, stop-tile boundary visibility, external translation-classifier disclosure, curated code-ledger preservation, release-boundary test exposure, finite validation-row visibility, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $B = (Q, S, T, L, R, V, H, C, P, N)$. The rows Q, S, T expose the finite codon window, the local translation boundary, and the external classifier before any biological reading is admitted.

The ledger and release rows L, R keep the packet anchored to the bio-reality boundary sibling and to a displayed recognition test. The validation row V records the observed table or assay class being tested, so the packet has a falsifiable contact surface rather than a kernel claim of biological necessity.

The structural rows H, C, P, N transport, replay, source, and name exactly the displayed boundary route. Since no further coordinate is present, the carrier cannot export global window-six identity, universal stop assignment, protein-folding realization, hidden channel tokens, or untested mechanism. □

Theorem 5760.3 (DNA window-six translation-boundary sibling handoff)**.** *Every accepted* DNAWindowSixTranslat *read that reaches a translation-boundary consumer must first expose the source-vision stop-tile row of subsection 9462.28.21, the curated code-boundary ledger row of* **??**, *and the finite trigger-threshold row of chapter 4217. The handoff is therefore a concrete finite boundary-tile NameCert route, not a narrative-only direction.*

Proof. Use Definition 5818.1. The source-vision row is carried by S, the code-boundary ledger is carried by L, and the trigger-facing finite boundary read is recorded in the same package provenance P.

Now apply Definition 5818.2. The local NameCert requires those rows before the translation-boundary consumer can read N. Hence the consumer sees the source vision, the bio-reality ledger sibling, and the trigger-threshold sibling as displayed packet data rather than as detached prose. □

Falsifiable prediction: An accepted $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet must expose a finite validation row naming the observed code table, organismal code row, or release-factor assay class before it can export a translation-boundary reading.

Independence witness: bioreality-q-six-leave-one-code-boundary-ledger, dna-window-six-trigger-threshold, synonymous-transition: the $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is not bijective to any listed sibling because it jointly carries codon-window, stop-tile, external translation-classifier, curated code-ledger, release-boundary, validation, transport, replay, provenance, and local naming rows.

The Lean follow-up must provide $\mathsf{Nontrivial}\ \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{DNAWindowSi}$ TasteGate instances before this packet can move beyond seed closure.

Closure status for $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is generated from codon Q-six window rows, stop-tile boundary rows, external translation-classifier rows, curated code-boundary ledgers, release-boundary tests, finite validation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, seed)

Scope closed: Definition 5818.1, Definition 5818.2, and Definition 5818.3 specify the finite translation-boundary carrier and sibling route.

Formal verification: FormalStatus(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim biological-code necessity, global window-six identity, universal stop assignment, protein-folding realization, hidden BEDC channel tokens, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding, TasteGate nontriviality, field faithfulness, validation-row exactness, sibling-route preservation, transport, replay, provenance, and local naming.

Chapter 5761

A Concrete Naming Certificate for $\mathsf{RegulatedConvergence}^{\uparrow}$

Following Bishop and Bridges on regulated functions and uniform convergence, the $\mathsf{RegulatedConvergence}^{\uparrow}$ packet records the finite route by which a displayed sequence of regulated real functions converges uniformly to a regulated endpoint. It sits after the regulated-function carrier of chapter 1906, the regulated-integral consumer boundary of chapter 1557, the uniform-convergence ledger of chapter 3417, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite convergence-and-handoff surface; it does not import measure completion, quotient equality of functions, selected host limits, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5761.1 (Regulated convergence carrier)**.** *A* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

with the following displayed rows:

1. *F is the source row naming the regulated-function family through* $\mathsf{RegulatedFunction}^{\uparrow}$ *data, including the displayed interval, step-window, endpoint, and oscillation ledgers available to each inspected member.*
2. *U is the* $\mathsf{UniformConvergence}^{\uparrow}$ *tail row, recording one shared tolerance schedule for the whole regulated family rather than pointwise schedules chosen separately at each argument.*
3. *W is the finite window row exposing exactly the function indices, domain windows, and endpoint reads used by the shared tail schedule.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the real-valued observations in those windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after F, U, W, R have been displayed.*
6. *I is the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *handoff row; it records that integral-facing consumers may read the regulated endpoint only through the same finite regulated-function, uniform-tail, window, readback, and Real-seal route.*
7. *H records componentwise* hsame *transport for F, U, W, R, E, I and for the structural rows.*
8. *C records displayed* Cont *replay for regulated-function reads, uniform-tail requests, finite window reads, regular rational readback, Real-seal requests, and integral handoff requests.*

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedConvergence}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, U, W, R, E, I, H, C, P, N$. It has no coordinate for a host function quotient, selected limiting function, measure completion, pointwise-only convergence, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceTasteGate single carrier alignment`

Theorem 5761.2 (Regulated convergence NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier*

$$G = (F, U, W, R, E, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the regulated-function family row F, uniform-convergence tail row U, finite window row W, regular rational readback row R, terminal Real seal E, regulated-integral handoff row I, componentwise transport row H, displayed replay row C, package provenance row P, and local naming row N. Every endpoint-facing or integral-facing consumer must read these rows in the displayed route and cannot replace them by pointwise convergence, a selected host limit, quotient equality of functions, measure completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 5819.1. The only analytic rows are the regulated-function family F, the shared uniform tail ledger U, the finite window row W, the regular rational readback R, the terminal Real seal E, and the integral handoff I.

The convergence route is uniform. A consumer must read the single tail schedule U before it can inspect the windows W and the regular readback R, so pointwise-only schedules and externally selected host limits are not part of the packet.

The endpoint and integral rows are downstream. The seal E is exposed only after F, U, W, R, and the integral-facing row I reads that same route rather than a separate measure-completion or function-quotient object.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded row occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 5761.3 (Regulated convergence integral handoff)**.** *Let*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

be an accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier. Every* $\mathsf{RegulatedIntegral}^{\uparrow}$ *consumer read of the limiting regulated function factors through the finite route*

$$\mathsf{RegulatedFunction}^{\uparrow}(F),\ \mathsf{UniformConvergence}^{\uparrow}(U),\ W,\ \mathsf{RegSeqRat}^{\uparrow}(R),\ \mathsf{Real}^{\uparrow}(E),\ \mathsf{RegulatedIntegral}^{\uparrow}(I).$$

Thus the handoff to integration uses the same regulated-family rows, shared uniform-tail ledger, finite windows, regular rational readback, and Real seal as the convergence certificate. It supplies no measure completion, quotient function equality, selected limiting function, open-cover compactness, or ambient real-completeness principle.

Proof. Start with an integral-facing request. By the carrier definition, the only integral row is I, and its replay route in C passes through the same regulated-family and convergence rows used by endpoint-facing consumers.

Read the regulated source through F and the uniform tail through U. The finite windows W then expose the inspected function indices and domain reads, and the regular rational row R records the real-valued observations visible at those windows.

Only after this route is displayed can the terminal seal E be consumed and handed to I. Componentwise transport in H and replay in C preserve the same rows, while P and N record their provenance and local naming.

The carrier has no coordinate for measure completion, quotient function equality, selected limits, open-cover compactness, or ambient real completeness. Therefore every regulated-integral handoff is confined to the finite route displayed in the statement. □

Falsifiable prediction: An accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ consumer that reaches a $\mathsf{RegulatedIntegral}^{\uparrow}$ handoff without first reading $F, U, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: regulated-function, regulated-integral, uniform-convergence, regseqrat, real: none is bijective to $\mathsf{RegulatedConvergence}^{\uparrow}$ because this packet jointly binds a regulated-function family, a shared uniform tail ledger, finite windows, regular rational readback, terminal Real seal, integral handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedConvergence}^{\uparrow}$ packet is generated from a regulated-function family row, UniformConvergence tail row, finite window row, RegSeqRat readback, terminal Real seal, RegulatedIntegral handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5819.1, Definition 5819.2, and Definition 5819.3 seed the finite regulated-convergence route over regulated functions, uniform convergence, regular rational readback, Real seals, and regulated-integral consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, quotient function equality, selected host limits, pointwise-only convergence, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated-family visibility, uniform-tail exactness, finite window readback, Real-seal nonescape, regulated-integral handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedConvergenceUp.

Chapter 5762

A Concrete Naming Certificate for $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$

Following Cantor and Bishop–Bridges, the $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet records the finite located nested-interval route by which displayed interval windows become a regular rational Cauchy name and then a terminal real seal. It refines the nested dyadic Cauchy route of chapter 1811, reads endpoint and radius rows through chapter 291, schedules finite observations through chapter 126, hands the scheduled rows to chapter 301, and reaches only the seal boundary of chapter 38. The chapter isolates the located interval-to-name handoff; it does not claim a host intersection point, quotient stream equality, selected limit, countable choice, or ambient completeness.

Definition 5762.1 (Located nested-interval limit carrier)**.** *A* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite nested located-interval window. It records the inspected interval chain, endpoint rows, located containment witnesses, and the finite separation reads available at each displayed stage.*
2. *D is the dyadic shrink ledger. It records the dyadic endpoint comparisons, width bounds, and tolerance requests read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It names exactly the finite endpoint, midpoint, and shrink-ledger observations that may be queried before regular rational readback.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the scheduled located-interval observations and the dyadic shrink ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after I, D, S, R have been displayed.*
6. *H records componentwise* hsame *transport for interval windows, shrink ledgers, stream schedules, regular rational handoffs, real seals, replay rows, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located nested-interval request through I, D, S, R, E and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$*,* $\mathsf{NestedDyadicCauchy}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, R, E, H, C, P, N$. It has no coordinate for completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.LocatedNestedIntervalLimitUp.LocatedNestedIntervalLimitTasteGate single carrier alignment`

Theorem 5762.2 (Located nested-interval limit NameCert obligations)**.** *For every accepted* LocatedNestedIntervalL *carrier*

$$L = (I, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite located interval window, dyadic shrink ledger, StreamName schedule, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming row;*
2. *located nesting exposure, requiring every interval read to be one of the displayed rows of I together with its displayed containment and located separation witnesses;*
3. *dyadic shrink exactness, requiring every tolerance request to be discharged by a visible width or endpoint comparison stored in D and read through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
4. *schedule compatibility, requiring S to expose only the finite interval, endpoint, midpoint, and ledger observations used by D and R;*
5. *RegSeqRat handoff exactness, requiring R to be formed only after the interval window, shrink ledger, and schedule rows have been projected;*
6. *Real-seal nonescape, requiring E to be consumed only after I, D, S, R and the structural rows H, C, P, N have been displayed.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5820.1. The projection exposes one finite located nested-interval window, one dyadic shrink ledger, one StreamName schedule, one RegSeqRat handoff, one Real seal, and the transport, replay, provenance, and naming rows.

Located nesting exposure is forced by I. A consumer may inspect only interval rows already present in the finite window, and each such row carries its displayed containment and located separation witnesses.

Dyadic shrink exactness is forced by D. Each tolerance request is answered by a displayed dyadic width or endpoint comparison, so no host intersection or selected limit is needed to choose a tail.

The schedule and handoff rows are downstream. The row S records the finite observations that may be opened, and R repacks exactly those observations under the shrink ledger as a regular rational Cauchy surface.

Finally E, H, C, P, N close the route. The Real seal is reachable only after the regular handoff has been displayed, while the structural rows only transport, replay, source, and name the same finite data. Therefore no completed intersection, quotient stream equality, host real equality, countable choice, ambient completeness, Lean verification, or bridge-checking coordinate is present. □

Theorem 5762.3 (Located nested-interval RegSeqRat handoff)**.** *Let* $L = (I, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read exported by* L *factors through the displayed route*

$$I \longmapsto D \longmapsto S \longmapsto R \longmapsto H, C, P, N.$$

The route reads a finite located nested-interval window, a dyadic shrink ledger, and the scheduled endpoint observations before it exports the regular rational Cauchy row. The terminal $\mathsf{Real}^{\uparrow}$ *seal* E *is available only after this handoff has been displayed.*

Proof. Start with the displayed located interval window I. Its rows give the only endpoint, midpoint, containment, and located separation data available to a regular rational consumer.

Use the dyadic shrink ledger D to answer the displayed tolerance request. The chosen comparison is part of the same finite packet and is read through $\mathsf{DyadicRatCore}^{\uparrow}$, so there is no external modulus, choice-selected tail, or host interval intersection.

The schedule row S then fixes which interval observations are opened. The handoff row R is obtained by reading those scheduled observations under the shrink discipline and repacking them as the $\mathsf{RegSeqRat}^{\uparrow}$ surface.

The rows H, C, P, N transport, replay, source, and name that handoff, and the seal row E remains downstream of it. Since the carrier has no quotient-stream, host-real, selected-limit, choice, or completeness coordinate, every regular rational read factors through the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5820.1, Definition 5820.2, and Definition 5820.3 seed the finite located nested-interval route from displayed interval windows and dyadic shrink ledgers to a RegSeqRat handoff and terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located nesting exposure, dyadic shrink exactness, schedule compatibility, RegSeqRat handoff exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedNestedIntervalLimitUp.

Constructive story: A $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet is generated from a finite nested located-interval window, a dyadic shrink ledger, a StreamName schedule, a RegSeqRat handoff row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5763

A Concrete Naming Certificate for $\mathsf{CauchyTailRequest}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailRequest}^{\uparrow}$ packet isolates the finite directed-tail request that a Cauchy or completion consumer must expose before it can read a regular rational name or a terminal real-name seal. It sits beside the finite window carrier of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal seal of chapter 38, and the finite filter surface of chapter 5817. The packet names the request row consumed by those sibling routes; it is not a quotient filter, a selected limit, a countable-choice schedule, host stream equality, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5763.1 (Cauchy tail request carrier)**.** *A* $\mathsf{CauchyTailRequest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, Q, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the request.*
2. Q *is the directed tail request row, naming the finite later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the directed tail request.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and tolerances.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, Q, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the window, request, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay of the same finite directed-tail route.*
8. P *records* Pkg *provenance over* $\mathsf{CauchyTailRequest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteCauchyFilter}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, Q, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 (definition) `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestUp`

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestTasteGate single carrier alignment`

Theorem 5763.2 (Cauchy tail request NameCert obligations)**.** *For the carrier of Definition 5821.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *consumer that reads a directed-tail row receives it through this displayed request surface.*

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestCarrier namecert obligations`

Proof. Project the accepted packet $T = (W, Q, D, R, E, H, C, P, N)$. The rows W, Q, D expose the finite windows, directed tail request, and dyadic tolerance ledger before any regular-rational or real-facing read is admitted.

The readback row R is downstream of those displayed rows. It therefore records only the $\mathsf{RegSeqRat}^{\uparrow}$ observation generated from the named windows and tolerance ledger, not an external sequence or choice schedule.

The seal row E is terminal for the request route. Transport through H and replay through C preserve exactly the displayed route, while P and N record provenance and local naming.

Finally compare the route with Definition 5817.2. The finite filter packet consumes its directed-tail row as a request coordinate, and the rows above are precisely the admitted request surface available to that consumer. Since no remaining coordinate exists, quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, and bridge checking are outside the chapter claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyTailRequest}^{\uparrow}$ packet is generated from finite StreamName windows, a directed tail request row, DyadicRatCore tolerance data, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, seed)

Scope closed: Definition 5821.1 and Definition 5821.2 specify the finite directed-tail request carrier and its filter-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for tail visibility, tolerance preservation, readback, seal routing, transport, replay, provenance, and local naming.

Chapter 5764

A Concrete Naming Certificate for $\mathsf{QuotientLeakageMarkov}^{\uparrow}$

The $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet realizes the quotient leakage transition matrix of Definition 9462.1376 as finite NameCert data. It consumes the DNA window-six boundary-tile source of subsection 9462.28.21, the codon-window carrier of chapter 2234, the boundary-tile packet of chapter 3393, the six-boundary coverage route of chapter 3470, and the translation-boundary packet of chapter 5818. The packet names a finite six-state Markov ledger only; it is not a biological stochastic model, empirical evolutionary claim, host quotient-codon semantics, or unrestricted state-space enumeration.

Definition 5764.1 (QuotientLeakageMarkov carrier)**.** *A* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, T, O, E, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the six-state orbit row listing* AGR*,* Anchor_6*,* $\mathrm{StopStart}_6$*,* UUR*,* CUR*, and* CUY*.*
2. *T is the transient transition-matrix row of Definition 9462.1376, with entries read as exact rational finite counts.*
3. *O is the outside-probability row recording* $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ *for the six displayed states.*
4. *E is the expected-exit ledger row recording the rational exit values of Definition 9462.1380.*
5. *W is the finite window-six source row tying the orbit states to the codon-window and boundary-tile siblings.*
6. *H records componentwise* hsame *transport for the state, transition, outside-probability, exit-ledger, source, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite Markov read through* S, T, O, E, W, H, P, N*.*
8. *P is the* Pkg *provenance over* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$*,* $\mathsf{CodonSixBitWindow}^{\uparrow}$*,* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$*, the source vision of subsection 9462.28.21,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, O, E, W, H, C, P, N$*. It has no coordinate for biological transition realization, hidden codon quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process.*

Theorem 5764.2 (QuotientLeakageMarkov NameCert obligations)**.** *For the carrier of Definition 5822.1, the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *surface consists exactly of six-state exposure, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, window-six sibling routing, componentwise transport, displayed replay, provenance, and local naming. Every accepted read preserves the outside probabilities displayed in Definition 9462.1378.*

Proof. Project the accepted carrier $Q = (S, T, O, E, W, H, C, P, N)$. The state row S fixes the six orbit states, and the transition row T is the only source of one-bit flip probabilities.

The outside-probability row O is read from the outside column of T and matches the finite rational list in Definition 9462.1378. Thus an accepted packet cannot alter leakage rates without changing a displayed row.

The expected-exit row E is downstream of the same finite matrix and records the rational ledger of Definition 9462.1380. The source row W ties these finite state rows back to the codon-window, boundary-tile, coverage, and translation-boundary siblings.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since no other coordinate is present, the NameCert surface cannot export biological mechanism, hidden quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process. □

Theorem 5764.3 (QuotientLeakageMarkov sibling dependency route)**.** *Every accepted* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *consumer first reads the finite codon-window source, boundary-tile classifier, six-boundary coverage route, and translation-boundary packet before it consumes the transition row* T*, outside row* O*, or expected-exit row* E*. The dependency route is*

$$\mathsf{CodonSixBitWindow}^{\uparrow}, \mathsf{DnaWindowSixBoundaryTile}^{\uparrow}, \mathsf{SixBoundaryTileCoverage}^{\uparrow}, \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$$

Proof. Use the provenance row P and source row W of Definition 5822.1. These rows name the finite codon-window and boundary-tile sources before the Markov matrix is admitted.

The transition row T then reads the six-state quotient matrix of Definition 9462.1376. The outside-probability row O and expected-exit row E are downstream ledger rows, so they cannot be consumed before the sibling source route has been displayed.

Transport and replay by H and C preserve this order, while N names it locally. Hence the consumer receives a concrete dependency route rather than a detached numerical table. □

Falsifiable prediction: Every accepted $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ read preserves the displayed outside probabilities $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ for AGR, Anchor_6, StopStart_6, UUR, CUR, and CUY.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, six-boundary-tile-coverage, dna-window-six-translation-boundary: $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries six orbit states, a rational transition matrix, outside probabilities, expected-exit ledgers, window-source routing, transport, replay, provenance, and local naming.

The Lean follow-up must provide explicit $\mathsf{Nontrivial}\ \mathsf{QuotientLeakageMarkov}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{QuotientLeakageM}$ TasteGate instances preserving $S, T, O, E, W, H, C, P, N$ as distinct displayed rows.

Closure status for $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$**.**

Constructive story: A $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet is generated from six orbit states, a rational transition matrix, outside-probability rows, expected-exit ledgers, a finite window-six source row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5822.1, Definition 5822.2, and Definition 5822.3 specify the finite quotient-leakage Markov carrier and sibling dependency route.

Formal verification: FormalStatus(NameCert$_{\text{QuotientLeakageMarkov}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological transition realization, empirical evolutionary mechanism, hidden codon quotient semantics, unbounded simulation, completed stochastic processes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, sibling routing, transport, replay, provenance, and local naming for BEDC.Derived.QuotientLeakage

Chapter 5765

A Concrete Naming Certificate for $\mathsf{CauchyCriterionUniform}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet records the uniform Cauchy criterion route used when a Real and Completion consumer asks for one displayed threshold discipline across a finite family of stream windows. It sits beside the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Cauchy hub of chapter 3413. The packet names a uniform criterion surface; it is not a quotient Cauchy class, selected limit, host equality theorem, countable-choice schedule, trichotomy principle, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5765.1 (Cauchy criterion uniform carrier)**.** *A* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *S records the* $\mathsf{StreamName}^{\uparrow}$ *window family inspected by the uniform criterion request.*
2. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the dyadic radii and comparison budgets shared by the family.*
3. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and dyadic tolerances.*
4. *E records the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, available only after S, D, R, M have been exposed.*
5. *M records the uniform modulus row, naming the common threshold discipline for all displayed windows in the family.*
6. *H records componentwise* hsame *transport for the stream windows, dyadic tolerances, regular readback, Real seal, uniform modulus, replay route, provenance, and local name.*
7. *C records displayed* Cont *replay of the same finite route.*
8. *P records* Pkg *provenance over* $\mathsf{CauchyCriterionUniform}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N records the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, R, E, M, H, C, P, N$. It has no coordinate for a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUniformUp.CauchyCriterionUniformTasteGate single carrier alignment`

Theorem 5765.2 (Cauchy criterion uniform NameCert obligations)**.** *For the carrier of Definition 5823.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the finite packet* $U = (S, D, R, E, M, H, C, P, N)$*;*
2. *uniform window exposure through the* $\mathsf{StreamName}^{\uparrow}$ *row* S *and the common modulus row* M*;*
3. *dyadic tolerance exactness through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*;*
4. *regular readback through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*;*
5. *ledger non-escape through* H, C, P, N*.*

Proof. Project the accepted packet $U = (S, D, R, E, M, H, C, P, N)$. Carrier admission is exactly the admission of this finite tuple, so a consumer can inspect only the displayed coordinates.

The uniform window obligation reads S together with the common threshold discipline M. The dyadic tolerance obligation reads D, and the regular readback obligation reads R before any terminal seal row E is available.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since the carrier has no remaining coordinate, the ledger cannot export a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient completeness claim. □

Theorem 5765.3 (Cauchy criterion uniform Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier factors through the finite route*

$$S, D, R, M \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer must read stream windows, dyadic tolerances, regular readback, and the uniform modulus before the terminal real seal is exposed. The route exports no quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 5823.1. The only terminal real-facing coordinate is E, and the definition places it downstream of the finite stream-window, dyadic-tolerance, regular-readback, and uniform-modulus rows.

Apply Definition 5823.2. The NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Therefore any Real-facing consumer receives exactly the finite packet route displayed above. No quotient Cauchy class, selected limit, host equality, countable-choice schedule, trichotomy row, or ambient-completeness coordinate supplies another path to the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet is generated from finite StreamName windows, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, a uniform modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, seed)

Scope closed: Definition 5823.1, Definition 5823.2, and Definition 5823.3 specify the finite uniform Cauchy criterion carrier and its Real-facing seal route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy classes, selected limits, host equality, countable choice, trichotomy, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for uniform window exposure, dyadic tolerance exactness, regular readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 5766

A Concrete Naming Certificate for CauchyProductCompletionProjection$^{\uparrow}$

Following Bishop and Bridges on constructive products of Cauchy completions and Kelley on product uniformities, the CauchyProductCompletionProjection$^{\uparrow}$ packet records the coordinate projection surface for an accepted product-completion read. It sits downstream of the product packet of chapter 3797 and the completion-product route of chapter 1540, while every coordinate read still passes through the StreamName$^{\uparrow}$ windows of chapter 126, the RegSeqRat$^{\uparrow}$ readbacks of chapter 301, the DyadicRatCore$^{\uparrow}$ budgets of chapter 291, and the terminal Real$^{\uparrow}$ seal of chapter 38.

Definition 5766.1 (CauchyProductCompletionProjection carrier)**.** *A* CauchyProductCompletionProjection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* CauchyProductCompletion$^{\uparrow}$ *product-completion packet whose coordinate route is being inspected.*
2. *π_0, π_1 are the left and right projection selector rows, each naming which displayed coordinate window is exposed.*
3. *S_0, S_1 are the coordinate* StreamName$^{\uparrow}$ *windows opened by the two projection selectors.*
4. *D_0, D_1 are the* DyadicRatCore$^{\uparrow}$ *budget rows attached to the finite coordinate observations read from those windows.*
5. *R_0, R_1 are the* RegSeqRat$^{\uparrow}$ *readback rows obtained from the same coordinate windows and dyadic budgets.*
6. *L_0, L_1 are the coordinate completion-seal rows witnessing that each projected read remains inside the product-completion packet.*
7. *H records componentwise* hsame *transport for the product packet, selectors, stream windows, dyadic budgets, regular readbacks, and coordinate completion seals.*
8. *C records the* Cont *replay from the product-completion packet through the selected coordinate window, dyadic budget, regular readback, and completion seal.*
9. *P is the* Pkg *provenance over* CauchyProductCompletionProjection$^{\uparrow}$, CauchyProductCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *row.*
The carrier compares accepted projections only through $Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, host product equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CauchyProductCompletionProjectionUp.CauchyProductCompletionProjectionTasteGate`
`single carrier alignment`

Theorem 5766.2 (CauchyProductCompletionProjection NameCert obligations)**.** *For an accepted packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *surface consists exactly of product-packet admission, selector exposure, coordinate stream-window exposure, dyadic-budget accounting, regular readback, coordinate completion-seal nonescape, componentwise transport, replay, provenance, and local naming for the displayed rows.*

Proof. Project the carrier of Definition 5824.1. The row Q supplies the already displayed product-completion packet, while π_0, π_1 determine which coordinate route is being opened.

For each selector, the corresponding stream window is read before any dyadic budget or regular readback is available. Thus S_0, S_1 precede D_0, D_1, and the regular rows R_0, R_1 are exposed only through those windows and budgets.

The completion-seal rows L_0, L_1 bind the coordinate read back to Q. The transport table H and replay table C preserve the same product packet, selector, window, budget, readback, and seal rows, while P and N record provenance and local naming.

Since these are the only carrier coordinates, the NameCert surface has no route to quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5766.3 (CauchyProductCompletionProjection route)**.** *Every coordinate read exported by an accepted* $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ *carrier factors through*

$\mathsf{CauchyProductCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameC

The left and right selectors expose only the displayed coordinate windows and their completion seals; they do not turn the product-completion packet into a host tuple, a quotient-completion equality, or a chosen representative.

Proof. Start with an accepted carrier J. The selector rows π_0, π_1 are not host projections; they are displayed BEDC rows attached to the product-completion packet Q.

Reading either selector first opens the matching $\mathsf{StreamName}^{\uparrow}$ window. The dyadic budget row is then inspected, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback is obtained from the same finite coordinate window.

The coordinate completion seal is the last coordinate-facing row before export. It keeps the read inside the product-completion packet named by Q, and the structural rows H, C, P, N attach transport, replay, provenance, and local naming to the same route.

Thus every projection read remains a finite NameCert route through the displayed rows. No coordinate of J supplies quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ packet is generated from an accepted CauchyProductCompletion packet, left and right projection selector rows, coordinate StreamName windows, DyadicRatCore budgets, RegSeqRat readbacks, coordinate completion seals, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5824.1, Definition 5824.2, and Definition 5824.3 seed the finite coordinate-projection route for product completions.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host product equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, selector exposure, coordinate window accounting, regular readback, completion-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductCompletionPro

Chapter 5767

A Concrete Naming Certificate for $\mathsf{CauchyModulusSubsequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet records the finite route by which a bounded regular Cauchy source exposes a modulus-indexed subsequence schedule without exporting an infinite selector. It sits between the bounded subsequence envelope of chapter 1698, the regular subsequence route of chapter 381, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a constructive completion-facing certificate: it supplies a monotone cofinal schedule, finite windows, tolerance accounting, and a Real seal, but not countable choice, quotient stream equality, a selected infinite subsequence, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5767.1 (Cauchy modulus subsequence carrier)**.** *A* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, M, T, W, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$ *source row whose bounded regular Cauchy data are available before any subsequence-modulus request is read.*
2. *M is the modulus row. It records the requested Cauchy tolerance discipline and the finite comparison budget used by the subsequence schedule.*
3. *T is the monotone cofinal schedule row. It records the finite evidence that requested indices are sent to later source windows and that the schedule is cofinal in the displayed source.*
4. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows selected by the schedule row T at the requested modulus levels.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed windows and dyadic tolerances.*
7. *R is the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff row reached from B, M, T, W, D, Q.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the bounded source, modulus, schedule, windows, tolerance ledger, regular readback, and regular subsequence handoff have been displayed.*

9. *H records componentwise* hsame *transport for the bounded source, modulus, cofinal schedule, windows, dyadic ledger, regular readback, regular subsequence handoff, terminal seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a subsequence-modulus request through $B, M, T, W, D, Q, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$, $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, M, T, W, D, Q, R, E, H, C, P, N$. It has no coordinate for a selected infinite subsequence, quotient stream equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusSubsequenceUp.CauchyModulusSubsequenceTasteGate single carrier alignment`

Theorem 5767.2 (Cauchy modulus subsequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier $S = (B, M, T, W, D, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequ}}$ *surface consists exactly of carrier admission, bounded-source admission through B, modulus monotonicity through M, monotone cofinal schedule admission through T, finite-window determinacy through W, dyadic tolerance accounting through D, regular rational readback through Q,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff through R, Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5825.1. Its analytic coordinates are exactly the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular readback Q, regular subsequence handoff R, and terminal Real seal E.

The modulus and schedule obligations are displayed before any support row is inspected. The row M supplies the tolerance discipline, while T records monotonicity and cofinality for the finite requested indices. The window row W and tolerance row D then determine which $\mathsf{StreamName}^{\uparrow}$ windows and dyadic bounds are visible at those requests.

The readback and seal obligations remain downstream. The row Q reads the visible windows as $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the $\mathsf{RegularCauchySubsequence}^{\uparrow}$ handoff, and E is reachable only after the preceding rows have been displayed. Rows H, C, P, N transport, replay, source, and name that same finite route, so no further NameCert obligation remains outside the listed coordinates. □

Theorem 5767.3 (Cauchy modulus subsequence window determinacy)**.** *Every consumer admitted by an accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier must read the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular rational readback Q, regular subsequence handoff R, and terminal Real seal E before reading the transport, replay, provenance, or local naming rows. The packet exports no selected infinite subsequence, quotient stream equality, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer read. By Definition 5825.1, the only consumer-facing route before the support rows is the ordered list B, M, T, W, D, Q, R, E.

The rows B, M, T fix the source, tolerance request, and monotone cofinal schedule. The row W then supplies only the finite windows named by that schedule, and D supplies the dyadic tolerance ledger attached to those windows. Thus the visible subsequence data are determined by displayed finite requests, not by an externally selected infinite object.

The remaining analytic rows are also fixed by the displayed windows. The readback row Q converts those windows into $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the regular subsequence handoff, and E is the terminal Real seal for that route. Since the carrier contains no coordinate for quotient stream equality, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the support rows H, C, P, N can only preserve the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet is generated from a bounded regular Cauchy source, a modulus row, a monotone cofinal schedule, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RegularCauchySubsequence handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5825.1, Definition 5825.2, and Definition 5825.3 seed the constructive subsequence-modulus route over bounded regular Cauchy data, finite windows, dyadic tolerances, regular readback, regular subsequence handoff, Real sealing, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, quotient stream equality, countable choice, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Lean verification requires carrier admission, modulus monotonicity, cofinal schedule admission, finite-window determinacy, dyadic tolerance accounting, RegSeqRat readback, RegularCauchySubsequence handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusSubsequenceUp.

Chapter 5768

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$

Following Mac Lane on monads and Eilenberg–Moore comparison, together with Bishop–Bridges constructive completion, the $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet records the finite BEDC surface where the L10 completion monad, its algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared as one NameCert boundary. The packet reads chapter 378, chapter 1845, chapter 1981, chapter 397, chapter 3351, chapter 126, chapter 301, chapter 291, and chapter 38. It names the comparison surface only; it does not assert quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5768.1 (CauchyCompletionMonadicity carrier)**.** *A* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion-monad row, displaying the unit and bind schedule before any algebra or comparison read is consumed.*
2. *A is the* $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ *action row, recording the Eilenberg–Moore algebra action over the displayed completion route.*
3. *K is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *row, exposing the unit, bind, and reassociated-bind consumer route.*
4. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row, carrying the extension and uniqueness ledger used by comparison consumers.*
5. *D is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *unit route, displaying the dense source-to-completion image before the algebra or universal-property read is exported.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row used by the monad, algebra, Kleisli, universal-property, and dense-embedding rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the same finite windows.*
8. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare completion-facing reads at the same finite precision.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *readback seal reached only after W, R, Q have all been displayed.*
10. *H records componentwise* hsame *transport for the monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from comparison requests through $T, A, K, U, D, W, R, Q, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, CauchyCompletionAlgebr $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, A, K, U, D, W, R, Q, E, H, C, P, N$. The carrier has no coordinate for quotient completion classes, selected limit representatives, host equality of completed objects, countable-choice schedules, ambient completeness, full $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadicityUp.TasteGate.CauchyCompletionMonadicityTasteGate`
`single carrier alignment`

Theorem 5768.2 (CauchyCompletionMonadicity NameCert obligations)**.** *For every accepted* CauchyCompletionM *carrier*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$ *surface consists exactly of carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, StreamName–RegSeqRat–DyadicRatCore–Real readback discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No local obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5827.1. The displayed tuple lists every row available to the classifier, so local comparison can inspect only the completion monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, transport, replay, provenance, and local naming.

The monadicity-facing rows are read in order. The monad row T displays the unit and bind schedule, the algebra row A records the Eilenberg–Moore action over that schedule, and the Kleisli row K keeps unit, bind, and reassociated-bind consumers on the same finite route.

The universal and dense rows then bind the comparison surface. The row U supplies extension and uniqueness data, while D supplies the dense source-to-completion unit route used before the comparison is exported.

Finally the readback and structural rows close the NameCert surface. The rows W, R, Q, E give finite windows, regular rational readback, dyadic tolerances, and the terminal Real seal; the rows H, C, P, N transport, replay, source, and name exactly that packet. Since no excluded coordinate occurs, no additional local obligation is available. □

Theorem 5768.3 (CauchyCompletionMonadicity comparison surface)**.** *Every comparison consumer of an accepted* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier factors through the finite route*

$$T, A, K, U, D \longmapsto W \longmapsto R \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the completion-monad route, the algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared only after the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$,

$\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback surface has been displayed. The comparison exports no quotient completion equality, selected limit, host equality of completed objects, countable choice, ambient completeness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the monad and algebra rows. The row T supplies the displayed completion transformer, and A reads its algebra action only as a row over that transformer.

Next attach the Kleisli and universal-property rows. The row K exposes the unit, bind, and reassociated-bind route, while U records the extension and uniqueness ledger for completion-facing consumers.

Now read the dense-embedding unit route D. It displays the source-to-completion image before the comparison reaches any terminal seal, so the route is a visible unit comparison rather than a selected representative.

Finally consume the readback and structural rows. The finite window W, regular readback R, dyadic tolerance ledger Q, and Real seal E precede transport, replay, provenance, and naming through H, C, P, N. Since the carrier contains no coordinate for the excluded objects, the comparison surface cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet is generated from a CauchyCompletionMonad route, CauchyCompletionAlgebra action row, CauchyCompletionKleisli route, CompletionUniversalProperty row, MetricCompletionDenseEmbedding unit route, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5827.1, Definition 5827.2, and Definition 5827.3 seed the finite monadicity comparison boundary for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, readback discipline, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionMonadicityUp.

Chapter 5769

A Concrete Naming Certificate for $\mathsf{BorsukUlam}^{\uparrow}$

Following Borsuk and Ulam, the $\mathsf{BorsukUlam}^{\uparrow}$ packet records the antipodal obstruction theorem as finite BEDC NameCert data rather than as a host topological principle. It sits after the degree surface of chapter 3745, the continuous-map rows of chapter 130, the real-name seal of chapter 38, the compact metric source of chapter 129, and the circle boundary model of chapter 58. The packet names the displayed antipodal route consumed by obstruction and degree-facing chapters; it does not select antipodal points, import unrestricted classical degree theory, identify quotient spheres, choose representatives, or appeal to ambient completeness.

Definition 5769.1 (Borsuk-Ulam carrier)**.** *A* $\mathsf{BorsukUlam}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, A, F, D, C, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the compact metric sphere row read through the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *surface and the* $\mathsf{S}^{1\uparrow}$ *boundary model.*
2. *A is the antipodal-pair ledger, exposing only named paired source rows and the finite equality-refusal data attached to them.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the map whose antipodal comparison is being inspected.*
4. *D is the* $\mathsf{BrouwerDegree}^{\uparrow}$ *obstruction row, read only through the displayed degree certificate and never through unrestricted host degree theory.*
5. *C is the* $\mathsf{Real}^{\uparrow}$ *comparison-seal row for the coordinate difference or collapsed real-valued comparison consumed by the obstruction route.*
6. *R is the refusal row excluding selected antipodal points, quotient equality of sphere points, choice, unrestricted classical degree theory, and ambient completeness.*
7. *H records componentwise* hsame *transport for the compact source, antipodal ledger, continuous-map row, degree row, real comparison seal, refusal row, provenance, and local naming.*
8. *K records displayed* Cont *replay from the compact metric source through the antipodal ledger, continuous-map row, degree obstruction, real comparison seal, and refusal row.*
9. *P is the* Pkg *provenance over* $\mathsf{BorsukUlam}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{BrouwerDegree}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *row.*
The classifier compares accepted packets only through $S, A, F, D, C, R, H, K, P, N$. It has no coordinate for a chosen antipodal pair, quotient equality on the sphere, unrestricted classical degree theory, countable choice, or ambient Real completeness.

Lean4 (definition) `BEDC.Derived.BorsukUlamUp.BorsukUlamUp`
Lean4 ✓ `BEDC.Derived.BorsukUlamUp.BorsukUlamTasteGate single carrier alignment`

Theorem 5769.2 (Borsuk-Ulam NameCert obligations)**.** *For every accepted* $\mathsf{BorsukUlam}^\uparrow$ *carrier* $U = (S, A, F, D, C, R, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *surface consists exactly of compact metric sphere admission, antipodal-pair ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, refusal of host and quotient shortcuts, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obstruction-facing consumer must read*

$$S, A, F \longmapsto D, C \longmapsto R, H, K, P, N$$

before treating the packet as a Borsuk-Ulam certificate.

Proof. Project the carrier of Definition 5828.1. The compact source row S, antipodal ledger A, and continuous-map row F are the only rows available before the obstruction is read.

The degree and real-comparison rows D, C are downstream of that source route. The degree row is the displayed $\mathsf{BrouwerDegree}^\uparrow$ certificate, and the real row is the displayed $\mathsf{Real}^\uparrow$ seal for the comparison consumed by the obstruction.

Finally R, H, K, P, N refuse shortcuts, transport the same rows, replay the finite route, source it, and name it locally. Since the carrier has no coordinate for selected antipodal points, quotient equality, unrestricted host degree theory, countable choice, or ambient Real completeness, no consumer can export those objects from the certificate. □

Theorem 5769.3 (Borsuk-Ulam antipodal route)**.** *Every accepted* $\mathsf{BorsukUlam}^\uparrow$ *antipodal-obstruction read factors through the displayed compact metric sphere row, the* $\mathsf{S}^{1\uparrow}$ *boundary model, the antipodal-pair ledger, the* $\mathsf{ContinuousMap}^\uparrow$ *row, the* $\mathsf{BrouwerDegree}^\uparrow$ *obstruction row, the terminal* $\mathsf{Real}^\uparrow$ *comparison seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert*. The route exports no selected antipodal point, unrestricted classical degree theorem, quotient equality of sphere points, choice principle, ambient completeness, Lean verification, or bridge-checked surface.*

Proof. Start with an accepted carrier $U = (S, A, F, D, C, R, H, K, P, N)$. The source read begins at S and A, so the antipodal data is visible only as a finite paired ledger over the displayed compact metric and circle rows.

Read the map through F and then the obstruction through D, C. The $\mathsf{ContinuousMap}^\uparrow$ row supplies the function-facing data, the $\mathsf{BrouwerDegree}^\uparrow$ row supplies the obstruction route, and the $\mathsf{Real}^\uparrow$ row supplies only the comparison seal reached from those displayed rows.

The refusal and structural rows close the route. The row R blocks selected points, quotient equality, unrestricted degree theory, choice, and ambient completeness, while H, K, P, N preserve the same finite certificate under transport, replay, provenance, and local naming. □

Falsifiable prediction: Every accepted $\mathsf{BorsukUlam}^\uparrow$ consumer reads compact metric sphere data, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a Real

comparison seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before it treats the packet as an antipodal obstruction certificate.

Independence witness: brouwer-degree, continuousmap, real, compactmetric, s1: $\mathsf{BorsukUlam}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact sphere data, antipodal pairing, continuous-map readback, degree obstruction, real comparison sealing, refusal, transport, replay, provenance, and local naming into one obstruction-facing certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}$.

Constructive story: A $\mathsf{BorsukUlam}^{\uparrow}$ packet is generated from a compact metric sphere row, an S1 boundary model, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a RealUp comparison seal, shortcut refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5828.1, Definition 5828.2, and Definition 5828.3 seed the finite antipodal obstruction route over compact metric, circle, continuous-map, degree, real-seal, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected antipodal points, unrestricted classical degree theory, quotient equality, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, antipodal ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, transport, replay, provenance, and local naming for BEDC.Derived.BorsukUlamUp.

Chapter 5770

A Concrete Naming Certificate for $\mathsf{DenjoyYoungSaks}^{\uparrow}$

Following Saks and Bishop–Bridges constructive real analysis, the $\mathsf{DenjoyYoungSaks}^{\uparrow}$ packet records the finite boundary at which a real-valued interval map can expose upper and lower Dini-derivative rows without importing the classical almost-everywhere Denjoy–Young–Saks theorem. It sits next to the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation window of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet is a finite classification boundary for displayed Dini rows, oscillation windows, regular-rational readback, and terminal Real seals; it is not a measure theorem, an almost-everywhere classifier, or a host-real differentiability principle.

Definition 5770.1 (Denjoy–Young–Saks finite Dini carrier)**.** *A* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the inspected interval row, listing the finitely presented source intervals and endpoint cells on which the local boundary is read.*
2. *F is the function-observation row, recording the finite source and target windows used to compare difference quotients.*
3. *U is the upper Dini row, storing the displayed upper right, upper left, and two-sided upper derivative bounds visible at the inspected windows.*
4. *L is the lower Dini row, storing the corresponding lower right, lower left, and two-sided lower derivative bounds.*
5. *O is the oscillation-window row, recording the finite alternation and stabilization tests used to classify a displayed window as one of the Dini-boundary cases.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by I, F, O and no hidden stream coordinates.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data extracted from the finite stream windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger supporting the difference-quotient comparisons and oscillation bounds.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the interval, function-observation, Dini, oscillation, stream, readback, and dyadic rows have been exposed.*

10. *H records componentwise* hsame *transport for intervals, function observations, Dini rows, oscillation windows, stream schedules, regular readbacks, dyadic ledgers, Real seals, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the inspected interval and function rows through U, L, O, S, R, D and into the Real seal E.*

12. *P is the* Pkg *provenance over* $\mathsf{DenjoyYoungSaks}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, U, L, O, S, R, D, E, H, C, P, N$. It has no coordinate for measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, host real order trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.DenjoyYoungSaksUp.DenjoyYoungSaksTasteGate single carrier alignment`

Theorem 5770.2 (Denjoy–Young–Saks finite boundary obligations)**.** *For every accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier $Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the inspected interval, function-observation, upper Dini, lower Dini, oscillation-window, stream-schedule, regular-readback, dyadic-ledger, Real-seal, transport, replay, provenance, and local naming rows;*

2. *interval and observation exactness, requiring every Dini comparison to read its source cell from I and its finite function window from F before any derivative row is accepted;*

3. *upper and lower Dini-row exactness, requiring U and L to store only the finite upper and lower derivative bounds justified by the displayed difference-quotient windows;*

4. *oscillation-window classification, requiring O to record the finite alternation, stabilization, and gap tests that separate the visible Dini-boundary cases;*

5. *stream, readback, and dyadic exactness, requiring S, R, D to expose only the finite observations, regular rational readbacks, and dyadic tolerance rows demanded by I, F, U, L, O;*

6. *Real seal nonescape, requiring E to remain downstream of I, F, U, L, O, S, R, D and never to serve as a selected derivative, a host real equality witness, or an almost-everywhere theorem;*

7. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve exactly the displayed finite route.*

No $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *obligation is stored outside these rows, and the packet makes no claim that the classical Denjoy–Young–Saks alternatives hold almost everywhere.*

Proof. Carrier admission is projection from Definition 5829.1. The accepted packet displays exactly the inspected interval row I, function-observation row F, upper and lower Dini rows U, L, oscillation row O, stream schedule S, regular readback R, dyadic ledger D, Real seal E, and structural rows H, C, P, N.

Interval and observation exactness follow from the row order. A Dini comparison first reads the source cell in I and the finite function-observation window in F; only then may it inspect the upper row U, lower row L, or oscillation row O attached to that window.

The stream, regular-readback, and dyadic rows are downstream of the same finite windows. The schedule S opens only the observations demanded by I, F, O, the row R records the resulting regular rational readback, and D stores the tolerance comparisons needed for the displayed difference-quotient bounds.

Finally, the Real seal E is terminal for this finite boundary route. The transport row H, replay row C, provenance row P, and local naming row N preserve the same packet, so measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness cannot become local obligations. □

Theorem 5770.3 (Denjoy–Young–Saks Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{StreamName}^{\uparrow}$ *consumer of an accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier reads the displayed route*

$$I, F, U, L, O, S, R, D, E, H, C, P, N.$$

Consequently the consumer may inspect finite interval cells, function observations, upper and lower Dini rows, oscillation windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal Real seal, componentwise transport, replay, provenance, and local naming. It cannot read a measure structure, an almost-everywhere assertion, a selected derivative, quotient real equality, host real trichotomy, countable choice, or ambient completeness from the packet.

Proof. Project the accepted carrier through Definition 5829.1. Its Real-facing and readback-facing rows are exactly S, R, D, E together with the preceding interval, function, Dini, and oscillation rows I, F, U, L, O and the structural rows H, C, P, N.

The route reaches E only after the finite Dini and oscillation boundary has been displayed. Thus any consumer that asks for a Real seal or regular rational readback must already have passed through the interval cells, function observations, upper and lower Dini rows, oscillation windows, stream schedule, and dyadic tolerance ledger.

Since the carrier has no row for measure, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, or ambient completeness, none of those objects can be read by a downstream consumer. □

Theorem 5770.4 (Denjoy–Young–Saks oscillation-window induction)**.** *For an accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier* $Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$*, induction over the finite oscillation-window row* O *preserves the separation between the upper Dini row* U *and the lower Dini row* L*. At every displayed stage the packet remains a finite boundary classifier over the rows of Definition 5829.1; the induction cannot promote the packet to an almost-everywhere measure theorem, cannot select a derivative, and cannot export a host-real differentiability principle.*

Proof. Induct over the displayed list of oscillation windows in O. The empty row has no Dini comparison to transport, so the upper and lower rows remain separated by the carrier projection.

For the step, assume the previously displayed windows preserve the separation of U and L. The next window is admitted only through the oscillation-window classification row in Definition 5829.2, so it may inspect the finite alternation, stabilization, and gap tests attached to that window but cannot rewrite the carrier outside $I, F, U, L, O, S, R, D, E, H, C, P, N$.

The Real-seal nonescape theorem Definition 5829.3 keeps every downstream read behind the same finite route. Thus adjoining the next oscillation window preserves the visible upper/lower Dini separation and leaves measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness outside the packet. □

Falsifiable prediction: Every $\mathsf{DenjoyYoungSaks}^{\uparrow}$ Real-facing or readback-facing read factors through finite interval cells, function-observation windows, upper and lower Dini rows, oscillation windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{DenjoyYoungSaks}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries upper and lower Dini rows, oscillation-window classification, regular-rational readback, dyadic tolerance data, and a terminal Real seal in one finite boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$.

Constructive story: A $\mathsf{DenjoyYoungSaks}^{\uparrow}$ packet is generated from inspected interval cells, function-observation windows, upper and lower Dini rows, oscillation-window classifications, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5829.1, Definition 5829.2, and Definition 5829.3 seed the finite Denjoy–Young–Saks boundary route over Dini rows, oscillation windows, regular-rational readback, dyadic tolerance rows, and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DenjoyYoungSaksUp.DenjoyYoungSaksTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close the classical almost-everywhere Denjoy–Young–Saks theorem, measure-null exceptional sets, selected derivatives, quotient real equality, trichotomy, countable choice, ambient completeness, or bridge checking beyond the carrier-alignment Lean target.

Upgrade path: Obligation closure requires checked carrier admission, Dini-row exactness, oscillation-window classification, stream-readback-dyadic exactness, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.DenjoyYoungSaksUp.

Chapter 5771

A Concrete Naming Certificate for $\mathsf{UniformlyConvexSpace}^{\uparrow}$

Following Clarkson's uniformly convex Banach-space reading and Bishop–Bridges constructive normed-space practice, the $\mathsf{UniformlyConvexSpace}^{\uparrow}$ packet records a finite modulus-of-convexity surface over the normed-space carrier of chapter 1950. It consumes the $\mathsf{NormedSpace}^{\uparrow}$ row, the real-valued norm and midpoint reads through chapter 38, the metric handoff of chapter 57, and the completion-facing route of chapter 95 and chapter 3413. The packet gives Banach, Hilbert, fixed-point, and convexity consumers a named uniform-convexity certificate without importing host Banach-space equality, selected minimizers, quotient completions, or choice.

Definition 5771.1 (UniformlyConvexSpace carrier)**.** *A* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (N, R, A, M, \Delta, Q, H, T, P, C)$$

with the following displayed rows:

1. *N is the* $\mathsf{NormedSpace}^{\uparrow}$ *row, exposing vector operations, the norm read, and the induced metric only through the normed-space NameCert surface.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by norm values, radius comparisons, midpoint estimates, and positive modulus outputs.*
3. *A is the midpoint row, reading $(x + y)/2$ through the vector addition, scalar action, and real scalar rows already visible in N and R.*
4. *M is the metric handoff row, routing distance and unit-ball comparisons through the* $\mathsf{Met}^{\uparrow}$ *read induced by N.*
5. *Δ is the convexity-modulus row: for each displayed positive separation request it supplies a positive real margin forcing the midpoint norm below the unit bound whenever the two admitted unit vectors are separated by that request.*
6. *Q is the completion-facing row, allowing Cauchy and completion consumers to read the same norm, metric, midpoint, and modulus data without selecting a completed point.*
7. *H records componentwise* hsame *transport for N, R, A, M, Δ, Q and for the local structural rows.*
8. *T records displayed* Cont *replay from a uniform-convexity request through $N, R, A, M, \Delta, Q, H, P, C$.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformlyConvexSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. C is the local $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for host Banach-space equality, strict-convexity as a pointwise substitute, quotient completion, selected closest points, compactness, reflexivity, or a choice principle.

Theorem 5771.2 (UniformlyConvexSpace NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *carrier* $U = (N, R, A, M, \Delta, Q, H, T, P, C)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, normed-space visibility, real-valued norm and midpoint readback, metric separation handoff, positive modulus admission, midpoint contraction under the displayed separation request, completion-facing nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside* $N, R, A, M, \Delta, Q, H, T, P, C$*.*

Lean4 ✓ `BEDC.Derived.UniformlyConvexSpaceUp.UniformlyConvexSpaceTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 5831.1. The rows $N, R, A, M, \Delta, Q, H, T, P, C$ are the whole accepted packet.

The normed-space, Real, midpoint, and metric obligations are read first. The row N supplies the normed vector carrier, R supplies real-valued comparisons, A supplies midpoint formation, and M supplies the induced metric separation route.

The uniform-convexity content is isolated in Δ. For a displayed positive separation request, Δ supplies a positive margin and forces the midpoint norm read through A, N, R below the unit bound. Since Q, H, T, P, C only hand off, transport, replay, source, and name the same route, no host Banach-space equality, quotient completion, selected point, compactness, reflexivity, or choice coordinate can enter. □

Theorem 5771.3 (UniformlyConvexSpace modulus convexity route)**.** *Every accepted* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *consumer that asks for uniform convexity factors through*

$$\mathsf{NormedSpace}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{Completion}^{\uparrow}, \mathsf{Cauchy}^{\uparrow} \longmapsto H, T, P, C.$$

The modulus row Δ may be read only after the normed-space carrier, real norm values, midpoint operation, and metric separation row have been displayed. The route exports a finite modulus-of-convexity NameCert surface, not host strict convexity, a selected minimizer, quotient completion equality, compactness, reflexivity, or countable choice.

Proof. Begin with a uniform-convexity request. The normed-space row N supplies the only vector and norm data, while R supplies the real-valued unit-ball and positivity comparisons.

Read midpoint and separation next. The midpoint row A is formed from the displayed operations of N and R, and the metric handoff M reads separation through the induced metric of the same normed-space packet.

Only then can the modulus row Δ answer the request. Its output is tied to the displayed positive separation and midpoint norm route, and the completion-facing row Q sends Cauchy or completion consumers through the same route rather than through a selected completed point.

Finally H, T, P, C transport, replay, source, and name the packet. The excluded host strict-convexity, selected-minimizer, quotient-completion, compactness, reflexivity, and choice objects are absent from the carrier, so the finite modulus route is the whole exported surface. □

Falsifiable prediction: An accepted $\mathsf{UniformlyConvexSpace}^{\uparrow}$ read is refuted if a consumer obtains a uniform-convexity margin without first displaying the $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, midpoint, $\mathsf{Met}^{\uparrow}$, completion-facing, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: normedspace, real, metric, completion, cauchy: no listed sibling is bijective to $\mathsf{UniformlyConvexSpace}^{\uparrow}$ because the packet jointly carries normed-space data, real norm comparisons, midpoint formation, metric separation, a positive convexity modulus, completion-facing handoff, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformlyConvexSpace}^{\uparrow}$ packet is generated from a NormedSpace row, Real norm-comparison rows, a midpoint row, an induced Metric separation row, a convexity-modulus row, a Completion and Cauchy handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5831.1, Definition 5831.2, and Definition 5831.3 seed the finite modulus-of-convexity route over normed-space, real, metric, completion, and Cauchy rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.UniformlyConvexSpaceUp.UniformlyConvexSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host Banach-space equality, strict-convexity substitution, selected minimizers, quotient completions, compactness, reflexivity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, midpoint formation, metric separation, positive modulus exactness, completion-facing nonescape, and local naming for BEDC.Derived.UniformlyConvexSpaceUp.

Chapter 5772

A Concrete Naming Certificate for $\mathsf{HyperbolicTranslationLength}^{\uparrow}$

Following the classical translation length of a hyperbolic isometry, the $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ packet records the finite invariant-length route visible to the hyperbolic phase geometry of chapter 9463. It consumes the metric-read surface of chapter 3474, the routed geodesic-flow surface of chapter 3856, the additive Busemann cocycle route of chapter 4134, the four-boundary-point comparison of chapter 3948, and the terminal real seal of chapter 38. The packet names stable displacement growth as finite BEDC data; it does not import a host hyperbolic manifold, quotient ideal boundary, selected axis, spectral radius, or global curvature theorem.

Definition 5772.1 (HyperbolicTranslationLength carrier)**.** *A* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, F, B, X, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row, exposing displacement reads for the source and its iterated image.*
2. *F is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row, recording the finite routed-flow data used to compare iterates along the same visible geodesic route.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row, supplying additive boundary-cocycle comparisons for the same displayed endpoints.*
4. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *row, recording the four-boundary-point invariant used to stabilize the length read.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by displacement values, additive cocycle values, cross-ratio reads, and the final nonnegative length seal.*
6. *D is the displacement-growth row, comparing the displayed iterate window through M, F, B, X, R without selecting an infinite orbit or an axis.*
7. *E is the endpoint-stability row, stating that the same boundary data are replayed by the metric, flow, Busemann, and cross-ratio rows.*
8. *H records componentwise* hsame *transport for M, F, B, X, R, D, E and for the local structural rows.*

9. *C records displayed* Cont *replay from a translation-length request through $M, F, B, X, R, D, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host isometry group, selected invariant axis, quotient boundary equality, spectral radius, completed hyperbolic manifold, or physical expansion law.

Lean4 ✓ `BEDC.Derived.HyperbolicTranslationLengthUp.HyperbolicTranslationLengthTasteGate single carrier alignment`

Theorem 5772.2 (HyperbolicTranslationLength NameCert obligations)**.** *For every accepted* HyperbolicTranslation *carrier $L = (M, F, B, X, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$ *surface consists exactly of metric displacement visibility, geodesic-flow routing, Busemann additivity, cross-ratio stabilization, real-valued length sealing, displacement-growth comparison, endpoint stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside $M, F, B, X, R, D, E, H, C, P, N$.*

Proof. Project the carrier of Definition 5832.1. The rows $M, F, B, X, R, D, E, H, C, P, N$ are the whole visible packet.

The geometric route is read first. Metric displacement comes from M, routed iteration from F, additive boundary comparison from B, and four-boundary-point stabilization from X.

The Real and displacement rows then seal the length read. The row R supplies the real-valued comparison surface, while D and E ensure that the same endpoint data are used by the metric, flow, Busemann, and cross-ratio reads.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate names a host isometry group, selected invariant axis, quotient boundary equality, spectral radius, completed manifold, or physical expansion law, the listed obligations exhaust the local surface. □

Theorem 5772.3 (HyperbolicTranslationLength invariant route)**.** *Every accepted* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *read factors through*

$$\mathsf{HyperbolicMetric}^{\uparrow}, \mathsf{HyperbolicGeodesicFlow}^{\uparrow}, \mathsf{HyperbolicBusemannCocycle}^{\uparrow}, \mathsf{HyperbolicCrossRatio}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto H, C, P$$

The finite route records displacement growth and boundary stabilization as a real-sealed invariant length, and it exports no host hyperbolic isometry, selected axis, quotient ideal-boundary equality, spectral radius, completed hyperbolic manifold, or cosmological expansion claim.

Proof. Begin with the displacement request. The metric row M supplies finite distance reads, and the geodesic-flow row F keeps the iterated comparison on the same displayed route.

Read boundary stabilization next. The Busemann cocycle row B supplies additive endpoint comparison, while the cross-ratio row X records the four-boundary-point invariant. The endpoint-stability row E requires these boundary reads to describe the same displayed data.

The Real row R and displacement-growth row D seal the invariant length as a finite real-valued read. The structural rows H, C, P, N preserve, replay, source, and name that route, while the excluded host and quotient objects remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ consumer is refuted if it obtains an invariant length without displaying the $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}$ $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, displacement-growth, endpoint-stability, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: hyperbolicmetric, hyperbolic-geodesic-flow, hyperbolic-busemann-cocycle, hyperbolic-cross-ratio, real: no listed sibling is bijective to $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ because the packet jointly carries metric displacement, routed flow, additive boundary cocycle, cross-ratio stabilization, Real sealing, displacement-growth comparison, endpoint stability, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ packet is generated from HyperbolicMetric displacement rows, HyperbolicGeodesicFlow routing rows, HyperbolicBusemannCocycle additive boundary rows, HyperbolicCrossRatio stabilization rows, Real sealing rows, displacement-growth and endpoint-stability rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5832.1, Definition 5832.2, and Definition 5832.3 seed the finite invariant-length packet over metric, flow, Busemann, cross-ratio, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host hyperbolic isometries, selected axes, quotient ideal-boundary equality, spectral radii, completed hyperbolic manifolds, physical expansion laws, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, displacement visibility, flow routing, Busemann additivity, cross-ratio stabilization, Real length sealing, endpoint stability, and local naming for BEDC.Derived.HyperbolicTranslationLengthUp.

Chapter 5773

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ packet records the finite envelope that carries a regular Cauchy rational readback into the terminal Real naming seal. It sits after the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational sequence interface of chapter 301, the terminal real-name packet of chapter 38, and the completion route of chapter 1506. The packet is a finite NameCert envelope for the handoff itself; it does not assert that the host real line is complete.

Definition 5773.1 (Regular Cauchy completion envelope carrier)**.** *A* $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (W, D, R, E_R, M, T, C, P, N)$$

where W *is the displayed* $\mathsf{StreamName}^{\uparrow}$ *window row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row,* E_R *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* T *records componentwise* $\mathsf{BHist}/\mathsf{hsame}$ *transport,* C *records displayed* Cont *replay,* P *is* Pkg *provenance over the displayed rows, and* N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}$ *row. A consumer of the carrier receives the completion handoff only through these nine coordinates.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionEnvelopeUp.RegularCauchyCompletionEnvelopeTasteGate`
`single carrier alignment`

Theorem 5773.2 (Regular Cauchy completion envelope obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletion}$ *carrier*

$$E = (W, D, R, E_R, M, T, C, P, N),$$

the local NameCert surface consists exactly of window admission, tolerance admission, regular readback admission, terminal Real-seal admission, metric-completion route admission, transport stability, continuation replay, provenance preservation, and local naming preservation for the displayed packet. No quotient stream equality, selected representative, countable choice schedule, host completeness principle, or $\mathsf{Real}^{\uparrow}$ *completeness theorem is a coordinate of this surface.*

Proof. Project the carrier of Definition 5833.1. Its only data rows are $W, D, R, E_R, M, T, C, P, N$, so the local NameCert can inspect exactly those displayed coordinates.

The first four rows bind the finite observation, dyadic tolerance, regular rational readback, and terminal Real seal. The metric-completion row M is therefore read as a route row over those data, not as an ambient completeness object.

The structural rows T, C, P, N preserve the same packet under componentwise transport, continuation replay, provenance, and local naming. Since the carrier has no slot for quotient stream equality, selected representatives, countable choice, host completeness, or Real completeness, none of those objects can be exported by the obligation surface. □

Theorem 5773.3 (Regular Cauchy completion envelope Real handoff)**.** *Every Real-facing completion consumer of an accepted* $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ *carrier reads the terminal handoff through the ordered finite route*

$$W, D, R, E_R, M, T, C, P, N.$$

In particular, the consumer reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal only after the* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed inside the same envelope.*

Proof. Start from Definition 5833.2. It makes $W, D, R, E_R, M, T, C, P, N$ the entire accepted surface of the envelope.

Read the Real-facing route through W, D, R, E_R. The StreamName windows expose the finite observations, the dyadic ledger records the tolerance budget, the regular-rational row gives the readback, and the terminal row gives the Real seal inside the same packet.

The completion route M and the structural rows T, C, P, N only replay and name that displayed handoff. Thus the consumer cannot replace the handoff by quotient stream equality, a chosen representative, countable choice, host completeness, or a completeness theorem for $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5833.1, Definition 5833.2, and Definition 5833.3 seed the finite regular-Cauchy-to-Real completion envelope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyCompletionEnvelopeUp.RegularCauchyCompletionEnvelopeTasteGate\_single\_car`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host completeness, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, row order, Real handoff, transport stability, replay stability, provenance preservation, and local NameCert preservation for BEDC.Derived.RegularCauchyCompletionEnvelopeUp.

Constructive story: A $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore tolerance, RegSeqRat readback, terminal Real seal, metric-completion routing, transport, replay, provenance, and local NameCert rows.

Chapter 5774

A Concrete Naming Certificate for $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$

Following Bishop–Bridges constructive locatedness, the $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ packet records the finite interval-selection surface that can be read by Cauchy and Real interval consumers without selecting an endpoint or importing compactness. It sits over the located interval carrier of chapter 394, the rational cell ledger of chapter 354, the optional dyadic refinement rows of chapter 306, the endpoint observation windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal Real seal of chapter 38. The packet names a finite route through displayed interval data; it does not assert endpoint choice, Heine–Borel compactness, trichotomy, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5774.1 (WeaklyLocatedIntervalSelection carrier)**.** *A* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, Q, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the source interval and its locatedness probes.*
2. *Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger listing the rational subinterval cells visible to the selection route.*
3. *D is an optional* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row; when present, it refines cells already displayed by Q and adds no independent selector.*
4. *W is the paired* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window row through which finite endpoint observations are read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same endpoint windows and rational cells.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by any Real-facing endpoint or interval consumer.*
7. *H records componentwise* hsame *transport for $L, Q, D, W, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from located interval probes through rational cells, optional dyadic refinements, endpoint windows, regular readbacks, and the Real seal.*
9. *P is* Pkg *provenance over* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$*,* $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets componentwise through these ten rows. There is no coordinate for an endpoint selector, an open-cover compactness argument, a trichotomy oracle, quotient equality of Real names, or host Real completeness.

Lean4 ✓ `BEDC.Derived.WeaklyLocatedIntervalSelectionUp.WeaklyLocatedIntervalSelectionTasteGate single carrier alignment`

Theorem 5774.2 (WeaklyLocatedIntervalSelection NameCert obligations)**.** *For every accepted* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *carrier*

$$S = (L, Q, D, W, R, E, H, C, P, N),$$

the local NameCert surface consists exactly of the following obligations:

1. *carrier admission for the finite* BHist *packet S and its displayed rows;*
2. *located-cell visibility from the* $\mathsf{LocatedInterval}^{\uparrow}$ *row L into the* $\mathsf{RationalInterval}^{\uparrow}$ *ledger Q;*
3. *finite selection-route exactness through the visible rational cells and any displayed* $\mathsf{DyadicInterval}^{\uparrow}$ *refinements D;*
4. *endpoint-window transport from Q, D into the* $\mathsf{StreamName}^{\uparrow}$ *windows W and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R;*
5. *Real-seal nonescape, requiring every Real-facing read to pass through the displayed* $\mathsf{Real}^{\uparrow}$ *row E;*
6. *componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance preservation, and local* NameCert *preservation through H, C, P, N.*

No endpoint choice principle, Heine–Borel theorem, trichotomy principle, quotient equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem is an obligation or an output of this surface.*

Theorem 5774.3 (Weakly located interval selection route exhaustion)**.** *For every accepted* WeaklyLocatedIntervalSe *carrier*

$$S = (L, Q, D, W, R, E, H, C, P, N),$$

every endpoint, interval, or Real-facing consumer factors through the displayed rows $L, Q, D, W, R, E, H, C, P, N$. Such a consumer cannot read endpoint choice, Heine–Borel compactness, trichotomy, quotient equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows of Definition 5834.1. The located interval source is L, the rational cell ledger is Q, and the optional dyadic refinement row is D.

Located-cell visibility therefore passes through L, Q, D. Endpoint or interval reads have no route around these rows because the packet stores no detached endpoint selector or host interval object.

The endpoint windows and regular rational readbacks are then W and R. A Real-facing consumer reaches the seal row E only after those finite windows and readbacks are visible.

Finally H, C, P, N transport, replay, source, and name the same route. Since endpoint choice, Heine–Borel compactness, trichotomy, quotient equality, and ambient completeness are absent from the tuple, the displayed rows exhaust every admitted consumer read. □

Closure status for $\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$ **·**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5834.1, Definition 5834.2, and Definition 5834.3 seed the finite weakly located interval-selection route over chapter 394, chapter 354, chapter 306, chapter 126, chapter 301, and chapter 38.

Formal verification: FormalStatus(NameCert$_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close endpoint choice, Heine–Borel compactness, trichotomy, quotient real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-cell visibility, finite selection-route exactness, endpoint-window transport, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.WeaklyLocatedIntervalSelectionUp.

Constructive story: A WeaklyLocatedIntervalSelection$^{\uparrow}$ packet is generated from LocatedInterval rows, RationalInterval cell ledgers, optional DyadicInterval refinements, StreamName endpoint windows, RegSeqRat readbacks, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5775

A Concrete Naming Certificate for $\mathsf{UniformInverseModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UniformInverseModulus}^{\uparrow}$ packet records compact inverse-modulus extraction from uniform homeomorphism data as finite NameCert data. It reads the homeomorphism and inverse-graph surface of chapter 1815, the compact finite-net rows of chapter 129, the graph and pointwise continuity rows of chapter 130, the exported modulus interface of chapter 369, the metric-source and metric-target rows of chapter 4230, and the terminal real-name seal of chapter 38. The chapter names the finite compact route that turns displayed inverse radii into a uniform inverse modulus; it is not a selected inverse function, host function equality, quotient real equality, open-cover compactness, or ambient completeness principle.

Definition 5775.1 (Uniform inverse modulus carrier)**.** *A* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A)$$

with the following displayed rows:

1. *X is the compact source row, exposing the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net data used to cover the compact domain of the homeomorphism.*
2. *Y is the target metric row, including the distance ledger into which the inverse-modulus estimate is reported.*
3. *F is the* $\mathsf{UniformHomeomorphism}^{\uparrow}$ *graph row from X to Y, carrying the forward graph and the homeomorphism naming data.*
4. *G is the inverse graph row displayed by the same homeomorphism packet.*
5. *E is the positive precision row, read through* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint histories when the consumer presents a real tolerance.*
6. *N is the finite net row of the compact source at the scale needed for the inverse-modulus extraction.*
7. *R lists the pointwise inverse radius rows attached to the centers named by N.*
8. *M is the finite radius-fold row, obtained only by folding the finite family R over the index list of N.*
9. *T is the target estimate row, combining inverse-graph exactness, finite-net coverage, the folded radius row, and the target metric triangle ledger.*

10. *H records componentwise* hsame *transport for the compact source, target metric, homeomorphism graph, inverse graph, precision, finite-net, inverse-radius, radius-fold, and estimate rows.*
11. *C records the displayed* Cont *replay route from compact homeomorphism data and pointwise inverse radii to the* $\mathsf{UniformModulus}^{\uparrow}$ *export.*
12. *P records* Pkg *provenance over* $\mathsf{UniformInverseModulus}^{\uparrow}$, $\mathsf{UniformHomeomorphism}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, RegSeqRat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *A is the local* $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$ *row.*

The carrier exposes only displayed compact finite nets, graph rows, inverse-graph rows, endpoint readbacks, finite radius rows, componentwise transport, replay, provenance, and local naming. It has no coordinate for a host inverse function, selected inverse choice, host function equality, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformInverseModulusUp.UniformInverseModulusTasteGate single carrier alignment`

Theorem 5775.2 (Uniform inverse modulus obligations)**.** *For every accepted* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the compact source, target metric, homeomorphism graph, inverse graph, precision, finite-net, inverse-radius, radius-fold, target-estimate, transport, replay, provenance, and local naming rows;*
2. *inverse-graph exactness, requiring every inverse read to pass through the displayed row G attached to the homeomorphism row F;*
3. *compact finite-net handoff, requiring the compact source row X and precision row E to determine the finite row N before any inverse radius is folded;*
4. *finite radius fold, requiring M to be obtained only by folding the pointwise inverse radius rows R over the finite indices of N;*
5. *target estimate, requiring T to combine compact-net coverage, inverse-graph exactness, folded-radius data, and the target metric ledger;*
6. *transport, replay, and provenance, requiring H, C, P, A to source the same displayed route componentwise;*
7. *nonescape, requiring the packet to export no host inverse function, selected inverse choice, host function equality, quotient real equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 5835.1. The projection exposes exactly the rows $X, Y, F, G, E, N, R, M, T, H$ so carrier admission and row inventory are finite.

The inverse read is confined to G. Since G is listed as a row of the same homeomorphism packet that supplies F, inverse-graph exactness is consumed as displayed graph data rather than as host function equality or selected inverse choice.

The compact handoff reads X and E before radius data. These rows determine the finite net N, and the pointwise inverse radii in R are indexed only by the centers listed by N.

Fold R over that finite index list to obtain M. The target estimate row T then combines the compact-net coverage, inverse-graph exactness, folded radius, and target metric triangle route. Finally H, C, P, A transport, replay, source, and name the same route, so no excluded equality, choice, open-cover, trichotomy, or completeness coordinate is introduced. □

Theorem 5775.3 (Uniform inverse modulus compact handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *export from an accepted* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A)$$

factors through the displayed finite route

$$X, F, G, E \longmapsto N, R \longmapsto M, T \longmapsto H, C, P, A.$$

Thus the inverse-modulus export is a compact finite-net and radius-fold handoff. It exports no host function equality, selected inverse choice, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from a $\mathsf{UniformModulus}^{\uparrow}$ consumer of I. By Definition 5835.2, the consumer must read the compact source, homeomorphism graph, inverse graph, and precision rows before the finite-net row is available.

The only finite-net row is N, and the only pointwise inverse-radius inventory is R. Hence the consumer reaches the exported modulus row M only after the finite fold over R indexed by N.

The target estimate T is downstream of that fold. It cannot be read as a host inverse function or as quotient equality of inverse values, because the carrier contains only displayed graph and metric-ledger rows.

Finally the structural rows H, C, P, A transport, replay, source, and name the same compact route. Since the carrier contains no coordinate for selected inverse choice, trichotomy, open-cover compactness, or ambient completeness, the export factors through exactly the displayed finite-net and radius-fold handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformInverseModulus}^{\uparrow}$ packet is generated from UniformHomeomorphism graph and inverse-graph rows, CompactMetric finite-net rows, ContinuousMap pointwise inverse-radius rows, UniformModulus export rows, MetricSpace distance ledgers, RealUp and RegSeqRat endpoint readbacks, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$, seed)

Scope closed: Definition 5835.1, Definition 5835.2, and Definition 5835.3 seed the finite compact route from displayed inverse radii to a UniformModulus consumer.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient completeness, host inverse functions, selected inverse choice, quotient real equality, trichotomy, open-cover compactness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inverse-graph exactness, compact finite-net handoff, finite radius fold, target estimate, transport, replay, provenance, and local naming for BEDC.Derived.UniformInverseModulusUp.

Chapter 5776

A Concrete Naming Certificate for $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$

Following Bishop and Bridges on constructive real intervals, the $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ packet records a bounded interval together with the finite nested-window route used by Real and completion consumers. It sits over the dyadic rational arithmetic of chapter 291, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names a bounded interval principle for displayed nested windows; it does not assert open-cover compactness, a global supremum operator, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5776.1 (BoundedCompleteRealInterval carrier)**.** *A* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded interval row. It records the inspected lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, the boundedness witness visible to the packet, and the local containment predicate for interval windows.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger. It records the dyadic rational cuts used to compare successive windows and to certify the displayed diameter bound.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It lists exactly the finite endpoint and interval observations that may be inspected by the nested-window route.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same dyadic cuts and stream windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by every Real-facing extraction from B, D, W, R.*
6. *H records componentwise* hsame *transport for bounded interval rows, dyadic ledgers, stream windows, regular rational readbacks, Real seals, replay, provenance, and the local name.*
7. *C records displayed* Cont *replay from a nested-window request through B, D, W, R, E.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, D, W, R, E, H, C, P, N$. There is no coordinate for open-cover compactness, a selected supremum, host interval equality, quotient equality of Real names, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedCompleteRealIntervalUp.TasteGate.BoundedCompleteRealIntervalTasteGate single carrier alignment`

Theorem 5776.2 (BoundedCompleteRealInterval NameCert obligations)**.** *For every accepted* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier*

$$I = (B, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded interval row, dyadic endpoint ledger, stream windows, regular rational readback, Real seal, componentwise transport, continuation replay, package provenance, and local naming row;*
2. *bounded-window visibility, requiring every interval read to pass through the displayed lower-upper row B and its local containment predicate;*
3. *dyadic diameter discipline, requiring D to witness the inspected endpoint comparisons and the shrinking-width estimates used by the extraction route;*
4. *stream-readback exactness, requiring W and R to reuse the same finite endpoint observations and dyadic cuts rather than selecting a second Real representative;*
5. *Real-seal nonescape, requiring every Real-facing output to pass through E after B, D, W, R have all been projected;*
6. *structural preservation through H, C, P, N, with no exported row for open-cover compactness, selected suprema, host interval equality, quotient Real equality, countable choice, trichotomy, or ambient Real completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5836.1. The accepted packet displays exactly the bounded interval row, dyadic endpoint ledger, stream windows, regular rational readback, Real seal, and the structural rows.

Bounded-window visibility is forced by B. A consumer can inspect only the finite lower-upper interval data and the local containment predicate already present in the carrier.

Dyadic diameter discipline is forced by D. The endpoint comparisons and shrinking-width estimates used by the packet are the only numerical rows available to the later stream and readback rows.

The rows W and R are downstream of the same dyadic ledger. They schedule finite observations and repack them as regular rational readback without replacing the bounded interval by a second Real representative.

Finally, E, H, C, P, N close the route. The Real seal is reached only after B, D, W, R, while transport, replay, provenance, and naming preserve the same displayed data. Since no excluded coordinate occurs in the carrier, the local NameCert surface has exactly the listed obligations. □

Theorem 5776.3 (BoundedCompleteRealInterval nested-interval extraction)**.** *Let $I = (B, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier. Every nested-window extraction exported by I factors through the finite route*

$$B \longmapsto D \longmapsto W \longmapsto R \longmapsto E$$

before it can inspect transport, replay, provenance, or local naming rows. The extracted Real-facing read is therefore determined by the bounded interval row, the dyadic diameter ledger, the stream windows, and the regular rational readback visible in the packet.

Proof. Begin with a nested-window extraction from I. The carrier gives no source row before the bounded interval row B, so the lower-upper interval data and local containment predicate are inspected first.

The extraction then projects the dyadic ledger D. This fixes the endpoint comparisons and diameter estimates available to the finite window schedule.

Next the extraction passes through W and R. The stream row exposes only the finite endpoint observations allowed by B, D, and the regular rational row repacks those same observations as the readback consumed by the Real seal.

Only after this route has been displayed can the extraction reach E. The remaining rows H, C, P, N preserve, replay, source, and name the same route, so the exported extraction is exhausted by the displayed bounded-window data. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5836.1, Definition 5836.2, and Definition 5836.3 seed the bounded real interval packet over dyadic endpoint ledgers, StreamName windows, RegSeqRat readbacks, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, a global supremum operator, host interval equality, quotient real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-window visibility, dyadic diameter discipline, stream-readback exactness, Real-seal nonescape, structural preservation, and nested-window extraction for BEDC.Derived.BoundedCompleteRealIntervalUp.

Constructive story: A $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ packet is generated from a bounded Real interval row, a DyadicRatCore endpoint ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5777

A Concrete Naming Certificate for $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Mac Lane on functoriality, the $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ packet records the finite BEDC surface where a displayed real-completion request is read functorially through bounded windows rather than through a quotient completion object. It sits over the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the completion-map discipline of chapter 1937. The packet gives downstream completion consumers one named window-functor route before any quotient stream, selected limit, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle is available.

Definition 5777.1 (RealCompletionWindowFunctor carrier)**.** *A* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (W, D, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row naming the source and target observation windows used by the completion request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the source and target windows at the requested precision.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and tolerances.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, D, R have all been displayed.*
5. *F is the functorial map row, read through* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$*, recording how the displayed source window is transported to the displayed target window.*
6. *H records componentwise* hsame *transport for W, D, R, E, F, C, P, N.*
7. *C records displayed* Cont *replay from a completion-window request through W, D, R, E, F, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the nine displayed rows. It has no coordinate for quotient completion classes, selected representatives, host real equality, countable-choice schedules, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealCompletionWindowFunctorUp.RealCompletionWindowFunctorTasteGate single carrier alignment`

Theorem 5777.2 (RealCompletionWindowFunctor NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *carrier*

$$Q = (W, D, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed finite packet* Q*;*
2. *analytic readback order* $W \longmapsto D \longmapsto R \longmapsto E$*;*
3. *functorial map exposure through the row* F *over the same windows and tolerances;*
4. *structural stability through* hsame *transport and displayed* Cont *replay;*
5. *provenance and local naming through* P *and* N*.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5777.1. The accepted packet displays exactly $W, D, R, E, F, H, C, P, N$, so every local NameCert read must be a read of one of those coordinates.

The analytic route is ordered by the displayed rows. The finite StreamName windows W are inspected before the dyadic tolerance ledger D, the regular rational readback R, and the terminal Real seal E.

The functorial row F is attached to the same window and tolerance ledger through $\mathsf{CauchyCompletionFunctoriality}$ Thus a completion consumer receives only the displayed map action on the finite route, not a quotient completion map or a selected representative.

Finally the rows H, C, P, N transport, replay, source, and name the same packet. Since no excluded object occurs as a carrier coordinate, no additional local obligation is available. □

Theorem 5777.3 (RealCompletionWindowFunctor finite route)**.** *Every completion-facing read exported by an accepted* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *carrier factors through the finite route*

$$W \longmapsto D \longmapsto R \longmapsto E \longmapsto F \longmapsto H, C, P, N.$$

Consequently the functorial completion-map row is consumed only after the StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, and Real seal boundary have been displayed inside the same packet.

Proof. Apply Definition 5777.2. Its obligation surface exposes exactly carrier admission, analytic readback order, functorial map exposure, structural stability, provenance, and local naming.

Read the analytic side first. The rows W, D, R, E display the finite observation windows, dyadic tolerance ledger, regular rational readback, and terminal Real seal.

Then read the functorial side through F and the structural rows. The rows H, C, P, N keep that map action attached to the same finite packet. Therefore the completion consumer cannot detach the functorial map from the displayed window route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5777.1, Definition 5777.2, and Definition 5777.3 seed the finite completion-window functor route over StreamName, DyadicRatCore, RegSeqRat, Real, CauchyCompletionFunctoriality, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, full functor laws for all completion objects, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window order, tolerance readback, Real-seal routing, functorial-map exposure, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionWindowFunctorUp.

Constructive story: A $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a terminal Real seal, a CauchyCompletionFunctoriality map row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5778

A Concrete Naming Certificate for $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$

The $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ packet realizes the Real and Completion route of chapter 9238 as finite window-functor data before any completion consumer reads a limit-facing object. It binds the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the displayed completion functor row of chapter 5777. The packet names a finite completion-window functor surface for the Real completeness spine; it does not assert quotient completion equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5778.1 (RealCompletenessWindowFunctor carrier)**.** *A* $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (V, W, D, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *V is the originating Real-completeness request row read from chapter 9238.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row exposed before any regular-rational or Real-seal read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same window request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that consumes W and D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, D, R have been displayed.*
6. *F is the* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *row that packages the finite functorial completion handoff.*
7. *H records componentwise* hsame *transport for $V, W, D, R, E, F, C, P, N$.*
8. *C records displayed* Cont *replay from a Real-completeness request through $V, W, D, R, E, F, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$, $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten rows. It has no coordinate for quotient completion classes, selected representatives, countable-choice schedules, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 5778.2 (RealCompletenessWindowFunctor NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ *carrier*

$$Q = (V, W, D, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission, originating Real-completeness request exposure, StreamName window exposure, DyadicRatCore tolerance exposure, RegSeqRat readback exposure, Real seal exposure, finite completion-window functor exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Carrier admission is projection from Definition 5778.1. The tuple displays exactly $V, W, D, R, E, F, H, C, P, N$ so the local NameCert can inspect only those rows.

The Real-completeness request row V is read before the finite analytic route. The rows W, D, R, E then display StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and the terminal Real seal.

The functorial row F is the only completion-window handoff. It packages the Real-completion functorial read after the displayed analytic route rather than replacing it by a quotient completion object.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded coordinate occurs, no additional local obligation is available. □

Falsifiable prediction: Every accepted $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ read displays $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ seal rows before any completion consumer reads the packet.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchycompletionfunctoriality: $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ is not bijective to any listed sibling because it jointly retains the originating Real-completeness request, finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, Real seal, completion-window functor row, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5778.1 and Definition 5778.2 seed the finite Real-completeness completion-window functor route over StreamName, DyadicRatCore, RegSeqRat, Real, RealCompletionWindowFunctor, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, full Real-completeness proof, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request exposure, finite-window exposure, tolerance exposure, regular readback, Real-seal exposure, completion-window functor exposure, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletenessWindowFunctorUp.

Constructive story: A $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ packet is generated from a Real-completeness request row, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, a RealCompletionWindowFunctor row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5779

A Concrete Naming Certificate for $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ packet records the explicit modulus route by which a bounded compact-real sequence yields inspected subsequence windows before any downstream consumer reads a real cluster seal. It sits over the constructive subsequence packet of chapter 5830, the sibling Bolzano–Weierstrass route of chapter 1254, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite subsequence-modulus carrier for compact-real consumers; it is not an open-cover compactness theorem, not an arbitrary-choice selector, not quotient real equality, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5779.1 (Compact real subsequence modulus carrier)**.** *A* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, S, B, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact real source row, exposing the bounded* $\mathsf{Real}^{\uparrow}$ *sequence request and the compact-metric inspection data visible to the packet.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing exactly the finite source windows inspected by the modulus.*
3. *B is the* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ *and* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *route row, carrying the interval-refinement and subsequence scheduling surface without adding a host compactness principle.*
4. *W is the subsequence-modulus row, recording selected indices, monotonicity, cofinal scheduling, and the finite window assignment for each requested precision.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording radius requests, split budgets, comparison windows, and common-scale data used by the selected windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same selected windows and tolerance ledger.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *cluster seal, visible only after K, S, B, W, D, R have been displayed.*
8. *H records componentwise* hsame *transport for the source, stream windows, route, modulus, tolerance, readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a compact-real subsequence request through source inspection, stream windows, route selection, modulus scheduling, dyadic tolerance accounting, regular rational readback, and the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$, $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, S, B, W, D, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, arbitrary choice, quotient real equality, selected least cluster points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactRealSubsequenceModulusUp.TasteGate.CompactRealSubsequenceModulusTasteGate`
`single carrier alignment`

Theorem 5779.2 (Compact real subsequence modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ *carrier*

$$M = (K, S, B, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}$ *surface consists exactly of compact real source exposure through K, finite stream-window exposure through S, constructive Bolzano–Weierstrass route exposure through B, subsequence-modulus scheduling through W, dyadic tolerance accounting through D, regular rational readback through R, terminal real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5779.1. Its analytic rows are the compact real source K, stream windows S, constructive route B, subsequence modulus W, tolerance ledger D, regular readback R, and real seal E.

The modulus obligation is finite because W records selected indices, monotonicity, cofinal scheduling, and selected windows as packet data. The route row B imports the displayed ConstructiveBolzanoWeierst and $\mathsf{BolzanoWeierstrass}^{\uparrow}$ subsequence construction rather than an ambient compactness theorem.

The readback obligation then passes through D and R. The same selected windows receive the dyadic tolerance budget before they can be read as a $\mathsf{RegSeqRat}^{\uparrow}$ sequence.

Finally E, H, C, P, N seal, transport, replay, source, and name only those rows. Since the carrier contains no open-cover, arbitrary-choice, quotient-equality, selected-least-cluster, or ambient-completeness coordinate, the listed rows exhaust the local certificate surface. □

Theorem 5779.3 (Constructive Bolzano–Weierstrass modulus route)**.** *Every* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ *consumer that reads a compact real subsequence route from an accepted carrier must factor through*

$$\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow},\quad \mathsf{BolzanoWeierstrass}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

The factorization exposes finite source windows, a displayed subsequence-modulus row, dyadic tolerance accounting, regular rational readback, and a terminal real seal; it exports no open-cover compactness, arbitrary-choice selector, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Apply Definition 5779.2. It places the constructive and sibling Bolzano–Weierstrass route row before the modulus row and before any regular rational readback.

The finite windows are exactly the row S, and the selected windows are exactly the row W. Thus any consumer that changes the source window or selected window must leave the displayed carrier.

The dyadic tolerance ledger D is read before R, and R is read before the terminal real seal E. This orders the packet through the stated route and prevents the excluded host principles from entering the subsequence-modulus handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5779.1, Definition 5779.2, and Definition 5779.3 seed the explicit compact-real subsequence-modulus route through finite windows, dyadic tolerances, regular readback, and real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, arbitrary choice, quotient real equality, selected least cluster points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exactness, constructive Bolzano–Weierstrass route exposure, subsequence-modulus scheduling, dyadic tolerance accounting, RegSeqRat readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactRealSubsequenceModulusUp.

Constructive story: A $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ packet is generated from compact real source data, finite StreamName windows, ConstructiveBolzanoWeierstrass and BolzanoWeierstrass route data, subsequence-modulus scheduling, DyadicRatCore tolerance accounting, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Chapter 5780

A Concrete Naming Certificate for MetaCICNormalEndpointComparator$^{\uparrow}$

The MetaCICNormalEndpointComparator$^{\uparrow}$ packet realizes the bounded-conversion endpoint bridge named by the MetaCIC decidability audit map of chapter 9379. It sits between the bounded normal conversion bridge of chapter 3439, the decidable conversion frontier of chapter 4097, the normalization frontier of chapter 892, the normal-form consistency seal of chapter 740, and the critical-path packet of chapter 765. The packet is a finite comparator for finished bounded normal endpoints; it is not a global beta-conversion decider, not a strong-normalization theorem, and not a host equality oracle.

Definition 5780.1 (MetaCIC normal endpoint comparator carrier)**.** *A* MetaCICNormalEndpointComparator$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, L, R, B, F, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed closed-term pair row supplied by the decidable conversion frontier.*
2. *L and R are the left and right bounded-normal computation traces, each carrying fuel, output syntax, and finished-endpoint evidence.*
3. *B is the* BoundedNormalConversionBridge$^{\uparrow}$ *row, exposing the bounded comparison result and its soundness route.*
4. *F is the* MetaCICNormalizationFrontier$^{\uparrow}$ *row, recording that both bounded traces have reached named normal endpoints at the comparator fuel.*
5. *S is the* NormalFormConsistencySeal$^{\uparrow}$ *row, checking that the two endpoint witnesses are read through the same normal-form consistency surface.*
6. *Q is the* MetaCICCriticalPath$^{\uparrow}$ *row that keeps the comparator tied to the decidability and normalization critical path rather than to an unrestricted conversion oracle.*
7. *H records componentwise* hsame *transport for the term pair, endpoint traces, bridge, frontier, seal, critical-path, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a bounded conversion request through endpoint computation, finished-normal evidence, endpoint comparison, consistency sealing, and critical-path accounting.*

9. *P is the* Pkg *provenance over* MetaCICNormalEndpointComparator$^{\uparrow}$, MetaCICDecidableConversionFrontier$^{\uparrow}$, BoundedNormalConversionBridge$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, NormalFormConsistencySeal$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, L, R, B, F, S, Q, H, C, P, N$. It has no coordinate for unrestricted conversion decidability, fuel-erased normalization, strong normalization, proof irrelevance, quotienting of syntax, or host equality.

Theorem 5780.2 (MetaCIC normal endpoint comparator NameCert obligations)**.** *For every accepted* MetaCICNormalEndpointComparator$^{\uparrow}$ *carrier*

$$E = (T, L, R, B, F, S, Q, H, C, P, N),$$

the local NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$ *surface consists exactly of typed closed-term pair admission through T, left and right bounded endpoint traces through L, R, bounded conversion bridge exposure through B, normalization-frontier endpoint evidence through F, normal-form consistency sealing through S, critical-path accounting through Q, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5780.1. The computational rows are exactly the term pair T, the endpoint traces L, R, the bounded conversion bridge B, the normalization frontier F, the consistency seal S, and the critical-path row Q.

The endpoint evidence is finite because L and R carry bounded traces at a displayed fuel. The row F records that those traces have reached finished normal endpoints before the comparator is consumed.

The comparison then passes through B and S. The bridge supplies the bounded conversion handoff, and the seal checks that the endpoint witnesses are compared through the same normal-form consistency surface.

Finally Q, H, C, P, N keep the packet on the MetaCIC critical path, transport it componentwise, replay it, source it, and name it. Since the carrier contains no unrestricted conversion, fuel-erased normalization, strong-normalization, proof-irrelevance, syntax-quotient, or host-equality coordinate, the listed rows exhaust the local certificate surface. □

Theorem 5780.3 (Bounded conversion endpoint handoff)**.** *Every* MetaCICNormalEndpointComparator$^{\uparrow}$ *consumer that promotes bounded conversion evidence to a finished endpoint comparison must factor through*

MetaCICDecidableConversionFrontier$^{\uparrow}$, BoundedNormalConversionBridge$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, No

The handoff supplies only typed closed-term pair data, bounded traces, finished endpoint evidence, endpoint consistency, critical-path accounting, transport, replay, provenance, and local naming.

Proof. Use Definition 5780.2. The typed closed-term pair is read first through T, while L and R record the bounded normal computations to be compared.

The row F is the endpoint boundary: it must be displayed before a bounded comparison can be read as a finished normal-form comparison. The bridge row B and seal row S then compare those endpoints through the bounded-conversion and normal-form consistency surfaces.

The critical-path row Q prevents the handoff from being read as a global conversion theorem. The structural rows H, C, P, N preserve and name only this finite route, so the consumer receives no unrestricted conversion decider or host equality oracle. □

Theorem 5780.4 (Closed-normal comparator vision obligations)**.** *The* MetaCICNormalEndpointComparator$^{\uparrow}$ *packet exposes exactly the finite comparator surface consumed by chapter 9376: closed normal endpoint rows, false-endpoint exclusion rows, and comparator determinacy rows are read through the displayed term pair T, bounded traces L, R, bounded conversion bridge B, normalization frontier F, normal-form consistency seal S, critical-path row Q, componentwise transport H, replay C, provenance P, and local naming N. No consumer of this surface receives unrestricted conversion decidability, fuel-erased normalization, proof irrelevance, syntax quotient equality, or host equality.*

Proof. Project the carrier of Definition 5780.1. The closed normal endpoint rows are precisely the finished bounded traces L, R read together with the normalization-frontier evidence F.

The false-endpoint exclusion row is read through the normal-form consistency seal S and the critical-path row Q. Those rows are the only coordinates tying the finished endpoint comparison to the closed-normal consistency boundary of chapter 9376.

Comparator determinacy is then read through the bounded conversion bridge B over the same typed pair T. The structural rows H, C, P, N transport, replay, source, and name this finite route.

Since the carrier contains no unrestricted conversion decider, fuel-erased normalizer, proof-irrelevance coordinate, syntax quotient, or host equality oracle, the listed rows are the complete comparator obligation surface consumed by the closed-normal consistency route. □

Falsifiable prediction: A MetaCIC conversion consumer that reads a finished endpoint comparison while omitting either bounded endpoint trace, the bounded-normal-conversion bridge, the normalization-frontier endpoint evidence, the normal-form consistency seal, the critical-path row, transport, replay, provenance, or local naming refutes MetaCICNormalEndpointComparator$^{\uparrow}$.

Independence witness: metacic-decidable-conversion-frontier, bounded-normal-conversion-bridge, metacicnormalizationfrontier, normal-form-consistency-seal, metaciccriticalpath: MetaCICNormalEndpointCompara is not bijective to any listed sibling because it jointly carries typed closed-term pair data, two bounded endpoint traces, bounded conversion bridge data, finished-normal endpoint evidence, consistency sealing, critical-path accounting, transport, replay, provenance, and local NameCert rows in one comparator packet.

The Lean follow-up must provide explicit Nontrivial MetaCICNormalEndpointComparator$^{\uparrow}$ and FieldFaithful MetaCICNormalEndpointComparator$^{\uparrow}$ instances in TasteGate.lean for the same finite carrier.

Closure status for NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$, seed)

Scope closed: Definition 5780.1, Definition 5780.2, and Definition 5780.3 seed the finite comparator that hands bounded conversion evidence to finished normal endpoints.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim unrestricted conversion decidability, fuel-erased normalization, strong normalization, proof irrelevance, quotient syntax equality, host equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint trace exactness, bounded bridge exposure, normalization-frontier endpoint evidence, normal-form consistency sealing, critical-path accounting, transport, replay, provenance, local naming, and TasteGate nontriviality with field faithfulness for BEDC.Derived.MetaCICNormalEndpointComparatorUp.

Constructive story: A MetaCICNormalEndpointComparator$^{\uparrow}$ packet is generated from typed closed-term pair data, two bounded endpoint traces, BoundedNormalConversionBridge data, MetaCICNormalizationFrontier endpoint evidence, NormalFormConsistencySeal data, MetaCICCriticalPath accounting, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Chapter 5781

A Concrete Naming Certificate for $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$

Following Riemann and Bishop–Bridges constructive integration, the $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ packet records the finite route by which a continuous function on a located closed real interval receives a Darboux/Riemann integrability certificate. It consumes the pointwise-modulus surface of chapter 59, the tag-bearing finite interval route of chapter 4296, the Darboux upper/lower boundary of chapter 1880, the integrability carrier of chapter 1960, the weak located interval selector of chapter 5834, and the real-name seal of chapter 38. The packet gives integration consumers a finite NameCert surface for continuous functions without importing measure integration, open-cover compactness, quotient equality of real names, selected limiting values, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5781.1 (Continuous Riemann integrability carrier)**.** *A* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, T, D, J, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Continuous}^{\uparrow}$ *row exposing the pointwise modulus and graph-stability data of the integrand over the displayed interval source.*
2. *T is the* $\mathsf{TaggedRealPartition}^{\uparrow}$ *row naming the finite partition cells, tag containment, window reads, regular readbacks, and terminal real seals used for integration.*
3. *D is the* $\mathsf{DarbouxSum}^{\uparrow}$ *row carrying lower and upper finite sums over the same displayed partition route.*
4. *J is the* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff row, read only after the Darboux gap row has been displayed.*
5. *W is the* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *row that exposes located cells and endpoint windows for the closed interval source.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened for interval endpoints, partition tags, and pointwise modulus reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family attached to the same finite windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, T, D, J, W, S, R have been displayed.*

9. *H records componentwise* hsame *transport for the continuous row, tagged partition, Darboux rows, integrability handoff, weak interval selector, window and readback rows, real seal, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from pointwise modulus requests through located cells, finite tagged partitions, Darboux lower/upper rows, the integrability handoff, and the terminal real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, T, D, J, W, S, R, E, H, C, P, N$. It has no coordinate for full integration theory, measure integration, open-cover compactness, quotient equality, selected limits, or ambient real completeness.

Theorem 5781.2 (Continuous Riemann integrability NameCert obligations)**.** *For every accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier*

$$I = (F, T, D, J, W, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the finite* BHist *packet and the displayed rows $F, T, D, J, W, S, R, E, H, C, P, N$;*

2. *interval-source visibility through the weakly located interval row W and its located cell, endpoint-window, and regular-readback route;*

3. *pointwise modulus exposure through the continuous-function row F, with every modulus read tied to displayed interval cells and finite windows;*

4. *finite tagged partition coverage through T, including cell containment, tag containment, and the same* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows;*

5. *Darboux gap control through D, read as finite lower and upper sums over the displayed tagged partition route;*

6. *integrability handoff through J, allowed only after the Darboux gap row and partition coverage rows are visible;*

7. *Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No full integration theory, measure integration, open-cover compactness, quotient equality of real names, selected limiting value, Lean verification, or bridge checking is an obligation or output of this packet.

Proof. Carrier admission is the projection of Definition 5838.1. The accepted packet displays the continuous row, tagged partition, Darboux row, integrability handoff, weak interval selector, window family, regular readback, real seal, transport, replay, provenance, and local name.

The interval and modulus rows are read first. The row W supplies located cells and endpoint windows, while F supplies pointwise modulus data only over those displayed cells and windows.

The finite partition route is then exposed by T. Tags and endpoints are read through S and R, so the integration-facing partition is a finite BEDC object rather than a host partition or a selected representative family.

The Darboux and integrability rows are downstream. The row D computes lower and upper finite sums over the displayed partition route, and J exports integrability evidence only after that gap control is visible.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no coordinate for the excluded analytic objects, the listed rows exhaust the local NameCert surface. □

Theorem 5781.3 (Continuous Riemann integrability Darboux handoff)**.** *Every integration-facing consumer of an accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier factors through the finite partition and Darboux rows*

$$W, F \longmapsto T, S, R \longmapsto D \longmapsto J \longmapsto E, H, C, P, N.$$

Consequently the consumer receives a finite located-cell, pointwise-modulus, tagged-partition, lower/upper Darboux, integrability-handoff, and Real-seal route rather than quotient reals, host equality, choice-selected witnesses, or ambient Real completeness.

Proof. Begin with an integration-facing read. The weak interval selector W and continuous row F force the request through located cells, endpoint windows, and pointwise modulus rows before any partition or sum row can be inspected.

Next read the tagged partition route T, S, R. The finite cells and tags are displayed together with their StreamName windows and RegSeqRat readbacks, so later rows cannot detach the partition from the interval source.

The Darboux row D is then read as lower and upper finite sums over those displayed cells and tags. The integrability row J is therefore a handoff from finite Darboux gap control, not from a quotient real or host equality judgment.

The terminal seal and structural rows E, H, C, P, N preserve that route. No excluded object is stored in the carrier, so every consumer factors through the displayed finite partition and Darboux rows. □

Theorem 5781.4 (Continuous Riemann integrability uniform-modulus handoff)**.** *Every accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier whose continuous row factors through a displayed uniform-modulus or composed-modulus route passes the Darboux gap and* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff through the finite chain*

$$\mathsf{Continuous}^{\uparrow},\ \mathsf{UniformContinuityComposition}^{\uparrow},\ \mathsf{TaggedRealPartition}^{\uparrow},\ \mathsf{DarbouxSum}^{\uparrow},\ \mathsf{RiemannIntegrable}^{\uparrow},\ \mathsf{StreamNar}$$

The handoff therefore reads composed modulus data before the Darboux row and exports no host integral selector, quotient function equality, open-cover compactness argument, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5838.1. The displayed rows are the continuous row F, tagged partition row T, Darboux row D, Riemann-integrable handoff J, weak interval selector W, StreamName windows S, RegSeqRat readbacks R, Real seal E, transport, replay, provenance, and local naming rows.

Use Definition 5838.2 for row exhaustion. When the continuous row is supplied by a uniform-modulus or composed-modulus route, the only admitted modulus source is the displayed $\mathsf{Continuous}^{\uparrow}$ row together with the $\mathsf{UniformContinuityComposition}^{\uparrow}$ composed-modulus handoff of chapter 3891.

Now apply Definition 5838.3. The tagged partition, Darboux lower and upper sums, and integrability row must be read after the same StreamName windows, RegSeqRat readbacks, and terminal Real seal, so the composed-modulus source cannot bypass the finite Darboux route.

Since the carrier stores no host integral selector, quotient function equality, open-cover compactness proof, or ambient completeness object, the listed finite rows are the whole uniform-modulus handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$.

Constructive story: A $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ packet is generated from a Continuous row, TaggedRealPartition row, DarbouxSum row, RiemannIntegrable handoff row, WeaklyLocatedIntervalSelection row, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5838.1, Definition 5838.2, Definition 5838.3, and Definition 5838.4 seed the finite Darboux/Riemann integrability route for continuous functions on located closed real intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full integration theory, measure integration, open-cover compactness, quotient equality, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source visibility, pointwise modulus exposure, finite tagged partition coverage, Darboux gap control, integrability handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ContinuousRiemannIntegrabilityUp.

Chapter 5782

A Concrete Naming Certificate for $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy approximations, the $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ packet binds Cauchy mesh refinement, cofinal dyadic mesh selection, and diagonal Real mesh budgets into one finite common-refinement route. It sits over the two-request refinement carrier of chapter 3832, the cofinal dyadic selector of chapter 2254, the diagonal mesh-budget surface of chapter 618, and the terminal real-name seal of chapter 38. The packet gives Real-completeness consumers a finite cofinal mesh handoff without quotient streams, selected limits, countable choice, host real equality, or ambient completeness as an extra row.

Definition 5782.1 (Regular Cauchy mesh cofinality carrier)**.** *A* $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, R, D, B, S, A, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyMeshRefinement}^{\uparrow}$ *row exposing source Cauchy requests, two displayed dyadic meshes, and their common finite refinement.*
2. *R is the* $\mathsf{CofinalDyadicMesh}^{\uparrow}$ *row refining the incoming observation request to a dyadic mesh window.*
3. *D is the* $\mathsf{RealDiagonalMeshBudget}^{\uparrow}$ *row listing the inspected diagonal indices, selected windows, dyadic tolerances, and aggregation ledger.*
4. *B is the shared budget row aligning the request precision of Q, the cofinal selector depth of R, and the diagonal finite mesh budget of D.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened by the shared budget.*
6. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family over the same windows, with all dyadic tolerances read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, R, D, B, S, A have been displayed.*
8. *H records componentwise* hsame *transport for the refinement row, cofinal selector row, diagonal budget row, shared budget, window and readback rows, seal row, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from an observation request through*

$$Q, R, D \longmapsto B \longmapsto S \longmapsto A \longmapsto E.$$

10. *P is the* Pkg *provenance over* RegularCauchyMeshCofinality$^{\uparrow}$, CauchyMeshRefinement$^{\uparrow}$, CofinalDyadicMesh$^{\uparrow}$, RealDiagonalMeshBudget$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{RegularCauchyMeshCofinality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, R, D, B, S, A, E, H, C, P, N$. It has no coordinate for quotient streams, hidden subnets, selected limits, countable-choice schedules, host real equality, trichotomy, or ambient Real completeness.

Theorem 5782.2 (Regular Cauchy mesh cofinality NameCert obligations)**.** *For every accepted* RegularCauchyMeshCofinality$^{\uparrow}$ *carrier*

$$K = (Q, R, D, B, S, A, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyMeshCofinality}^{\uparrow}}$ *surface consists exactly of carrier admission, Cauchy mesh-refinement exposure through Q, cofinal dyadic mesh exposure through R, Real diagonal mesh-budget exposure through D, shared precision and mesh-budget alignment through B, finite* StreamName$^{\uparrow}$ *window exposure through S,* RegSeqRat$^{\uparrow}$ *readback and* DyadicRatCore$^{\uparrow}$ *tolerance visibility through A, terminal* Real$^{\uparrow}$ *seal admission through E, componentwise transport through H, route replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 5839.1. The accepted packet displays exactly the Cauchy refinement, cofinal selector, diagonal budget, shared budget, windows, readbacks, seal, transports, replay, provenance, and local name.

The three mesh sources are read before any Real-facing seal. The row Q displays the common refinement of source Cauchy meshes, R displays the cofinal dyadic selector for the observation request, and D displays the finite diagonal mesh budget.

The shared row B aligns these sources. It is the only place where the precision request, cofinal selector depth, and diagonal inspected indices meet, so the window row S and regular readback row A inherit one finite route.

The seal and structural rows E, H, C, P, N preserve that route. Since the carrier has no coordinate for the excluded completion objects, the listed rows exhaust the local certificate surface. □

Theorem 5782.3 (Regular Cauchy mesh cofinality Real-completeness handoff)**.** *Every Real-completeness or diagonal-limit consumer of an accepted* RegularCauchyMeshCofinality$^{\uparrow}$ *carrier receives its seal-facing data only through the cofinal finite route*

$$Q, R, D \longmapsto B \longmapsto S \longmapsto A \longmapsto E, H, C, P, N.$$

Thus the consumer factors through Cauchy mesh refinement, cofinal dyadic mesh selection, Real diagonal mesh budgeting, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, and the RealUp seal before any completion-facing conclusion is exported.

Proof. Start from a Real-completeness consumer request. The packet first exposes Q, so the two source Cauchy requests and their common refinement are finite displayed data.

The request then passes through R and D. The cofinal dyadic selector supplies a finite mesh window, while the diagonal mesh-budget row supplies the finite inspected indices and dyadic tolerance ledger.

The budget row B is the common meeting point. It forces the StreamName windows S and RegSeqRat readbacks A to use the same finite refinement and the same dyadic tolerance rows.

Only after this route is displayed may the Real seal E be read. Transport, replay, provenance, and local naming preserve the route, and the excluded quotient or choice-based completion objects are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ packet is generated from CauchyMeshRefinement, CofinalDyadicMesh, RealDiagonalMeshBudget, a shared precision and mesh-budget row, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5839.1, Definition 5839.2, and Definition 5839.3 seed the finite cofinal common-refinement mesh route used by Real-completeness and diagonal-limit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, hidden subnets, selected limits, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy mesh-refinement exposure, cofinal dyadic mesh exposure, Real diagonal mesh-budget exposure, shared-budget alignment, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance visibility, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMeshCofinalityUp.

Chapter 5783

A Concrete Naming Certificate for $\mathsf{OneSidedLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{OneSidedLimit}^{\uparrow}$ packet records the left- and right-hand real-limit interface as finite BEDC data. It sits next to the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation schedule of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet names only displayed side-tagged approach windows, regular rational reads, dyadic tolerance rows, transport, replay, provenance, and a terminal Real seal; it does not import two-sided completeness, host real equality, quotient streams, trichotomy, or a selected limiting point.

Definition 5783.1 (One-sided limit carrier)**.** *A* $\mathsf{OneSidedLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, L, W, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the approach-anchor row, naming the source point or endpoint cell at which the one-sided read is taken.*
2. *L is the side classifier row, with each visible approach window tagged as left-hand or right-hand before any limiting seal is inspected.*
3. *W is the finite approach-window row, listing only windows compatible with the tag in L and the anchor in A.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by the side-tagged windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data observed on S.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the displayed one-sided comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from A, L, W, S, R, D.*
8. *H records componentwise* hsame *transport for the anchor, side classifier, windows, stream schedule, regular readback, dyadic ledger, Real seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from the side-tagged approach windows through the stream, readback, dyadic, and Real-seal rows.*
10. *P is the* Pkg *provenance over* $\mathsf{OneSidedLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $A, L, W, S, R, D, E, H, C, P, N$. It has no coordinate for a two-sided completion theorem, quotient real equality, host order trichotomy, countable choice, or a selected limit outside the named side-tagged windows.

Lean4 ✓ `BEDC.Derived.OneSidedLimitUp.OneSidedLimitTasteGate single carrier alignment`

Theorem 5783.2 (One-sided limit NameCert obligations)**.** *For every accepted* $\mathsf{OneSidedLimit}^{\uparrow}$ *carrier $K = (A, L, W, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the approach anchor, side classifier, approach windows, stream schedule, regular readback, dyadic ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *side classifier stability, requiring each transported window to retain its left-hand or right-hand tag before a readback row is consumed;*
3. *dyadic tolerance ledger exactness, requiring D to expose only the tolerance rows demanded by the side-tagged windows in W;*
4. $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring S and R to read only the finite observations selected by A, L, W;*
5. *Real seal nonescape, requiring E to remain downstream of A, L, W, S, R, D and never to serve as a two-sided completeness witness or host real equality row;*
6. *componentwise transport, replay, provenance, and local naming through H, C, P, N.*

No $\mathsf{OneSidedLimit}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5841.1. The accepted packet displays the approach anchor A, side classifier L, finite approach windows W, stream schedule S, regular readback R, dyadic ledger D, Real seal E, and structural rows H, C, P, N.

Side classifier stability is componentwise. A transported window may be read only with the left-hand or right-hand tag already recorded in L, and the replay row C keeps the same tag attached while the stream and regular-rational rows are inspected.

The tolerance and readback rows are downstream of the same finite windows. The ledger D records the dyadic comparisons demanded by W, the schedule S opens only those observations, and R records the regular rational readback.

Finally, the Real seal E is terminal for the route. Since the carrier contains no row for two-sided completeness, quotient real equality, host order trichotomy, countable choice, or a selected limit outside the displayed windows, those objects cannot become local obligations. □

Theorem 5783.3 (One-sided limit Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{OneSidedLimit}^{\uparrow}$ *packet reads the proposed one-sided limit only through the displayed finite route*

$$A, L, W, S, R, D, E, H, C, P, N.$$

Consequently the handoff to $\mathsf{Real}^{\uparrow}$ *is available only after the approach anchor, side classifier, finite approach windows, StreamName schedule, RegSeqRat readback, and DyadicRatCore tolerance ledger have been exposed. The handoff exports no two-sided completeness theorem, quotient stream equality, host real equality, order trichotomy, countable choice principle, or selected limiting point.*

Proof. Project the accepted carrier through Definition 5841.1. Its Real-facing row is the single terminal coordinate E, and the only route to E passes through A, L, W, S, R, D and the structural rows H, C, P, N.

The finite approach windows determine the side of approach before readback begins. Thus a consumer that asks for a Real seal must already have read the side classifier, the compatible windows, the stream schedule, the regular rational row, and the dyadic tolerance ledger.

The remaining coordinates transport and name the same route. Because no carrier row stores a two-sided completion principle, quotient equality, host equality, trichotomy, choice, or an independent selected limit, the Real-seal handoff cannot export any of those objects. □

Falsifiable prediction: Every $\mathsf{OneSidedLimit}^{\uparrow}$ Real-facing read factors through an approach anchor, a left/right side classifier, finite approach windows, a StreamName schedule, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{OneSidedLimit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a side classifier, finite approach windows, scheduled regular-rational readback, dyadic tolerance data, and a terminal Real seal in one one-sided packet.

Closure status for $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{OneSidedLimit}^{\uparrow}$ packet is generated from an approach anchor, a left/right side classifier, finite approach windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5841.1, Definition 5841.2, and Definition 5841.3 seed the finite one-sided real-limit route through side-tagged approach windows and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.OneSidedLimitUp.OneSidedLimitTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close two-sided real completeness, quotient stream equality, host real equality, trichotomy, countable choice, selected limits outside the displayed windows, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, side classifier stability, dyadic tolerance exactness, StreamName and RegSeqRat readback, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.OneSidedLimitUp.

Chapter 5784

A Concrete Naming Certificate for $\mathsf{BertrandSeriesTest}^{\uparrow}$

Following Bertrand's logarithmic refinement of ratio-type convergence tests and Bishop–Bridges constructive real-series practice, the $\mathsf{BertrandSeriesTest}^{\uparrow}$ packet records the finite second-order quotient-defect route that turns displayed positive-series tail data into a regular Cauchy comparison handoff. It sits beside the neighboring quotient-defect surfaces of chapter 1719, chapter 2113, and chapter 2130, refines the ratio and comparison routes of chapter 1461 and chapter 1459, and exports endpoints only through the dyadic, stream, regular-rational, and Real seals of chapter 291, chapter 126, chapter 301, and chapter 38. The packet names finite Bertrand-test evidence only through inspected source windows, adjacent quotient windows, a logarithmic defect ledger, dyadic domination, comparison-test routing, regular rational readback, and terminal Real sealing; it is not host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 5784.1 (Bertrand series test carrier)**.** *A* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Q, L, D, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source real-series row, exposing only positive-term windows, partial-sum windows, and tail-threshold requests used by the current convergence test.*
2. *Q is the adjacent quotient-window row, recording the inspected neighboring-term quotients on the same displayed tail window.*
3. *L is the logarithmic defect ledger, storing the finite index, logarithmic scale, rational margin, and second-order defect rows used by the Bertrand comparison.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *domination ledger, converting the displayed logarithmic defect and margin rows into a finite majorant or minorant comparison.*
5. *T is the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff row that consumes S, Q, L, D before any convergence conclusion is exposed.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the source, quotient, logarithmic defect, domination, and comparison rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after the comparison handoff and stream windows have been displayed.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint-facing consumers.*
9. *H stores componentwise* hsame *transport for the source, quotient, logarithmic defect, domination, comparison, window, readback, seal, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay from each tail request through Q, L, D, T, W, R, E.*
11. *P is the* Pkg *provenance over* $\mathsf{BertrandSeriesTest}^{\uparrow}$, $\mathsf{RaabeDuhamelTest}^{\uparrow}$, $\mathsf{KummerTest}^{\uparrow}$, $\mathsf{GaussTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, L, D, T, W, R, E, H, C, P, N$. It has no coordinate for host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BertrandSeriesTestUp.BertrandSeriesTestTasteGate single carrier alignment`

Theorem 5784.2 (Bertrand series test NameCert obligations)**.** *For every accepted* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier*

$$B = (S, Q, L, D, T, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source real-series windows, adjacent quotient windows, logarithmic defect ledger, dyadic domination ledger, comparison-test handoff, stream windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming row;*
2. *quotient-window exactness, requiring every quotient read used by the Bertrand defect to be read from the displayed neighboring positive-term windows in S and Q;*
3. *logarithmic-defect stability, requiring the finite index, logarithmic scale, rational margin, and second-order defect rows in L to remain attached to the accepted tail request;*
4. *dyadic domination routing, requiring D and W to convert the displayed logarithmic defect data into the same finite comparison windows consumed by T;*
5. *regular and Real handoff, requiring endpoint-facing data to pass through T, W, R, E in that order before a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives data;*
6. *ledger non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed rows and to exclude host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 5842.1. Carrier admission is exactly the inventory $S, Q, L, D, T, W, R, E, H, C$ so the local certificate has no detached row for an infinite sum, quotient series equality, selected sum, or ambient completeness theorem.

The quotient and logarithmic-defect clauses are read before the comparison handoff. The row S exposes only inspected positive-term and partial-sum windows, the row Q exposes only neighboring-term quotient windows, and L records the finite index, logarithmic scale, rational margin, and second-order defect attached to the current tail request.

The domination route is then forced through D, W, T. The dyadic ledger D converts the displayed logarithmic defect data into comparison evidence, the window row W fixes the finite stream windows, and the comparison-test row T is the only route that may export a regular Cauchy conclusion.

Finally, R and E supply the regular rational and Real-facing endpoint route. The structural rows H, C, P, N preserve, replay, source, and name the same route, so none of them can introduce host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge data. □

Theorem 5784.3 (Bertrand series test tail route)**.** *Every endpoint-facing read of an accepted* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier factors through*

$$\mathsf{RaabeDuhamelTest}^{\uparrow},\ \mathsf{KummerTest}^{\uparrow},\ \mathsf{GaussTest}^{\uparrow},\ \mathsf{RegularCauchyRatioTest}^{\uparrow},\ \mathsf{RegularCauchyComparisonTest}^{\uparrow},\ \mathsf{Dyadic}$$

Concretely, the read consumes source real-series windows and adjacent quotient rows, reads the logarithmic second-order defect ledger, converts that ledger into dyadic domination and stream-window evidence, enters the $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff, and reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *only through the displayed readback and seal rows.*

Proof. Begin with an endpoint-facing read of an accepted carrier. By Definition 5842.1, the only source data available before the defect estimate are the source windows in S and the adjacent quotient windows in Q.

The Bertrand-specific data are then read from L and D. The logarithmic ledger supplies the finite index, logarithmic scale, rational margin, and second-order defect, while the dyadic ledger turns those rows into the domination evidence needed for comparison.

The neighboring quotient-defect tests are reference faces in the same lattice. The Raabe–Duhamel, Kummer, and Gauss packets identify the adjacent first-order and auxiliary defect surfaces, while the ratio route supplies the shared adjacent-quotient discipline. The accepted $\mathsf{BertrandSeriesTest}^{\uparrow}$ endpoint route still has to enter the comparison handoff T.

After T is displayed, the route proceeds through the finite $\mathsf{StreamName}^{\uparrow}$ windows in W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E. The transport, replay, provenance, and naming rows keep the same route, so no host summability, quotient series equality, selected sums, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness can enter. □

Falsifiable prediction: Every accepted $\mathsf{BertrandSeriesTest}^{\uparrow}$ endpoint-facing read factors through source real-series windows, adjacent quotient rows, a logarithmic defect ledger, dyadic domination, a RegularCauchyComparisonTest handoff, StreamName windows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: raabeduhameltest, kummertest, gausstest, regularcauchyratiotest, regularcauchycomparisontest, dyadicratcore, streamname, regseqrat, real: $\mathsf{BertrandSeriesTest}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source series windows, adjacent quotient windows, a logarithmic second-order defect ledger, dyadic domination, comparison-test routing, regular rational readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BertrandSeriesTest}^{\uparrow}$ packet is generated from source real-series windows, adjacent quotient windows, a logarithmic second-order defect ledger, dyadic domination, a RegularCauchyComparisonTest handoff, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5842.1, Definition 5842.2, and Definition 5842.3 seed the finite Bertrand convergence-test boundary over displayed source series, quotient, logarithmic defect, comparison, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier admission, quotient-window exactness, logarithmic-defect stability, dyadic domination routing, regular and Real handoff, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.BertrandSeriesTestUp.

Chapter 5785

A Concrete Naming Certificate for $\mathsf{RationalCanonicalForm}^{\uparrow}$

Following Frobenius and standard linear algebra treatments of finite-dimensional operators, the $\mathsf{RationalCanonicalForm}^{\uparrow}$ packet records the rational canonical form of a displayed finite linear operator as BEDC NameCert data. It consumes the finite matrix rows of chapter 49, the linear-map surface of chapter 48, the polynomial source of chapter 50, the module and vector-space carriers of chapter 46 and chapter 47, and the invariant-factor route supplied by chapter 2262. The packet names only a finite certificate surface for companion-block assembly; it does not assert a host Jordan form theorem, algebraic closure, eigenvalue selection, basis choice outside the displayed rows, or a global classification oracle.

Definition 5785.1 (Rational canonical form carrier)**.** *A* $\mathsf{RationalCanonicalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (V, L, M, S, I, B, A, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *or* $\mathsf{Module}^{\uparrow}$ *source row naming the finite underlying carrier and its scalar action.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row naming the endomorphism whose canonical form is being read.*
3. *M is the* $\mathsf{Mat}^{\uparrow}$ *presentation row for the same endomorphism over the displayed finite basis data already carried by V and L.*
4. *S is the consumed* $\mathsf{SmithNormalForm}^{\uparrow}$ *dependency row applied to the polynomial matrix route attached to M.*
5. *I is the invariant-factor* $\mathsf{Poly}^{\uparrow}$ *row, listing monic polynomial factors with the divisibility ledger exposed by S.*
6. *B is the companion-block row, assembling one finite block for each invariant factor in I and recording the row and column positions used by the assembly.*
7. *A is the block-assembly exactness row, stating that the displayed* $\mathsf{Mat}^{\uparrow}$ *presentation is transported to the companion-block matrix through the same* $\mathsf{LinMap}^{\uparrow}$ *and* $\mathsf{Poly}^{\uparrow}$ *rows.*
8. *H stores componentwise* hsame *transport for the vector or module source, linear map, matrix presentation, Smith-normal dependency, invariant factors, companion blocks, assembly row, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from a canonical-form request through V, L, M, S, I, B, A and back to the same finite operator surface.*
10. *P is the* Pkg *provenance over* $\mathsf{RationalCanonicalForm}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{SmithNormalForm}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$ *row.*

The carrier has no coordinate for selected eigenvalues, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, or a detached canonical-form oracle.

Lean4 ✓ `BEDC.Derived.RationalCanonicalFormUp.TasteGate.RationalCanonicalFormTasteGate single carrier alignment`

Theorem 5785.2 (Rational canonical form NameCert obligations)**.** *For every accepted* $\mathsf{RationalCanonicalForm}^{\uparrow}$ *carrier*

$$F = (V, L, M, S, I, B, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$ *surface consists exactly of finite source admission for V, L, M, Smith-normal dependency routing through S, invariant-factor exposure through I, companion-block assembly through B, block-assembly exactness through A, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5843.1. The algebraic source rows are exactly the vector or module carrier V, the endomorphism row L, the finite matrix presentation M, the Smith-normal dependency row S, the invariant-factor row I, and the companion-block assembly rows B, A.

The invariant factors are not read from a host classification theorem. They are exposed as $\mathsf{Poly}^{\uparrow}$ rows whose divisibility and matrix-reduction dependency is routed through $\mathsf{SmithNormalForm}^{\uparrow}$ before any companion block is assembled.

The companion-block row B is finite because it is indexed by the displayed invariant-factor list I. The exactness row A then compares the assembled block matrix with the original $\mathsf{Mat}^{\uparrow}$ presentation through the same $\mathsf{LinMap}^{\uparrow}$ endpoint and componentwise hsame transport.

Finally H, C, P, N transport, replay, source, and name only this finite route. Since the carrier contains no coordinate for eigenvalue selection, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, or a detached canonical-form oracle, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: A $\mathsf{RationalCanonicalForm}^{\uparrow}$ consumer that exports a canonical-form matrix while omitting the Smith-normal dependency row, invariant-factor polynomial row, companion-block assembly row, componentwise hsame, displayed Cont, Pkg, or local NameCert rows refutes the carrier of Definition 5843.1.

Independence witness: matrix, linearmap, polynomial, module, vecspace, smith-normal-form: $\mathsf{RationalCanonicalForm}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite operator source, matrix presentation, invariant-factor polynomial ledger, Smith-normal dependency, companion-block assembly, exactness row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RationalCanonicalForm}^{\uparrow}$ packet is generated from VecSpaceUp or ModuleUp source data, a LinearMapUp endomorphism row, a MatrixUp presentation, a SmithNormalFormUp dependency route, invariant-factor PolynomialUp rows, companion-block assembly rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RationalCanonicalForm}\uparrow}$, seed)

Scope closed: Definition 5843.1 and Definition 5843.2 seed the finite rational-canonical-form packet over matrix, linear-map, polynomial, module, vector-space, and Smith-normal rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RationalCanonicalForm}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim eigenvalue selection, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, invariant-factor exposure, Smith-normal dependency routing, companion-block assembly, exactness, transport, replay, provenance, and local naming for BEDC.Derived.RationalCanonicalForn

Chapter 5786

A Concrete Naming Certificate for $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$

The $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ packet realizes the Rule 110 pattern-classifier branch of chapter 9390 as finite BEDC NameCert data. It consumes the cellular automaton carrier of chapter 934, the row-classifier surface of chapter 941, the pattern catalog of chapter 995, the local-stencil observation route of chapter 1036, and the Rule 110 glider catalog of chapter 1045. The packet names finite row windows, transition-table reads, orbit prefixes, pattern tags, transport, replay, provenance, and a local NameCert row; it is not a universality theorem, an infinite-orbit classifier, an undecidable continuation oracle, or a hidden substrate semantics.

Definition 5786.1 (Rule 110 pattern classifier carrier)**.** *A* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (W, T, O, G, K, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite row-window row, naming the inspected Rule 110 space-time rectangle and its boundary cells.*
2. *T is the transition-table row, exposing the eight local update cases used to advance the window.*
3. *O is the orbit-prefix row, recording the finite sequence of rows replayed from the initial window by T.*
4. *G is the glider and ether catalog row consumed from* $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$ *and* $\mathsf{CellularPatternCatalog}^{\uparrow}$*.*
5. *K is the classifier-tag row, assigning each inspected subwindow to a displayed ether, glider, collision, boundary, or unknown tag.*
6. *H stores componentwise* hsame *transport for windows, transition-table rows, orbit prefixes, tags, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a classifier request through W, T, O, G, K.*
8. *P is the* Pkg *provenance over* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$*,* $\mathsf{CellularAutomaton}^{\uparrow}$*,* $\mathsf{CellularRowClassifier}^{\uparrow}$*,* $\mathsf{CellularPatternCatalog}^{\uparrow}$*,* $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$*,* $\mathsf{LocalStencilObservation}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$ *row.*

The carrier has no coordinate for infinite continuation, termination of all continuations, host universality, unbounded pattern search, quotient orbit equality, or a substrate semantics outside the displayed rows.

Theorem 5786.2 (Rule 110 pattern classifier NameCert obligations)**.** *For every accepted* RuleOneTenPatternClassif *carrier*

$$R = (W, T, O, G, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$ *surface consists exactly of row-window admission through* W*, transition-table exposure through* T*, orbit-prefix replay through* O*, catalog lookup through* G*, classifier-tag exactness through* K*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier of Definition 5844.1. The finite cellular rows are exactly the inspected window W, transition table T, orbit prefix O, catalog row G, classifier row K, and the structural rows H, C, P, N.

The transition-table row is read before the orbit prefix, so every displayed successor row is justified by the same eight local Rule 110 cases. The classifier tag is then attached to a finite subwindow already present in O and compared against the catalog row G.

The transport and replay rows preserve that order. Since the carrier contains no infinite continuation coordinate, no all-continuations termination field, no unbounded pattern search, no quotient orbit equality, and no host universality proof, the local NameCert obligations are exhausted by the listed finite rows. □

Falsifiable prediction: A $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ classifier read that assigns a glider, ether, collision, boundary, or unknown tag without exposing the finite row window, transition-table row, orbit-prefix row, catalog row, componentwise hsame, displayed Cont, Pkg, and local NameCert rows refutes the carrier of Definition 5844.1.

Independence witness: continuationautomaton, finiteprefixautomaton, continuationtermination, typecheckingmembershiptrace, classifiermorphism: $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Rule 110 row windows, the transition table, orbit prefixes, catalog tags, classifier transport, replay, provenance, and local NameCert rows.

The Lean TasteGate file for this packet must provide Nontrivial $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ and FieldFaithful $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ instances for the displayed rows $W, T, O, G, K, H, C, P, N$ before the classifier can serve as a verified taste-gate consumer.

Closure status for $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ packet is generated from a finite Rule 110 row window, transition table, orbit prefix, pattern catalog, classifier tags, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$, seed)

Scope closed: Definition 5844.1 and Definition 5844.2 seed the finite Rule 110 pattern-classifier packet over row-window, transition-table, orbit-prefix, catalog, tag, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a universality theorem, infinite-orbit classification, continuation termination, unbounded pattern search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked row-window admission, transition-table exposure, orbit-prefix replay, catalog lookup, classifier-tag exactness, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.RuleOneTenPatternClassifierUp.

Chapter 5787

A Concrete Naming Certificate for $\mathsf{ObservabilityGramian}^{\uparrow}$

The $\mathsf{ObservabilityGramian}^{\uparrow}$ interface records the finite observability Gramian packet of a finite-dimensional linear control system. Its textbook source is the finite-horizon observability Gramian in Kalman's control-theoretic duality and the matrix-ledger presentation used by Kailath, Sayed, and Hassibi for linear estimation. The BEDC packet is the finite dual certificate read beside $\mathsf{ReachabilityGramian}^{\uparrow}$ in chapter 455; it is not an ambient analytic observability theorem.

The dependency anchors are the finite observation surface of chapter 294, the reachability dual surface of chapter 297, the matrix rows of chapter 49, the vector-space rows of chapter 47, and the linear-map rows of chapter 48. These anchors force the Gramian to be read as displayed $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{LinMap}^{\uparrow}$ data before a control consumer can compare it with the reachability Gramian.

5787.1 Carrier definition

Definition 5787.1 (ObservabilityGramianUp finite carrier)**.** *An* $\mathsf{ObservabilityGramian}^{\uparrow}$ *carrier is a finite* BHist *packet with rows*

$$(A, C, n, W, L, R, P, N).$$

Here A is the displayed transition-matrix row, C is the displayed output-matrix row, n is a unary finite-horizon row, W is the displayed finite Gramian-sum ledger with summand rows

$$C^{\mathsf{T}}C, \quad A^{\mathsf{T}}C^{\mathsf{T}}CA, \quad (A^{\mathsf{T}})^2C^{\mathsf{T}}CA^2, \quad \ldots, \quad (A^{\mathsf{T}})^{n-1}C^{\mathsf{T}}CA^{n-1},$$

L is the componentwise hsame *transport ledger for the transition, output, horizon, summand, and Gramian endpoint rows, R is the finite dual-readback row comparing W with the observation-matrix rows $C, CA, \ldots, CA^{n-1}$ of* $\mathsf{ControlObservability}^{\uparrow}$*, P is the* Pkg *provenance over* $\mathsf{ObservabilityGramian}^{\uparrow}$*,* $\mathsf{ControlObservability}^{\uparrow}$*,* $\mathsf{ControlControllability}^{\uparrow}$*,* $\mathsf{ReachabilityGramian}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*, and N is the local* $\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by componentwise hsame *transport of the A, C, n, W, L, R, P, N rows. It does not quotient by a host unobservable subspace, analytic trajectory family, Riccati equation, spectral factorization, infinite-horizon Gramian, or external estimator object.*

Lean4 ✓ `BEDC.Derived.ObservabilityGramianUp.ObservabilityGramianTasteGate single carrier alignment`

5787.2 Certificate surface

Theorem 5787.2 (ObservabilityGramianUp NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}$ *obligation surface has exactly five finite rows:*

1. *carrier admission for the displayed* A, C, n, W, L, R, P, N *packet of Definition 5787.1;*
2. *classifier transport under componentwise* hsame *of the transition, output, horizon, Gramian, summand-ledger, dual-readback, package, and local certificate rows;*
3. *finite sum ledger exactness, saying that the Gramian endpoint inside* W *is read only as the finite sum of the displayed adjoint-output summands inside* W*;*
4. *observability handoff, saying that the observation-matrix surface of* $\mathsf{ControlObservability}^{\uparrow}$ *can consume* A*,* C*,* n*,* W*,* L*, and* R *only through the displayed* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* Cont*, and* Pkg *rows;*
5. *dual non-escape, saying that no accepted route exports a host unobservable subspace, analytic output trajectory, Riccati solution, spectral factorization, infinite-horizon Gramian, covariance process, or external estimator.*

Proof. The carrier row is Definition 5787.1. It displays the transition row, output row, unary horizon, Gramian endpoint, summand ledger, transport ledger, dual-readback row, package provenance, and local naming row as finite BHist coordinates.

Classifier transport is componentwise. Replacing each displayed coordinate by an hsame-matched coordinate leaves the same finite packet shape, so the transported packet is again admitted by the carrier.

For finite sum exactness, inspect W. Each summand is a displayed matrix product formed from A, C, and transposes, and the Gramian endpoint is the finite fold of precisely those rows. The readback row R ties that ledger to the observation rows without introducing a host observability theorem.

The observability handoff is a projection to the shared A, C, and n rows, to the finite observation rows of $\mathsf{ControlObservability}^{\uparrow}$, and to the Gramian sum named by W. Because those rows are already packaged with $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{LinMap}^{\uparrow}$ provenance, a downstream observability certificate can read them without importing analytic control-system semantics.

Dual non-escape follows from constructor inspection of the carrier. The packet has no coordinate for a host unobservable subspace, analytic output trajectory, Riccati solution, spectral factorization, infinite-horizon Gramian, covariance process, or external estimator, so none of those objects can be projected by a consumer route. □

Theorem 5787.3 (ObservabilityGramianUp finite dual handoff)**.** *Every* $\mathsf{ControlObservability}^{\uparrow}$*,* $\mathsf{ControlControllability}^{\uparrow}$*, or* $\mathsf{ReachabilityGramian}^{\uparrow}$ *consumer of an accepted* $\mathsf{ObservabilityGramian}^{\uparrow}$ *packet can read only the displayed* A *row,* C *row, unary horizon row* n*, finite Gramian-summand and endpoint row* W*,* hsame *transport ledger* L*, dual-readback row* R*,* Pkg *provenance, and local* NameCert *row of Definition 5787.1. The handoff supplies the finite dual route from observation rows to the reachability-side Gramian ledger, but it supplies no host Kalman decomposition, no analytic trajectory semantics, and no infinite-horizon duality theorem.*

Proof. Project the accepted packet to the rows A, C, n, W, L, R, P, N. The first three rows are the finite control-system coordinates shared with $\mathsf{ControlObservability}^{\uparrow}$, while W records the finite adjoint-output Gramian ledger and L records componentwise transport over those same coordinates.

The dual-readback row R ties the summands in W to the observation rows $C, CA, \ldots, CA^{n-1}$. Thus a $\mathsf{ControlObservability}^{\uparrow}$ consumer reads the packet through the observation matrix surface, and a $\mathsf{ControlControllability}^{\uparrow}$ or $\mathsf{ReachabilityGramian}^{\uparrow}$ consumer reads only the dual comparison route named by the shared package provenance.

The carrier contains no row for a host Kalman decomposition, analytic trajectory semantics, or infinite-horizon duality theorem. Therefore the handoff is exactly the finite BEDC packet projection and does not add a control-theory semantic bridge. □

Theorem 5787.4 (ObservabilityGramianUp ledger non-escape)**.** *Every exported route from an accepted* $\mathsf{ObservabilityGramian}^{\uparrow}$ *packet factors through the finite rows* A, C, n, W, L, R, P, N *of Definition 5787.1. In particular, the packet exports no ambient unobservable subspace, no analytic output trajectory family, no Riccati solution, no spectral factorization, no stochastic covariance process, no infinite-horizon Gramian, and no external numerical estimator.*

Proof. Take an exported consumer route and project the carrier. The available coordinates are exactly the transition row, output row, horizon row, finite Gramian-summand and endpoint row, transport ledger, dual-readback row, package provenance, and local certificate row.

The NameCert obligations account for carrier admission, classifier transport, finite sum exactness, observability handoff, and dual non-escape. Each obligation is stated over those displayed coordinates and is preserved by the stored hsame, Cont, and Pkg rows.

Thus every export factors through the listed finite coordinates. Since the carrier contains no ambient unobservable subspace, analytic output trajectory family, Riccati solution, spectral factorization, stochastic covariance process, infinite-horizon Gramian, or external numerical estimator, no accepted route can supply one downstream. □

Closure status for $\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}$.

Constructive story: An $\mathsf{ObservabilityGramian}^{\uparrow}$ packet is generated from displayed transition and output matrix rows, a unary finite horizon, the finite adjoint-output Gramian summand and endpoint row, componentwise hsame transport ledger, a dual-readback row to the observation-matrix surface, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5787.1, Definition 5787.2, Definition 5787.3, and Definition 5787.4 bind the finite carrier, five-row NameCert surface, dual handoff, and non-escape boundary for observability Gramian packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host unobservable-subspace semantics, analytic output trajectories, Riccati theory, spectral factorization, stochastic covariance, infinite-horizon Gramians, numerical estimators, or a checked Lean certificate.

Upgrade path: Obligation closure requires a Lean carrier encoding and checked finite-ledger theorems for finite sum exactness, dual handoff, and non-escape.

Chapter 5788

A Concrete Naming Certificate for $\mathsf{HelmholtzDecomposition}^{\uparrow}$

Following Helmholtz and Hodge-style decomposition theory, the $\mathsf{HelmholtzDecomposition}^{\uparrow}$ packet records the finite BEDC surface by which a displayed vector-field row is read as the sum of a gradient-potential row and a divergence-free row over a Hilbert source. It consumes the Hilbert carrier of chapter 91, the vector-space operations of chapter 47, the linear-map rows of chapter 48, and the projection-theorem surface of chapter 2374. The packet names only the displayed analytic decomposition route; it does not assert PDE solvability, global boundary regularity, unique gauges, Sobolev completeness, or a host Hodge theorem.

Definition 5788.1 (Helmholtz decomposition carrier)**.** *A* $\mathsf{HelmholtzDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (H, V, G, D, O, B, T, C, P, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row. It supplies the ambient inner-product and norm-facing carrier on which the vector field and both components are read.*
2. *V is the vector-field row. It records the admitted field endpoint together with the* $\mathsf{VecSpace}^{\uparrow}$ *addition, subtraction, and scalar rows used to state the splitting.*
3. *G is the gradient-potential row. It names a potential window and the displayed* $\mathsf{LinMap}^{\uparrow}$ *route that reads its gradient as a vector-field component.*
4. *D is the divergence-free row. It records the classifier saying that the second component lies in the displayed kernel row selected by the divergence operator.*
5. *O is the orthogonal-projection row. It reads the gradient component and the divergence-free component through the projection-theorem surface of chapter 2374.*
6. *B is the boundary ledger. It records exactly which boundary observations are available before a projection or divergence-free read is exposed.*
7. *T records componentwise* hsame *transport for the Hilbert source, vector field, gradient-potential row, divergence-free row, projection row, boundary ledger, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a Helmholtz-decomposition request through $H, V, G, D, O, B, T, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{HelmholtzDecomposition}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, OrthogonalProjectionThec BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $H, V, G, D, O, B, T, C, P, N$. It has no coordinate for a host PDE solution operator, selected gauge, ambient Sobolev space, hidden boundary regularity theorem, quotient vector-field equality, or unrestricted Hodge decomposition.

Lean4 ✓ `BEDC.Derived.HelmholtzDecompositionUp.HelmholtzDecompositionTasteGate single carrier alignment`

Theorem 5788.2 (Helmholtz decomposition NameCert obligations)**.** *For every accepted* $\mathsf{HelmholtzDecomposition}^{\uparrow}$ *carrier $K = (H, V, G, D, O, B, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}^{\uparrow}}$ *surface consists exactly of the following finite obligation families:*

1. *Hilbert-source admission for the displayed* $\mathsf{Hilbert}^{\uparrow}$ *row H;*
2. *vector-field admission for the field endpoint and* $\mathsf{VecSpace}^{\uparrow}$ *operations stored in V;*
3. *gradient-potential admission for the potential window and* $\mathsf{LinMap}^{\uparrow}$ *gradient route stored in G;*
4. *divergence-free admission for the kernel classifier stored in D;*
5. *orthogonal-projection admission for the projection row O over the gradient and divergence-free components;*
6. *boundary-ledger admission for the displayed boundary observations stored in B;*
7. *componentwise transport, displayed replay, provenance, and local naming through T, C, P, N.*

Consequently a downstream PDE, variational, or Hodge-facing consumer may read Helmholtz data only through the displayed Hilbert, vector-space, linear-map, projection, boundary, transport, replay, provenance, and local naming rows. The packet exports no host PDE solver, gauge selector, Sobolev-completion theorem, quotient vector-field equality, or unrestricted Hodge decomposition.

Proof. Project the carrier of Definition 5788.1. The visible analytic rows are the Hilbert source H, the vector-field row V, the gradient-potential row G, the divergence-free row D, the orthogonal-projection row O, and the boundary ledger B.

The source and algebraic rows are read first. The Hilbert row comes from chapter 91, while V supplies the vector operations inherited from chapter 47. Thus the decomposition statement is formed only inside a displayed carrier.

Next the two component rows are exposed. The gradient-potential row G factors its gradient read through the linear-map surface of chapter 48, and the divergence-free row D supplies the displayed kernel classifier before any splitting conclusion is available.

The projection and boundary rows then bind the route. The row O reads the orthogonal splitting discipline through chapter 2374, while B restricts the boundary observations available to that read.

Finally T, C, P, N transport, replay, source, and name the same displayed rows. Since no excluded analytic object is a coordinate of K, the listed obligation families exhaust the local NameCert surface. □

Theorem 5788.3 (Helmholtz decomposition orthogonal splitting route)**.** *Every splitting read accepted from a* $\mathsf{HelmholtzDecomposition}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Hilbert}^{\uparrow} \longmapsto \mathsf{VecSpace}^{\uparrow} \longmapsto \mathsf{LinMap}^{\uparrow} \longmapsto \mathsf{OrthogonalProjectionTheorem}^{\uparrow} \longmapsto \mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}^{\uparrow}}.$$

The exported surface is a displayed field row together with a gradient-potential component, a divergence-free component, an orthogonal projection ledger, and a boundary ledger. It does not provide a global PDE solution operator, a selected gauge, Sobolev regularity, quotient equality of vector fields, or the full Hodge decomposition theorem.

Proof. Start from an accepted packet $K = (H, V, G, D, O, B, T, C, P, N)$. A consumer first opens the Hilbert row H, so every norm, orthogonality, and projection read remains attached to the same displayed source.

The vector-space row V then supplies the algebra needed to read the field as the sum of two displayed components. This step uses only the finite operations exposed by chapter 47.

The gradient-potential component is read through G and the linear-map surface of chapter 48. The divergence-free component is read through D, whose kernel classifier is already part of the packet.

The orthogonal splitting claim is finally routed through O and the projection-theorem packet of chapter 2374. The boundary ledger B records the available boundary observations before the local name N is exposed.

Transport and replay through T and C preserve this order, while P records the provenance of the same finite route. No host solver, gauge selector, Sobolev regularity theorem, quotient equality, or unrestricted Hodge theorem is introduced. □

Closure status for $\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5788.1, Definition 5788.2, and Definition 5788.3 seed the finite Helmholtz decomposition packet over Hilbert, vector-space, linear-map, projection, boundary, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HelmholtzDecompositionUp.HelmholtzDecompositionTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim PDE solvability, global gauges, Sobolev regularity, quotient vector-field equality, unrestricted Hodge decomposition, or bridge checking.

Upgrade path: Obligation closure asks for checked Hilbert-source admission, vector-field admission, gradient-potential admission, divergence-free admission, orthogonal-projection admission, boundary-ledger admission, transport, replay, provenance, and local naming for BEDC.Derived.HelmholtzDecompositionUp.

Constructive story: A $\mathsf{HelmholtzDecomposition}^{\uparrow}$ packet is generated from a displayed Hilbert source, a vector-field row, a gradient-potential row read through LinearMapUp, a divergence-free kernel row, an orthogonal-projection row, a boundary ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5789

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet records the separated completion boundary needed by the L10 Real and Completion route as finite BEDC data. It sits after the separation predicate of chapter 1925, the separated-completion carrier of chapter 1612, the metric completion route of chapter 1506, the finite stream interface of chapter 126, the dyadic tolerance core of chapter 291, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the envelope through displayed rows only; it does not quotient filters, select representatives, identify host equalities, invoke countable choice, or import ambient completeness.

Definition 5789.1 (Hausdorff completion envelope carrier)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (H, S, M, W, D, R, L, T, K, P, N)$$

where H *is the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$ *separation row,* S *is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* L *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal,* T *is componentwise* $\mathsf{BHist/hsame}$ *transport,* K *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *row. A consumer of* E *receives a separated completion boundary only through these coordinates.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeTasteGate single carrier alignment`

Theorem 5789.2 (Hausdorff completion envelope obligations)**.** *Every accepted* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *read must expose the carrier of Definition 5789.1 in the order*

$$H, S, M, W, D, R, L, T, K, P, N.$$

The separation row H *and separated-completion row* S *are available before metric completion, stream observation, dyadic tolerance, regular readback, and real-seal rows are consumed; the transport, replay, provenance, and naming rows preserve the same displayed packet.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeNameCertObligations`

Proof. Project the carrier of Definition 5789.1. The packet has no completion-facing coordinates except $H, S, M, W, D, R, L, T, K, P, N$.

The Hausdorff and separated-completion rows are the first boundary data in the packet. Thus a consumer cannot inspect the metric completion route, finite stream windows, dyadic tolerances, regular readback, or terminal real seal without first reading the displayed separation surface.

Finally, the structural rows T, K, P, N only transport, replay, source, and name the same finite packet. They do not create quotient filters, selected representatives, host equality, choice-selected routes, or ambient completeness. □

Theorem 5789.3 (Hausdorff completion separated metric route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier factors through the separated route*

$$H, S \longmapsto M \longmapsto W, D, R, L.$$

The route records a separated metric-completion boundary for the L10 Real and Completion interface, not a quotient completion, a host equality theorem, a choice-selected representative, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier separated metric route`

Proof. Start from Definition 5789.2. It places the Hausdorff row H and separated-completion row S before the metric completion row M and before the stream, dyadic, regular-rational, and real-seal rows.

Read the metric completion route through M. Since M is downstream of H, S, every completion-facing use of M carries the displayed separated boundary with it.

The final Real-facing read is the finite route W, D, R, L. Because these rows are still coordinates of the same carrier, the route cannot be replaced by quotient representatives, host equality, countable choice, or ambient completeness. □

Theorem 5789.4 (Hausdorff completion envelope sibling route)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *consumer may hand its separated boundary to* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *only through the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$*,* $\mathsf{SeparatedCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows of*

$$E = (H, S, M, W, D, R, L, T, K, P, N).$$

The handoff contains no quotient-filter coordinate, representative-selection coordinate, host-equality coordinate, or ambient-completeness coordinate.

Proof. Apply Definition 5789.2. It places the Hausdorff row H, separated-completion row S, metric-completion row M, stream row W, dyadic row D, regular-rational row R, and terminal Real row L inside one displayed packet.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

The sibling $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ consumer therefore reads the same separated boundary as its input surface rather than receiving a separate primitive. Since the carrier only has the displayed rows and the structural rows T, K, P, N, quotient filters, selected representatives, host equality, and ambient completeness remain outside the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier sibling route`

Theorem 5789.5 (Hausdorff completion envelope Cauchy-net consumer link)**.** *Every* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier must read the same* $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before its directed-net completion route is consumed. The downstream sibling is chapter 3794, and the handoff is the displayed route*

$$H, S, M, W, D, R, L \longmapsto \mathsf{CauchyNetCompletion}^{\uparrow}.$$

It exports no quotient net, selected representative, host equality, countable-choice schedule, or ambient completeness coordinate.

Proof. Project the carrier $E = (H, S, M, W, D, R, L, T, K, P, N)$ of Definition 5789.1. The only completion-facing rows available to a consumer are the Hausdorff row H, separated-completion row S, metric-completion route M, finite stream row W, dyadic tolerance row D, regular readback row R, and terminal Real row L.

Apply Definition 5789.2. It places H, S, M, W, D, R, L inside one displayed packet before the structural rows T, K, P, N are used for transport, replay, provenance, and local naming.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

Therefore a downstream $\mathsf{CauchyNetCompletion}^{\uparrow}$ read can only consume the envelope through the same separated metric route before its directed-net completion surface is inspected. Since the packet has no quotient-net, selected-representative, host-equality, countable-choice, or ambient-completeness row, none of those objects can enter the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeForwardLink`

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5789.1, Definition 5789.2, and Definition 5789.3 name the separated completion envelope surface for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, host equality, choice-selected representatives, or ambient completeness.

Upgrade path: Obligation closure requires the carrier route to be tied to the sibling completion obligation theorems and then exposed as a public chapter surface.

Constructive story: A $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet is generated from Hausdorff separation, separated-completion boundary, metric-completion route, finite stream windows, dyadic tolerance, regular-rational readback, Real seal, transport, replay, provenance, and local NameCert rows.

Chapter 5790

A Concrete Naming Certificate for $\mathsf{BoundedLinearFunctional}^{\uparrow}$

Following Banach and Bourbaki functional analysis, the $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet records the scalar-valued bounded-linear-operator row that duality and weak-star consumers inspect before any host dual space is available. It sits over the linear-map route of chapter 48, the bounded-linear-operator surface of chapter 1644, the scalar-bound neighbour chapter 3603, the Banach-dual row of chapter 2265, the finite weak-star window of chapter 3420, the scalar endpoint seal of chapter 38, and the normed source surface of chapter 1950. The chapter names only displayed scalar-functional data: source rows, linearity rows, scalar target readback, norm-bound evidence, transport, replay, provenance, and local naming.

Definition 5790.1 (Bounded linear functional carrier)**.** *For a displayed* $\mathsf{NormedSpace}^{\uparrow}$ *source row* E *over the scalar endpoint surface of* $\mathsf{Real}^{\uparrow}$*, a* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E)$ *carrier is a finite* BHist *packet*

$$\Lambda = (E, L, T, K, O, H, C, P, N)$$

with the following displayed rows:

1. *E is the source normed-space row, including its carrier endpoints, scalar action, additive row, norm row, and classifier.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row from E to the scalar* $\mathsf{Real}^{\uparrow}$ *target.*
3. *T is the scalar-valued* $\mathsf{BoundedLinearOperator}^{\uparrow}(E, \mathsf{Real}^{\uparrow})$ *row carrying the same endpoint action as L.*
4. *K is the* $\mathsf{Real}^{\uparrow}$ *nonnegative bound endpoint for the functional.*
5. *O is the* $\mathsf{OperatorNorm}^{\uparrow}$ *handoff row exposing where the bound K is used.*
6. *H records componentwise* hsame *transport for the source, linear-map row, bounded-operator row, scalar bound, operator-norm handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a scalar-functional request through E, L, T, K, O, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedLinearFunctional}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{BanachDual}^{\uparrow}$, $\mathsf{BanachAlaoglu}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed source classifier, scalar endpoint transport, bounded-operator transport, bound transport, norm-bound ledger transport, replay, provenance, and local naming rows. It has no coordinate for a host dual space, quotient equality of functions, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BoundedLinearFunctionalUp.BoundedLinearFunctionalTasteGate single carrier alignment`

Theorem 5790.2 (Bounded linear functional NameCert obligations)**.** *For every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *carrier* $\Lambda = (E, L, T, K, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *surface consists exactly of source normed-space admission, linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from host dual objects. A consumer may inspect* $E, L, T, K, O, H, C, P, N$*, but it receives no ambient function space, quotient operator equality, selected representative, Hahn–Banach witness, unrestricted weak-star compactness theorem, or bridge data.*

Proof. Project the carrier rows. The analytic coordinates are exactly the source normed-space row E, the linear-map row L, the scalar-valued bounded-operator row T, the RealUp bound endpoint K, and the operator-norm handoff O.

The linearity obligation is read through $\mathsf{LinMap}^{\uparrow}$, while boundedness is read through $\mathsf{BoundedLinearOperator}^{\uparrow}(E,$ The scalar target is already the displayed $\mathsf{Real}^{\uparrow}$ endpoint surface, so the functional row never becomes a host-level function.

The bound exactness is the shared route through K and O. The operator-norm handoff records where the scalar bound is used, and componentwise hsame transport moves the source, action, bound, ledger, replay, provenance, and local naming rows together.

No remaining coordinate can manufacture a dual-space quotient, selected representative, Hahn–Banach witness, unrestricted compactness theorem, or bridge check. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 5790.3 (Bounded linear functional operator-norm handoff)**.** *Every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E$ *packet exports the finite route*

$$\mathsf{LinMap}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{OperatorNorm}^{\uparrow} \longmapsto \mathsf{BoundedLinearFunctional}^{\uparrow}$$

to functional-analysis consumers. The route first exposes the carried scalar-valued linear action, then the bounded-operator row, then the RealUp bound endpoint and operator-norm ledger; it does not expose a host supremum, quotient equality of functionals, selected norm-attaining vector, or hidden Banach completeness.

Proof. Begin with an accepted packet $\Lambda = (E, L, T, K, O, H, C, P, N)$. The read of L supplies only the displayed linear-map action from the source row to the scalar target.

The read of T then packages the same action as a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row. Its target row is $\mathsf{Real}^{\uparrow}$, and its bound endpoint is the displayed scalar K.

Finally the operator-norm handoff O records the norm-bound ledger that downstream consumers may inspect. Because no host norm function, quotient functional equality, selected vector, or hidden completion row is present, the exported handoff is exactly the displayed scalar-bound route. □

Theorem 5790.4 (Bounded linear functional dual-row nonescape)**.** *Any read of a* $\mathsf{BanachDual}^{\uparrow}$ *or* $\mathsf{BanachAlaoglu}^{\uparrow}$ *consumer that uses a* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *row factors through the same source normed-space row, scalar-valued bounded-operator row, RealUp bound endpoint, operator-norm handoff, componentwise transport, replay, provenance, and local naming rows of Definition 5790.1. The duality consumer receives a finite scalar-functional row, not a host dual space, a quotient function class, an unrestricted weak-star compactness theorem, or a selected cluster point.*

Proof. Read the duality consumer first. A $\mathsf{BanachDual}^{\uparrow}$ request needs a scalar-functional row over a displayed source, while a $\mathsf{BanachAlaoglu}^{\uparrow}$ request needs a finite family of such scalar-functional observations.

In either case the only scalar-functional packet available here is Λ. Its source row, bounded-operator row, bound endpoint, operator-norm handoff, and structural rows are projected in the order displayed by Definition 5790.1.

The downstream dual chapters may reuse those rows, but they cannot add coordinates that are absent from the packet. Thus quotient dual objects, host function classes, unrestricted weak-star compactness, selected cluster points, and bridge checks remain outside the read. □

Falsifiable prediction: Every accepted $\mathsf{BoundedLinearFunctional}^{\uparrow}$ scalar-functional read factors through a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ action row, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, and the local hsame, Cont, Pkg, and NameCert rows.

Independence witness: linearmap, boundedlinearoperator, operatornorm, banachdual, banachalaoglu, real, and normedspace: no listed sibling is bijective to $\mathsf{BoundedLinearFunctional}^{\uparrow}$ because this packet stores the scalar target restriction, the dual-facing provenance row, the operator-norm handoff, transport, replay, and local naming together as one finite scalar-functional surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet is generated from a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ scalar action, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5790.1, Definition 5790.2, Definition 5790.3, and Definition 5790.4 seed the scalar-functional row consumed by BanachDualUp and BanachAlaogluUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host dual spaces, quotient equality of functionals, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, scalar linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm handoff exactness, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BoundedLinearFunctionalUp.

Chapter 5791

A Concrete Naming Certificate for $\mathsf{CompletionModulusCategory}^{\uparrow}$

Following Bishop and Bridges on constructive completion and the functorial treatment of completions, the $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet records the finite category surface whose arrows preserve displayed completion moduli. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the completion functor of chapter 426, and the Cauchy completion functor of chapter 423. The packet names modulus-preserving completion morphisms as BEDC rows; it does not export quotient completions, selected representatives, host continuous maps, countable choice, or ambient completeness.

Definition 5791.1 (CompletionModulusCategory carrier)**.** *A* $\mathsf{CompletionModulusCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, A, S, R, D, E, F, H, C, P, N)$$

with the following displayed rows:

1. *O is the object ledger. Each object row records a completion-facing source, its displayed Cauchy-modulus discipline, and the local completion target read through the surrounding completion chapters.*
2. *A is the arrow ledger. Each arrow row records a finite morphism request together with the modulus transformation that sends source tolerances to target tolerances.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source and target names of an arrow.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the stream windows have been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare source and target moduli.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row read only after S, R, D have supplied the displayed tolerance route.*
7. *F records identity and composition rows for the completion functoriality surface, with identity arrows preserving the same modulus and composite arrows composing the displayed modulus transformations.*
8. *H records componentwise* hsame *transport for object rows, arrow rows, stream windows, regular readback, dyadic tolerances, Real seals, functoriality rows, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an arrow request through $O, A, S, R, D, E, F, H, P, N$.*
10. *P is the* Pkg *provenance over* CompletionModulusCategory$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, CauchyCompletionFunctor$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{CompletionModulusCategory}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite category packet for modulus-preserving completion morphisms. It has no coordinate for quotient completion points, selected representatives, host functions, global choice schedules, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryTasteGate single carrier alignment`

Theorem 5791.2 (CompletionModulusCategory NameCert obligations)**.** *For every accepted* CompletionModulusCa *carrier $M = (O, A, S, R, D, E, F, H, C, P, N)$, the local* NameCert$_{\text{CompletionModulusCategory}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed object ledger, arrow ledger, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, identity and composition rows, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface additionally requires each arrow row in A to expose its source modulus, target modulus, and modulus transformation before any Real$^{\uparrow}$*-facing read is accepted; each identity row in F to preserve the displayed modulus without adding a choice coordinate; and each composition row in F to compose the two displayed modulus transformations before the downstream seal is visible.*

Proof. Project the accepted carrier. The packet contains only the rows $O, A, S, R, D, E, F, H, C, P, N$, so carrier admission and ledger exhaustion are componentwise.

An arrow-facing request first reads the object and arrow ledgers O, A. The source and target names are then inspected through the finite stream windows S, regular rational readback R, and dyadic tolerance ledger D.

The functoriality rows F are local to the same displayed moduli. Identity preserves the stored modulus transformation, and composition combines the two stored transformations before the terminal seal E can be read.

Finally H, C, P, N transport, replay, source, and name this same finite route. Since quotient completions, selected representatives, host functions, global choice schedules, and ambient completeness are not carrier coordinates, they cannot be exported by the local NameCert. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryNameCertObligations`

Theorem 5791.3 (CompletionModulusCategory modulus functoriality)**.** *Every completion-facing consumer of an accepted* CompletionModulusCategory$^{\uparrow}$ *packet reads a modulus-preserving morphism through the finite route*

$$O, A, S, R, D, F, E, H, C, P, N.$$

Thus identity and composition of completion morphisms preserve the displayed modulus data before any Real$^{\uparrow}$ *seal or completion-functor read is exposed. The route factors through* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, CompletionFunctor$^{\uparrow}$, *and* CauchyCompletionFunctor$^{\uparrow}$ *rather than through quotient completion equality, selected representatives, host continuous maps, countable choice, or ambient completeness.*

Proof. Start with a completion-facing morphism request. The object ledger O fixes the source and target completion rows, and the arrow ledger A fixes the modulus transformation to be checked.

The readback rows S, R, D display the inspected stream windows, regular rational observations, and dyadic tolerance comparisons. These rows are the only route by which the requested modulus can face the terminal Real seal.

The functoriality row F then supplies the identity or composition clause. In the identity case the same displayed modulus is replayed. In the composition case the two displayed modulus transformations are composed as finite rows before the result is handed to E.

The structural rows H, C, P, N preserve and name the same route. Therefore every completion-functor consumer receives finite modulus preservation data and no excluded quotient, selection, host-map, choice, or ambient-completeness surface. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryModulusFunctoriality`

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}$.

Constructive story: A $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet is generated from completion object rows, modulus-preserving arrow rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, RealUp seals, identity and composition rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5791.1, Definition 5791.2, and Definition 5791.3 seed the finite category surface for modulus-preserving completion morphisms.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host continuous maps, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-preserving arrow exactness, identity and composition rows, tolerance readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionModulusCategoryUp.

Chapter 5792

A Concrete Naming Certificate for $\mathsf{MarkovTriggerDynamics}^{\uparrow}$

The $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet realizes the finite rank-trigger dynamics of Definition 9462.1541, Definition 9462.1542, and Definition 9462.1546 as BEDC NameCert data. It records the state, support-rank, transition-count, drift, trigger-time, classifier, continuation, provenance, and naming rows needed by a downstream finite-dynamics consumer. The packet is a finite BHist surface for trigger-time readback; it is not a stochastic process on an ambient probability space, not an infinite sample path, not a hidden field model, and not a host Markov-chain object.

Definition 5792.1 (MarkovTriggerDynamics carrier)**.** *A* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, K, A, D, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite state row. It records the consumed external-codon count m and the covered support rank r for the current trigger state.*
2. *K is the support-rank row. It records the finite support coordinates currently covered by the observed codon rows and the rank read from that support.*
3. *A is the transition-count row. It stores the finite count of rank-preserving and rank-increasing next draws available from the current state.*
4. *D is the drift row. It records the displayed one-step rank drift computed from the same transition counts.*
5. *G is the trigger-time row. It records the finite recursion for the time to reach full rank and the deterministic threshold row consumed by trigger-time readers.*
6. *H records componentwise* hsame *transport for state, support-rank, transition-count, drift, trigger-time, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a state read through S, K, A, D, G, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$, BHist, hsame, Cont, *finite rank-trigger rows, finite transition-count rows, finite trigger-time rows, and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient probability space, hidden generator field, infinite sample path, external random oracle, host Markov-chain semantics, or unstated independence assumption.

Lean4 ✓ `BEDC.Derived.MarkovTriggerDynamicsUp.MarkovTriggerDynamicsTasteGate single carrier alignment`

Theorem 5792.2 (MarkovTriggerDynamics NameCert obligations)**.** *For every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier* $T = (S, K, A, D, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed state row, support-rank row, transition-count row, drift row, trigger-time row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface requires the transition-count row A *to be computed from the finite support-rank row* K*, the drift row* D *to read only the transition counts in* A*, and the trigger-time row* G *to replay the finite recursion from the displayed state row* S *without adding an external probability carrier.*

Proof. Project the accepted carrier. The packet exposes only $S, K, A, D, G, H, C, P, N$, so every NameCert obligation is a componentwise obligation on those rows.

The state and support rows S, K determine the finite rank-trigger situation. The transition-count row A counts rank-preserving and rank-increasing next draws from that finite support surface.

The drift row D is downstream of A, and the trigger-time row G is downstream of the same state and transition-count data. Thus the trigger-time read is a finite recursion over displayed rows, not an imported Markov-chain object.

Transport, replay, provenance, and local naming preserve the same coordinates. Since the excluded ambient and hidden objects are not coordinates of T, no consumer can read them from the packet. □

Theorem 5792.3 (MarkovTriggerDynamics finite trigger readback)**.** *Every trigger-time consumer of an accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *packet reads the finite route*

$$S, K, A, D, G, H, C, P, N.$$

Consequently the transition law, drift, and trigger-time rows are all determined by finite BHist transition-count data. No trigger-time read exports an infinite sample path, host Markov process, hidden field, or unstated independence source.

Proof. Start with the state row S and support-rank row K. They display the finite input state and the rank information that determines which next-draw counts are available.

The transition-count row A is the only row from which the drift row D may be read. The trigger-time row G then replays the finite recursion from those same transition counts.

Finally H, C, P, N transport, replay, source, and name the finite trigger route. Because no other row exists in the carrier, the stated nonescape clauses follow. □

Falsifiable prediction: Every $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ trigger-time read factors through finite state, support-rank, transition-count, drift, trigger-time, hsame, Cont, Pkg, and NameCert rows.

Independence witness: dna-boundary-tile, rank-trigger, finite-markov-transition: $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries state rows, support-rank rows, transition-count rows, drift rows, trigger-time rows, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Theorem 5792.4 (MarkovTriggerDynamics sibling dependency route)**.** *Every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *trigger-time read routes its finite state and transition-count rows through chapter 189 or chapter 4074 when the carrier is read as a Markov surface, through chapter 195 when it is read as finite transition evolution, and through chapter 3508 for the DNA boundary-trigger consumer.*

Proof. Project the existing carrier rows $S, K, A, D, G, H, C, P, N$. The state row S, support-rank row K, and transition-count row A provide exactly the finite Markov read, so a Markov-surface consumer reaches this packet through the Markov-chain or finite Markov-partition certificates.

The same rows, together with drift row D and trigger-time row G, form the finite transition-evolution route consumed by the dynamical-system certificate. The structural rows H, C, P, N then transport, replay, source, and name that route for the DNA boundary-trigger consumer.

This is a dependency route only. It does not add an ambient probability space, infinite sample path, unstated independence source, or host Markov-chain object to the carrier. □

Nontrivial TasteGate and FieldFaithful instances remain required before this finite trigger surface can be read as a checked biological field-faithfulness claim.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet is generated from finite state rows, support-rank rows, transition-count rows, drift rows, trigger-time recursion rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5792.1, Definition 5792.2, and Definition 5792.3 seed the finite rank-trigger Markov readback surface for DNA boundary-tile dynamics.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient probability spaces, infinite sample paths, hidden field models, host Markov-chain semantics, biological field-faithfulness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-count exactness, drift readback, trigger-time recursion, nontrivial TasteGate coverage, FieldFaithful evidence, transport, replay, provenance, and local naming for BEDC.Derived.MarkovTriggerDynamicsUp.

Chapter 5793

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet records the finite constructive route from regular Cauchy rational names to located completion data and then to the terminal $\mathsf{Real}^{\uparrow}$ seal. It reads the dyadic arithmetic surface of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the completion service exposed by chapter 128, and the real-name boundary of chapter 38. The packet supplies a located completion neighbour for the regular-Cauchy real route without asserting quotient completion equality, selected representatives, host order completeness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5793.1 (Regular Cauchy located completion carrier)**.** *A* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, Q, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the Cauchy name is inspected at requested precision scales.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for tolerance comparison, shrinkage, and rational distance estimates.*
4. *Q is the located completion row, recording the displayed located-distance and approximation data extracted from S, R, D.*
5. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row used only as a finite completion handoff for the displayed located data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback and located completion rows have been displayed.*
7. *H records componentwise* hsame *transport for stream windows, regular rational readbacks, dyadic arithmetic, located completion data, completion service, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a located-completion request through $S, R, D, Q, K, E, H, P, N$.*

9. *P is the* Pkg *provenance over* RegularCauchyLocatedCompletion$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RegularCauchyLocatedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, K, E, H, C, P, N$. The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host order completeness, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedCompletionUp.RegularCauchyLocatedCompletionTasteGate`
`single carrier alignment`

Theorem 5793.2 (Regular Cauchy located completion obligations)**.** *For every accepted* RegularCauchyLocatedCom *carrier*

$$L = (S, R, D, Q, K, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyLocatedCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream-window row, regular rational readback row, dyadic arithmetic ledger, located completion row, complete-metric handoff, real seal, transport, replay, provenance, and local name;*
2. *window-readback coherence, requiring S to expose the finite inspection windows before R may be consumed as a regular rational name;*
3. *dyadic locatedness, requiring D to supply the tolerance comparisons and distance estimates used by the located completion row Q;*
4. *completion handoff ordering, requiring Q to be displayed before the* CompleteMetric$^{\uparrow}$ *row K is exposed;*
5. *real-seal ordering, requiring E to be read only after S, R, D, Q, K have been displayed;*
6. *classifier stability, requiring componentwise* hsame *transport and displayed* Cont *replay to preserve all visible rows;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no quotient completion equality, selected representative, countable choice, host order completeness, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5793.1. Its rows list the finite stream windows, regular rational readback, dyadic arithmetic ledger, located completion data, complete-metric handoff, real seal, and the structural rows.

Window-readback coherence follows because R has no independent observation coordinate in this packet. The regular rational read must pass through S, and the tolerance computations used by that read are then checked against the dyadic row D.

The located completion row Q is the only row that records located-distance data. The completion handoff K consumes that displayed row, and the real seal E is exposed only after the handoff has been displayed.

Transport, replay, provenance, and local naming are exhausted by H, C, P, N. Since quotient completion equality, selected representatives, countable choice, host order completeness, and ambient Real$^{\uparrow}$ completeness are absent from the carrier, no NameCert obligation can export them. □

Theorem 5793.3 (Regular Cauchy located completion Real seal route)**.** *Let* $L = (S, R, D, Q, K, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the located completion read factors through the finite route*

$$S, R, D \longmapsto Q \longmapsto K \longmapsto E \longmapsto H, C, P, N.$$

Thus the packet reaches the real-name boundary only through displayed $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic, located completion data, and the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff. It does not export quotient completion equality, selected representatives, countable choice, host order completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing read of the packet. The only observable name data are the stream windows S and the regular rational readback R, so any request for a real seal must first inspect those rows.

The dyadic row D supplies the tolerance and distance comparisons used by the located completion data Q. The complete-metric handoff K is then read as a service row for that displayed located data, not as an ambient completeness theorem.

Finally the seal row E exposes the $\mathsf{Real}^{\uparrow}$ boundary, and H, C, P, N transport, replay, source, and name the same displayed route. No remaining carrier coordinate can provide quotient completion equality, selected representatives, choice data, host order completeness, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5793.1, Definition 5793.2, and Definition 5793.3 seed a finite route from regular Cauchy names through located completion data to the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host order completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback coherence, dyadic locatedness, completion handoff ordering, real-seal ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLocatedCompletionU

Constructive story: A $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore arithmetic, located completion data, a CompleteMetric handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5794

A Concrete Naming Certificate for $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$

Following Banach, Picard, and Bishop–Bridges constructive analysis, the $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet records the finite handoff from an explicit contraction estimate to the Cauchy threshold consumed by the regular-rational and real endpoint routes. It sits between the Banach fixed-point modulus packet of chapter 4188, the Picard iteration and error-estimate packets of chapter 2359 and chapter 2233, and the regular Cauchy completion boundary of chapter 5793. The packet gives the endpoint route a single displayed Cauchy-threshold surface without selecting a fixed point, quotienting completion names, or importing ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5794.1 (Picard threshold Cauchy handoff carrier)**.** *A* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, I, E, M, R, K, S, T, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BanachFixedPointModulus}^{\uparrow}$ *source row whose contraction-rate route has already exposed the rational Lipschitz and finite Picard ledgers.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *ledger of adjacent iterate windows and replay order.*
3. *E is the* $\mathsf{PicardErrorEstimate}^{\uparrow}$ *row, carrying the residual-and-ratio estimate used to bound the Picard tail.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row produced from B, I, E for each requested dyadic or rational tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row made available only after the threshold row M has been displayed.*
6. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row consumed at the handoff boundary, not an ambient completeness theorem.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, R, K have been read.*
8. *T stores componentwise* hsame *transports for the Banach-modulus, Picard-iteration, error-estimate, Cauchy-threshold, regular-rational, complete-metric, real-seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from the contraction-rate request through $B, I, E, M, R, K, S, T, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$, $\mathsf{BanachFixedPointModulus}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{PicardErrorEstimate}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, I, E, M, R, K, S, T, C, P, N$. It has no coordinate for a selected fixed point, host fixed-point equality, quotient completion equality, detached Cauchy selector, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.PicardThresholdCauchyHandoffUp.PicardThresholdCauchyHandoffTasteGate`
`single carrier alignment`

Theorem 5794.2 (Picard threshold Cauchy handoff NameCert obligations)**.** *For every accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier $H = (B, I, E, M, R, K, S, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyH}}$ *surface consists exactly of carrier admission for the displayed rows; Banach-modulus source visibility through B; Picard-iteration visibility through I; error-estimate visibility through E; Cauchy-threshold construction through M; regular-rational readback through R; complete-metric service access through K; real seal access through S; classifier stability through T and C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 5794.1. The accepted packet exposes exactly the Banach-modulus source row, the Picard-iteration ledger, the error-estimate row, the Cauchy-threshold row, the regular-rational readback, the complete-metric service, the real seal, and the structural rows.

The threshold rows are ordered. The rows B, I, E must be displayed before M can answer a tolerance request, since M is the only coordinate that records the finite Cauchy threshold.

The endpoint rows are downstream. The row R reads the threshold as regular rational data, K is the visible complete-metric service row, and S is exposed only after those rows have been displayed. Transport, replay, provenance, and local naming are exhausted by T, C, P, N, so no further NameCert obligation is present. □

Theorem 5794.3 (Picard threshold Cauchy handoff Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing endpoint read of an accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{BanachFixedPointModulus}^{\uparrow},\ \mathsf{PicardIteration}^{\uparrow},\ \mathsf{PicardErrorEstimate}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Complete}$$

Thus the real seal is reached only after the explicit Picard threshold has been displayed as a $\mathsf{CauchyModulus}^{\uparrow}$ *row and repacked through the regular-rational and complete-metric handoff rows. The route exports no selected fixed point, quotient completion equality, detached Cauchy selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing endpoint request. The only contraction-rate source row is B, and its Picard data are refined in the visible rows I and E, so the request first reads those rows.

The threshold stage is forced by M. Apply the Banach fixed-point modulus route of Definition 4188.3 together with the Picard iteration surface of chapter 2359 and the error-estimate surface of chapter 2233. These sources supply the displayed threshold row without adding a selected endpoint.

After M is fixed, the readback and completion rows R and K expose the regular-rational and complete-metric boundary used by chapter 301 and chapter 128. The seal row S is then the only $\mathsf{Real}^{\uparrow}$ coordinate, and the structural rows T, C, P, N preserve the same route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5794.1, Definition 5794.2, and Definition 5794.3 seed the finite Picard-threshold handoff from BanachFixedPointModulus, PicardIteration, and PicardErrorEstimate rows to CauchyModulus, RegSeqRat, CompleteMetric, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, host fixed-point equality, quotient completion equality, detached Cauchy selectors, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard-threshold construction, regular-rational readback, complete-metric service access, real-seal ordering, classifier stability, provenance, and local naming for BEDC.Derived.PicardThreshol

Constructive story: A $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet is generated from a BanachFixedPointModulus source row, PicardIteration ledger, PicardErrorEstimate row, CauchyModulus threshold, RegSeqRat readback, CompleteMetric service row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5795

A Concrete Naming Certificate for $\mathsf{DiniUniformLimitModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the classical Dini theorem, the $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet extracts the finite uniform-modulus ledger visible in compact-metric monotone convergence data. It sits over chapter 2196, chapter 1436, chapter 129, chapter 130, chapter 463, chapter 369, chapter 301, and chapter 38. The packet names the finite net, rational tolerance budget, and extracted modulus route; it does not import open-cover compactness, chosen limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5795.1 (Dini uniform-limit modulus carrier)**.** *A* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row naming the compact-metric finite-source observations consumed by the extraction.*
2. *F is the monotone* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, recording the displayed continuous approximants and their pointwise monotone order.*
3. *W is the pointwise window row supplied by the Dini-continuity and Dini-uniform-convergence routes.*
4. *E is the finite net row over K, naming the finite mesh on which pointwise windows are inspected.*
5. *Q is the rational tolerance-budget row, storing the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerances assigned to the finite net and to the later readback.*
6. *U is the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row, obtained from E, Q, W and the monotone continuous family row F.*
7. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row, exposing only the modulus-controlled limit route supplied by U.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance transport.*
9. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row, naming the real-valued read without adding ambient real completeness.*

13. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, W, E, Q, U, L, R, S, H, C, P, N$. It has no coordinate for open-cover compactness, selected limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiniUniformLimitModulusUp.TasteGate.DiniUniformLimitModulusTasteGate`
`single carrier alignment`

Theorem 5795.2 (Dini uniform-limit modulus NameCert obligations)**.** *For every accepted* DiniUniformLimitModulu *carrier*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact-metric source, monotone continuous family, pointwise window, finite net, rational tolerance budget, extracted uniform modulus, UniformLimit handoff, RegSeqRat readback, Real seal, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires monotone-window visibility through F and W, finite-net extraction through E and Q, modulus handoff through U and L, Real-seal nonescape through S, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses open-cover compactness, selected limiting values, quotient function equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only computational rows are the compact-metric source K, monotone family F, pointwise windows W, finite net E, rational budget Q, extracted modulus U, uniform-limit handoff L, rational readback R, and real seal S.

The monotone-window step is local to F and W. The finite-net step is local to E and Q, so the modulus row U is extracted from displayed finite data rather than from an open cover or a choice of limiting values.

The handoff to $\mathsf{UniformLimit}^{\uparrow}$ passes only through U and L. The rational and real readback rows R and S name the downstream values without adding quotient function equality or ambient completeness.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded objects are not coordinates of D, no NameCert consumer can read them from this carrier. □

Falsifiable prediction: Every accepted $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ read must expose compact-metric source rows, monotone continuous-family rows, pointwise window rows, a finite net, a rational tolerance budget, an extracted uniform modulus, a UniformLimit handoff, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dini-continuity, diniuniformconvergence, compactmetric, continuousmap, uniformlimit, uniformmodulus, regseqrat, real: $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ is not bijective to any

listed sibling because it binds the finite net and rational tolerance budget to an extracted uniform-modulus handoff before UniformLimit and Real consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5795.1 and Definition 5795.2 seed the finite uniform-modulus ledger extracted from compact-metric monotone convergence data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limiting values, quotient function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window visibility, finite-net extraction, modulus handoff, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniUniformLimitModulusUp.

Constructive story: A $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet is generated from compact-metric source rows, monotone continuous-family rows, pointwise windows, finite net rows, rational tolerance-budget rows, extracted uniform-modulus rows, UniformLimit handoff rows, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5796

A Concrete Naming Certificate for $\mathsf{SummationByParts}^{\uparrow}$

Following Abel and Dirichlet, the $\mathsf{SummationByParts}^{\uparrow}$ packet records the finite identity surface by which displayed partial sums, coefficient windows, adjacent differences, and endpoint terms are bound into one NameCert row. It sits beside the Abel-summation route of chapter 1763, the Abel-test consumer of chapter 1496, and the Dirichlet-test consumer of chapter 1497. Its source rows use the finite series carrier of chapter 121; its regular readback, dyadic tolerance, and endpoint seal use chapter 301, chapter 291, and chapter 38. The packet names a finite algebraic identity for downstream convergence tests; it does not import infinite sums, quotient series equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5796.1 (Summation by parts carrier)**.** *A* $\mathsf{SummationByParts}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Series}^{\uparrow}$ *source row, exposing only the inspected finite term window and its displayed partial sums.*
2. *A is the coefficient-window row, naming the coefficient entries read over the same finite interval.*
3. *Δ is the adjacent-difference row, recording the displayed values $a_k - a_{k+1}$ used by the identity.*
4. *P is the partial-sum-window row, naming the cumulative sums paired with A and Δ.*
5. *B is the boundary-term row, displaying the endpoint products and the finite interior products determined by S, A, Δ, P.*
6. *T is the convergence-test handoff row consumed by* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$.
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed finite identity data.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the finite additions, subtractions, products, and endpoint comparisons used by B.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after $S, A, \Delta, P, B, T, R, D$ have been displayed.*
10. *H records componentwise* hsame *transport for the source, coefficient, difference, partial-sum, boundary, handoff, readback, dyadic, endpoint, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the route*

$$S, A, \Delta, P, B, T, R, D \longmapsto E.$$

12. *Q is the* Pkg *provenance over* $\mathsf{SummationByParts}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$. It has no coordinate for an infinite sum, quotient series equality, selected convergence witness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SummationByPartsUp.SummationByPartsTasteGate single carrier alignment`

Theorem 5796.2 (Summation by parts NameCert obligations)**.** *For every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *carrier*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet; source and partial-sum exposure through S and P; coefficient-window and adjacent-difference exposure through A and Δ; boundary-term exactness through B; convergence-test handoff through T; regular readback, dyadic accounting, and endpoint sealing through R, D, E; and transport, replay, provenance, and local naming through H, C, Q, N.*

Proof. Project the accepted carrier. The projection exposes exactly the rows $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$, so every naming obligation must be read from one of those displayed coordinates.

The identity rows are finite. The source row S and partial-sum row P display the inspected cumulative sums, the coefficient row A displays the paired coefficients, and Δ displays the adjacent differences used by the interior terms. The boundary row B records only the endpoint products and interior products determined by those rows.

The consumer handoff is downstream of the identity. A convergence-test consumer first reads T, and the regular and real-facing route then passes through R, D, E. These rows can transport the displayed finite calculation, but they do not introduce an independent summation principle.

Finally H, C, Q, N preserve, replay, source, and name the same route. Because the carrier has no coordinate for infinite sums, quotient series equality, selected convergence witnesses, countable choice, trichotomy, or ambient real completeness, the stated rows exhaust the local NameCert surface. □

Theorem 5796.3 (Summation by parts Cauchy-series handoff)**.** *Every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *packet that is consumed by an* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$ *route hands off only the finite identity chain*

$$\mathsf{Series}^{\uparrow} \longmapsto S, A, \Delta, P, B, T \longmapsto R, D, E, H, C, Q, N.$$

Thus a Cauchy-series or real-seal consumer may read the summation-by-parts row only after the series window, coefficient window, adjacent-difference ledger, partial-sum window, boundary ledger, and test handoff have been displayed. The handoff supplies no infinite sum, quotient series equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a convergence-test read. Carrier admission exposes the source row S and the finite identity rows A, Δ, P, B before the handoff row T is available.

The downstream chapters may add their own test-specific rows. The $\mathsf{AbelSummation}^{\uparrow}$ consumer reads the displayed finite identity as its transform row, the $\mathsf{AbelTest}^{\uparrow}$ consumer combines it with a monotone null coefficient ledger, and the $\mathsf{DirichletTest}^{\uparrow}$ consumer combines it with bounded partial sums and a null-tail schedule. In each case the summation-by-parts contribution remains the same displayed finite packet.

The Cauchy-facing route is therefore forced through R and D before E can seal the endpoint. Transport, replay, provenance, and local naming preserve that same route, so no excluded summation or completeness datum can be read from the packet. □

Falsifiable prediction: An accepted $\mathsf{SummationByParts}^{\uparrow}$ consumer that reaches an $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without reading the displayed source, coefficient, adjacent-difference, partial-sum, boundary-term, and handoff rows refutes the carrier surface.

Independence witness: abel-summation, abel-test, dirichlet-test, series, regseqrat, dyadicratcore, real: no listed sibling supplies the whole thirteen-row packet $K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$, because each sibling contributes only a transform consumer, convergence-test consumer, source series, regular readback, dyadic ledger, or endpoint seal while this chapter binds the finite identity itself.

Closure status for $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$.

Constructive story: A $\mathsf{SummationByParts}^{\uparrow}$ packet is generated from a SeriesUp finite source row, coefficient windows, adjacent-difference rows, partial-sum windows, boundary-term ledgers, AbelSummation/AbelTest/DirichletTest handoff rows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$, seed)

Scope closed: Definition 5796.1, Definition 5796.2, and Definition 5796.3 seed the finite summation-by-parts identity packet over $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite summation, quotient series equality, selected convergence witnesses, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite identity exactness, convergence-test handoff, Cauchy-series readback, dyadic accounting, endpoint sealing, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.SummationByPartsUp.

Chapter 5797

A Concrete Naming Certificate for $\mathsf{RealLineOrder}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealLineOrder}^{\uparrow}$ packet records the constructive real-line order and apartness boundary visible to finite BEDC NameCert consumers. It sits over the dyadic tolerance ledger of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the rational Cauchy completion route of chapter 3670, and the Bishop regular Cauchy limit seal of chapter 1821. The packet gives L10 consumers a located comparison interface before any real-order algebra can read it; it does not import trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5797.1 (Real line order carrier)**.** *A* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D, S, R, L, A, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the positive dyadic radius used by every finite comparison request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing only the finite stream observations inspected at that tolerance.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream windows into regular rational comparison data.*
4. *L is the located comparison row, recording the finite verdict surface for $x < y$ as a witnessed positive gap at the displayed tolerance, an unresolved window requiring a smaller displayed tolerance, or a symmetric failure of the current request.*
5. *A is the apartness row, recording positive-gap readback for $x \# y$ only through D, S, R, L.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same displayed stream and regular-rational data, not from host real equality.*
7. *H records componentwise* hsame *transport for dyadic tolerance, stream windows, regular-rational readback, located comparison, apartness, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite order request through $D, S, R, L, A, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, L, A, E, H, C, P, N$. It has no coordinate for trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderTasteGate single carrier alignment`

Theorem 5797.2 (Real line order NameCert obligations)**.** *For every accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier*

$$O = (D, S, R, L, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance row, stream-window row, regular-rational readback row, located comparison row, apartness row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise transport row, replay row, provenance row, and local naming row.*

The obligation surface requires finite tolerance visibility through D, window visibility through S, regular-rational comparison readback through R, located order exposure through L, apartness exposure through A, real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier of Definition 5797.1. The only analytic rows are the dyadic tolerance D, the finite stream windows S, the regular-rational readback R, the located comparison row L, the apartness row A, and the terminal real seal E.

The comparison step is located rather than trichotomic. A finite request may display a positive gap, request a smaller displayed tolerance, or fail symmetrically at the current window; none of these outcomes supplies a global three-way case split.

The equality-sensitive routes are absent. The readback row R is regular-rational data over the displayed windows, and the seal row E is reached only after D, S, R, L, A have been inspected. Thus the packet refuses quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded principles are not coordinates of O, no local NameCert obligation can demand them. □

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderNameCertObligations`

Theorem 5797.3 (Real line order apartness readback)**.** *Every apartness read exported by an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The apartness row A may expose only a positive-gap witness already visible through D, S, R, L. It exports no trichotomy datum, quotient equality, selected representative, host real equality, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Proof. Start with an apartness request. The request must first choose a displayed positive dyadic tolerance in D and inspect the finite windows in S.

The regular-rational readback R is then the only comparison source. The located comparison row L reads this finite data and either displays a positive gap at the requested tolerance or leaves the request unresolved for a smaller displayed tolerance.

The apartness row A can cite only the positive-gap branch already exposed by L. It refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$ because those objects are not carrier rows.

The terminal seal E preserves the same finite route into $\mathsf{Real}^{\uparrow}$. Transport and replay through H and C keep the route stable, while P and N only record provenance and local naming. □

Theorem 5797.4 (Real line order L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier must read the dyadic tolerance, stream-window, regular-rational readback, located comparison, apartness, and* $\mathsf{Real}^{\uparrow}$ *seal rows in the order*

$$D, S, R, L, A, E.$$

Consequently the handoff supplies a finite non-quotient comparison boundary for later real algebra and order packets, while refusing trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. An L10 order request begins with finite tolerance data. The row D fixes the displayed dyadic radius, and S opens only the stream windows inspected at that radius.

The row R repacks those windows as regular-rational readback. The located comparison row L can then answer only with the finite comparison surface generated from D, S, R.

Apartness is downstream of located comparison. The row A may expose a positive gap only when L has already displayed one, and E seals the same finite route as a $\mathsf{Real}^{\uparrow}$-facing endpoint.

Because no earlier or later row stores trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$, the L10 handoff cannot export those principles to later consumers. □

Falsifiable prediction: Every accepted $\mathsf{RealLineOrder}^{\uparrow}$ read must expose dyadic tolerance, StreamName windows, RegSeqRat readback, located comparison, apartness, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before an L10 order consumer can read a comparison boundary.

Independence witness: dyadicratcore, streamname, regseqrat, real, rational-cauchy-completion, bishop-regular-cauchy-limit-seal: $\mathsf{RealLineOrder}^{\uparrow}$ is not bijective to any listed sibling because it binds located comparison and apartness rows to the finite readback route before the RealUp seal is available.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5797.1, Definition 5797.2, Definition 5797.3, and Definition 5797.4 seed the finite non-quotient order and apartness boundary for displayed RealUp names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient equality, selected representatives, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite tolerance visibility, stream-window visibility, regular-rational readback, located comparison, apartness readback, RealUp seal handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.RealLineOrderUp.

Constructive story: A $\mathsf{RealLineOrder}^{\uparrow}$ packet is generated from a DyadicRatCoreUp tolerance row, StreamName finite windows, RegSeqRat readback, located comparison, apartness, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5798

A Concrete Naming Certificate for $\mathsf{SchwartzKernel}^{\uparrow}$

Following Schwartz and Gelfand–Shilov, the $\mathsf{SchwartzKernel}^{\uparrow}$ packet records the finite NameCert route by which a distribution kernel is read as a bilinear action between Schwartz test probes and tempered-distribution endpoints. It sits over the Schwartz-function carrier of chapter 3399, the tempered-distribution endpoint of chapter 2310, the nuclear factorization row of chapter 215, the projective tensor norm route of chapter 4088, the tensor-product source of chapter 87, and the real seal of chapter 38. The chapter exposes the kernel theorem as finite action, tensor, nuclearity, bound, transport, replay, provenance, and local naming rows; it does not import a host distribution space, quotient test-function equality, selected representatives, or an unrestricted topological-vector-space oracle.

Definition 5798.1 (Schwartz kernel carrier)**.** *A* $\mathsf{SchwartzKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, U, J, B, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SchwartzFunction}^{\uparrow}$ *test-probe row naming the finite seminorm windows inspected on the source side.*
2. *T is the* $\mathsf{TemperedDistribution}^{\uparrow}$ *endpoint row naming the distributional action read after the test windows are displayed.*
3. *U is the* $\mathsf{TensorProduct}^{\uparrow}$ *row naming the finite tensor source on which the two test-probe sides are paired.*
4. *J is the* ***??*** *row recording the projective-tensor bound used to compare the paired test windows.*
5. *B is the* $\mathsf{Nuclear}^{\uparrow}$ *factorization row, exposing the finite nuclear decomposition route by which the kernel action is read.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed scalar bounds and kernel-action readbacks.*
7. *H records componentwise* hsame *transport for test probes, tempered endpoint, tensor source, projective bound, nuclear factorization, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite kernel request through $S, T, U, J, B, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SchwartzKernel}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{Nuclear}^{\uparrow}$, ***??***, $\mathsf{TensorProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $S, T, U, J, B, R, H, C, P, N$. It has no coordinate for a host distribution space, quotient equality of test functions, selected representatives, ambient bornological completeness, or a topological-vector-space theorem outside the displayed rows.

Lean4 ✓ `BEDC.Derived.SchwartzKernelUp.SchwartzKernelTasteGate single carrier alignment`

Theorem 5798.2 (Schwartz kernel NameCert obligations)**.** *For every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *carrier*

$$K = (S, T, U, J, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *surface consists exactly of Schwartz test-probe admission through S, tempered-distribution endpoint admission through T, tensor-source admission through U, projective-bound exposure through J, nuclear-factorization exposure through B, scalar RealUp sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every kernel consumer must read the distributional action through these ten rows. No consumer may replace them by an ambient kernel theorem, quotient test-function equality, selected representative, hidden topological vector space, or host nuclear-space completion.

Proof. Project the accepted carrier of Definition 5798.1. The analytic rows are the Schwartz test row S, the tempered-distribution endpoint T, the tensor source U, the projective bound J, the nuclear factorization B, and the RealUp seal R.

The action route is finite. The tensor row U supplies the paired test-probe source, J records the displayed projective bound, and B records the nuclear factorization by which the kernel action becomes readable by a finite consumer.

Transport and replay do not create new analytic structure. The rows H and C preserve the displayed packet componentwise and replay only the same kernel request. The provenance and naming rows P, N package the route without adding host quotient equality or a hidden completion theorem.

Thus the listed rows are exactly the local NameCert obligations for $\mathsf{SchwartzKernel}^\uparrow$. □

Theorem 5798.3 (Schwartz kernel nuclear factorization boundary)**.** *Every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *read factors through the finite route*

$$\mathsf{SchwartzFunction}^\uparrow,\ \mathsf{TensorProduct}^\uparrow,\ ??,\ \mathsf{Nuclear}^\uparrow \longmapsto \mathsf{TemperedDistribution}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The nuclear row may expose only the displayed factorization and bound data already routed through S, U, J. It exports no host theorem identifying all kernels with all continuous bilinear forms, no quotient equality of test probes, no selected representative of a distribution, and no ambient completeness claim for the surrounding function spaces.

Proof. Start with a kernel read. The request first displays the finite Schwartz windows in S and the tensor source U on which the two test-probe sides are paired.

The projective tensor bound J is the only bound row available to the consumer. The nuclear factorization row B can cite only this displayed tensor-bound route, so its readback is a finite factorization certificate rather than an ambient nuclear-space theorem.

The tempered-distribution endpoint T then reads the resulting action, and R seals the scalar outputs as RealUp data. Transport through H and replay through C keep the same row order, while P and N record source and local naming.

Since no carrier coordinate stores host quotient equality, selected representatives, or ambient completeness, those principles cannot be exported by the factorization boundary. □

Falsifiable prediction: Every accepted $\mathsf{SchwartzKernel}^{\uparrow}$ packet must expose SchwartzFunctionUp test probes, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, TemperedDistributionUp endpoint action, RealUp scalar sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a kernel consumer can read the action.

Independence witness: schwartz-function, tempered-distribution, nuclear, projective-tensor-norm, tensorproduct, real: $\mathsf{SchwartzKernel}^{\uparrow}$ is not bijective to any listed sibling because it binds the test-probe tensor route, nuclear factorization boundary, distribution endpoint, and scalar seal as one finite kernel-action packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{SchwartzKernel}^{\uparrow}$ packet is generated from SchwartzFunctionUp test probes, a TemperedDistributionUp endpoint, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, RealUp scalar seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5798.1, Definition 5798.2, Definition 5798.3, the falsifiable prediction, and the independence witness seed the finite kernel-action route over Schwartz, tempered-distribution, tensor, nuclear, bound, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host distribution-space semantics, quotient equality of test functions, selected distribution representatives, ambient nuclear-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, test-probe visibility, tensor-source admission, projective-bound exactness, nuclear-factorization exposure, tempered-endpoint action, RealUp scalar sealing, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SchwartzKernelUp.

Chapter 5799

A Concrete Naming Certificate for $\mathsf{SynonymousTransition}^{\uparrow}$

The $\mathsf{SynonymousTransition}^{\uparrow}$ packet realizes the finite synonymous-transition geometry of Definition 9462.1186 as BEDC NameCert data. It sits beside the six-bit codon-window carrier of chapter 2234, the codon transition matrix of chapter 2245, the DNA boundary-tile packet of chapter 3393, the window-coverage trigger algebra of chapter 3478, and the DNA-window trigger threshold of chapter 4217. The packet names finite codon-window, class-adjacency, boundary-spectrum, threshold, transport, replay, provenance, and local naming rows; it is not a biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Definition 5799.1 (Synonymous transition carrier)**.** *A* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (W, M, A, B, T, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *row naming the finite Q_6 codon-window surface.*
2. *M is the* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *row naming one-bit codon transitions inspected by the packet.*
3. *A is the class-adjacency row recording the displayed synonymous and cross-class adjacency counts, including the largest weights of Definition 9462.1186.*
4. *B is the boundary-spectrum row recording internal edge counts, external boundary degrees, and the control-pair corner-contact data.*
5. *T is the* $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$ *row naming the finite threshold at which an adjacency or boundary-spectrum read may trigger a downstream tile consumer.*
6. *H records componentwise* hsame *transport for codon windows, transition matrix, class adjacency, boundary spectrum, trigger threshold, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite synonymous-transition request through W, M, A, B, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{SynonymousTransition}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{CodonTransitionMatrix}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, M, A, B, T, H, C, P, N$. It has no coordinate for biological mechanism, stochastic fitness, quotient codon equality, hidden enumeration, or an ambient graph-theory oracle outside the displayed finite rows.

Theorem 5799.2 (Synonymous transition NameCert obligations)**.** *For every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier*

$$G = (W, M, A, B, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *surface consists exactly of codon-window admission through W, transition-matrix admission through M, class-adjacency exposure through A, boundary-spectrum exposure through B, trigger-threshold exposure through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every downstream synonymous-transition consumer must read the graph through these nine rows. It cannot replace them by biological causation, stochastic selection, quotient codon semantics, an unrecorded enumeration, or a hidden graph oracle.

Proof. Project the accepted carrier of Definition 5799.1. The finite codon surface is W, the one-bit transition source is M, and the named graph data are the class-adjacency row A and boundary-spectrum row B.

The trigger row T records when the displayed adjacency or boundary-spectrum data may be read by a downstream tile or trigger consumer. It does not add a biological mechanism or a stochastic model; it only names the finite threshold over the same graph rows.

Transport and replay are componentwise. The rows H and C preserve and replay W, M, A, B, T with the same finite endpoints, while P and N record provenance and local naming.

Since the carrier has no coordinate for quotient codon equality, hidden enumeration, biological causation, or ambient graph semantics, the listed rows exhaust the local NameCert obligations. □

Theorem 5799.3 (Synonymous transition boundary-spectrum handoff)**.** *Every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *read factors through the finite route*

$$\mathsf{CodonSixBitWindow}^{\uparrow},\ \mathsf{CodonTransitionMatrix}^{\uparrow} \longmapsto \mathsf{SynonymousTransition}^{\uparrow} \longmapsto \mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{Windo}$$

The handoff exposes class-adjacency weights, internal-edge counts, external boundary degrees, and control-pair corner contacts only as finite packet rows. It exports no biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Proof. Start with the codon-window row W and the one-bit transition matrix row M. These rows supply the finite Q_6 source and the adjacency relation inspected by the packet.

The class-adjacency row A records the largest displayed weights, and B records the boundary-spectrum data. The downstream boundary-tile and trigger-algebra consumers therefore receive a finite graph packet rather than a biological or stochastic explanation.

The threshold row T names when the finite rows can be consumed by the trigger route. Transport through H and replay through C keep the same graph rows visible, while P and N only package their provenance and local name.

Thus every public read of the synonymous-transition geometry remains inside the finite codon-window, transition, adjacency, boundary-spectrum, threshold, transport, replay, provenance, and naming surface. □

Falsifiable prediction: Every accepted $\mathsf{SynonymousTransition}^{\uparrow}$ packet must expose CodonSixBitWindowUp, CodonTransitionMatrixUp, class-adjacency, boundary-spectrum, DNAWindowSixTriggerThresholdUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ rows before a downstream tile or trigger consumer can read the synonymous-transition graph.

Independence witness: codon-six-bit-window, codon-transition-matrix, dna-window-six-boundary-tile, window-coverage-trigger-algebra, dna-window-six-trigger-threshold: $\mathsf{SynonymousTransition}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries class-adjacency weights, boundary-spectrum rows, and trigger-threshold handoff over the finite codon-window graph.

Closure status for $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$.

Constructive story: A $\mathsf{SynonymousTransition}^{\uparrow}$ packet is generated from a CodonSixBitWindowUp source, a CodonTransitionMatrixUp one-bit transition row, class-adjacency counts, boundary-spectrum data, DNAWindowSixTriggerThresholdUp rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5799.1, Definition 5799.2, Definition 5799.3, the falsifiable prediction, and the independence witness seed the finite synonymous-transition packet over codon-window, transition, adjacency, boundary-spectrum, threshold, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic fitness, quotient codon semantics, hidden enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, codon-window visibility, transition-matrix exactness, class-adjacency exposure, boundary-spectrum exposure, trigger-threshold handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SynonymousTransitionUp.

Chapter 5800

A Concrete Naming Certificate for $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$

Following Feller and Billingsley on finite-sum normal approximation, the $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet records the finite BEDC surface by which an iid random-variable window is centered, scaled, read as a distribution row, and handed to a real-normal comparison seal. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the law readback of chapter 186, the regular rational window of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite central-limit-facing certificate; it is not an asymptotic central limit theorem, a characteristic-function convergence theorem, a host probability-limit operator, countable choice, quotient distribution equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5800.1 (Central-limit finite-window carrier)**.** *A* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, V, S, K, D, R, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row V is the displayed iid* $\mathsf{RandomVar}^{\uparrow}$ *window over P, including the finite index range and the shared law token read by the window. The row S is the finite partial-sum ledger naming the displayed sum, the sample count, and the centered numerator. The row K is the centering and scaling row, recording the finite mean token, variance or spread token, positive scale request, and normalized finite-sum expression. The row D is the* $\mathsf{Distribution}^{\uparrow}$ *readback for the normalized finite sum and its comparison request. The row R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *window that presents rational test intervals, tolerances, and finite comparison samples for the distribution read. The row E is the* $\mathsf{Real}^{\uparrow}$ *normal-window seal naming the terminal real comparison against the displayed normal row at the requested finite window. The row H records componentwise* hsame *transport for the probability source, iid window, partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat window, Real normal-window seal, continuation, provenance, and local naming rows. The row C records* Cont *replay from a normal-facing read through P, V, S, K, D, R, E and then through the structural rows. The row Q is the* Pkg *provenance over* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*. The row N is the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these eleven rows.*

Lean4 ✓ `BEDC.Derived.CentralLimitFiniteWindowUp.TasteGate.CentralLimitFiniteWindowTasteGate single carrier alignment`

Theorem 5800.2 (Central-limit finite-window NameCert obligations)**.** *For every accepted* CentralLimitFiniteWindo *carrier* $(P, V, S, K, D, R, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 5800.1. Carrier admission displays the probability source, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, transport, replay, provenance, and local naming row. The certificate imports no host asymptotic central limit theorem, characteristic-function limit, Lindeberg replacement principle, countable-choice schedule, quotient distribution equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Project the carrier rows in order. The probability source P and iid random-variable window V are the only stochastic data exposed to the certificate, and the partial-sum ledger S fixes the finite sum before any normal-facing read is visible.

The centering and scaling row K then determines the normalized finite expression. The distribution row D and RegSeqRat window R provide the only comparison surface through which a finite law read can reach the terminal $\mathsf{Real}^{\uparrow}$ normal-window seal E.

Finally H, C, Q, N transport, replay, source, and name the same displayed route. Since the carrier has no coordinate for an asymptotic theorem, characteristic-function limit, quotient law equality, countable choice, or ambient completeness, the listed rows exhaust the local finite NameCert surface. □

Theorem 5800.3 (Central-limit finite-window normal handoff)**.** *Every normal-facing read of an accepted* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier factors through the finite route*

$$P \longmapsto V \longmapsto S \longmapsto K \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, Q, N$$

before any consumer receives a normal-window comparison. Thus the read is the displayed iid finite-sum, normalization, distribution, RegSeqRat, and RealUp handoff itself; it exports no host asymptotic CLT, countable choice, quotient distribution equality, characteristic-function convergence principle, or ambient real completeness.

Proof. Begin with a normal-facing request. The only probability data available are the source row P and the finite iid window V, so the request must first read the displayed sample range and shared law token.

The partial-sum row S and normalization row K are then forced. They provide the finite sum, centering token, scaling token, and normalized expression that the downstream distribution read consumes.

The request can reach a normal-window comparison only through D, R, E. The distribution row D names the finite law read, the RegSeqRat row R exposes rational windows and tolerances, and the RealUp row E seals the displayed normal comparison. The structural rows H, C, Q, N preserve that route without adding analytic content.

Therefore every accepted read factors through the finite iid-sum, normalization, distribution, RegSeqRat, and RealUp rows. The excluded asymptotic, choice, quotient, characteristic-function, and completeness principles cannot be inserted into the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet is generated from a probability source row, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5800.1, Definition 5800.2, and Definition 5800.3 seed the finite central-limit-facing handoff through ProbSpace, RandomVar, Distribution, RegSeqRat, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CentralLimitFiniteWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the asymptotic central limit theorem, characteristic-function convergence, Lindeberg replacement, countable-choice schedules, quotient distribution equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, iid-window routing, partial-sum ledger exactness, normalization stability, distribution-to-RegSeqRat handoff, RealUp normal-window nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.CentralLimitFiniteWindowUp.

Chapter 5801

A Concrete Naming Certificate for $\mathsf{LipschitzRealMap}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LipschitzRealMap}^{\uparrow}$ packet records a constructive real-map certificate whose continuity is controlled by a displayed dyadic Lipschitz constant and finite regular-rational windows. It sits after the dyadic tolerance ledger of chapter 291, the countable-name window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the located order and apartness neighbour of chapter 5797. The packet names the finite L10 route by which later continuous-map and metric-uniform-continuity consumers may read a real-valued map without importing host function extensionality, quotient representatives, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5801.1 (Lipschitz real-map carrier)**.** *A* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, K, W, R, M, H, C, P, N)$$

with the following rows:

1. *S is the source* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real input surface through displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
2. *T is the target* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real output surface through the same kind of finite readback.*
3. *K is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *Lipschitz constant row, including the positive dyadic bound and the displayed tolerance ledger used by every modulus request.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the source and target names inspected by the request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the displayed source and target windows into rational comparison data.*
6. *M is the modulus-inequality row, recording that every accepted finite pair of source reads with displayed apartness or distance bound is sent to a target read whose displayed difference is bounded by the dyadic constant in K times the source bound, up to the requested displayed tolerance.*
7. *H records componentwise* hsame *transport for source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a finite map request through $S, T, K, W, R, M, H, P, N$.*
9. *P is the* Pkg *provenance over* LipschitzRealMap$^{\uparrow}$, Real$^{\uparrow}$, RealLineOrder$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{LipschitzRealMap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, T, K, W, R, M, H, C, P, N$. It has no coordinate for host function equality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, or ambient completeness of Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LipschitzRealMapUp.LipschitzRealMapTasteGate single carrier alignment`

Theorem 5801.2 (Lipschitz real-map NameCert obligations)**.** *For every accepted* LipschitzRealMap$^{\uparrow}$ *carrier*

$$F = (S, T, K, W, R, M, H, C, P, N),$$

the local NameCert$_{\text{LipschitzRealMap}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* Real$^{\uparrow}$ *seal, target* Real$^{\uparrow}$ *seal, dyadic Lipschitz constant, finite StreamName windows, RegSeqRat readback, modulus inequality, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires finite source and target visibility through S and T, dyadic bound visibility through K, finite window visibility through W, rational readback through R, modulus-inequality exposure through M, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses host function extensionality, quotient equality of real presentations, selected representatives, global uniform-continuity principles, and ambient completeness of Real$^{\uparrow}$.

Proof. Project the carrier of Definition 5801.1. The source and target real seals are the only real-name endpoints, and both are read through finite StreamName and RegSeqRat windows rather than through host real equality.

The Lipschitz datum is the dyadic row K. A map request can inspect only the finite windows W and their rational readback R before the modulus row M exposes the displayed inequality for the requested tolerance.

The structural rows do not add analytic content. The transport row H preserves the already displayed source, target, constant, window, readback, and modulus rows componentwise, while C replays the same route and P, N record provenance and local naming.

Since no carrier coordinate stores host function equality, quotient real equality, selected representatives, global uniform continuity, or ambient completeness, no local NameCert obligation can require those objects. □

Theorem 5801.3 (Lipschitz real-map modulus stability)**.** *Let F_0 and F_1 be accepted* LipschitzRealMap$^{\uparrow}$ *carriers whose source seals, target seals, dyadic Lipschitz constant rows, finite StreamName windows, and RegSeqRat readback rows are componentwise* hsame*-transported. Then every displayed modulus-inequality read exported by F_0 transports to the corresponding displayed modulus-inequality read exported by F_1.*

The stability claim is confined to the finite rows $S, T, K, W, R, M, H, C, P, N$. It does not identify host functions, quotient real presentations, selected Cauchy names, or ambient complete metric structures.

Proof. Start with a displayed modulus request for F_0. Its source and target real seals are read only through the finite StreamName windows and RegSeqRat readback rows named by S, T, W, R.

Use the componentwise hsame hypotheses. They transport the dyadic constant row K and the finite window/readback rows into the corresponding rows of F_1, so the same displayed source tolerance and target tolerance are available after transport.

The modulus row M is a row of the carrier rather than a host theorem about all representatives. Therefore the transported request reads the F_1 modulus row with the same displayed dyadic bound and the transported finite readback data.

Finally C, P, N replay, source, and name the transported route. No quotient equality, host function equality, selected representative, or ambient completeness principle is introduced by this transport. □

Theorem 5801.4 (Lipschitz real-map L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier must read the route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{LipschitzRealMap}^{\uparrow}$$

through the finite source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, transport, replay, provenance, and local NameCert rows. The handoff supplies a finite Lipschitz-control surface for later continuous-map and metric-uniform-continuity packets, while refusing host function extensionality, quotient equality, selected representatives, global uniform-continuity principles, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. An L10 map request begins with source and target real-name seals. By the carrier definition, these seals are visible only through the finite StreamName windows and RegSeqRat readback rows used by S, T, W, R.

The request then reads the dyadic constant row K and the located comparison surface supplied by the real-line order neighbour. These rows provide the displayed source difference and target tolerance against which the modulus inequality is checked.

The modulus row M is the only analytic output of the packet. It hands a consumer a finite inequality route, not a host-level function theorem.

The rows H, C, P, N transport, replay, source, and name the same route. Thus later continuous-map and metric-uniform-continuity packets can consume the finite Lipschitz surface without receiving quotient equality, selected representatives, host function extensionality, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzRealMap}^{\uparrow}$ packet is generated from source and target RealUp seal rows, a DyadicRatCore Lipschitz constant, finite StreamName windows, RegSeqRat readback, a displayed modulus-inequality row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, seed)

Scope closed: Definition 5801.1, Definition 5801.2, Definition 5801.3, and Definition 5801.4 seed the finite Lipschitz real-map surface over the current L10 real and completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and target RealUp sealing, dyadic constant visibility, finite window readback, modulus-inequality stability, transport, replay, provenance, and local naming for future BEDC.Derived.LipschitzRealMapUp.

Chapter 5802

A Concrete Naming Certificate for HyperbolicQuasiGeodesicShadow$^{\uparrow}$

The HyperbolicQuasiGeodesicShadow$^{\uparrow}$ packet realizes the observer-expansion shadow route of section 9463.4 as finite quasi-geodesic, boundary, visual-metric, Busemann, and lamination-compatible rows. It sits after disk readout through chapter 377, the metric surface of chapter 3474, the visual-metric packet of chapter 3866, the Busemann cocycle route of chapter 4134, the geodesic-lamination packet of chapter 4203, and the observer-expansion packet of chapter 4167. The packet names a finite shadow tied to a displayed quasi-geodesic route; it does not complete the boundary, choose a global geodesic representative, identify quotient ideal points, or import host hyperbolic geometry.

Definition 5802.1 (Hyperbolic quasi-geodesic shadow carrier)**.** *A* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, G, E, V, B, L, H, C, P, A, N)$$

with the following rows:

1. *D is the disk readout row, exposing only displayed* UnitDisk$^{\uparrow}$ *coordinates and the associated* HyperbolicMetric$^{\uparrow}$ *metric-read data.*
2. *G is the quasi-geodesic route row, recording the finite path samples, distortion budget, endpoint-facing direction, and local route ledger inspected by the shadow request.*
3. *E is the boundary endpoint row named by the displayed route, not by a completed ideal-boundary quotient.*
4. *V is the visual-metric shadow row, recording the finite shadow window read through* HyperbolicVisualMetric$^{\uparrow}$ *and the boundary endpoint E.*
5. *B is the Busemann cocycle tolerance row, recording the displayed additive tolerance used to compare the route and the shadow window.*
6. *L is the geodesic-lamination compatibility row, recording whether the displayed route is compatible with the finite noncrossing leaf data consumed by* HyperbolicGeodesicLamination$^{\uparrow}$.
7. *H records componentwise* hsame *transport for disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, replay, provenance, refusal, and local naming rows.*
8. *C records displayed* Cont *replay from an observer-expansion shadow request through $D, G, E, V, B, L, H, P, A, N$.*

9. *P is the* Pkg *provenance over* HyperbolicQuasiGeodesicShadow$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HyperbolicGeodesicLamination$^{\uparrow}$, HyperbolicObserverExpar BHist, hsame, Cont, *and* NameCert.
10. *A is the refusal row excluding completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, and host curvature semantics.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, G, E, V, B, L, H, C, P, A, N$.

Theorem 5802.2 (Hyperbolic quasi-geodesic shadow NameCert obligations)**.** *For every accepted* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier*

$$Q = (D, G, E, V, B, L, H, C, P, A, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *surface consists exactly of disk-readout visibility, quasi-geodesic route visibility, boundary endpoint exposure, visual-metric shadow-window exposure, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise transport, replay, provenance, refusal, and local naming rows.*

The packet exports no completed ideal boundary, quotient boundary equality, selected global geodesic, ambient hyperbolic compactification, physical observer trajectory, host curvature theorem, or global field semantics.

Proof. Project the carrier rows in order. The disk readout D supplies the only coordinate and metric source, while G supplies the displayed route samples and distortion budget inspected by the request.

The endpoint and shadow rows are downstream of that route. The endpoint row E names only the boundary read visible from G, and the visual row V records the finite shadow window tied to that endpoint.

The comparison rows B and L keep the shadow route finite. The Busemann tolerance is a displayed cocycle budget, and lamination compatibility is a finite noncrossing-leaf check, not a global geodesic-foliation theorem.

Finally H, C, P, A, N transport, replay, source, refuse, and name the same packet. Since the excluded host objects are not carrier rows, they cannot appear as NameCert obligations. □

Theorem 5802.3 (Hyperbolic quasi-geodesic shadow stability)**.** *Let Q_0 and Q_1 be accepted* HyperbolicQuasiGeodesi *carriers whose disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow window, Busemann tolerance, lamination compatibility, refusal, provenance, and local naming rows are componentwise* hsame*-transported. Then every observer-expansion consumer reads the same finite shadow surface through Q_0 and Q_1.*

The stability claim is confined to the finite rows $D, G, E, V, B, L, H, C, P, A, N$. It does not identify completed boundaries, quotient ideal points, selected geodesics, ambient compactifications, physical observer trajectories, host curvature data, or global fields.

Proof. Start with an observer-expansion shadow request for Q_0. The request must read disk coordinates and metric data through D and then the finite route samples and distortion budget through G.

Use the componentwise hsame transport. It carries the endpoint E, visual shadow window V, Busemann tolerance B, and lamination compatibility row L to the corresponding rows of Q_1.

The refusal row is transported with the same packet. Therefore the transported consumer sees the same excluded host objects and cannot insert completed boundary quotients, selected global geodesics, ambient compactifications, physical trajectories, curvature theorems, or global fields.

The replay row C and the provenance and naming rows P, N then present the transported shadow as the same finite observer-expansion surface. □

Theorem 5802.4 (Hyperbolic quasi-geodesic shadow vision handoff)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ *carrier must read the route*

$\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicGeodesicLaminatio}$

through disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, transport, replay, provenance, refusal, and local NameCert rows. The handoff realizes the vision-level shadow route as finite NameCert data without turning observer expansion into physical cosmology or a host hyperbolic-boundary theorem.

Proof. The vision handoff begins with disk and metric data. Rows D and G ensure that the consumer reads only displayed disk observations, metric readouts, finite route samples, and a distortion budget.

The endpoint and shadow window are then forced. Rows E and V bind the boundary endpoint and visual-metric shadow to the same route, while B records the Busemann tolerance needed to compare route and shadow.

Lamination compatibility is read through L. This makes the packet consumable by geodesic-lamination and observer-expansion rows without selecting a global geodesic representative or completing the boundary.

The rows H, C, P, A, N transport, replay, source, refuse, and name the handoff. Thus the vision-level quasi-geodesic shadow is realized as finite NameCert data and not as ambient hyperbolic geometry. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ read must expose a boundary endpoint, visual-metric shadow window, Busemann cocycle tolerance, quasi-geodesic route, transport row, provenance row, refusal row, and local NameCert before any observer-expansion consumer may read the shadow.

Independence witness: hyperbolic-visual-metric, hyperbolic-busemann-cocycle, hyperbolic-geodesic-lamination, hyperbolic-observer-expansion: $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ is not bijective to these siblings because it binds the quasi-geodesic route and shadow window together before the observer-expansion packet may consume the boundary read.

The Lean TasteGate for this packet must later provide Nontrivial $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ in `lean4/BEDC/Derived/HyperbolicQuasiGeodesicShadowUp/` Those instances must keep $D, G, E, V, B, L, H, C, P, A, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ packet is generated from disk readout rows, a quasi-geodesic route, a boundary endpoint, a visual-metric shadow window, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, refusal, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5802.1, Definition 5802.2, Definition 5802.3, and Definition 5802.4 seed the finite quasi-geodesic shadow route for observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, host curvature semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk readout, quasi-geodesic route admission, endpoint exposure, visual-metric shadow windows, Busemann tolerance, lamination compatibility, TasteGate nontriviality, field faithfulness, refusal exactness, transport, replay, provenance, and local naming for future BEDC.Derived.HyperbolicQuasiGeodesicShadowUp.

Chapter 5803

A Concrete Naming Certificate for $\mathsf{Dendrite}^{\uparrow}$

Following Nadler and Kuratowski on continuum theory, the $\mathsf{Dendrite}^{\uparrow}$ packet records the finite BEDC surface for a locally connected compact metric continuum whose tree-like form is read through unique arcs and cutpoint separation. It sits over the compact metric carrier of chapter 129, the locally connected surface of chapter 5809, the Peano continuum boundary of chapter 2160, and the tree certificate of chapter 119. The packet names displayed endpoint, unique-arc, and cutpoint-separation rows; it does not import host continua, arbitrary path spaces, open-cover compactness, or quotient equality of arcs.

Definition 5803.1 (Dendrite carrier)**.** *A* $\mathsf{Dendrite}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric distance rows, finite ProbeBundle-net rows, complete-limit witness rows, and rational tolerance comparisons already certified by the compact-metric chapter.*
2. *L is the* $\mathsf{LocallyConnected}^{\uparrow}$ *row, recording the displayed connected neighbourhood refinements through which local arc and cutpoint requests are inspected.*
3. *P is the* $\mathsf{PeanoContinuum}^{\uparrow}$ *row, binding the compact metric and locally connected continuum surfaces before any dendrite consumer reads an arc boundary.*
4. *T is the* $\mathsf{Tree}^{\uparrow}$ *row, recording the finite tree-like separation surface used to rule out cycle-shaped routes.*
5. *E is the endpoint ledger, listing endpoint rows and their neighbourhood-read witnesses.*
6. *A is the unique-arc ledger, recording for every displayed endpoint or carried point pair the finite arc row, its endpoint membership rows, and its non-branching comparison rows.*
7. *C is the cutpoint-separation ledger, recording the displayed separation rows used when removing a carried point disconnects the relevant finite tree-like boundary.*
8. *H records componentwise* hsame *transport for compact metric data, local connectedness data, Peano-continuum data, tree data, endpoint rows, unique-arc rows, cutpoint-separation rows, replay, provenance, and local naming.*

9. *R records displayed* Cont *replay from a dendrite request through* $K, L, P, T, E, A, C, H, G, Q, N$.
10. *G is the* Pkg *provenance over* $\mathsf{Dendrite}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{PeanoContinuum}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *Q records the local source and consumer provenance for endpoint, unique-arc, and cutpoint-separation reads.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host continuum, arbitrary path selection, open-cover compactness, cycle elimination by excluded middle, or quotient equality of arcs.

Lean4 ✓ `BEDC.Derived.DendriteUp.DendriteTasteGate single carrier alignment`

Theorem 5803.2 (Dendrite NameCert obligations)**.** *For every accepted* $\mathsf{Dendrite}^{\uparrow}$ *carrier*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source, locally connected row, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming;*
2. *compact-continuum visibility, requiring every dendrite consumer to read compact metric and local connectedness data through K, L, P before reading endpoint or arc rows;*
3. *tree-like exactness, requiring the non-cycle and separation information to pass through T and the cutpoint-separation ledger C;*
4. *unique-arc exactness, requiring every arc-facing read to use the displayed ledger A with its endpoint membership and non-branching comparison rows;*
5. *endpoint exactness, requiring endpoint reads to use only the displayed endpoint ledger E and not a host boundary predicate;*
6. hsame, Cont, *and* Pkg *stability, requiring componentwise transport, displayed replay, and provenance to preserve precisely the listed rows;*
7. *non-escape, excluding host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, and quotient equality of arcs.*

No dendrite obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5803.1. The accepted tuple displays exactly the compact metric source, local connectedness, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming.

The compact-continuum route is K, L, P. The compact metric source supplies distance, finite-net, complete-limit, and tolerance-comparison rows; the locally connected row supplies connected neighbourhood refinements; and the Peano-continuum row binds those surfaces before endpoint or arc data are exposed.

The tree-like route is T, E, A, C. The tree row supplies the finite non-cycle surface, the endpoint ledger records boundary reads, the unique-arc ledger records the displayed arc row between

carried point pairs, and the cutpoint-separation ledger records the separation witnesses used by downstream consumers.

Finally, H, R, G, Q, N transport, replay, source, and name the same finite packet. Since the carrier has no row for a host continuum, arbitrary path space, open-cover compactness principle, selected arc representative, or quotient equality of arcs, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$ surface. □

Theorem 5803.3 (Dendrite unique-arc handoff)**.** *Every unique-arc or cutpoint-facing consumer of an accepted* $\mathsf{Dendrite}^\uparrow$ *carrier must read the finite route*

$$\mathsf{CompactMetric}^\uparrow,\ \mathsf{LocallyConnected}^\uparrow,\ \mathsf{PeanoContinuum}^\uparrow,\ \mathsf{Tree}^\uparrow \longmapsto E, A, C, H, R, G, Q, N.$$

The handoff exposes endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It does not expose arbitrary host paths, open-cover compactness, selected arc representatives, quotient equality of arcs, or a continuum object outside the displayed packet.*

Proof. Start with the compact-continuum source. The rows K, L, P force a consumer to read the compact metric, locally connected, and Peano-continuum surfaces before any arc-facing data can be inspected.

Next read the tree row T. This is the only row carrying the tree-like non-cycle surface, so a later cutpoint or arc argument cannot replace it by a host graph or a classical continuum theorem.

The endpoint and arc data are then E, A, C. Endpoint reads pass through E, unique-arc reads pass through A, and cutpoint-separation reads pass through C; the three ledgers remain tied to the same compact-continuum and tree source rows.

The structural rows H, R, G, Q, N preserve this route under transport, replay, provenance, and local naming. Because no excluded host-side row appears in the carrier, the consumer receives exactly the displayed unique-arc handoff and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{Dendrite}^\uparrow$ read must expose CompactMetric, LocallyConnected, PeanoContinuum, Tree, endpoint, unique-arc, cutpoint-separation, componentwise hsame, displayed Cont, Pkg, source provenance, and local NameCert rows before a continuum or arc consumer can inspect the dendrite boundary.

Independence witness: compactmetric, locally-connected, peano-continuum, tree: $\mathsf{Dendrite}^\uparrow$ is not bijective to any listed sibling because it binds endpoint, unique-arc, and cutpoint-separation ledgers over their common compact-continuum and tree-like source.

Closure status for $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$**.**

Constructive story: A $\mathsf{Dendrite}^\uparrow$ packet is generated from CompactMetricUp, LocallyConnectedUp, PeanoContinuumUp, TreeUp, endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, source provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, seed)

Scope closed: Definition 5803.1, Definition 5803.2, and Definition 5803.3 seed the finite dendrite certificate over compact metric, locally connected, Peano-continuum, tree, endpoint, unique-arc, cutpoint-separation, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, quotient equality of arcs, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-continuum visibility, tree-like exactness, endpoint exactness, unique-arc exactness, cutpoint-separation exactness, transport, replay, provenance, and local naming for BEDC.Derived.DendriteUp.

Chapter 5804

A Concrete Naming Certificate for $\mathsf{YoungIntegration}^{\uparrow}$

Following Young's integration theorem and Bishop–Bridges constructive analysis, the $\mathsf{YoungIntegration}^{\uparrow}$ packet records the finite dyadic route for integrating one Holder-controlled path against another. It sits beside the Holder-continuity surface of chapter 1766, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the tagged-mesh Riemann integral boundary of chapter 1526. The chapter names only a finite partition-and-error certificate; it does not import host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5804.1 (Young integration finite partition carrier)**.** *A* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the integrand path row, read through a* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
2. *G is the integrator path row, read through a second* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its own source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
3. *A and B are the two Holder exponent ledgers. They include the finite comparison row witnessing that the displayed exponents have a Young margin for the dyadic partition family.*
4. *W is the dyadic partition-window row. It lists the inspected endpoints, dyadic mesh refinements, cell order, adjacent-cell handoffs, and the finite cells on which the integration read is allowed to form sums.*
5. *V is the cross-variation tolerance ledger. It records the cellwise oscillation products, Holder-bound products, Young-margin comparisons, and finite sum-difference tolerances consumed by the route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for endpoint radii, mesh widths, exponent-comparison margins, oscillation products, and final error bounds.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational trace of dyadic Young sums.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the integral value, reached only after the two Holder rows, dyadic windows, cross-variation ledger, dyadic tolerances, and regular readback have been displayed.*
9. *H records componentwise* hsame *transport for the two Holder paths, exponent ledgers, partition windows, cross-variation ledger, dyadic ledger, readback, Real seal, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from a Young-integration request through Holder admission, dyadic partition windows, cross-variation tolerances, regular rational readback, and the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{YoungIntegration}^{\uparrow}$, $\mathsf{HolderContinuity}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, G, A, B, W, V, D, R, E, H, C, P, N$. It has no coordinate for an ambient path space, quotient equality of functions, a selected sequence of partitions, a hidden limiting argument, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.YoungIntegrationUp.YoungIntegrationTasteGate single carrier alignment`

Theorem 5804.2 (Young integration NameCert obligations)**.** *For every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier $Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *surface is exhausted by admission of two* $\mathsf{HolderContinuity}^{\uparrow}$ *path rows, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting,* $\mathsf{DyadicRatCore}^{\uparrow}$ *exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No accepted consumer may replace these rows by host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5804.1. The rows F and G expose the two Holder-controlled paths, and A, B expose only the finite exponent and Young-margin comparisons attached to those rows.

The partition and tolerance data are then forced. The row W lists the dyadic windows available to the route, while V records the cross-variation products and sum-difference tolerances over exactly those windows.

The terminal read is D, R, E. Dyadic exactness is read through D, the regular rational trace through R, and the Real integral seal through E only after the preceding rows have been consumed.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5804.3 (Young integration dyadic error budget)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *read that reaches the* $\mathsf{Real}^{\uparrow}$ *seal factors through the finite dyadic budget*

$$\mathsf{HolderContinuity}^{\uparrow}, \mathsf{HolderContinuity}^{\uparrow} \longmapsto \mathsf{DyadicPartition}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The row V must display the cross-variation tolerance consumed between the partition windows and the rational readback. Therefore the exported integral value is a finite dyadic Young-sum seal, not a Riemann-integral replacement, a measure-completion integral, a quotient path equality, a selected limiting partition, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the two Holder rows. Their displayed exponents and constants are read through F, G, A, B, so the route has only the finite power-law data needed to bound oscillations on dyadic cells.

Next read the dyadic partition windows. The row W fixes the cells, endpoints, mesh refinements, and adjacent-cell handoffs before any sum-difference comparison is requested.

The error budget is the pair V, D. The cross-variation ledger V records the oscillation products and Young-margin comparisons, and the dyadic ledger D records the exact rational tolerances used to compare any two displayed sums.

The readback and seal are downstream. The regular sequence row R is the only rational trace exported from the finite budgets, and E is the only Real seal. Thus the consumer cannot obtain any of the excluded host-level or choice-level objects from the packet. □

Theorem 5804.4 (Young integration Riemann boundary)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet reads it only as a finite tagged-mesh boundary: two Holder path rows, a dyadic partition-window row, a cross-variation tolerance ledger, dyadic exactness, regular rational readback, Real sealing, transport, replay, provenance, and local naming. The consumer receives no independent Riemann-integral certificate, no Darboux gap claim, no quotient equality of integrands, no measure-completion object, and no selected mesh-limit principle.*

Proof. The only Riemann-facing data in the carrier are the displayed dyadic windows and finite sum budgets. The two Holder path rows provide values to be sampled, while W supplies the finite tagged-mesh boundary.

The cross-variation ledger is not a Darboux or measure-theoretic claim. It records only the tolerance comparisons needed for the Young-sum route before the regular rational readback is sealed as a Real value.

The provenance row may name $\mathsf{RiemannIntegral}^{\uparrow}$ as a consumer boundary, but the local certificate remains $F, G, A, B, W, V, D, R, E, H, C, P, N$. Therefore a Riemann-integral consumer receives a finite boundary row rather than any independent integral theorem or hidden limiting principle. □

Theorem 5804.5 (Young integration Cauchy-modulus consumer)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet whose cross-variation ledger* V *requests a tail precision must consume the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route before* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *sealing. The route remains finite: it exports the displayed Young partition windows, dyadic error budget, explicit Cauchy-modulus handoff, regular rational readback, and terminal Real seal, but it exports no selected limiting partition, countable-choice schedule, hidden modulus oracle, or ambient completion theorem.*

Proof. Project the carrier of Definition 5804.1. The rows W, V, D, R, E expose the partition windows, cross-variation tolerance ledger, dyadic error budget, regular rational readback, and terminal Real seal.

Use Definition 5804.3. The row V is the place where sum-difference tolerances and tail precision demands are recorded, and D is the dyadic ledger that makes those demands finite.

When such a tail precision is requested, apply the effective handoff of Definition 5728.3 and the schedule determinacy of Definition 5728.4. They force the precision request through an explicit $\mathsf{CauchyModulusBridge}^{\uparrow}$ schedule before R can be read and before E can seal the result.

The remaining rows H, C, P, N transport, replay, source, and name the same finite route. Since neither the Young carrier nor the bridge carrier contains a selected limiting partition, countable-choice schedule, hidden oracle, or ambient completion coordinate, no such object is exported. □

Falsifiable prediction: An accepted $\mathsf{YoungIntegration}^{\uparrow}$ packet is refuted if a consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting either $\mathsf{HolderContinuity}^{\uparrow}$ path row, the dyadic partition-window row W, the cross-variation ledger V, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: HolderContinuity, DyadicPartition, DyadicRatCore, RegSeqRat, Real, RiemannIntegral: none is bijective with $\mathsf{YoungIntegration}^{\uparrow}$ because the packet jointly carries two Holder paths, Young-margin exponent rows, dyadic partition windows, cross-variation tolerances, dyadic exactness, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$.

Constructive story: A $\mathsf{YoungIntegration}^{\uparrow}$ packet is generated from two HolderContinuityUp path rows, exponent-margin ledgers, dyadic partition windows, cross-variation tolerance accounting, DyadicRatCore exactness, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5804.1, Definition 5804.2, Definition 5804.3, Definition 5804.4, and Definition 5804.5 seed the finite dyadic Young-integration route over HolderContinuityUp, DyadicPartitionUp, DyadicRatCoreUp, CauchyModulusBridgeUp, RegSeqRatUp, RealUp, and RiemannIntegralUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked two-path admission, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting, dyadic exactness, regular rational readback, Real-seal nonescape, and structural transport for BEDC.Derived.YoungIntegrationUp.

Chapter 5805

A Concrete Naming Certificate for $\mathsf{VariationDiminishing}^{\uparrow}$

Following Schoenberg and Karlin, the $\mathsf{VariationDiminishing}^{\uparrow}$ packet records a finite analysis row for transformations that do not increase displayed sign variation. It consumes the total-variation function surface of chapter 2257, the bounded-variation real-function carrier of chapter 3654, the regulated-function source of chapter 1554, and the tagged integration boundary of chapter 1526. The packet names the finite comparison by which a kernel or transformation row is read as variation-diminishing without importing a host operator algebra, total-positivity theorem, selected partitions, quotient functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5805.1 (Variation-diminishing carrier)**.** *A* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (B, T, R, I, K, M, H, C, P, N)$$

with the following rows:

1. *B is the* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *source row naming the accepted bounded-variation input surface.*
2. *T is the* $\mathsf{TotalVariationFunction}^{\uparrow}$ *row naming the displayed total-variation ledger used to count variation before and after the transformation.*
3. *R is the* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *row naming the regulated readback through which input and output functions are compared by finite step windows.*
4. *I is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *row naming the finite tagged-mesh integration boundary used when the transformation is read by kernel action or integral averaging.*
5. *K is the kernel or transformation row, including its displayed positivity-order or sign-regularity window.*
6. *M is the variation comparison row recording that each accepted finite sign-change ledger for the output is routed to a no-larger sign-change ledger for the input.*
7. *H records componentwise* hsame *transport for bounded-variation source, total-variation ledger, regulated readback, integral boundary, kernel row, comparison row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite transformation request through $B, T, R, I, K, M, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{VariationDiminishing}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RegulatedRealFunction}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and sibling* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, T, R, I, K, M, H, C, P, N$. It has no coordinate for host function equality, quotient representatives, selected limiting partitions, a global total-positivity theorem, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.VariationDiminishingUp.VariationDiminishingTasteGate single carrier alignment`

Theorem 5805.2 (Variation-diminishing NameCert obligations)**.** *For every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier*

$$V = (B, T, R, I, K, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded-variation source row B, total-variation ledger T, regulated-function readback R, Riemann-integral boundary I, kernel or transformation row K, variation comparison row M, componentwise transport H, displayed replay C, provenance P, and local naming N.*

The obligation surface requires every output variation read to pass through the displayed comparison row M after B, T, R, I, K have been projected. It refuses host operator equality, quotient equality of functions, selected partitions, unrestricted total positivity, measure-theoretic kernels, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5805.1. The source row B supplies the bounded-variation input, while T supplies the total-variation ledger on which finite sign-change comparisons can be read.

The rows R and I keep the analytic route finite. Regulated readback gives step-window access to input and output functions, and the Riemann-integral boundary records only the tagged-mesh action needed by a kernel or averaging read.

The row K names the transformation window, and M is the only row that compares variation before and after the transformation. Thus the NameCert consumer obtains a variation-diminishing assertion only through the displayed comparison row, not through a host theorem about all kernels.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores quotient functions, selected limiting partitions, unrestricted total positivity, measure completion, or ambient real completeness, no local obligation can require them. □

Theorem 5805.3 (Variation-diminishing total-variation route)**.** *Every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *consumer read factors through the route*

$$\mathsf{BoundedVariationRealFunction}^{\uparrow},\ \mathsf{TotalVariationFunction}^{\uparrow},\ \mathsf{RegulatedRealFunction}^{\uparrow},\ \mathsf{RiemannIntegral}^{\uparrow} \longmapsto \mathsf{VariationD}$$

The output variation ledger is accepted only after the bounded-variation input, cumulative total-variation ledger, regulated readback, tagged integration boundary, kernel row, and comparison row have been displayed. The route exports no selected limit, quotient function equality, global total-positivity principle, measure-completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. A variation-diminishing request first projects B and T. These rows bind the input function to the bounded-variation and total-variation sibling surfaces, so the requested comparison starts from finite variation data rather than from a host function space.

Next project R and I. The regulated row supplies finite step-window readback, while the integral boundary supplies the tagged-mesh route through which a kernel or averaging transformation can be inspected.

The transformation row K and comparison row M then give the only accepted variation comparison. They state that the displayed output sign-change ledger routes to a no-larger input ledger in the same finite packet.

Finally H, C, P, N preserve the route under transport, replay, provenance, and local naming. Hence every public read of $\mathsf{VariationDiminishing}^{\uparrow}$ passes through the four cited sibling anchors and does not acquire the excluded host-level principles. □

Falsifiable prediction: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet whose output variation read bypasses the displayed total-variation ledger or the regulated readback row is not accepted by the local NameCert.

Independence witness: total-variation-function, bounded-variation-real-function, regulatedrealfunction, riemannintegral: $\mathsf{VariationDiminishing}^{\uparrow}$ is not bijective to any listed sibling because it binds the source variation ledger, regulated readback, tagged integration boundary, transformation row, and no-increase comparison as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet is generated from bounded-variation source data, a total-variation ledger, regulated readback, Riemann tagged-mesh boundary, a kernel or transformation row, a variation comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5805.1, Definition 5805.2, Definition 5805.3, the falsifiable prediction, and the independence witness seed the finite variation-diminishing route over the current analysis rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host operator equality, quotient equality of functions, selected limiting partitions, unrestricted total positivity, measure completion, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation source visibility, total-variation ledger exactness, regulated readback, tagged integration boundary, transformation-row exposure, comparison-row stability, transport, replay, provenance, and local naming for future BEDC.Derived.VariationDiminishingUp.

$\mathsf{FrobeniusReciprocity}^{\uparrow}$ routes induction–restriction comparison through chapter 247, chapter 246, and chapter 245 before the child file states the local certificate.

Chapter 5806

A Concrete Naming Certificate for $\mathsf{FrobeniusReciprocity}^{\uparrow}$

Following Frobenius on induced characters, Serre's finite-group representation theory, and the induction–restriction formulation used by Fulton–Harris, the $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet records the finite comparison row between induction from a subgroup and restriction to that subgroup. It consumes the action rows of chapter 3662, the subgroup source of chapter 80, the representation-ring ledger of chapter 246, the induction–restriction packet of chapter 247, and the character-pairing surface of chapter 245. The packet names only finite source rows, adjunction ledgers, character-pairing boundaries, transport, replay, provenance, and downstream handoff rows; it does not assert a host category of representations, a functor equality, semisimplicity, Schur orthogonality, or a completed character table.

Theorem 5806.1 (FrobeniusReciprocityUp source obligations)**.** *For every accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet, the source surface is the displayed finite tuple*

$$\mathcal{F} = (G, H, R, I, Q, \Phi, \eta, \epsilon, \chi, \lambda, C, P, N),$$

where G is the consumed $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *action row, H is the consumed* $\mathsf{Subgroup}^{\uparrow}$ *row, R is the consumed* $\mathsf{RepresentationRing}^{\uparrow}$ *ledger, I is the consumed* $\mathsf{InducedRep}^{\uparrow}$ *induction–restriction row, Q is the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *pairing row, Φ is the Frobenius comparison row, η, ϵ are the displayed unit and counit rows, χ is the character-pairing boundary, λ is the finite ledger of visible source and endpoint reads, C is componentwise* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *row. No source obligation is imported from a host representation category, quotient carrier, functor category, or external adjunction object.*

Proof. Project the accepted packet. The source rows are precisely G, H, R, I, Q together with the local comparison rows $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

The consumed rows are already finite BEDC certificates. The finite-group representation row supplies the action display, the subgroup row supplies the inclusion boundary, the representation-ring row supplies the Grothendieck ledger, the induced-representation row supplies the induction–restriction endpoints, and the character-theory row supplies the pairing surface.

Since the tuple has no coordinate for a host representation category, quotient carrier, functor category, or external adjunction object, the listed rows exhaust the source obligations. □

Theorem 5806.2 (FrobeniusReciprocityUp adjunction ledger)**.** *The adjunction data of an accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet are exactly the finite rows $\Phi, \eta, \epsilon, \lambda$ over the consumed sources*

H, R, I. The row Φ compares the displayed induction endpoint with the displayed restriction endpoint, η and ϵ record the unit and counit witnesses as BHist *rows, and λ records the visible continuations among source, endpoint, and Frobenius reads. The ledger exports no host naturality square, functor equality, adjunction object, or semisimple decomposition.*

Proof. Begin with the induction–restriction source. The packet consumes the $\mathsf{InducedRep}^{\uparrow}$ row I, so the available endpoints are the displayed induction and restriction rows already carried by that certificate.

The Frobenius comparison is read through Φ. The unit and counit witnesses are read through η and ϵ, and every visible path among source and endpoint reads is recorded by the finite ledger λ.

Exactness is projection from the tuple. Any row outside $\Phi, \eta, \epsilon, \lambda$ is not part of the adjunction ledger, and no host naturality square or functor equality can be recovered from a coordinate that the packet does not carry. □

Theorem 5806.3 (FrobeniusReciprocityUp character-pairing boundary)**.** *Every character-pairing read of a* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet factors through the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *row Q, the representation-ring source R, the induction–restriction source I, and the displayed pairing boundary χ before it can inspect Φ, η, ϵ or λ. The boundary supplies only the finite character-pairing comparison needed for reciprocity and does not export Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra.*

Proof. Read the character side first. The only character-theory coordinate is Q, and the only representation-ring coordinate feeding it is R.

The induction and restriction endpoints enter through I. The displayed pairing boundary χ then names the finite comparison used by the Frobenius row before the ledger reads $\Phi, \eta, \epsilon, \lambda$.

Because the tuple has no coordinate for Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra, every character-pairing read remains inside the stated finite boundary. □

Theorem 5806.4 (FrobeniusReciprocityUp NameCert surface)**.** *The* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *obligation surface is the conjunction of the source obligations of Definition 5806.1, the adjunction ledger of Definition 5806.2, the character-pairing boundary of Definition 5806.3, componentwise* hsame *transport on all displayed source and ledger rows, finite* Cont *replay through C, and* Pkg *provenance through P. The surface exports no obligation outside the displayed tuple $\mathcal{F}$.*

Proof. First combine the source obligations with the adjunction ledger. The source theorem identifies the consumed BEDC certificates, and the ledger theorem identifies the only Frobenius comparison, unit, counit, and continuation rows.

Next add the character-pairing boundary. It places every character read behind Q, R, I, χ before the Frobenius ledger can be inspected.

Finally apply componentwise transport and replay. The rows C and P preserve exactly the displayed tuple, and the local row N names the resulting certificate. Since no obligation outside $\mathcal{F}$ is available, these clauses give the stated NameCert surface. □

Theorem 5806.5 (FrobeniusReciprocityUp consumer handoff)**.** *A downstream consumer of* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *may read exactly the consumed finite-group action row G, subgroup row H, representation-ring row R, induced-representation row I, character-theory row Q, Frobenius rows Φ, η, ϵ, character-pairing boundary χ, visible ledger λ, replay row C, provenance row P, and local name row N. Any consumer handoff to* $\mathsf{InducedRep}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, *or* $\mathsf{CharacterTheory}^{\uparrow}$ *factors through those*

rows and cannot bypass them through a host category, functor equality, semisimplicity theorem, or character-table computation.

Proof. Start with a downstream read. The only visible source coordinates are G, H, R, I, Q, and the only local Frobenius coordinates are $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

For an $\mathsf{InducedRep}^{\uparrow}$ consumer, the handoff is through I together with the Frobenius rows. For a $\mathsf{RepresentationRing}^{\uparrow}$ consumer, the handoff is through R and the source ledger. For a $\mathsf{CharacterTheory}^{\uparrow}$ consumer, the handoff is through Q and the pairing boundary χ.

The replay and provenance rows preserve the same finite route. Thus a consumer cannot bypass the displayed packet through a host category, functor equality, semisimplicity theorem, or character-table computation. □

Theorem 5806.6 (FrobeniusReciprocityUp sibling lattice)**.** *The* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet is a finite comparison consumer of the sibling carriers in chapter 3662, chapter 80, chapter 246, chapter 247, and chapter 245. Its local rows compare induction and restriction after those carriers are visible; they do not form an isolated kernel row and do not replace the representation, subgroup, ring, induced-representation, or character-theory certificates.*

Proof. Read the source tuple of Definition 5806.1. The rows G, H, R, I, Q are precisely the five sibling certificates named in the statement.

The consumer handoff of Definition 5806.5 permits downstream reads only through those rows together with the Frobenius comparison, unit, counit, pairing boundary, ledger, replay, provenance, and local name rows.

Therefore the packet sits inside the displayed representation-theory lattice. It is a comparison consumer over the sibling carriers, not a standalone kernel surface from which the sibling certificates can be reconstructed. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5806.1, Definition 5806.2, Definition 5806.3, Definition 5806.4, Definition 5806.5, and Definition 5806.6 seed the finite Frobenius reciprocity certificate over displayed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, semisimplicity, Schur orthogonality, irreducible decomposition, character-table computation, functor-category equality, or a host adjunction theorem.

Upgrade path: Obligation closure requires checked carrier admission, adjunction-ledger exactness, character-pairing boundary, NameCert surface, and downstream handoff for the same finite packet.

Constructive story: A $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet is generated from consumed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows, then records a finite Frobenius comparison, unit and counit rows, character-pairing boundary, visible continuation ledger, package provenance, and local NameCert evidence.

Chapter 5807

A Concrete Naming Certificate for $\mathsf{NormalOperator}^{\uparrow}$

Following Reed and Simon, the $\mathsf{NormalOperator}^{\uparrow}$ packet records the standard normal-operator surface as finite NameCert data over displayed Hilbert and inner-product candidates. It consumes the inner-product carrier of chapter 86, the Hilbert carrier of chapter 91, the linear-map rows of chapter 48, the operator-norm boundary of chapter 3603, and the downstream spectral-theorem consumer of chapter 214. The packet exposes only a bounded linear operator, its displayed adjoint-action row, the norm ledger, and the normality commutator row; it does not claim spectral measure existence, functional calculus, diagonalization, projection-valued measures, or a host operator algebra.

Definition 5807.1 (NormalOperator carrier)**.** *For a displayed* $\mathsf{Hilbert}^{\uparrow}$ *candidate* H *with* $\mathsf{InnerProduct}^{\uparrow}$ *row* I*, a* $\mathsf{NormalOperator}^{\uparrow}(H)$ *carrier is a finite* BHist *packet*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N)$$

with the following ten displayed fields:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *carrier row and I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row over the same point-history carrier.*
2. *T is a bounded* $\mathsf{LinMap}^{\uparrow}$ *endpoint action on the carried Hilbert endpoints.*
3. *T^* is the displayed adjoint-action row, certified by the finite inner-product comparison*

   $$\langle Tx, y\rangle_I \ \mathsf{hsame}\ \langle x, T^*y\rangle_I$$

   for the vector histories inspected by the packet.
4. *A is the adjoint-domain ledger, recording that the adjoint row is read over the same Hilbert, inner-product, linear-map, and boundedness surfaces as T.*
5. *K is the* $\mathsf{OperatorNorm}^{\uparrow}$ *bound row for T and for the displayed adjoint action T^*.*
6. *Q is the normality commutator row*

   $$T^*T \ \mathsf{hsame}\ TT^*$$

   read only on certified vector histories.
7. *L is the operator graph ledger: it stores inspected input histories, output histories, linearity rows, adjoint rows, norm-bound rows, and the commutator row.*

8. *H_T records componentwise* hsame *transport for the Hilbert source, inner-product row, endpoint actions, adjoint row, norm row, commutator row, and ledger.*
9. *C records displayed* Cont *replay for endpoint action requests, adjoint-action requests, norm-bound requests, and commutator inspections.*
10. *P, N are the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *naming rows.*

The classifier compares accepted carriers by action agreement on certified vector histories, adjoint-action agreement on the same inspected histories, transport of the operator-norm row, and transport of the graph, adjoint, normality, continuation, provenance, and local-name ledgers. It has no coordinate for host operator equality, quotient completion, spectral measures, eigenvector bases, or external functional calculus.

Lean4 ✓ `BEDC.Derived.NormalOperatorUp.NormalOperatorTasteGate single carrier alignment`

Theorem 5807.2 (NormalOperator NameCert obligations)**.** *For every accepted* $\mathsf{NormalOperator}^\uparrow$ *carrier*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the common* $\mathsf{Hilbert}^\uparrow$ *and* $\mathsf{InnerProduct}^\uparrow$ *rows;*
2. *bounded* $\mathsf{LinMap}^\uparrow$ *action for T on certified vector histories;*
3. *adjoint-action agreement for T^* against the displayed inner product;*
4. $\mathsf{OperatorNorm}^\uparrow$ *bound rows for the operator action and adjoint action;*
5. *normality commutator exactness through the displayed row Q;*
6. *graph-ledger exactness for input histories, output histories, linearity rows, adjoint rows, norm rows, and commutator rows;*
7. *classifier transport by action agreement, adjoint-action agreement, norm-row agreement, and componentwise ledger transport;*
8. Cont *replay,* Pkg *provenance, and local naming for exactly the displayed packet;*
9. *refusal of spectral measure existence, diagonalization, projection-valued measures, host operator quotients, and unrecorded functional calculus.*

Proof. Project the carrier of Definition 5807.1. The Hilbert and inner-product source rows, endpoint action, adjoint-action row, adjoint-domain ledger, norm row, commutator row, graph ledger, transport row, continuation row, provenance row, and local name are the full displayed inventory.

The adjoint and boundedness obligations are read before any spectral consumer appears. The adjoint row is the finite inner-product comparison for certified vector histories, and the norm row is the displayed $\mathsf{OperatorNorm}^\uparrow$ bound attached to both endpoint actions.

Normality is exactly the commutator row Q. Because Q compares T^*T and TT^* only through inspected vector histories and their graph ledger, the packet does not appeal to host equality of operators.

Finally H_T, C, P, N transport, replay, source, and name those rows. Since the carrier has no spectral-measure, diagonalization, projection-valued-measure, quotient, or functional-calculus coordinate, the listed rows exhaust the local normal-operator NameCert obligations. □

Theorem 5807.3 (NormalOperator InnerProduct spectral anchor)**.** *Every downstream spectral read of an accepted* $\mathsf{NormalOperator}^{\uparrow}$ *packet factors through the common Hilbert and inner-product rows, the bounded linear action, the displayed adjoint-action row, the operator-norm bound, and the normality commutator ledger before it can be consumed by the* $\mathsf{SpectralTheorem}^{\uparrow}$ *surface. The route is*

$$(H, I) \longmapsto (T, T^*, A, K, Q, L) \longmapsto (H_T, C, P, N),$$

and it exports no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality.

Proof. Expose the accepted packet by Definition 5807.1. The only analytic source rows are the Hilbert carrier, inner-product comparison row, endpoint action, displayed adjoint action, norm bound, and normality commutator.

Apply Definition 5807.2. The graph ledger forces the operator action, adjoint action, boundedness evidence, and commutator evidence to be read from one finite packet, and classifier transport keeps the operator and adjoint rows over the same certified vector histories.

It remains to hand the packet to spectral consumers. The $\mathsf{SpectralTheorem}^{\uparrow}$ chapter may consume the normality anchor only through the displayed rows already named here. Because no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality is a field of the carrier, the anchor supplies a pre-spectral normal-operator surface rather than a spectral theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5807.1, Definition 5807.2, and Definition 5807.3 seed the normal-operator surface over Hilbert, inner-product, bounded linear-map, adjoint-action, operator-norm, and commutator rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim spectral measures, spectral projections, diagonalization, eigenbasis construction, Borel functional calculus, host operator quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, adjoint-action agreement, norm-bound stability, normality commutator exactness, classifier transport, graph-ledger exactness, spectral-consumer nonescape, and bridge data for BEDC.Derived.NormalOperatorUp.

Constructive story: A $\mathsf{NormalOperator}^{\uparrow}$ packet is generated from a Hilbert source, an inner-product row, a bounded linear endpoint action, a displayed adjoint action, operator-norm bounds, a normality commutator row, graph and transport ledgers, continuation replay, provenance, and a local NameCert row.

Chapter 5808

A Concrete Naming Certificate for $\mathsf{HausdorffMeasure}^{\uparrow}$

Following Hausdorff and Federer's metric measure theory, the $\mathsf{HausdorffMeasure}^{\uparrow}$ packet records the finite dyadic-cover surface through which Hausdorff content and scale-stable measure reads become visible inside BEDC. It sits over the metric carrier of chapter 57, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the cover-valued outer-measure boundary of chapter 3385, and the finite scale-cover comparison surface of chapter 3877. The packet names only displayed dyadic cover packets, diameter budgets, weighted cover sums, scale comparison, transport, replay, provenance, and local naming; it is not a quotient cover family, not a selected infimum, not countable choice over covers, and not an ambient measure primitive.

Definition 5808.1 (Hausdorff measure dyadic-cover carrier)**.** *A* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (M, D, R, O, B, C, S, T, E, K, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the finite point classifier and distance comparisons used to bound cover diameters.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row, naming the dyadic radius budget and dyadic exponent used by the cover packet.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *value-seal row for diameter powers and finite cover sums.*
4. *O is the* $\mathsf{OuterMeasure}^{\uparrow}$ *handoff row, read only as a finite cover-valued boundary and not as a completed measure primitive.*
5. *B is the* $\mathsf{BoxDimension}^{\uparrow}$ *comparison row, exposing finite scale-cover counts against the same dyadic scale.*
6. *C is the finite dyadic cover packet, listing the displayed cover cells, their metric diameter witnesses, and their membership reads.*
7. *S is the cover-sum ledger, recording the finite Real-sealed sum of dyadic diameter weights.*
8. *T is the scale-stability ledger, recording that dyadic refinement reads the same metric source, outer-measure boundary, and box-dimension comparison rows.*
9. *E records componentwise* hsame *transport for metric, dyadic scale, Real seal, outer-measure handoff, box-dimension comparison, cover packet, cover sum, and stability rows.*

10. *K records displayed* Cont *replay from a metric source and dyadic scale through C, S, T, E, P, N.*
11. *P is the* Pkg *provenance over* $\mathsf{HausdorffMeasure}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{OuterMeasure}^{\uparrow}$, $\mathsf{BoxDimension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D, R, O, B, C, S, T, E, K, P, N$. It has no coordinate for quotient cover families, selected infima, countable-choice schedules over covers, host sigma-algebras, or ambient measure primitives.

Lean4 ✓ `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate single carrier alignment`

Theorem 5808.2 (Hausdorff measure NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier $H = (M, D, R, O, B, C, S, T, E, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *surface consists exactly of metric source admission, dyadic scale exposure, Real value sealing, finite outer-measure handoff, box-dimension scale comparison, finite dyadic cover admission, cover-sum exactness, scale-stability replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every measure-facing or dimension-facing consumer must read the displayed route*

$$\mathsf{Met}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto C, S, T \longmapsto \mathsf{OuterMeasure}^{\uparrow}, \mathsf{BoxDimension}^{\uparrow} \longmapsto E, K, P, N$$

before treating the packet as a Hausdorff-measure read.

Proof. Project the carrier of Definition 5808.1. The metric row M, dyadic row D, and Real seal row R are the only sources for distances, scales, and finite value readback.

The cover packet C and cover-sum ledger S are finite rows. They record displayed cover cells and dyadic diameter weights, so no step selects a minimizing cover family or takes an external infimum.

The outer-measure and box-dimension rows O, B are downstream comparison boundaries. They can read the same finite cover data, but they do not add a completed host measure, a quotient of covers, or countable choice over refinements.

Finally T, E, K, P, N transport, replay, source, and name the same finite route. Since every exported obligation is one of the listed rows, the local classifier cannot expose an ambient measure primitive or any detached cover selector. □

Theorem 5808.3 (Hausdorff measure dyadic-cover stability)**.** *Let $H = (M, D, R, O, B, C, S, T, E, K, P, N)$ be an accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier. For any displayed dyadic refinement of the scale row D, the scale-stability ledger T forces the refined read to reuse the same* $\mathsf{Met}^{\uparrow}$ *source, the same* $\mathsf{Real}^{\uparrow}$ *value-seal route, the same finite* $\mathsf{OuterMeasure}^{\uparrow}$ *cover boundary, and the same* $\mathsf{BoxDimension}^{\uparrow}$ *scale-count comparison before any consumer reads a Hausdorff-measure claim. The stable route is*

$$M, D, R, C, S, T \longmapsto O, B \longmapsto E, K, P, N.$$

It exports no quotient cover family, selected infimum, countable-choice cover schedule, host sigma-algebra closure, or ambient measure primitive.

Proof. Read the carrier of Definition 5808.1. A dyadic refinement changes only the displayed scale request inside D and the finite cover packet admitted by C.

Use the stability ledger T. It records that the refined cover is replayed against the same metric source and that its finite cover sum is sealed through the same Real row, so the refinement cannot introduce a detached minimizing cover or a host infimum.

The comparison rows O and B then read the refined packet as finite outer-measure and box-dimension boundary data. Componentwise transport and displayed replay through E, K, P, N preserve that route, while quotient covers, countable choice, host sigma-algebras, and ambient measure primitives remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HausdorffMeasure}^{\uparrow}$ consumer that reaches a Hausdorff-measure read without first exposing a MetricUp source row, a DyadicRatCore scale row, a RealUp value seal, a finite dyadic cover packet, a finite cover-sum ledger, an OuterMeasureUp handoff, a BoxDimensionUp comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row refutes the carrier surface.

Independence witness: metric, dyadicratcore, real, outermeasure, boxdimension: $\mathsf{HausdorffMeasure}^{\uparrow}$ is not bijective to any listed sibling because it binds metric diameter data, dyadic scales, Real-sealed finite cover sums, outer-measure cover boundaries, and box-dimension scale counts into one finite cover-stability NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffMeasure}^{\uparrow}$ packet is generated from a MetricUp source row, DyadicRatCore scale row, RealUp value-seal row, finite OuterMeasureUp handoff, BoxDimensionUp comparison row, finite dyadic cover packet, cover-sum ledger, scale-stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5808.1, Definition 5808.2, and Definition 5808.3 seed the finite dyadic-cover Hausdorff-measure interface over MetricUp, DyadicRatCoreUp, RealUp, OuterMeasureUp, and BoxDimensionUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient cover families, selected infima, countable choice over covers, host sigma-algebra completion, ambient measure primitives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic scale exposure, finite cover admission, cover-sum exactness, scale-stability replay, outer-measure handoff, box-dimension comparison, transport, provenance, and no-escape for BEDC.Derived.HausdorffMeasureUp.

Chapter 5809

A Concrete Naming Certificate for $\mathsf{LocallyConnected}^{\uparrow}$

Following Kelley and Bourbaki on local connectedness, the $\mathsf{LocallyConnected}^{\uparrow}$ packet records finite neighbourhood-component data rather than a selected basis of connected open sets. It sits beside the global connectedness carrier of chapter 2353, the compact metric source discipline of chapter 129, the metric ball rows of chapter 57, and the open-neighbourhood ledger of chapter 88. The packet exposes the local component route needed by compact-metric and connected-space consumers without importing path selection, arc connectedness, open-cover compactness, or a host topological basis.

Definition 5809.1 (Locally connected carrier)**.** *A* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, M, G, K, B, C, H, R, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-neighbourhood row whose entries name the ambient open requests.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *ball-observation row used when the local request is metric.*
3. *G is the* $\mathsf{ConnectedSpace}^{\uparrow}$ *global component row available to consumers that compare local and global connectedness.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-source row available to compact-metric consumers.*
5. *B is the finite neighbourhood-refinement row: each displayed point and open request has a named smaller neighbourhood row.*
6. *C is the local connected-component row attached to the refinement in B.*
7. *H records componentwise* hsame *transport for the topology, metric, connectedness, compact-metric, refinement, component, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from an ambient open request through metric ball observations when present, the finite refinement row, and the local component row.*
9. *P is the* Pkg *provenance over* $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConnectedSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, M, G, K, B, C, H, R, P, N$. It has no coordinate for selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, or a host basis of connected neighbourhoods.

Lean4 ✓ `BEDC.Derived.LocallyConnectedUp.TasteGate.LocallyConnectedTasteGate single carrier alignment`

Theorem 5809.2 (Locally connected NameCert obligations)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier* $L = (T, M, G, K, B, C, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *surface consists exactly of carrier admission for the topology, metric, connected-space, compact-metric, finite neighbourhood-refinement, local component, transport, replay, provenance, and naming rows; neighbourhood refinement from T through B; component exposure through C; metric compatibility through M when the request is ball-based; compact-metric compatibility through K for compact finite-source consumers; connected-space comparison through G; and non-escape from selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice.*

Proof. Project the carrier of Definition 5809.1. The projection exposes exactly the rows $T, M, G, K, B, C, H, R, P, N$ so every local naming obligation must be read from those coordinates.

The neighbourhood part is finite. An ambient open request is first read in T, then refined by the displayed row B, and only then receives the local component row C.

The metric and compact-metric rows are compatibility rows rather than extra selectors. A ball-based request may inspect M, and a compact-metric consumer may inspect K, but both routes still pass through the same B and C rows before local connectedness is exported.

Finally, H and R transport and replay the displayed route, while P and N source and name it. Since paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice are not rows of the carrier, the NameCert surface cannot export them. □

Theorem 5809.3 (Locally connected neighbourhood component route)**.** *Every connected-space or compact-metric consumer of an accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *packet reaches local connectedness through*

$$\mathsf{Topology}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{ConnectedSpace}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The finite route reads an ambient neighbourhood, optionally reads metric ball observations, refines to a displayed smaller neighbourhood, and then reads the named local connected component. It does not select a path, an arc, a subcover, a quotient component representative, or a host connected-neighbourhood basis.

Proof. Start with a consumer that asks for local connectedness around a displayed point. Carrier admission gives the consumer the topology row T, the metric row M when a ball observation is part of the request, the global connectedness row G, and the compact-metric row K.

The route then passes through B and C. The row B supplies the finite neighbourhood refinement, and C supplies the local component attached to that refinement.

The structural rows H, R, P, N do not add a hidden selector. They transport, replay, source, and name the same finite route, so no path, arc, arbitrary subcover, quotient representative, or host basis can replace the displayed neighbourhood-component data. □

Theorem 5809.4 (Locally connected obligation closure surface)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier* $L = (T, M, G, K, B, C, H, R, P, N)$*, the obligation-closure surface is exhausted by the displayed finite topology, metric, connected-space, compact-metric, neighbourhood-refinement, local-component, transport, replay, provenance, and naming rows. The row T supplies the open-neighbourhood*

source, M supplies metric-ball observations, G supplies connected-space comparison, K supplies compact-metric finite-source compatibility, B, C supply the local refinement and component rows, and H, R, P, N supply transport, replay, provenance, and local naming.

The local component route therefore consumes the connected-space carrier of chapter 2353, the compact-metric finite neighbourhood discipline of chapter 129, the metric-ball rows of chapter 57, and the topology neighbourhood ledger of chapter 88 before a local component can be named.

Proof. Apply Definition 5809.2 to the accepted carrier. It identifies the complete NameCert surface with the rows $T, M, G, K, B, C, H, R, P, N$.

Apply Definition 5809.3. The route from an open request to a local component passes through topology, optional metric-ball observations, connected-space comparison, compact-metric compatibility, finite refinement, and component rows before the structural rows transport and name the result.

The sibling lattice is read in that order: topology supplies the neighbourhood ledger, metric supplies ball observations, connected-space supplies the comparison carrier, and compact metric supplies the finite neighbourhood discipline. The local refinement and component rows then bind those sibling contributions into the $\mathsf{LocallyConnected}^{\uparrow}$ packet.

Thus the obligation surface is the stated finite route. Path or arc selection, open-cover compactness, quotient components, and a host basis are refused because none of them is a carrier coordinate or a row used by the two preceding theorems. □

Falsifiable prediction: Every accepted $\mathsf{LocallyConnected}^{\uparrow}$ read must expose a $\mathsf{Topology}^{\uparrow}$ open-neighbourhood row, optional $\mathsf{Met}^{\uparrow}$ ball observations, the $\mathsf{ConnectedSpace}^{\uparrow}$ comparison row when a global consumer is present, the $\mathsf{CompactMetric}^{\uparrow}$ finite-source row when a compact-metric consumer is present, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: topology, metric, connected-space, compactmetric: $\mathsf{LocallyConnected}^{\uparrow}$ is not bijective to any listed sibling because it binds a local neighbourhood-refinement row to a local component row before connected-space or compact-metric consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5809.1, Definition 5809.2, and Definition 5809.3 seed the finite local neighbourhood-component route over topology, metric, connected-space, and compact-metric rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close path connectedness, arc connectedness, arbitrary open-cover compactness, quotient component spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, neighbourhood refinement, local component exposure, connected-space comparison, compact-metric compatibility, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.LocallyConnectedUp.

Constructive story: A $\mathsf{LocallyConnected}^{\uparrow}$ packet is generated from an open-neighbourhood row, optional metric ball observations, connected-space and compact-metric compatibility rows, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5810

A Concrete Naming Certificate for $\mathsf{BishopCauchyMean}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{BishopCauchyMean}^{\uparrow}$ packet records the finite averaging step used when a Cauchy source is read through displayed rational windows and sealed as a Real-facing name. It sits after the $\mathsf{Cauchy}^{\uparrow}$ source route of chapter 3413, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names finite averages of observed Cauchy data; it does not assert a selected limit, quotient stream equality, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5810.1 (Bishop Cauchy mean carrier)**.** *A* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Cauchy}^{\uparrow}$ *source row naming the Cauchy data whose finite observations are being averaged.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested dyadic radius, denominator budget, and comparison scale for the average.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the source entries inspected at tolerance D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream window into regular rational data.*
5. *A is the finite averaging ledger: it lists the inspected rational entries, their displayed weights, the denominator row, the partial-sum row, and the final mean row consumed by the certificate.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, W, R, A have been displayed.*
7. *H records componentwise* hsame *transport for the source, tolerance, window, readback, averaging ledger, Real seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a finite mean request through $S, D, W, R, A, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyMean}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, D, W, R, A, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness of $\mathsf{Real}^{\uparrow}$*, or an infinite averaging oracle.*

Lean4 ✓ `BEDC.Derived.BishopCauchyMeanUp.BishopCauchyMeanTasteGate single carrier alignment`

Theorem 5810.2 (Bishop Cauchy mean NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier*

$$M = (S, D, W, R, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cauchy source row, dyadic tolerance row, finite stream window, regular rational readback, finite averaging ledger, terminal Real seal, componentwise transport row, displayed continuation replay, package provenance, and local naming row.*

The obligation surface requires Cauchy-source visibility through S, tolerance accounting through D, finite-window visibility through W, regular rational readback through R, average-ledger exactness through A, Real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It refuses selected limits, quotient stream equality, host real equality, countable choice, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the accepted carrier of Definition 5810.1. The only analytic rows are the Cauchy source S, the dyadic tolerance D, the finite window W, the regular rational readback R, the averaging ledger A, and the terminal Real seal E.

The averaging step is finite. The ledger A displays the inspected rational entries, their weights, the denominator row, the partial sums, and the final mean; no later consumer can ask for an average outside this listed window.

The terminal seal is downstream of the displayed route. Since the carrier has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness, or an infinite averaging oracle, those objects cannot enter the local NameCert surface.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. They preserve the displayed rows and do not add analytic content. □

Theorem 5810.3 (Bishop Cauchy mean finite-average stability)**.** *Let*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

be an accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier. Every accepted consumer read of the mean row factors through the finite route*

$$\mathsf{Cauchy}^{\uparrow}(S),\ \mathsf{DyadicRatCore}^{\uparrow}(D),\ \mathsf{StreamName}^{\uparrow}(W),\ \mathsf{RegSeqRat}^{\uparrow}(R),\ A,\ \mathsf{Real}^{\uparrow}(E).$$

If the source row, tolerance row, finite window, readback row, and averaging ledger are transported componentwise by the displayed hsame *rows in H and replayed through C, then the consumer-visible mean row is unchanged as a* $\mathsf{BishopCauchyMean}^{\uparrow}$ *read. No quotient stream equality, selected limit, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row participates in the stability claim.*

Proof. Start with the consumer route. By the carrier definition, a mean read must first inspect the Cauchy source S, choose the displayed dyadic tolerance D, open the finite window W, and read the regular rational row R.

The average itself is then the ledger row A. Its entries, weights, denominator, partial sums, and final mean are finite displayed data, so componentwise hsame transport preserves exactly the rows that the consumer can inspect.

Replay through C exposes the transported packet with the same provenance and local naming rows P, N. The terminal Real seal E is reached from that transported finite route, not from a quotient stream or selected limit.

Thus any consumer-visible equality of mean reads is exhausted by $S, D, W, R, A, E, H, C, P, N$. The excluded rows are absent from the carrier and cannot affect the stability conclusion. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ read must expose a Cauchy source, dyadic tolerance, StreamName window, RegSeqRat readback, finite averaging ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a Real or Completion consumer can read the mean boundary.

Independence witness: cauchy, dyadicratcore, streamname, regseqrat, real: $\mathsf{BishopCauchyMean}^{\uparrow}$ is not bijective to any listed sibling because it binds a finite averaging ledger between regular rational readback and the Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyMean}^{\uparrow}$ packet is generated from a Cauchy source row, DyadicRatCore tolerance row, StreamName finite window, RegSeqRat readback, finite averaging ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5810.1, Definition 5810.2, and Definition 5810.3 seed the finite Cauchy-mean certificate over Cauchy, DyadicRatCore, StreamName, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite average ledger exactness, tolerance-window readback, regular rational handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyMeanUp.

Chapter 5811

A Concrete Naming Certificate for $\mathsf{BishopFixedPointInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet records the constructive interval fixed-point route as finite NameCert data. It sits after the located interval source of chapter 394, the bisection discipline of chapter 1465, the finite Cauchy-modulus rows used by chapter 292, the regular rational readback of chapter 301, the finite name windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the fixed-point certificate for a displayed interval self-map; it does not import a host compactness theorem, quotient real equality, choice-selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5811.1 (Bishop fixed-point interval carrier)**.** *A* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, T, M, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the closed located interval, its endpoint reads, and its dyadic radius ledger.*
2. *T is the contraction self-map row over I, recording that every admitted interval point is sent back into the same located interval.*
3. *M is an explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *or Lipschitz modulus row that turns each tolerance request into a finite contraction budget.*
4. *B is the* $\mathsf{IntervalBisection}^{\uparrow}$ *or nested located interval row that records the displayed shrinking interval chain.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the rational midpoint, endpoint, and radius observations.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *fixed-point seal reached only after the interval, contraction, modulus, bisection, and readback rows have been exposed.*
7. *H records componentwise* hsame *transport for I, T, M, B, R, E and for the structural rows.*
8. *C records displayed* Cont *replay for interval requests, contraction reads, modulus reads, nested interval reads, rational readback, and real-seal requests.*

9. *P is the* Pkg *provenance over* BishopFixedPointInterval$^{\uparrow}$, LocatedInterval$^{\uparrow}$, IntervalBisection$^{\uparrow}$, CauchyModulus$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{BishopFixedPointInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, T, M, B, R, E, H, C, P, N$. It has no coordinate for a host fixed-point theorem, quotient completion, selected limit, trichotomy, countable choice, or ambient compactness principle.

Lean4 ✓ `BEDC.Derived.BishopFixedPointIntervalUp.BishopFixedPointIntervalTasteGate single carrier alignment`

Theorem 5811.2 (Bishop fixed-point interval NameCert obligations)**.** *For every accepted* BishopFixedPointInterval$^{\uparrow}$ *carrier*

$$F = (I, T, M, B, R, E, H, C, P, N),$$

the local NameCert$_{\text{BishopFixedPointInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the located interval row I, contraction self-map row T, explicit modulus row M, nested bisection row B, regular rational readback row R, terminal real seal E, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N. Every fixed-point consumer must read these rows in the displayed order and cannot replace them by host interval compactness, quotient real equality, a selected limit, or an unrecorded convergence principle.*

Proof. Carrier admission is the finite packet of Definition 5811.1. The rows $I, T, M, B, R, E, H, C, P, N$ are the only coordinates available to the local certificate.

The positive interval route is then forced. The interval source is I, the self-map evidence is T, the contraction budget is M, and the nested interval chain is B; each row is compared only through the componentwise transport row H and replayed only through C.

The readback and seal are downstream. Rational observations pass through R and the dyadic and stream-name data named in P before the terminal Real$^{\uparrow}$ row E is exposed. Since no host compactness, quotient equality, selected limit, or external convergence coordinate occurs in the carrier, the listed rows exhaust the NameCert surface. □

Theorem 5811.3 (Bishop fixed-point interval Cauchy-modulus route)**.** *Let $F = (I, T, M, B, R, E, H, C, P, N)$ be an accepted* BishopFixedPointInterval$^{\uparrow}$ *packet. Each tolerance request for the fixed-point name is answered by first reading the* LocatedInterval$^{\uparrow}$ *row I, then the contraction self-map row T, then the explicit* CauchyModulus$^{\uparrow}$ *or Lipschitz row M, and only then the* IntervalBisection$^{\uparrow}$ *or nested located interval row B. The resulting finite observations are read through* StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* RegSeqRat$^{\uparrow}$ *as recorded by P, so no consumer can infer convergence from an unbounded host iteration or a choice-selected subsequence.*

Proof. Start with a tolerance request. The packet has no direct convergence row, so the request must project I to know the interval source and T to know that the displayed map remains inside the interval.

Next read the modulus row M. This row converts the tolerance into a finite contraction or Lipschitz budget. The nested row B can then expose only the finite bisection or located-interval observations licensed by that budget.

Finally use the readback rows listed in P. Stream windows, dyadic tolerances, and regular rational observations feed R, and H, C, N transport and name the same route. Thus the Cauchy route is explicit and finite, with no unbounded host iteration or selected subsequence. □

Theorem 5811.4 (Bishop fixed-point interval real-seal nonescape)**.** *For every accepted* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *packet, the terminal row* E *is exposed only as the* $\mathsf{Real}^{\uparrow}$ *seal of the displayed nested interval and Cauchy-modulus route*

$$I, T, M, B, R \longmapsto E \longmapsto H, C, P, N.$$

The seal may be consumed as the named fixed-point endpoint of the packet, but it cannot escape as quotient real equality, a proof of ambient $\mathsf{Real}^{\uparrow}$ *completeness, a host fixed-point theorem, an unrestricted interval compactness principle, or a selected representative outside the displayed rows.*

Proof. Read E from the carrier. It is terminal in the packet: the interval, self-map, modulus, nested interval, and rational readback rows precede it, and the structural rows only transport, replay, source, and name the resulting read.

Apply Definition 5811.3. Every tolerance request reaching E has already passed through the finite interval, contraction, modulus, bisection, stream, dyadic, and regular rational observations recorded by I, T, M, B, R, P.

It remains to rule out escape. The carrier has no coordinate for quotient real equality, ambient completeness, a host fixed-point theorem, unrestricted compactness, or selected representatives. Therefore E seals only the displayed fixed-point name of this packet. □

Falsifiable prediction: An accepted $\mathsf{BishopFixedPointInterval}^{\uparrow}$ consumer that reaches the terminal $\mathsf{Real}^{\uparrow}$ row E without first reading $I, T, M, B, R, H, C, P, N$ refutes the carrier surface.

Independence witness: locatedinterval, intervalbisection, cauchymodulus, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the full interval self-map packet $F = (I, T, M, B, R, E, H, C, P, N$ because each sibling contributes only a located interval source, a bisection route, a modulus row, a readback row, a finite name window, a dyadic ledger, or a terminal real seal while this chapter binds them into one fixed-point NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet is generated from a located interval row, contraction self-map row, explicit Cauchy or Lipschitz modulus row, nested bisection row, regular rational readback row, terminal Real seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5811.1, Definition 5811.2, Definition 5811.3, and Definition 5811.4 seed the finite constructive interval fixed-point route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point compactness, quotient real equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction self-map admission, explicit modulus routing, nested interval readback, terminal Real seal nonescape, and a Lean carrier/obligation formalization for BEDC.Derived.BishopFixedPointIntervalUp.

Chapter 5812

A Concrete Naming Certificate for $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$

The $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet realizes the private-coordinate minimal-cover theorem of Definition 9462.1678 as finite NameCert data. It records a trigger-coordinate carrier, a support-family cover ledger, and one private-coordinate witness row for each displayed support before any minimal-trigger criterion may be consumed. The packet keeps the enumeration theorem auditable without identifying it with a generic finite set, word list, Boolean classifier, regular-language recognizer, or finite automaton presentation.

Falsifiable prediction: Every accepted $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ consumer must display a cover row and one private-coordinate witness row for each support before using the minimal-trigger criterion.

Independence witness: finset, list, bool, regularlanguage, finite-automaton: $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ is not bijective to these siblings because it carries a support-family cover ledger plus a private-coordinate witness for every support row.

Definition 5812.1 (Private-coordinate trigger carrier)**.** *A* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the finite trigger-coordinate row.*
2. A *is the finite support-family row whose entries are displayed subsets of* Ω*.*
3. U *is the cover ledger asserting that the displayed supports cover every coordinate of* Ω*.*
4. V *is the private-coordinate witness ledger, with one row for each support in* A*.*
5. π *maps each support row to its selected private coordinate and records membership in that support.*
6. E *records exclusion from every other support row for the selected private coordinate.*
7. K *is the minimal-cover criterion row, readable only after* U, V, π, E *have been displayed.*
8. H *stores componentwise* hsame *transport for coordinate, support, cover, witness, exclusion, and criterion rows.*

9. *C stores* Cont *replay from a trigger query through the cover ledger and the private-coordinate witness rows.*
10. *P stores* Pkg *provenance over* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Omega, A, U, V, \pi, E, K, H, C, P, N$. It has no coordinate for a bare finite set, unordered list, Boolean truth table, regular-language recognizer, finite automaton run, or support family without displayed private witnesses.

Theorem 5812.2 (Private-coordinate trigger NameCert obligations)**.** *For every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *surface consists exactly of coordinate exposure, support-family exposure, cover-ledger replay, one private-coordinate witness row for each support, membership and exclusion checks for the selected witnesses, minimal-cover criterion exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5812.1. The rows Ω, A, U display the finite coordinate space, the support family, and the fact that the supports cover the full coordinate row.

The rows V, π, E attach a private coordinate to each support. Membership is recorded by π, and exclusion from every other support is recorded by E, so deleting the support removes at least one displayed coordinate from the cover.

The criterion row K is therefore readable only after the cover and private-witness rows have been exposed. The remaining rows H, C, P, N preserve transport, replay, provenance, and local naming for the same finite packet, and no omitted sibling surface supplies the private-coordinate ledger. □

Theorem 5812.3 (Private-coordinate minimal-cover criterion)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier exposes a minimal full trigger exactly through the displayed cover row U together with the private-coordinate witness rows V, π, E. A consumer may use the criterion row K only after reading a cover of Ω and one witness coordinate for every support row in A that belongs to that support and belongs to no other displayed support. The packet does not turn the support family into a regular language, finite automaton, Boolean table, or list quotient.*

Proof. The forward read uses the cover ledger U and the private-coordinate witness rows. If a support row is removed, its selected witness coordinate remains outside all other displayed supports by E, so the remaining family no longer covers Ω.

For the reverse read, the cover row already gives full coverage. The witness rows ensure that every support has a coordinate lost by deleting that support, so no displayed support is redundant.

Thus the criterion row K is exactly the finite private-coordinate minimal-cover test. The transport, replay, provenance, and local naming rows carry this test without converting it into any sibling classifier. □

Theorem 5812.4 (Private-coordinate trigger finite-set cover route)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *packet reads its support-family row as a finite-set-indexed cover through chapter 112. The exclusions from regular-language and automaton presentations are bounded by chapter 351 and chapter 2364: the private-coordinate carrier may display finite support rows, recognizer-like acceptance tests, or transition-like exclusion checks, but it exports the minimal-cover criterion only through the rows $\Omega, A, U, V, \pi, E, K, H, C, P, N$.*

Proof. Project the accepted carrier

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N).$$

The row Ω is the displayed coordinate object, and A is read as a finite family of supports indexed by the finite-set surface. The cover ledger U then witnesses coverage of every coordinate in Ω by those displayed supports.

The rows V, π, E are the extra private-coordinate ledger. They attach one witness coordinate to each support, record membership in that support, and record exclusion from every other displayed support. These rows are not supplied by the finite-set sibling, nor by the regular-language or finite-automaton presentations.

Consequently K is a private-coordinate minimal-cover read rather than a bare finite-set cover, a regular-language recognizer, or an automaton acceptance predicate. The structural rows H, C, P, N transport and replay only this displayed packet, so the sibling route records the finite-combinatorial surface without replacing the private-coordinate data. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$.

Constructive story: A $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet is generated from a finite trigger-coordinate row, support-family row, cover ledger, per-support private-coordinate witness ledger, membership and exclusion rows, minimal-cover criterion row, componentwise transport, continuation replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5812.1, Definition 5812.2, Definition 5812.3, and Definition 5812.4 seed the finite NameCert packet for private-coordinate minimal-cover witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, regular-language recognition, finite-automaton minimization, Boolean classifier completeness, or enumeration beyond the displayed private-coordinate criterion.

Upgrade path: Obligation closure requires checked carrier admission, cover-ledger replay, private-coordinate witness coverage, exclusion exactness, minimal-cover criterion replay, TasteGate nontriviality, FieldFaithful projection, transport, replay, provenance, and local naming for BEDC.Derived.PrivateCoordinateTriggerUp.

Chapter 5813

A Concrete Naming Certificate for $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet records the finite modulus by which a located real comparison request is read through displayed apartness or equality evidence, dyadic tolerances, explicit Cauchy-modulus schedules, regular rational readback, and the terminal real-name seal. It sits after the comparison surface of chapter 1730, the tail envelope of chapter 1769, the Cauchy-modulus bridge of chapter 5728, the rational readback of chapter 301, and the public real route of chapter 38. The packet names a finite comparison-schedule carrier; it is not trichotomy, quotient real equality, a selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5813.1 (Located real comparison modulus carrier)**.** *A* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, A, D, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{LocatedRealComparison}^{\uparrow}$ *request row for the two located real endpoints and the comparison direction being inspected.*
2. *A is the located evidence row. It records the displayed positive apartness witness when the request separates the endpoints, or the displayed equality-facing refusal row when the request reaches only an overlap tolerance.*
3. *D is the dyadic tolerance schedule. It lists the requested precision, comparison slack, endpoint radii, and finite tolerance refinements consumed by the comparison read.*
4. *B is the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route connecting the comparison request to an explicit Cauchy-modulus schedule before regular rational readback is allowed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected rational tails exposed by B and bounded by D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the comparison-facing read, available only after Q, A, D, B, R have been displayed.*
7. *H records componentwise* hsame *transport for the comparison request, evidence row, dyadic tolerance schedule, bridge route, readback, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from the comparison request through located evidence, dyadic scheduling, Cauchy-modulus bridging, regular rational readback, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, LocatedRealTailEnvelop $\mathsf{CauchyModulusBridge}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, A, D, B, R, E, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, a hidden selector, countable choice, a host comparison oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedRealComparisonModulusUp.LocatedRealComparisonModulusTasteGate`
`single carrier alignment`

Theorem 5813.2 (Located real comparison modulus obligations)**.** *For every accepted* LocatedRealComparisonModu *carrier*

$$M = (Q, A, D, B, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *surface consists exactly of comparison-request admission, located apartness-or-equality evidence, dyadic tolerance scheduling,* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *routing,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer of the comparison schedule must read those rows in the displayed order and receives no trichotomy split, quotient real equality, hidden selector, countable-choice schedule, host comparison oracle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 5813.1. The comparison request is Q, and the only evidence row attached to it is A.

The schedule is then forced through D and B. The dyadic row D records the finite tolerances to be inspected, while the $\mathsf{CauchyModulusBridge}^{\uparrow}$ row B turns those tolerance requests into explicit tail thresholds before any rational readback is exposed.

The terminal read is downstream. The regular rational row R reads only the displayed tails opened by B, and the $\mathsf{Real}^{\uparrow}$ seal E is available only after that readback.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for the excluded host-level or choice-level objects, the listed rows exhaust the local NameCert surface. □

Theorem 5813.3 (Located real comparison modulus nontrichotomy boundary)**.** *Every accepted* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *packet exports a positive schedule for comparison reads without exporting trichotomy. If the evidence row A records positive apartness, a downstream consumer may read that apartness only through Q, D, B, R, E; if A records only an equality-facing overlap tolerance, the consumer receives the displayed tolerance route and no forced left-or-right order verdict.*

Proof. Read the evidence row A together with the comparison request Q. The carrier does not contain a three-way order coordinate, so the two possible reads are positive displayed apartness or finite overlap tolerance.

For the positive branch, the dyadic tolerance row D and bridge row B determine which tails are inspected before R and E can be consumed. The apartness read is therefore a finite schedule read, not a global order split.

For the overlap branch, the same schedule exposes only the inspected tolerance data. Since no trichotomy coordinate or hidden selector appears in $M = (Q, A, D, B, R, E, H, C, P, N)$, the packet refuses any forced left-or-right verdict not displayed by the rows. □

Falsifiable prediction: An accepted $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is refuted if a comparison consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting the $\mathsf{LocatedRealComparison}^{\uparrow}$ request row Q, the evidence row A, the dyadic tolerance schedule D, the $\mathsf{CauchyModulusBridge}^{\uparrow}$ route B, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: LocatedRealComparison, LocatedRealTailEnvelope, CauchyModulusBridge, RegSeqRat, Real: none is bijective with $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ because the packet jointly carries a comparison request, apartness-or-equality evidence, dyadic tolerance scheduling, explicit Cauchy-modulus bridging, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is generated from a LocatedRealComparison request row, located apartness-or-equality evidence, a dyadic tolerance schedule, a CauchyModulusBridge route, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5813.1, Definition 5813.2, and Definition 5813.3 seed the finite comparison-modulus route over LocatedRealComparisonUp, LocatedRealTailEnvelopeUp, CauchyModulusBridgeUp, RegSeqRatUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, host comparison oracles, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, evidence-row exactness, dyadic schedule determinacy, Cauchy-modulus bridge routing, regular rational readback, Real-seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealComparisonModulusUp.

Chapter 5814

A Concrete Naming Certificate for $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$

The $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet realizes the boundary-shadow and observer-expansion route of chapter 9463 as finite cocycle-level NameCert data. It sits after the boundary-shadow route of chapter 3813, the observer-shadow metric of chapter 4154, the Busemann cocycle of chapter 4134, the horosphere-flow ledger of chapter 4051, and the observer-expansion packet of chapter 4167. The chapter names a finite expansion cocycle over displayed boundary and horosphere rows; it is not a completed hyperbolic boundary, quotient geodesic ray space, physical observer dynamics, selected ideal point, or ambient manifold theorem.

Definition 5814.1 (Boundary-shadow expansion cocycle carrier)**.** *A* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, O, B, F, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row recording the visible boundary shadow through which the cocycle is read.*
2. *O is the* $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ *row recording the observer-facing shadow metric comparison for the same boundary read.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row recording the additive Busemann comparison consumed by the expansion read.*
4. *F is the* $\mathsf{HorosphereFlowLedger}^{\uparrow}$ *row recording the horosphere-flow level through which boundary and Busemann rows are replayed.*
5. *E is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *row recording the displayed observer-expansion magnitude or direction attached to S, O, B, F.*
6. *H records componentwise* hsame *transport for boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow ledger, observer expansion, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, and observer-expansion read.*

8. *P is the* Pkg *provenance over* BoundaryShadowExpansionCocycle$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicObserverShadowMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HorosphereFlowLedger$^{\uparrow}$, HyperbolicObserverExp BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* NameCert$_{\text{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, O, B, F, E, H, C, P, N$. It has no coordinate for completed boundary points, quotient geodesic rays, a hidden expansion selector, physical observer dynamics, selected ideal endpoints, or ambient hyperbolic manifold data.

Theorem 5814.2 (Boundary-shadow expansion cocycle NameCert obligations)**.** *For every accepted* BoundaryShadowExpansionCocycle$^{\uparrow}$ *carrier*

$$X = (S, O, B, F, E, H, C, P, N),$$

the local NameCert$_{\text{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *surface consists exactly of boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, observer-expansion read, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any accepted expansion read that omits either the boundary-shadow row S or the Busemann cocycle row B is outside the packet.*

Proof. Project the carrier of Definition 5814.1. The boundary-facing rows are S and O, while the cocycle and horosphere-flow rows are B and F.

The expansion row E is downstream from those four rows. It can be read only after the visible boundary shadow, observer-shadow metric, Busemann cocycle, and horosphere-flow ledger have all been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for completed boundary data, quotient geodesic rays, hidden selectors, physical observer dynamics, selected endpoints, or ambient manifold structure, the listed rows exhaust the local NameCert surface. □

Theorem 5814.3 (Boundary-shadow expansion cocycle dependency route)**.** *Every accepted* BoundaryShadowExpan *read factors through*

HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicObserverShadowMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HorosphereFlowLed

before a consumer may inspect the expansion cocycle as a local NameCert row. The route is finite and preserves the boundary-shadow row and Busemann cocycle row as separate coordinates.

Proof. Use Definition 5814.2. It places the boundary-shadow row, observer-shadow metric row, Busemann cocycle row, and horosphere-flow ledger before the expansion row.

The cocycle dependency is not reducible to one sibling. The boundary-shadow row supplies the boundary face, the observer-shadow metric supplies the observer-facing comparison, the Busemann row supplies the additive cocycle read, and the horosphere-flow row supplies the level ledger.

Only after those rows are present can E, H, C, P, N expose the expansion cocycle as a local packet. Therefore a consumer cannot collapse the route to a single hyperbolic object or bypass the separate boundary-shadow and Busemann coordinates. □

Falsifiable prediction: Any accepted BoundaryShadowExpansionCocycle$^{\uparrow}$ packet is refuted if the expansion read omits either the boundary-shadow row S or the Busemann cocycle row B.

Independence witness: hyperbolic_boundary_shadow, hyperbolic_observer_shadow_metric, hyperbolic_busemann_cocycle, horosphere_flow_ledger, hyperbolic_observer_expansion: none

is bijective with $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ because the packet jointly carries boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow level, observer expansion, transport, replay, provenance, and local naming.

The Lean TasteGate route for this packet must provide `Nontrivial BoundaryShadowExpansionCocycleUp` and `FieldFaithful BoundaryShadowExpansionCocycleUp` instances in `lean4/BEDC/Derived/BoundaryShadowE` Those instances must preserve $S, O, B, F, E, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet is generated from HyperbolicBoundaryShadow rows, HyperbolicObserverShadowMetric rows, HyperbolicBusemannCocycle rows, HorosphereFlowLedger rows, HyperbolicObserverExpansion rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5814.1, Definition 5814.2, and Definition 5814.3 seed the finite boundary-shadow expansion cocycle route over boundary, observer-shadow, Busemann, horosphere-flow, expansion, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic boundaries, quotient geodesic ray spaces, physical observer dynamics, selected ideal endpoints, ambient manifold theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow exactness, observer-shadow metric readback, Busemann cocycle separation, horosphere-flow routing, observer-expansion exposure, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.BoundaryShadowExpansionCocycleUp.

The $\mathsf{HellyBraySelection}^{\uparrow}$ hub routes bounded-variation selection through chapter 398, chapter 2069, chapter 301, chapter 126, and chapter 38 before the child files expose the finite selection packet.

Chapter 5815

A Concrete Naming Certificate for $\mathsf{HellyBraySelection}^{\uparrow}$

Following Helly and Bray, the $\mathsf{HellyBraySelection}^{\uparrow}$ packet records the finite selection surface by which bounded-variation source data are read through Jordan signed-variation rows, finite stream windows, regular rational readback, and terminal real seals before a downstream selection consumer may use the packet. It sits after the bounded-variation carrier of chapter 398, the Jordan variation decomposition rows of chapter 2069, the regular rational readback route of chapter 301, the finite observation windows of chapter 126, and the terminal real-name boundary of chapter 38. Helly–Bray selection also feeds distribution-facing compactness through chapter 186, chapter 92, and chapter 4008 when the bounded-variation read is consumed as a tight probability-family route. The chapter names a finite BEDC selection packet, not host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5815.1 (Helly–Bray selection carrier)**.** *A* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, J, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, carrying the bounded-variation object, finite variation ledger, and endpoint budget exposed to the selection request.*
2. *J is the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *row, displaying the signed-variation split and the positive and negative variation rows read from B.*
3. *S is the family of* $\mathsf{StreamName}^{\uparrow}$ *finite windows opened by the inspected variation rows and by the downstream Real-facing request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, recording the rational comparisons used before any Real seal is visible.*
5. *E is the finite family of* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after B, J, S, R have been displayed.*
6. *T records componentwise* hsame *transport for the bounded-variation source, Jordan rows, finite windows, readbacks, Real seals, continuation, provenance, and local naming.*
7. *C records displayed* Cont *replay from bounded-variation data through Jordan signed-variation rows, finite windows, regular rational readback, Real seals, transport, provenance, and local naming.*

8. *P is the* Pkg *provenance over* $\mathsf{HellyBraySelection}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, J, S, R, E, T, C, P, N$. The carrier has no coordinate for host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5815.2 (Helly–Bray selection NameCert obligations)**.** *For every accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier*

$$H = (B, J, S, R, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded-variation source row, Jordan signed-variation decomposition row, StreamName finite windows, RegSeqRat readback row, Real seal rows, transport, replay, provenance, and local naming;*
2. *variation-source exposure, requiring every selection-facing read to begin with B and then pass through the signed-variation rows J rather than through a host weak-convergence theorem;*
3. *finite-window locality, requiring S to list the exact stream windows opened by the variation rows and the Real-facing request;*
4. *readback ordering, requiring R to consume the displayed windows in S before any row of E is exposed;*
5. *componentwise transport, displayed replay, provenance, and local naming for the same rows through T, C, P, N;*
6. *nonescape, excluding host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Helly–Bray selection obligation is stored outside these rows.

Proof. Project the accepted carrier. The only source coordinate is the bounded-variation row B, and the only signed-variation coordinate is the Jordan row J.

The finite observation surface is then forced by row order. The StreamName windows S are opened from the displayed variation rows, the RegSeqRat readback R reads only those windows, and the Real seals E appear only after that readback has been displayed.

Transport and replay preserve the same route componentwise through T and C. Provenance P and local naming N record that route as the local certificate surface.

Since none of the excluded objects occurs as a carrier coordinate, a consumer cannot add weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient Real completeness to the local NameCert obligations. □

Theorem 5815.3 (Helly–Bray selection finite-window route)**.** *Every Real-facing or variation-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier factors its read through*

$$\mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{JordanVariationDecomposition}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto T, C, P, N$$

Thus the consumer receives bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise transport, continuation replay, provenance, and local naming. The route supplies no host weak convergence, measure completion, quotient function equality, selected subsequence, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier $H = (B, J, S, R, E, T, C, P, N)$. The first projection gives the bounded-variation source row B, and the next projection gives the Jordan signed-variation row J over that source.

The finite-window part is local. The windows S are the only observation rows available to the packet, and R is the only regular rational readback attached to those windows.

The Real-facing boundary is reached only at E. The remaining rows T, C, P, N transport, replay, source, and name the same finite route; they do not add a new selection principle.

Because the carrier omits host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient Real completeness, every accepted consumer read is exhausted by the displayed finite-window route. □

Theorem 5815.4 (Helly–Bray distribution forward link)**.** *Every* $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, *or* $\mathsf{ProkhorovTightProbabi}$ *consumer that cites an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier must first read the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *signed-variation row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows of Definition 5815.1. The downstream route to chapter 186, chapter 92, and chapter 4008 therefore receives only bounded-variation source data, Jordan variation data, displayed windows, rational readback, Real seals, componentwise transport, replay, provenance, and local naming. It receives no host weak convergence theorem, measure completion, quotient equality, selected subsequence, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $H = (B, J, S, R, E, T, C, P, N)$. The only distribution-facing source row is B, and the only signed-measure decomposition row available to the packet is J.

Use the finite-window route of Definition 5815.3. It forces every Real-facing and variation-facing read through S, R, E before the transport, replay, provenance, and local naming rows can be consumed.

Now attach a downstream distribution, measure, or tight-probability request. Since those consumers cite the Helly–Bray packet only through the displayed route, the request reaches chapter 186, chapter 92, or chapter 4008 after $B, J, S, R, E, T, C, P, N$ have already been displayed.

The excluded objects are not carrier coordinates. Thus the forward link cannot export host weak convergence, measure completion, quotient equality, selected subsequences, countable choice, or ambient Real completeness to any distribution-facing consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5815.1, Definition 5815.2, Definition 5815.3, and Definition 5815.4 seed the finite Helly–Bray selection route over bounded-variation data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, transport, replay, provenance, local naming, and distribution-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, variation-source exposure, finite-window locality, readback ordering, transport, replay, provenance, local naming, and finite-window routing for BEDC.Derived.HellyBraySelectionUp.

Constructive story: A $\mathsf{HellyBraySelection}^{\uparrow}$ packet is generated from bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

The Helly–Bray route is a distribution-facing read of the finite selection surface already named by chapter 1732; its bounded real sequence and compactness rows are supplied through chapter 1415 before the distribution consumer is allowed to inspect the signed-variation packet.

Theorem 5815.5 (Helly–Bray Helly-selection dependency route)**.** *Every* $\mathsf{Distribution}^{\uparrow}$ *or compactness-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *packet must first expose the finite* $\mathsf{HellySelection}^{\uparrow}$ *selection surface of chapter 1732 together with the bounded real sequence route of chapter 1415. In carrier notation, the read passes through the bounded-variation source row, Jordan signed-variation row, finite window rows, regular rational readback, terminal Real seals, componentwise transport, replay, provenance, and local naming rows before the distribution-facing route of Definition 5815.4 is public. It is therefore not a free weak-convergence theorem, measure-completion theorem, quotient-function equality, choice-selected subsequence, or ambient compactness principle.*

Proof. Start with the carrier of Definition 5815.1. Its only sequence-facing data are the bounded-variation row, Jordan signed-variation row, finite windows, regular rational readback, and terminal Real seals.

Read those rows through the finite-window route of Definition 5815.3. The same bounded source discipline is the one exported by the $\mathsf{HellySelection}^{\uparrow}$ packet, and the bounded real sequence route supplies the finite window and bound rows before any compactness-facing consumer can inspect them.

Finally attach the distribution forward link. Since Definition 5815.4 exposes distribution consumers only after the Helly–Bray carrier rows have been displayed, the downstream route receives the Helly-selection and bounded-sequence surfaces as dependencies rather than as hidden host compactness or choice principles. □

Chapter 5816

A Concrete Naming Certificate for DiniFiniteMinimumBudget$^{\uparrow}$

Following Dini's theorem and Bishop–Bridges constructive compactness, the DiniFiniteMinimumBudget$^{\uparrow}$ packet records the finite extraction row that turns a monotone compact-window Dini certificate into one displayed tolerance budget. It consumes the CompactMetric$^{\uparrow}$ source, monotone ContinuousMap$^{\uparrow}$ family rows, the DiniTheorem$^{\uparrow}$ compact-window route, UniformModulus$^{\uparrow}$ handoff data, DyadicRatCore$^{\uparrow}$ tolerance cells, the terminal Real$^{\uparrow}$ seal, BHist history rows, hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data. The packet names only the finite minimum-budget route; it is not host supremum selection, a selected minimum outside the carrier, open-cover compactness, quotient equality, or ambient Real$^{\uparrow}$ completeness.

The dependency surface is horizontal: chapter 1387 supplies the compact-window Dini route, chapter 129 supplies the inspected compact carrier, chapter 130 supplies the monotone continuous-family rows, and chapter 369 receives the extracted budget. Thus the minimum-budget row is a downstream finite extraction from those sibling carriers, not an isolated tolerance selector.

Definition 5816.1 (Dini finite-minimum budget carrier)**.** *A* DiniFiniteMinimumBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, D, U, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row naming the finite compact-metric windows inspected by the extraction.*
2. *F is the monotone* ContinuousMap$^{\uparrow}$ *family row, including the displayed pointwise comparison ledger used by the Dini route.*
3. *D is the* DiniTheorem$^{\uparrow}$ *row that supplies the monotone uniform-window certificate over K and F.*
4. *U is the* UniformModulus$^{\uparrow}$ *handoff row consumed by uniform-limit and compact-uniform-modulus readers.*
5. *Q is the* DyadicRatCore$^{\uparrow}$ *tolerance row, listing the candidate dyadic budgets and their finite comparison cells.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row reached by every displayed tolerance and value comparison.*
7. *H records componentwise* hsame *transport for $K, F, D, U, Q, E, C, P, N$.*

8. *C records displayed* Cont *replay from compact windows and monotone family rows through the Dini row, the finite dyadic budget comparisons, the uniform-modulus handoff, and the Real seal.*
9. *P is the* Pkg *provenance over* DiniFiniteMinimumBudget$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DiniTheorem$^{\uparrow}$, UniformModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for an ambient supremum, an externally selected minimum, open-cover compactness, quotient equality of real names, countable choice, or host Real completeness.

Lean4 ✓ `BEDC.Derived.DiniFiniteMinimumBudgetUp.DiniFiniteMinimumBudgetTasteGate single carrier alignment`

Theorem 5816.2 (Dini compact finite-minimum budget)**.** *For every accepted* DiniFiniteMinimumBudget$^{\uparrow}$ *carrier*

$$B = (K, F, D, U, Q, E, H, C, P, N),$$

the finite probe cover displayed by K, F, D and the dyadic tolerance cells displayed by Q determine one displayed minimum tolerance budget before the uniform-modulus handoff U is exported. The extraction route is

$$K, F, D, Q, E, H, C, P, N \longrightarrow U.$$

Thus a UniformLimit$^{\uparrow}$ *or compact-uniform-modulus consumer receives a finite* DyadicRatCore$^{\uparrow}$ *budget sealed by* Real$^{\uparrow}$ *and transported by* hsame *and* Cont*, without host supremum, selected minimum outside the carrier, open-cover compactness, quotient equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the accepted packet. The compact source row K, monotone family row F, and Dini row D are the only rows that can name the finite probe cover for the tolerance request.

The dyadic row Q lists the candidate tolerance cells. Since the carrier is finite, the budget comparison is a displayed finite comparison among the cells in Q, with every real-valued read sealed through E before the handoff row is exposed.

The route to U is then replayed by C and transported componentwise by H. The provenance and naming rows P, N record the same finite route as the local certificate surface.

No excluded object is a coordinate of B. Consequently the exported budget is the displayed finite minimum-budget row inside the carrier, not an ambient supremum, external selector, open-cover argument, quotient equality, choice schedule, or completeness argument. □

Falsifiable prediction: Every accepted DiniFiniteMinimumBudget$^{\uparrow}$ consumer that exports a UniformModulus$^{\uparrow}$ handoff must first expose the compact-metric windows, monotone continuous-family rows, DiniTheorem route, finite DyadicRatCore$^{\uparrow}$ budget cells, Real$^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: dini-theorem, compactmetric, continuousmap, uniformmodulus, dyadicratcore, real: DiniFiniteMinimumBudget$^{\uparrow}$ is not bijective to any listed sibling because it binds the finite Dini probe cover to one displayed dyadic minimum-budget handoff before uniform-limit or compact-uniform-modulus consumers may read the result.

Closure status for NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, seed)

Scope closed: Definition 5816.1 and Definition 5816.2 seed the finite minimum-budget extraction route from compact Dini data to a uniform-modulus-facing handoff.

Formal verification: FormalStatus(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host supremum selection, selected minima outside the carrier, open-cover compactness, quotient equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite probe-cover exposure, dyadic minimum-budget extraction, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniFiniteMinimumBudgetUp.

Constructive story: A DiniFiniteMinimumBudget$^{\uparrow}$ packet is generated from compact-metric source rows, monotone ContinuousMap family rows, a DiniTheorem compact-window route, UniformModulus handoff rows, DyadicRatCore tolerance cells, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5817

A Concrete Naming Certificate for $\mathsf{FiniteCauchyFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet records the finite directed-tail surface used when a completion consumer asks for Cauchy-filter evidence before reading a regular rational name or a terminal real-name seal. It sits beside the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite filter basis for tail requests; it is not a quotient filter, a selected limit, countable choice, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5817.1 (Finite Cauchy filter carrier)**.** *A* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (W, T, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the filter request.*
2. T *is the directed-tail request row, naming the finite family of later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii and comparison budgets used by the directed tails.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and tolerance ledger.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, T, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the stream windows, tail requests, dyadic ledgers, regular readback, and real seal.*
7. C *records displayed* Cont *replay of the same finite filter route.*
8. P *records* Pkg *provenance over* $\mathsf{FiniteCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, T, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.FiniteCauchyFilterUp.FiniteCauchyFilterTasteGate single carrier alignment`

Theorem 5817.2 (Finite Cauchy filter NameCert obligations)**.** *For the carrier of Definition 5817.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^\uparrow}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^\uparrow$ *window exposure, directed-tail request visibility,* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance-ledger preservation,* $\mathsf{RegSeqRat}^\uparrow$ *readback,* $\mathsf{Real}^\uparrow$ *seal access, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $F = (W, T, D, R, E, H, C, P, N)$. The rows W, T, D expose the finite source windows, directed tail requests, and dyadic tolerance budgets before any regular-rational or real-facing read is admitted.

The readback row R is then determined by the displayed windows and tolerance ledger. Since the carrier stores no second regular-rational coordinate, every $\mathsf{RegSeqRat}^\uparrow$ consumer reads the same finite route.

The seal row E is downstream of W, T, D, R. The transport row H, continuation row C, package provenance row P, and local naming row N preserve exactly that route and provide no coordinate for quotient filters, selected limits, countable choice, host stream equality, host real equality, or ambient completeness. □

Theorem 5817.3 (Finite Cauchy filter Real route)**.** *Every* $\mathsf{Real}^\uparrow$*-facing consumer of an accepted* $\mathsf{FiniteCauchyFilter}^\uparrow$ *carrier factors through the finite route*

$$W, T, D, R, E, H, C, P, N.$$

In particular, the consumer must first read $\mathsf{StreamName}^\uparrow$ *windows, directed tail requests,* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance ledgers, and the* $\mathsf{RegSeqRat}^\uparrow$ *readback before the terminal* $\mathsf{Real}^\uparrow$ *seal is consumed.*

Proof. Start with the carrier definition. The only real-facing row is E, and it is displayed after the stream windows, directed-tail row, dyadic ledger, and regular readback row.

Apply Definition 5817.2. The local NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Thus any Real-facing consumer receives the finite packet $W, T, D, R, E, H, C, P, N$ and no quotient-filter, selected-limit, countable-choice, host-equality, or ambient-completeness substitute. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^\uparrow}$.

Constructive story: A $\mathsf{FiniteCauchyFilter}^\uparrow$ packet is generated from finite StreamName windows, directed tail requests, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^\uparrow}$, seed)

Scope closed: Definition 5817.1, Definition 5817.2, and Definition 5817.3 specify the finite directed-tail filter carrier and its Real-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filter construction, selected limits, countable choice, host stream equality, host real equality, ambient completeness of $\mathsf{Real}^\uparrow$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for directed-tail visibility, tolerance-ledger preservation, readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 5818

A Concrete Naming Certificate for DNAWindowSixTranslationBoundary$^{\uparrow}$

The DNAWindowSixTranslationBoundary$^{\uparrow}$ packet realizes the local translation-boundary branch of subsection 9462.28.21 as finite NameCert data. It consumes the codon-window and stop-tile boundary analysis in the source vision, the curated code-boundary ledger of **??**, and the trigger-threshold surface of chapter 4217. The packet names only a finite window-six translation-boundary carrier; biological translation realization, universality, protein function, and evolutionary mechanism remain outside the BEDC kernel packet.

Definition 5818.1 (DNA window-six translation-boundary carrier)**.** *A* DNAWindowSixTranslationBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, S, T, L, R, V, H, C, P, N)$$

with the following displayed rows:

1. *Q is the codon Q_6 window row recording the six-bit coordinate readback for the inspected codon window.*
2. *S is the stop-tile boundary row recording the local halt boundary and continuation-corner split from the source vision.*
3. *T is the translation-classifier row supplied by external biological bridge data.*
4. *L is the curated code-boundary ledger row inherited from* BioRealityQSixLeaveOneCodeBoundaryLedger$^{\uparrow}$*.*
5. *R is the release-factor or release-mechanism row that records which external recognition boundary is being tested.*
6. *V is the finite validation row recording which observed table, organismal code row, or assay class is used for the test.*
7. *H records componentwise* hsame *transport for the window, tile, classifier, ledger, release, and validation rows.*
8. *C records displayed* Cont *replay of the boundary read through those rows.*
9. *P records* Pkg *provenance over the source vision, the bio-reality ledger sibling,* DNAWindowSixTriggerThreshold$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and local naming rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for biological necessity, global identification of the genetic code with the window-six fold, protein-folding realization, universal stop assignment, hidden BEDC channel tokens, or untested mechanism.

Theorem 5818.2 (DNA window-six translation-boundary obligations)**.** *For the carrier of Definition 5818.1, the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *surface consists exactly of codon-window exposure, stop-tile boundary visibility, external translation-classifier disclosure, curated code-ledger preservation, release-boundary test exposure, finite validation-row visibility, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $B = (Q, S, T, L, R, V, H, C, P, N)$. The rows Q, S, T expose the finite codon window, the local translation boundary, and the external classifier before any biological reading is admitted.

The ledger and release rows L, R keep the packet anchored to the bio-reality boundary sibling and to a displayed recognition test. The validation row V records the observed table or assay class being tested, so the packet has a falsifiable contact surface rather than a kernel claim of biological necessity.

The structural rows H, C, P, N transport, replay, source, and name exactly the displayed boundary route. Since no further coordinate is present, the carrier cannot export global window-six identity, universal stop assignment, protein-folding realization, hidden channel tokens, or untested mechanism. □

Theorem 5818.3 (DNA window-six translation-boundary sibling handoff)**.** *Every accepted* DNAWindowSixTranslat *read that reaches a translation-boundary consumer must first expose the source-vision stop-tile row of subsection 9462.28.21, the curated code-boundary ledger row of* **??**, *and the finite trigger-threshold row of chapter 4217. The handoff is therefore a concrete finite boundary-tile NameCert route, not a narrative-only direction.*

Proof. Use Definition 5818.1. The source-vision row is carried by S, the code-boundary ledger is carried by L, and the trigger-facing finite boundary read is recorded in the same package provenance P.

Now apply Definition 5818.2. The local NameCert requires those rows before the translation-boundary consumer can read N. Hence the consumer sees the source vision, the bio-reality ledger sibling, and the trigger-threshold sibling as displayed packet data rather than as detached prose. □

Falsifiable prediction: An accepted $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet must expose a finite validation row naming the observed code table, organismal code row, or release-factor assay class before it can export a translation-boundary reading.

Independence witness: bioreality-q-six-leave-one-code-boundary-ledger, dna-window-six-trigger-threshold, synonymous-transition: the $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is not bijective to any listed sibling because it jointly carries codon-window, stop-tile, external translation-classifier, curated code-ledger, release-boundary, validation, transport, replay, provenance, and local naming rows.

The Lean follow-up must provide $\mathsf{Nontrivial}\ \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{DNAWindowSi}$ TasteGate instances before this packet can move beyond seed closure.

Closure status for $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is generated from codon Q-six window rows, stop-tile boundary rows, external translation-classifier rows, curated code-boundary ledgers, release-boundary tests, finite validation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, seed)

Scope closed: Definition 5818.1, Definition 5818.2, and Definition 5818.3 specify the finite translation-boundary carrier and sibling route.

Formal verification: FormalStatus(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim biological-code necessity, global window-six identity, universal stop assignment, protein-folding realization, hidden BEDC channel tokens, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding, TasteGate nontriviality, field faithfulness, validation-row exactness, sibling-route preservation, transport, replay, provenance, and local naming.

Chapter 5819

A Concrete Naming Certificate for $\mathsf{RegulatedConvergence}^{\uparrow}$

Following Bishop and Bridges on regulated functions and uniform convergence, the $\mathsf{RegulatedConvergence}^{\uparrow}$ packet records the finite route by which a displayed sequence of regulated real functions converges uniformly to a regulated endpoint. It sits after the regulated-function carrier of chapter 1906, the regulated-integral consumer boundary of chapter 1557, the uniform-convergence ledger of chapter 3417, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite convergence-and-handoff surface; it does not import measure completion, quotient equality of functions, selected host limits, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5819.1 (Regulated convergence carrier)**.** *A* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

with the following displayed rows:

1. *F is the source row naming the regulated-function family through* $\mathsf{RegulatedFunction}^{\uparrow}$ *data, including the displayed interval, step-window, endpoint, and oscillation ledgers available to each inspected member.*
2. *U is the* $\mathsf{UniformConvergence}^{\uparrow}$ *tail row, recording one shared tolerance schedule for the whole regulated family rather than pointwise schedules chosen separately at each argument.*
3. *W is the finite window row exposing exactly the function indices, domain windows, and endpoint reads used by the shared tail schedule.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the real-valued observations in those windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after F, U, W, R have been displayed.*
6. *I is the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *handoff row; it records that integral-facing consumers may read the regulated endpoint only through the same finite regulated-function, uniform-tail, window, readback, and Real-seal route.*
7. *H records componentwise* hsame *transport for F, U, W, R, E, I and for the structural rows.*
8. *C records displayed* Cont *replay for regulated-function reads, uniform-tail requests, finite window reads, regular rational readback, Real-seal requests, and integral handoff requests.*

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedConvergence}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, U, W, R, E, I, H, C, P, N$. It has no coordinate for a host function quotient, selected limiting function, measure completion, pointwise-only convergence, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceTasteGate single carrier alignment`

Theorem 5819.2 (Regulated convergence NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier*

$$G = (F, U, W, R, E, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the regulated-function family row F, uniform-convergence tail row U, finite window row W, regular rational readback row R, terminal Real seal E, regulated-integral handoff row I, componentwise transport row H, displayed replay row C, package provenance row P, and local naming row N. Every endpoint-facing or integral-facing consumer must read these rows in the displayed route and cannot replace them by pointwise convergence, a selected host limit, quotient equality of functions, measure completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 5819.1. The only analytic rows are the regulated-function family F, the shared uniform tail ledger U, the finite window row W, the regular rational readback R, the terminal Real seal E, and the integral handoff I.

The convergence route is uniform. A consumer must read the single tail schedule U before it can inspect the windows W and the regular readback R, so pointwise-only schedules and externally selected host limits are not part of the packet.

The endpoint and integral rows are downstream. The seal E is exposed only after F, U, W, R, and the integral-facing row I reads that same route rather than a separate measure-completion or function-quotient object.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded row occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 5819.3 (Regulated convergence integral handoff)**.** *Let*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

be an accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier. Every* $\mathsf{RegulatedIntegral}^{\uparrow}$ *consumer read of the limiting regulated function factors through the finite route*

$$\mathsf{RegulatedFunction}^{\uparrow}(F),\ \mathsf{UniformConvergence}^{\uparrow}(U),\ W,\ \mathsf{RegSeqRat}^{\uparrow}(R),\ \mathsf{Real}^{\uparrow}(E),\ \mathsf{RegulatedIntegral}^{\uparrow}(I).$$

Thus the handoff to integration uses the same regulated-family rows, shared uniform-tail ledger, finite windows, regular rational readback, and Real seal as the convergence certificate. It supplies no measure completion, quotient function equality, selected limiting function, open-cover compactness, or ambient real-completeness principle.

Proof. Start with an integral-facing request. By the carrier definition, the only integral row is I, and its replay route in C passes through the same regulated-family and convergence rows used by endpoint-facing consumers.

Read the regulated source through F and the uniform tail through U. The finite windows W then expose the inspected function indices and domain reads, and the regular rational row R records the real-valued observations visible at those windows.

Only after this route is displayed can the terminal seal E be consumed and handed to I. Componentwise transport in H and replay in C preserve the same rows, while P and N record their provenance and local naming.

The carrier has no coordinate for measure completion, quotient function equality, selected limits, open-cover compactness, or ambient real completeness. Therefore every regulated-integral handoff is confined to the finite route displayed in the statement. □

Falsifiable prediction: An accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ consumer that reaches a $\mathsf{RegulatedIntegral}^{\uparrow}$ handoff without first reading $F, U, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: regulated-function, regulated-integral, uniform-convergence, regseqrat, real: none is bijective to $\mathsf{RegulatedConvergence}^{\uparrow}$ because this packet jointly binds a regulated-function family, a shared uniform tail ledger, finite windows, regular rational readback, terminal Real seal, integral handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedConvergence}^{\uparrow}$ packet is generated from a regulated-function family row, UniformConvergence tail row, finite window row, RegSeqRat readback, terminal Real seal, RegulatedIntegral handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5819.1, Definition 5819.2, and Definition 5819.3 seed the finite regulated-convergence route over regulated functions, uniform convergence, regular rational readback, Real seals, and regulated-integral consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, quotient function equality, selected host limits, pointwise-only convergence, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated-family visibility, uniform-tail exactness, finite window readback, Real-seal nonescape, regulated-integral handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedConvergenceUp.

Chapter 5820

A Concrete Naming Certificate for $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$

Following Cantor and Bishop–Bridges, the $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet records the finite located nested-interval route by which displayed interval windows become a regular rational Cauchy name and then a terminal real seal. It refines the nested dyadic Cauchy route of chapter 1811, reads endpoint and radius rows through chapter 291, schedules finite observations through chapter 126, hands the scheduled rows to chapter 301, and reaches only the seal boundary of chapter 38. The chapter isolates the located interval-to-name handoff; it does not claim a host intersection point, quotient stream equality, selected limit, countable choice, or ambient completeness.

Definition 5820.1 (Located nested-interval limit carrier)**.** *A* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite nested located-interval window. It records the inspected interval chain, endpoint rows, located containment witnesses, and the finite separation reads available at each displayed stage.*
2. *D is the dyadic shrink ledger. It records the dyadic endpoint comparisons, width bounds, and tolerance requests read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It names exactly the finite endpoint, midpoint, and shrink-ledger observations that may be queried before regular rational readback.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the scheduled located-interval observations and the dyadic shrink ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after I, D, S, R have been displayed.*
6. *H records componentwise* hsame *transport for interval windows, shrink ledgers, stream schedules, regular rational handoffs, real seals, replay rows, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located nested-interval request through I, D, S, R, E and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$*,* $\mathsf{NestedDyadicCauchy}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, R, E, H, C, P, N$. It has no coordinate for completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.LocatedNestedIntervalLimitUp.LocatedNestedIntervalLimitTasteGate single carrier alignment`

Theorem 5820.2 (Located nested-interval limit NameCert obligations)**.** *For every accepted* LocatedNestedIntervalL *carrier*

$$L = (I, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite located interval window, dyadic shrink ledger, StreamName schedule, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming row;*
2. *located nesting exposure, requiring every interval read to be one of the displayed rows of I together with its displayed containment and located separation witnesses;*
3. *dyadic shrink exactness, requiring every tolerance request to be discharged by a visible width or endpoint comparison stored in D and read through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
4. *schedule compatibility, requiring S to expose only the finite interval, endpoint, midpoint, and ledger observations used by D and R;*
5. *RegSeqRat handoff exactness, requiring R to be formed only after the interval window, shrink ledger, and schedule rows have been projected;*
6. *Real-seal nonescape, requiring E to be consumed only after I, D, S, R and the structural rows H, C, P, N have been displayed.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5820.1. The projection exposes one finite located nested-interval window, one dyadic shrink ledger, one StreamName schedule, one RegSeqRat handoff, one Real seal, and the transport, replay, provenance, and naming rows.

Located nesting exposure is forced by I. A consumer may inspect only interval rows already present in the finite window, and each such row carries its displayed containment and located separation witnesses.

Dyadic shrink exactness is forced by D. Each tolerance request is answered by a displayed dyadic width or endpoint comparison, so no host intersection or selected limit is needed to choose a tail.

The schedule and handoff rows are downstream. The row S records the finite observations that may be opened, and R repacks exactly those observations under the shrink ledger as a regular rational Cauchy surface.

Finally E, H, C, P, N close the route. The Real seal is reachable only after the regular handoff has been displayed, while the structural rows only transport, replay, source, and name the same finite data. Therefore no completed intersection, quotient stream equality, host real equality, countable choice, ambient completeness, Lean verification, or bridge-checking coordinate is present. □

Theorem 5820.3 (Located nested-interval RegSeqRat handoff)**.** *Let* $L = (I, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read exported by* L *factors through the displayed route*

$$I \longmapsto D \longmapsto S \longmapsto R \longmapsto H, C, P, N.$$

The route reads a finite located nested-interval window, a dyadic shrink ledger, and the scheduled endpoint observations before it exports the regular rational Cauchy row. The terminal $\mathsf{Real}^{\uparrow}$ *seal* E *is available only after this handoff has been displayed.*

Proof. Start with the displayed located interval window I. Its rows give the only endpoint, midpoint, containment, and located separation data available to a regular rational consumer.

Use the dyadic shrink ledger D to answer the displayed tolerance request. The chosen comparison is part of the same finite packet and is read through $\mathsf{DyadicRatCore}^{\uparrow}$, so there is no external modulus, choice-selected tail, or host interval intersection.

The schedule row S then fixes which interval observations are opened. The handoff row R is obtained by reading those scheduled observations under the shrink discipline and repacking them as the $\mathsf{RegSeqRat}^{\uparrow}$ surface.

The rows H, C, P, N transport, replay, source, and name that handoff, and the seal row E remains downstream of it. Since the carrier has no quotient-stream, host-real, selected-limit, choice, or completeness coordinate, every regular rational read factors through the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5820.1, Definition 5820.2, and Definition 5820.3 seed the finite located nested-interval route from displayed interval windows and dyadic shrink ledgers to a RegSeqRat handoff and terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located nesting exposure, dyadic shrink exactness, schedule compatibility, RegSeqRat handoff exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedNestedIntervalLimitUp.

Constructive story: A $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet is generated from a finite nested located-interval window, a dyadic shrink ledger, a StreamName schedule, a RegSeqRat handoff row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5821

A Concrete Naming Certificate for $\mathsf{CauchyTailRequest}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailRequest}^{\uparrow}$ packet isolates the finite directed-tail request that a Cauchy or completion consumer must expose before it can read a regular rational name or a terminal real-name seal. It sits beside the finite window carrier of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal seal of chapter 38, and the finite filter surface of chapter 5817. The packet names the request row consumed by those sibling routes; it is not a quotient filter, a selected limit, a countable-choice schedule, host stream equality, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5821.1 (Cauchy tail request carrier)**.** *A* $\mathsf{CauchyTailRequest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, Q, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the request.*
2. Q *is the directed tail request row, naming the finite later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the directed tail request.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and tolerances.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, Q, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the window, request, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay of the same finite directed-tail route.*
8. P *records* Pkg *provenance over* $\mathsf{CauchyTailRequest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteCauchyFilter}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, Q, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 (definition) `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestUp`

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestTasteGate single carrier alignment`

Theorem 5821.2 (Cauchy tail request NameCert obligations)**.** *For the carrier of Definition 5821.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *consumer that reads a directed-tail row receives it through this displayed request surface.*

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestCarrier namecert obligations`

Proof. Project the accepted packet $T = (W, Q, D, R, E, H, C, P, N)$. The rows W, Q, D expose the finite windows, directed tail request, and dyadic tolerance ledger before any regular-rational or real-facing read is admitted.

The readback row R is downstream of those displayed rows. It therefore records only the $\mathsf{RegSeqRat}^{\uparrow}$ observation generated from the named windows and tolerance ledger, not an external sequence or choice schedule.

The seal row E is terminal for the request route. Transport through H and replay through C preserve exactly the displayed route, while P and N record provenance and local naming.

Finally compare the route with Definition 5817.2. The finite filter packet consumes its directed-tail row as a request coordinate, and the rows above are precisely the admitted request surface available to that consumer. Since no remaining coordinate exists, quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, and bridge checking are outside the chapter claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyTailRequest}^{\uparrow}$ packet is generated from finite StreamName windows, a directed tail request row, DyadicRatCore tolerance data, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, seed)

Scope closed: Definition 5821.1 and Definition 5821.2 specify the finite directed-tail request carrier and its filter-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for tail visibility, tolerance preservation, readback, seal routing, transport, replay, provenance, and local naming.

Chapter 5822

A Concrete Naming Certificate for $\mathsf{QuotientLeakageMarkov}^{\uparrow}$

The $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet realizes the quotient leakage transition matrix of Definition 9462.1376 as finite NameCert data. It consumes the DNA window-six boundary-tile source of subsection 9462.28.21, the codon-window carrier of chapter 2234, the boundary-tile packet of chapter 3393, the six-boundary coverage route of chapter 3470, and the translation-boundary packet of chapter 5818. The packet names a finite six-state Markov ledger only; it is not a biological stochastic model, empirical evolutionary claim, host quotient-codon semantics, or unrestricted state-space enumeration.

Definition 5822.1 (QuotientLeakageMarkov carrier)**.** *A* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, T, O, E, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the six-state orbit row listing* AGR*,* Anchor_6*,* $\mathrm{StopStart}_6$*,* UUR*,* CUR*, and* CUY*.*
2. *T is the transient transition-matrix row of Definition 9462.1376, with entries read as exact rational finite counts.*
3. *O is the outside-probability row recording* $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ *for the six displayed states.*
4. *E is the expected-exit ledger row recording the rational exit values of Definition 9462.1380.*
5. *W is the finite window-six source row tying the orbit states to the codon-window and boundary-tile siblings.*
6. *H records componentwise* hsame *transport for the state, transition, outside-probability, exit-ledger, source, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite Markov read through* S, T, O, E, W, H, P, N*.*
8. *P is the* Pkg *provenance over* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$*,* $\mathsf{CodonSixBitWindow}^{\uparrow}$*,* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$*, the source vision of subsection 9462.28.21,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, O, E, W, H, C, P, N$*. It has no coordinate for biological transition realization, hidden codon quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process.*

Theorem 5822.2 (QuotientLeakageMarkov NameCert obligations)**.** *For the carrier of Definition 5822.1, the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *surface consists exactly of six-state exposure, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, window-six sibling routing, componentwise transport, displayed replay, provenance, and local naming. Every accepted read preserves the outside probabilities displayed in Definition 9462.1378.*

Proof. Project the accepted carrier $Q = (S, T, O, E, W, H, C, P, N)$. The state row S fixes the six orbit states, and the transition row T is the only source of one-bit flip probabilities.

The outside-probability row O is read from the outside column of T and matches the finite rational list in Definition 9462.1378. Thus an accepted packet cannot alter leakage rates without changing a displayed row.

The expected-exit row E is downstream of the same finite matrix and records the rational ledger of Definition 9462.1380. The source row W ties these finite state rows back to the codon-window, boundary-tile, coverage, and translation-boundary siblings.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since no other coordinate is present, the NameCert surface cannot export biological mechanism, hidden quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process. □

Theorem 5822.3 (QuotientLeakageMarkov sibling dependency route)**.** *Every accepted* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *consumer first reads the finite codon-window source, boundary-tile classifier, six-boundary coverage route, and translation-boundary packet before it consumes the transition row* T*, outside row* O*, or expected-exit row* E*. The dependency route is*

$$\mathsf{CodonSixBitWindow}^{\uparrow}, \mathsf{DnaWindowSixBoundaryTile}^{\uparrow}, \mathsf{SixBoundaryTileCoverage}^{\uparrow}, \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$$

Proof. Use the provenance row P and source row W of Definition 5822.1. These rows name the finite codon-window and boundary-tile sources before the Markov matrix is admitted.

The transition row T then reads the six-state quotient matrix of Definition 9462.1376. The outside-probability row O and expected-exit row E are downstream ledger rows, so they cannot be consumed before the sibling source route has been displayed.

Transport and replay by H and C preserve this order, while N names it locally. Hence the consumer receives a concrete dependency route rather than a detached numerical table. □

Falsifiable prediction: Every accepted $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ read preserves the displayed outside probabilities $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ for AGR, Anchor_6, StopStart_6, UUR, CUR, and CUY.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, six-boundary-tile-coverage, dna-window-six-translation-boundary: $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries six orbit states, a rational transition matrix, outside probabilities, expected-exit ledgers, window-source routing, transport, replay, provenance, and local naming.

The Lean follow-up must provide explicit $\mathsf{Nontrivial}\ \mathsf{QuotientLeakageMarkov}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{QuotientLeakageM}$ TasteGate instances preserving $S, T, O, E, W, H, C, P, N$ as distinct displayed rows.

Closure status for $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$**.**

Constructive story: A $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet is generated from six orbit states, a rational transition matrix, outside-probability rows, expected-exit ledgers, a finite window-six source row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5822.1, Definition 5822.2, and Definition 5822.3 specify the finite quotient-leakage Markov carrier and sibling dependency route.

Formal verification: FormalStatus(NameCert$_{\text{QuotientLeakageMarkov}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological transition realization, empirical evolutionary mechanism, hidden codon quotient semantics, unbounded simulation, completed stochastic processes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, sibling routing, transport, replay, provenance, and local naming for BEDC.Derived.QuotientLeakage

Chapter 5823

A Concrete Naming Certificate for $\mathsf{CauchyCriterionUniform}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet records the uniform Cauchy criterion route used when a Real and Completion consumer asks for one displayed threshold discipline across a finite family of stream windows. It sits beside the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Cauchy hub of chapter 3413. The packet names a uniform criterion surface; it is not a quotient Cauchy class, selected limit, host equality theorem, countable-choice schedule, trichotomy principle, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5823.1 (Cauchy criterion uniform carrier)**.** *A* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *S records the* $\mathsf{StreamName}^{\uparrow}$ *window family inspected by the uniform criterion request.*
2. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the dyadic radii and comparison budgets shared by the family.*
3. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and dyadic tolerances.*
4. *E records the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, available only after S, D, R, M have been exposed.*
5. *M records the uniform modulus row, naming the common threshold discipline for all displayed windows in the family.*
6. *H records componentwise* hsame *transport for the stream windows, dyadic tolerances, regular readback, Real seal, uniform modulus, replay route, provenance, and local name.*
7. *C records displayed* Cont *replay of the same finite route.*
8. *P records* Pkg *provenance over* $\mathsf{CauchyCriterionUniform}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N records the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, R, E, M, H, C, P, N$. It has no coordinate for a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUniformUp.CauchyCriterionUniformTasteGate single carrier alignment`

Theorem 5823.2 (Cauchy criterion uniform NameCert obligations)**.** *For the carrier of Definition 5823.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the finite packet* $U = (S, D, R, E, M, H, C, P, N)$*;*
2. *uniform window exposure through the* $\mathsf{StreamName}^{\uparrow}$ *row* S *and the common modulus row* M*;*
3. *dyadic tolerance exactness through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*;*
4. *regular readback through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*;*
5. *ledger non-escape through* H, C, P, N*.*

Proof. Project the accepted packet $U = (S, D, R, E, M, H, C, P, N)$. Carrier admission is exactly the admission of this finite tuple, so a consumer can inspect only the displayed coordinates.

The uniform window obligation reads S together with the common threshold discipline M. The dyadic tolerance obligation reads D, and the regular readback obligation reads R before any terminal seal row E is available.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since the carrier has no remaining coordinate, the ledger cannot export a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient completeness claim. □

Theorem 5823.3 (Cauchy criterion uniform Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier factors through the finite route*

$$S, D, R, M \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer must read stream windows, dyadic tolerances, regular readback, and the uniform modulus before the terminal real seal is exposed. The route exports no quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 5823.1. The only terminal real-facing coordinate is E, and the definition places it downstream of the finite stream-window, dyadic-tolerance, regular-readback, and uniform-modulus rows.

Apply Definition 5823.2. The NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Therefore any Real-facing consumer receives exactly the finite packet route displayed above. No quotient Cauchy class, selected limit, host equality, countable-choice schedule, trichotomy row, or ambient-completeness coordinate supplies another path to the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet is generated from finite StreamName windows, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, a uniform modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, seed)

Scope closed: Definition 5823.1, Definition 5823.2, and Definition 5823.3 specify the finite uniform Cauchy criterion carrier and its Real-facing seal route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy classes, selected limits, host equality, countable choice, trichotomy, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for uniform window exposure, dyadic tolerance exactness, regular readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 5824

A Concrete Naming Certificate for CauchyProductCompletionProjection$^{\uparrow}$

Following Bishop and Bridges on constructive products of Cauchy completions and Kelley on product uniformities, the CauchyProductCompletionProjection$^{\uparrow}$ packet records the coordinate projection surface for an accepted product-completion read. It sits downstream of the product packet of chapter 3797 and the completion-product route of chapter 1540, while every coordinate read still passes through the StreamName$^{\uparrow}$ windows of chapter 126, the RegSeqRat$^{\uparrow}$ readbacks of chapter 301, the DyadicRatCore$^{\uparrow}$ budgets of chapter 291, and the terminal Real$^{\uparrow}$ seal of chapter 38.

Definition 5824.1 (CauchyProductCompletionProjection carrier)**.** *A* CauchyProductCompletionProjection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* CauchyProductCompletion$^{\uparrow}$ *product-completion packet whose coordinate route is being inspected.*
2. *π_0, π_1 are the left and right projection selector rows, each naming which displayed coordinate window is exposed.*
3. *S_0, S_1 are the coordinate* StreamName$^{\uparrow}$ *windows opened by the two projection selectors.*
4. *D_0, D_1 are the* DyadicRatCore$^{\uparrow}$ *budget rows attached to the finite coordinate observations read from those windows.*
5. *R_0, R_1 are the* RegSeqRat$^{\uparrow}$ *readback rows obtained from the same coordinate windows and dyadic budgets.*
6. *L_0, L_1 are the coordinate completion-seal rows witnessing that each projected read remains inside the product-completion packet.*
7. *H records componentwise* hsame *transport for the product packet, selectors, stream windows, dyadic budgets, regular readbacks, and coordinate completion seals.*
8. *C records the* Cont *replay from the product-completion packet through the selected coordinate window, dyadic budget, regular readback, and completion seal.*
9. *P is the* Pkg *provenance over* CauchyProductCompletionProjection$^{\uparrow}$, CauchyProductCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *row.*
The carrier compares accepted projections only through $Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, host product equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CauchyProductCompletionProjectionUp.CauchyProductCompletionProjectionTasteGate`
`single carrier alignment`

Theorem 5824.2 (CauchyProductCompletionProjection NameCert obligations)**.** *For an accepted packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *surface consists exactly of product-packet admission, selector exposure, coordinate stream-window exposure, dyadic-budget accounting, regular readback, coordinate completion-seal nonescape, componentwise transport, replay, provenance, and local naming for the displayed rows.*

Proof. Project the carrier of Definition 5824.1. The row Q supplies the already displayed product-completion packet, while π_0, π_1 determine which coordinate route is being opened.

For each selector, the corresponding stream window is read before any dyadic budget or regular readback is available. Thus S_0, S_1 precede D_0, D_1, and the regular rows R_0, R_1 are exposed only through those windows and budgets.

The completion-seal rows L_0, L_1 bind the coordinate read back to Q. The transport table H and replay table C preserve the same product packet, selector, window, budget, readback, and seal rows, while P and N record provenance and local naming.

Since these are the only carrier coordinates, the NameCert surface has no route to quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5824.3 (CauchyProductCompletionProjection route)**.** *Every coordinate read exported by an accepted* $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ *carrier factors through*

$\mathsf{CauchyProductCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameC

The left and right selectors expose only the displayed coordinate windows and their completion seals; they do not turn the product-completion packet into a host tuple, a quotient-completion equality, or a chosen representative.

Proof. Start with an accepted carrier J. The selector rows π_0, π_1 are not host projections; they are displayed BEDC rows attached to the product-completion packet Q.

Reading either selector first opens the matching $\mathsf{StreamName}^{\uparrow}$ window. The dyadic budget row is then inspected, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback is obtained from the same finite coordinate window.

The coordinate completion seal is the last coordinate-facing row before export. It keeps the read inside the product-completion packet named by Q, and the structural rows H, C, P, N attach transport, replay, provenance, and local naming to the same route.

Thus every projection read remains a finite NameCert route through the displayed rows. No coordinate of J supplies quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ packet is generated from an accepted CauchyProductCompletion packet, left and right projection selector rows, coordinate StreamName windows, DyadicRatCore budgets, RegSeqRat readbacks, coordinate completion seals, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5824.1, Definition 5824.2, and Definition 5824.3 seed the finite coordinate-projection route for product completions.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host product equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, selector exposure, coordinate window accounting, regular readback, completion-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductCompletionPro

Chapter 5825

A Concrete Naming Certificate for $\mathsf{CauchyModulusSubsequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet records the finite route by which a bounded regular Cauchy source exposes a modulus-indexed subsequence schedule without exporting an infinite selector. It sits between the bounded subsequence envelope of chapter 1698, the regular subsequence route of chapter 381, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a constructive completion-facing certificate: it supplies a monotone cofinal schedule, finite windows, tolerance accounting, and a Real seal, but not countable choice, quotient stream equality, a selected infinite subsequence, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5825.1 (Cauchy modulus subsequence carrier)**.** *A* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, M, T, W, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$ *source row whose bounded regular Cauchy data are available before any subsequence-modulus request is read.*
2. *M is the modulus row. It records the requested Cauchy tolerance discipline and the finite comparison budget used by the subsequence schedule.*
3. *T is the monotone cofinal schedule row. It records the finite evidence that requested indices are sent to later source windows and that the schedule is cofinal in the displayed source.*
4. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows selected by the schedule row T at the requested modulus levels.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed windows and dyadic tolerances.*
7. *R is the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff row reached from B, M, T, W, D, Q.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the bounded source, modulus, schedule, windows, tolerance ledger, regular readback, and regular subsequence handoff have been displayed.*

9. *H records componentwise* hsame *transport for the bounded source, modulus, cofinal schedule, windows, dyadic ledger, regular readback, regular subsequence handoff, terminal seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a subsequence-modulus request through $B, M, T, W, D, Q, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$, $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, M, T, W, D, Q, R, E, H, C, P, N$. It has no coordinate for a selected infinite subsequence, quotient stream equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusSubsequenceUp.CauchyModulusSubsequenceTasteGate single carrier alignment`

Theorem 5825.2 (Cauchy modulus subsequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier $S = (B, M, T, W, D, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequ}}$ *surface consists exactly of carrier admission, bounded-source admission through B, modulus monotonicity through M, monotone cofinal schedule admission through T, finite-window determinacy through W, dyadic tolerance accounting through D, regular rational readback through Q,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff through R, Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5825.1. Its analytic coordinates are exactly the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular readback Q, regular subsequence handoff R, and terminal Real seal E.

The modulus and schedule obligations are displayed before any support row is inspected. The row M supplies the tolerance discipline, while T records monotonicity and cofinality for the finite requested indices. The window row W and tolerance row D then determine which $\mathsf{StreamName}^{\uparrow}$ windows and dyadic bounds are visible at those requests.

The readback and seal obligations remain downstream. The row Q reads the visible windows as $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the $\mathsf{RegularCauchySubsequence}^{\uparrow}$ handoff, and E is reachable only after the preceding rows have been displayed. Rows H, C, P, N transport, replay, source, and name that same finite route, so no further NameCert obligation remains outside the listed coordinates. □

Theorem 5825.3 (Cauchy modulus subsequence window determinacy)**.** *Every consumer admitted by an accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier must read the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular rational readback Q, regular subsequence handoff R, and terminal Real seal E before reading the transport, replay, provenance, or local naming rows. The packet exports no selected infinite subsequence, quotient stream equality, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer read. By Definition 5825.1, the only consumer-facing route before the support rows is the ordered list B, M, T, W, D, Q, R, E.

The rows B, M, T fix the source, tolerance request, and monotone cofinal schedule. The row W then supplies only the finite windows named by that schedule, and D supplies the dyadic tolerance ledger attached to those windows. Thus the visible subsequence data are determined by displayed finite requests, not by an externally selected infinite object.

The remaining analytic rows are also fixed by the displayed windows. The readback row Q converts those windows into $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the regular subsequence handoff, and E is the terminal Real seal for that route. Since the carrier contains no coordinate for quotient stream equality, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the support rows H, C, P, N can only preserve the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet is generated from a bounded regular Cauchy source, a modulus row, a monotone cofinal schedule, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RegularCauchySubsequence handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5825.1, Definition 5825.2, and Definition 5825.3 seed the constructive subsequence-modulus route over bounded regular Cauchy data, finite windows, dyadic tolerances, regular readback, regular subsequence handoff, Real sealing, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, quotient stream equality, countable choice, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Lean verification requires carrier admission, modulus monotonicity, cofinal schedule admission, finite-window determinacy, dyadic tolerance accounting, RegSeqRat readback, RegularCauchySubsequence handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusSubsequenceUp.

$\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ reads its comparison surface through chapter 126, chapter 301, chapter 291, chapter 1820, and chapter 38 before the child NameCert body is input.

Chapter 5826

A Concrete Naming Certificate for $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ packet records the finite comparison surface at which two regular Cauchy presentations can be inspected before a real-name or completion-facing consumer reads them. It sits on the finite observation windows of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the non-quotient classifier boundary of chapter 1820.

Falsifiable prediction: If a purported $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ consumer compares two regular Cauchy presentations without exposing finite StreamName windows, RegSeqRat readbacks, the DyadicRatCore tolerance ledger, the CauchyEquivalenceSetoid classifier, and the terminal Real seal, then the consumer has left the certificate.

Definition 5826.1 (Regular Cauchy sequence comparison carrier)**.** *A* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows available to the comparison request.*
2. R_0 *and* R_1 *are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, exposing regular rational values before any real-name seal is consumed.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the displayed precision cells and refinement rows used by the comparison.*
4. Q *is the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier row over* S_0, S_1, R_0, R_1, D.
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite windows, readbacks, tolerance ledger, and classifier row are visible.*
6. H *records componentwise* hsame *transport for the two stream rows, two readback rows, dyadic ledger, classifier, real seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from a comparison request through* $S_0, S_1, R_0, R_1, D, Q, E, H, P, N$.
8. P *is the* Pkg *provenance over* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}$ *row.*
The carrier compares accepted packets only through $S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, host real equality, choice of representatives, selected limits, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchySequenceComparisonUp.RegularCauchySequenceComparisonTasteGate`
`single carrier alignment`

Theorem 5826.2 (Regular Cauchy sequence comparison NameCert obligations)**.** *For the carrier of Definition 5826.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$K = (S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N),$$

finite StreamName window exposure through S_0, S_1, regular rational readback through R_0, R_1, dyadic tolerance accountability through D, Cauchy-equivalence classifier exposure through Q, Real seal nonescape through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.

Proof. Carrier admission is projection from Definition 5826.1. The projection exposes exactly the two StreamName windows, two RegSeqRat readbacks, DyadicRatCore tolerance ledger, CauchyEquivalenceSetoid classifier, Real seal, transport, replay, provenance, and local naming rows.

The comparison route reads those rows in order. The two finite windows are inspected before the regular rational readbacks, the readbacks feed the dyadic tolerance ledger, and the ledger feeds the classifier row Q.

The Real seal E is downstream of the displayed comparison surface. The rows H, C, P, N transport, replay, source, and name that same finite route; none of them adds quotient stream equality, selected representatives, host real equality, choice, or ambient completeness. □

Theorem 5826.3 (Regular Cauchy sequence comparison carrier transport)**.** *Let*

$$K = (S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N)$$

and

$$K' = (S'_0, S'_1, R'_0, R'_1, D', Q', E', H', C', P', N')$$

be $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *carrier packets. If the displayed row H supplies componentwise* hsame *transport from each row of K to the corresponding row of K', then carrier admission for K transports to carrier admission for K' along exactly the rows*

$$S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N.$$

The transported packet has no added coordinate for quotient stream equality, host real equality, selected representative, countable choice, selected limit, or ambient completeness.

Proof. Project the carrier tuple of Definition 5826.1. The only exposed coordinates are the two StreamName rows, two RegSeqRat readback rows, DyadicRatCore tolerance ledger, classifier, Real seal, transport, replay, provenance, and local naming rows.

Use the NameCert obligations of Definition 5826.2. They require componentwise transport to act row by row on the displayed packet rather than by replacing the packet with a host quotient or selected real representative.

The sibling routes keep each transported row inside its own finite surface: StreamName supplies finite windows, RegSeqRat supplies rational readbacks, DyadicRatCore supplies tolerance cells,

CauchyEquivalenceSetoid supplies the classifier boundary, and Real supplies only the terminal seal. Therefore the transported accepted packet is still read through the same carrier coordinates, and no excluded equality, choice, limit, or completeness datum is introduced. □

Theorem 5826.4 (Regular Cauchy sequence comparison classifier stability)**.** *For an accepted packet*

$$K = (S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N),$$

replace the finite StreamName windows, RegSeqRat readbacks, and DyadicRatCore tolerance rows by rows displayed in H as componentwise hsame*-stable. Then the CauchyEquivalenceSetoid classifier row Q remains the classifier row for the transported comparison route. In particular, classifier stability is witnessed before any Real seal is consumed and does not use quotient stream equality or host real equality.*

Proof. Start from the carrier projection in Definition 5826.1. The row Q is named there only over S_0, S_1, R_0, R_1, D, so its inputs are the finite StreamName windows, the RegSeqRat readbacks, and the DyadicRatCore tolerance ledger.

Apply the obligation surface of Definition 5826.2. It places componentwise transport in the displayed row H and keeps replay in C, so replacing the finite windows, readbacks, and tolerance rows by H-stable rows preserves the same inspected classifier boundary.

The chapter's sibling routes enforce the order of reading: finite windows first, regular rational readbacks next, dyadic tolerance accounting next, and only then the CauchyEquivalenceSetoid row. The Real seal E is downstream, so classifier stability is decided without a host quotient, host equality, selected representative, choice, selected limit, or ambient completeness row. □

Theorem 5826.5 (Regular Cauchy sequence comparison ledger exactness)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer of an accepted* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *comparison packet factors through exactly*

$$S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N.$$

The exported ledger gives the consumer finite StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, the CauchyEquivalenceSetoid classifier, the Real seal, componentwise transport, displayed replay, provenance, and local naming, and gives no selected representative, quotient equality, host real equality, countable choice, selected limit, or ambient completeness row.

Proof. Project the accepted carrier of Definition 5826.1. Its displayed coordinates are exactly $S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N$, and the definition explicitly leaves out representative selection, quotient equality, host equality, choice, selected limits, and ambient completeness.

Use Definition 5826.2 to read the ledger as a NameCert surface. Carrier admission exposes the finite windows, readbacks, tolerance ledger, classifier, Real seal, transport, replay, provenance, and local name as the complete comparison route.

The StreamName, RegSeqRat, DyadicRatCore, CauchyEquivalenceSetoid, and Real sibling chapters provide only their named local rows to this route. Hence any $\mathsf{Real}^{\uparrow}$ or completion-facing consumer receives precisely the displayed packet rows and cannot obtain any excluded external equality, selection, choice, limit, or completeness datum from the ledger. □

Theorem 5826.6 (Regular Cauchy sequence comparison transitive window)**.** *Let*

$$K_{01} = (S_0, S_1, R_0, R_1, D_{01}, Q_{01}, E_{01}, H_{01}, C_{01}, P_{01}, N_{01})$$

and

$$K_{12} = (S_1', S_2, R_1', R_2, D_{12}, Q_{12}, E_{12}, H_{12}, C_{12}, P_{12}, N_{12})$$

be accepted $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *packets. If the middle presentation rows* S_1, R_1 *and* S_1', R_1' *are linked by the displayed componentwise* hsame *transport, and the dyadic tolerance/readback rows* D_{01} *and* D_{12} *expose compatible comparison windows, then the composed comparison from the first presentation to the third is forced through the same finite route*

$$S_0, S_1, S_2, R_0, R_1, R_2, D_{01}, D_{12}, Q_{01}, Q_{12}, E_{01}, E_{12}, H_{01}, H_{12}, C_{01}, C_{12}, P_{01}, P_{12}, N_{01}, N_{12}.$$

In particular, a Real or Completion consumer of the composed read receives only finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows, and receives no quotient stream equality, selected representative, host real equality, countable choice, selected limit, or ambient completeness datum.*

Proof. Project the two accepted carriers. The first packet exposes the finite route from S_0, R_0 to S_1, R_1 through $D_{01}, Q_{01}, E_{01}, H_{01}, C_{01}, P_{01}, N_{01}$, and the second exposes the corresponding route from S_1', R_1' to S_2, R_2 through $D_{12}, Q_{12}, E_{12}, H_{12}, C_{12}, P_{12}, N_{12}$.

Use the displayed componentwise hsame data on the shared middle presentation. It identifies only the carried StreamName and RegSeqRat rows needed to splice the two finite comparison windows; it does not create a quotient equality of streams or a host equality of real names.

The compatible dyadic rows concatenate the displayed tolerance/readback windows. Therefore the composed read is still inspected through the listed StreamName, RegSeqRat, DyadicRatCore, classifier, Real seal, transport, replay, provenance, and local naming rows.

Since neither carrier has a coordinate for selected representatives, host real equality, selected limits, choice, or ambient completeness, the composed comparison has no such coordinate either. The transitive window is exactly the finite route displayed above. □

Theorem 5826.7 (Regular Cauchy sequence comparison RegSeqRat handoff)**.** *Every completion-facing or Real-facing consumer of an accepted* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *packet reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff before it reaches the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier or the* $\mathsf{Real}^{\uparrow}$ *seal. More precisely, every exported comparison factors through*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N$$

and no consumer receives quotient stream equality, host real equality, selected representatives, countable choice, or ambient completeness from the packet.

Proof. Project the carrier of Definition 5826.1. The only pre-classifier rows are the finite StreamName windows S_0, S_1, the RegSeqRat readbacks R_0, R_1, and the DyadicRatCore ledger D.

Apply the NameCert obligations of Definition 5826.2. They force the CauchyEquivalenceSetoid classifier row Q to be read through those finite windows, readbacks, and tolerance rows before the Real seal E is available.

Finally use the sibling routes named in the chapter introduction: StreamName supplies finite windows, RegSeqRat supplies regular rational readback, DyadicRatCore supplies tolerance cells, CauchyEquivalenceSetoid supplies the non-quotient classifier, and Real supplies the terminal seal. The carrier contains no row for any excluded equality or selection principle. □

Theorem 5826.8 (Regular Cauchy sequence comparison Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *packet reads comparison evidence only after passing through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *boundary. Thus equality or separation evidence is available only along the finite route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N,$$

and not through host quotient equality, a selected representative, countable choice, selected limits, or ambient completeness.

Proof. Start with the RegSeqRat handoff of Definition 5826.7. It already forces every completion-facing or Real-facing read through finite StreamName windows, RegSeqRat readbacks, and the DyadicRatCore ledger before the classifier row Q and Real seal E are available.

The classifier row Q is the Cauchy-equivalence boundary for the displayed rows S_0, S_1, R_0, R_1, D. Reading equality or separation evidence before Q would skip the boundary named by the carrier, while reading it after E without Q would replace the packet by a host quotient.

The structural rows H, C, P, N preserve and name the same route. This is therefore a substantive sibling dependency among StreamName, RegSeqRat, DyadicRatCore, CauchyEquivalenceSetoid, and Real, not a host quotient or a selected representative. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ packet is generated from two StreamName finite-window rows, two RegSeqRat readback rows, a DyadicRatCore tolerance ledger, a CauchyEquivalenceSetoid classifier row, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 5826.1, Definition 5826.2, Definition 5826.3, Definition 5826.4, Definition 5826.5, Definition 5826.6, and Definition 5826.7 bind the obligation surface for the finite comparison route of regular Cauchy presentations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected representatives, countable choice, selected limits, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires binding the displayed BHist, hsame, Cont, Pkg, NameCert, StreamName, RegSeqRat, DyadicRatCore, CauchyEquivalenceSetoid, and Real rows as the complete BEDC primitive scope for the same comparison packet.

Chapter 5827

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$

Following Mac Lane on monads and Eilenberg–Moore comparison, together with Bishop–Bridges constructive completion, the $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet records the finite BEDC surface where the L10 completion monad, its algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared as one NameCert boundary. The packet reads chapter 378, chapter 1845, chapter 1981, chapter 397, chapter 3351, chapter 126, chapter 301, chapter 291, and chapter 38. It names the comparison surface only; it does not assert quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5827.1 (CauchyCompletionMonadicity carrier)**.** *A* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion-monad row, displaying the unit and bind schedule before any algebra or comparison read is consumed.*
2. *A is the* $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ *action row, recording the Eilenberg–Moore algebra action over the displayed completion route.*
3. *K is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *row, exposing the unit, bind, and reassociated-bind consumer route.*
4. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row, carrying the extension and uniqueness ledger used by comparison consumers.*
5. *D is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *unit route, displaying the dense source-to-completion image before the algebra or universal-property read is exported.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row used by the monad, algebra, Kleisli, universal-property, and dense-embedding rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the same finite windows.*
8. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare completion-facing reads at the same finite precision.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *readback seal reached only after W, R, Q have all been displayed.*
10. *H records componentwise* hsame *transport for the monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from comparison requests through $T, A, K, U, D, W, R, Q, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, CauchyCompletionAlgebr $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, A, K, U, D, W, R, Q, E, H, C, P, N$. The carrier has no coordinate for quotient completion classes, selected limit representatives, host equality of completed objects, countable-choice schedules, ambient completeness, full $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓  BEDC.Derived.CauchyCompletionMonadicityUp.TasteGate.CauchyCompletionMonadicityTasteGate
single carrier alignment
```

Theorem 5827.2 (CauchyCompletionMonadicity NameCert obligations)**.** *For every accepted* CauchyCompletionM *carrier*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$ *surface consists exactly of carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, StreamName–RegSeqRat–DyadicRatCore–Real readback discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No local obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5827.1. The displayed tuple lists every row available to the classifier, so local comparison can inspect only the completion monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, transport, replay, provenance, and local naming.

The monadicity-facing rows are read in order. The monad row T displays the unit and bind schedule, the algebra row A records the Eilenberg–Moore action over that schedule, and the Kleisli row K keeps unit, bind, and reassociated-bind consumers on the same finite route.

The universal and dense rows then bind the comparison surface. The row U supplies extension and uniqueness data, while D supplies the dense source-to-completion unit route used before the comparison is exported.

Finally the readback and structural rows close the NameCert surface. The rows W, R, Q, E give finite windows, regular rational readback, dyadic tolerances, and the terminal Real seal; the rows H, C, P, N transport, replay, source, and name exactly that packet. Since no excluded coordinate occurs, no additional local obligation is available. □

Theorem 5827.3 (CauchyCompletionMonadicity comparison surface)**.** *Every comparison consumer of an accepted* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier factors through the finite route*

$$T, A, K, U, D \longmapsto W \longmapsto R \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the completion-monad route, the algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared only after the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$,

$\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback surface has been displayed. The comparison exports no quotient completion equality, selected limit, host equality of completed objects, countable choice, ambient completeness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the monad and algebra rows. The row T supplies the displayed completion transformer, and A reads its algebra action only as a row over that transformer.

Next attach the Kleisli and universal-property rows. The row K exposes the unit, bind, and reassociated-bind route, while U records the extension and uniqueness ledger for completion-facing consumers.

Now read the dense-embedding unit route D. It displays the source-to-completion image before the comparison reaches any terminal seal, so the route is a visible unit comparison rather than a selected representative.

Finally consume the readback and structural rows. The finite window W, regular readback R, dyadic tolerance ledger Q, and Real seal E precede transport, replay, provenance, and naming through H, C, P, N. Since the carrier contains no coordinate for the excluded objects, the comparison surface cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet is generated from a CauchyCompletionMonad route, CauchyCompletionAlgebra action row, CauchyCompletionKleisli route, CompletionUniversalProperty row, MetricCompletionDenseEmbedding unit route, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5827.1, Definition 5827.2, and Definition 5827.3 seed the finite monadicity comparison boundary for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, readback discipline, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionMonadicityUp.

Chapter 5828

A Concrete Naming Certificate for $\mathsf{BorsukUlam}^{\uparrow}$

Following Borsuk and Ulam, the $\mathsf{BorsukUlam}^{\uparrow}$ packet records the antipodal obstruction theorem as finite BEDC NameCert data rather than as a host topological principle. It sits after the degree surface of chapter 3745, the continuous-map rows of chapter 130, the real-name seal of chapter 38, the compact metric source of chapter 129, and the circle boundary model of chapter 58. The packet names the displayed antipodal route consumed by obstruction and degree-facing chapters; it does not select antipodal points, import unrestricted classical degree theory, identify quotient spheres, choose representatives, or appeal to ambient completeness.

Definition 5828.1 (Borsuk-Ulam carrier)**.** *A* $\mathsf{BorsukUlam}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, A, F, D, C, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the compact metric sphere row read through the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *surface and the* $\mathsf{S}^{1\uparrow}$ *boundary model.*
2. *A is the antipodal-pair ledger, exposing only named paired source rows and the finite equality-refusal data attached to them.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the map whose antipodal comparison is being inspected.*
4. *D is the* $\mathsf{BrouwerDegree}^{\uparrow}$ *obstruction row, read only through the displayed degree certificate and never through unrestricted host degree theory.*
5. *C is the* $\mathsf{Real}^{\uparrow}$ *comparison-seal row for the coordinate difference or collapsed real-valued comparison consumed by the obstruction route.*
6. *R is the refusal row excluding selected antipodal points, quotient equality of sphere points, choice, unrestricted classical degree theory, and ambient completeness.*
7. *H records componentwise* hsame *transport for the compact source, antipodal ledger, continuous-map row, degree row, real comparison seal, refusal row, provenance, and local naming.*
8. *K records displayed* Cont *replay from the compact metric source through the antipodal ledger, continuous-map row, degree obstruction, real comparison seal, and refusal row.*
9. *P is the* Pkg *provenance over* $\mathsf{BorsukUlam}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{BrouwerDegree}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *row.*
The classifier compares accepted packets only through $S, A, F, D, C, R, H, K, P, N$. It has no coordinate for a chosen antipodal pair, quotient equality on the sphere, unrestricted classical degree theory, countable choice, or ambient Real completeness.

Lean4 (definition) `BEDC.Derived.BorsukUlamUp.BorsukUlamUp`
Lean4 ✓ `BEDC.Derived.BorsukUlamUp.BorsukUlamTasteGate single carrier alignment`

Theorem 5828.2 (Borsuk-Ulam NameCert obligations)**.** *For every accepted* $\mathsf{BorsukUlam}^\uparrow$ *carrier* $U = (S, A, F, D, C, R, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *surface consists exactly of compact metric sphere admission, antipodal-pair ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, refusal of host and quotient shortcuts, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obstruction-facing consumer must read*

$$S, A, F \longmapsto D, C \longmapsto R, H, K, P, N$$

before treating the packet as a Borsuk-Ulam certificate.

Proof. Project the carrier of Definition 5828.1. The compact source row S, antipodal ledger A, and continuous-map row F are the only rows available before the obstruction is read.

The degree and real-comparison rows D, C are downstream of that source route. The degree row is the displayed $\mathsf{BrouwerDegree}^\uparrow$ certificate, and the real row is the displayed $\mathsf{Real}^\uparrow$ seal for the comparison consumed by the obstruction.

Finally R, H, K, P, N refuse shortcuts, transport the same rows, replay the finite route, source it, and name it locally. Since the carrier has no coordinate for selected antipodal points, quotient equality, unrestricted host degree theory, countable choice, or ambient Real completeness, no consumer can export those objects from the certificate. □

Theorem 5828.3 (Borsuk-Ulam antipodal route)**.** *Every accepted* $\mathsf{BorsukUlam}^\uparrow$ *antipodal-obstruction read factors through the displayed compact metric sphere row, the* $\mathsf{S}^{1\uparrow}$ *boundary model, the antipodal-pair ledger, the* $\mathsf{ContinuousMap}^\uparrow$ *row, the* $\mathsf{BrouwerDegree}^\uparrow$ *obstruction row, the terminal* $\mathsf{Real}^\uparrow$ *comparison seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert*. The route exports no selected antipodal point, unrestricted classical degree theorem, quotient equality of sphere points, choice principle, ambient completeness, Lean verification, or bridge-checked surface.*

Proof. Start with an accepted carrier $U = (S, A, F, D, C, R, H, K, P, N)$. The source read begins at S and A, so the antipodal data is visible only as a finite paired ledger over the displayed compact metric and circle rows.

Read the map through F and then the obstruction through D, C. The $\mathsf{ContinuousMap}^\uparrow$ row supplies the function-facing data, the $\mathsf{BrouwerDegree}^\uparrow$ row supplies the obstruction route, and the $\mathsf{Real}^\uparrow$ row supplies only the comparison seal reached from those displayed rows.

The refusal and structural rows close the route. The row R blocks selected points, quotient equality, unrestricted degree theory, choice, and ambient completeness, while H, K, P, N preserve the same finite certificate under transport, replay, provenance, and local naming. □

Falsifiable prediction: Every accepted $\mathsf{BorsukUlam}^\uparrow$ consumer reads compact metric sphere data, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a Real

comparison seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before it treats the packet as an antipodal obstruction certificate.

Independence witness: brouwer-degree, continuousmap, real, compactmetric, s1: $\mathsf{BorsukUlam}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact sphere data, antipodal pairing, continuous-map readback, degree obstruction, real comparison sealing, refusal, transport, replay, provenance, and local naming into one obstruction-facing certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}$.

Constructive story: A $\mathsf{BorsukUlam}^{\uparrow}$ packet is generated from a compact metric sphere row, an S1 boundary model, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a RealUp comparison seal, shortcut refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5828.1, Definition 5828.2, and Definition 5828.3 seed the finite antipodal obstruction route over compact metric, circle, continuous-map, degree, real-seal, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected antipodal points, unrestricted classical degree theory, quotient equality, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, antipodal ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, transport, replay, provenance, and local naming for BEDC.Derived.BorsukUlamUp.

Chapter 5829

A Concrete Naming Certificate for $\mathsf{DenjoyYoungSaks}^{\uparrow}$

Following Saks and Bishop–Bridges constructive real analysis, the $\mathsf{DenjoyYoungSaks}^{\uparrow}$ packet records the finite boundary at which a real-valued interval map can expose upper and lower Dini-derivative rows without importing the classical almost-everywhere Denjoy–Young–Saks theorem. It sits next to the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation window of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet is a finite classification boundary for displayed Dini rows, oscillation windows, regular-rational readback, and terminal Real seals; it is not a measure theorem, an almost-everywhere classifier, or a host-real differentiability principle.

Definition 5829.1 (Denjoy–Young–Saks finite Dini carrier)**.** *A* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the inspected interval row, listing the finitely presented source intervals and endpoint cells on which the local boundary is read.*
2. *F is the function-observation row, recording the finite source and target windows used to compare difference quotients.*
3. *U is the upper Dini row, storing the displayed upper right, upper left, and two-sided upper derivative bounds visible at the inspected windows.*
4. *L is the lower Dini row, storing the corresponding lower right, lower left, and two-sided lower derivative bounds.*
5. *O is the oscillation-window row, recording the finite alternation and stabilization tests used to classify a displayed window as one of the Dini-boundary cases.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by I, F, O and no hidden stream coordinates.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data extracted from the finite stream windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger supporting the difference-quotient comparisons and oscillation bounds.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the interval, function-observation, Dini, oscillation, stream, readback, and dyadic rows have been exposed.*
10. *H records componentwise* hsame *transport for intervals, function observations, Dini rows, oscillation windows, stream schedules, regular readbacks, dyadic ledgers, Real seals, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from the inspected interval and function rows through U, L, O, S, R, D and into the Real seal E.*
12. *P is the* Pkg *provenance over* $\mathsf{DenjoyYoungSaks}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, U, L, O, S, R, D, E, H, C, P, N$. It has no coordinate for measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, host real order trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.DenjoyYoungSaksUp.DenjoyYoungSaksTasteGate single carrier alignment`

Theorem 5829.2 (Denjoy–Young–Saks finite boundary obligations)**.** *For every accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier $Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the inspected interval, function-observation, upper Dini, lower Dini, oscillation-window, stream-schedule, regular-readback, dyadic-ledger, Real-seal, transport, replay, provenance, and local naming rows;*
2. *interval and observation exactness, requiring every Dini comparison to read its source cell from I and its finite function window from F before any derivative row is accepted;*
3. *upper and lower Dini-row exactness, requiring U and L to store only the finite upper and lower derivative bounds justified by the displayed difference-quotient windows;*
4. *oscillation-window classification, requiring O to record the finite alternation, stabilization, and gap tests that separate the visible Dini-boundary cases;*
5. *stream, readback, and dyadic exactness, requiring S, R, D to expose only the finite observations, regular rational readbacks, and dyadic tolerance rows demanded by I, F, U, L, O;*
6. *Real seal nonescape, requiring E to remain downstream of I, F, U, L, O, S, R, D and never to serve as a selected derivative, a host real equality witness, or an almost-everywhere theorem;*
7. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve exactly the displayed finite route.*

No $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *obligation is stored outside these rows, and the packet makes no claim that the classical Denjoy–Young–Saks alternatives hold almost everywhere.*

Proof. Carrier admission is projection from Definition 5829.1. The accepted packet displays exactly the inspected interval row I, function-observation row F, upper and lower Dini rows U, L, oscillation row O, stream schedule S, regular readback R, dyadic ledger D, Real seal E, and structural rows H, C, P, N.

Interval and observation exactness follow from the row order. A Dini comparison first reads the source cell in I and the finite function-observation window in F; only then may it inspect the upper row U, lower row L, or oscillation row O attached to that window.

The stream, regular-readback, and dyadic rows are downstream of the same finite windows. The schedule S opens only the observations demanded by I, F, O, the row R records the resulting regular rational readback, and D stores the tolerance comparisons needed for the displayed difference-quotient bounds.

Finally, the Real seal E is terminal for this finite boundary route. The transport row H, replay row C, provenance row P, and local naming row N preserve the same packet, so measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness cannot become local obligations. □

Theorem 5829.3 (Denjoy–Young–Saks Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{StreamName}^{\uparrow}$ *consumer of an accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier reads the displayed route*

$$I, F, U, L, O, S, R, D, E, H, C, P, N.$$

Consequently the consumer may inspect finite interval cells, function observations, upper and lower Dini rows, oscillation windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal Real seal, componentwise transport, replay, provenance, and local naming. It cannot read a measure structure, an almost-everywhere assertion, a selected derivative, quotient real equality, host real trichotomy, countable choice, or ambient completeness from the packet.

Proof. Project the accepted carrier through Definition 5829.1. Its Real-facing and readback-facing rows are exactly S, R, D, E together with the preceding interval, function, Dini, and oscillation rows I, F, U, L, O and the structural rows H, C, P, N.

The route reaches E only after the finite Dini and oscillation boundary has been displayed. Thus any consumer that asks for a Real seal or regular rational readback must already have passed through the interval cells, function observations, upper and lower Dini rows, oscillation windows, stream schedule, and dyadic tolerance ledger.

Since the carrier has no row for measure, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, or ambient completeness, none of those objects can be read by a downstream consumer. □

Theorem 5829.4 (Denjoy–Young–Saks oscillation-window induction)**.** *For an accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier* $Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$*, induction over the finite oscillation-window row* O *preserves the separation between the upper Dini row* U *and the lower Dini row* L*. At every displayed stage the packet remains a finite boundary classifier over the rows of Definition 5829.1; the induction cannot promote the packet to an almost-everywhere measure theorem, cannot select a derivative, and cannot export a host-real differentiability principle.*

Proof. Induct over the displayed list of oscillation windows in O. The empty row has no Dini comparison to transport, so the upper and lower rows remain separated by the carrier projection.

For the step, assume the previously displayed windows preserve the separation of U and L. The next window is admitted only through the oscillation-window classification row in Definition 5829.2, so it may inspect the finite alternation, stabilization, and gap tests attached to that window but cannot rewrite the carrier outside $I, F, U, L, O, S, R, D, E, H, C, P, N$.

The Real-seal nonescape theorem Definition 5829.3 keeps every downstream read behind the same finite route. Thus adjoining the next oscillation window preserves the visible upper/lower Dini separation and leaves measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness outside the packet. □

Falsifiable prediction: Every $\mathsf{DenjoyYoungSaks}^{\uparrow}$ Real-facing or readback-facing read factors through finite interval cells, function-observation windows, upper and lower Dini rows, oscillation windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{DenjoyYoungSaks}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries upper and lower Dini rows, oscillation-window classification, regular-rational readback, dyadic tolerance data, and a terminal Real seal in one finite boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$.

Constructive story: A $\mathsf{DenjoyYoungSaks}^{\uparrow}$ packet is generated from inspected interval cells, function-observation windows, upper and lower Dini rows, oscillation-window classifications, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5829.1, Definition 5829.2, and Definition 5829.3 seed the finite Denjoy–Young–Saks boundary route over Dini rows, oscillation windows, regular-rational readback, dyadic tolerance rows, and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DenjoyYoungSaksUp.DenjoyYoungSaksTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close the classical almost-everywhere Denjoy–Young–Saks theorem, measure-null exceptional sets, selected derivatives, quotient real equality, trichotomy, countable choice, ambient completeness, or bridge checking beyond the carrier-alignment Lean target.

Upgrade path: Obligation closure requires checked carrier admission, Dini-row exactness, oscillation-window classification, stream-readback-dyadic exactness, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.DenjoyYoungSaksUp.

Chapter 5830

A Concrete Naming Certificate for $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ packet records the bounded-sequence subsequence route in the form used by constructive real analysis: finite inspection of a bounded $\mathsf{Real}^{\uparrow}$ sequence, repeated interval refinement, monotone-cofinal subsequence scheduling, regular rational readback, and only then a $\mathsf{Real}^{\uparrow}$ cluster seal. The packet is anchored by the existing $\mathsf{BolzanoWeierstrass}^{\uparrow}$ route of chapter 1254, the sequential compactness naming surface of chapter 2372, the compact metric carrier of chapter 129, finite stream windows from chapter 126, regular rational readback from chapter 301, and the real-name seal of chapter 38. It is a displayed subsequence construction for bounded real sequences, not an open-cover compactness theorem, a quotient equality of real names, an ambient completeness principle, or a choice-selected arbitrary subsequence.

Definition 5830.1 (Constructive Bolzano–Weierstrass carrier)**.** *A* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, B, I, T, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded* $\mathsf{Real}^{\uparrow}$ *sequence source, read through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and the bounded-source handoff of chapter 1415.*
2. *B is the* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier row, exposing the interval-net and regular-subsequence route without adding a separate host compactness object.*
3. *I is the finite interval-refinement ledger, read through the closed bounded interval net and compact metric rows consumed by the sibling* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet.*
4. *T is the* $\mathsf{SequentialCompact}^{\uparrow}$ *comparison row, recording that the same finite subsequence schedule is the sequential-compactness-facing surface of the construction.*
5. *R is the monotone-cofinal subsequence row, read as a regular Cauchy schedule before any cluster seal is exposed.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected finite windows and their dyadic tolerance comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *cluster seal, reached only after S, B, I, T, R, Q have been displayed.*

8. *H records componentwise* hsame *transport for the bounded sequence, interval ledger, sequential compactness row, subsequence schedule, regular rational readback, and real seal.*
9. *C records displayed* Cont *replay from finite bounded-sequence inspection through interval refinement, subsequence scheduling, RegSeqRat readback, and Real sealing.*
10. *P is the* Pkg *provenance over* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, $\mathsf{SequentialCompact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, I, T, R, Q, E, H, C, P, N$. It has no coordinate for open-cover compactness, quotient real equality, a selected least cluster point, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ConstructiveBolzanoWeierstrassUp.ConstructiveBolzanoWeierstrassTasteGate`
`single carrier alignment`

Theorem 5830.2 (Constructive Bolzano–Weierstrass NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ *carrier*

$$W = (S, B, I, T, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}}$ *surface consists exactly of bounded sequence admission through S, Bolzano–Weierstrass route admission through B, finite interval-refinement admission through I, sequential compactness comparison through T, monotone-cofinal subsequence scheduling through R, RegSeqRat readback through Q, RealUp cluster sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5830.1. The rows $S, B, I, T, R, Q, E, H, C, P, N$ are the only coordinates exposed to a consumer.

The bounded source is read first through S, and the sibling $\mathsf{BolzanoWeierstrass}^{\uparrow}$ row B supplies the interval-net and regular-subsequence route. The interval ledger I keeps that route finite and tied to compact metric inspection rather than open-cover compactness.

The comparison row T then records the sequential compactness view of the same subsequence schedule. Rows R and Q expose the monotone-cofinal indices and regular rational readback before the real seal E can be consumed.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since the carrier contains no further coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 5830.3 (Constructive bounded Real subsequence obligation)**.** *Every* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ *consumer that reads a bounded* $\mathsf{Real}^{\uparrow}$ *sequence from an accepted carrier must traverse the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{BolzanoWeierstrass}^{\uparrow} \longmapsto \mathsf{SequentialCompact}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exposes finite source windows, interval-refinement rows, a monotone-cofinal subsequence schedule, regular rational readback, and a terminal Real seal; it does not export an arbitrary subsequence selector, quotient real equality, open-cover compactness, or ambient completeness.

Proof. Use Definition 5830.2. It places S and the finite stream windows before the interval-refinement ledger I and before any subsequence schedule is read.

The row B imports the existing Bolzano–Weierstrass naming route as a displayed carrier row, while T records the sequential compactness comparison over the same finite schedule. Neither row adds a host open-cover object or a choice coordinate.

Rows R and Q provide the cofinal subsequence schedule and the regular rational readback. Only after these rows are displayed may E be consumed as a $\mathsf{Real}^{\uparrow}$ cluster seal, so the consumer route is the stated finite subsequence route. □

Theorem 5830.4 (Constructive cluster seal boundary obligation)**.** *For an accepted* ConstructiveBolzanoWeierstrass *carrier* $W = (S, B, I, T, R, Q, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *cluster seal* E *is downstream of the bounded source row, the interval-refinement ledger, the sequential compactness comparison, the monotone-cofinal subsequence schedule, and the RegSeqRat readback. Any consumer of* E *must preserve the same* H, C, P, N *support rows and receives no additional host completeness, quotient equality, or open-cover compactness datum.*

Proof. Start from the bounded subsequence route of Definition 5830.3. It identifies the finite route through source windows, compact metric inspection, the sibling Bolzano–Weierstrass packet, sequential compactness comparison, and regular rational readback.

In the carrier definition the seal row E occurs only after S, B, I, T, R, Q. The support rows H, C, P, N can transport, replay, source, and name that route, but they cannot introduce a new endpoint selector or an ambient completeness principle.

Thus the cluster seal is a boundary object for the displayed constructive route. It is a $\mathsf{Real}^{\uparrow}$ seal over the named finite data, not a quotient-real equality witness, open-cover compactness theorem, or hidden host-level limit. □

Theorem 5830.5 (Constructive finite subsequence envelope)**.** *For an accepted* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ *carrier* $W = (S, B, I, T, R, Q, E, H, C, P, N)$*, the monotone-cofinal subsequence row* R *is determined by the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in* S*, the interval-refinement ledger rows in* I*, the* $\mathsf{SequentialCompact}^{\uparrow}$ *comparison row* T*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q *before the* $\mathsf{Real}^{\uparrow}$ *cluster seal* E *is exposed. Consequently every endpoint consumer reads the same finite envelope and receives no arbitrary subsequence selector, countable-choice schedule, quotient equality, or ambient completeness datum.*

Proof. Use the carrier definition of Definition 5830.1. It places the bounded source windows S, the sibling Bolzano–Weierstrass route B, the interval ledger I, and the sequential compactness comparison row T before the subsequence schedule R and the readback row Q.

The bounded-real-subsequence route of Definition 5830.3 identifies this as a finite route through StreamName windows, compact metric inspection, interval refinement, sequential compactness comparison, and RegSeqRat readback. Thus R is not an independently selected subsequence coordinate; it is the schedule visible through the same finite rows.

The cluster seal boundary of Definition 5830.4 keeps E downstream of S, B, I, T, R, Q and the support rows H, C, P, N. Any endpoint consumer therefore receives the same finite envelope before the seal.

Since the carrier has no row for an arbitrary subsequence selector, countable choice, quotient equality, or ambient completeness, none of those data can be exported by the cluster read. □

Theorem 5830.6 (Constructive Bolzano–Weierstrass selector nonescape)**.** *For an accepted* ConstructiveBolzanoWe *carrier*

$$W = (S, B, I, T, R, Q, E, H, C, P, N),$$

the $\mathsf{Real}^{\uparrow}$ *cluster-seal read* E *is available only through the displayed interval-refinement ledger* I*, the finite subsequence envelope* S, B, I, T, R, Q*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and the terminal Real seal row* E *together with* H, C, P, N*. No consumer may detach* R *as a hidden selector, replace the route by countable choice, or read a cluster point without the finite interval-refinement and regular-rational rows.*

Proof. Start from the bounded Real subsequence route of Definition 5830.3. It forces every accepted read through finite StreamName windows, compact metric inspection, the sibling Bolzano–Weierstrass route, sequential compactness comparison, RegSeqRat readback, and the Real seal.

Apply the cluster seal boundary theorem Definition 5830.4. The seal row E is downstream of S, B, I, T, R, Q, and the support rows H, C, P, N preserve that route without adding a selected endpoint.

Use the finite subsequence envelope of Definition 5830.5. The subsequence schedule R is determined by the visible source windows, interval ledger, sequential compactness comparison, and regular rational readback before E is exposed.

Thus the selector cannot escape the displayed envelope. A consumer that reads R or E without the interval-refinement, finite envelope, RegSeqRat, and Real-seal rows is no longer reading an accepted $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ packet is generated from a bounded RealUp sequence source, the sibling Bolzano–Weierstrass interval route, compact metric inspection, sequential compactness comparison, monotone-cofinal subsequence scheduling, RegSeqRat readback, a RealUp cluster seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5830.1, Definition 5830.2, Definition 5830.3, Definition 5830.4, and Definition 5830.5 seed the Bishop-style bounded Real sequence subsequence route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, quotient equality of real names, selected least cluster points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-refinement exactness, sequential compactness comparison, subsequence scheduling, RegSeqRat readback, Real cluster sealing, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveBolzanoWeierstrassUp.

Chapter 5831

A Concrete Naming Certificate for $\mathsf{UniformlyConvexSpace}^{\uparrow}$

Following Clarkson's uniformly convex Banach-space reading and Bishop–Bridges constructive normed-space practice, the $\mathsf{UniformlyConvexSpace}^{\uparrow}$ packet records a finite modulus-of-convexity surface over the normed-space carrier of chapter 1950. It consumes the $\mathsf{NormedSpace}^{\uparrow}$ row, the real-valued norm and midpoint reads through chapter 38, the metric handoff of chapter 57, and the completion-facing route of chapter 95 and chapter 3413. The packet gives Banach, Hilbert, fixed-point, and convexity consumers a named uniform-convexity certificate without importing host Banach-space equality, selected minimizers, quotient completions, or choice.

Definition 5831.1 (UniformlyConvexSpace carrier)**.** *A* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (N, R, A, M, \Delta, Q, H, T, P, C)$$

with the following displayed rows:

1. *N is the* $\mathsf{NormedSpace}^{\uparrow}$ *row, exposing vector operations, the norm read, and the induced metric only through the normed-space NameCert surface.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by norm values, radius comparisons, midpoint estimates, and positive modulus outputs.*
3. *A is the midpoint row, reading $(x + y)/2$ through the vector addition, scalar action, and real scalar rows already visible in N and R.*
4. *M is the metric handoff row, routing distance and unit-ball comparisons through the* $\mathsf{Met}^{\uparrow}$ *read induced by N.*
5. *Δ is the convexity-modulus row: for each displayed positive separation request it supplies a positive real margin forcing the midpoint norm below the unit bound whenever the two admitted unit vectors are separated by that request.*
6. *Q is the completion-facing row, allowing Cauchy and completion consumers to read the same norm, metric, midpoint, and modulus data without selecting a completed point.*
7. *H records componentwise* hsame *transport for N, R, A, M, Δ, Q and for the local structural rows.*
8. *T records displayed* Cont *replay from a uniform-convexity request through $N, R, A, M, \Delta, Q, H, P, C$.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformlyConvexSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. C is the local $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for host Banach-space equality, strict-convexity as a pointwise substitute, quotient completion, selected closest points, compactness, reflexivity, or a choice principle.

Theorem 5831.2 (UniformlyConvexSpace NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *carrier* $U = (N, R, A, M, \Delta, Q, H, T, P, C)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, normed-space visibility, real-valued norm and midpoint readback, metric separation handoff, positive modulus admission, midpoint contraction under the displayed separation request, completion-facing nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside* $N, R, A, M, \Delta, Q, H, T, P, C$*.*

Lean4 ✓ `BEDC.Derived.UniformlyConvexSpaceUp.UniformlyConvexSpaceTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 5831.1. The rows $N, R, A, M, \Delta, Q, H, T, P, C$ are the whole accepted packet.

The normed-space, Real, midpoint, and metric obligations are read first. The row N supplies the normed vector carrier, R supplies real-valued comparisons, A supplies midpoint formation, and M supplies the induced metric separation route.

The uniform-convexity content is isolated in Δ. For a displayed positive separation request, Δ supplies a positive margin and forces the midpoint norm read through A, N, R below the unit bound. Since Q, H, T, P, C only hand off, transport, replay, source, and name the same route, no host Banach-space equality, quotient completion, selected point, compactness, reflexivity, or choice coordinate can enter. □

Theorem 5831.3 (UniformlyConvexSpace modulus convexity route)**.** *Every accepted* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *consumer that asks for uniform convexity factors through*

$$\mathsf{NormedSpace}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{Completion}^{\uparrow}, \mathsf{Cauchy}^{\uparrow} \longmapsto H, T, P, C.$$

The modulus row Δ may be read only after the normed-space carrier, real norm values, midpoint operation, and metric separation row have been displayed. The route exports a finite modulus-of-convexity NameCert surface, not host strict convexity, a selected minimizer, quotient completion equality, compactness, reflexivity, or countable choice.

Proof. Begin with a uniform-convexity request. The normed-space row N supplies the only vector and norm data, while R supplies the real-valued unit-ball and positivity comparisons.

Read midpoint and separation next. The midpoint row A is formed from the displayed operations of N and R, and the metric handoff M reads separation through the induced metric of the same normed-space packet.

Only then can the modulus row Δ answer the request. Its output is tied to the displayed positive separation and midpoint norm route, and the completion-facing row Q sends Cauchy or completion consumers through the same route rather than through a selected completed point.

Finally H, T, P, C transport, replay, source, and name the packet. The excluded host strict-convexity, selected-minimizer, quotient-completion, compactness, reflexivity, and choice objects are absent from the carrier, so the finite modulus route is the whole exported surface. □

Falsifiable prediction: An accepted $\mathsf{UniformlyConvexSpace}^{\uparrow}$ read is refuted if a consumer obtains a uniform-convexity margin without first displaying the $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, midpoint, $\mathsf{Met}^{\uparrow}$, completion-facing, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: normedspace, real, metric, completion, cauchy: no listed sibling is bijective to $\mathsf{UniformlyConvexSpace}^{\uparrow}$ because the packet jointly carries normed-space data, real norm comparisons, midpoint formation, metric separation, a positive convexity modulus, completion-facing handoff, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformlyConvexSpace}^{\uparrow}$ packet is generated from a NormedSpace row, Real norm-comparison rows, a midpoint row, an induced Metric separation row, a convexity-modulus row, a Completion and Cauchy handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5831.1, Definition 5831.2, and Definition 5831.3 seed the finite modulus-of-convexity route over normed-space, real, metric, completion, and Cauchy rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.UniformlyConvexSpaceUp.UniformlyConvexSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host Banach-space equality, strict-convexity substitution, selected minimizers, quotient completions, compactness, reflexivity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, midpoint formation, metric separation, positive modulus exactness, completion-facing nonescape, and local naming for BEDC.Derived.UniformlyConvexSpaceUp.

Chapter 5832

A Concrete Naming Certificate for $\mathsf{HyperbolicTranslationLength}^{\uparrow}$

Following the classical translation length of a hyperbolic isometry, the $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ packet records the finite invariant-length route visible to the hyperbolic phase geometry of chapter 9463. It consumes the metric-read surface of chapter 3474, the routed geodesic-flow surface of chapter 3856, the additive Busemann cocycle route of chapter 4134, the four-boundary-point comparison of chapter 3948, and the terminal real seal of chapter 38. The packet names stable displacement growth as finite BEDC data; it does not import a host hyperbolic manifold, quotient ideal boundary, selected axis, spectral radius, or global curvature theorem.

Definition 5832.1 (HyperbolicTranslationLength carrier)**.** *A* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, F, B, X, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row, exposing displacement reads for the source and its iterated image.*
2. *F is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row, recording the finite routed-flow data used to compare iterates along the same visible geodesic route.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row, supplying additive boundary-cocycle comparisons for the same displayed endpoints.*
4. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *row, recording the four-boundary-point invariant used to stabilize the length read.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by displacement values, additive cocycle values, cross-ratio reads, and the final nonnegative length seal.*
6. *D is the displacement-growth row, comparing the displayed iterate window through M, F, B, X, R without selecting an infinite orbit or an axis.*
7. *E is the endpoint-stability row, stating that the same boundary data are replayed by the metric, flow, Busemann, and cross-ratio rows.*
8. *H records componentwise* hsame *transport for M, F, B, X, R, D, E and for the local structural rows.*

9. *C records displayed* Cont *replay from a translation-length request through $M, F, B, X, R, D, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host isometry group, selected invariant axis, quotient boundary equality, spectral radius, completed hyperbolic manifold, or physical expansion law.

Lean4 ✓ `BEDC.Derived.HyperbolicTranslationLengthUp.HyperbolicTranslationLengthTasteGate single carrier alignment`

Theorem 5832.2 (HyperbolicTranslationLength NameCert obligations)**.** *For every accepted* HyperbolicTranslation *carrier $L = (M, F, B, X, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$ *surface consists exactly of metric displacement visibility, geodesic-flow routing, Busemann additivity, cross-ratio stabilization, real-valued length sealing, displacement-growth comparison, endpoint stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside $M, F, B, X, R, D, E, H, C, P, N$.*

Proof. Project the carrier of Definition 5832.1. The rows $M, F, B, X, R, D, E, H, C, P, N$ are the whole visible packet.

The geometric route is read first. Metric displacement comes from M, routed iteration from F, additive boundary comparison from B, and four-boundary-point stabilization from X.

The Real and displacement rows then seal the length read. The row R supplies the real-valued comparison surface, while D and E ensure that the same endpoint data are used by the metric, flow, Busemann, and cross-ratio reads.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate names a host isometry group, selected invariant axis, quotient boundary equality, spectral radius, completed manifold, or physical expansion law, the listed obligations exhaust the local surface. □

Theorem 5832.3 (HyperbolicTranslationLength invariant route)**.** *Every accepted* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *read factors through*

$$\mathsf{HyperbolicMetric}^{\uparrow}, \mathsf{HyperbolicGeodesicFlow}^{\uparrow}, \mathsf{HyperbolicBusemannCocycle}^{\uparrow}, \mathsf{HyperbolicCrossRatio}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto H, C, P$$

The finite route records displacement growth and boundary stabilization as a real-sealed invariant length, and it exports no host hyperbolic isometry, selected axis, quotient ideal-boundary equality, spectral radius, completed hyperbolic manifold, or cosmological expansion claim.

Proof. Begin with the displacement request. The metric row M supplies finite distance reads, and the geodesic-flow row F keeps the iterated comparison on the same displayed route.

Read boundary stabilization next. The Busemann cocycle row B supplies additive endpoint comparison, while the cross-ratio row X records the four-boundary-point invariant. The endpoint-stability row E requires these boundary reads to describe the same displayed data.

The Real row R and displacement-growth row D seal the invariant length as a finite real-valued read. The structural rows H, C, P, N preserve, replay, source, and name that route, while the excluded host and quotient objects remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ consumer is refuted if it obtains an invariant length without displaying the $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}$ $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, displacement-growth, endpoint-stability, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: hyperbolicmetric, hyperbolic-geodesic-flow, hyperbolic-busemann-cocycle, hyperbolic-cross-ratio, real: no listed sibling is bijective to $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ because the packet jointly carries metric displacement, routed flow, additive boundary cocycle, cross-ratio stabilization, Real sealing, displacement-growth comparison, endpoint stability, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ packet is generated from HyperbolicMetric displacement rows, HyperbolicGeodesicFlow routing rows, HyperbolicBusemannCocycle additive boundary rows, HyperbolicCrossRatio stabilization rows, Real sealing rows, displacement-growth and endpoint-stability rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5832.1, Definition 5832.2, and Definition 5832.3 seed the finite invariant-length packet over metric, flow, Busemann, cross-ratio, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host hyperbolic isometries, selected axes, quotient ideal-boundary equality, spectral radii, completed hyperbolic manifolds, physical expansion laws, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, displacement visibility, flow routing, Busemann additivity, cross-ratio stabilization, Real length sealing, endpoint stability, and local naming for BEDC.Derived.HyperbolicTranslationLengthUp.

Chapter 5833

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ packet records the finite envelope that carries a regular Cauchy rational readback into the terminal Real naming seal. It sits after the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational sequence interface of chapter 301, the terminal real-name packet of chapter 38, and the completion route of chapter 1506. The packet is a finite NameCert envelope for the handoff itself; it does not assert that the host real line is complete.

Definition 5833.1 (Regular Cauchy completion envelope carrier)**.** *A* $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (W, D, R, E_R, M, T, C, P, N)$$

where W *is the displayed* $\mathsf{StreamName}^{\uparrow}$ *window row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row,* E_R *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* T *records componentwise* $\mathsf{BHist}/\mathsf{hsame}$ *transport,* C *records displayed* Cont *replay,* P *is* Pkg *provenance over the displayed rows, and* N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}$ *row. A consumer of the carrier receives the completion handoff only through these nine coordinates.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionEnvelopeUp.RegularCauchyCompletionEnvelopeTasteGate`
`single carrier alignment`

Theorem 5833.2 (Regular Cauchy completion envelope obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletion}$ *carrier*

$$E = (W, D, R, E_R, M, T, C, P, N),$$

the local NameCert surface consists exactly of window admission, tolerance admission, regular readback admission, terminal Real-seal admission, metric-completion route admission, transport stability, continuation replay, provenance preservation, and local naming preservation for the displayed packet. No quotient stream equality, selected representative, countable choice schedule, host completeness principle, or $\mathsf{Real}^{\uparrow}$ *completeness theorem is a coordinate of this surface.*

Proof. Project the carrier of Definition 5833.1. Its only data rows are $W, D, R, E_R, M, T, C, P, N$, so the local NameCert can inspect exactly those displayed coordinates.

The first four rows bind the finite observation, dyadic tolerance, regular rational readback, and terminal Real seal. The metric-completion row M is therefore read as a route row over those data, not as an ambient completeness object.

The structural rows T, C, P, N preserve the same packet under componentwise transport, continuation replay, provenance, and local naming. Since the carrier has no slot for quotient stream equality, selected representatives, countable choice, host completeness, or Real completeness, none of those objects can be exported by the obligation surface. □

Theorem 5833.3 (Regular Cauchy completion envelope Real handoff)**.** *Every Real-facing completion consumer of an accepted* $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ *carrier reads the terminal handoff through the ordered finite route*

$$W, D, R, E_R, M, T, C, P, N.$$

In particular, the consumer reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal only after the* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed inside the same envelope.*

Proof. Start from Definition 5833.2. It makes $W, D, R, E_R, M, T, C, P, N$ the entire accepted surface of the envelope.

Read the Real-facing route through W, D, R, E_R. The StreamName windows expose the finite observations, the dyadic ledger records the tolerance budget, the regular-rational row gives the readback, and the terminal row gives the Real seal inside the same packet.

The completion route M and the structural rows T, C, P, N only replay and name that displayed handoff. Thus the consumer cannot replace the handoff by quotient stream equality, a chosen representative, countable choice, host completeness, or a completeness theorem for $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5833.1, Definition 5833.2, and Definition 5833.3 seed the finite regular-Cauchy-to-Real completion envelope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyCompletionEnvelopeUp.RegularCauchyCompletionEnvelopeTasteGate\_single\_car`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host completeness, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, row order, Real handoff, transport stability, replay stability, provenance preservation, and local NameCert preservation for BEDC.Derived.RegularCauchyCompletionEnvelopeUp.

Constructive story: A $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore tolerance, RegSeqRat readback, terminal Real seal, metric-completion routing, transport, replay, provenance, and local NameCert rows.

Chapter 5834

A Concrete Naming Certificate for $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$

Following Bishop–Bridges constructive locatedness, the $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ packet records the finite interval-selection surface that can be read by Cauchy and Real interval consumers without selecting an endpoint or importing compactness. It sits over the located interval carrier of chapter 394, the rational cell ledger of chapter 354, the optional dyadic refinement rows of chapter 306, the endpoint observation windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal Real seal of chapter 38. The packet names a finite route through displayed interval data; it does not assert endpoint choice, Heine–Borel compactness, trichotomy, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5834.1 (WeaklyLocatedIntervalSelection carrier)**.** *A* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, Q, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the source interval and its locatedness probes.*
2. *Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger listing the rational subinterval cells visible to the selection route.*
3. *D is an optional* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row; when present, it refines cells already displayed by Q and adds no independent selector.*
4. *W is the paired* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window row through which finite endpoint observations are read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same endpoint windows and rational cells.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by any Real-facing endpoint or interval consumer.*
7. *H records componentwise* hsame *transport for $L, Q, D, W, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from located interval probes through rational cells, optional dyadic refinements, endpoint windows, regular readbacks, and the Real seal.*
9. *P is* Pkg *provenance over* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$*,* $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets componentwise through these ten rows. There is no coordinate for an endpoint selector, an open-cover compactness argument, a trichotomy oracle, quotient equality of Real names, or host Real completeness.

Lean4 ✓ `BEDC.Derived.WeaklyLocatedIntervalSelectionUp.WeaklyLocatedIntervalSelectionTasteGate`
`single carrier alignment`

Theorem 5834.2 (WeaklyLocatedIntervalSelection NameCert obligations)**.** *For every accepted* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *carrier*

$$S = (L, Q, D, W, R, E, H, C, P, N),$$

the local NameCert surface consists exactly of the following obligations:

1. *carrier admission for the finite* BHist *packet S and its displayed rows;*
2. *located-cell visibility from the* $\mathsf{LocatedInterval}^{\uparrow}$ *row L into the* $\mathsf{RationalInterval}^{\uparrow}$ *ledger Q;*
3. *finite selection-route exactness through the visible rational cells and any displayed* $\mathsf{DyadicInterval}^{\uparrow}$ *refinements D;*
4. *endpoint-window transport from Q, D into the* $\mathsf{StreamName}^{\uparrow}$ *windows W and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R;*
5. *Real-seal nonescape, requiring every Real-facing read to pass through the displayed* $\mathsf{Real}^{\uparrow}$ *row E;*
6. *componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance preservation, and local* NameCert *preservation through H, C, P, N.*

No endpoint choice principle, Heine–Borel theorem, trichotomy principle, quotient equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem is an obligation or an output of this surface.*

Theorem 5834.3 (Weakly located interval selection route exhaustion)**.** *For every accepted* WeaklyLocatedIntervalSe *carrier*

$$S = (L, Q, D, W, R, E, H, C, P, N),$$

every endpoint, interval, or Real-facing consumer factors through the displayed rows $L, Q, D, W, R, E, H, C, P, N$. Such a consumer cannot read endpoint choice, Heine–Borel compactness, trichotomy, quotient equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows of Definition 5834.1. The located interval source is L, the rational cell ledger is Q, and the optional dyadic refinement row is D.

Located-cell visibility therefore passes through L, Q, D. Endpoint or interval reads have no route around these rows because the packet stores no detached endpoint selector or host interval object.

The endpoint windows and regular rational readbacks are then W and R. A Real-facing consumer reaches the seal row E only after those finite windows and readbacks are visible.

Finally H, C, P, N transport, replay, source, and name the same route. Since endpoint choice, Heine–Borel compactness, trichotomy, quotient equality, and ambient completeness are absent from the tuple, the displayed rows exhaust every admitted consumer read. □

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5834.1, Definition 5834.2, and Definition 5834.3 seed the finite weakly located interval-selection route over chapter 394, chapter 354, chapter 306, chapter 126, chapter 301, and chapter 38.

Formal verification: FormalStatus(NameCert$_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close endpoint choice, Heine–Borel compactness, trichotomy, quotient real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-cell visibility, finite selection-route exactness, endpoint-window transport, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.WeaklyLocatedIntervalSelectionUp.

Constructive story: A WeaklyLocatedIntervalSelection$^{\uparrow}$ packet is generated from LocatedInterval rows, RationalInterval cell ledgers, optional DyadicInterval refinements, StreamName endpoint windows, RegSeqRat readbacks, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5835

A Concrete Naming Certificate for $\mathsf{UniformInverseModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UniformInverseModulus}^{\uparrow}$ packet records compact inverse-modulus extraction from uniform homeomorphism data as finite NameCert data. It reads the homeomorphism and inverse-graph surface of chapter 1815, the compact finite-net rows of chapter 129, the graph and pointwise continuity rows of chapter 130, the exported modulus interface of chapter 369, the metric-source and metric-target rows of chapter 4230, and the terminal real-name seal of chapter 38. The chapter names the finite compact route that turns displayed inverse radii into a uniform inverse modulus; it is not a selected inverse function, host function equality, quotient real equality, open-cover compactness, or ambient completeness principle.

Definition 5835.1 (Uniform inverse modulus carrier)**.** *A* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A)$$

with the following displayed rows:

1. *X is the compact source row, exposing the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net data used to cover the compact domain of the homeomorphism.*
2. *Y is the target metric row, including the distance ledger into which the inverse-modulus estimate is reported.*
3. *F is the* $\mathsf{UniformHomeomorphism}^{\uparrow}$ *graph row from X to Y, carrying the forward graph and the homeomorphism naming data.*
4. *G is the inverse graph row displayed by the same homeomorphism packet.*
5. *E is the positive precision row, read through* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint histories when the consumer presents a real tolerance.*
6. *N is the finite net row of the compact source at the scale needed for the inverse-modulus extraction.*
7. *R lists the pointwise inverse radius rows attached to the centers named by N.*
8. *M is the finite radius-fold row, obtained only by folding the finite family R over the index list of N.*
9. *T is the target estimate row, combining inverse-graph exactness, finite-net coverage, the folded radius row, and the target metric triangle ledger.*

10. *H records componentwise* hsame *transport for the compact source, target metric, homeomorphism graph, inverse graph, precision, finite-net, inverse-radius, radius-fold, and estimate rows.*
11. *C records the displayed* Cont *replay route from compact homeomorphism data and pointwise inverse radii to the* $\mathsf{UniformModulus}^{\uparrow}$ *export.*
12. *P records* Pkg *provenance over* $\mathsf{UniformInverseModulus}^{\uparrow}$, $\mathsf{UniformHomeomorphism}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, RegSeqRat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *A is the local* $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$ *row.*

The carrier exposes only displayed compact finite nets, graph rows, inverse-graph rows, endpoint readbacks, finite radius rows, componentwise transport, replay, provenance, and local naming. It has no coordinate for a host inverse function, selected inverse choice, host function equality, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformInverseModulusUp.UniformInverseModulusTasteGate single carrier alignment`

Theorem 5835.2 (Uniform inverse modulus obligations)**.** *For every accepted* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the compact source, target metric, homeomorphism graph, inverse graph, precision, finite-net, inverse-radius, radius-fold, target-estimate, transport, replay, provenance, and local naming rows;*
2. *inverse-graph exactness, requiring every inverse read to pass through the displayed row G attached to the homeomorphism row F;*
3. *compact finite-net handoff, requiring the compact source row X and precision row E to determine the finite row N before any inverse radius is folded;*
4. *finite radius fold, requiring M to be obtained only by folding the pointwise inverse radius rows R over the finite indices of N;*
5. *target estimate, requiring T to combine compact-net coverage, inverse-graph exactness, folded-radius data, and the target metric ledger;*
6. *transport, replay, and provenance, requiring H, C, P, A to source the same displayed route componentwise;*
7. *nonescape, requiring the packet to export no host inverse function, selected inverse choice, host function equality, quotient real equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 5835.1. The projection exposes exactly the rows $X, Y, F, G, E, N, R, M, T, H$ so carrier admission and row inventory are finite.

The inverse read is confined to G. Since G is listed as a row of the same homeomorphism packet that supplies F, inverse-graph exactness is consumed as displayed graph data rather than as host function equality or selected inverse choice.

The compact handoff reads X and E before radius data. These rows determine the finite net N, and the pointwise inverse radii in R are indexed only by the centers listed by N.

Fold R over that finite index list to obtain M. The target estimate row T then combines the compact-net coverage, inverse-graph exactness, folded radius, and target metric triangle route. Finally H, C, P, A transport, replay, source, and name the same route, so no excluded equality, choice, open-cover, trichotomy, or completeness coordinate is introduced. □

Theorem 5835.3 (Uniform inverse modulus compact handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *export from an accepted* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A)$$

factors through the displayed finite route

$$X, F, G, E \longmapsto N, R \longmapsto M, T \longmapsto H, C, P, A.$$

Thus the inverse-modulus export is a compact finite-net and radius-fold handoff. It exports no host function equality, selected inverse choice, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from a $\mathsf{UniformModulus}^{\uparrow}$ consumer of I. By Definition 5835.2, the consumer must read the compact source, homeomorphism graph, inverse graph, and precision rows before the finite-net row is available.

The only finite-net row is N, and the only pointwise inverse-radius inventory is R. Hence the consumer reaches the exported modulus row M only after the finite fold over R indexed by N.

The target estimate T is downstream of that fold. It cannot be read as a host inverse function or as quotient equality of inverse values, because the carrier contains only displayed graph and metric-ledger rows.

Finally the structural rows H, C, P, A transport, replay, source, and name the same compact route. Since the carrier contains no coordinate for selected inverse choice, trichotomy, open-cover compactness, or ambient completeness, the export factors through exactly the displayed finite-net and radius-fold handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformInverseModulus}^{\uparrow}$ packet is generated from UniformHomeomorphism graph and inverse-graph rows, CompactMetric finite-net rows, ContinuousMap pointwise inverse-radius rows, UniformModulus export rows, MetricSpace distance ledgers, RealUp and RegSeqRat endpoint readbacks, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$, seed)

Scope closed: Definition 5835.1, Definition 5835.2, and Definition 5835.3 seed the finite compact route from displayed inverse radii to a UniformModulus consumer.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient completeness, host inverse functions, selected inverse choice, quotient real equality, trichotomy, open-cover compactness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inverse-graph exactness, compact finite-net handoff, finite radius fold, target estimate, transport, replay, provenance, and local naming for BEDC.Derived.UniformInverseModulusUp.

Chapter 5836

A Concrete Naming Certificate for $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$

Following Bishop and Bridges on constructive real intervals, the $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ packet records a bounded interval together with the finite nested-window route used by Real and completion consumers. It sits over the dyadic rational arithmetic of chapter 291, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names a bounded interval principle for displayed nested windows; it does not assert open-cover compactness, a global supremum operator, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5836.1 (BoundedCompleteRealInterval carrier)**.** *A* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded interval row. It records the inspected lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, the boundedness witness visible to the packet, and the local containment predicate for interval windows.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger. It records the dyadic rational cuts used to compare successive windows and to certify the displayed diameter bound.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It lists exactly the finite endpoint and interval observations that may be inspected by the nested-window route.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same dyadic cuts and stream windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by every Real-facing extraction from B, D, W, R.*
6. *H records componentwise* hsame *transport for bounded interval rows, dyadic ledgers, stream windows, regular rational readbacks, Real seals, replay, provenance, and the local name.*
7. *C records displayed* Cont *replay from a nested-window request through B, D, W, R, E.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, D, W, R, E, H, C, P, N$. There is no coordinate for open-cover compactness, a selected supremum, host interval equality, quotient equality of Real names, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedCompleteRealIntervalUp.TasteGate.BoundedCompleteRealIntervalTasteGate single carrier alignment`

Theorem 5836.2 (BoundedCompleteRealInterval NameCert obligations)**.** *For every accepted* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier*

$$I = (B, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded interval row, dyadic endpoint ledger, stream windows, regular rational readback, Real seal, componentwise transport, continuation replay, package provenance, and local naming row;*
2. *bounded-window visibility, requiring every interval read to pass through the displayed lower-upper row B and its local containment predicate;*
3. *dyadic diameter discipline, requiring D to witness the inspected endpoint comparisons and the shrinking-width estimates used by the extraction route;*
4. *stream-readback exactness, requiring W and R to reuse the same finite endpoint observations and dyadic cuts rather than selecting a second Real representative;*
5. *Real-seal nonescape, requiring every Real-facing output to pass through E after B, D, W, R have all been projected;*
6. *structural preservation through H, C, P, N, with no exported row for open-cover compactness, selected suprema, host interval equality, quotient Real equality, countable choice, trichotomy, or ambient Real completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5836.1. The accepted packet displays exactly the bounded interval row, dyadic endpoint ledger, stream windows, regular rational readback, Real seal, and the structural rows.

Bounded-window visibility is forced by B. A consumer can inspect only the finite lower-upper interval data and the local containment predicate already present in the carrier.

Dyadic diameter discipline is forced by D. The endpoint comparisons and shrinking-width estimates used by the packet are the only numerical rows available to the later stream and readback rows.

The rows W and R are downstream of the same dyadic ledger. They schedule finite observations and repack them as regular rational readback without replacing the bounded interval by a second Real representative.

Finally, E, H, C, P, N close the route. The Real seal is reached only after B, D, W, R, while transport, replay, provenance, and naming preserve the same displayed data. Since no excluded coordinate occurs in the carrier, the local NameCert surface has exactly the listed obligations. □

Theorem 5836.3 (BoundedCompleteRealInterval nested-interval extraction)**.** *Let $I = (B, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier. Every nested-window extraction exported by I factors through the finite route*

$$B \longmapsto D \longmapsto W \longmapsto R \longmapsto E$$

before it can inspect transport, replay, provenance, or local naming rows. The extracted Real-facing read is therefore determined by the bounded interval row, the dyadic diameter ledger, the stream windows, and the regular rational readback visible in the packet.

Proof. Begin with a nested-window extraction from I. The carrier gives no source row before the bounded interval row B, so the lower-upper interval data and local containment predicate are inspected first.

The extraction then projects the dyadic ledger D. This fixes the endpoint comparisons and diameter estimates available to the finite window schedule.

Next the extraction passes through W and R. The stream row exposes only the finite endpoint observations allowed by B, D, and the regular rational row repacks those same observations as the readback consumed by the Real seal.

Only after this route has been displayed can the extraction reach E. The remaining rows H, C, P, N preserve, replay, source, and name the same route, so the exported extraction is exhausted by the displayed bounded-window data. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5836.1, Definition 5836.2, and Definition 5836.3 seed the bounded real interval packet over dyadic endpoint ledgers, StreamName windows, RegSeqRat readbacks, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, a global supremum operator, host interval equality, quotient real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-window visibility, dyadic diameter discipline, stream-readback exactness, Real-seal nonescape, structural preservation, and nested-window extraction for BEDC.Derived.BoundedCompleteRealIntervalUp.

Constructive story: A $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ packet is generated from a bounded Real interval row, a DyadicRatCore endpoint ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5837

A Concrete Naming Certificate for $\mathsf{FreeGroup}^{\uparrow}$

Following Magnus–Karrass–Solitar, *Combinatorial Group Theory*, the $\mathsf{FreeGroup}^{\uparrow}$ packet records the free group on a displayed finite generator interface as reduced signed words rather than as a quotient presentation. It sits after the word carrier of chapter 36, the unit and multiplication rows of chapter 40, and the inverse-bearing algebra surface of chapter 41. The packet gives the algebra hierarchy a finite reduced-word constructor; it does not identify a quotient group, complete a presentation theory, select normal forms outside the carrier, or assert host equality of generated subgroups.

Definition 5837.1 (Free group reduced-word carrier)**.** *A* $\mathsf{FreeGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (G, S, W, R, M, I, U, J, H, C, P, N)$$

with the following displayed rows:

1. *G is the finite generator row, exposing exactly the accepted generator names.*
2. *S is the signed-generator row, whose entries are pairs of a generator from G and an orientation bit.*
3. *W is the finite word row over S, read through the list discipline of chapter 36.*
4. *R is the reduction row that deletes adjacent inverse pairs until no adjacent cancellation cell remains.*
5. *M is the multiplication row, concatenating two word rows and then applying R.*
6. *I is the inverse row, reversing the word row and flipping each orientation bit.*
7. *U is the unit row, naming the empty reduced word.*
8. *J is the handoff row into the* $\mathsf{Group}^{\uparrow}$ *surface of chapter 41.*
9. *H records componentwise* hsame *transport for $G, S, W, R, M, I, U, J, C, P, N$.*
10. *C records displayed* Cont *replay from generator inspection through signed words, reduction, multiplication, inverse, unit, and the group handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{FreeGroup}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{Monoid}^{\uparrow}$*,* $\mathsf{Group}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

12. N is the local $\mathsf{NameCert}_{\mathsf{FreeGroup}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve rows. It has no coordinate for quotient presentation equality, a host word problem solver, a chosen normal form outside R, unrestricted subgroup generation, or completed presentation theory.

Lean4 ✓ `BEDC.Derived.FreeGroupUp.taste gate`

Theorem 5837.2 (Free group NameCert obligations)**.** *For every accepted* $\mathsf{FreeGroup}^{\uparrow}$ *packet* $F = (G, S, W, R, M, I, U, J, H, C, P, N)$*, carrier admission, signed-generator classification, reduced-word stability, multiplication replay, inverse replay, unit exposure, and the group-facing handoff are all exhausted by the displayed rows of Definition 5837.1. Any* $\mathsf{Group}^{\uparrow}$ *consumer receives the finite reduced-word packet through J after $G, S, W, R, M, I, U, H, C, P, N$ have been displayed.*

Proof. Project the carrier. The generator row G, signed row S, word row W, reduction row R, multiplication row M, inverse row I, unit row U, and handoff row J are the only algebraic coordinates available to a consumer.

The list-facing part is finite because W is read through chapter 36. The monoid-facing operation is not a host concatenation oracle: it is the displayed concatenate-then-reduce row M, with U as the empty reduced word and R as the cancellation boundary.

The inverse-bearing group-facing part is then exposed through I and J. Componentwise transport H, replay C, provenance P, and local naming N preserve the same rows under accepted package reads, so no quotient presentation equality, selected external normal form, subgroup-generation closure, or completed presentation theory can enter the certificate. □

Theorem 5837.3 (Free group reduction normal-form stability)**.** *In an accepted* $\mathsf{FreeGroup}^{\uparrow}$ *packet, the reduction row R is stable under the finite cancellation scan: if a signed word has no adjacent inverse pair after R has acted, then concatenating with the unit row U, applying the inverse row I twice, or transporting the word componentwise by H leaves the same reduced-word row for every downstream read.*

Proof. Begin with the finite word row W and reduction row R. The scan performed by R inspects adjacent signed-generator cells in the displayed list and deletes only inverse neighbours, so the result is a word row whose remaining adjacent cells are not inverse pairs.

The unit cases use the empty word row U. Concatenating a reduced word with U on either side introduces no signed-generator cell, hence no new adjacent inverse pair, and the reduction row returns the same displayed word row.

For inverse stability, I reverses the word and flips orientations. Applying I twice restores the original finite list of signed cells, and R has no new cancellation cell to remove beyond those already absent after the first reduction.

Finally, H transports the generator, signed-word, reduction, multiplication, inverse, and unit rows componentwise. Therefore normal-form stability is a property of the displayed reduced-word rows, not of an external quotient or a selected host representative. □

Theorem 5837.4 (Free group universal word handoff)**.** *Every group-facing consumer of an accepted* $\mathsf{FreeGroup}^{\uparrow}$ *packet must receive the handoff*

$$G, S, W, R, M, I, U, H, C, P, N \longrightarrow J$$

before it reads the target $\mathsf{Group}^{\uparrow}$ *surface. The handoff says that a generator interpretation is consumed as finite signed words, reduction, multiplication, inverse, unit, transport, replay, provenance, and local naming; it does not export quotient group equality, a completed presentation, or a proof that every external group element has a selected word representative.*

Proof. Read the handoff row J through the carrier. Its source rows are exactly the generator row, signed-generator row, word row, reduction row, multiplication row, inverse row, unit row, transport row, replay row, provenance row, and local name row.

Use the obligation surface of Definition 5837.2. Any $\mathsf{Group}^{\uparrow}$ consumer has already passed through the list, monoid, and group sibling surfaces named in the chapter introduction, so the only algebra it sees is the finite reduced-word packet.

The normal-form stability of Definition 5837.3 supplies the cancellation boundary needed by the handoff. Since the packet has no quotient-presentation coordinate, no selected external representative, and no completed presentation row, the universal read is a finite word handoff into $\mathsf{Group}^{\uparrow}$ rather than a claim of quotient group equality. □

Falsifiable prediction: Every accepted $\mathsf{FreeGroup}^{\uparrow}$ consumer that reaches the $\mathsf{Group}^{\uparrow}$ handoff first exposes finite generator rows, signed-generator rows, finite list-word rows, cancellation reduction, multiplication, inverse, unit, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: list, monoid, group: $\mathsf{FreeGroup}^{\uparrow}$ is not bijective to any listed sibling because it binds signed-generator words and cancellation reduction before exposing the inverse-bearing group handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{FreeGroup}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FreeGroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5837.1, Definition 5837.2, Definition 5837.3, and Definition 5837.4 seed the finite reduced-word constructor and its group-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FreeGroup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient group equality, completed presentation theory, subgroup generation, selected external normal forms, host word-problem decidability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, signed-generator classification, cancellation reduction stability, multiplication and inverse replay, unit stability, and group handoff exactness for BEDC.Derived.FreeGroupUp.

Constructive story: A $\mathsf{FreeGroup}^{\uparrow}$ packet is generated from finite generator rows, signed-generator rows, finite list-word rows, cancellation reduction rows, multiplication, inverse, unit, a group-facing handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 5838

A Concrete Naming Certificate for $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$

Following Riemann and Bishop–Bridges constructive integration, the $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ packet records the finite route by which a continuous function on a located closed real interval receives a Darboux/Riemann integrability certificate. It consumes the pointwise-modulus surface of chapter 59, the tag-bearing finite interval route of chapter 4296, the Darboux upper/lower boundary of chapter 1880, the integrability carrier of chapter 1960, the weak located interval selector of chapter 5834, and the real-name seal of chapter 38. The packet gives integration consumers a finite NameCert surface for continuous functions without importing measure integration, open-cover compactness, quotient equality of real names, selected limiting values, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5838.1 (Continuous Riemann integrability carrier)**.** *A* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, T, D, J, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Continuous}^{\uparrow}$ *row exposing the pointwise modulus and graph-stability data of the integrand over the displayed interval source.*
2. *T is the* $\mathsf{TaggedRealPartition}^{\uparrow}$ *row naming the finite partition cells, tag containment, window reads, regular readbacks, and terminal real seals used for integration.*
3. *D is the* $\mathsf{DarbouxSum}^{\uparrow}$ *row carrying lower and upper finite sums over the same displayed partition route.*
4. *J is the* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff row, read only after the Darboux gap row has been displayed.*
5. *W is the* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *row that exposes located cells and endpoint windows for the closed interval source.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened for interval endpoints, partition tags, and pointwise modulus reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family attached to the same finite windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, T, D, J, W, S, R have been displayed.*

9. *H records componentwise* hsame *transport for the continuous row, tagged partition, Darboux rows, integrability handoff, weak interval selector, window and readback rows, real seal, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from pointwise modulus requests through located cells, finite tagged partitions, Darboux lower/upper rows, the integrability handoff, and the terminal real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, T, D, J, W, S, R, E, H, C, P, N$. It has no coordinate for full integration theory, measure integration, open-cover compactness, quotient equality, selected limits, or ambient real completeness.

Theorem 5838.2 (Continuous Riemann integrability NameCert obligations)**.** *For every accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier*

$$I = (F, T, D, J, W, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the finite* BHist *packet and the displayed rows $F, T, D, J, W, S, R, E, H, C, P, N$;*

2. *interval-source visibility through the weakly located interval row W and its located cell, endpoint-window, and regular-readback route;*

3. *pointwise modulus exposure through the continuous-function row F, with every modulus read tied to displayed interval cells and finite windows;*

4. *finite tagged partition coverage through T, including cell containment, tag containment, and the same* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows;*

5. *Darboux gap control through D, read as finite lower and upper sums over the displayed tagged partition route;*

6. *integrability handoff through J, allowed only after the Darboux gap row and partition coverage rows are visible;*

7. *Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No full integration theory, measure integration, open-cover compactness, quotient equality of real names, selected limiting value, Lean verification, or bridge checking is an obligation or output of this packet.

Proof. Carrier admission is the projection of Definition 5838.1. The accepted packet displays the continuous row, tagged partition, Darboux row, integrability handoff, weak interval selector, window family, regular readback, real seal, transport, replay, provenance, and local name.

The interval and modulus rows are read first. The row W supplies located cells and endpoint windows, while F supplies pointwise modulus data only over those displayed cells and windows.

The finite partition route is then exposed by T. Tags and endpoints are read through S and R, so the integration-facing partition is a finite BEDC object rather than a host partition or a selected representative family.

The Darboux and integrability rows are downstream. The row D computes lower and upper finite sums over the displayed partition route, and J exports integrability evidence only after that gap control is visible.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no coordinate for the excluded analytic objects, the listed rows exhaust the local NameCert surface. □

Theorem 5838.3 (Continuous Riemann integrability Darboux handoff)**.** *Every integration-facing consumer of an accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier factors through the finite partition and Darboux rows*

$$W, F \longmapsto T, S, R \longmapsto D \longmapsto J \longmapsto E, H, C, P, N.$$

Consequently the consumer receives a finite located-cell, pointwise-modulus, tagged-partition, lower/upper Darboux, integrability-handoff, and Real-seal route rather than quotient reals, host equality, choice-selected witnesses, or ambient Real completeness.

Proof. Begin with an integration-facing read. The weak interval selector W and continuous row F force the request through located cells, endpoint windows, and pointwise modulus rows before any partition or sum row can be inspected.

Next read the tagged partition route T, S, R. The finite cells and tags are displayed together with their StreamName windows and RegSeqRat readbacks, so later rows cannot detach the partition from the interval source.

The Darboux row D is then read as lower and upper finite sums over those displayed cells and tags. The integrability row J is therefore a handoff from finite Darboux gap control, not from a quotient real or host equality judgment.

The terminal seal and structural rows E, H, C, P, N preserve that route. No excluded object is stored in the carrier, so every consumer factors through the displayed finite partition and Darboux rows. □

Theorem 5838.4 (Continuous Riemann integrability uniform-modulus handoff)**.** *Every accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier whose continuous row factors through a displayed uniform-modulus or composed-modulus route passes the Darboux gap and* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff through the finite chain*

$$\mathsf{Continuous}^{\uparrow},\ \mathsf{UniformContinuityComposition}^{\uparrow},\ \mathsf{TaggedRealPartition}^{\uparrow},\ \mathsf{DarbouxSum}^{\uparrow},\ \mathsf{RiemannIntegrable}^{\uparrow},\ \mathsf{StreamNar}$$

The handoff therefore reads composed modulus data before the Darboux row and exports no host integral selector, quotient function equality, open-cover compactness argument, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5838.1. The displayed rows are the continuous row F, tagged partition row T, Darboux row D, Riemann-integrable handoff J, weak interval selector W, StreamName windows S, RegSeqRat readbacks R, Real seal E, transport, replay, provenance, and local naming rows.

Use Definition 5838.2 for row exhaustion. When the continuous row is supplied by a uniform-modulus or composed-modulus route, the only admitted modulus source is the displayed $\mathsf{Continuous}^{\uparrow}$ row together with the $\mathsf{UniformContinuityComposition}^{\uparrow}$ composed-modulus handoff of chapter 3891.

Now apply Definition 5838.3. The tagged partition, Darboux lower and upper sums, and integrability row must be read after the same StreamName windows, RegSeqRat readbacks, and terminal Real seal, so the composed-modulus source cannot bypass the finite Darboux route.

Since the carrier stores no host integral selector, quotient function equality, open-cover compactness proof, or ambient completeness object, the listed finite rows are the whole uniform-modulus handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$.

Constructive story: A $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ packet is generated from a Continuous row, TaggedRealPartition row, DarbouxSum row, RiemannIntegrable handoff row, WeaklyLocatedIntervalSelection row, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5838.1, Definition 5838.2, Definition 5838.3, and Definition 5838.4 seed the finite Darboux/Riemann integrability route for continuous functions on located closed real intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full integration theory, measure integration, open-cover compactness, quotient equality, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source visibility, pointwise modulus exposure, finite tagged partition coverage, Darboux gap control, integrability handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ContinuousRiemannIntegrabilityUp.

Chapter 5839

A Concrete Naming Certificate for $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy approximations, the $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ packet binds Cauchy mesh refinement, cofinal dyadic mesh selection, and diagonal Real mesh budgets into one finite common-refinement route. It sits over the two-request refinement carrier of chapter 3832, the cofinal dyadic selector of chapter 2254, the diagonal mesh-budget surface of chapter 618, and the terminal real-name seal of chapter 38. The packet gives Real-completeness consumers a finite cofinal mesh handoff without quotient streams, selected limits, countable choice, host real equality, or ambient completeness as an extra row.

Definition 5839.1 (Regular Cauchy mesh cofinality carrier)**.** *A* $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, R, D, B, S, A, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyMeshRefinement}^{\uparrow}$ *row exposing source Cauchy requests, two displayed dyadic meshes, and their common finite refinement.*
2. *R is the* $\mathsf{CofinalDyadicMesh}^{\uparrow}$ *row refining the incoming observation request to a dyadic mesh window.*
3. *D is the* $\mathsf{RealDiagonalMeshBudget}^{\uparrow}$ *row listing the inspected diagonal indices, selected windows, dyadic tolerances, and aggregation ledger.*
4. *B is the shared budget row aligning the request precision of Q, the cofinal selector depth of R, and the diagonal finite mesh budget of D.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened by the shared budget.*
6. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family over the same windows, with all dyadic tolerances read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, R, D, B, S, A have been displayed.*
8. *H records componentwise* hsame *transport for the refinement row, cofinal selector row, diagonal budget row, shared budget, window and readback rows, seal row, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from an observation request through*

$$Q, R, D \longmapsto B \longmapsto S \longmapsto A \longmapsto E.$$

10. *P is the* Pkg *provenance over* RegularCauchyMeshCofinality$^{\uparrow}$, CauchyMeshRefinement$^{\uparrow}$, CofinalDyadicMesh$^{\uparrow}$, RealDiagonalMeshBudget$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{RegularCauchyMeshCofinality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, R, D, B, S, A, E, H, C, P, N$. It has no coordinate for quotient streams, hidden subnets, selected limits, countable-choice schedules, host real equality, trichotomy, or ambient Real completeness.

Theorem 5839.2 (Regular Cauchy mesh cofinality NameCert obligations)**.** *For every accepted* RegularCauchyMeshCofinality$^{\uparrow}$ *carrier*

$$K = (Q, R, D, B, S, A, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyMeshCofinality}^{\uparrow}}$ *surface consists exactly of carrier admission, Cauchy mesh-refinement exposure through Q, cofinal dyadic mesh exposure through R, Real diagonal mesh-budget exposure through D, shared precision and mesh-budget alignment through B, finite* StreamName$^{\uparrow}$ *window exposure through S,* RegSeqRat$^{\uparrow}$ *readback and* DyadicRatCore$^{\uparrow}$ *tolerance visibility through A, terminal* Real$^{\uparrow}$ *seal admission through E, componentwise transport through H, route replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 5839.1. The accepted packet displays exactly the Cauchy refinement, cofinal selector, diagonal budget, shared budget, windows, readbacks, seal, transports, replay, provenance, and local name.

The three mesh sources are read before any Real-facing seal. The row Q displays the common refinement of source Cauchy meshes, R displays the cofinal dyadic selector for the observation request, and D displays the finite diagonal mesh budget.

The shared row B aligns these sources. It is the only place where the precision request, cofinal selector depth, and diagonal inspected indices meet, so the window row S and regular readback row A inherit one finite route.

The seal and structural rows E, H, C, P, N preserve that route. Since the carrier has no coordinate for the excluded completion objects, the listed rows exhaust the local certificate surface. □

Theorem 5839.3 (Regular Cauchy mesh cofinality Real-completeness handoff)**.** *Every Real-completeness or diagonal-limit consumer of an accepted* RegularCauchyMeshCofinality$^{\uparrow}$ *carrier receives its seal-facing data only through the cofinal finite route*

$$Q, R, D \longmapsto B \longmapsto S \longmapsto A \longmapsto E, H, C, P, N.$$

Thus the consumer factors through Cauchy mesh refinement, cofinal dyadic mesh selection, Real diagonal mesh budgeting, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, and the RealUp seal before any completion-facing conclusion is exported.

Proof. Start from a Real-completeness consumer request. The packet first exposes Q, so the two source Cauchy requests and their common refinement are finite displayed data.

The request then passes through R and D. The cofinal dyadic selector supplies a finite mesh window, while the diagonal mesh-budget row supplies the finite inspected indices and dyadic tolerance ledger.

The budget row B is the common meeting point. It forces the StreamName windows S and RegSeqRat readbacks A to use the same finite refinement and the same dyadic tolerance rows.

Only after this route is displayed may the Real seal E be read. Transport, replay, provenance, and local naming preserve the route, and the excluded quotient or choice-based completion objects are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ packet is generated from CauchyMeshRefinement, CofinalDyadicMesh, RealDiagonalMeshBudget, a shared precision and mesh-budget row, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5839.1, Definition 5839.2, and Definition 5839.3 seed the finite cofinal common-refinement mesh route used by Real-completeness and diagonal-limit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, hidden subnets, selected limits, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy mesh-refinement exposure, cofinal dyadic mesh exposure, Real diagonal mesh-budget exposure, shared-budget alignment, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance visibility, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMeshCofinalityUp.

Chapter 5840

A Concrete Naming Certificate for LocatedCauchyFilterBasis$^{\uparrow}$

Following Bishop and Bridges, the LocatedCauchyFilterBasis$^{\uparrow}$ packet names the finite located-basis interface used by the L10 Real and Completion route before the data are promoted to a located Cauchy filter. It refines the basis-generator surface of chapter 1501 and the located filter route of chapter 1661; its finite reads pass through chapter 126, chapter 301, chapter 291, and finally the downstream seal boundary of chapter 38. The chapter isolates the basis-level located witness, not a completed filter, quotient Cauchy name, selected real, or ambient completeness principle.

Definition 5840.1 (Located Cauchy filter basis carrier)**.** *A* LocatedCauchyFilterBasis$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, L, S, R, D, W, T, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* CauchyFilterBasis$^{\uparrow}$ *row naming the finite basis elements and their common-refinement witnesses.*
2. *L is the located-basis request row. It records the displayed dyadic ball request and the basis element that is asserted to meet it.*
3. *S is the* StreamName$^{\uparrow}$ *finite-window row attached to the same located request.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the windows in S.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger for the requested ball, inclusion comparison, and refinement radius.*
6. *W is the finite witness row that the selected basis element meets the requested located ball after S, R, D have been replayed.*
7. *T is the tail-refinement row sending the located basis witness to the filter-level route of* LocatedCauchyFilter$^{\uparrow}$.
8. *E is the downstream* Real$^{\uparrow}$ *seal boundary, reachable only after the basis, located request, finite windows, readback, tolerance, witness, and tail-refinement rows have been consumed.*
9. *H records componentwise* hsame *transport for all displayed rows.*
10. *C records displayed* Cont *replay from a located basis request through $B, L, S, R, D, W, T, E, H, P, N$.*
11. *P is the* Pkg *provenance over* LocatedCauchyFilterBasis$^{\uparrow}$, CauchyFilterBasis$^{\uparrow}$, LocatedCauchyFilter$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for completed filters, quotient stream equality, selected representatives, countable choice, trichotomy, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterBasisUp.LocatedCauchyFilterBasisTasteGate single carrier alignment`

Theorem 5840.2 (Located Cauchy filter basis NameCert obligations)**.** *For every accepted* LocatedCauchyFilterBasis *carrier* $K = (B, L, S, R, D, W, T, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterBasis}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the finite basis row, located request row, stream windows, regular rational readback, dyadic tolerance ledger, located witness, tail-refinement handoff, seal boundary, transport, continuation, provenance, and local naming row;*
2. *located basis classification, requiring two accepted reads to agree precisely when their displayed requests admit a common basis refinement after H transports the B, L, S, R, D, W rows;*
3. *finite-window replay, requiring the located request to inspect only the windows in S before the readback row R and tolerance ledger D are available;*
4. *witness exactness, requiring W to show that the displayed basis element meets the requested dyadic ball using only the finite rows S, R, D;*
5. *tail refinement, requiring T to hand the located basis witness to the* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *route before any real-facing seal can be read;*
6. *nonescape, excluding completed filters, quotient streams, selected representatives, countable choice, trichotomy, host real equality, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterBasisUp.LocatedCauchyFilterBasisCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 5840.1. The visible rows are exactly the finite basis data, located request, stream windows, rational readback, dyadic ledger, witness, tail refinement, seal boundary, transport, replay, provenance, and name.

The dependency anchors are the basis carrier of chapter 1501 and the located filter consumer of chapter 1661. The finite observations, rational readbacks, tolerance ledgers, and terminal seal are read through chapter 126, chapter 301, chapter 291, and chapter 38.

Classifier comparison is componentwise. Transport by H moves the basis row, located request, window row, readback row, tolerance ledger, and witness row to a common finite comparison surface, while C replays the same order.

The located witness is finite. A request first reads S, then R, then D, and only then may W certify that the displayed basis element meets the requested dyadic ball.

The tail-refinement row T is the only route to $\mathsf{LocatedCauchyFilter}^{\uparrow}$, and E is downstream from that route. Hence P and N cannot export completed filters, quotient streams, selected representatives, choice, trichotomy, host real equality, or real completeness. □

Theorem 5840.3 (Located Cauchy filter basis tail refinement)**.** *Let* $K = (B, L, S, R, D, W, T, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedCauchyFilterBasis}^{\uparrow}$ *carrier. Every located basis read factors through the finite route*

$$B, L \longmapsto S \longmapsto R \longmapsto D \longmapsto W \longmapsto T.$$

The row T then exposes the same witness as a filter-level located tail request for $\mathsf{LocatedCauchyFilter}^{\uparrow}$*, with no bypass around the* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, or* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger.*

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterBasisUp.LocatedCauchyFilterBasisCarrier tail refinement`

Proof. Start with a located basis read. The rows B and L fix the displayed basis element and the dyadic ball request; neither row contains a sequence readback or a filter-level located-tail witness by itself.

Replay the continuation row C. The request reaches the finite window row S, then the regular rational readback row R, and then the dyadic tolerance ledger D.

Only after those finite rows have been consumed can W certify the located hit. The row T repackages that same finite witness for the $\mathsf{LocatedCauchyFilter}^{\uparrow}$ route, so the handoff cannot skip the StreamName, RegSeqRat, or DyadicRatCore ledgers. □

Theorem 5840.4 (Located Cauchy filter basis Real seal handoff)**.** *For every accepted* $\mathsf{LocatedCauchyFilterBasis}^{\uparrow}$ *carrier* $K = (B, L, S, R, D, W, T, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$*-facing read exposed by* P *factors through the tail-refinement row* T *and then through the seal boundary* E*. Equivalently, the only real-facing route visible in the packet is*

$$B, L, S, R, D, W \longmapsto T \longmapsto E \longmapsto H, C, P, N.$$

Thus the Real seal is downstream of the located basis witness and cannot be read from basis elements, windows, rational readbacks, or dyadic tolerances alone.

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterBasisUp.LocatedCauchyFilterBasisCarrier real seal handoff`

Proof. Project the seal boundary row. The carrier lists E after the finite basis route and after the tail-refinement row T, so the seal is not a coordinate of B, L, S, R, D, or W.

Replay the route by C. A real-facing request must first consume the basis row, located request, window row, readback row, tolerance ledger, and located witness, and must then pass through T.

Transport by H preserves the same dependency order under classifier comparison. The provenance and local naming rows therefore record a downstream Real seal handoff rather than a selected limit, quotient equality, host real equality, or completeness witness. □

Theorem 5840.5 (Located Cauchy filter basis nonescape)**.** *An accepted* $\mathsf{LocatedCauchyFilterBasis}^{\uparrow}$ *packet cannot export any consumer route that reaches outside the finite rows*

$$B, L, S, R, D, W, T, E, H, C, P, N.$$

In particular, any consumer asking for a completed filter, quotient Cauchy name, selected representative, countable-choice schedule, trichotomy decision, host real equality, or ambient completeness proof is refused by the carrier and by the local $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterBasis}^{\uparrow}}$ *obligations.*

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterBasisUp.LocatedCauchyFilterBasisRealNonescape`

Proof. Inspect the carrier rows of Definition 5840.1. They include only finite BHist data, hsame transport, Cont replay, dyadic tolerance ledgers, StreamName windows, RegSeqRat readbacks, the located basis witness, the LocatedCauchyFilter tail route, and the Real seal boundary.

The obligation surface of Definition 5840.2 is exhaustive. Every accepted consumer must pass through those listed rows, and no obligation names a hidden completed filter, quotient stream, selected representative, choice schedule, trichotomy decision, host equality, or completeness proof.

The tail and seal theorems keep the downstream routes ordered. Since T and E are reached only after the finite located basis witness is replayed, the packet has no escape path around its displayed finite data. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterBasis}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterBasis}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5840.1, Definition 5840.2, Definition 5840.3, Definition 5840.4, and Definition 5840.5 seed the located finite-basis interface between CauchyFilterBasis, LocatedCauchyFilter, StreamName, RegSeqRat, DyadicRatCore, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterBasis}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed filters, quotient Cauchy names, selected representatives, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Lean closure requires carrier admission, the located basis obligation surface, tail refinement, Real seal handoff, and nonescape for BEDC.Derived.LocatedCauchyFilterBasisUp.

Constructive story: The construction starts from a CauchyFilterBasis row, reads a located dyadic request through StreamName windows, RegSeqRat readbacks, and DyadicRatCore ledgers, packages the finite witness as a LocatedCauchyFilter tail route, and treats Real access only as downstream seal provenance.

Chapter 5841

A Concrete Naming Certificate for $\mathsf{OneSidedLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{OneSidedLimit}^{\uparrow}$ packet records the left- and right-hand real-limit interface as finite BEDC data. It sits next to the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation schedule of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet names only displayed side-tagged approach windows, regular rational reads, dyadic tolerance rows, transport, replay, provenance, and a terminal Real seal; it does not import two-sided completeness, host real equality, quotient streams, trichotomy, or a selected limiting point.

Definition 5841.1 (One-sided limit carrier)**.** *A* $\mathsf{OneSidedLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, L, W, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the approach-anchor row, naming the source point or endpoint cell at which the one-sided read is taken.*
2. *L is the side classifier row, with each visible approach window tagged as left-hand or right-hand before any limiting seal is inspected.*
3. *W is the finite approach-window row, listing only windows compatible with the tag in L and the anchor in A.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by the side-tagged windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data observed on S.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the displayed one-sided comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from A, L, W, S, R, D.*
8. *H records componentwise* hsame *transport for the anchor, side classifier, windows, stream schedule, regular readback, dyadic ledger, Real seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from the side-tagged approach windows through the stream, readback, dyadic, and Real-seal rows.*
10. *P is the* Pkg *provenance over* $\mathsf{OneSidedLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $A, L, W, S, R, D, E, H, C, P, N$. It has no coordinate for a two-sided completion theorem, quotient real equality, host order trichotomy, countable choice, or a selected limit outside the named side-tagged windows.

Lean4 ✓ `BEDC.Derived.OneSidedLimitUp.OneSidedLimitTasteGate single carrier alignment`

Theorem 5841.2 (One-sided limit NameCert obligations)**.** *For every accepted* $\mathsf{OneSidedLimit}^{\uparrow}$ *carrier $K = (A, L, W, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the approach anchor, side classifier, approach windows, stream schedule, regular readback, dyadic ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *side classifier stability, requiring each transported window to retain its left-hand or right-hand tag before a readback row is consumed;*
3. *dyadic tolerance ledger exactness, requiring D to expose only the tolerance rows demanded by the side-tagged windows in W;*
4. $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring S and R to read only the finite observations selected by A, L, W;*
5. *Real seal nonescape, requiring E to remain downstream of A, L, W, S, R, D and never to serve as a two-sided completeness witness or host real equality row;*
6. *componentwise transport, replay, provenance, and local naming through H, C, P, N.*

No $\mathsf{OneSidedLimit}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5841.1. The accepted packet displays the approach anchor A, side classifier L, finite approach windows W, stream schedule S, regular readback R, dyadic ledger D, Real seal E, and structural rows H, C, P, N.

Side classifier stability is componentwise. A transported window may be read only with the left-hand or right-hand tag already recorded in L, and the replay row C keeps the same tag attached while the stream and regular-rational rows are inspected.

The tolerance and readback rows are downstream of the same finite windows. The ledger D records the dyadic comparisons demanded by W, the schedule S opens only those observations, and R records the regular rational readback.

Finally, the Real seal E is terminal for the route. Since the carrier contains no row for two-sided completeness, quotient real equality, host order trichotomy, countable choice, or a selected limit outside the displayed windows, those objects cannot become local obligations. □

Theorem 5841.3 (One-sided limit Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{OneSidedLimit}^{\uparrow}$ *packet reads the proposed one-sided limit only through the displayed finite route*

$$A, L, W, S, R, D, E, H, C, P, N.$$

Consequently the handoff to $\mathsf{Real}^{\uparrow}$ *is available only after the approach anchor, side classifier, finite approach windows, StreamName schedule, RegSeqRat readback, and DyadicRatCore tolerance ledger have been exposed. The handoff exports no two-sided completeness theorem, quotient stream equality, host real equality, order trichotomy, countable choice principle, or selected limiting point.*

Proof. Project the accepted carrier through Definition 5841.1. Its Real-facing row is the single terminal coordinate E, and the only route to E passes through A, L, W, S, R, D and the structural rows H, C, P, N.

The finite approach windows determine the side of approach before readback begins. Thus a consumer that asks for a Real seal must already have read the side classifier, the compatible windows, the stream schedule, the regular rational row, and the dyadic tolerance ledger.

The remaining coordinates transport and name the same route. Because no carrier row stores a two-sided completion principle, quotient equality, host equality, trichotomy, choice, or an independent selected limit, the Real-seal handoff cannot export any of those objects. □

Falsifiable prediction: Every $\mathsf{OneSidedLimit}^{\uparrow}$ Real-facing read factors through an approach anchor, a left/right side classifier, finite approach windows, a StreamName schedule, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{OneSidedLimit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a side classifier, finite approach windows, scheduled regular-rational readback, dyadic tolerance data, and a terminal Real seal in one one-sided packet.

Closure status for $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{OneSidedLimit}^{\uparrow}$ packet is generated from an approach anchor, a left/right side classifier, finite approach windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5841.1, Definition 5841.2, and Definition 5841.3 seed the finite one-sided real-limit route through side-tagged approach windows and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.OneSidedLimitUp.OneSidedLimitTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close two-sided real completeness, quotient stream equality, host real equality, trichotomy, countable choice, selected limits outside the displayed windows, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, side classifier stability, dyadic tolerance exactness, StreamName and RegSeqRat readback, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.OneSidedLimitUp.

Chapter 5842

A Concrete Naming Certificate for $\mathsf{BertrandSeriesTest}^{\uparrow}$

Following Bertrand's logarithmic refinement of ratio-type convergence tests and Bishop–Bridges constructive real-series practice, the $\mathsf{BertrandSeriesTest}^{\uparrow}$ packet records the finite second-order quotient-defect route that turns displayed positive-series tail data into a regular Cauchy comparison handoff. It sits beside the neighboring quotient-defect surfaces of chapter 1719, chapter 2113, and chapter 2130, refines the ratio and comparison routes of chapter 1461 and chapter 1459, and exports endpoints only through the dyadic, stream, regular-rational, and Real seals of chapter 291, chapter 126, chapter 301, and chapter 38. The packet names finite Bertrand-test evidence only through inspected source windows, adjacent quotient windows, a logarithmic defect ledger, dyadic domination, comparison-test routing, regular rational readback, and terminal Real sealing; it is not host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 5842.1 (Bertrand series test carrier)**.** *A* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Q, L, D, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source real-series row, exposing only positive-term windows, partial-sum windows, and tail-threshold requests used by the current convergence test.*
2. *Q is the adjacent quotient-window row, recording the inspected neighboring-term quotients on the same displayed tail window.*
3. *L is the logarithmic defect ledger, storing the finite index, logarithmic scale, rational margin, and second-order defect rows used by the Bertrand comparison.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *domination ledger, converting the displayed logarithmic defect and margin rows into a finite majorant or minorant comparison.*
5. *T is the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff row that consumes S, Q, L, D before any convergence conclusion is exposed.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the source, quotient, logarithmic defect, domination, and comparison rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after the comparison handoff and stream windows have been displayed.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint-facing consumers.*
9. *H stores componentwise* hsame *transport for the source, quotient, logarithmic defect, domination, comparison, window, readback, seal, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay from each tail request through Q, L, D, T, W, R, E.*
11. *P is the* Pkg *provenance over* $\mathsf{BertrandSeriesTest}^{\uparrow}$, $\mathsf{RaabeDuhamelTest}^{\uparrow}$, $\mathsf{KummerTest}^{\uparrow}$, $\mathsf{GaussTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, L, D, T, W, R, E, H, C, P, N$. It has no coordinate for host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BertrandSeriesTestUp.BertrandSeriesTestTasteGate single carrier alignment`

Theorem 5842.2 (Bertrand series test NameCert obligations)**.** *For every accepted* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier*

$$B = (S, Q, L, D, T, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source real-series windows, adjacent quotient windows, logarithmic defect ledger, dyadic domination ledger, comparison-test handoff, stream windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming row;*
2. *quotient-window exactness, requiring every quotient read used by the Bertrand defect to be read from the displayed neighboring positive-term windows in S and Q;*
3. *logarithmic-defect stability, requiring the finite index, logarithmic scale, rational margin, and second-order defect rows in L to remain attached to the accepted tail request;*
4. *dyadic domination routing, requiring D and W to convert the displayed logarithmic defect data into the same finite comparison windows consumed by T;*
5. *regular and Real handoff, requiring endpoint-facing data to pass through T, W, R, E in that order before a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives data;*
6. *ledger non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed rows and to exclude host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 5842.1. Carrier admission is exactly the inventory $S, Q, L, D, T, W, R, E, H, C$ so the local certificate has no detached row for an infinite sum, quotient series equality, selected sum, or ambient completeness theorem.

The quotient and logarithmic-defect clauses are read before the comparison handoff. The row S exposes only inspected positive-term and partial-sum windows, the row Q exposes only neighboring-term quotient windows, and L records the finite index, logarithmic scale, rational margin, and second-order defect attached to the current tail request.

The domination route is then forced through D, W, T. The dyadic ledger D converts the displayed logarithmic defect data into comparison evidence, the window row W fixes the finite stream windows, and the comparison-test row T is the only route that may export a regular Cauchy conclusion.

Finally, R and E supply the regular rational and Real-facing endpoint route. The structural rows H, C, P, N preserve, replay, source, and name the same route, so none of them can introduce host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge data. □

Theorem 5842.3 (Bertrand series test tail route)**.** *Every endpoint-facing read of an accepted* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier factors through*

$$\mathsf{RaabeDuhamelTest}^{\uparrow},\ \mathsf{KummerTest}^{\uparrow},\ \mathsf{GaussTest}^{\uparrow},\ \mathsf{RegularCauchyRatioTest}^{\uparrow},\ \mathsf{RegularCauchyComparisonTest}^{\uparrow},\ \mathsf{Dyadic}$$

Concretely, the read consumes source real-series windows and adjacent quotient rows, reads the logarithmic second-order defect ledger, converts that ledger into dyadic domination and stream-window evidence, enters the $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff, and reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *only through the displayed readback and seal rows.*

Proof. Begin with an endpoint-facing read of an accepted carrier. By Definition 5842.1, the only source data available before the defect estimate are the source windows in S and the adjacent quotient windows in Q.

The Bertrand-specific data are then read from L and D. The logarithmic ledger supplies the finite index, logarithmic scale, rational margin, and second-order defect, while the dyadic ledger turns those rows into the domination evidence needed for comparison.

The neighboring quotient-defect tests are reference faces in the same lattice. The Raabe–Duhamel, Kummer, and Gauss packets identify the adjacent first-order and auxiliary defect surfaces, while the ratio route supplies the shared adjacent-quotient discipline. The accepted $\mathsf{BertrandSeriesTest}^{\uparrow}$ endpoint route still has to enter the comparison handoff T.

After T is displayed, the route proceeds through the finite $\mathsf{StreamName}^{\uparrow}$ windows in W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E. The transport, replay, provenance, and naming rows keep the same route, so no host summability, quotient series equality, selected sums, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness can enter. □

Falsifiable prediction: Every accepted $\mathsf{BertrandSeriesTest}^{\uparrow}$ endpoint-facing read factors through source real-series windows, adjacent quotient rows, a logarithmic defect ledger, dyadic domination, a RegularCauchyComparisonTest handoff, StreamName windows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: raabeduhameltest, kummertest, gausstest, regularcauchyratiotest, regularcauchycomparisontest, dyadicratcore, streamname, regseqrat, real: $\mathsf{BertrandSeriesTest}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source series windows, adjacent quotient windows, a logarithmic second-order defect ledger, dyadic domination, comparison-test routing, regular rational readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BertrandSeriesTest}^{\uparrow}$ packet is generated from source real-series windows, adjacent quotient windows, a logarithmic second-order defect ledger, dyadic domination, a RegularCauchyComparisonTest handoff, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5842.1, Definition 5842.2, and Definition 5842.3 seed the finite Bertrand convergence-test boundary over displayed source series, quotient, logarithmic defect, comparison, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier admission, quotient-window exactness, logarithmic-defect stability, dyadic domination routing, regular and Real handoff, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.BertrandSeriesTestUp.

Chapter 5843

A Concrete Naming Certificate for $\mathsf{RationalCanonicalForm}^{\uparrow}$

Following Frobenius and standard linear algebra treatments of finite-dimensional operators, the $\mathsf{RationalCanonicalForm}^{\uparrow}$ packet records the rational canonical form of a displayed finite linear operator as BEDC NameCert data. It consumes the finite matrix rows of chapter 49, the linear-map surface of chapter 48, the polynomial source of chapter 50, the module and vector-space carriers of chapter 46 and chapter 47, and the invariant-factor route supplied by chapter 2262. The packet names only a finite certificate surface for companion-block assembly; it does not assert a host Jordan form theorem, algebraic closure, eigenvalue selection, basis choice outside the displayed rows, or a global classification oracle.

Definition 5843.1 (Rational canonical form carrier)**.** *A* $\mathsf{RationalCanonicalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (V, L, M, S, I, B, A, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *or* $\mathsf{Module}^{\uparrow}$ *source row naming the finite underlying carrier and its scalar action.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row naming the endomorphism whose canonical form is being read.*
3. *M is the* $\mathsf{Mat}^{\uparrow}$ *presentation row for the same endomorphism over the displayed finite basis data already carried by V and L.*
4. *S is the consumed* $\mathsf{SmithNormalForm}^{\uparrow}$ *dependency row applied to the polynomial matrix route attached to M.*
5. *I is the invariant-factor* $\mathsf{Poly}^{\uparrow}$ *row, listing monic polynomial factors with the divisibility ledger exposed by S.*
6. *B is the companion-block row, assembling one finite block for each invariant factor in I and recording the row and column positions used by the assembly.*
7. *A is the block-assembly exactness row, stating that the displayed* $\mathsf{Mat}^{\uparrow}$ *presentation is transported to the companion-block matrix through the same* $\mathsf{LinMap}^{\uparrow}$ *and* $\mathsf{Poly}^{\uparrow}$ *rows.*
8. *H stores componentwise* hsame *transport for the vector or module source, linear map, matrix presentation, Smith-normal dependency, invariant factors, companion blocks, assembly row, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from a canonical-form request through V, L, M, S, I, B, A and back to the same finite operator surface.*
10. *P is the* Pkg *provenance over* $\mathsf{RationalCanonicalForm}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{SmithNormalForm}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$ *row.*

The carrier has no coordinate for selected eigenvalues, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, or a detached canonical-form oracle.

Lean4 ✓ `BEDC.Derived.RationalCanonicalFormUp.TasteGate.RationalCanonicalFormTasteGate single carrier alignment`

Theorem 5843.2 (Rational canonical form NameCert obligations)**.** *For every accepted* $\mathsf{RationalCanonicalForm}^{\uparrow}$ *carrier*

$$F = (V, L, M, S, I, B, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$ *surface consists exactly of finite source admission for V, L, M, Smith-normal dependency routing through S, invariant-factor exposure through I, companion-block assembly through B, block-assembly exactness through A, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5843.1. The algebraic source rows are exactly the vector or module carrier V, the endomorphism row L, the finite matrix presentation M, the Smith-normal dependency row S, the invariant-factor row I, and the companion-block assembly rows B, A.

The invariant factors are not read from a host classification theorem. They are exposed as $\mathsf{Poly}^{\uparrow}$ rows whose divisibility and matrix-reduction dependency is routed through $\mathsf{SmithNormalForm}^{\uparrow}$ before any companion block is assembled.

The companion-block row B is finite because it is indexed by the displayed invariant-factor list I. The exactness row A then compares the assembled block matrix with the original $\mathsf{Mat}^{\uparrow}$ presentation through the same $\mathsf{LinMap}^{\uparrow}$ endpoint and componentwise hsame transport.

Finally H, C, P, N transport, replay, source, and name only this finite route. Since the carrier contains no coordinate for eigenvalue selection, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, or a detached canonical-form oracle, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: A $\mathsf{RationalCanonicalForm}^{\uparrow}$ consumer that exports a canonical-form matrix while omitting the Smith-normal dependency row, invariant-factor polynomial row, companion-block assembly row, componentwise hsame, displayed Cont, Pkg, or local NameCert rows refutes the carrier of Definition 5843.1.

Independence witness: matrix, linearmap, polynomial, module, vecspace, smith-normal-form: $\mathsf{RationalCanonicalForm}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite operator source, matrix presentation, invariant-factor polynomial ledger, Smith-normal dependency, companion-block assembly, exactness row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RationalCanonicalForm}^{\uparrow}$ packet is generated from VecSpaceUp or ModuleUp source data, a LinearMapUp endomorphism row, a MatrixUp presentation, a SmithNormalFormUp dependency route, invariant-factor PolynomialUp rows, companion-block assembly rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RationalCanonicalForm}\uparrow}$, seed)

Scope closed: Definition 5843.1 and Definition 5843.2 seed the finite rational-canonical-form packet over matrix, linear-map, polynomial, module, vector-space, and Smith-normal rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RationalCanonicalForm}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim eigenvalue selection, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, invariant-factor exposure, Smith-normal dependency routing, companion-block assembly, exactness, transport, replay, provenance, and local naming for BEDC.Derived.RationalCanonicalForn

Chapter 5844

A Concrete Naming Certificate for $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$

The $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ packet realizes the Rule 110 pattern-classifier branch of chapter 9390 as finite BEDC NameCert data. It consumes the cellular automaton carrier of chapter 934, the row-classifier surface of chapter 941, the pattern catalog of chapter 995, the local-stencil observation route of chapter 1036, and the Rule 110 glider catalog of chapter 1045. The packet names finite row windows, transition-table reads, orbit prefixes, pattern tags, transport, replay, provenance, and a local NameCert row; it is not a universality theorem, an infinite-orbit classifier, an undecidable continuation oracle, or a hidden substrate semantics.

Definition 5844.1 (Rule 110 pattern classifier carrier)**.** *A* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (W, T, O, G, K, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite row-window row, naming the inspected Rule 110 space-time rectangle and its boundary cells.*
2. *T is the transition-table row, exposing the eight local update cases used to advance the window.*
3. *O is the orbit-prefix row, recording the finite sequence of rows replayed from the initial window by T.*
4. *G is the glider and ether catalog row consumed from* $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$ *and* $\mathsf{CellularPatternCatalog}^{\uparrow}$*.*
5. *K is the classifier-tag row, assigning each inspected subwindow to a displayed ether, glider, collision, boundary, or unknown tag.*
6. *H stores componentwise* hsame *transport for windows, transition-table rows, orbit prefixes, tags, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a classifier request through W, T, O, G, K.*
8. *P is the* Pkg *provenance over* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$*,* $\mathsf{CellularAutomaton}^{\uparrow}$*,* $\mathsf{CellularRowClassifier}^{\uparrow}$*,* $\mathsf{CellularPatternCatalog}^{\uparrow}$*,* $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$*,* $\mathsf{LocalStencilObservation}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$ *row.*

The carrier has no coordinate for infinite continuation, termination of all continuations, host universality, unbounded pattern search, quotient orbit equality, or a substrate semantics outside the displayed rows.

Theorem 5844.2 (Rule 110 pattern classifier NameCert obligations)**.** *For every accepted* RuleOneTenPatternClassif *carrier*

$$R = (W, T, O, G, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$ *surface consists exactly of row-window admission through* W*, transition-table exposure through* T*, orbit-prefix replay through* O*, catalog lookup through* G*, classifier-tag exactness through* K*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier of Definition 5844.1. The finite cellular rows are exactly the inspected window W, transition table T, orbit prefix O, catalog row G, classifier row K, and the structural rows H, C, P, N.

The transition-table row is read before the orbit prefix, so every displayed successor row is justified by the same eight local Rule 110 cases. The classifier tag is then attached to a finite subwindow already present in O and compared against the catalog row G.

The transport and replay rows preserve that order. Since the carrier contains no infinite continuation coordinate, no all-continuations termination field, no unbounded pattern search, no quotient orbit equality, and no host universality proof, the local NameCert obligations are exhausted by the listed finite rows. □

Falsifiable prediction: A $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ classifier read that assigns a glider, ether, collision, boundary, or unknown tag without exposing the finite row window, transition-table row, orbit-prefix row, catalog row, componentwise hsame, displayed Cont, Pkg, and local NameCert rows refutes the carrier of Definition 5844.1.

Independence witness: continuationautomaton, finiteprefixautomaton, continuationtermination, typecheckingmembershiptrace, classifiermorphism: $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Rule 110 row windows, the transition table, orbit prefixes, catalog tags, classifier transport, replay, provenance, and local NameCert rows.

The Lean TasteGate file for this packet must provide Nontrivial $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ and FieldFaithful $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ instances for the displayed rows $W, T, O, G, K, H, C, P, N$ before the classifier can serve as a verified taste-gate consumer.

Closure status for $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ packet is generated from a finite Rule 110 row window, transition table, orbit prefix, pattern catalog, classifier tags, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$, seed)

Scope closed: Definition 5844.1 and Definition 5844.2 seed the finite Rule 110 pattern-classifier packet over row-window, transition-table, orbit-prefix, catalog, tag, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a universality theorem, infinite-orbit classification, continuation termination, unbounded pattern search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked row-window admission, transition-table exposure, orbit-prefix replay, catalog lookup, classifier-tag exactness, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.RuleOneTenPatternClassifierUp.

Chapter 5845

A Concrete Naming Certificate for $\mathsf{RealizerSpace}^{\uparrow}$

Following Weihrauch-style realizability over represented spaces, the $\mathsf{RealizerSpace}^{\uparrow}$ packet records the finite interface at which a represented input name, an admissible Cauchy route, and a target readback are allowed to meet. It sits between the represented-space syntax of chapter 1494 and the admissible Cauchy consumption of chapter 1760, while routing every real-facing read through chapter 1680, chapter 126, chapter 301, chapter 291, and chapter 38. The carrier treats a realizer as displayed finite NameCert data, not as a quotient of names or a selected host function.

Definition 5845.1 (RealizerSpace carrier)**.** *A* $\mathsf{RealizerSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, A, K, W, Q, D, E, F, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{RepresentedSpace}^{\uparrow}$ *source row whose input observations are read only through its finite representation interface.*
2. *A is the* $\mathsf{AdmissibleRepresentation}^{\uparrow}$ *row exposing the finality route for represented-space consumers.*
3. *K is the* $\mathsf{CauchyRepresentation}^{\uparrow}$ *source row used by the admissible consumer before any real-facing output is read.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule shared by the input name, Cauchy source, and output request.*
5. *Q is the realizer-relation row; it relates displayed input windows to displayed output windows only through the local finite schedule.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the output readback.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the stream, regular rational, Cauchy, and dyadic rows have been replayed.*
8. *F is the admissible-finality handoff row, forcing every displayed represented-space consumer to factor through A, K, W, Q, D, E before output data are read.*
9. *H records componentwise* hsame *transport for the represented source, admissible row, Cauchy row, window schedule, relation row, dyadic ledger, real seal, finality row, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from an input precision request through X, A, K, W, Q, D, E, F.*
11. *P is the* Pkg *provenance over* $\mathsf{RealizerSpace}^{\uparrow}$, $\mathsf{RepresentedSpace}^{\uparrow}$, $\mathsf{AdmissibleRepresentation}^{\uparrow}$, $\mathsf{CauchyRepresentation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealizerSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only after transporting these rows to a common finite surface. It has no coordinate for quotient names, selected realizers, host function equality, countable choice, metric completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealizerSpaceUp.RealizerSpaceTasteGate single carrier alignment`

Theorem 5845.2 (RealizerSpace NameCert obligations)**.** *For every accepted* $\mathsf{RealizerSpace}^{\uparrow}$ *carrier $R = (X, A, K, W, Q, D, E, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealizerSpace}^{\uparrow}}$ *surface consists exactly of the following rows:*

1. *carrier admission for the displayed represented source, admissible row, Cauchy source, finite windows, realizer relation, dyadic ledger, real seal, finality handoff, transport, replay, provenance, and local naming;*
2. *realizer-relation exposure, requiring Q to be the only displayed route from input windows to output windows;*
3. *admissible finality, requiring A and F to force consumer access through the same Cauchy route before output data are read;*
4. *the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *handoff through W, K, D, E;*
5. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, N.*

No obligation is stored outside these rows.

Proof. Project the carrier of Definition 5845.1. Carrier admission exposes $X, A, K, W, Q, D, E, F, H, C, P, N$ and no further coordinate.

The realizer relation is the row Q. By construction it is read after the represented source, admissible row, Cauchy source, and finite stream schedule, so a consumer cannot replace it by a selected host function or quotient-name map.

Admissible finality is supplied by A and F. These rows force every represented-space consumer to pass through the same Cauchy route, with the regular rational, dyadic, and real-facing rows opened before output data are available.

Finally attach H, C, P, N. Transport, replay, provenance, and local naming preserve exactly the displayed packet. Since none of the excluded objects is a carrier coordinate, the listed rows exhaust the NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealizerSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{RealizerSpace}^{\uparrow}$ packet is generated from a $\mathsf{RepresentedSpace}^{\uparrow}$ source, an $\mathsf{AdmissibleRepresentation}^{\uparrow}$ row, a $\mathsf{CauchyRepresentation}^{\uparrow}$ source, finite $\mathsf{StreamName}^{\uparrow}$ windows, a realizer relation, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance data, a $\mathsf{Real}^{\uparrow}$ seal, finality handoff, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealizerSpace}^{\uparrow}}$, seed)

Scope closed: Definition 5845.1 and Definition 5845.2 seed the finite realizer interface from represented input names through admissible Cauchy consumption to real-facing output seals.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealizerSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient names, selected realizers, host function equality, countable choice, metric completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, realizer relation exposure, admissible finality, StreamName/RegSeqRat/DyadicRatCore/Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.RealizerSpaceUp.

Chapter 5846

A Concrete Naming Certificate for $\mathsf{RuleOneTenCausalCone}^{\uparrow}$

Following Cook's Rule 110 universality theorem and Wolfram's cellular automata classification, the $\mathsf{RuleOneTenCausalCone}^{\uparrow}$ packet records a finite causal cone rather than an ambient infinite cellular universe. It consumes the cellular automaton carrier of chapter 934, the local update surface of chapter 984, the cellular substrate row of chapter 942, and the Rule 110 glider catalog of chapter 1045. The packet names only finite windows, update-ledger rows, boundary rows, traces, transport, replay, provenance, and a local NameCert row.

Definition 5846.1 (Rule 110 causal-cone carrier)**.** *A* $\mathsf{RuleOneTenCausalCone}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, U, T, L, B, O, H, C, P, N)$$

with the following displayed rows:

1. *I is the initial finite window row, naming the cells inspected at time 0 together with their left and right indices.*
2. *U is the local Rule 110 update ledger, exposing the eight radius-one cases used to compute successor cells inside the window.*
3. *T is the time-depth row, bounding the number of successor rows present in the cone.*
4. *L is the left boundary row, recording the finite boundary cells needed to replay the left edge of the cone.*
5. *B is the right boundary row, recording the finite boundary cells needed to replay the right edge of the cone.*
6. *O is the observed cone-trace row, listing the finite space-time cells computed from I, U, T, L, B.*
7. *H records componentwise* hsame *transport for the initial window, update ledger, time depth, boundary rows, observed trace, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a cone observation request through I, U, T, L, B, O.*
9. *P is the* Pkg *provenance over* $\mathsf{RuleOneTenCausalCone}^{\uparrow}$, $\mathsf{CellularAutomaton}^{\uparrow}$, $\mathsf{CellularLocalUpdateRule}^{\uparrow}$, $\mathsf{CellularSubstrate}^{\uparrow}$, $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenCausalCone}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It contains no coordinate for an infinite configuration, a full orbit, a universality proof, unbounded glider search, quotient orbit equality, or a substrate semantics outside the finite cone.

Lean4 ✓ `BEDC.Derived.RuleOneTenCausalConeUp.TasteGate.RuleOneTenCausalConeTasteGate single carrier alignment`

Theorem 5846.2 (Rule 110 causal-cone NameCert obligations)**.** *For every accepted* $\mathsf{RuleOneTenCausalCone}^{\uparrow}$ *carrier* $R = (I, U, T, L, B, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenCausalCone}^{\uparrow}}$ *surface consists exactly of initial-window admission through* I*, local Rule 110 update-ledger exposure through* U*, time-depth bounding through* T*, left and right boundary replay through* L, B*, observed cone trace exposure through* O*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Lean4 ✓ `BEDC.Derived.RuleOneTenCausalConeUp.RuleOneTenCausalConeCarrier namecert obligations`

Proof. Project the carrier of Definition 5846.1. The finite cellular data are exactly I, U, T, L, B, O together with the structural rows H, C, P, N.

The update ledger is read locally. Each displayed successor cell in O is justified by the Rule 110 radius-one case stored in U, with T bounding the number of rows and L, B supplying the finite edge data needed for replay.

Transport and replay preserve that finite cone. The componentwise hsame rows compare only displayed rows, while C replays the same local-window route and P, N source and name it. Since no infinite configuration, full orbit, unbounded search, quotient orbit equality, or host universality coordinate is present, the listed rows exhaust the NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{RuleOneTenCausalCone}^{\uparrow}}$.

Constructive story: A $\mathsf{RuleOneTenCausalCone}^{\uparrow}$ packet is generated from an initial finite window, local Rule 110 update ledger, time-depth row, left and right boundary rows, observed cone trace, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RuleOneTenCausalCone}^{\uparrow}}$, seed)

Scope closed: Definition 5846.1 and Definition 5846.2 seed the finite Rule 110 causal-cone packet over local windows, update ledgers, boundary rows, observed traces, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RuleOneTenCausalCone}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Rule 110 universality, an ambient infinite cellular universe, a full orbit, unbounded glider search, quotient orbit equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite-window admission, local update exposure, time-depth bounding, boundary replay, trace exposure, transport, replay, provenance, and local naming for BEDC.Derived.RuleOneTenCausalConeUp.

Chapter 5847

A Concrete Naming Certificate for $\mathsf{BaireTreeModulus}^{\uparrow}$

Following Brouwer and Troelstra–van Dalen on bars, spreads, and choice sequences, the $\mathsf{BaireTreeModulus}^{\uparrow}$ packet records the finite-prefix tree/bar modulus that a continuity consumer may read before it reaches a Baire-space or real-facing handoff. It sits beside the Baire-space prefix-cylinder surface of chapter 334, the choice-sequence prefix rows of chapter 1482, the spread-law admission route of chapter 1532, and the finite-modulus boundary of chapter 3465. The packet is a finite NameCert carrier for tree admission, bar coverage, modulus extraction, and handoff provenance; it is not a host Baire function, a selected infinite branch, a countable-choice principle, a quotient stream, or an ambient real-completeness theorem.

Definition 5847.1 (Baire tree/bar modulus carrier)**.** *A* $\mathsf{BaireTreeModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, S, Q, W, M, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite tree/bar admission row, recording the decidable finite-prefix tree, the bar classifier, and the displayed depth window.*
2. *S is the* $\mathsf{SpreadLaw}^{\uparrow}$ *row that admits the same prefixes and records extension compatibility for the tree.*
3. *Q is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *row carrying the displayed choice-sequence prefix answers that the modulus may inspect.*
4. *W is the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix-cylinder window, aligning the tree/bar prefixes with the stream-name schedule and unary answer rows.*
5. *M is the modulus row, extracting a finite prefix bound from B, S, Q, W for the downstream continuity read.*
6. *H records componentwise* hsame *transport for the tree/bar, spread, choice-sequence, Baire-window, modulus, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite route*

$$B, S, Q, W \longmapsto M.$$

8. *P is the* Pkg *provenance over* $\mathsf{BaireTreeModulus}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{BrouwerContinuityPrinciple}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireTreeModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, S, Q, W, M, H, C, P, N$. It has no coordinate for a completed host stream, a selected branch through the tree, countable choice, quotient stream equality, an external topology on Baire space, or real-completeness data.

Lean4 ✓ `BEDC.Derived.BaireTreeModulusUp.TasteGate.BaireTreeModulusTasteGate single carrier alignment`

Theorem 5847.2 (Baire tree/bar modulus NameCert obligations)**.** *For every accepted* $\mathsf{BaireTreeModulus}^{\uparrow}$ *carrier $T = (B, S, Q, W, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireTreeModulus}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *tree/bar admission through B, including the decidable finite-prefix tree, bar classifier, and displayed depth window;*
2. *spread and choice compatibility through S, Q, requiring every admitted prefix to be a* $\mathsf{SpreadLaw}^{\uparrow}$ *prefix and every inspected answer to be a displayed* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix row;*
3. *Baire prefix-cylinder alignment through W, tying the tree window to the* $\mathsf{BaireSpace}^{\uparrow}$ *stream schedule,* $\mathsf{Nat}^{\uparrow}$ *index rows, unary answers, and prefix-cylinder classifier;*
4. *finite modulus extraction through M, producing the bound used by the* $\mathsf{BrouwerContinuityPrinciple}^{\uparrow}$ *consumer without selecting a branch;*
5. *transport, replay, provenance, and local naming through H, C, P, N.*

No obligation is stored outside these rows, and no accepted packet exports a completed Baire function, a selected infinite branch, countable choice, quotient stream equality, external topology, or ambient real completeness.

Proof. Project the carrier of Definition 5847.1. The tuple displays exactly the tree/bar row, spread-law row, choice-sequence row, Baire prefix-window row, modulus row, transport, replay, provenance, and local naming data.

The tree and bar obligations are finite. Row B gives the decidable prefix tree, the bar classifier, and the displayed depth window, so the argument ranges over named finite prefixes rather than a selected infinite branch.

Rows S, Q, W supply the cross-chapter route. The spread-law row admits the same prefixes as legal tree extensions, the choice-sequence row supplies only displayed prefix answers, and the Baire-space row aligns those answers with the prefix-cylinder schedule of chapter 334.

The modulus row M is then read as a finite bound for the continuity consumer of chapter 3465. Since M is computed from B, S, Q, W, it cannot introduce a host stream, branch selector, quotient equality, topology, or completeness datum.

Finally, H, C, P, N transport, replay, source, and name the same finite route. These rows exhaust the local NameCert surface, so the listed five obligation rows are the whole accepted packet. □

Theorem 5847.3 (Baire tree/bar modulus continuity handoff)**.** *Every continuity read of an accepted* $\mathsf{BaireTreeModulus}^{\uparrow}$ *packet factors through*

$$B, S, Q, W, M, H, C, P, N.$$

Before any BrouwerContinuityPrinciple$^{\uparrow}$ *or real-facing handoff is available, the consumer must display the finite tree/bar row, the* SpreadLaw$^{\uparrow}$ *admission route, the* ChoiceSequence$^{\uparrow}$ *prefix answers, the* BaireSpace$^{\uparrow}$ *prefix-cylinder window, the extracted modulus row, and the structural provenance rows. The handoff cannot obtain quotient stream equality, a completed Baire function, a selected branch, countable choice, or ambient real completeness from the packet.*

Proof. Start with Definition 5847.2. It forces every accepted consumer to read B, S, Q, W before the modulus row M is available.

The sibling chapters determine the handoff route. The Baire-space surface of chapter 334 supplies the prefix-cylinder window, chapter 1482 supplies displayed choice-sequence answers, and chapter 1532 supplies legal prefix extension.

Once M is displayed, chapter 3465 may consume the finite modulus as its prefix bound. The structural rows H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming.

No excluded datum appears in T. Thus a continuity or real-facing read cannot bypass the tree/bar, spread, choice, Baire-window, modulus, and provenance rows. □

Closure status for NameCert$_{\text{BaireTreeModulus}\uparrow}$.

Constructive story: A BaireTreeModulus$^{\uparrow}$ packet is generated from finite tree/bar admission, SpreadLaw prefix admission, ChoiceSequence prefix answers, BaireSpace prefix-cylinder windows, finite modulus extraction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BaireTreeModulus}\uparrow}$, seed)

Scope closed: Definition 5847.1, Definition 5847.2, and Definition 5847.3 seed the finite-prefix tree/bar modulus route consumed by BaireSpace, ChoiceSequence, SpreadLaw, and BrouwerContinuityPrinciple rows.

Formal verification: FormalStatus(NameCert$_{\text{BaireTreeModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Brouwer continuity as a theorem, fan compactness, selected infinite branches, countable choice, quotient stream equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tree/bar admission, SpreadLaw compatibility, ChoiceSequence prefix inspection, BaireSpace prefix-cylinder alignment, modulus extraction, transport, replay, provenance, and local naming for BEDC.Derived.BaireTreeModulusUp.

Chapter 5848

Located Uniform Cauchy Principle NameCert Construction

Following Bishop and Bridges on regular Cauchy approximations and located apartness data, the $\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}$ packet records the finite BEDC surface of a uniform Cauchy budget that can be read from dyadic tolerance evidence. It consumes the dyadic tolerance ledger of chapter 291, the finite observation schedules of chapter 126, the rational regular-sequence route of chapter 301, and the terminal seal interface of chapter 38. The packet names only finite budgets, located comparison rows, stability transport, replay, provenance, and a local NameCert row; it does not claim Real completeness, open-cover compactness, quotient stream equality, or selected limits.

Definition 5848.1 (Located uniform Cauchy principle carrier)**.** *A* $\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, S, R, L, B, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, naming the finite dyadic radii and the scale-window comparisons used by the request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, naming the finite observation windows that ask for simultaneous tail control.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-sequence row, exposing the rational approximants and the finite tail-index data visible to the schedule.*
4. *L is the located-comparison row, listing the dyadic inequalities that decide whether two displayed rational approximants are already within the requested tolerance window.*
5. *B is the uniform-budget row, assigning to each displayed dyadic request a finite tail threshold shared by the named observation windows.*
6. *E is the exactness row, stating that every comparison consumed by B is witnessed by the rows D, S, R, L and by no ambient real-equality oracle.*
7. *H stores componentwise* hsame *transport for tolerance rows, schedules, rational sequence rows, located comparisons, uniform budgets, exactness, replay, provenance, and local naming.*

8. *C stores displayed* Cont *replay from a uniform Cauchy request through D, S, R, L, B, E and back to the same finite request surface.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}}$ *row.*

The carrier has no coordinate for Real completeness, open-cover compactness, quotient stream equality, selected limits, countable choice, or host real equality.

Lean4 ✓ `BEDC.Derived.LocatedUniformCauchyPrincipleUp.LocatedUniformCauchyPrincipleTasteGate`
`single carrier alignment`

Theorem 5848.2 (Located uniform Cauchy obligation surface)**.** *For every accepted* LocatedUniformCauchyPrinciple *carrier*

$$U = (D, S, R, L, B, E, H, C, P, N),$$

the public obligation surface consists exactly of dyadic tolerance admission through D, finite observation scheduling through S, rational regular-sequence exposure through R, located comparison exposure through L, uniform tail-budget assignment through B, exactness through E, componentwise hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5848.1. The finite source rows are exactly the dyadic tolerance row D, the schedule row S, the regular-sequence row R, the located-comparison row L, and the budget and exactness rows B, E.

The uniform budget is read from finite dyadic and rational data. Each threshold in B is indexed by a displayed tolerance request from D and a displayed observation window from S, while L records the comparison evidence that the rational approximants exposed by R fit the same request.

The exactness row E prevents the budget from using a hidden Real-completeness or quotient-stream coordinate. The remaining rows H, C, P, N transport, replay, source, and name only this finite route, so the listed rows exhaust the public obligation surface. □

Theorem 5848.3 (Located uniform Cauchy NameCert)**.** *Every accepted* $\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}$ *carrier*

$$U = (D, S, R, L, B, E, H, C, P, N)$$

presents a local $\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}}$ *whose dependency boundary is confined to* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the finite* $\mathsf{Real}^{\uparrow}$ *terminal seal interface named in P.*

Proof. Use Definition 5848.2. The rows D, S, R, L, B, E provide the complete finite budget route, and H, C, P, N provide stability, replay, provenance, and naming for that route.

Since P names $\mathsf{Real}^{\uparrow}$ only as a terminal seal interface and the carrier contains no field for selected limits, quotient stream equality, open-cover compactness, countable choice, or Real completeness, any consumer of N can recover only the finite located uniform Cauchy certificate described by the displayed rows. □

Falsifiable prediction: A $\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}$ consumer that exports a uniform Cauchy budget without exposing dyadic tolerance data, stream observation schedules, regular-sequence rational rows, located comparison rows, componentwise hsame, displayed Cont, Pkg, and local NameCert rows refutes the carrier of Definition 5848.1.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic tolerance requests, finite observation schedules, rational regular-sequence rows, located comparison evidence, shared tail budgets, exactness, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}$ packet is generated from finite dyadic tolerance requests, stream observation schedules, rational regular-sequence rows, located comparison evidence, shared tail budgets, exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5848.1, Definition 5848.2, and Definition 5848.3 seed the finite located uniform Cauchy packet over dyadic, stream-name, regular-sequence, and Real terminal-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, open-cover compactness, quotient stream equality, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic tolerance admission, finite schedule admission, regular-sequence exposure, located comparison exposure, shared budget exactness, transport, replay, provenance, and local naming for BEDC.Derived.LocatedUniformCauchyPrincipleUp.

Chapter 5849

A Concrete Naming Certificate for $\mathsf{BaireSpaceCompactOpen}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{BaireSpaceCompactOpen}^{\uparrow}$ packet records the compact-open reading of Baire-space maps as finite BEDC NameCert data. It sits after the Baire prefix carrier of chapter 334, the compact-open topology surface of chapter 4138, the continuous-map graph rows of chapter 130, and the L10 real-name route through chapter 126, chapter 301, and chapter 38. The packet names only finite prefix cylinders, compact-window tests, graph readbacks, regular rational handoffs, and real seals; it does not import a host function space.

Definition 5849.1 (Baire-space compact-open carrier)**.** *A* $\mathsf{BaireSpaceCompactOpen}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, O, F, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix-cylinder row, exposing only finite natural-index windows.*
2. *O is the* $\mathsf{CompactOpenTopology}^{\uparrow}$ *subbasic-window row, recording the compact-open request as a finite list of prefix-cylinder probes and target-radius budgets.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row whose source inspections all pass through B and whose target inspections pass through the L10 real-name route.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule used by the compact-open request and by every target readback.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational handoff row attached to the finite target windows in W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed target values.*
7. *H records componentwise* hsame *transport for $B, O, F, W, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from compact-open requests through prefix windows, graph inspection, regular readback, and the real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{BaireSpaceCompactOpen}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{CompactOpenTopology}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireSpaceCompactOpen}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, O, F, W, R, E, H, C, P, N$. It has no coordinate for host function equality, quotient streams, arbitrary open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BaireSpaceCompactOpenUp.BaireSpaceCompactOpenTasteGate single carrier alignment`

Theorem 5849.2 (Baire-space compact-open NameCert obligations)**.** *For every accepted* $\mathsf{BaireSpaceCompactOpen}$ *carrier $K = (B, O, F, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireSpaceCompactOpen}^{\uparrow}}$ *surface consists exactly of carrier admission for the Baire prefix row, compact-open subbasic-window row, continuous-map graph row, StreamName observation schedule, RegSeqRat target readback, Real seal, componentwise transport, displayed continuation replay, provenance, and local naming. Every compact-open read must inspect the prefix row B and the subbasic-window row O before it may consume F, W, R, E.*

Proof. Project the carrier of Definition 5849.1. The rows B and O display the source prefix and compact-open request before any graph or target row is available.

The continuous-map row F is therefore read only after the compact-open window has been fixed. Its target observations pass through the same W, R, E route used by StreamName, RegSeqRat, and Real consumers.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since the carrier contains no coordinate for host function equality, quotient streams, open-cover compactness, countable choice, or ambient completeness, the listed rows exhaust the local obligation surface. □

Theorem 5849.3 (Baire-space compact-open prefix handoff)**.** *Every compact-open consumer of an accepted* $\mathsf{BaireSpaceCompactOpen}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{BaireSpace}^{\uparrow} \longrightarrow \mathsf{CompactOpenTopology}^{\uparrow} \longrightarrow \mathsf{ContinuousMap}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The handoff exports only displayed prefix cylinders, compact-open subbasic windows, graph rows, finite target observations, regular readbacks, and real seals.

Proof. Begin with the NameCert obligations of Definition 5849.2. They force the Baire prefix row and compact-open subbasic window to be present before any graph read is replayed.

Use the Baire prefix discipline of chapter 334. It supplies finite source cylinders rather than an infinite host sequence. The compact-open row then consumes those cylinders through the topology surface of chapter 4138.

The target side is the existing L10 route: StreamName windows feed RegSeqRat readbacks, and the Real row seals the displayed target value. Thus the public handoff is exactly the stated finite route. □

Theorem 5849.4 (Baire-space compact-open nonescape)**.** *An accepted* $\mathsf{BaireSpaceCompactOpen}^{\uparrow}$ *packet exports no compact-open or function-space read outside $B, O, F, W, R, E, H, C, P, N$. In particular, it cannot export host function equality, quotient streams, open-cover compactness, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or a completed space of all Baire-to-real functions.*

Proof. Project the carrier of Definition 5849.1. The only analytic rows are the prefix row, compact-open request row, continuous-map graph row, finite observation schedule, regular readback, and real seal.

Apply the prefix handoff of Definition 5849.3. Every downstream read is routed through the same displayed rows before the structural rows H, C, P, N can replay or name it.

The excluded objects require coordinates that are absent from the carrier. Since transport and replay preserve only displayed rows, the packet cannot leave the finite compact-open route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireSpaceCompactOpen}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireSpaceCompactOpen}^{\uparrow}$ packet is generated from BaireSpace prefix rows, compact-open subbasic-window rows, continuous-map graph rows, StreamName observations, RegSeqRat readbacks, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireSpaceCompactOpen}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5849.1, Definition 5849.2, Definition 5849.3, and Definition 5849.4 seed the finite compact-open route for Baire-space maps.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireSpaceCompactOpen}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host function equality, quotient streams, arbitrary open-cover compactness, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-open window exposure, prefix handoff exactness, graph replay, Real seal nonescape, and local naming for BEDC.Derived.BaireSpaceCompactOpenUp.

Chapter 5850

A Concrete Naming Certificate for $\mathsf{CompactApartnessProfile}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactApartnessProfile}^{\uparrow}$ packet records the finite compact-metric apartness profile used when total-bounded finite nets, completion service rows, and apartness-topology separation rows must be read together without importing open-cover compactness. It sits between the compact metric source of chapter 129, the total-boundedness surface of chapter 127, the complete-metric boundary of chapter 128, and the apartness topology route of chapter 1663. The packet exposes a finite profile for compact-metric consumers: named net centers, mesh bounds, completion handoff, apartness separation, transport, replay, provenance, and local naming, not an arbitrary open-cover compactness theorem.

Definition 5850.1 (Compact apartness profile carrier)**.** *A* $\mathsf{CompactApartnessProfile}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, T, C, S, F, R, H, E, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric, finite compactness request, and compact-metric provenance visible to downstream consumers.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row, naming the displayed centers, mesh tolerance, and finite coverage ledger.*
3. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row, available only as the completion-facing handoff attached to accepted Cauchy-style reads.*
4. *S is the* $\mathsf{ApartnessTopology}^{\uparrow}$ *separation row, recording the apartness neighbourhood and located separation data used by profile consumers.*
5. *F is the finite handoff row tying T to S: each requested mesh cell carries the apartness-visible boundary data that the consumer may inspect.*
6. *R is the completion handoff row tying T and C: finite net reads may request a completion service only through the displayed compact-metric and complete-metric rows.*
7. *H records componentwise* hsame *transport for compact-metric, total-bounded, complete-metric, apartness, handoff, provenance, and local naming rows.*
8. *E records displayed* Cont *replay from a profile request through the finite-net, apartness, and completion handoff rows.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactApartnessProfile}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ApartnessTopology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactApartnessProfile}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, T, C, S, F, R, H, E, P, N$. It has no coordinate for arbitrary open covers, selected subcovers, quotient completion equality, an apartness-free compactness principle, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CompactApartnessProfileUp.CompactApartnessProfileTasteGate single carrier alignment`

Theorem 5850.2 (Compact apartness profile NameCert obligations)**.** *For every accepted* $\mathsf{CompactApartnessProfile}^{\uparrow}$ *carrier*

$$A = (K, T, C, S, F, R, H, E, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactApartnessProfile}^{\uparrow}}$ *surface consists exactly of finite obligation rows for compact-metric source exposure, total-bounded finite-net exposure, complete-metric service exposure, apartness-topology separation exposure, finite-net apartness handoff, finite-net completion handoff, componentwise transport, displayed replay, provenance, and local naming. No obligation row may be discharged by arbitrary open-cover compactness, a selected subcover, quotient completion equality, apartness-free compactness, or ambient real completeness.*

Proof. Project the carrier of Definition 5850.1. The tuple displays the compact-metric source, total-bounded finite-net row, complete-metric service row, apartness-topology separation row, the two handoff rows, transport, replay, provenance, and local naming.

The finite-net obligations are exhausted by T, F, R. The row T supplies centers and mesh bounds, while F and R state exactly how those finite reads are handed to apartness and completion consumers.

The nonescape clauses follow by coordinate inspection. Since no row names an arbitrary cover, a selected subcover, quotient completion equality, apartness-free compactness, or ambient real-completeness theorem, the local NameCert surface cannot export such data. □

Theorem 5850.3 (Compact apartness profile finite-net apartness handoff)**.** *Every accepted* $\mathsf{CompactApartnessProfile}^{\uparrow}$ *packet sends a finite-net read to an apartness-topology consumer only through*

$$K, \quad T, \quad S, \quad F, \quad H, \quad E, \quad P, \quad N.$$

The same packet sends any completion-facing read only through K, T, C, R, H, E, P, N. Thus the profile connects total-boundedness, completion service, and apartness separation by displayed finite rows, without exporting an open-cover compactness principle or an apartness-free completion theorem.

Proof. Start with a finite-net request. The compact-metric source K names the metric side, and the total-bounded row T supplies the finite centers and mesh tolerance inspected by the consumer.

For apartness-facing reads, the only separation coordinate is S, and the only finite-net-to-apartness connector is F. Transport and replay must therefore pass through H, E, P, N after those rows have been selected.

For completion-facing reads, the only service coordinate is C, and the finite-net-to-completion connector is R. Coordinate exhaustion separates this route from the apartness handoff and leaves no coordinate for arbitrary open covers, selected subcovers, apartness-free compactness, quotient completion equality, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactApartnessProfile}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactApartnessProfile}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5850.1, Definition 5850.2, and Definition 5850.3 seed the finite profile connecting compact-metric, total-bounded, complete-metric, and apartness-topology rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactApartnessProfile}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcover existence, quotient completion equality, apartness-free compactness, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exposure, apartness handoff, completion handoff, transport replay, provenance, and nonescape for BEDC.Derived.CompactApartnessProfileUp.

Constructive story: A $\mathsf{CompactApartnessProfile}^{\uparrow}$ packet is generated from compact-metric source data, total-bounded finite-net data, complete-metric service data, apartness-topology separation data, two handoff rows, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Chapter 5851

A Concrete Naming Certificate for RiemannIntegralCauchy$^{\uparrow}$

Following Riemann and Bishop–Bridges constructive integration, the RiemannIntegralCauchy$^{\uparrow}$ packet records the finite Cauchy convergence route by which tagged-gauge sums, Darboux upper/lower gaps, integrability evidence, regular rational readback, and a terminal real seal are named as one integration-facing certificate. It sits after the tagged-gauge surface of chapter 4115, the Darboux finite-sum boundary of chapter 1880, the gap witness of chapter 1960, the regular rational sequence row of chapter 301, and the real-name seal of chapter 38. The packet names a finite Cauchy convergence certificate for later integral-value consumers; it does not import host limits, quotient equality, choice, measure completion, or ambient Real$^{\uparrow}$ completeness.

Definition 5851.1 (Riemann integral Cauchy carrier)**.** *A* RiemannIntegralCauchy$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, D, I, R, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the* RiemannSumGauge$^{\uparrow}$ *row naming the tagged finite partitions, gauge-radius requests, mesh comparisons, and finite Riemann-sum reads.*
2. *D is the* DarbouxSum$^{\uparrow}$ *row naming the lower and upper finite Darboux sums, their shared partition interface, and their upper-minus-lower gap comparison.*
3. *I is the* RiemannIntegrable$^{\uparrow}$ *gap witness row, recording that the displayed Darboux gap answers the carried tolerance request before an integral value is read.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the same tagged-gauge and Darboux-gap route, with no detached sequence coordinate.*
5. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after G, D, I, R have been displayed.*
6. *H records componentwise* hsame *transport for tagged-gauge rows, Darboux rows, integrability rows, regular readback rows, real-seal rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from gauge requests to finite sums, from finite sums to Darboux gaps, from gaps to regular rational readback, and from readback to the terminal real seal.*
8. *P is the* Pkg *provenance over* RiemannIntegralCauchy$^{\uparrow}$, RiemannSumGauge$^{\uparrow}$, DarbouxSum$^{\uparrow}$, RiemannIntegrable$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RiemannIntegralCauchy}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $G, D, I, R, E, H, C, P, N$. It has no coordinate for a host limit, quotient equality of functions, a choice-selected partition family, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RiemannIntegralCauchyUp.RiemannIntegralCauchyTasteGate single carrier alignment`

Theorem 5851.2 (Riemann integral Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{RiemannIntegralCauchy}^{\uparrow}$ *carrier $K = (G, D, I, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegralCauchy}^{\uparrow}}$ *surface consists exactly of carrier admission, tagged-gauge admission, Darboux upper/lower gap admission, Riemann-integrability gap witnessing,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise transport, displayed replay, provenance, local naming, and non-escape from host limits, quotient equality, choice, measure completion, and ambient real completeness.*

Proof. Carrier admission is projection from Definition 5851.1. The accepted packet displays exactly the tagged-gauge row G, Darboux-sum row D, integrability witness I, regular readback R, real seal E, transports H, replay rows C, provenance P, and local name N.

The Cauchy evidence is finite. The row G supplies tagged-gauge sums, the row D supplies the upper and lower Darboux sums, and the row I records the finite gap witness before any readback or real-facing value appears.

The readback and seal rows are downstream. The row R reads the same finite route as regular rational convergence data, and E seals only that displayed readback. Transport, replay, provenance, and naming preserve the same coordinates, so the listed rows exhaust the local certificate surface. □

Theorem 5851.3 (Riemann integral Cauchy Darboux handoff)**.** *Every accepted* $\mathsf{RiemannIntegralCauchy}^{\uparrow}$ *packet hands a Cauchy integral value to* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *only through the finite route*

$$\mathsf{RiemannSumGauge}^{\uparrow} \longmapsto \mathsf{DarbouxSum}^{\uparrow} \longmapsto \mathsf{RiemannIntegrable}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The Darboux handoff uses the same tagged-gauge row cited by chapter 4115 and the same upper/lower gap row cited by chapter 1880; it cannot be replaced by a detached host limit, quotient equality of functions, selected partitions, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier of Definition 5851.1. The tagged-gauge row G must be read before the Darboux row D, and D must be read before the integrability gap witness I.

The row I is the only bridge from Darboux gap evidence to a Cauchy readback. Once I is displayed, R repacks the same data as a $\mathsf{RegSeqRat}^{\uparrow}$ row, and E seals that readback as the real-facing value.

The structural rows H, C, P, N transport, replay, source, and name this same route. Since the carrier contains no host limit, quotient equality, selected partition family, measure-completion row, or ambient completeness coordinate, every Cauchy integral handoff factors through the displayed Darboux route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannIntegralCauchy}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannIntegralCauchy}^{\uparrow}$ packet is generated from a RiemannSumGaugeUp tagged-gauge row, DarbouxSumUp upper/lower gap row, RiemannIntegrableUp gap witness, RegSeqRatUp readback, RealUp terminal seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RiemannIntegralCauchy}^{\uparrow}}$, seed)

Scope closed: Definition 5851.1, Definition 5851.2, and Definition 5851.3 seed the finite Cauchy integration route over tagged-gauge, Darboux-gap, integrability, regular-rational, and real-seal rows.

Formal verification: FormalStatus(NameCert$_{\text{RiemannIntegralCauchy}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host limits, quotient equality of functions, selected partition families, measure completion, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tagged-gauge admission, Darboux-gap admission, integrability gap witnessing, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RiemannIntegralCauchyUp.

The inactive cubical-support route is read through the codon-window and DNA boundary-trigger sibling lattice of chapter 2234, chapter 3393, chapter 3470, and chapter 3508.

Chapter 5852

A Concrete Naming Certificate for InactiveAnchorCubicalSupport$^{\uparrow}$

The InactiveAnchorCubicalSupport$^{\uparrow}$ packet realizes the inactive-anchor closure and cubical-support complex of Definition 9462.1307 and Definition 9462.1308 as finite BEDC NameCert data. It consumes the six-coordinate codon source of chapter 2234, the DNA boundary-tile classifier of chapter 3393, the six-boundary coverage route of chapter 3470, and the boundary-trigger closure packet of chapter 3508. The cubical support row K is meaningful only after the codon six-bit window and DNA boundary-tile classifier have both been displayed. The packet records inactive anchors, cubical support cells, the displayed f-vector, and the no-3-cell row as finite data; it is not a biological mechanism, stochastic fitness model, quotient codon semantics, or hidden cubical-homology oracle.

Definition 5852.1 (Inactive-anchor cubical support carrier)**.** *An* InactiveAnchorCubicalSupport$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, T, A, K, F, H, C, P, N)$$

with the following displayed rows:

1. *W is the* CodonSixBitWindow$^{\uparrow}$ *source-window row exposing the six bit coordinates used to read support vertices.*
2. *T is the* DnaWindowSixBoundaryTile$^{\uparrow}$ *boundary-tile row exposing the stop/Trp and Ile/Met boundary classifiers consumed by the support window.*
3. *A records the inactive-anchor row, including* UGG*,* AAG*, and* ACA *as displayed inactive boundary vertices rather than as a hidden biological table.*
4. *K records the cubical support complex row, whose cells are exactly the displayed axis-aligned subcubes whose vertices lie in the carried active support.*
5. *F records the displayed active-support f-vector row and no-3-cell row from Definition 9462.1309.*
6. *H records componentwise* hsame *transport for source windows, boundary tiles, inactive anchors, cubical cells, f-vector rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from source windows to boundary tiles, from boundary tiles to inactive-anchor rows, from anchor rows to cubical cells, and from cells to the displayed f-vector and no-3-cell row.*

8. *P is the* Pkg *provenance over* $\mathsf{InactiveAnchorCubicalSupport}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$ $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{InactiveAnchorCubicalSupport}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, T, A, K, F, H, C, P, N$. It has no coordinate for an empirical code table, stochastic evolutionary law, quotient codon semantics, unrestricted cell enumeration, or host homology computation.

Theorem 5852.2 (Inactive-anchor cubical support NameCert obligations)**.** *For every accepted* $\mathsf{InactiveAnchorCubicalSupport}^{\uparrow}$ *carrier $S = (W, T, A, K, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{InactiveAnchorCubicalSupport}^{\uparrow}}$ *surface consists exactly of source-window admission, boundary-tile admission, inactive-anchor admission, cubical-support cell admission, displayed f-vector and no-3-cell admission, componentwise transport, displayed replay, provenance, local naming, and non-escape from empirical code tables, stochastic dynamics, quotient codon equality, unrestricted enumeration, and host homology oracles.*

Proof. Project the carrier in Definition 5852.1. The rows $W, T, A, K, F, H, C, P, N$ are the only rows available to an accepted packet.

The source and boundary rows are read first. The $\mathsf{CodonSixBitWindow}^{\uparrow}$ row exposes the six-coordinate source window, and the $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$ row exposes the boundary-tile classifier before any inactive anchor or cubical cell can be consumed.

The finite cubical rows are downstream. The anchor row A displays the inactive vertices, K displays the cells supported by the carried vertices, and F records the active-support f-vector and no-3-cell boundary. Transport, replay, provenance, and local naming preserve that same finite route, so no excluded host object can be exported. □

Theorem 5852.3 (Inactive-anchor cubical support nonescape)**.** *Every accepted* $\mathsf{InactiveAnchorCubicalSupport}^{\uparrow}$ *read factors through*

$$\mathsf{CodonSixBitWindow}^{\uparrow},\ \mathsf{DnaWindowSixBoundaryTile}^{\uparrow} \longmapsto A \longmapsto K \longmapsto F \longmapsto H, C, P, N.$$

The read preserves the displayed active-support f-vector and no-3-cell row, and it cannot escape to an empirical code table, stochastic dynamics, quotient codon semantics, unrestricted cubical enumeration, or host homology oracle.

Proof. Start with the NameCert obligations. They force source-window and boundary-tile admission before any inactive-anchor or cubical-support read.

The anchor and cubical rows then determine the support data. The row A supplies the inactive anchors, K supplies the finite cubical support complex, and F records the displayed f-vector and no-3-cell row.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since none of the excluded host structures is a carrier coordinate, every accepted read remains inside the displayed route. □

Falsifiable prediction: Any accepted $\mathsf{InactiveAnchorCubicalSupport}^{\uparrow}$ packet that changes the displayed active-support f-vector or admits a 3-cell while preserving $W, T, A, K, F, H, C, P, N$ refutes the carrier of Definition 5852.1.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, six-boundary-tile-coverage, dna-boundary-trigger-closure: $\mathsf{InactiveAnchorCubicalSupport}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries inactive-anchor rows, cubical-support cell rows, displayed f-vector data, no-3-cell refusal, transport, replay, provenance, and local naming.

The Lean follow-up `BEDC.Derived.InactiveAnchorCubicalSupportUp` must provide explicit Nontrivial InactiveAnchorCubicalSupport$^{\uparrow}$ and FieldFaithful InactiveAnchorCubicalSupport$^{\uparrow}$ instances preserving $W, T, A, K, F, H, C, P, N$ as separate displayed fields.

Closure status for NameCert$_{\text{InactiveAnchorCubicalSupport}^{\uparrow}}$.

Constructive story: An InactiveAnchorCubicalSupport$^{\uparrow}$ packet is generated from CodonSixBitWindowUp source windows, DnaWindowSixBoundaryTileUp boundary tiles, inactive-anchor rows, cubical-support cells, displayed f-vector and no-3-cell rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{InactiveAnchorCubicalSupport}^{\uparrow}}$, seed)

Scope closed: Definition 5852.1, Definition 5852.2, and Definition 5852.3 seed the finite inactive-anchor cubical support route over codon-window, boundary-tile, anchor, cubical-cell, and f-vector rows.

Formal verification: FormalStatus(NameCert$_{\text{InactiveAnchorCubicalSupport}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close empirical code tables, stochastic evolutionary dynamics, quotient codon semantics, unrestricted cubical enumeration, host homology computation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window admission, boundary-tile admission, inactive-anchor admission, cubical-support cell admission, f-vector preservation, no-3-cell nonescape, Nontrivial InactiveAnchorCubicalSupportUp, and FieldFaithful InactiveAnchorCubicalSupportUp for BEDC.Derived.InactiveAnchorCubicalSupportUp.

Chapter 5853

A Concrete Naming Certificate for $\mathsf{BoundedRegulatedFunction}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BoundedRegulatedFunction}^{\uparrow}$ packet records a regulated function together with a displayed uniform dyadic envelope, so boundedness-facing consumers receive finite step data rather than a host supremum or selected limit. It sits over the regulated-function schedule of chapter 1906, the dyadic step-function carrier of chapter 428, the terminal real-name seal of chapter 38, and the dyadic mesh ledger of chapter 358. The packet is an integration-facing and variation-facing certificate: it exposes a bounded route through displayed approximants and does not import host function equality, selected limits, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5853.1 (Bounded regulated function carrier)**.** *A* $\mathsf{BoundedRegulatedFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, B, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the accepted* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row, carrying the domain, mesh, step schedule, tolerance-tail ledger, and finite-sum handoff of Definition 1906.1.*
2. *B is the displayed uniform dyadic envelope row. It records a finite dyadic bound and the mesh-indexed scope on which the bound is offered to downstream consumers.*
3. *E records that every visible* $\mathsf{DyadicStepFunction}^{\uparrow}$ *approximant in the regulated schedule lies inside the envelope displayed by B.*
4. *H records componentwise* hsame *transport for the regulated source, envelope, approximant-enclosure, replay, provenance, and local naming rows.*
5. *C records displayed* Cont *replay from a boundedness request through F, B, E, H, P, N.*
6. *P is the* Pkg *provenance over* $\mathsf{BoundedRegulatedFunction}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
7. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedRegulatedFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through F, B, E, H, C, P, N. It has no coordinate for host function equality, a selected pointwise representative, an ambient supremum, measure completion, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ BEDC.Derived.BoundedRegulatedFunctionUp.TasteGate.BoundedRegulatedFunctionTasteGate
single carrier alignment

Theorem 5853.2 (Bounded regulated function NameCert obligations)**.** *For every accepted* $\mathsf{BoundedRegulatedFunct}$ *carrier* $G = (F, B, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedRegulatedFunction}^{\uparrow}}$ *surface consists exactly of carrier admission, regulated-source admission, uniform dyadic envelope admission, visible step-approximant enclosure, componentwise transport, displayed continuation replay, provenance, local naming, and non-escape from host function equality, selected representatives, ambient suprema, measure completion, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5853.1. The accepted packet displays only the regulated source row F, the uniform dyadic envelope B, the approximant-enclosure row E, transports H, continuations C, provenance P, and local name N.

The regulated source is already finite. By Definition 1906.1, the row F opens through the real-domain row, dyadic mesh ledger, dyadic step-function schedule, tolerance-tail ledger, and finite-sum handoff before any integration-facing consumer can inspect it.

The boundedness data are displayed in B and E. The row B names the dyadic envelope, while E attaches each visible step approximant from the schedule in F to that same envelope. Rows H, C, P, N preserve and name this finite route, so the excluded host structures never become local obligations. □

Theorem 5853.3 (Bounded regulated function uniform bound route)**.** *Every boundedness-facing read exported by an accepted* $\mathsf{BoundedRegulatedFunction}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{RegulatedFunction}^{\uparrow} \longmapsto \mathsf{DyadicStepFunction}^{\uparrow} \longmapsto B, E.$$

Thus an integral, bounded-variation, or completion consumer may request the finite dyadic envelope only after the regulated source row, mesh-indexed step approximants, and approximant-enclosure row have been displayed.

Proof. Start with a boundedness-facing request. The continuation row C first replays the regulated source F, so the request reaches the dyadic mesh ledger and step-function schedule through the route fixed in Definition 1906.3.

Next read the envelope row. The row B supplies only a displayed dyadic bound, and the row E records that the visible step approximants supplied by F lie inside that envelope. No separate pointwise function or selected representative is introduced.

Finally use the structural rows. Componentwise transport, replay, provenance, and local naming preserve the same route through F, B, E, H, C, P, N. Since the carrier has no coordinate for an ambient supremum, measure completion, host function equality, selected limit, or $\mathsf{Real}^{\uparrow}$ completeness, the uniform bound route is exhausted by the displayed rows. □

Theorem 5853.4 (Bounded regulated function obligation closure)**.** *For every accepted* $\mathsf{BoundedRegulatedFunction}^{\uparrow}$ *carrier* $G = (F, B, E, H, C, P, N)$*, the carrier block of Definition 5853.1, the NameCert surface of Definition 5853.2, and the uniform-bound route of Definition 5853.3 jointly close carrier admission, regulated-source admission, dyadic-envelope admission, visible step-approximant enclosure, componentwise transport, displayed replay, provenance, local naming, and ledger refusal for the bounded regulated-function packet. The closure is over the displayed* $\mathsf{RegulatedFunction}^{\uparrow}$ *source route and does not add host function equality, selected representatives, ambient suprema, measure completion, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project $G = (F, B, E, H, C, P, N)$ from the carrier definition. The row F is the only regulated-source coordinate, B is the only dyadic-envelope coordinate, and E is the only visible step-approximant enclosure coordinate.

Apply Definition 5853.2 to identify carrier admission, regulated-source admission, dyadic-envelope admission, approximant enclosure, transport, replay, provenance, naming, and the ledger refusals as the whole local NameCert surface.

Apply Definition 5853.3. That route forces every boundedness-facing read through the displayed $\mathsf{RegulatedFunction}^{\uparrow}$ source row and the finite B, E envelope data before any consumer can use the packet.

The carrier has no further coordinate beyond F, B, E, H, C, P, N. Thus the listed obligations are closed by the three local blocks together with the sibling $\mathsf{RegulatedFunction}^{\uparrow}$ source boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRegulatedFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedRegulatedFunction}^{\uparrow}$ packet is generated from a RegulatedFunction source row, a displayed uniform dyadic envelope, a visible step-approximant enclosure row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRegulatedFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5853.1, Definition 5853.2, and Definition 5853.3 seed the bounded regulated-function route over regulated sources, dyadic step approximants, displayed envelopes, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRegulatedFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, selected representatives, ambient suprema, measure completion, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Lean verification requires carrier admission, regulated-source admission, dyadic-envelope admission, step-approximant enclosure, transport, replay, provenance, and local naming for BEDC.Derived.BoundedRegulatedFunctionUp.

Chapter 5854

A Concrete Naming Certificate for CompactnessSequentialEquivalence$^{\uparrow}$

Following Bishop and Bridges constructive compactness practice, the CompactnessSequentialEquivalence$^{\uparrow}$ packet records the finite BEDC surface on which finite-cover compactness and sequential compactness can be compared without importing an ambient equivalence theorem. It sits between the bounded-subsequence route of chapter 1254, the finite-cover finite-net route of chapter 3471, the compact-metric source of chapter 129, the stream inspection surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite NameCert comparison surface for compact metric consumers; it is not a host proof that all compactness notions coincide, not countable choice, not quotient stream equality, and not ambient real completeness.

Definition 5854.1 (Compactness sequential equivalence carrier)**.** *A* CompactnessSequentialEquivalence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, B, S, W, R, D, Q, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row whose metric, total-boundedness, and completeness-facing reads bound both sides of the comparison.*
2. *F is the finite-cover row read through* HeineBorelFiniteNet$^{\uparrow}$*, including the displayed finite net, cover request, and finite subcover ledger.*
3. *B is the bounded-subsequence row read through* BolzanoWeierstrass$^{\uparrow}$*, including the interval-net and selected regular-subsequence route.*
4. *S is the* StreamName$^{\uparrow}$ *window row naming the finite source indices inspected by the sequence side.*
5. *W is the finite subsequence-window row, recording selected indices, selected windows, and monotonicity evidence.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the selected windows and their regular rational tail budgets.*
7. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row, recording net mesh, cover-radius comparison, and rational slack checks used by both directions.*

8. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular rational readback and cover-radius comparisons are accepted.*
9. *H records componentwise* hsame *transports for K, F, B, S, W, R, D, Q.*
10. *C records displayed* Cont *replays from compact-metric reads to finite covers, finite nets, stream windows, subsequence windows, dyadic tolerance checks, regular rational readbacks, and the terminal real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactnessSequentialEquivalence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactnessSequentialEquivalence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, B, S, W, R, D, Q, H, C, P, N$. It has no coordinate for a global open-cover compactness theorem, an unrestricted sequential compactness principle, countable choice, quotient equality of streams, a selected host subsequence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactnessSequentialEquivalenceUp.TasteGate.CompactnessSequentialEquivalenceTaste`
`single carrier alignment`

Theorem 5854.2 (Compactness sequential equivalence NameCert obligations)**.** *For every accepted* $\mathsf{CompactnessSequentialEquivalence}^{\uparrow}$ *carrier*

$$E = (K, F, B, S, W, R, D, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactnessSequentialEquivalence}^{\uparrow}}$ *surface consists exactly of finite rows for compact-metric source exposure, finite-cover finite-net exposure, bounded-subsequence exposure, stream-window inspection, subsequence-window monotonicity, regular rational readback, dyadic tolerance comparison, Real seal nonescape, componentwise transport, continuation replay, provenance, and local naming. No obligation row may be discharged by a host compactness-equivalence theorem, countable choice, quotient stream equality, an externally selected subsequence, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.CompactnessSequentialEquivalenceUp.CompactnessSequentialEquivalenceCarrier`
`namecert obligations`

Proof. Project the carrier of Definition 5854.1. Its rows expose exactly the compact-metric source, finite-cover finite-net route, bounded-subsequence route, stream windows, subsequence windows, regular rational readback, dyadic tolerance checks, Real seal, transport, continuation, provenance, and local naming data.

The cover side is finite because F records only the displayed net and the finite subcover ledger from chapter 3471. The sequence side is finite because B, S, and W record only the bounded-subsequence route, inspected stream windows, and selected finite windows.

The comparison between the two sides passes through D and Q. These rows record tolerance and seal data already visible to the packet, so the local NameCert surface has no remaining coordinate in which a host compactness-equivalence theorem, countable choice, quotient stream equality, external subsequence, or ambient Real completeness could enter. □

Theorem 5854.3 (Finite subcover data yields a subsequence-window route)**.** *Let*

$$E = (K, F, B, S, W, R, D, Q, H, C, P, N)$$

be an accepted CompactnessSequentialEquivalence$^{\uparrow}$ *carrier. If a downstream compact-metric consumer reads the finite subcover side through F, then the same packet exposes a subsequence-window route through*

$$K, \quad F, \quad S, \quad W, \quad R, \quad D, \quad Q$$

without adding a host subsequence selector, quotient stream equality, countable choice, or ambient Real completeness row.

Proof. Begin with the finite-cover row F. It supplies only a finite net, finite cover request, and finite subcover ledger over the compact-metric source K.

Use the stream window S to record the finite source positions inspected by the consumer. The row W then records the selected finite windows and their monotonicity evidence; it is packet data, not a choice functional supplied from outside the carrier.

Finally apply R, D, and Q. The regular rational readback consumes the selected windows, the dyadic row records the cover-radius and tolerance comparisons, and the Real row seals only those accepted finite reads. Therefore the route remains inside the displayed packet and exports none of the excluded host principles. □

Theorem 5854.4 (Subsequence-window data yields a finite-net cover route)**.** *Let*

$$E = (K, F, B, S, W, R, D, Q, H, C, P, N)$$

be an accepted CompactnessSequentialEquivalence$^{\uparrow}$ *carrier. If a downstream compact-metric consumer reads the sequential side through B, S, W, R, then the same packet exposes a finite-net cover route through*

$$K, \quad B, \quad S, \quad W, \quad R, \quad D, \quad F, \quad Q$$

without adding a global open-cover compactness theorem, an unrestricted sequential compactness principle, quotient stream equality, countable choice, or ambient Real completeness row.

Proof. Read the sequential rows first. The bounded-subsequence row B, stream row S, subsequence-window row W, and regular rational row R expose only finite windows and regular readback data.

The dyadic row D transports that finite readback into the tolerance scale used by the finite-net cover ledger. It records mesh, radius, and slack comparisons; it does not create a second compactness principle.

The finite-net route is then the already carried row F, sealed by Q over the same compact-metric source K. Since all rows are components of the same accepted carrier and are replayed by H and C, the consumer obtains a finite-net cover route without any appeal to the excluded host principles. □

Closure status for NameCert$_{\text{CompactnessSequentialEquivalence}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{CompactnessSequentialEquivalence}^{\uparrow}}$, seed)

Scope closed: Definition 5854.1, Definition 5854.2, Definition 5854.3, and Definition 5854.4 seed the finite comparison boundary between finite-cover compactness and sequential compactness for compact-metric consumers.

Formal verification: FormalStatus(NameCert$_{\text{CompactnessSequentialEquivalence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host compactness-equivalence theorem, unrestricted sequential compactness, countable choice, quotient stream equality, external subsequence selection, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-cover and subsequence-window classifier exposure, dyadic tolerance exactness, RegSeqRat handoff exactness, RealUp seal nonescape, and host-principle refusal proofs for BEDC.Derived.CompactnessSequentialEquivalenceUp.

Constructive story: A CompactnessSequentialEquivalence$^{\uparrow}$ packet is generated from CompactMetric source data, HeineBorelFiniteNet finite-cover data, BolzanoWeierstrass bounded-subsequence data, StreamName windows, subsequence windows, RegSeqRat readback, DyadicRatCore tolerance checks, Real seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Chapter 5855

A Concrete Naming Certificate for $\mathsf{ArensEellsSpace}^{\uparrow}$

Following Arens–Eells and Weaver on Lipschitz-free spaces, the $\mathsf{ArensEellsSpace}^{\uparrow}$ packet names the finite molecule ledger by which a pointed metric source is linearized before normed-space and completion consumers read it. It sits beside the metric carrier of chapter 57, the Lipschitz map surface of chapter 410, the normed-space carrier of chapter 1950, the vector-space rows of chapter 47, the Real seal of chapter 38, and the completion boundary of chapter 95. The packet records only displayed molecules, zero-sum accounting, norm budgets, linear handoff rows, transport, replay, provenance, and local naming; it does not quotient a free vector space, select representatives, invoke duality, or assert an ambient Banach completion.

Definition 5855.1 (Arens–Eells space carrier)**.** *An* $\mathsf{ArensEellsSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, b, L, Z, Q, N, H, C, P, R)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the finite distance reads used by molecule budgets.*
2. *b is the basepoint row, naming the distinguished source point against which zero-sum molecules are displayed.*
3. *L is the finite molecule ledger, listing signed point-coefficient rows whose support is finite.*
4. *Z is the zero-sum coefficient row, recording that the displayed coefficients in L balance over the basepoint boundary.*
5. *Q is the Arens–Eells norm budget, read through* $\mathsf{Real}^{\uparrow}$ *rows as a finite infimum ledger over decompositions into elementary molecules.*
6. *N is the* $\mathsf{NormedSpace}^{\uparrow}$*-facing handoff row, with vector-space operations routed through* $\mathsf{VecSpace}^{\uparrow}$ *and norm exposure routed through Q.*
7. *H records componentwise* hsame *transport for the metric source, basepoint, molecule ledger, zero-sum row, norm budget, normed-space handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from metric-source inspection through molecule formation, zero-sum checking, norm-budget accounting, and the normed-space handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{ArensEellsSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. R is the local $\mathsf{NameCert}_{\mathsf{ArensEellsSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a quotient presentation, selected molecule representative, unrestricted dual space, host linearization theorem, completed Banach envelope, or choice of an optimal decomposition.

Lean4 ✓ `BEDC.Derived.ArensEellsSpaceUp.ArensEellsSpaceTasteGate single carrier alignment`

Theorem 5855.2 (Arens–Eells NameCert obligations)**.** *For every accepted* $\mathsf{ArensEellsSpace}^{\uparrow}$ *carrier* $A = (M, b, L, Z, Q, N, H, C, P, R)$*, the local* $\mathsf{NameCert}_{\mathsf{ArensEellsSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric source row, basepoint row, finite molecule ledger, zero-sum coefficient row, Arens–Eells norm budget, normed-space handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. In particular, every accepted molecule read must first expose* M, b, L, Z*, every accepted norm read must pass through the Real-valued budget* Q*, and every normed-space consumer must enter through* N, H, C, P, R*.*

Proof. Project the carrier of Definition 5855.1. The metric source M and basepoint b are the only rows from which point distances and pointed molecule data can be read.

The molecule ledger is finite. The row L lists the signed point-coefficient entries, while Z records the zero-sum boundary that permits the ledger to behave as an Arens–Eells molecule rather than as an arbitrary formal sum.

The norm budget is likewise displayed. The row Q reads Real-valued distance budgets over finite decompositions of the molecule ledger, and the handoff row N exposes only the resulting vector-space and normed-space interface.

Finally the structural rows H, C, P, R transport, replay, source, and name the same packet. Since no other coordinate occurs in the carrier, the NameCert surface cannot import quotient equality, a selected representative, unrestricted duality, a host linearization theorem, ambient completion, or an optimal-decomposition choice principle. □

Theorem 5855.3 (Arens–Eells Lipschitz linearization handoff)**.** *Let* $A = (M, b, L, Z, Q, N, H, C, P, R)$ *be an accepted* $\mathsf{ArensEellsSpace}^{\uparrow}$ *carrier. Any downstream* $\mathsf{LipschitzMap}^{\uparrow}$ *consumer that asks for a linearized normed-space route must factor through the finite handoff*

$$M, b, L, Z, Q \longmapsto N \longmapsto H, C, P, R.$$

The handoff records only that Lipschitz reads from the pointed metric source may be replayed against finite molecules and their Real-valued norm budgets before entering the $\mathsf{NormedSpace}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *surfaces; it does not assert a completed free Banach space, host universal property, quotient by molecule equality, selected extension, or dual representation.*

Proof. Start with a Lipschitz-facing request. The source data are the pointed metric rows M, b, so the request cannot inspect a linear object before the finite molecule ledger is exposed.

Replay the molecule rows by C. The ledger L supplies finite signed point-coefficient data, and the zero-sum row Z supplies the balancing boundary required for molecule consumption.

The normed-space handoff is reached only after the budget row Q has been read. That row supplies the Real-valued Arens–Eells norm account over displayed decompositions, and N is the only row that passes this account to $\mathsf{NormedSpace}^{\uparrow}$ and $\mathsf{VecSpace}^{\uparrow}$ consumers.

The transport, provenance, and local naming rows H, P, R preserve this same route. Therefore the linearization handoff is a finite BEDC route from pointed metric and Lipschitz data to a normed-space interface, not a quotient construction, selected extension, ambient completion, or host universal-property theorem. □

Theorem 5855.4 (Arens–Eells molecule zero-sum transport)**.** *Let $A = (M, b, L, Z, Q, N, H, C, P, R)$ and $A' = (M', b', L', Z', Q', N', H', C', P', R')$ be accepted* $\mathsf{ArensEellsSpace}^{\uparrow}$ *carriers. If the pointed metric rows M, b, the finite molecule ledger L, and the zero-sum row Z transport componentwise through the displayed* hsame *rows, then the transported packet preserves both the displayed molecule ledger and the zero-sum boundary over the pointed* $\mathsf{Met}^{\uparrow}$ *source. In particular, no transported read may replace L by an unlisted formal sum or replace Z by a host equality proof.*

Proof. Project the two carriers through Definition 5855.1. The only rows that expose molecule data are M, b, L, Z, and the only transport coordinate is the componentwise row H.

Use the NameCert obligations of Definition 5855.2. Molecule admission reads the signed point-coefficient ledger L, while zero-sum admission reads the balancing row Z over the same pointed metric source M, b.

Transport is componentwise. Hence a valid hsame replay can rename or move the displayed rows, but it must carry M, b, L, Z together. Since the carrier has no coordinate for host formal sums or quotient equality, the transported molecule remains the finite displayed ledger with the displayed zero-sum boundary. □

Theorem 5855.5 (Arens–Eells norm-budget stability)**.** *For every accepted* $\mathsf{ArensEellsSpace}^{\uparrow}$ *carrier $A = (M, b, L, Z, Q, N, H, C, P, R)$, each* $\mathsf{Real}^{\uparrow}$*-valued norm-budget read through Q remains tied to the displayed molecule decomposition rows M, b, L, Z. The read may expose finite decomposition budgets and their Real comparisons, but it cannot select an optimal decomposition, choose a quotient representative, or detach the budget from the molecule ledger named by L.*

Proof. Begin with the carrier projection. The row Q is introduced only after the pointed source, molecule ledger, and zero-sum rows M, b, L, Z have already been displayed.

Apply Definition 5855.2. The theorem makes every accepted norm read pass through Q, and it makes Q the Real-valued account over displayed decompositions rather than an external norm primitive.

Finally use the handoff theorem Definition 5855.3. Downstream normed-space and vector-space consumers reach N only after Q is read. Thus the budget remains attached to the finite molecule data, with no coordinate for an optimal-decomposition selector or quotient representative. □

Theorem 5855.6 (Arens–Eells Lipschitz-free universal window)**.** *Let $A = (M, b, L, Z, Q, N, H, C, P, R)$ be an accepted* $\mathsf{ArensEellsSpace}^{\uparrow}$ *carrier. Every finite consumer window that treats A as a Lipschitz-free handoff factors through*

$$\mathsf{LipschitzMap}^{\uparrow},\ \mathsf{NormedSpace}^{\uparrow},\ \mathsf{VecSpace}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{Completion}^{\uparrow}$$

only by reading the displayed route $M, b, L, Z, Q, N, H, C, P, R$. The packet supplies the finite universal-window data needed by Lipschitz, normed-space, vector-space, Real, and completion-facing consumers, but it refuses the classical ambient Banach-space universal property.

Proof. Start with a consumer that asks for a Lipschitz-free route. By Definition 5855.3, the request must first pass through the pointed metric rows M, b, the molecule ledger L, the zero-sum row Z, and the norm-budget row Q.

The consumer then reaches the normed and vector interfaces through N. The rows H, C, P, R preserve the same finite route by componentwise transport, displayed replay, provenance, and local naming.

The completion-facing boundary has no additional coordinate in the carrier. Therefore a $\mathsf{Completion}^{\uparrow}$ read can only receive the already displayed Lipschitz-to-normed-space window, not a

completed Banach envelope, unrestricted extension theorem, selected quotient representative, or host universal property. □

Falsifiable prediction: Any consumer that claims an $\mathsf{ArensEellsSpace}^{\uparrow}$ molecule, norm, Lipschitz-linearization, normed-space, vector-space, Real, or Completion read while omitting $M, b, L, Z, Q, N, H, C, P$, or the local NameCert row refutes the carrier of Definition 5855.1.

Independence witness: metric, lipschitzmap, normedspace, vecspace, real, completion: $\mathsf{ArensEellsSpace}^{\uparrow}$ is not bijective to any listed sibling because it carries a pointed metric source, finite molecule ledger, zero-sum coefficient boundary, Arens–Eells norm budget, and a normed-space linearization handoff before any completion-facing consumer may read the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ArensEellsSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{ArensEellsSpace}^{\uparrow}$ packet is generated from a pointed metric source, finite molecule ledger, zero-sum coefficient row, Real-valued norm budget, normed-space handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArensEellsSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5855.1, Definition 5855.2, and Definition 5855.3 seed the finite molecule and norm-budget route from pointed metric data to Lipschitz and normed-space consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArensEellsSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient vector-space equality, a selected molecule representative, unrestricted duality, a completed free Banach space, an ambient universal property, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, molecule ledger replay, zero-sum boundary, Real-valued norm-budget exactness, and Lipschitz-to-normed-space handoff for BEDC.Derived.ArensEellsSpaceUp.

Chapter 5856

A Concrete Naming Certificate for $\mathsf{BanachFixedPointStability}^{\uparrow}$

Following Banach and Bishop–Bridges constructive metric analysis, the $\mathsf{BanachFixedPointStability}^{\uparrow}$ packet records the finite stability surface by which a displayed contraction orbit keeps its fixed-point seal attached to explicit Picard and Cauchy-modulus data. It sits after the fixed-point certificate of chapter 396, the iteration ledger of chapter 2359, the contraction surface of chapter 1418, the complete-metric boundary of chapter 128, the modulus schedule of chapter 292, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a stability handoff for fixed-point consumers; it is not ambient real completeness, a selected host fixed point, a quotient orbit, a global contraction theorem, or a choice principle.

Definition 5856.1 (Banach fixed point stability carrier)**.** *A* $\mathsf{BanachFixedPointStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, I, T, M, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{BanachFixedPoint}^{\uparrow}$ *source row naming the fixed-point certificate whose stability is being inspected.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *orbit row, recording the finite prefix and tail schedule consumed by the stability packet.*
3. *T is the* $\mathsf{ContractionMapping}^{\uparrow}$ *row that exposes the displayed contraction constant, comparison window, and contraction replay surface.*
4. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *dependency row, available only as the completion boundary used by the Picard orbit and not as ambient completeness for* $\mathsf{Real}^{\uparrow}$*.*
5. *Q is the* $\mathsf{CauchyModulus}^{\uparrow}$ *stability schedule for the orbit tail and perturbation tolerance.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after I, T, M, Q have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the fixed-point source, Picard orbit, contraction row, completion boundary, modulus schedule, and regular-rational readback have been read.*
8. *H records componentwise* hsame *transport for the displayed source, orbit, contraction, completion, modulus, readback, real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from the fixed-point source through $F, I, T, M, Q, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{BanachFixedPointStability}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachFixedPointStability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, I, T, M, Q, R, E, H, C, P, N$. It has no coordinate for a selected host fixed point, quotient orbit equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, global contraction soundness, trichotomy, or countable choice.*

Lean4 ✓ `BEDC.Derived.BanachFixedPointStabilityUp.BanachFixedPointStabilityTasteGate single carrier alignment`

Theorem 5856.2 (Banach fixed point stability NameCert obligations)**.** *For every accepted* BanachFixedPointStabili *carrier $B = (F, I, T, M, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachFixedPointStability}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed fixed-point source F, Picard orbit I, contraction row T, complete-metric dependency M, Cauchy-modulus schedule Q, regular-rational readback R, terminal real seal E, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 5856.1. The analytic rows visible to a stability consumer are exactly F, I, T, M, Q, R, E, followed by transport, replay, provenance, and naming.

The fixed-point source is not read alone. The Picard row I and contraction row T display the orbit and contraction comparison before the complete-metric dependency M and modulus schedule Q can be consumed.

The Real-facing endpoint is downstream from the same finite route. The regular-rational row R is read only from the displayed orbit, contraction, completion, and modulus rows, and the terminal seal E is read only after R.

Finally H, C, P, N transport, replay, source, and name this packet. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5856.3 (Banach fixed point stability Picard-Cauchy handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BanachFixedPointStability}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{BanachFixedPoint}^{\uparrow} \longmapsto \mathsf{PicardIteration}^{\uparrow} \longmapsto \mathsf{ContractionMapping}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{Re}$$

The handoff exposes only the displayed fixed-point source, Picard orbit, contraction comparison, complete-metric dependency, Cauchy-modulus schedule, regular-rational readback, terminal real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. It exports no selected host fixed point, quotient orbit equality, hidden completion theorem, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, global contraction soundness, trichotomy, or countable-choice schedule.*

Proof. Begin with Definition 5856.2. It places every stability read behind the fixed-point source, Picard orbit, contraction comparison, complete-metric dependency, and explicit modulus schedule.

Next open the handoff to regular-rational data. The rows I, T, M, Q determine the displayed Cauchy tail route, so the $\mathsf{RegSeqRat}^{\uparrow}$ row R is a finite readback from those rows rather than a quotient orbit or host-selected fixed point.

The terminal real seal is last. The $\mathsf{Real}^{\uparrow}$ row E is consumed only after R has been displayed, while H, C, P, N preserve the same dependency order under transport, replay, provenance, and local naming.

Thus any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer sees exactly the stated Picard-Cauchy route and cannot bypass it through an ambient completeness or choice object. □

Theorem 5856.4 (Banach fixed point stability modulus nonescape)**.** *Let $B = (F, I, T, M, Q, R, E, H, C, P, N)$ be an accepted* $\mathsf{BanachFixedPointStability}^{\uparrow}$ *carrier. Every perturbation consumer and every tail-stability consumer of B must read the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule Q before it can read the regular-rational row R or the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E.*

Consequently no such consumer can obtain a selected host fixed point, quotient orbit equality, hidden completion theorem, ambient $\mathsf{Real}^{\uparrow}$ *completeness, global contraction soundness, trichotomy, or countable-choice schedule from R or E without first exposing the displayed modulus row Q.*

Proof. Project the carrier of Definition 5856.1. The rows are ordered so that Q is the displayed Cauchy-modulus schedule for the orbit tail and perturbation tolerance, while R and E are downstream readback and seal rows.

Apply Definition 5856.2. It says that the local NameCert surface contains the fixed-point source, Picard orbit, contraction row, complete-metric dependency, Cauchy-modulus schedule, regular-rational readback, and terminal real seal as listed carrier rows, with no excluded coordinate.

Next apply Definition 5856.3. The displayed route reaches $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ only after $\mathsf{CauchyModulus}^{\uparrow}$, so a perturbation or tail-stability request that tries to read R or E has already passed through Q.

The refusal clauses follow because the carrier and handoff theorems export no selected host fixed point, quotient orbit equality, hidden completion theorem, ambient Real completeness, global contraction theorem, trichotomy, or countable-choice row. Thus Q is a nonescape boundary for all tail-stability and perturbation reads. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachFixedPointStability}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachFixedPointStability}^{\uparrow}$ packet is generated from a BanachFixedPoint source row, PicardIteration orbit, ContractionMapping comparison, CompleteMetric dependency, CauchyModulus schedule, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachFixedPointStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5856.1, Definition 5856.2, and Definition 5856.3 seed the finite stability handoff from Banach fixed-point data through Picard, contraction, completion, modulus, regular-rational, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachFixedPointStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected host fixed points, quotient orbit equality, hidden completion theorems, ambient RealUp completeness, global contraction soundness, trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard orbit ordering, contraction comparison stability, complete-metric dependency confinement, Cauchy-modulus exactness, RegSeqRat handoff, RealUp seal confinement, transport stability, continuation replay, and provenance nonescape for BEDC.Derived.BanachFixedPointStabilityUp.

Chapter 5857

A Concrete Naming Certificate for $\mathsf{RealTriangleInequality}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of metric real names, the $\mathsf{RealTriangleInequality}^{\uparrow}$ packet records the finite three-leg route by which a displayed real distance estimate is assembled without importing quotient real equality or an ambient completeness theorem. It sits beside the real-name seal of chapter 38, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, and the stream-window discipline of chapter 126.

Definition 5857.1 (Real triangle inequality carrier)**.** *A* $\mathsf{RealTriangleInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, B, M, D, W, H, C, P, N)$$

with the following displayed coordinates:

1. *A and B are the two endpoint* $\mathsf{Real}^{\uparrow}$ *equality rows whose distance comparison is being bounded.*
2. *M is the intermediate* $\mathsf{RegSeqRat}^{\uparrow}$ *row that supplies the middle leg of the finite rational comparison.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the three displayed radii and the exact middle-leg budget.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which the two endpoints and the intermediate row are inspected.*
5. *H stores componentwise* hsame *transport for endpoint rows, the middle readback row, dyadic budgets, windows, replay, provenance, and local naming rows.*
6. *C stores displayed* Cont *replay from a consumer request through A, B, M, D, W, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{RealTriangleInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealTriangleInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite coordinates. It has no coordinate for host real equality, quotient streams, selected limits, trichotomy, or ambient completeness.

Theorem 5857.2 (Real triangle inequality NameCert obligations)**.** *For an accepted* $\mathsf{RealTriangleInequality}^{\uparrow}$ *carrier $T = (A, B, M, D, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealTriangleInequality}^{\uparrow}}$ *surface consists exactly of endpoint admission through the two displayed* $\mathsf{Real}^{\uparrow}$ *equality rows A, B, dyadic middle-leg*

exactness through the ledger D, $\mathsf{RegSeqRat}^{\uparrow}$ *replay through M,* $\mathsf{StreamName}^{\uparrow}$ *window inspection through W, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff for the three-leg comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row N. No consumer can escape from this surface to host real equality, quotient streams, selected limits, trichotomy, or ambient completeness.*

Proof. Project the carrier of Definition 5857.1. The two endpoint rows A, B, the intermediate readback row M, the dyadic ledger D, the stream windows W, transport, replay, provenance, and naming row are all displayed coordinates of the finite packet.

Endpoint admission is therefore read only through A and B. The middle leg is read through M, while D records the exact dyadic budget that joins the two endpoint comparisons through the displayed intermediate row.

Replay the consumer request through C after transporting coordinates with H. The replay order exposes the $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ middle row, and the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger before any terminal $\mathsf{Real}^{\uparrow}$ seal is inspected.

The exclusions are the carrier inventory. Since no coordinate stores host real equality, a quotient stream object, a selected limit, trichotomy data, or an ambient completeness theorem, the local naming certificate cannot export any of them. □

Lean4 ✓ `BEDC.Derived.RealTriangleInequalityUp.RealTriangleInequalityTasteGate single carrier alignment`

Closure status for $\mathsf{NameCert}_{\mathsf{RealTriangleInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{RealTriangleInequality}^{\uparrow}$ packet is generated from two endpoint $\mathsf{Real}^{\uparrow}$ equality rows, one intermediate $\mathsf{RegSeqRat}^{\uparrow}$ row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, finite $\mathsf{StreamName}^{\uparrow}$ windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealTriangleInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5857.1 and Definition 5857.2 seed the finite three-leg real route over RealUp, RegSeqRatUp, DyadicRatCoreUp, StreamNameUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealTriangleInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient stream equality, selected limits, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, dyadic middle-leg exactness, RegSeqRat replay, RealUp seal handoff, and non-escape for BEDC.Derived.RealTriangleInequalityUp.

$\mathsf{LowerDarbouxSum}^{\uparrow}$ is the lower finite-sum side consumed by chapter 1880 and paired with chapter 4083.

Chapter 5858

A Concrete Naming Certificate for $\mathsf{LowerDarbouxSum}^{\uparrow}$

Following Darboux and Riemann, the $\mathsf{LowerDarbouxSum}^{\uparrow}$ packet isolates the lower-sum side of Darboux integration before the full upper/lower gap is read. It is the lower companion to chapter 4083 and supplies the missing finite half used by chapter 1880. The packet reads the integrability boundary of chapter 1960, the displayed finite partition mesh of chapter 3496, and the step-function bracket rows of chapter 428; it exports no host infimum, selected mesh limit, quotient function equality, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate.

Definition 5858.1 (Lower Darboux sum carrier)**.** *A* $\mathsf{LowerDarbouxSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (P, B, D, S, I, R, H, C, Q, N)$$

with the following displayed rows:

1. *P is the finite partition-mesh row, naming the ordered displayed cells, endpoint ledger, width ledger, and refinement handle used by every lower-sum read.*
2. *B is the cell lower-bound ledger. For each displayed cell it records the chosen lower value row and the comparison proof that the carried value is below every admitted sample value in that cell.*
3. *D is the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *row over the same partition cells, carrying the step values used to display the lower envelope.*
4. *S is the finite lower Darboux-sum row computed from the displayed widths in P and the lower values exposed by B and D.*
5. *I is the* $\mathsf{RiemannIntegrable}^{\uparrow}$ *and* $\mathsf{DarbouxSum}^{\uparrow}$ *handoff row, recording that the lower-sum read is available before any upper-sum, gap, or integral seal is requested.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *comparison row, exposing only the finite real-name comparison needed by lower-bound consumers.*
7. *H records componentwise* hsame *transport for the partition mesh, lower-bound ledger, dyadic step row, finite lower sum, handoff, comparison row, replay, provenance, and local naming row.*
8. *C records displayed* Cont *replay from partition cells to lower-bound reads, from lower-bound reads to the dyadic step row, from the dyadic step row to the finite lower sum, and from the lower sum to the handoff row.*

9. *Q is the* Pkg *provenance over* $\mathsf{LowerDarbouxSum}^{\uparrow}$, *??*, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{FinitePartitionMesh}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LowerDarbouxSum}^{\uparrow}}$ *row.*

The classifier reads accepted packets only through $P, B, D, S, I, R, H, C, Q, N$. It has no coordinate for a host infimum, a selected mesh limit, an upper Darboux sum, an upper-minus-lower gap, quotient equality of functions, open-cover compactness, or ambient real completeness.

Theorem 5858.2 (Lower Darboux sum NameCert obligations)**.** *For every accepted* $\mathsf{LowerDarbouxSum}^{\uparrow}$ *carrier*

$$L = (P, B, D, S, I, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{LowerDarbouxSum}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the displayed partition mesh, cell lower-bound ledger, dyadic step row, finite lower sum, Darboux and Riemann handoff, comparison row, transport, replay, provenance, and local naming row;*
2. *partition-mesh stability, requiring each transported refinement of P to preserve the displayed cell-width ledger and to route lower-bound reads through the same refinement handle;*
3. *lower-bound ledger transport, requiring B and D to move componentwise by* hsame *while preserving the stated lower relation on every displayed cell;*
4. *finite lower-sum replay, requiring S to be recomputed from the transported cell widths and transported lower values before any handoff row can be consumed;*
5. *ledger non-escape, requiring I, R, H, C, Q, N to expose only the displayed lower-sum route and to exclude host infima, selected mesh limits, quotient function equality, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, upper-sum rows, and gap rows.*

Proof. Carrier admission is the projection of Definition 5858.1. The accepted packet displays exactly the partition mesh, lower-bound ledger, dyadic step row, finite lower sum, handoff, comparison, transport, replay, provenance, and local naming rows.

Partition-mesh stability is read before any numerical sum. The row P fixes the displayed cells and widths, so a transported refinement can only expose a lower-bound read through the same finite mesh ledger and refinement handle.

The lower-bound ledger is then transported componentwise. The rows B and D move together under H, while replay through C rebuilds the lower envelope and then the finite lower sum row S.

The handoff and non-escape clauses are exhausted by S, I, R, H, C, Q, N. Since no carrier coordinate stores a host infimum, selected mesh limit, quotient function equality, open-cover compactness theorem, ambient completeness row, upper-sum row, or gap row, the local NameCert surface is exactly the five listed obligations. □

Theorem 5858.3 (Lower Darboux finite partition handoff)**.** *Every* $\mathsf{DarbouxSum}^{\uparrow}$ *or* $\mathsf{RiemannIntegrable}^{\uparrow}$ *consumer of an accepted* $\mathsf{LowerDarbouxSum}^{\uparrow}$ *carrier $L = (P, B, D, S, I, R, H, C, Q, N)$ must first read the finite partition mesh P, the lower-bound ledger B, the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *row D, the finite lower sum S, and the comparison row R, with transport, replay, provenance, and local naming supplied by H, C, Q, N. The consumer therefore receives a finite partition-and-lower-envelope route rather than a host infimum, a selected mesh limit, quotient function equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The rows upstream of every exported lower-sum read are P, B, D, S, R together with the structural rows H, C, Q, N.

For a $\mathsf{DarbouxSum}^{\uparrow}$ read, the handoff row I is reachable only after the partition mesh, lower-bound ledger, dyadic step row, and finite lower sum have been replayed. For a $\mathsf{RiemannIntegrable}^{\uparrow}$ read, the same row S is the lower finite half that a later upper/lower gap comparison must consume.

Coordinate exhaustion closes the handoff. The packet has no analytic coordinate beyond the displayed rows, so the consumer cannot bypass the finite route through a host infimum, selected mesh limit, quotient equality, compactness theorem, or ambient completeness row. □

Theorem 5858.4 (Lower Darboux gap boundary)**.** *Let $L = (P, B, D, S, I, R, H, C, Q, N)$ be an accepted* $\mathsf{LowerDarbouxSum}^{\uparrow}$ *carrier. Any later* $\mathsf{DarbouxSum}^{\uparrow}$ *upper-minus-lower gap row that uses L must take S as its lower finite sum over the displayed partition mesh P and the displayed lower envelope B, D. The lower-sum side of the gap therefore remains fixed by the finite lower packet and cannot be replaced by a host infimum, quotient function equality, selected limiting mesh, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or an independently chosen lower bracket.*

Proof. Start with the finite partition handoff of Definition 5858.3. Any Darboux-facing consumer already reads P, B, D, S with H, C, Q, N before it can ask for a gap row.

Compare this lower half with the upper half named by chapter 4083 and the combined surface of chapter 1880. The gap row can combine a transported upper finite sum with the transported lower finite sum, but the lower input remains the row S replayed from the displayed mesh and lower envelope.

The boundary is therefore finite and local. Since L contains no coordinate for an alternate lower bracket, host infimum, selected mesh limit, quotient equality, compactness theorem, or ambient completeness row, no later gap consumer can replace the lower side without leaving the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LowerDarbouxSum}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LowerDarbouxSum}^{\uparrow}$ packet is generated from finite partition-mesh rows, cell lower-bound ledgers, dyadic step-function rows, finite lower-sum rows, Darboux and Riemann handoff rows, Real comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LowerDarbouxSum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5858.1, Definition 5858.2, Definition 5858.3, and Definition 5858.4 seed the finite lower-sum packet over displayed partition meshes, cell lower-bound reads, dyadic-step rows, finite-sum rows, Darboux and Riemann handoff, $\mathsf{Real}^{\uparrow}$ comparison, transport, replay, provenance, local naming, and Darboux gap-boundary rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LowerDarbouxSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host infima, selected mesh limits, quotient function equality, open-cover compactness, upper Darboux sums, upper-minus-lower gap construction, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition-mesh stability, lower-bound ledger transport, finite lower-sum replay, finite partition handoff, Darboux gap boundary, componentwise transport, displayed replay, provenance, local naming, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.LowerDarbouxSumUp.

The $\mathsf{LowerDarbouxSum}^{\uparrow}$ packet consumes the shared $\mathsf{DarbouxSum}^{\uparrow}$ partition ledger of chapter 1880 and is paired with **??** through the same finite interval, cell-width, and partition rows of chapter 4083. A lower-sum consumer therefore reads the lower envelope as one half of the displayed Darboux partition lattice rather than as an isolated kernel row.

Chapter 5859

A Concrete Naming Certificate for $\mathsf{BoundedMetricSpace}^{\uparrow}$

Following Hausdorff and Kelley metric-space practice, the $\mathsf{BoundedMetricSpace}^{\uparrow}$ packet records the bounded metric-space interface as finite BEDC NameCert data. It sits between the metric carrier of chapter 4230, the center-radius containment row of chapter 1450, the bounded-subset surface of chapter 1757, the diameter handoff of chapter 1503, the ordered-real bound route of chapter 766, the terminal real-name seal of chapter 38, and the completion-facing consumers of chapter 95 and chapter 1506. The packet supplies finite-net, Cauchy, compact-metric, and diameter consumers with a displayed bounded metric source without importing compactness, host suprema, selected centers, quotient equality, or ambient completeness.

Definition 5859.1 (BoundedMetricSpace carrier)**.** *A* $\mathsf{BoundedMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, B, D, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *carrier row. It supplies the point classifier, metric-source data, real-valued distance route, zero-distance classifier, symmetry row, and triangle row.*
2. *B is the bounded-containment row. It records the* $\mathsf{MetricBall}^{\uparrow}$ *center-radius ledger together with the* $\mathsf{BoundedSet}^{\uparrow}$ *membership classifier that every admitted point must read before boundedness is exposed.*
3. *D is the* $\mathsf{MetricDiameter}^{\uparrow}$ *row. It names the finite diameter-bound handoff consumed by diameter, finite-net, Cauchy, and compact-metric readers.*
4. *R is the real-bound readback row. It routes the radius and diameter bounds through* $\mathsf{Real}^{\uparrow}$ *and the ordered comparison surface of* $\mathsf{RealAlgOrder}^{\uparrow}$*.*
5. *H records componentwise* hsame *transport for the metric carrier, containment row, diameter row, real-bound readback, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a bounded-metric request through metric admission, bounded-set containment, metric-ball comparison, diameter-bound readback, ordered-real comparison, and completion-facing handoff.*
7. *P is the* Pkg *provenance over* $\mathsf{BoundedMetricSpace}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{MetricBall}^{\uparrow}$*,* $\mathsf{BoundedSet}^{\uparrow}$*,* $\mathsf{MetricDiameter}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RealAlgOrder}^{\uparrow}$*,* $\mathsf{Completion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

8. N is the local $\mathsf{NameCert}_{\mathsf{BoundedMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through X, B, D, R, H, C, P, N. It has no coordinate for a host subset, host supremum, selected bounding center, selected diameter witness, compactness theorem, quotient completion, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedMetricSpaceUp.BoundedMetricSpaceTasteGate single carrier alignment`

Theorem 5859.2 (BoundedMetricSpace NameCert obligations)**.** *For every accepted* $\mathsf{BoundedMetricSpace}^{\uparrow}$ *carrier $Q = (X, B, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedMetricSpace}^{\uparrow}}$ *surface consists exactly of the following obligation families:*

1. *metric-source admission for the displayed* $\mathsf{Met}^{\uparrow}$ *row X;*
2. *bounded-containment admission for the* $\mathsf{MetricBall}^{\uparrow}$ *and* $\mathsf{BoundedSet}^{\uparrow}$ *rows stored in B;*
3. *diameter-bound admission for the* $\mathsf{MetricDiameter}^{\uparrow}$ *row D;*
4. *real-bound readback through* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RealAlgOrder}^{\uparrow}$ *in R;*
5. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N.*

Consequently a downstream finite-net, Cauchy, compact-metric, diameter, or completion-facing consumer may read bounded metric-space data only through the displayed metric, containment, diameter, ordered-real, and structural rows. The packet exports no host supremum, compactness theorem, selected bound, quotient completion, countable-choice selector, or ambient real completeness coordinate.

Proof. Project the carrier of Definition 5859.1. The only analytic rows are the metric source X, the bounded-containment row B, the diameter row D, and the real-bound readback row R.

The containment side is read first. The row B combines the center-radius ledger of chapter 1450 with the bounded-subset classifier of chapter 1757, so membership containment is visible before any bounded-space consumer receives the packet.

The diameter and real-bound rows are downstream from that containment. The row D supplies the sibling handoff of chapter 1503, and R records that the bound is read through $\mathsf{Real}^{\uparrow}$ and $\mathsf{RealAlgOrder}^{\uparrow}$ rather than through a host supremum.

Finally H, C, P, N transport, replay, source, and name the same displayed rows. Since no excluded analytic object is a coordinate of Q, the listed obligation families exhaust the local NameCert surface. □

Theorem 5859.3 (BoundedMetricSpace diameter-bound handoff)**.** *Every diameter, finite-net, Cauchy, compact-metric, or completion-facing read accepted from a* $\mathsf{BoundedMetricSpace}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{MetricBall}^{\uparrow}, \mathsf{BoundedSet}^{\uparrow} \longmapsto \mathsf{MetricDiameter}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, \mathsf{RealAlgOrder}^{\uparrow} \longmapsto \mathsf{Completion}^{\uparrow}, \mathsf{MetricCompletio}$$

The exported handoff is a displayed bounded metric source with containment and diameter-bound rows already visible. It does not provide compactness, a host supremum, a selected bounding center, a selected maximum pair, quotient completion equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from an accepted packet $Q = (X, B, D, R, H, C, P, N)$. A consumer first opens the metric row X, so every subsequent boundedness or diameter read remains attached to the same point classifier and distance route.

Read containment through B. This exposes the center-radius and bounded-subset rows before any finite-net or Cauchy consumer can treat the source as bounded.

Next read the diameter row D and the ordered-real readback R. These rows hand the displayed bound to the sibling diameter packet and to the $\mathsf{Real}^{\uparrow}$ and $\mathsf{RealAlgOrder}^{\uparrow}$ comparison surfaces, with no host supremum or selected maximum pair.

The completion-facing route is only a consumer of that finite surface. The structural rows H, C, P, N preserve the same path under transport and replay, so no quotient completion, choice schedule, or ambient completeness principle is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedMetricSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5859.1, Definition 5859.2, and Definition 5859.3 seed the finite bounded metric-space packet over metric, ball-containment, bounded-subset, diameter, ordered-real, and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim compactness, host suprema, selected bounds, quotient completions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked metric admission, bounded-containment admission, diameter-bound handoff, real-bound readback, transport, replay, provenance, and local naming for BEDC.Derived.BoundedMetricSpaceUp.

Constructive story: A $\mathsf{BoundedMetricSpace}^{\uparrow}$ packet is generated from a MetricSpaceUp carrier, MetricBallUp and BoundedSetUp containment rows, a MetricDiameterUp bound row, RealUp and RealAlgOrderUp readback, completion-facing handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The Legendre–Fenchel envelope concrete instance is housed in its thematic spine so the root concrete-instance index stays structural; its convex-optimization route is read through chapter 208, chapter 321, chapter 3713, chapter 3563, and chapter 300.

Chapter 5860

A Concrete Naming Certificate for $\mathsf{LegendreFenchelEnvelope}^{\uparrow}$

Following Rockafellar, the $\mathsf{LegendreFenchelEnvelope}^{\uparrow}$ packet names the finite convex-envelope surface obtained by reading epigraph windows, supporting affine minorants, convex-conjugate data, and biconjugate comparison rows before any optimization consumer may inspect the result. It sits after the convex-set carrier of chapter 208, the Fenchel-duality ledger of chapter 321, and the proximal-resolvent handoff of chapter 3713; it also exposes KKT-facing and convex-conjugate-facing rows for certificates that need a displayed envelope without importing an ambient lower-semicontinuous hull, host supremum operator, quotient function space, or choice-selected minimizer.

Definition 5860.1 (Legendre–Fenchel envelope carrier)**.** *A* $\mathsf{LegendreFenchelEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (W, A, D, B, R, K, H, C, P, N)$$

with the following displayed rows:

1. *W is the epigraph window row, read through the* $\mathsf{ConvexSet}^{\uparrow}$ *carrier and recording the finite domain, value, and order comparisons visible to the envelope request.*
2. *A is the supporting affine minorant ledger, listing the finitely displayed affine lower bounds and their compatibility with the same epigraph window.*
3. *D is the convex conjugate readback row, exposing the pairing, dual-vector, and budgeted conjugacy data that a* $\mathsf{ConvexConjugate}^{\uparrow}$ *or* $\mathsf{FenchelDuality}^{\uparrow}$ *consumer may inspect.*
4. *B is the biconjugate-envelope row, recording the displayed comparison between the primal epigraph window and the conjugate readback route.*
5. *R is the proximal consumer row, allowing a* $\mathsf{ProximalMap}^{\uparrow}$ *request to read the envelope only after the window, minorant, conjugate, and biconjugate rows have been displayed.*
6. *K is the KKT and Fenchel ledger row, tying stationarity, supporting minorants, and dual comparison data to the* $\mathsf{KKT}^{\uparrow}$ *and* $\mathsf{FenchelDuality}^{\uparrow}$ *packets.*
7. *H records componentwise* hsame *transport for the epigraph window, affine minorants, conjugate readback, biconjugate envelope, proximal consumer, KKT and Fenchel ledger, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from epigraph admission through supporting minorants, conjugate readback, biconjugate comparison, proximal consumption, and KKT/Fenchel ledger inspection.*

9. *P is the* Pkg *provenance over* $\mathsf{LegendreFenchelEnvelope}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ConvexConjugate}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, $\mathsf{ProximalMap}^{\uparrow}$, $\mathsf{KKT}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LegendreFenchelEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, A, D, B, R, K, H, C, P, N$. It has no coordinate for an external lower-semicontinuous hull, host biconjugation theorem, selected supremum witness, quotient equality of functions, ambient locally convex topology, or global minimization principle.

Falsifiable prediction: Every accepted $\mathsf{LegendreFenchelEnvelope}^{\uparrow}$ consumer read factors through an epigraph window, supporting affine minorant ledger, convex conjugate readback, biconjugate-envelope row, proximal consumer row, KKT/Fenchel ledger row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: convexset, fenchelduality, proximal-map, convex-conjugate, kkt: LegendreFenchelEnvelop is not bijective to any listed sibling because it jointly carries an epigraph window, supporting affine minorants, conjugate readback, biconjugate envelope comparison, proximal consumer route, and KKT/Fenchel ledger in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LegendreFenchelEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{LegendreFenchelEnvelope}^{\uparrow}$ packet is generated from an epigraph window, supporting affine minorant ledger, convex conjugate readback, biconjugate-envelope row, proximal consumer row, KKT and Fenchel ledger row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LegendreFenchelEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 5860.1 seeds the finite envelope certificate surface over convex-set, convex-conjugate, Fenchel-duality, proximal-map, and KKT rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LegendreFenchelEnvelope}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a host biconjugation theorem, lower-semicontinuous hull existence, selected supporting functional, quotient function equality, ambient locally convex topology, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, affine-minorant ledger exactness, conjugate readback, biconjugate-envelope comparison, proximal consumer boundary, KKT/Fenchel ledger visibility, transport, replay, provenance, and local naming for BEDC.Derived.LegendreFenchelEnvelopeUp.

Chapter 5861

A Concrete Naming Certificate for $\mathsf{PrefixTree}^{\uparrow}$

Following Brouwer and Kleene on spreads and finite choice sequences, the $\mathsf{PrefixTree}^{\uparrow}$ packet records the finite prefix-tree carrier used before StreamName and compact fan routes ask for branch-facing data. It sits between the finite window discipline of chapter 126, the binary obstruction route of chapter 1622, the fan boundary of chapter 400, and the Cantor prefix reads of chapter 1475. The packet names a finite frontier and branch-window surface; it is not an infinite branch selector, host tree equality, countable choice, bar induction, compactness, or ambient stream equality.

Definition 5861.1 (PrefixTree frontier carrier)**.** *A* $\mathsf{PrefixTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (V, E, F, W, H, C, P, N)$$

with the following displayed rows:

1. *V is the prefix-closed* BHist *node row. It lists the root, every displayed node, every displayed parent-prefix row, and the finite prefix relation used by the packet.*
2. *E is the finite child* $\mathsf{ProbeBundle}$ *row. For each displayed node in V, it records the listed child probes, the edge labels, and the finite immediate-extension checks.*
3. *F is the frontier row. It lists the exposed leaves and boundary nodes whose child probes are not opened by this packet, together with their parent-prefix witnesses in V.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *branch-window row. It records exactly the finite stream-name windows read along displayed root-to-frontier paths before any fan, Cantor, or compact route may consume the tree.*
5. *H records componentwise* hsame *transport for prefix nodes, child probes, frontier rows, branch windows, replay rows, provenance rows, and local naming rows.*
6. *C records displayed* Cont *replay from a tree request through V, E, F, W and then into the downstream* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{KleeneTree}^{\uparrow}$*, or* $\mathsf{CantorSpace}^{\uparrow}$ *consumer route that asked for the prefix data.*
7. *P is the* Pkg *provenance over* $\mathsf{PrefixTree}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{KleeneTree}^{\uparrow}$*,* $\mathsf{CantorSpace}^{\uparrow}$*,* BHist*,* $\mathsf{ProbeBundle}$*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{PrefixTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through V, E, F, W, H, C, P, N. It has no coordinate for selected infinite branches, quotient stream equality, host tree equality, countable choice, open-cover compactness, or ambient fan compactness.

Lean4 (definition) `BEDC.Derived.PrefixTreeUp.PrefixTreeUp`

Theorem 5861.2 (PrefixTree frontier NameCert obligation surface)**.** *For every accepted* $\mathsf{PrefixTree}^{\uparrow}$ *carrier*

$$T = (V, E, F, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrefixTree}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the prefix-closed node row, child probe bundle, frontier row, branch-window row, componentwise transport, continuation replay, provenance, and local naming;*
2. *prefix closure, requiring every non-root node in V to display its parent-prefix chain inside V before any child probe in E is consumed;*
3. *finite branching, requiring each child request to be read from the finite* ProbeBundle *row E attached to the currently displayed node;*
4. *frontier coverage, requiring every exposed leaf or boundary node in F to be reached by a displayed finite path through V and E;*
5. *branch-window stability, requiring every* $\mathsf{StreamName}^{\uparrow}$ *window in W to be attached to a displayed root-to-frontier path and to transport through H and replay through C without changing the prefix path;*
6. *non-escape from selected infinite branches, requiring P and N to export no selected branch, quotient stream equality, host tree equality, countable choice, open-cover compactness, or ambient fan compactness.*

Thus any downstream $\mathsf{StreamName}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{KleeneTree}^{\uparrow}$, *or* $\mathsf{CantorSpace}^{\uparrow}$ *consumer receives only compact finite prefix data.*

Proof. Carrier admission is projection from Definition 5861.1. The accepted packet displays exactly the prefix-node row, finite child probes, frontier ledger, branch windows, and structural rows.

Prefix closure is read from V. A non-root node has no entry point except its displayed parent-prefix chain, so a consumer cannot jump to an unlisted node or compare nodes by host tree equality.

Finite branching is read from E. For a displayed node, the packet exposes only the listed child probes and edge labels, and each such probe is attached to the node already admitted by V.

Frontier coverage is read from F. Every exposed leaf or boundary node carries a finite path back through the node and child rows, so the frontier is a finite BEDC ledger rather than a completed branch object.

Branch-window stability is read from W, H, C. The $\mathsf{StreamName}^{\uparrow}$ window is attached to the same displayed root-to-frontier path, componentwise hsame transport preserves that path, and displayed Cont replay repeats the same finite route for fan, Kleene-tree, and Cantor-space consumers.

Finally, provenance and local naming in P, N add no excluded coordinate. Since selected infinite branches, quotient streams, host tree equality, countable choice, open-cover compactness, and ambient fan compactness are absent from the carrier, the local NameCert surface cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrefixTree}^{\uparrow}}$.

Constructive story: A $\mathsf{PrefixTree}^{\uparrow}$ packet is generated from prefix-closed BHist node rows, finite ProbeBundle child rows, frontier rows, finite $\mathsf{StreamName}^{\uparrow}$ branch windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrefixTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5861.1 and Definition 5861.2 seed the finite prefix-tree frontier route for StreamName, fan, Kleene-tree, and Cantor-space consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrefixTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite branch selection, quotient stream equality, host tree equality, countable choice, bar induction, compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix closure, finite branching, frontier coverage, branch-window stability, replay, provenance, local naming, and non-escape for BEDC.Derived.PrefixTreeUp.

$\mathsf{ChomskyNormalForm}^{\uparrow}$ reads its grammar-normalization route through chapter 356, finite word rows through chapter 36, and language-preservation comparison through chapter 351; the child files below keep the carrier and proof rows separate.

Chapter 5862

A Concrete Naming Certificate for $\mathsf{ChomskyNormalForm}^{\uparrow}$

Following Hopcroft–Ullman and Sipser, the $\mathsf{ChomskyNormalForm}^{\uparrow}$ packet records the finite normal-form handoff for a context-free grammar as BEDC NameCert data. It sits beside the grammar carrier of chapter 356, the finite word rows of chapter 36, and the regular-language comparison surface of chapter 351, with parse-tree rows consumed by downstream grammar chapters. The packet names the displayed nonterminal, terminal, production, start, nullable, unit-production, binarization, and language-preservation rows before any consumer may read a grammar as a Chomsky-normal-form grammar. The language-preservation row L is the shared boundary read consumed by the regular-language surface of chapter 351 and by parse-tree or CFG consumers through chapter 356.

Definition 5862.1 (ChomskyNormalForm carrier)**.** *A* $\mathsf{ChomskyNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (G, N, T, S, P, E, U, B, L, H, C, K, A)$$

with the following displayed rows:

1. *G is the source* $\mathsf{ContextFreeGrammar}^{\uparrow}$ *row whose variables, terminals, productions, start symbol, derivation relation, and language surface are visible to the packet.*
2. *N is the nonterminal vocabulary row for the normal-form grammar, including the finite renamed variables introduced by binarization.*
3. *T is the terminal vocabulary row inherited from the source grammar and exposed through finite word rows.*
4. *S is the start-symbol row, including the displayed fresh-start handling used when the source grammar derives the empty word.*
5. *P is the production-shape row, requiring every displayed production to be terminal, binary nonterminal, or the admitted start-empty row.*
6. *E is the nullable and empty-word ledger, recording exactly where the construction retains or removes empty productions.*
7. *U is the unit-production elimination ledger, recording the finite route by which unit edges are replaced by ordinary productions.*

8. *B is the binarization ledger, recording the finite chain of helper variables used to replace long right-hand sides.*
9. *L is the language-preservation row comparing the source grammar and the normal-form grammar through finite derivation trees and finite word reads.*
10. *H records componentwise* hsame *transport for the source grammar, vocabulary rows, start row, production-shape row, elimination ledgers, binarization ledger, language-preservation row, replay, provenance, and naming rows.*
11. *C records displayed* Cont *replay from a grammar consumer through $G, N, T, S, P, E, U, B, L$.*
12. *K is the* Pkg *provenance over* $\mathsf{ChomskyNormalForm}^{\uparrow}$, $\mathsf{ContextFreeGrammar}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{RegularLanguage}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
13. *A is the local* $\mathsf{NameCert}_{\mathsf{ChomskyNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an unrestricted grammar quotient, an erased derivation equivalence, a host parser, countable grammar enumeration, or ambient language equality.

Theorem 5862.2 (ChomskyNormalForm NameCert obligations)**.** *For every accepted* $\mathsf{ChomskyNormalForm}^{\uparrow}$ *carrier*

$$F = (G, N, T, S, P, E, U, B, L, H, C, K, A),$$

the local $\mathsf{NameCert}_{\mathsf{ChomskyNormalForm}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed grammar rows, production-shape certification, empty-production handling, unit-production elimination, binarization, language-preservation readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside the finite rows of F.*

Proof. Carrier admission is projection from Definition 5862.1. The packet displays the source grammar, the normal-form vocabulary, the start row, the production-shape row, the nullable and unit ledgers, the binarization ledger, the language-preservation row, and the structural rows.

Production-shape certification is read from P. The row admits only terminal productions, binary nonterminal productions, and the displayed start-empty case, so the local certificate has no remaining route to arbitrary grammar productions.

Empty-production and unit-production handling are read from E and U. These ledgers record the finite eliminations before L may compare languages, preventing a consumer from replacing the construction by an erased grammar equivalence.

Binarization is read from B, and language preservation is read from L. The structural rows H, C, K, A transport, replay, source, and name the same finite route, while no carrier coordinate contains a quotient grammar, host parser, countable enumeration, or ambient language equality. □

Theorem 5862.3 (ChomskyNormalForm CFG handoff)**.** *Every* $\mathsf{ContextFreeGrammar}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{ChomskyNormalForm}^{\uparrow}$ *packet must pass through the displayed route*

$$G \longrightarrow E, U, B \longrightarrow P \longrightarrow L$$

and then through H, C, K, A. Thus the packet hands a context-free grammar to downstream normal-form consumers only after the empty-production ledger, unit-production ledger, binarization ledger, production-shape row, and language-preservation row have been displayed. It does not export a host

parser, a quotient grammar equality, an erased derivation equivalence, a countable-choice grammar selector, or ambient language extensionality.

Proof. Begin with a consumer read of the source grammar row G. The carrier does not expose the normal-form grammar as a bare replacement; it orders the read through the finite ledgers E, U, B.

The production-shape row P is downstream of those ledgers. It verifies that the resulting productions have the Chomsky-normal-form shape before a language-facing read is available.

The language-preservation row L then compares only finite derivation-tree and finite word reads. Finally H, C, K, A transport, replay, source, and name that route for CFG consumers. Since the excluded parser, quotient, erased-equivalence, selector, and ambient-extensionality objects are absent from the carrier, the handoff is exactly the displayed finite BEDC route. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChomskyNormalForm}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChomskyNormalForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5862.1, Definition 5862.2, and Definition 5862.3 seed the finite context-free grammar route from source grammar rows through Chomsky-normal-form ledgers to language-preservation readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChomskyNormalForm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close parser implementation, quotient grammar equality, erased derivation equivalence, countable grammar selection, ambient language extensionality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, production-shape exactness, empty-production handling, unit-production elimination, binarization, language-preservation readback, transport, replay, provenance, and local naming for BEDC.Derived.ChomskyNormalFormUp.

Constructive story: A $\mathsf{ChomskyNormalForm}^{\uparrow}$ packet is generated from a source CFG row, normal-form vocabulary rows, a start row, production-shape evidence, nullable and unit-production ledgers, a binarization ledger, language-preservation readback, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Chapter 5863

A Concrete Naming Certificate for $\mathsf{FiniteFanTheorem}^{\uparrow}$

Following Brouwer and Bishop-style finite fan practice, the $\mathsf{FiniteFanTheorem}^{\uparrow}$ packet records the bounded bar evidence that a Cantor or Baire prefix consumer may inspect before it exports a finite branch-window conclusion. It sits after the $\mathsf{StreamName}^{\uparrow}$ finite-window interface of chapter 126, the binary prefix carrier of chapter 1475, the countable prefix carrier of chapter 334, the endpoint rows of chapter 32, and the unary depth ledger of chapter 28. The chapter names a finite prefix-bar packet; it does not claim open-cover compactness, countable choice, selected branches, quotient stream equality, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5863.1 (Finite fan theorem carrier)**.** *A* $\mathsf{FiniteFanTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{B} = (S, C, B, I, W, H, T, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *prefix-window row, exposing the finite observation schedule read by every branch-facing consumer.*
2. *C is the* $\mathsf{CantorSpace}^{\uparrow}$ *tree row, recording binary prefix extensions, Boolean endpoint labels, and the Cantor branch rows retained by the fan packet.*
3. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *branch row, recording the countable prefix route through which Baire-style consumers reuse the same finite observation window.*
4. *I is the* $\mathsf{Bool}^{\uparrow}$ *and* $\mathsf{Nat}^{\uparrow}$ *finite prefix ledger, pairing endpoint decisions with unary prefix-depth indices and branch-length comparisons.*
5. *W is the finite bar-window row. It lists the prefixes inspected at the displayed depths and the bar decision read at each retained prefix.*
6. *H records componentwise* hsame *transport for the StreamName, CantorSpace, BaireSpace, prefix-ledger, bar-window, traversal, provenance, and local naming rows.*
7. *T records displayed* Cont *traversal from a branch request through S, C, B, I, W, H and into the local certificate.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteFanTheorem}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{CantorSpace}^{\uparrow}$*,* $\mathsf{BaireSpace}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{FiniteFanTheorem}^{\uparrow}}$ *row.*
The carrier has no coordinate for an infinite branch, a selected bar witness, countable choice, open-cover compactness, quotient stream equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteFanTheoremUp.FiniteFanTheoremTasteGate single carrier alignment`

Theorem 5863.2 (Finite fan theorem NameCert obligations)**.** *For every accepted* $\mathsf{FiniteFanTheorem}^{\uparrow}$ *carrier*

$$\mathcal{B} = (S, C, B, I, W, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteFanTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed StreamName prefix windows, CantorSpace tree rows, BaireSpace branch rows, Bool and Nat finite prefix ledger, finite bar-window row, componentwise* hsame *transport, displayed* Cont *traversal,* Pkg *provenance, and local naming. Every public read of the packet must inspect S before C or B, must read the finite prefix ledger I before the bar window W, and must pass through H, T, P, N before export.*

Thus a downstream fan, Cantor, Baire, Real, or Completion consumer receives only finite prefix-bar evidence. The packet exports no open-cover compactness theorem, countable-choice selector, selected branch, quotient stream equality, or $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Carrier admission is projection from Definition 5863.1. The accepted packet displays exactly the StreamName window, Cantor tree, Baire branch, finite prefix ledger, bar window, transport, traversal, provenance, and local naming rows.

The prefix order is forced by the carrier. A branch-facing request first reads S as the finite observation schedule, then reads the Cantor and Baire rows C, B only through the prefixes exposed by that schedule.

The bar evidence is finite because I and W are displayed ledgers. The Bool endpoint rows and Nat depth rows in I determine which retained prefixes are inspected, and W records the corresponding bar decisions without adding an infinite branch or a choice-selected witness.

Finally H, T, P, N transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for open covers, countable choice, selected branches, quotient streams, or completed real data, the listed rows exhaust the local NameCert surface. □

Theorem 5863.3 (Finite fan prefix-order exactness)**.** *Let*

$$\mathcal{B} = (S, C, B, I, W, H, T, P, N)$$

be an accepted $\mathsf{FiniteFanTheorem}^{\uparrow}$ *carrier. Every accepted branch-facing read exposes the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row S before it can read either the* $\mathsf{CantorSpace}^{\uparrow}$ *prefix row C or the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix row B, and exposes the* $\mathsf{Nat}^{\uparrow}$ *depth ledger inside I before it can read the finite bar-window row W.*

Consequently the public prefix order of the packet is exactly

$$S \longrightarrow C, B \quad \textit{and} \quad I \longrightarrow W$$

with all exported reads then transported and named through H, T, P, N.

Proof. Project the accepted packet through Definition 5863.1. The row S is the only displayed finite observation schedule for branch-facing consumers, while C and B are retained as tree and branch prefix rows read through that schedule.

The depth order is also a carrier projection. The row I pairs Boolean endpoint decisions with Nat depth indices and branch-length comparisons, while W only lists the prefixes inspected at the displayed depths. Thus W cannot be read before the depth coordinates in I have been exposed.

Finally H, T, P, N preserve the same ordered rows under transport, traversal, provenance, and local naming. No listed carrier row supplies an alternate prefix order. □

Theorem 5863.4 (Finite fan bar-window coverage)**.** *For every accepted* $\mathsf{FiniteFanTheorem}^{\uparrow}$ *carrier*

$$\mathcal{B} = (S, C, B, I, W, H, T, P, N),$$

each accepted finite bar window in W *is covered by a displayed finite prefix family read from* S, C, B, I*. The bar-window read cannot inspect a branch outside the recorded* $\mathsf{Bool}^{\uparrow}/\mathsf{Nat}^{\uparrow}$ *finite ledger* I*, and every prefix used by the read is one of the prefixes retained by the finite observation schedule* S *and the Cantor or Baire prefix rows* C, B*.*

Proof. Use the carrier rows from Definition 5863.1. The finite observation schedule S records the inspected windows, the Cantor and Baire rows C, B retain the branch prefixes available to the packet, and I records the Boolean endpoint labels and Nat depth comparisons.

The bar row W is defined only as a finite bar-window row over those displayed depths. Hence an accepted read of W is already indexed by the prefixes and depths carried by S, C, B, I; there is no carrier coordinate for a branch outside that finite ledger.

The transport and replay rows do not add new branches. They move the same finite family through H, T, P, N, so coverage remains exactly the displayed finite prefix family. □

Theorem 5863.5 (Finite fan nonescape)**.** *Let*

$$\mathcal{B} = (S, C, B, I, W, H, T, P, N)$$

be an accepted $\mathsf{FiniteFanTheorem}^{\uparrow}$ *carrier. Any consumer reaching the local* $\mathsf{NameCert}_{\mathsf{FiniteFanTheorem}^{\uparrow}}$ *row* N *factors through* $S, C, B, I, W, H, T, P, N$ *and therefore exports no open-cover compactness, countable choice, selected infinite branch, or quotient stream equality.*

Proof. Carrier admission gives the complete row list $S, C, B, I, W, H, T, P, N$. A consumer that reaches N must first pass through the displayed traversal row T, provenance row P, and transport row H attached to the same finite prefix-bar packet.

The source rows are exhausted by S, C, B, I, W. These rows carry finite windows, prefix trees, branch rows, endpoint and depth ledgers, and finite bar decisions only. None of them contains an open cover, a countable-choice selector, an infinite branch choice, or a quotient equality of streams.

Thus the local naming row can export only the displayed finite packet. The nonlisted principles are outside the carrier and cannot be recovered by a NameCert consumer. □

Falsifiable prediction: Every $\mathsf{FiniteFanTheorem}^{\uparrow}$ branch-facing read factors through one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{CantorSpace}^{\uparrow}$ binary tree row, one $\mathsf{BaireSpace}^{\uparrow}$ branch row, one combined $\mathsf{Bool}^{\uparrow}$ and $\mathsf{Nat}^{\uparrow}$ finite prefix ledger, one finite bar-window row, componentwise hsame transport, displayed Cont traversal, Pkg provenance, and local naming.

Independence witness: streamname, cantorspace, bairespace, bool, nat: $\mathsf{FiniteFanTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries binary and countable prefix rows with a finite bar-window ledger as one branch-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteFanTheorem}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteFanTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5863.1 and Definition 5863.2 seed the finite prefix-bar route through StreamName$^{\uparrow}$, CantorSpace$^{\uparrow}$, BaireSpace$^{\uparrow}$, Bool$^{\uparrow}$, and Nat$^{\uparrow}$ rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteFanTheorem}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected branches, quotient stream equality, Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-order exactness, finite bar-window coverage, componentwise transport, traversal replay, provenance, local naming, and non-escape for BEDC.Derived.FiniteFanTheoremUp.

Constructive story: A FiniteFanTheorem$^{\uparrow}$ packet is generated from finite StreamName windows, CantorSpace tree rows, BaireSpace branch rows, Bool endpoint decisions, Nat depth indices, a finite bar-window ledger, componentwise transport, displayed traversal, package provenance, and a local NameCert row.

Chapter 5864

A Concrete Naming Certificate for $\mathsf{SpecializationOrder}^{\uparrow}$

Following Alexandroff and standard topology, the specialization preorder of a topological space is read through open-neighbourhood implication rather than host point equality. The $\mathsf{SpecializationOrder}^{\uparrow}$ packet sits after the indexed-open topology of chapter 88, the observable-open truth classifier of chapter 1860, the membership discipline of chapter 3668, and the separated order surface of chapter 53. It is also the topology-side order interface consumed by the metric-generated topology handoff of chapter 1655. The packet names only finite open-set implication data; it does not import quotient point equality, selected representatives, powerset extensionality, excluded middle over opens, or choice-based separation.

Definition 5864.1 (SpecializationOrder carrier)**.** *A* $\mathsf{SpecializationOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, O, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the topology row, carrying the accepted indexed-open source, finite open-neighbourhood requests, and topology closure witnesses read from chapter 88.*
2. *O is the open-set membership classifier, recording for each displayed point and accepted open index whether the point is observed inside that open through the local open-row interface.*
3. *R is the specialization relation row. A displayed comparison $x \leq_{\mathsf{spec}} y$ is admitted only when every open-membership read true at x in O is replayed as true at y through the same topology row T.*
4. *H records componentwise* hsame *transport for the topology row, open-set membership classifier, specialization relation row, replay, provenance, and local naming rows.*
5. *C records displayed* Cont *replay from an open-neighbourhood request through T and O into the specialization relation row R.*
6. *P is the* Pkg *provenance over* $\mathsf{SpecializationOrder}^{\uparrow}$*, the topology, Sierpinski, SetLike, Poset, metric-topology,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *surfaces.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{SpecializationOrder}^{\uparrow}}$ *row.*

The carrier has no coordinate for host point equality, quotient points, selected separated representatives, powerset equality of opens, excluded middle over open membership, or choice-based separation.

Lean4 ✓ `BEDC.Derived.SpecializationOrderUp.SpecializationOrderTasteGate single carrier alignment`

Theorem 5864.2 (SpecializationOrder NameCert obligations)**.** *For every accepted* $\mathsf{SpecializationOrder}^{\uparrow}$ *carrier* $K = (T, O, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SpecializationOrder}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the topology row, open-set membership classifier, specialization relation row, transport, replay, provenance, and local naming;*
2. *classifier transport, requiring* H *to preserve every open-membership read in* O *along displayed* hsame *moves;*
3. *reflexivity, read by replaying each open-membership observation for a point back to the same point through* O*;*
4. *transitivity, read by composing two displayed open-neighbourhood implication rows inside* R*;*
5. *topology handoff, requiring every public order comparison to factor through the indexed-open row* T *before it reaches* R*;*
6. *sibling nonescape, forbidding quotient point equality, host separation, selected representatives, powerset extensionality, excluded middle, and choice data not displayed in* K*;*
7. *local naming through the provenance row* P *and the local certificate row* N*.*

These rows exhaust the packet obligations. A downstream T0-reflection, formal-topology, metric-topology, or separated-order consumer receives only the displayed open-neighbourhood implication route.

Proof. Carrier admission is projection from Definition 5864.1. The packet exposes only T, O, R, H, C, P, N, so each local obligation must be read from the topology row, the open-membership classifier, the specialization relation, or the structural rows.

Classifier transport is componentwise. The H row moves topology indices, point reads, open-membership observations, and specialization comparisons together, so an accepted classifier read cannot detach from the topology row that generated it.

Reflexivity and transitivity are internal to R. Reflexivity reuses the same open-membership read at the same point, while transitivity composes the two displayed implication routes through the common open index. No quotient or host equality coordinate is involved.

The topology handoff and sibling nonescape follow from the carrier boundary. Every public order read passes through T and O before R, and the rows P, N name only that route. Since quotient points, selected representatives, powerset extensionality, excluded middle, and choice-based separation are absent from the packet, none can be exported as a NameCert obligation. □

Theorem 5864.3 (SpecializationOrder topology handoff)**.** *Every accepted* $\mathsf{SpecializationOrder}^{\uparrow}$ *packet reads its preorder only from open-set implication:*

$x \leq_{\mathsf{spec}} y$ *means that every displayed open-neighbourhood read true at* x *is replayed as true at* y*.*

The handoff exports no quotient point equality, no selected representative, and no choice-based separation principle.

Proof. Start with an accepted carrier $K = (T, O, R, H, C, P, N)$. The topology row T supplies the only accepted open indices, and O supplies the only membership reads for those opens.

The specialization row R is defined as the replay of those membership reads from source point to target point. Thus a preorder comparison can be inspected by checking the displayed implication from each open-neighbourhood observation at x to the corresponding observation at y.

Finally H, C, P, N preserve, replay, source, and name that same implication route. The carrier has no coordinate for quotient points, selected representatives, host equality, or choice-based separation, so the topology handoff cannot export any of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{SpecializationOrder}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpecializationOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5864.1, Definition 5864.2, and Definition 5864.3 seed the open-neighbourhood implication interface between topology rows and order-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpecializationOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient point equality, T0 reflection, formal topology, metric separation, choice-based separation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, open-membership classifier transport, reflexivity, transitivity, topology handoff, sibling nonescape, provenance, and local naming for BEDC.Derived.SpecializationOrderUp.

Constructive story: A $\mathsf{SpecializationOrder}^{\uparrow}$ packet is generated from a topology row, an open-set membership classifier, a specialization relation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5865

A Concrete Naming Certificate for $\mathsf{FiniteModulusReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteModulusReal}^{\uparrow}$ packet records a real-name route whose modulus ledger is finite and explicit at every consumer read. It sits between the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the real-modulus criterion of chapter 3415. The packet gives Real and Completion consumers a modulus-visible carrier without quotienting Cauchy streams, selecting host limits, invoking countable choice, or asserting ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5865.1 (FiniteModulusReal carrier)**.** *A* $\mathsf{FiniteModulusReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, R, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, naming exactly the finite observation windows read by the carrier at the requested precision.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, translating the inspected stream windows into regular rational approximation data.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic scales and comparison rows used by the displayed approximations.*
4. *M is the explicit finite modulus ledger, assigning to each retained precision request the finite window of S and dyadic tolerance data in D required before the readback row R may be consumed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after S, R, D, M have been displayed.*
6. *H records componentwise* hsame *transport for the stream windows, regular readback, dyadic tolerance ledger, finite modulus ledger, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite Real or Completion read through S, R, D, M, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteModulusReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *the real-modulus criterion,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, M, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected host limits, countable choice, undecorated Real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteModulusRealUp.FiniteModulusRealTasteGate single carrier alignment`

Theorem 5865.2 (FiniteModulusReal NameCert obligations)**.** *For every accepted* $\mathsf{FiniteModulusReal}^{\uparrow}$ *carrier*

$$F = (S, R, D, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteModulusReal}^{\uparrow}}$ *surface consists exactly of carrier admission for stream windows, regular rational readback, dyadic tolerances, explicit finite modulus rows, terminal Real seal routing, componentwise transport, displayed continuation replay, package provenance, and local naming. Every Real or Completion consumer read of the packet must expose the finite modulus row M before it consumes R or E.*

Proof. Project the carrier of Definition 5865.1. The analytic rows are S, R, D, M, E, and the structural rows H, C, P, N transport, replay, source, and name the same packet.

The read order is finite. A precision request first selects the window named in S and the dyadic tolerance data recorded in D. The finite modulus ledger M binds those two rows to the requested read before the regular rational row R may be consumed.

The terminal seal E is downstream of S, R, D, M. Componentwise transport through H and continuation replay through C preserve the same displayed rows, while P and N record provenance and local naming. Since the carrier has no additional coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5865.3 (FiniteModulusReal RegSeqRat handoff)**.** *For every accepted* $\mathsf{FiniteModulusReal}^{\uparrow}$ *carrier $F = (S, R, D, M, E, H, C, P, N)$, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R is consumed only after the finite stream windows S, dyadic tolerance ledger D, and explicit modulus ledger M have been displayed. Thus downstream regular rational consumers receive a finite modulus-indexed approximation route, not a quotient Cauchy stream or selected host limit.*

Proof. Project Definition 5865.1. The row R is the only regular rational readback coordinate, and it is listed after the stream-window row S, dyadic tolerance ledger D, and explicit finite modulus ledger M.

Apply Definition 5865.2. A consumer read must expose M before consuming R, so the demanded regular rational approximation is tied to a displayed finite window and a displayed dyadic tolerance row.

Transport and replay add no hidden readback source. The rows H, C, P, N preserve and name the same finite route, so a downstream $\mathsf{RegSeqRat}^{\uparrow}$ consumer cannot inspect quotient stream equality, a selected limit, countable choice, or ambient Real completeness through this handoff. □

Theorem 5865.4 (FiniteModulusReal Real seal nonescape)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal read of an accepted* $\mathsf{FiniteModulusReal}^{\uparrow}$ *carrier factors through*

$$S, D, M \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

No Real or Completion consumer can bypass the explicit finite modulus ledger before reading the terminal seal.

Proof. Start with an accepted packet $F = (S, R, D, M, E, H, C, P, N)$. By Definition 5865.1, the only terminal Real boundary is the row E.

Use Definition 5865.2. The seal row E is downstream of the stream windows, dyadic tolerance ledger, explicit modulus ledger, and regular rational readback. Therefore a consumer that has not displayed S, D, M, R has not reached the packet's terminal seal.

The structural rows do not create another Real-facing boundary. They transport, replay, source, and name the same finite packet, so the seal route cannot escape to quotient equality, selected host limits, countable choice, undecorated Real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: An accepted $\mathsf{FiniteModulusReal}^{\uparrow}$ consumer that reaches $\mathsf{RegSeqRat}^{\uparrow}$ readback or the terminal $\mathsf{Real}^{\uparrow}$ seal without the displayed finite modulus ledger M refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real, real-modulus-criterion: no listed sibling supplies the whole nine-row packet $F = (S, R, D, M, E, H, C, P, N)$, because each sibling contributes finite windows, regular readback, dyadic tolerance data, terminal Real sealing, or a modulus criterion while this chapter binds them into one local NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteModulusReal}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteModulusReal}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, an explicit finite modulus ledger, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteModulusReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5865.1, Definition 5865.2, Definition 5865.3, and Definition 5865.4 seed the finite explicit-modulus Real carrier over StreamName, RegSeqRat, DyadicRatCore, Real, and real-modulus criterion rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteModulusReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected host limits, countable choice, undecorated Real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, dyadic tolerance exactness, explicit modulus routing, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteModulusRealUp.

Chapter 5866

A Concrete Naming Certificate for $\mathsf{CompactUniformSubordinateCover}^{\uparrow}$

Following Heine–Cantor and Bishop–Bridges constructive analysis, the $\mathsf{CompactUniformSubordinateCover}^{\uparrow}$ packet records the subordinate finite cover used before the compact-uniform-continuity lower-bound fold in chapter 9237. It sits over the compact source of chapter 60, the metric source of chapter 57, the continuous-map pointwise modulus rows of chapter 59, the rational positivity surface of chapter 37, and the sibling subordinate-cover packets of chapter 596 and chapter 3937. The packet names the finite ProbeBundle cover and its lower-bound handoff; it does not export open-cover compactness, a host Lebesgue number, a selected subcover, quotient point equality, or an external modulus function.

Definition 5866.1 (Compact-uniform subordinate-cover carrier)**.** *A* $\mathsf{CompactUniformSubordinateCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, G, Q, F, L, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row, combining the* $\mathsf{Compact}^{\uparrow}$ *admission and the* $\mathsf{Met}^{\uparrow}$ *distance carrier over the same source.*
2. *G is the continuous graph row, exposing pointwise modulus requests for the same source and target metric carriers.*
3. *Q is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance row read by the pointwise-modulus requests.*
4. *F is the finite* ProbeBundle *subordinate-cover row, naming bundled centers, coverage witnesses, and the source-distance windows attached to those centers.*
5. *L is the rational lower-bound fold over the displayed subordinate radii in F.*
6. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced only after K, G, Q, F, L have been displayed.*
7. *H records componentwise* hsame *transport for K, G, Q, F, L, M and for the replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from compact-source inspection through pointwise-modulus reads, finite-cover coverage, rational lower-bound folding, and uniform-modulus handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformSubordinateCover}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, Pkg, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactUniformSubordinateCover}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, G, Q, F, L, M, H, C, P, N$. It has no coordinate for open-cover compactness, host lower-bound extraction, a selected infinite subcover, quotient point equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactUniformSubordinateCoverUp.CompactUniformSubordinateCoverTasteGate single carrier alignment`

Theorem 5866.2 (Compact-uniform subordinate cover handoff)**.** *For every accepted* CompactUniformSubordinateC *carrier $U = (K, G, Q, F, L, M, H, C, P, N)$, the finite* ProbeBundle *row F is the unique subordinate-cover input to the uniform-modulus handoff. A consumer reaches M only by first reading the compact metric source K, the continuous graph row G, the positive rational tolerance row Q, the bundled center and coverage row F, and the rational lower-bound fold L, with H, C, P, N preserving that route.*

Consequently the packet supplies the ProbeBundle modulus-fold route used in chapter 9237 without exposing open-cover compactness, a host Lebesgue-number choice, a selected subcover, quotient point equality, or an external modulus selector.

Proof. Project the carrier of Definition 5866.1. The compact metric source is K, the continuous graph row is G, the tolerance row is Q, the finite subordinate cover is F, the rational lower-bound fold is L, and the uniform-modulus handoff is M.

The cover row F is the only coordinate carrying bundled centers and coverage witnesses. Thus every local pointwise-modulus read used by the handoff is tied to a displayed probe name and to the same source metric row in K.

The fold row L is read after F and before M. It computes the tolerance-only radius through finite rational data rather than through a host minimum or an external Lebesgue-number selector.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no coordinate for the excluded host objects, every $\mathsf{UniformModulus}^{\uparrow}$ consumer of M factors through the displayed subordinate cover. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformSubordinateCover}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactUniformSubordinateCover}^{\uparrow}$ packet is generated from CompactUp and MetricUp source rows, ContinuousUp pointwise-modulus rows, RatUp tolerance rows, a finite ProbeBundle subordinate-cover row, a rational lower-bound fold, a UniformModulusUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactUniformSubordinateCover}^{\uparrow}}$, seed)

Scope closed: Definition 5866.1 and Definition 5866.2 seed the finite subordinate-cover carrier used before compact-uniform-continuity lower-bound folding.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactUniformSubordinateCover}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CompactUniformSubordinateCoverUp.CompactUniformSubordinateCoverTasteGate\_single\_carri`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host lower-bound extraction, selected infinite subcovers, quotient point equality, countable choice, ambient RealUp completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact metric source exposure, continuous graph exposure, RatUp tolerance exposure, ProbeBundle coverage exactness, rational lower-bound folding, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformSubordinateCoverUp.

Chapter 5867

A Concrete Naming Certificate for $\mathsf{BishopIntervalContraction}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopIntervalContraction}^{\uparrow}$ packet records a finite interval-contraction handoff from located bisection data to regular Cauchy names. It consumes the located bisection route of chapter 1711, the dyadic arithmetic ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite L10 neighbor of interval bisection and regular Cauchy handoff; it is not a quotient real construction, a selected infinite branch, a host fixed-point theorem, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5867.1 (Bishop interval contraction carrier)**.** *A* $\mathsf{BishopIntervalContraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, F, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located source interval row, carrying endpoints, locator evidence, and the admitted interval boundary as BEDC data.*
2. *F is the contraction self-map row, recording the displayed map on the interval together with its contraction witness.*
3. *L is the Lipschitz or shrinkage ledger, exposing the dyadic contraction budget and the requested depth.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *midpoint and error ledger used by the retained interval windows.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row recording which contraction stages are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic tolerances.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, F, L, D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the interval, contraction, dyadic, stream, regular-rational, real-seal, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the interval-contraction request through I, F, L, D, W, R, E, H.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalContraction}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalContraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient real equality, a chosen infinite branch, a host contraction theorem, selected limits, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.BishopIntervalContractionUp.BishopIntervalContractionTasteGate single carrier alignment`

Theorem 5867.2 (Bishop interval contraction NameCert obligations)**.** *For every accepted* BishopIntervalContractio *carrier*

$$B = (I, F, L, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopIntervalContraction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed located interval, contraction self-map, dyadic shrinkage ledger, finite windows, regular rational readback, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *contraction stability, requiring every replayed self-map read to preserve the located source interval through I and to expose its shrinkage budget through L, D;*
3. *bisection compatibility, requiring the retained interval windows to factor through the located interval bisection route before any* $\mathsf{StreamName}^{\uparrow}$ *window or* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is consumed;*
4. *dyadic budget exactness, requiring every tolerance request to read the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *midpoint and error ledger D before it reaches W, R, E;*
5. *Cauchy handoff, requiring the completion-facing consumer to pass through W, R, E, H, C, P, N after the interval and contraction rows have been displayed.*

No NameCert obligation is stored outside $I, F, L, D, W, R, E, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.BishopIntervalContractionUp.BishopIntervalContractionCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 5867.1. The accepted packet displays the located interval, contraction, dyadic ledger, finite windows, regular readback, real seal, transport, replay, provenance, and local naming rows.

Contraction stability is read through I, F, L, D. The self-map row F is not a host function detached from the interval; it is paired with the located interval row I and with the shrinkage ledger L, D.

Bisection compatibility follows from the dependency route. A retained interval window must be displayed before a stream or regular-rational readback can be consumed, so the packet reaches W and R only after the located bisection and dyadic rows have been read.

Finally, the handoff rows E, H, C, P, N preserve the same finite route. Since the carrier contains no quotient equality, selected branch, host contraction theorem, selected limit, countable-choice row, or ambient completeness coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 5867.3 (Bishop interval contraction Cauchy handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopIntervalContraction}^{\uparrow}$ *packet must read the finite route*

$$I, F, L, D \longmapsto W, R, E \longmapsto H, C, P, N$$

before it can treat the contraction stages as a regular Cauchy real name. The consumer receives located interval data, a displayed contraction self-map, dyadic shrinkage budgets, finite stream windows, regular rational readback, a terminal real seal, componentwise transport, continuation replay, provenance, and local naming. It receives no quotient completion, selected limit, chosen infinite branch, countable choice, host fixed-point object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.BishopIntervalContractionUp.BishopIntervalContractionCauchyHandoff`

Proof. Start with the interval-contraction request. The source interval is read through I, while the self-map and contraction budget are read through F, L, D.

The finite windows then expose the Cauchy route. The row W records the inspected contraction stages, and R reads the corresponding regular rational approximants against the same dyadic tolerance ledger.

The terminal seal E is reached only after those rows are present. The structural rows H, C, P, N transport, replay, source, and name the same route for downstream completion consumers.

Thus the packet hands off a regular Cauchy name through displayed BEDC rows. No quotient completion, selected limit, chosen infinite branch, countable-choice row, host fixed-point object, or ambient real-completeness coordinate is present in the carrier. □

Theorem 5867.4 (Bishop interval contraction RegSeqRat endpoint stability)**.** *Let* $B = (I, F, L, D, W, R, E, H, C,$ *be an accepted* $\mathsf{BishopIntervalContraction}^{\uparrow}$ *carrier. If the contraction route preserves the located interval row* I *and the shrinkage ledger rows* L, D*, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *is stable under componentwise* hsame *transport before the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is passed to fixed-point endpoint consumers.*

Lean4 ✓ `BEDC.Derived.BishopIntervalContractionUp.BishopIntervalContractionRegSeqRatEndpointStability`

Proof. Project the carrier definition Definition 5867.1. The regular readback row R is downstream of the located interval, contraction, shrinkage, dyadic, and finite-window rows.

Apply the NameCert obligations of Definition 5867.2. They require contraction stability through I, F, L, D and bisection-compatible windows before the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows can be consumed.

Use the Cauchy handoff theorem Definition 5867.3. It places R on the same displayed route as I, F, L, D, W and exposes the terminal $\mathsf{Real}^{\uparrow}$ seal E only after that route has been read.

The componentwise hsame row H therefore transports the readback without changing the endpoint corridor. The packet supplies no host fixed-point object, chosen limit, quotient completion, countable-choice row, or ambient Real-completeness datum, so fixed-point endpoint consumers receive only the displayed RegSeqRat-to-Real handoff. □

Theorem 5867.5 (Bishop interval contraction endpoint readback)**.** *Every fixed-point endpoint consumer reading the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *from an accepted* $\mathsf{BishopIntervalContraction}^{\uparrow}$ *packet must first read the located interval row* I*, the contraction row* F*, the shrinkage ledger* L, D*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the structural rows* H, C, P, N*. Only after that displayed L10 route is present may the consumer hand* E *to* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *or* $\mathsf{BanachFixedPointStability}^{\uparrow}$*. The readback exports no host fixed point, chosen limit, quotient completion, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopIntervalContractionUp.BishopIntervalContractionEndpointReadback`

Proof. Project the accepted carrier of Definition 5867.1. The endpoint row E is terminal in the displayed inventory, and the only rows preceding it are the located interval, contraction, shrinkage, dyadic, window, and regular-rational readback rows.

Apply the Cauchy handoff of Definition 5867.3. It forces every completion-facing consumer to pass through $I, F, L, D, W, R, E, H, C, P, N$ before treating the contraction stages as a regular Cauchy real name.

The fixed-point endpoint consumer is a special consumer of that route. It may pass the terminal seal onward to $\mathsf{BishopFixedPointInterval}^{\uparrow}$ or $\mathsf{BanachFixedPointStability}^{\uparrow}$, but the handoff carries only the displayed rows and none of the excluded host fixed-point or completeness data. □

Theorem 5867.6 (Bishop interval contraction shrinkage composition)**.** *Let $B = (I, F, L, D, W, R, E, H, C, P, N)$ be an accepted $\mathsf{BishopIntervalContraction}^{\uparrow}$ carrier. If two accepted contraction-stage reads share the located interval row I and expose their shrinkage ledgers through the displayed rows L, D, then their composed finite stage route reaches W, R, E, H, C, P, N only through that same dyadic shrinkage budget. The composition exports no host fixed-point composition, selected limit, quotient completion, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.*

Proof. Project the carrier of Definition 5867.1. The only rows available for contraction-stage reads are the located interval row I, the contraction row F, and the shrinkage ledger rows L, D before any stream or completion-facing data is visible.

Use the NameCert obligations of Definition 5867.2. They force contraction stability through I, F, L, D, so two stage reads sharing I can be composed inside the certificate only by replaying the displayed dyadic shrinkage ledger.

Apply the Cauchy handoff of Definition 5867.3. The composed stage route reaches the finite windows W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E after the shared interval and shrinkage rows have been read.

Finally use endpoint readback from Definition 5867.5. The structural rows H, C, P, N preserve the same route for endpoint consumers, and no carrier coordinate supplies a host composition theorem, a selected fixed point, quotient completion, countable choice, or ambient Real completeness. □

Falsifiable prediction: An accepted $\mathsf{BishopIntervalContraction}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without reading the displayed rows $I, F, L, D, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: located-interval-bisection, dyadicratcore, streamname, regseqrat, real, bishop-fixed-point-interval: no listed sibling supplies the joint packet containing a located interval source, contraction self-map, dyadic shrinkage ledger, finite windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalContraction}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalContraction}^{\uparrow}$ packet is generated from a located interval row, a contraction self-map row, a dyadic shrinkage ledger, StreamName finite windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalContraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5867.1, Definition 5867.2, and Definition 5867.3 seed the finite interval-contraction route from located bisection and dyadic shrinkage data to regular Cauchy and Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalContraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient real equality, selected limits, chosen infinite branches, countable choice, a host fixed-point theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, contraction stability, bisection compatibility, dyadic budget exactness, and Cauchy handoff for BEDC.Derived.BishopIntervalContractionUp.

Chapter 5868

A Concrete Naming Certificate for $\mathsf{SeminormedSpace}^{\uparrow}$

Following Bourbaki and Bishop–Bridges on seminormed and locally convex structures, the $\mathsf{SeminormedSpace}^{\uparrow}$ packet records the finite family-seminorm interface between the single norm route of chapter 1950, the displayed variation-seminorm ledger of chapter 5730, the locally convex family surface of chapter 3386, and completion-facing functional-analysis packets. It consumes the $\mathsf{VecSpace}^{\uparrow}$ source of chapter 47 and the $\mathsf{Real}^{\uparrow}$ scalar seal of chapter 38; it does not collapse finite seminorm families to one $\mathsf{Norm}^{\uparrow}$ row or to a host topology.

Definition 5868.1 (SeminormedSpace carrier)**.** *A* $\mathsf{SeminormedSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (V, R, I, F, Z, T, A, U, M, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *source row, exposing the vector carrier, classifier, zero vector, addition, negation, and scalar action only through displayed BEDC data.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar and budget row used by seminorm values, scalar absolute values, uniform entourages, and metric handoff tolerances.*
3. *I is the finite family-index row. It lists the displayed seminorm labels admitted by the packet and exposes no hidden index set.*
4. *F is the seminorm-family ledger. For each displayed index in I, it records the nonnegativity, zero-row compatibility, triangle, and scalar-budget rows of the corresponding seminorm read.*
5. *Z is the common zero-row compatibility ledger, comparing the vector zero classifier of V with every zero-value row displayed in F.*
6. *T is the triangle-budget ledger, routing every read of a displayed sum through vector addition in V, the selected seminorm row in F, and the real addition and order rows in R.*
7. *A is the scalar-budget ledger, routing every scalar multiplication read through scalar action in V, the absolute-value row in R, and the selected seminorm row in F.*
8. *U is the induced uniform-structure handoff row. It reads finite intersections of seminorm balls through I, F, R before any uniform consumer can inspect them.*
9. *M is the induced metric or pseudometric handoff row for downstream completion packets, available only after V, R, I, F, U have been displayed.*

10. *H records componentwise* hsame *transport for vector, Real, family-index, seminorm-ledger, zero, triangle, scalar, uniform, metric, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from every seminorm-family, uniform, or metric request through $V, R, I, F, Z, T, A, U, M, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{SeminormedSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{VariationSeminorm}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, *completion-facing functional-analysis rows,* BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{SeminormedSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host locally convex topology, a single hidden norm, a completed quotient, an unbounded seminorm index set, a selected Cauchy limit, or classical duality.

Lean4 ✓ `BEDC.Derived.SeminormedSpaceUp.TasteGate.SeminormedSpaceTasteGate single carrier alignment`

Theorem 5868.2 (SeminormedSpace NameCert obligations)**.** *For every accepted* $\mathsf{SeminormedSpace}^{\uparrow}$ *carrier*

$$S = (V, R, I, F, Z, T, A, U, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SeminormedSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed vector-space, Real, finite family-index, seminorm-family, zero, triangle, scalar, induced uniform, induced metric, transport, replay, provenance, and local naming rows;*
2. *family-index exposure, requiring every seminorm read to name an index from the finite row I before any value row in F can be consumed;*
3. *zero-row compatibility, requiring every zero seminorm read to compare with the displayed vector-zero classifier in V through Z and not through host vector equality;*
4. *triangle-budget routing, requiring reads of $p_i(x + y)$ to pass through vector addition in V, the i-row of F, and the addition and order rows of R;*
5. *scalar-budget routing, requiring reads of $p_i(ax)$ to pass through scalar action in V, the absolute-value and multiplication rows of R, and the selected seminorm row of F;*
6. *induced uniform and metric handoff, requiring U and M to be read only after V, R, I, F, Z, T, A are displayed;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming through H, C, P, N.*

No $\mathsf{SeminormedSpace}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5868.1. The accepted packet lists the vector-space, Real, finite index, seminorm-family, zero, triangle, scalar, uniform, metric, transport, replay, provenance, and local naming rows.

Family-index exposure comes next. A seminorm read first chooses a displayed index in I, and the corresponding row in F is the only place where nonnegativity, zero compatibility, triangle, and scalar-budget evidence may be read.

The zero, triangle, and scalar obligations are ledger routes. The row Z compares zero seminorm reads with the vector-zero classifier in V; the row T sends displayed sums through V, F, R; and the row A sends scalar multiples through V, R, F.

Finally U and M are handoff rows derived from the same family ledger. Transport, replay, provenance, and local naming preserve this route through H, C, P, N. Since the carrier has no host topology, hidden norm, completed quotient, unbounded index set, selected limit, or classical-duality coordinate, the listed rows exhaust the NameCert surface. □

Theorem 5868.3 (SeminormedSpace functional-analysis handoff)**.** *Every locally convex, variation-seminorm, normed-space comparison, or completion-facing functional-analysis consumer of an accepted* $\mathsf{SeminormedSpace}^{\uparrow}$ *packet must read the displayed route*

$$V, R, I, F, Z, T, A \longmapsto U, M \longmapsto H, C, P, N.$$

Thus the consumer receives a finite family of seminorm rows over $\mathsf{VecSpace}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, together with induced uniform and metric handoff data. It does not receive a single host norm, a host locally convex topology, an unbounded seminorm family, quotient completion, selected limits, or classical duality.*

Proof. Start with a downstream consumer request. A vector operation can be answered only from V, and a scalar or seminorm budget can be answered only after the Real row R and a displayed family index from I have been read.

Use Definition 5868.2. The seminorm-family ledger F is guarded by the zero, triangle, and scalar rows Z, T, A, so a consumer cannot inspect an induced uniform or metric handoff before the finite family surface has been exposed.

The rows U and M are therefore handoff rows rather than independent analytic objects. They package finite intersections of seminorm balls and metric or pseudometric reads for LocallyConvexSpace, VariationSeminorm, NormedSpace comparison, and completion-facing consumers.

The structural rows H, C, P, N transport, replay, source, and name the same packet. With no host norm, host locally convex topology, unbounded family, quotient completion, selected limit, or classical-duality row in the carrier, the displayed route is the entire handoff surface. □

Falsifiable prediction: An accepted $\mathsf{SeminormedSpace}^{\uparrow}$ consumer that reaches a locally convex, variation-seminorm, normed-space comparison, or completion-facing read without first exposing $V, R, I, F, Z, T, A, U, M, H, C, P, N$ refutes the packet.

Independence witness: normedspace, variation-seminorm, locally-convex-space, vecspace, real: no listed sibling is bijective to $\mathsf{SeminormedSpace}^{\uparrow}$ because this packet jointly binds finite family-index exposure, zero-row compatibility, triangle and scalar budget ledgers, induced uniform and metric handoff, transport, replay, provenance, and local naming over the displayed vector and Real rows.

Closure status for $\mathsf{NameCert}_{\mathsf{SeminormedSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SeminormedSpace}^{\uparrow}$ packet is generated from a displayed VecSpace row, a Real scalar row, a finite family-index row, a seminorm-family ledger, zero, triangle, and scalar budget ledgers, induced uniform and metric handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeminormedSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5868.1, Definition 5868.2, and Definition 5868.3 seed the finite family-seminorm interface consumed by locally convex, variation-seminorm, normed-space comparison, and completion-facing functional-analysis packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeminormedSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host locally convex topology, hidden single-norm reduction, unbounded seminorm families, quotient completions, selected limits, classical duality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, family-index exposure, zero-row compatibility, triangle and scalar budget routing, induced uniform and metric handoff, transport, replay, provenance, and local naming for BEDC.Derived.SeminormedSpaceUp.

Chapter 5869

A Concrete Naming Certificate for ReassignmentMassSubcube$^{\uparrow}$

The ReassignmentMassSubcube$^{\uparrow}$ packet realizes the maximum-mass subcube geometry branch of the DNA six-bit boundary tile analysis as finite NameCert data. It reads the reassignment weight row, the subcube mass ledger, and the nested maximum-mass subcube theorem of Definition 9462.1232 and Definition 9462.1233 through displayed codon-window and reassignment sibling packets. The packet consumes the CodonSixBitWindow$^{\uparrow}$ row of chapter 2234, the SixBoundaryTileCoverage$^{\uparrow}$ row of chapter 3470, the ReassignmentSupportCompression$^{\uparrow}$ row of chapter 3558, and the AlternativeCodeReassignmen row of chapter 3589 before any maximum-mass face can be named; it is not a biological mechanism claim, a host optimization oracle, or a hidden table-family search.

Definition 5869.1 (ReassignmentMassSubcube carrier)**.** *A* ReassignmentMassSubcube$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (W, B, S, A, R, Q, L, N, H, C, P, K)$$

with the following displayed rows:

1. *W is the* CodonSixBitWindow$^{\uparrow}$ *source-window row exposing the six coordinate bits for codon subcube reads.*
2. *B is the* SixBoundaryTileCoverage$^{\uparrow}$ *boundary-coverage row used to keep boundary-trigger coverage visible while subcubes are inspected.*
3. *S is the* ReassignmentSupportCompression$^{\uparrow}$ *support row, exposing the finite reassigned support and motif-cover surface.*
4. *A is the* AlternativeCodeReassignment$^{\uparrow}$ *comparison-table row from which reassignment weights are read.*
5. *R is the reassignment-weight row, recording each displayed codon weight $w(c)$ from the curated comparison surface.*
6. *Q is the finite subcube ledger, listing the inspected axis-aligned Q_5, Q_4, Q_3, Q_2 faces and their fixed-coordinate conditions.*
7. *L is the subcube-mass ledger, recording each displayed mass $M(S)$ as a finite sum over the visible weight row R.*
8. *N is the nested maximum-mass row, recording the unique maximum-mass chain $Q_5 \supset Q_4 \supset Q_3 \supset Q_2$ displayed by the source theorem.*

9. *H records componentwise* hsame *transport for source-window, boundary-coverage, support-compression, alternative-code, weight, subcube, mass, nested-chain, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from reassignment comparison to weights, from weights to finite subcube masses, and from masses to the nested maximum-mass row.*

11. *P is the* Pkg *provenance over* $\mathsf{ReassignmentMassSubcube}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{ReassignmentSupportCompression}^{\uparrow}$, $\mathsf{AlternativeCodeReassignment}^{\uparrow}$, *the source reassignment-mass geometry vision,* BHist, hsame, Cont, *and* NameCert.

12. *K is the local* $\mathsf{NameCert}_{\mathsf{ReassignmentMassSubcube}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve rows. It has no coordinate for uncurated code tables, stochastic evolutionary dynamics, biochemical causality, a host argmax operator, quotient codon equality, or hidden biological semantics.

Theorem 5869.2 (ReassignmentMassSubcube NameCert obligations)**.** *For every accepted* ReassignmentMassSubcu *carrier $M = (W, B, S, A, R, Q, L, N, H, C, P, K)$, the local* $\mathsf{NameCert}_{\mathsf{ReassignmentMassSubcube}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed codon window, boundary coverage, support compression, alternative-code comparison, reassignment-weight, finite subcube, mass, nested maximum-mass, transport, replay, provenance, and local naming rows. The mass row must compute only finite sums over the displayed weight row, and the nested row must expose the unique maximum-mass chain only after W, B, S, A, R, Q, L are visible.*

Proof. Project the carrier of Definition 5869.1. The first four rows provide the source coordinate, boundary coverage, reassignment support, and alternative-table comparison surfaces.

The weight row R is then a finite comparison read from A, and the subcube ledger Q lists the inspected axis-aligned faces over the six-bit source window W. The mass ledger L can therefore compute only finite sums of displayed weights.

The nested maximum-mass row N is downstream of those finite sums. It records the displayed chain from the vision theorem rather than invoking a host optimization oracle.

Finally H, C, P, K transport, replay, source, and name the same packet. Since no uncurated table family, stochastic dynamics, biochemical mechanism, host argmax, quotient codon equality, or hidden biological semantics occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 5869.3 (ReassignmentMassSubcube sibling route)**.** *Every accepted* $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ *read factors through*

$$\mathsf{CodonSixBitWindow}^{\uparrow}, \mathsf{SixBoundaryTileCoverage}^{\uparrow}, \mathsf{ReassignmentSupportCompression}^{\uparrow}, \mathsf{AlternativeCodeReassignment}^{\uparrow}$$

Thus a maximum-mass subcube claim is read as finite reassignment geometry over displayed codon coordinates, boundary-tile coverage, support compression, and alternative-code comparison rows. It cannot be consumed as a free-standing biological mechanism, host optimization theorem, unbounded genetic-code survey, or quotient of codon labels.

Proof. Begin with the sibling sources. The codon six-bit window supplies the coordinate carrier, the six-boundary tile coverage row keeps trigger support visible, the reassignment-support-compression row exposes the finite support surface, and the alternative-code-reassignment row supplies the comparison table data.

Only after those sources are displayed can the packet read reassignment weights and subcube masses. The rows R, Q, L bind the finite weights, inspected faces, and mass sums, while N records the nested maximum-mass chain.

The structural rows then preserve that route. Transport, replay, provenance, and local naming cannot add the excluded biological or host-optimization coordinates, so every accepted read remains inside the displayed sibling lattice. □

Falsifiable prediction: An accepted $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ read is refuted if the finite maximum-mass subcube route can bypass reassignment-support-compression, alternative-code-reassignment, codon-six-bit-window, or six-boundary-tile-coverage rows.

Independence witness: reassignment-support-compression, alternative-code-reassignment, codon-six-bit-window, six-boundary-tile-coverage: no listed sibling is bijective with $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ because the siblings respectively expose support compression, comparison-table reassignment, coordinate windows, or trigger coverage, while this packet jointly binds reassignment weights, subcube ledgers, finite mass sums, nested maximum-mass exposure, transport, replay, provenance, and local naming.

The Lean TasteGate.lean development for $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ must include explicit Nontrivial $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ and FieldFaithful $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ instances preserving $W, B, S, A, R, Q, L, N, H, C, P, K$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{ReassignmentMassSubcube}^{\uparrow}}$.

Constructive story: A $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ packet is generated from codon six-bit windows, six-boundary tile coverage rows, reassignment-support compression rows, alternative-code comparison rows, reassignment weights, finite subcube ledgers, mass sums, nested maximum-mass rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ReassignmentMassSubcube}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5869.1, Definition 5869.2, and Definition 5869.3 seed the finite maximum-mass subcube NameCert surface for reassignment geometry.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ReassignmentMassSubcube}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, uncurated genetic-code surveys, stochastic evolutionary dynamics, host optimization, quotient codon equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sibling-source exposure, reassignment-weight exactness, finite subcube ledger exposure, mass-sum exactness, nested maximum-mass routing, Nontrivial ReassignmentMassSubcubeUp, and FieldFaithful ReassignmentMassSubcubeUp for BEDC.Derived.ReassignmentMassSubcubeUp.

Chapter 5870

A Concrete Naming Certificate for $\mathsf{CauchyInterlacing}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyInterlacing}^{\uparrow}$ packet records the finite interlacing route by which two regular rational names are merged into one Real-facing seal. It sits over the finite StreamName schedules of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, the tail-equivalence handoff of chapter 1738, and the terminal Real seal of chapter 38. The packet names the even/odd merge as displayed certificate data; it is not a quotient stream, selected limit, countable-choice schedule, or ambient completeness principle.

Definition 5870.1 (Cauchy interlacing carrier)**.** *A* $\mathsf{CauchyInterlacing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, W, D, T, R, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular tails are to be merged.*
2. *W is the even/odd* $\mathsf{StreamName}^{\uparrow}$ *schedule row. Even windows read A, odd windows read B, and the row records the finite requests needed by the merged consumer.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the two source tails and the interlaced tail.*
4. *T is the* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *handoff row witnessing that the even and odd tails feed the same regular Cauchy boundary.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after A, B, W, D, T have been displayed.*
6. *H records componentwise* hsame *transport for the two source rows, schedule, tolerance ledger, tail-equivalence handoff, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite route*

$$A, B, W, D, T \longmapsto R.$$

8. *P is the* Pkg *provenance over* $\mathsf{CauchyInterlacing}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyTailEquivalence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyInterlacing}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through $A, B, W, D, T, R, H, C, P, N$ and has no coordinate for quotient stream equality, selected representatives, countable choice, host limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyInterlacingUp.CauchyInterlacingTasteGate single carrier alignment`

Theorem 5870.2 (Cauchy interlacing NameCert obligations)**.** *For every accepted* $\mathsf{CauchyInterlacing}^{\uparrow}$ *carrier*

$$K = (A, B, W, D, T, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyInterlacing}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, even/odd* $\mathsf{StreamName}^{\uparrow}$ *schedule, dyadic tolerance ledger, tail-equivalence handoff, Real seal, transport, replay, provenance, and local naming row;*
2. *schedule discipline, requiring every merged read to identify whether it is reading the even source row A or the odd source row B through W;*
3. *dyadic tolerance exactness, requiring D to record the source-tail and merged-tail tolerances consumed by the interlacing route;*
4. *tail handoff stability, requiring T to mediate the passage from the two regular tails to one common Cauchy boundary before R is visible;*
5. *real-seal nonescape, requiring R to remain downstream of A, B, W, D, T;*
6. *componentwise transport, displayed replay, package provenance, and local naming stability through H, C, P, N;*
7. *ledger refusal, excluding quotient streams, selected limits, countable choice, host sequence limits, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Cauchy interlacing obligation is stored outside these rows.

Proof. Project the accepted carrier $K = (A, B, W, D, T, R, H, C, P, N)$. The visible coordinates are exactly the two regular rational source rows, one finite even/odd schedule, one dyadic tolerance ledger, one tail-equivalence handoff, one Real seal row, and the structural rows.

The schedule row W fixes the finite interlacing order. Even requests read A and odd requests read B, so no merged consumer can inspect an unrecorded source position.

The dyadic ledger D and tail-equivalence row T then bind the two regular tails to one Cauchy boundary. The Real seal R is downstream of that route, while H, C, P, N transport, replay, source, and name the same displayed rows.

Since the excluded host objects have no carrier coordinate, replay edge, provenance entry, or local naming row, the listed rows exhaust the local NameCert surface. □

Theorem 5870.3 (Cauchy interlacing RegSeqRat handoff)**.** *Every accepted* $\mathsf{CauchyInterlacing}^{\uparrow}$ *carrier exposes the merged regular rational read only through the finite route*

$$A, B, W, D, T \longmapsto R \longmapsto H, C, P, N.$$

Thus a consumer receives the two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the even/odd* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *handoff, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise transport, continuation replay, provenance, and local naming before it can use the merged real-facing name.*

Proof. Start with the carrier projection. The two source rows A and B are independent displayed $\mathsf{RegSeqRat}^{\uparrow}$ inputs, and the only row that relates them to one merged stream is the even/odd schedule W.

Read the dyadic ledger and tail handoff. The row D supplies the tolerances for both source tails and for the interlaced tail, while T records the CauchyTailEquivalence passage from those two tails to one common boundary.

Only after A, B, W, D, T have been displayed can R be read as the Real-facing seal. The structural rows H, C, P, N preserve the same dependency order, so the merged regular rational handoff cannot bypass the displayed schedule or tolerance ledger. □

Theorem 5870.4 (Cauchy interlacing Real seal nonescape)**.** *An accepted* $\mathsf{CauchyInterlacing}^{\uparrow}$ *consumer that reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal must have already displayed the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the even/odd* $\mathsf{StreamName}^{\uparrow}$ *interlacing schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *handoff. Consequently the seal cannot be used as a shortcut to quotient stream equality, selected limits, countable choice, host limit existence, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the seal row R from an accepted carrier. By the carrier definition, R is downstream of A, B, W, D, T and records only the Real-facing boundary reached from those displayed rows.

The replay row C has no branch beginning at R. It replays the route from the two regular rational sources through the even/odd schedule, dyadic tolerance ledger, and tail-equivalence handoff before the seal can be consumed.

The transport and provenance rows H and P preserve that route componentwise, and the local name N names only the displayed interlacing packet. Hence no excluded host object can escape through the Real seal. □

Falsifiable prediction: Every $\mathsf{CauchyInterlacing}^{\uparrow}$ Real-facing read factors through two RegSeqRat source rows, one even/odd StreamName schedule, one DyadicRatCore tolerance ledger, one CauchyTailEquivalence handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, local naming, and one terminal RealUp seal.

Independence witness: streamname, regseqrat, dyadicratcore, cauchy-tail-equivalence, real: $\mathsf{CauchyInterlacing}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two regular rational source rows, an even/odd interlacing schedule, a dyadic tolerance ledger, one tail-equivalence handoff, structural transport, replay, provenance, local naming, and a single Real-facing seal.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyInterlacing}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyInterlacing}^{\uparrow}$ packet is generated from two RegSeqRat source rows, one even/odd StreamName schedule, one DyadicRatCore tolerance ledger, one CauchyTailEquivalence handoff, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyInterlacing}^{\uparrow}}$, seed)

Scope closed: Definition 5870.1, Definition 5870.2, Definition 5870.3, and Definition 5870.4 seed the finite constructive route for merging two regular rational names into one Real-facing seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyInterlacing}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient stream equality, selected limits, countable choice, host sequence limits, trichotomy, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, even/odd schedule discipline, dyadic tolerance exactness, CauchyTailEquivalence handoff, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyInterlacingUp.

Chapter 5871

A Concrete Naming Certificate for $\mathsf{RealLocallyCompact}^{\uparrow}$

Following Bishop–Bridges and Kelley local compactness, the $\mathsf{RealLocallyCompact}^{\uparrow}$ packet records the finite Real-facing route by which a displayed real endpoint receives a compact neighbourhood certificate. It refines the generic local compactness row of chapter 1726 over the real uniformity surface of chapter 3445, with endpoint data from chapter 38, finite windows from chapter 126, regular rational readback from chapter 301, dyadic radius accounting from chapter 291, closed ball rows from chapter 1451, and compact metric witnesses from chapter 129. The packet names the local closed-ball compactness surface for $\mathsf{Real}^{\uparrow}$; it does not supply a host-selected neighbourhood base, open-cover compactness theorem, quotient real equality, countable choice, or ambient completeness row.

Definition 5871.1 (Real locally compact carrier)**.** *A* $\mathsf{RealLocallyCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, U, W, D, B, K, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint row whose local neighbourhood is inspected.*
2. *U is the* $\mathsf{RealUniformSpace}^{\uparrow}$ *entourage row attached to the same endpoint data.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to read endpoint names, entourage requests, and radius comparisons.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *radius-accounting row, carrying dyadic radii and regular rational readback for the displayed window.*
5. *B is the* $\mathsf{MetricClosedBall}^{\uparrow}$ *row centred at the displayed real endpoint and radius.*
6. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *witness for the displayed closed-ball window.*
7. *A is the* $\mathsf{LocallyCompact}^{\uparrow}$ *handoff row, read only after R, U, W, D, B, K have been exposed.*
8. *H records componentwise* hsame *transport for the endpoint, uniformity, window, radius, closed-ball, compactness, handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a Real local-neighbourhood request through $R, U, W, D, B, K, A, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{RealLocallyCompact}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealUniformSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocallyCompact}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLocallyCompact}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows and exports no host neighbourhood selector, open-cover compactness, quotient real equality, countable choice, selected representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RealLocallyCompactUp.RealLocallyCompactUp`

Theorem 5871.2 (Real locally compact NameCert obligations)**.** *For every accepted* $\mathsf{RealLocallyCompact}^{\uparrow}$ *carrier* $L = (R, U, W, D, B, K, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealLocallyCompact}^{\uparrow}}$ *surface consists exactly of endpoint admission through R, real-uniform entourage exposure through U, finite-window routing through W, dyadic and regular-rational radius accounting through D, closed-ball exposure through B, compact metric witnessing through K, local compactness handoff through A, componentwise transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5871.1. The endpoint and uniformity rows R, U provide the Real-facing source before any radius or compactness data are read.

The radius route is finite. The window row W selects the inspected names and tolerance requests, while D records the dyadic radius ledger and regular rational readback needed to form the closed-ball row B.

Compactness enters only through K for the displayed closed-ball window. The handoff row A then presents the same data to the generic $\mathsf{LocallyCompact}^{\uparrow}$ surface, not to an ambient neighbourhood base or open-cover compactness theorem.

Transport, replay, provenance, and local naming preserve the same rows through H, C, P, N. Since the carrier has no coordinate for quotient real equality, countable choice, selected representatives, or ambient completeness, the listed rows exhaust the local certificate. □

Theorem 5871.3 (Real locally compact handoff)**.** *Every Real or Completion consumer that reads local compactness from an accepted* $\mathsf{RealLocallyCompact}^{\uparrow}$ *packet factors through*

$$\mathsf{Real}^{\uparrow} \longmapsto \mathsf{RealUniformSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{MetricClosedBall}^{\uparrow} \longmapsto \mathsf{CompactM}$$

The handoff exports only the displayed endpoint, uniformity, finite-window, radius-accounting, closed-ball, compact metric, transport, replay, provenance, and local naming rows of Definition 5871.1.

Proof. Start with a consumer request for a compact neighbourhood of a displayed real endpoint. The request first reads R and U, so the endpoint and real-uniformity data are fixed before any compactness row can be inspected.

Next read the finite radius route. The window row W and accounting row D expose the dyadic and regular-rational budget used to construct the closed-ball row B.

The compact witness K is attached to that same closed ball. The handoff row A is therefore a local compactness read over a displayed Real closed-ball window, not a host-selected neighbourhood or open-cover principle.

The structural rows H, C, P, N preserve the route for downstream Real and Completion consumers. No excluded equality, choice, selected representative, or ambient completeness row is available to the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealLocallyCompact}^{\uparrow}}$.

Constructive story: A $\mathsf{RealLocallyCompact}^{\uparrow}$ packet is generated from RealUp endpoint rows, RealUniformSpaceUp entourage rows, StreamName finite windows, DyadicRatCore and RegSeqRat radius accounting, a MetricClosedBall row, a CompactMetric witness, a LocallyCompact handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLocallyCompact}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5871.1, Definition 5871.2, and Definition 5871.3 seed the Real-facing local compactness certificate over closed-ball and compact metric sibling rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLocallyCompact}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host neighbourhood bases, open-cover compactness, quotient real equality, countable choice, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, finite radius accounting, closed-ball compactness witnessing, local compactness handoff, replay stability, provenance exhaustion, and local naming for BEDC.Derived.RealLocallyCompactUp.

Chapter 5872

A Concrete Naming Certificate for CompactUniformModulusStability$^{\uparrow}$

Following the Bishop–Bridges compact finite-net proof of uniform continuity, the CompactUniformModulusStability$^{\uparrow}$ packet records the stability surface that keeps compact nets, pointwise moduli, lower-bound folds, and the final uniform-modulus handoff synchronized. It sits over the compact selector of chapter 914, the compact uniform modulus row of chapter 2299, the finite lower-bound fold of chapter 619, the consumer surface of chapter 369, the metric triangle estimate of chapter 1159, and the compact metric source of chapter 129. The packet supplies a finite stability object for compact-uniform consumers; it does not select a host modulus, a hidden center, a quotient equality, or an ambient compactness theorem.

Definition 5872.1 (Compact uniform modulus stability carrier)**.** *A* CompactUniformModulusStability$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, N, M, F, U, T, H, C, P, L)$$

with the following displayed rows:

1. K *is the* CompactMetric$^{\uparrow}$ *finite-net source row.*
2. N *is the* CompactNetModulusSelector$^{\uparrow}$ *selector row carrying bundled centers, pointwise radii, and selected precision data.*
3. M *is the* CompactUniformModulus$^{\uparrow}$ *compact-uniform handoff row.*
4. F *is the* FiniteLowerBoundFold$^{\uparrow}$ *row that synchronizes the finite radius ledger with the selected precision.*
5. U *is the downstream* UniformModulus$^{\uparrow}$ *consumer row.*
6. T *is the* MetricTriangleUniformEstimate$^{\uparrow}$ *row that transports the selected center estimates into the final source-target bound.*
7. H *records componentwise* hsame *transport for compact, selector, modulus, fold, triangle, consumer, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from a compact-uniform tolerance request through* $K, N, M, F, U, T, H, P, L$.
9. P *is the* Pkg *provenance over* CompactUniformModulusStability$^{\uparrow}$, CompactMetric$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, CompactUniformModulus$^{\uparrow}$, FiniteLowerBoundFold$^{\uparrow}$, UniformModulus$^{\uparrow}$, MetricTriangleUniformEstimate$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

10. L is the local $\mathsf{NameCert}_{\mathsf{CompactUniformModulusStability}^{\uparrow}}$ *row.*
The carrier compares accepted stability packets only through these rows. It contains no host compactness principle, selected center outside the finite net, external modulus function, quotient point equality, or choice schedule.

Lean4 ✓ `BEDC.Derived.CompactUniformModulusStabilityUp.CompactUniformModulusStabilityTasteGate`
`single carrier alignment`

Theorem 5872.2 (Compact uniform modulus stability NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformModulusStability}^{\uparrow}$ *carrier* $S = (K, N, M, F, U, T, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulus}}$ *surface consists exactly of compact finite-net admission through* K*, compact selector exposure through* N*, compact-uniform modulus handoff through* M*, lower-bound fold synchronization through* F*, uniform-modulus consumer export through* U*, metric-triangle estimate transport through* T*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* L*.*

Proof. Project the carrier of Definition 5872.1. The compact source row K and selector row N provide the finite centers, pointwise modulus rows, subordinate radii, and selected precision before any consumer reads a modulus.

The lower-bound fold row F synchronizes those finite radius rows with the selected precision. The compact-uniform row M and uniform-modulus row U therefore read the same finite ledger rather than an external modulus function.

The triangle row T is the final estimate route. It uses the selected center and the two source-distance bounds already exposed by the selector and fold rows, so it cannot introduce a hidden center or host compactness argument.

Transport, replay, provenance, and local naming preserve the same packet through H, C, P, L. Since no excluded object appears among the coordinates, the listed rows exhaust the local certificate. □

Theorem 5872.3 (Compact uniform modulus stability handoff)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{CompactUniformModulusStability}^{\uparrow}$ *packet reads the stable route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{CompactNetModulusSelector}^{\uparrow} \longmapsto \mathsf{FiniteLowerBoundFold}^{\uparrow} \longmapsto \mathsf{MetricTriangleUniformEstimate}^{\uparrow}$$

Thus the consumer receives one synchronized finite packet of compact-net rows, pointwise-modulus rows, lower-bound fold data, selected precision, metric-triangle estimates, transport, replay, provenance, and local naming.

Proof. Start from a tolerance request. The compact metric row K and selector row N expose the finite net, selected center candidates, pointwise radii, and compact selector data.

Apply the fold row F. It binds the selected precision to the same finite radius ledger, so the request cannot move to a different center family or a host minimum.

Use the triangle estimate row T to transport the source bounds and pointwise estimates into the target bound consumed by M and then by U. The compact-uniform and uniform-modulus rows therefore receive the same synchronized finite route.

The structural rows H, C, P, L keep this route componentwise stable. No selected center outside the packet, quotient equality, choice schedule, host compactness, or external modulus function is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusStability}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformModulusStability}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, CompactNetModulusSelector rows, CompactUniformModulus rows, FiniteLowerBoundFold rows, UniformModulus consumer rows, MetricTriangleUniformEstimate rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5872.1, Definition 5872.2, and Definition 5872.3 seed the stability certificate tying compact-net selectors, folds, triangle estimates, compact-uniform rows, and uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host compactness, selected centers outside the finite packet, quotient point equality, choice schedules, external modulus functions, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, selector stability, fold synchronization, metric-triangle handoff, uniform-modulus export, replay stability, provenance exhaustion, and local naming for BEDC.Derived.CompactUniformModulu

Chapter 5873

A Concrete Naming Certificate for $\mathsf{CauchyFilterSelector}^{\uparrow}$

Following Bishop and Bridges and Kelley filter terminology, the $\mathsf{CauchyFilterSelector}^{\uparrow}$ packet records the finite selector interface by which a Cauchy-filter read can be inspected through named windows before any Real or Completion consumer reads the resulting boundary. It sits after the Cauchy-filter surface of chapter 333, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the completion handoff of chapter 1506. The packet gives the Phase Real and Completion route a finite selector row without quotient filters, host-selected representatives, countable choice, or ambient Real completeness.

Definition 5873.1 (Cauchy filter selector carrier)**.** *A* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row, including its displayed base packets, directed refinement ledger, and Cauchy evidence surface.*
2. *W is the finite selector-window row. It records the displayed filter request, the finite family of inspected base packets, and the chosen window among those already exposed by F.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the selected windows in W.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the filter request, the selector comparison, and the readback radius consumed by R.*
5. *E is the completion-or-Real seal row, read either as a* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff or as the downstream* $\mathsf{Real}^{\uparrow}$ *seal after F, W, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the filter row, selector windows, regular readback, dyadic ledger, seal row, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a Cauchy-filter request through F, W, R, D, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterSelector}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, W, R, D, E, H, C, P, N$. It has no coordinate for quotient filters, host-selected representatives, countable-choice schedules, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyFilterSelectorUp.CauchyFilterSelectorTasteGate single carrier alignment`

Theorem 5873.2 (Cauchy filter selector NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier $S = (F, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source Cauchy-filter data, selector windows, regular readback, dyadic tolerance ledger, completion-or-Real seal, transport, replay, provenance, and local naming row;*
2. *selector-window exactness, requiring the selected window to be one of the finite windows already displayed in W over the source filter row F;*
3. *regular readback handoff, requiring every numeric read to pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R after the selector window is fixed;*
4. *dyadic ledger stability, requiring the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D to govern the selector comparison and the readback radius;*
5. *seal boundary, requiring any* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer to read E only after F, W, R, D have been displayed and replayed;*
6. *nonescape, excluding quotient filters, host-selected representatives, countable choice, host real equality, and ambient Real completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5886.1. The visible packet consists of the source filter row F, selector windows W, regular readback R, dyadic ledger D, seal boundary E, and the structural rows H, C, P, N.

Selector-window exactness is row-local. The selector does not choose from an undisplayed filter; it names one of the finite windows stored in W and read over the already exposed Cauchy-filter row F.

The readback and tolerance obligations are ordered by the carrier. A numeric read reaches R only after W fixes the finite window, and the same dyadic ledger D supplies the tolerance budget for both the selector comparison and the regular readback radius.

The seal boundary is downstream. The replay row C routes every completion-facing or real-facing request through F, W, R, D before E, while H preserves this order under componentwise transport.

Since the carrier contains no quotient-filter coordinate, host-selected representative, choice schedule, host real equality, or Real completeness row, the listed obligations exhaust the local NameCert surface. □

Theorem 5873.3 (Cauchy filter selector RegSeqRat handoff)**.** *Let $S = (F, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier. Every selector read that exports regular numerical data factors through the finite route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}.$$

Concretely, the source filter row F exposes the finite base request, the selector-window row W exposes the inspected $\mathsf{StreamName}^{\uparrow}$ *windows, the readback row R exposes the* $\mathsf{RegSeqRat}^{\uparrow}$ *data, and the dyadic ledger D supplies the tolerance budget used by that readback.*

Proof. Project the accepted carrier. The source request is held in F, but F alone does not expose a regular rational name to downstream consumers.

Replay the selector route by C. The request first reaches the finite selector windows W, and those windows are the only place where the relevant $\mathsf{StreamName}^{\uparrow}$ observations are visible.

After W is fixed, the readback row R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ data. The tolerance row D is then read as the dyadic budget controlling the selector comparison and the regular readback.

Transport by H preserves the same order. Thus the handoff is a finite BEDC route from Cauchy filters to stream windows, regular readbacks, and dyadic tolerances, not a quotient of filters or a selected host representative. □

Theorem 5873.4 (Cauchy filter selector Real and completion seal boundary)**.** *For every accepted* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier* $S = (F, W, R, D, E, H, C, P, N)$*, every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer read exposed by* P *factors through the seal row* E *only after the source Cauchy-filter data, finite selector windows, regular readback, and dyadic tolerance ledger have been displayed. The visible boundary is*

$$F, W, R, D \longmapsto E \longmapsto H, C, P, N.$$

Therefore the packet provides a finite selector interface for the Real and Completion route without exporting quotient filters, host-selected representatives, countable choice, host real equality, or ambient Real completeness.

Proof. Read the seal row in the carrier. The row E is placed after the source filter data, selector windows, regular readback, and dyadic tolerance ledger, so a completion-facing or real-facing consumer cannot reach it from F alone.

The replay row C fixes the same order for every accepted request. It first consumes F, then the selector windows W, then the regular readback R, and then the dyadic tolerance ledger D before the seal row is available.

Componentwise transport by H does not add a new route. It preserves the displayed rows under classifier comparison, while P and N record only the provenance and local naming boundary of that finite route.

The excluded objects are absent from the carrier and from the replay path. Hence the completion-or-Real seal is exactly the displayed downstream boundary, not a quotient filter, selected representative, choice schedule, host equality, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5886.1, Definition 5886.2, Definition 5886.3, and Definition 5886.4 seed the finite selector interface between CauchyFilter, StreamName, RegSeqRat, DyadicRatCore, Real, and MetricCompletion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filters, host-selected representatives, countable choice, host real equality, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Lean closure requires carrier admission, selector-window exactness, RegSeqRat handoff, dyadic ledger stability, and Real or Completion seal boundary for BEDC.Derived.CauchyFilterSelectorUp.

Constructive story: The construction starts from a displayed CauchyFilter row, reads a finite selector window through StreamName observations, extracts RegSeqRat data under a DyadicRatCore tolerance ledger, and exposes Real or MetricCompletion access only through the downstream seal row.

The sandwich hub routes its cofinal common-tail read through chapter 7532 before the child files expose the lower and upper RegSeqRat readbacks.

Chapter 5874

A Concrete Naming Certificate for $\mathsf{RegularCauchySandwich}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchySandwich}^{\uparrow}$ packet names the two-sided bracketing surface used when regular Cauchy data is read by a real-completion consumer. It sits between the dyadic tolerance ledger of chapter 291, the finite window route of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the tail agreement boundary of chapter 1738. The packet records lower and upper regular tails as finite BEDC rows; it is not a quotient stream, a selected limit, a trichotomy principle, or an ambient completeness theorem.

Definition 5874.1 (Regular Cauchy sandwich carrier)**.** *A* $\mathsf{RegularCauchySandwich}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, U, T, D, W_L, W_U, R_L, R_U, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower regular-Cauchy row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
2. *U is the upper regular-Cauchy row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
3. *T is the common tail-agreement row inherited from* $\mathsf{CauchyTailEquivalence}^{\uparrow}$*.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling both bracket sides at the same precision request.*
5. *W_L and W_U are the finite* $\mathsf{StreamName}^{\uparrow}$ *windows opened for the lower and upper sides.*
6. *R_L and R_U are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows exposed after the windows are displayed.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after both sides, the common tail row, the dyadic ledger, the windows, and the readbacks have been consumed.*
8. *H records componentwise* hsame *transport for the lower side, upper side, tail row, ledger, windows, readbacks, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each finite precision request through*

$$L, U, T, D, W_L, W_U, R_L, R_U \longmapsto E, H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySandwich}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CauchyTailEquivalence}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySandwich}^{\uparrow}}$ *row.*
The classifier accepts only packets in which the lower and upper regular rows, common tail agreement, dyadic tolerance ledger, finite windows, readbacks, and terminal seal belong to the same displayed bracketing route. It has no coordinate for quotient stream equality, selected limits, trichotomy, apartness decision, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5874.2 (Regular Cauchy sandwich NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySandwich}^{\uparrow}$ *carrier*

$$S = (L, U, T, D, W_L, W_U, R_L, R_U, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySandwich}^{\uparrow}}$ *surface consists exactly of lower regular-row exposure, upper regular-row exposure, common tail-agreement exposure, shared dyadic tolerance accounting, lower and upper finite-window exposure, lower and upper RegSeqRat readback, terminal Real seal routing, componentwise transport, continuation replay, package provenance, and local naming through N.*

Proof. Project the carrier tuple in Definition 5874.1. The lower and upper sides are displayed as L and U, and the only row that binds them is the common tail-agreement coordinate T.

The shared ledger D fixes the precision request for both sides. The finite windows W_L, W_U are opened against that same ledger, and the readback rows R_L, R_U expose exactly the inspected regular rational data.

The seal row E is downstream of those rows, while H, C, P, N transport, replay, source, and name the same packet. Since no excluded analytic coordinate occurs in the carrier, the local NameCert surface is exactly the displayed bracketing route. □

Theorem 5874.3 (Regular Cauchy sandwich window bracketing)**.** *Let*

$$S = (L, U, T, D, W_L, W_U, R_L, R_U, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchySandwich}^{\uparrow}$ *carrier. Every finite precision request consumed by the packet reads the two-sided route*

$$L, U, T, D \longmapsto W_L, W_U \longmapsto R_L, R_U \longmapsto E, H, P, N.$$

Thus lower and upper regular windows are bracketed by one displayed tolerance ledger and one common tail-agreement row, not by quotient representatives, selected limits, trichotomy, apartness decision, countable choice, host real equality, or ambient completeness.

Proof. Start with a finite precision request. The packet exposes only one dyadic tolerance ledger D, so both sides of the bracket are read against the same displayed tolerance data.

The lower and upper windows W_L, W_U are then opened after the common tail row T has been displayed. Their readbacks R_L, R_U remain attached to the same packet, so neither side can be replaced by an external quotient stream or a selected representative.

The terminal seal E is reached only after both readbacks. Transport, replay, provenance, and local naming through H, C, P, N preserve that order for every accepted request, which gives the claimed two-sided bracketing route. □

Theorem 5874.4 (Regular Cauchy sandwich Real seal nonescape)**.** *No* $\mathsf{Real}^{\uparrow}$ *seal read accepted by a* $\mathsf{RegularCauchySandwich}^{\uparrow}$ *carrier can bypass the displayed route through the lower and upper regular rows, common tail agreement, shared dyadic ledger, lower and upper StreamName windows,*

lower and upper RegSeqRat readbacks, and local structural rows. Equivalently, every accepted terminal seal read is attached to

$$S = (L, U, T, D, W_L, W_U, R_L, R_U, E, H, C, P, N)$$

and cannot be separated from those rows by quotient stream equality, selected limits, trichotomy, apartness decision, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 5874.2. It exposes the Real seal row E only as part of the local NameCert surface containing the two regular rows, common tail row, ledger, windows, readbacks, and structural rows.

Now use Definition 5874.3. Every precision request reaches the readbacks through the same two-sided route, so a seal read detached from one side of the bracket is not a read of this packet.

Finally inspect Definition 5874.1. The carrier contains no coordinate for quotient stream equality, selected limits, trichotomy, apartness decision, countable choice, host real equality, or ambient Real completeness. A purported seal read using such data therefore lies outside the accepted $\mathsf{RegularCauchySandwich}^{\uparrow}$ carrier. □

Theorem 5874.5 (Regular Cauchy sandwich Cantor intersection seal)**.** *Let* $S = (L, U, T, D, W_L, W_U, R_L, R_U, E, H$ *be an accepted* $\mathsf{RegularCauchySandwich}^{\uparrow}$ *carrier. If the lower and upper rows are supplied by a nested-shrink or Cantor-intersection route, then the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed by* S *is available only through the displayed sandwich route, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. In particular, the consumer-facing seal factors through Definition 5874.3, Definition 5874.4, chapter 4227, and chapter 7754, without asserting a selected intersection point.*

Proof. Apply Definition 5874.3. It forces every finite precision request for S through the common tail row, shared dyadic ledger, two StreamName windows, and two RegSeqRat readbacks before the seal row is visible.

The nested-shrink and Cantor-intersection inputs supply the lower and upper rows only as finite interval or shrink data. Those routes provide the source rows for the sandwich, but they do not add a coordinate for a selected point, quotient stream equality, or ambient completeness.

Now apply Definition 5874.4. Any terminal $\mathsf{Real}^{\uparrow}$ read detached from the displayed carrier is outside the accepted packet, so the Cantor-facing consumer receives only the finite sandwich seal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySandwich}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySandwich}^{\uparrow}$ packet is generated from lower and upper regular-Cauchy rows, a common tail-agreement row, a shared dyadic tolerance ledger, lower and upper StreamName windows, lower and upper RegSeqRat readbacks, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySandwich}^{\uparrow}}$, seed)

Scope closed: Definition 5874.1, Definition 5874.2, Definition 5874.3, and Definition 5874.4 seed the finite two-sided regular-Cauchy bracketing route over DyadicRatCore, StreamName, RegSeqRat, Real, and CauchyTailEquivalence rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySandwich}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, trichotomy, apartness decision, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common tail exactness, shared dyadic tolerance accounting, two-sided StreamName window routing, RegSeqRat readback, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySandwichUp.

Theorem 5874.6 (Regular Cauchy sandwich sibling dependency route)**.** *Every accepted* $\mathsf{RegularCauchySandwich}^{\uparrow}$ *sandwich packet depends on the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback rows of chapter 301 and the* $\mathsf{StreamName}^{\uparrow}$ *pointwise window rows of chapter 126 before it exposes a terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route consumes those siblings only through the displayed lower and upper windows, lower and upper regular readbacks, common tail row, shared dyadic ledger, transport, replay, provenance, and local naming rows of Definition 5874.1.*

Proof. Read the carrier rows from Definition 5874.1. The lower and upper windows W_L, W_U are the pointwise $\mathsf{StreamName}^{\uparrow}$ windows, and the rows R_L, R_U are the regular rational readbacks supplied by $\mathsf{RegSeqRat}^{\uparrow}$.

The bracketing theorem Definition 5874.3 orders every precision request through those windows and readbacks before the seal row is consumed. The Real-seal nonescape theorem Definition 5874.4 prevents bypass through quotient stream equality, selected limits, host real equality, or ambient completeness.

Thus the chapter's sibling dependency is the concrete route through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$, not an external analytic carrier. □

Theorem 5874.7 (Regular Cauchy sandwich cofinal tail-mesh dependency)**.** *Every accepted* $\mathsf{RegularCauchySandwic}$ *packet whose common tail row is presented cofinally must read the* $\mathsf{CofinalTailMesh}^{\uparrow}$ *route of chapter 7532 before the lower and upper* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks and the terminal* $\mathsf{Real}^{\uparrow}$ *seal are consumed. The dependency is the displayed route through the sandwich carrier, the window bracketing theorem, and the sibling dependency route; it is not an appeal to quotient streams, selected limits, trichotomy, choice, host real equality, or ambient completeness.*

Proof. Read the carrier rows in Definition 5874.1. The common tail coordinate T is displayed before the lower and upper StreamName windows, the lower and upper RegSeqRat readbacks, and the Real seal row.

When T is presented cofinally, consume the CofinalTailMesh route of chapter 7532. That route supplies the shared finite tail-window mesh before any Real or completion-facing seal is read.

Apply the window bracketing theorem Definition 5874.3. It keeps the lower and upper readbacks downstream of the common tail row and the shared dyadic ledger.

Finally use the sibling dependency route Definition 5874.6. It already requires the StreamName and RegSeqRat siblings before the Real seal, so adding the cofinal tail-mesh read fixes the horizontal dependency without adding any external analytic coordinate. □

Chapter 5875

A Concrete Naming Certificate for $\mathsf{DynamicProgramming}^{\uparrow}$

Following Bellman's finite dynamic programming principle, the $\mathsf{DynamicProgramming}^{\uparrow}$ packet records finite backward recursion data as BEDC NameCert rows. It sits after the finite path and edge ledger of chapter 236, the transition-row discipline of chapter 189, the probability-row carrier of chapter 184, the terminal real-name seal of chapter 38, and the finite horizon counter of chapter 28. The chapter names only finite states, finite actions, displayed transition and cost rows, horizon-indexed Bellman tables, policy readback, transport, replay, provenance, and local naming; it does not assert an infinite-horizon fixed point, host minimizer, choice-selected policy, quotient value equality, or ambient completeness theorem.

Definition 5875.1 (Dynamic programming carrier)**.** *A* $\mathsf{DynamicProgramming}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, A, T, C, H, V, P, R, N)$$

with the following displayed rows:

1. *S is the finite displayed state row, sharing its path endpoints with chapter 236.*
2. *A is the finite action row, listing exactly the actions admitted at the displayed states.*
3. *T is the transition row, read through the finite Markov and probability surfaces of chapter 189 and chapter 184.*
4. *C is the cost row, exposing the finite real-valued immediate costs and terminal costs through the* $\mathsf{Real}^{\uparrow}$ *seal.*
5. *H is the horizon row, a* $\mathsf{Nat}^{\uparrow}$*-indexed finite counter for the backward recursion stages.*
6. *V is the Bellman value table, giving one displayed value row for each state and horizon stage.*
7. *P is the policy readback row, recording only actions whose value entry is witnessed by the same finite transition and cost rows.*
8. *R records componentwise* hsame *transport, displayed* Cont *replay, and* Pkg *provenance over S, A, T, C, H, V, P and the cited sibling packets.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DynamicProgramming}^{\uparrow}}$ *row.*

The classifier reads accepted packets only through $S, A, T, C, H, V, P, R, N$. It has no coordinate for a host minimizer, selected infinite policy, analytic contraction theorem, quotient value function, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DynamicProgrammingUp.DynamicProgrammingTasteGate single carrier alignment`

Theorem 5875.2 (Dynamic programming Bellman obligations)**.** *For every accepted* $\mathsf{DynamicProgramming}^{\uparrow}$ *carrier* $D = (S, A, T, C, H, V, P, R, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DynamicProgramming}^{\uparrow}}$ *surface consists exactly of carrier admission for finite states, finite actions, transition rows, cost rows, horizon rows, Bellman value-table rows, policy readback rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and ledger refusal for host minimizers, selected infinite policies, quotient value equality, countable choice, and ambient completeness.*

Proof. Carrier admission is projection from Definition 5875.1. The finite state and action rows are displayed before transition and cost rows can be read, and the horizon row fixes which backward stages may appear.

The Bellman table row V is then read stage by stage over the same displayed horizon. A policy readback row P is exposed only after the corresponding state, action, transition, cost, and value rows have all been displayed.

Transport, replay, provenance, and local naming are exhausted by R and N. Since the carrier has no further coordinate beyond $S, A, T, C, H, V, P, R, N$, no accepted read can import a host minimizer, selected infinite policy, quotient value equality, countable choice, or ambient completeness. □

Theorem 5875.3 (Dynamic programming finite-horizon induction)**.** *Every accepted* $\mathsf{DynamicProgramming}^{\uparrow}$ *Bellman table is generated by finite backward induction over the displayed* $\mathsf{Nat}^{\uparrow}$ *horizon row. The terminal stage reads the terminal cost row from* C *and the* $\mathsf{Real}^{\uparrow}$ *seal; each predecessor stage reads only the previously displayed successor-stage value row, the transition row* T*, the action row* A*, the immediate cost row* C*, and the same local NameCert route.*

Proof. Project the horizon row H and read it through the unary source discipline of chapter 28. The empty endpoint is the terminal stage, so the value entry is the displayed terminal cost row sealed through $\mathsf{Real}^{\uparrow}$.

For a one-step predecessor, use the closed generation of the horizon row. The successor-stage table has already been displayed, and the new value row is computed from the finite transition row, finite action row, immediate cost row, and successor value row.

Repeating the one-step construction along the finite horizon supplies every value-table row. No step asks for an infinite horizon, a global fixed point, or an external minimizer; the induction is only the BEDC finite-history recursion named by the carrier. □

Theorem 5875.4 (Dynamic programming policy readback)**.** *Every policy row exported by an accepted* $\mathsf{DynamicProgramming}^{\uparrow}$ *packet is a readback from the displayed Bellman table. For each displayed state and horizon stage, the row* P *may expose an action only after the state row* S*, action row* A*, transition row* T*, cost row* C*, horizon row* H*, value row* V*, componentwise transport, replay, provenance, and local naming have all been read.*

Proof. Start with a policy-facing read. The carrier forces the read through the finite state and action rows, then through the transition and cost rows that define the local Bellman entry.

Next read the horizon row and the value-table row. The policy row is not an independent selector: it is attached to the displayed value entry at the same state and horizon stage.

Finally apply the structural row R and local naming row N. These rows preserve the finite route under transport and replay, so any action exposed by P remains tied to the same Bellman table entry and cannot become a host choice function or infinite policy. □

Theorem 5875.5 (Dynamic programming NameCert package)**.** *The* $\mathsf{DynamicProgramming}^{\uparrow}$ *NameCert package is the finite Bellman-recursion packet whose public surface is exactly the route*

$$\mathsf{Nat}^{\uparrow}, \mathsf{ShortestPath}^{\uparrow}, \mathsf{MarkovChain}^{\uparrow}, \mathsf{ProbSpace}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{DynamicProgramming}^{\uparrow}.$$

It exports the state, action, transition, cost, horizon, value-table, policy-readback, transport, replay, provenance, and local naming rows of Definition 5875.1. It exports no host optimization theorem, no selected global policy, no infinite-horizon convergence theorem, no quotient value-function equality, and no bridge to a standard dynamic-programming model.

Proof. The cited sibling chapters supply the input rows: shortest-path data for finite route endpoints, Markov and probability data for transition rows, real data for cost and value seals, and natural-number data for the finite horizon.

Apply Definition 5875.2 to identify the local obligation surface. Apply Definition 5875.3 to generate the value table from the terminal stage backward through the displayed horizon. Apply Definition 5875.4 to expose policy rows only as readbacks from that table.

The package is therefore a finite NameCert surface over the displayed rows. Because no carrier coordinate stores host optimization, global choice, infinite convergence, quotient equality, or a standard bridge, those objects are not exported. □

Falsifiable prediction: A claimed $\mathsf{DynamicProgramming}^{\uparrow}$ read that exposes a policy action without first displaying S, A, T, C, H, V, R, N refutes the finite Bellman carrier.

Independence witness: shortestpath, markovchain, probspace, real, nat: no listed sibling is bijective to $\mathsf{DynamicProgramming}^{\uparrow}$ because this packet binds finite state-action data, transition and cost rows, horizon-indexed Bellman value tables, policy readback, transport, replay, provenance, and local naming as one finite recursion surface.

Closure status for $\mathsf{NameCert}_{\mathsf{DynamicProgramming}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DynamicProgramming}^{\uparrow}$ packet is generated from finite state rows, finite action rows, transition rows, cost rows, a Nat-indexed horizon, Bellman value-table rows, policy readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DynamicProgramming}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5875.1, Definition 5875.2, Definition 5875.3, Definition 5875.4, and Definition 5875.5 seed the finite Bellman-recursion NameCert route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DynamicProgramming}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host minimizers, selected infinite policies, quotient value equality, infinite-horizon convergence, ambient RealUp completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, Bellman table construction, finite-horizon induction, policy readback exactness, transport, replay, provenance, and local naming for BEDC.Derived.DynamicProgrammingUp.

Chapter 5876

Regular Cauchy Even-Odd Substreams NameCert Construction

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ packet records the standard constructive passage from one regular Cauchy name to its even and odd substreams before a Real or Completion consumer reads either side. It sits over the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the two-source interleaving packet of chapter 414, and the finite interleaving criterion of chapter 3405. The packet supplies a displayed subsequence route for the L10 Real and Completion corridor; it does not choose a new limit, quotient streams, or import ambient completeness.

Definition 5876.1 (Regular Cauchy even-odd substreams carrier)**.** *A* $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, E, O, D, R, A, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular Cauchy row. It names one* $\mathsf{RegSeqRat}^{\uparrow}$ *source together with the finite precision requests inspected by the parity split.*
2. *E is the even selector-window row. It displays the finite windows read from the source at indices $2n$ and records no schedule beyond the even selector.*
3. *O is the odd selector-window row. It displays the finite windows read from the source at indices $2n + 1$ and records no schedule beyond the odd selector.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row. It stores the shared dyadic radius, split tolerance, comparison windows, and common-scale data used by both selector windows.*
5. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the even and odd windows under the budget D.*
6. *A is the* $\mathsf{Real}^{\uparrow}$ *seal boundary for the even readback, available only after S, E, D, R have been displayed.*
7. *B is the* $\mathsf{Real}^{\uparrow}$ *seal boundary for the odd readback, available only after S, O, D, R have been displayed.*

8. *H records componentwise* hsame *transport for the source, even selector windows, odd selector windows, dyadic budget, paired readbacks, two Real seal boundaries, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from an even or odd substream request through $S, E, O, D, R, A, B, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyInterleaving}^{\uparrow}$, $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, E, O, D, R, A, B, H, C, P, N$. The carrier has no coordinate for quotient stream equality, a selected host limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyEvenOddSubstreamsUp.RegularCauchyEvenOddSubstreamsTasteGate`
`single carrier alignment`

Theorem 5876.2 (Regular Cauchy even-odd substreams NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ *carrier*

$$X = (S, E, O, D, R, A, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source regular Cauchy row, even selector windows, odd selector windows, dyadic budget, paired readbacks, two Real seal boundaries, transport, replay, provenance, and local naming rows;*
2. *source visibility, requiring both parity branches to read the same displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row S;*
3. *even-window exactness, requiring every even branch request to pass through the selector windows E and the budget D before any readback is visible;*
4. *odd-window exactness, requiring every odd branch request to pass through the selector windows O and the same budget D before any readback is visible;*
5. *paired regular readback admission through R, requiring the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks to use the selector windows and the shared dyadic ledger already displayed;*
6. *two Real seal boundaries through A and B, requiring the even and odd Real-facing reads to remain downstream from their parity windows, D, R, H, and C;*
7. *componentwise transport, displayed replay, package provenance, and local naming for exactly $S, E, O, D, R, A, B, H, C, P, N$;*
8. *refusal of quotient stream equality, selected host limits, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local certificate data.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5876.1. Its displayed inventory is exactly $S, E, O, D, R, A, B, H, C, P, N$, so the source row, parity selector windows, dyadic budget, paired readbacks, two seals, and structural rows exhaust the packet.

The source visibility clause is read from S. Both parity branches share that row, so neither branch can replace the source by a second hidden regular name.

Even-window and odd-window exactness are read from E and O under the shared dyadic row D. The even branch exposes only indices of the form $2n$, while the odd branch exposes only indices of the form $2n+1$, and both branches use the same tolerance ledger before the readback row is consumed.

The paired readback row R is downstream from those windows. It repacks the two selector routes as $\mathsf{RegSeqRat}^{\uparrow}$ readbacks without adding a quotient stream or selected host limit.

Finally the Real seals A and B are reached only after the corresponding parity route has been transported by H and replayed by C. Since P and N name only the displayed packet, the listed rows are the complete local NameCert surface. □

Theorem 5876.3 (Regular Cauchy even-odd Real-seal nonescape)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ *carrier factors through one of the two finite parity routes*

$$S, E, D \longmapsto R \longmapsto A \longmapsto H, C, P, N,$$
$$S, O, D \longmapsto R \longmapsto B \longmapsto H, C, P, N.$$

The even route reads the even selector windows and the odd route reads the odd selector windows, but both routes share the same source row, dyadic budget, paired regular readback, transport, replay, provenance, and local naming. Hence no consumer reaches a $\mathsf{Real}^{\uparrow}$ *seal through quotient stream equality, a chosen host limit, countable choice, trichotomy, or ambient completeness.*

Proof. Apply the obligation surface of Definition 5876.2. It confines every accepted packet to the displayed source, two parity selector rows, one dyadic budget, paired readback, two seal rows, and structural data.

For an even request, the consumer reads S, E, D before R and then reaches A. The route has no coordinate other than the even selector windows and the shared budget, so the even seal cannot bypass the displayed packet.

For an odd request, the consumer reads S, O, D before R and then reaches B. This is the same source and budget route with the odd selector row in place of the even selector row.

The structural rows H, C, P, N transport, replay, source, and name the two routes componentwise. Because the carrier contains no quotient stream equality, selected host limit, countable-choice row, trichotomy branch, or ambient completeness coordinate, every Real or Completion consumer remains inside one of the two displayed parity routes. □

Theorem 5876.4 (Regular Cauchy parity cofinality)**.** *Let* $X = (S, E, O, D, R, A, B, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ *carrier over one source* $\mathsf{RegSeqRat}^{\uparrow}$ *row* S*. The even selector windows* E *and the odd selector windows* O *determine cofinal tail-shift reads of that same source row. Their Real-facing seals factor through the same ordered four-face packet*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The assertion is only this cofinal finite-window factorization. It does not identify quotient streams, select a limit, use countable choice, use trichotomy, or invoke ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the source row S and the two selector-window rows E, O from Definition 5876.1. The rows are displayed as windows over one source $\mathsf{RegSeqRat}^{\uparrow}$ carrier, so no second regular name is introduced by the parity split.

Apply Definition 301.257 to transport late reads along the even and odd tail shifts. The tail-shift result keeps each parity branch inside the same regular-rational source route.

Next use Definition 126.670. It supplies one finite request section for the displayed selector windows, so both parity reads are compared at the finite StreamName surface rather than at a completed stream quotient.

Apply Definition 1647.3 to fuse the two parity budgets through the shared dyadic tolerance ledger. The shared D row is the DyadicRatCore face of the ordered packet.

Finally use Definition 38.713. The terminal Real seal is reached only after the dyadic budget, finite StreamName window, and RegSeqRat readback have been displayed. Thus the two parity seals are cofinal views of the same finite four-face route, with no selected limit, countable-choice selector, trichotomy branch, quotient stream equality, or ambient completeness principle. □

Falsifiable prediction: Every $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ Real or Completion read is refuted if it reaches either $\mathsf{Real}^{\uparrow}$ seal without displaying the source RegSeqRat row, the selected even or odd StreamName windows, the shared DyadicRatCore budget, the paired RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: regseqrat, streamname, dyadicratcore, real, regular-cauchy-interleaving, cauchy-interleaving-criterion: $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries one source regular Cauchy name, two parity selector-window routes, one shared dyadic budget, paired regular readbacks, two Real seal boundaries, transport, replay, provenance, and local naming as one displayed packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ packet is generated from one RegSeqRat source, even selector windows, odd selector windows, a shared DyadicRatCore budget, paired RegSeqRat readbacks, two RealUp seal boundaries, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5876.1, Definition 5876.2, Definition 5876.3, and Definition 5876.4 seed the parity-substream route used by L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient stream equality, selected host limits, countable choice, trichotomy, ambient RealUp completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, parity-window exactness, shared dyadic budget exactness, paired regular readback admission, two Real-seal nonescape clauses, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.RegularCauchyEvenOddSubstreamsUp.

Chapter 5877

A Concrete Naming Certificate for $\mathsf{SchwartzSpace}^{\uparrow}$

Following Schwartz and Treves on test-function spaces, the $\mathsf{SchwartzSpace}^{\uparrow}$ packet records the finite locally convex carrier surface behind rapidly decreasing smooth test functions. It sits beside the complete locally convex interface of chapter 3495, the finite family-seminorm route of chapter 5868, the pointwise test-function carrier of chapter 3399, and the derivative observation route of chapter 2210. The packet gives Fourier, tempered-distribution, weak-derivative, and PDE-facing consumers a displayed test-function-space surface without importing a host topological vector space, quotient function equality, unrestricted seminorm enumeration, selected representatives, or classical completeness.

Definition 5877.1 (SchwartzSpace carrier)**.** *A* $\mathsf{SchwartzSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, V, I, G, D, R, T, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FrechetSpace}^{\uparrow}$ *source row, exposing complete metrizability and locally convex handoff only through the displayed Frechet carrier.*
2. *V is the* $\mathsf{SeminormedSpace}^{\uparrow}$ *finite-family row, naming the seminorm labels used by the Schwartz test-function space read.*
3. *I is the* $\mathsf{SchwartzFunction}^{\uparrow}$ *test-function row, recording the accepted rapidly decreasing smooth windows inspected by the packet.*
4. *G is the polynomial-growth and rapid-decay ledger. It binds each displayed seminorm index to a derivative order, a polynomial weight, and the real-valued budget read used to test decay.*
5. *D is the* $\mathsf{WeakDerivative}^{\uparrow}$ *stability row, recording derivative-window shifts and sign conventions that remain inside the same Schwartz test-function-space surface.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar readback row used by seminorm values, decay budgets, and completion-facing estimates.*
7. *T is the completion and distribution nonescape row. It permits Frechet and tempered-distribution consumers to read the displayed test-function-space boundary only after F, V, I, G, D, R have been exposed.*

8. *H records componentwise* hsame *transport for Frechet, seminorm-family, test-function, rapid-decay, derivative, Real, nonescape, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from every test-function-space request through $F, V, I, G, D, R, T, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{SchwartzSpace}^{\uparrow}$, $\mathsf{FrechetSpace}^{\uparrow}$, $\mathsf{SeminormedSpace}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SchwartzSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host Schwartz topology, a quotient of functions, an unrestricted seminorm family, a selected completion point, a distribution dual, nuclearity, Fourier inversion, or classical choice.

Lean4 ✓ `BEDC.Derived.SchwartzSpaceUp.SchwartzSpaceTasteGate single carrier alignment`

Theorem 5877.2 (SchwartzSpace NameCert obligations)**.** *For every accepted* $\mathsf{SchwartzSpace}^{\uparrow}$ *carrier*

$$S = (F, V, I, G, D, R, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwartzSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed Frechet-space, seminorm-family, Schwartz-function, rapid-decay, weak-derivative, Real, nonescape, transport, replay, provenance, and local naming rows;*
2. *seminorm growth routing, requiring every seminorm read to choose a displayed finite-family row in V and a polynomial-growth budget in G before a Real value can be consumed from R;*
3. *rapid-decay test-function closure, requiring every accepted test window from I to satisfy the displayed derivative-order and polynomial-weight ledger in G;*
4. *derivative-row stability, requiring weak-derivative shifts to pass through D and return to the same I, G, R surface rather than to host smooth-function equality;*
5. *completion and distribution nonescape, requiring T to mediate every Frechet, completion-facing, Fourier-facing, tempered-distribution, or PDE-facing read after F, V, I, G, D, R have been displayed.*

No $\mathsf{SchwartzSpace}^{\uparrow}$ *obligation is stored outside these rows.*

Lean4 ✓ `BEDC.Derived.SchwartzSpaceUp.TasteGate.SchwartzSpaceTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 5877.1. The analytic rows are exactly F, V, I, G, D, R, T, and the structural rows are exactly H, C, P, N.

Seminorm growth routing is forced by the order of the carrier. A consumer first reads the finite family row V, then the derivative and polynomial-weight budget in G, and only then may read a Real scalar estimate through R.

Rapid-decay closure and derivative stability are the two test-function-space checks. The row I supplies accepted Schwartz test windows, while G records their rapid-decay budgets and D records the weak-derivative shifts that stay inside the same displayed surface.

Finally T is a boundary row rather than an additional topological object. It lets Frechet, completion-facing, Fourier-facing, tempered-distribution, and PDE consumers replay the same rows without receiving a host Schwartz topology, quotient function equality, selected completion point, distribution dual, nuclearity, inversion theorem, or choice principle. Thus the listed rows exhaust the local NameCert obligations. □

Theorem 5877.3 (SchwartzSpace functional-analysis handoff)**.** *Every accepted* $\mathsf{SchwartzSpace}^{\uparrow}$ *packet exported to a Frechet, Fourier, tempered-distribution, weak-derivative, or PDE-facing consumer factors through*

$$\mathsf{FrechetSpace}^{\uparrow},\ \mathsf{SeminormedSpace}^{\uparrow},\ \mathsf{SchwartzFunction}^{\uparrow},\ \mathsf{WeakDerivative}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto F, V, I, G, D, R, T, H, C, P, N.$$

The exported object is a finite test-function-space NameCert surface with displayed seminorm growth budgets and derivative stability. It is not a host locally convex function space, an unrestricted seminorm enumeration, a selected completion, a dual-space quotient, or a classical distribution theorem.

Proof. Open the accepted carrier using Definition 5877.1. Any functional-analysis request must first choose one of the displayed source rows F, V, I, D, R and then pass through the growth ledger G.

Use Definition 5877.2. The seminorm and rapid-decay obligations keep polynomial weights and derivative orders attached to finite displayed rows, while the derivative-row obligation prevents a consumer from replacing weak-derivative stability by host smooth-function equality.

The nonescape row T is then the only export boundary. Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite route for every downstream consumer. Since no excluded host object is a carrier coordinate, the displayed route is the whole handoff surface. □

Falsifiable prediction: An accepted $\mathsf{SchwartzSpace}^{\uparrow}$ consumer that reaches a Frechet, Fourier, tempered-distribution, weak-derivative, or PDE-facing read without first exposing $F, V, I, G, D, R, T, H, C, P, N$ refutes the carrier surface of Definition 5877.1.

Independence witness: frechet-space, seminormed-space, schwartz-function, weak-derivative, real: no listed sibling is bijective to $\mathsf{SchwartzSpace}^{\uparrow}$ because this packet jointly binds complete locally convex source rows, finite seminorm-family exposure, rapid-decay test-function windows, derivative stability, Real budget readback, completion and distribution nonescape, transport, replay, provenance, and local naming in one test-function-space carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwartzSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SchwartzSpace}^{\uparrow}$ packet is generated from a FrechetSpace row, a finite SeminormedSpace family row, SchwartzFunction test windows, rapid-decay and polynomial-growth ledgers, WeakDerivative stability rows, Real scalar readback, completion and distribution nonescape, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SchwartzSpace}^{\uparrow}}$, seed)

Scope closed: Definition 5877.1, Definition 5877.2, and Definition 5877.3 seed the finite locally convex test-function-space surface consumed by Frechet, Fourier, tempered-distribution, weak-derivative, and PDE-facing packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SchwartzSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host Schwartz topology, quotient function equality, unrestricted seminorm enumeration, selected completion, distribution duality, nuclearity, Fourier inversion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, seminorm growth routing, rapid-decay test-function closure, derivative-row stability, completion and distribution nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SchwartzSpaceUp.

Chapter 5878

A Concrete Naming Certificate for $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$

The $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ packet realizes the private/shared decoration model of chapter 9390 as finite Rule 110 classifier-decoration NameCert data. It consumes the cellular automaton carrier of chapter 934, the row-classifier surface of chapter 941, the finite pattern catalog of chapter 995, the Rule 110 classifier of chapter 5844, and the finite partition carrier of chapter 201. The packet names quotient support families, private blocks, shared-coordinate incidence rows, Rule 110 pattern-classifier rows, decoration-count provenance, transport, replay, provenance, and local naming; it does not import a host cellular semantics, an infinite orbit classifier, quotient support equality, a biological model, or a hidden enumeration oracle.

Definition 5878.1 (Rule 110 private/shared decoration carrier)**.** *A* $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (Q, B, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the quotient support family row, naming the finite family of support blocks inspected by the decoration.*
2. *B is the private-block row, recording for each accepted support a displayed nonempty private coordinate block.*
3. *S is the shared-coordinate incidence row. For each shared coordinate it records the displayed set of incident private blocks and requires cardinality at least two.*
4. *R is the* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ *row, attaching the decorated support family to finite Rule 110 row-window and pattern-tag reads.*
5. *E is the decoration-count provenance row. It records the partition and row-set enumeration data used by the private/shared decoration theorem without exposing a host generating-function oracle.*
6. *H records componentwise* hsame *transport for quotient support, private-block, shared-incidence, classifier, enumeration, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a decoration request through Q, B, S, R, E, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$, $\mathsf{CellularAutomaton}^{\uparrow}$, $\mathsf{CellularRowClassifier}^{\uparrow}$, $\mathsf{CellularPatternCatalog}^{\uparrow}$, $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$, $\mathsf{Partition}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for absent private blocks, singleton shared incidence, host quotient equality, unbounded Rule 110 evolution, biological interpretation, or an external enumeration procedure.

Theorem 5878.2 (Rule 110 private/shared decoration NameCert obligations)**.** *For every accepted* $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ *carrier*

$$D = (Q, B, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}}$ *surface consists exactly of quotient support family admission through Q, private-block nonemptiness through B, shared-coordinate incidence through S, Rule 110 pattern-classifier routing through R, decoration-count provenance through E, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5878.1. The decoration data are exactly the quotient support row Q, the private-block row B, the shared-incidence row S, the Rule 110 classifier row R, and the enumeration provenance row E.

Private-block nonemptiness is read before a support can be accepted. Shared-coordinate incidence is then read as a displayed row set of size at least two, so a shared coordinate cannot be collapsed into a private coordinate or erased from the decoration.

The Rule 110 classifier row R attaches the decorated support family to finite row-window and pattern-tag reads from the cellular siblings. The count provenance row E records the finite partition and row-set enumeration route and does not supply an external counting oracle.

Finally H, C, P, N transport, replay, source, and name the same carrier. Since no excluded host object is present as a coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5878.3 (Private/shared decoration classifier handoff)**.** *Every accepted* RuleOneTenPrivateSharedDecorati
consumer that reads a decorated Rule 110 support family factors through

$$\mathsf{CellularAutomaton}^{\uparrow},\ \mathsf{CellularRowClassifier}^{\uparrow},\ \mathsf{CellularPatternCatalog}^{\uparrow},\ \mathsf{RuleOneTenPatternClassifier}^{\uparrow},\ \mathsf{Partition}^{\uparrow} \longmapsto Q$$

The exported object is a finite classifier-decoration packet with private-block nonemptiness, shared incidence, and decoration-count provenance. It is not an infinite cellular-orbit classifier, a host quotient-support equality, a biological stochastic model, or an unrestricted enumeration theorem.

Proof. Open the accepted carrier using Definition 5878.1. A support-family read can inspect only Q, and each support must expose its nonempty private block through B before shared coordinates are consumed.

The shared-coordinate row S supplies the incidence sets whose size is at least two. The classifier row R then routes the accepted decoration into the existing cellular automaton, row-classifier, pattern-catalog, and Rule 110 pattern-classifier surfaces.

The provenance row E records the finite decoration-count route, while H, C, P, N preserve the same data under transport, replay, package provenance, and local naming. Thus every accepted consumer receives exactly the displayed finite packet and none of the excluded host semantics. □

Falsifiable prediction: Any accepted $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ consumer that omits private-block nonemptiness or shared-coordinate incidence rows while reading a decorated Rule 110 support family refutes the carrier surface of Definition 5878.1.

Independence witness: cellularautomaton, cellularrowclassifier, cellularpatterncatalog, rule110patternclassifier: no listed sibling is bijective to $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ because this packet jointly binds quotient support families, nonempty private blocks, shared-coordinate incidence, Rule 110 classifier routing, decoration-count provenance, transport, replay, provenance, and local naming.

The Lean TasteGate file for this packet must provide $\mathsf{Nontrivial}\ \mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ instances for the displayed rows $Q, B, S, R, E, H, C, P, N$ before the decoration carrier can serve as a verified classifier-decoration consumer.

Closure status for $\mathsf{NameCert}_{\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}}$.

Constructive story: A $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ packet is generated from quotient support family rows, nonempty private-block rows, shared-coordinate incidence rows, Rule 110 pattern-classifier rows, decoration-count provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5878.1, Definition 5878.2, and Definition 5878.3 seed the finite private/shared classifier-decoration surface for Rule 110 support-family consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite Rule 110 orbit classification, host quotient-support equality, biological interpretation, unrestricted enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked quotient support admission, private-block nonemptiness, shared-coordinate incidence, Rule 110 classifier routing, decoration-count provenance, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.RuleOneTenPrivateSharedDecorationUp.

Chapter 5879

A Concrete Naming Certificate for $\mathsf{ConstructiveCantorTheorem}^{\uparrow}$

Following Cantor and Bishop–Bridges, the $\mathsf{ConstructiveCantorTheorem}^{\uparrow}$ packet records the finite diagonal obstruction to enumerating Cantor-space bit names. It sits over the binary prefix carrier of chapter 1475, the finite bar-facing tree discipline of chapter 1622, the fan-theoretic bounded-window route of chapter 400, and the Real-facing non-surjection boundary of chapter 3793. The packet names only finite rows: an attempted enumeration window, its displayed diagonal bit schedule, the disagreement row at each inspected index, and the no-enumeration handoff. It is not a host-cardinality theorem, not a completed powerset construction, and not a quotient-stream principle.

Definition 5879.1 (Constructive Cantor finite diagonal carrier)**.** *A* $\mathsf{ConstructiveCantorTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (E, W, D, G, T, F, R, H, C, P, N)$$

with the following visible rows:

1. *E is the displayed finite enumeration attempt row, listing the first n candidate Cantor-space names through finite prefix windows;*
2. *W is the finite binary observation window, naming the inspected coordinates and the finite prefix depth used for each candidate;*
3. *D is the diagonal-bit row, obtained by flipping the displayed ith bit of the ith candidate whenever that coordinate is present in W;*
4. *G is the disagreement ledger, recording for every inspected index $i < n$ that the diagonal row disagrees with the ith candidate at the displayed coordinate;*
5. *T is the tree-read row through* $\mathsf{KleeneTree}^{\uparrow}$*, ensuring that finite prefix extension and absence of a completed path are read as finite branch data;*
6. *F is the fan-window row through* $\mathsf{FanTheorem}^{\uparrow}$*, recording the bounded prefix surface consumed by any compact Cantor-space handoff;*
7. *R is the Real-facing route through* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$*, used only after the Cantor-space disagreement ledger has been displayed;*

8. *H records componentwise* hsame *transport for enumeration rows, prefix windows, diagonal bits, disagreement ledgers, tree rows, fan rows, Real-facing routes, replay rows, provenance, and local naming;*
9. *C records displayed* Cont *replay from an enumeration window to diagonal-bit construction, disagreement verification, Cantor-space handoff, and Real-facing non-surjection routing;*
10. *P is the* Pkg *provenance over* ConstructiveCantorTheorem$^{\uparrow}$, CantorSpace$^{\uparrow}$, KleeneTree$^{\uparrow}$, FanTheorem$^{\uparrow}$, RealDiagonalNonSurjection$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* NameCert$_{\text{ConstructiveCantorTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, W, D, G, T, F, R, H, C, P, N$. It has no coordinate for a completed enumeration of all binary streams, host powersets, quotient stream equality, countable choice, or classical cardinal comparison.

Theorem 5879.2 (Finite diagonal obligations)**.** *For every accepted* ConstructiveCantorTheorem$^{\uparrow}$ *carrier $K = (E, W, D, G, T, F, R, H, C, P, N)$, the local* NameCert$_{\text{ConstructiveCantorTheorem}^{\uparrow}}$ *surface consists exactly of finite enumeration-window admission through E, binary observation through W, diagonal-bit formation through D, inspected-index disagreement through G, tree and fan routing through T, F, Real-facing non-surjection routing through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ConstructiveCantorTheoremUp.ConstructiveCantorTheoremTasteGate single carrier alignment`

Proof. Project the carrier of Definition 5879.1. The enumeration and observation rows are E and W, so every candidate read is confined to a displayed finite prefix window.

Build the diagonal row by induction on the finite index spine of W. The empty window contributes no bit and no disagreement row. At a successor index, read the displayed candidate bit at the diagonal coordinate and place the opposite bit in D.

The same induction fills G. Each successor step adds exactly the disagreement between the new diagonal bit and the candidate bit just inspected, while previous rows are transported componentwise by H and replayed by C.

The rows T, F, R do not add an infinite object. They only route the same finite disagreement ledger through the Kleene-tree, fan-window, and Real-facing non-surjection surfaces, so the listed rows exhaust the certificate without a host powerset, quotient stream equality, choice principle, or classical cardinal comparison. □

Theorem 5879.3 (No-enumeration window)**.** *Let K be an accepted* ConstructiveCantorTheorem$^{\uparrow}$ *carrier with a displayed enumeration window E of length n. The diagonal row D determines a Cantor-space prefix window such that for every inspected index $i < n$, the ith candidate of E differs from D at the displayed diagonal coordinate recorded in G. Hence the window cannot certify that its listed candidates exhaust the displayed Cantor-space prefixes.*

Proof. Induct on the finite enumeration window. For the empty window, there is no inspected candidate and the exhaustion claim has no displayed row.

At a successor window, the induction hypothesis supplies the disagreement rows for the previous candidates. The new candidate has a displayed diagonal coordinate in W, and the diagonal construction places the opposite binary value in D.

The new row of G records this disagreement. Componentwise hsame transport preserves the previous rows and the displayed Cont replay keeps the construction inside the same finite packet.

Therefore every inspected candidate is separated from the diagonal prefix at its own displayed coordinate. A finite window containing these disagreement rows cannot also certify that the same listed candidates exhaust the displayed Cantor-space prefix surface. □

Theorem 5879.4 (Cantor-space handoff)**.** *Every downstream consumer of a* ConstructiveCantorTheorem$^{\uparrow}$ *packet receives only the finite handoff formed by the enumeration window, binary observation window, diagonal-bit row, disagreement ledger, Kleene-tree row, fan-window row, Real-facing non-surjection route, transport, replay, provenance, and local naming. The handoff may be read by* CantorSpace$^{\uparrow}$ *and then by* RealDiagonalNonSurjection$^{\uparrow}$*, but it exports no completed stream quotient, powerset object, countable-choice selector, or classical uncountability principle.*

Proof. Start with the finite rows E, W, D, G of the carrier. By Definition 5879.2, these are the only rows that form and verify the diagonal disagreement.

Next read the Cantor-space side through chapter 1475. The Kleene-tree and fan rows T, F preserve finite prefix extension and bounded-window routing; they do not select a completed path or add an ambient compactness theorem.

Finally route the same disagreement ledger to chapter 3793 through R. Since the carrier has no coordinate for quotient stream equality, countable choice, host powersets, or classical cardinal comparison, the consumer receives exactly the finite handoff named in the statement. □

Falsifiable prediction: A purported ConstructiveCantorTheorem$^{\uparrow}$ consumer that reads a no-enumeration conclusion while omitting the enumeration window, diagonal-bit row, inspected-index disagreement ledger, Cantor-space prefix row, transport, replay, provenance, or local naming refutes the packet.

Independence witness: cantorspace, kleene-tree, fantheorem, real-diagonal-non-surjection: ConstructiveCantorT is not bijective to any listed sibling because it jointly carries an attempted enumeration window, a diagonal-bit construction, an inspected-index disagreement ledger, and a downstream Cantor-space-to-Real non-surjection route in one finite NameCert packet.

Closure status for NameCert$_{\text{ConstructiveCantorTheorem}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\text{ConstructiveCantorTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 5879.1, Definition 5879.2, Definition 5879.3, and Definition 5879.4 seed the finite diagonal non-enumeration packet over Cantor-space prefix rows.

Formal verification: FormalStatus(NameCert$_{\text{ConstructiveCantorTheorem}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.ConstructiveCantorTheoremUp.ConstructiveCantorTheoremTasteGate\_single\_carrier\_alignm`

Bridge status: none

Not claimed: This chapter does not claim a completed stream quotient, a host powerset object, a countable-choice selector, a classical cardinal comparison, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean targets for carrier admission, diagonal-bit exactness, inspected-index disagreement, Cantor-space handoff, Real-facing route preservation, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveCantorTheoremUp.

Constructive story: A ConstructiveCantorTheorem$^{\uparrow}$ packet is generated from a finite attempted enumeration window, a finite binary observation window, a diagonal-bit row, an inspected-index disagreement ledger, Kleene-tree and fan-window rows, Real-facing non-surjection routing, componentwise transport, displayed replay, provenance, and a local NameCert row.

MarkovKakutaniFixedPoint$^{\uparrow}$ routes its common fixed-window packet through the compact-convex and set-valued fixed-point surfaces of chapter 1923 and chapter 3511.

Chapter 5880

Markov-Kakutani Fixed Point NameCert Construction

Following Markov and Kakutani, the $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$ packet records the finite BEDC surface for a commuting affine family acting on a compact convex carrier. It is anchored by the convex carrier of chapter 208, the functional-analysis ambient rows of chapter 94, the compact-convex self-map handoff of chapter 1923, and the set-valued fixed-point surface of chapter 3511. The packet names a finite common fixed-point obligation route; it does not import a host compactness theorem, a global choice selector, an ambient locally convex space, or a completed real vector topology outside the displayed rows.

Definition 5880.1 (Markov-Kakutani fixed point carrier)**.** *A* $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, A, F, C, W, I, H, R, P, N)$$

with the following displayed rows:

1. *D is the compact convex domain row, read through the carried* $\mathsf{ConvexSet}^{\uparrow}$ *and compact support surfaces.*
2. *A is the affine ambient row, exposing only the finite vector-operation and scalar-stability data required by the displayed family.*
3. *F is the commuting-family row, listing the finite subfamily of affine self-maps and their source and target admissions.*
4. *C is the commutation ledger, recording pairwise commutation only for the displayed finite family windows.*
5. *W is the finite fixed-window row, recording the common approximate fixed rows inspected by downstream consumers.*
6. *I is the invariant-subcarrier row, exposing the finite intersection handoff used to keep the common fixed-window route inside the compact convex carrier.*
7. *H records componentwise* hsame *transport for domain, affine ambient, family, commutation, fixed-window, invariant-subcarrier, replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from a family request through $D, A, F, C, W, I, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{SchauderFixedPoint}^{\uparrow}$, $\mathsf{KakutaniFixedPoint}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, A, F, C, W, I, H, R, P, N$. It has no coordinate for an unbounded operator family, host compactness, selected fixed point, quotient equality of nets, or an ambient topological-vector-space theorem.

Theorem 5880.2 (Markov-Kakutani fixed point obligation surface)**.** *For every accepted* MarkovKakutaniFixedPoint *carrier*

$$M = (D, A, F, C, W, I, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}}$ *surface consists exactly of compact-convex domain admission through D, affine ambient admission through A, finite commuting-family admission through F, pairwise commutation exposure through C, fixed-window exposure through W, invariant-subcarrier handoff through I, componentwise* hsame *stability through H, displayed* Cont *replay through R,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5880.1. The compact-convex, affine, commuting-family, commutation, fixed-window, and invariant-subcarrier data are exactly the rows D, A, F, C, W, I.

The domain and affine rows bind the finite ambient context before any map in the family is read. The family row F then lists only displayed affine self-maps, and the commutation ledger C records pairwise commutation inside that finite list.

The fixed-window and invariant-subcarrier rows W, I are the only route to a common fixed-point obligation. Finally H, R, P, N transport, replay, source, and name the same packet. Since no additional coordinate is present, the listed rows exhaust the NameCert surface. □

Theorem 5880.3 (Markov-Kakutani commuting handoff)**.** *Every accepted consumer of a* MarkovKakutaniFixedPoi *packet that asks for a common fixed-window read factors through*

$$\mathsf{ConvexSet}^{\uparrow},\ \mathsf{FunctionalAnalysis}^{\uparrow},\ \mathsf{SchauderFixedPoint}^{\uparrow},\ \mathsf{KakutaniFixedPoint}^{\uparrow} \longmapsto D, A, F, C, W, I, H, R, P, N.$$

The exported object is a finite commuting-family fixed-window packet. It is not a selected fixed point, a host compactness theorem, a global choice principle, a quotient of approximating nets, or an ambient locally convex-space completion.

Proof. Open the accepted carrier using Definition 5880.1. A consumer must first read the compact convex domain row D and the affine ambient row A, so the route is grounded in the displayed convex and functional-analysis siblings.

Next read the finite family row F and the commutation ledger C. These rows expose only the listed affine self-maps and their pairwise commutation windows, so no unbounded operator family or host selection principle enters the packet.

The fixed-window row W is then interpreted inside the invariant-subcarrier row I. The Schauder and Kakutani siblings provide fixed-point handoff surfaces for the displayed compact-convex route, but the Markov-Kakutani packet exports only the finite common-window ledger named by W, I.

Finally H, R, P, N preserve the same carrier under transport, replay, provenance, and local naming. The exclusion clauses in the carrier therefore prevent selected fixed points, host compactness, quotient-net equality, and ambient completion from leaving the packet. □

Falsifiable prediction: Every accepted $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$ consumer must expose compact-convex domain, affine ambient, finite commuting-family, pairwise commutation, fixed-window,

invariant-subcarrier, hsame, Cont, Pkg, and NameCert rows before it can read a common fixed-window obligation.

Independence witness: convexset, functionalanalysis, schauder-fixed-point, kakutani-fixed-point: $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite commuting affine family, commutation ledger, fixed-window rows, invariant-subcarrier handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$ packet is generated from compact-convex domain rows, affine ambient rows, finite commuting-family rows, pairwise commutation ledgers, fixed-window rows, invariant-subcarrier handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5880.1, Definition 5880.2, and Definition 5880.3 seed the finite Markov-Kakutani fixed-point packet over displayed compact-convex, affine, commuting-family, fixed-window, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host compactness, selected common fixed points, global choice, quotient equality of nets, ambient locally convex completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-convex domain admission, affine-family routing, commutation ledger coverage, fixed-window exposure, invariant-subcarrier handoff, transport, replay, provenance, and local naming for BEDC.Derived.MarkovKakutaniFixedPointUp.

Proposition 5880.4 (Markov-Kakutani fixed-window dependency route)**.** *Every accepted* MarkovKakutaniFixedPoi *consumer that reads the common fixed-window row W consumes* $\mathsf{KakutaniFixedPoint}^{\uparrow}$ *from chapter 3511 and* $\mathsf{SchauderFixedPoint}^{\uparrow}$ *from chapter 1923 only through the displayed compact-convex fixed-window route $D, A, F, C, W, I, H, R, P, N$ of Definition 5880.3. The route records the horizontal fixed-point dependency while refusing a detached host compactness theorem, selected common fixed point, or ambient locally convex completion.*

$\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ routes its private/shared row-set ledger to the defect-refined decoration consumer of chapter 7630, while the child files keep the NameCert carrier and forward route separate.

Chapter 5881

Window-Six Private/Shared Decoration NameCert Construction

The WindowSixPrivateSharedDecoration$^{\uparrow}$ packet realizes the private/shared decoration enumeration of Definition 9462.1699 inside the DNA window-six boundary-tile source of subsection 9462.28.21. It consumes the boundary-tile packet of chapter 3393, the six-boundary coverage packet of chapter 3470, the boundary-trigger closure packet of chapter 3508, and the trigger-threshold packet of chapter 4217. The packet records private blocks, shared row sets, trigger coverage, decoration counts, transport, replay, provenance, and local naming as finite rows; it is not a biological mechanism, stochastic fitness model, hidden enumeration oracle, or quotient codon semantics.

Definition 5881.1 (Window-six private/shared decoration carrier)**.** *A* WindowSixPrivateSharedDecoration$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (B, S, T, E, D, H, C, P, N)$$

with the following displayed rows:

1. *B is the private-block row, recording the nonempty private coordinate blocks attached to each accepted decorated support.*
2. *S is the shared-row-set ledger, assigning every shared coordinate to a finite row set of size at least two.*
3. *T is the trigger-coverage row, read through the carried DNA boundary-tile, six-boundary coverage, closure, and threshold packets.*
4. *E is the decoration-count row, recording the finite enumeration factors from the source private/shared theorem.*
5. *D is the defect ledger, recording row-set-size contribution to the defect-refined decoration polynomial.*
6. *H records componentwise* hsame *transport for private blocks, shared row sets, trigger coverage, decoration count, defect ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a window-six decoration request through B, S, T, E, D, H, P, N.*
8. *P is the* Pkg *provenance over* WindowSixPrivateSharedDecoration$^{\uparrow}$, DnaWindowSixBoundaryTile$^{\uparrow}$, SixBoundaryTileCoverage$^{\uparrow}$, DnaBoundaryTriggerClosure$^{\uparrow}$, DNAWindowSixTriggerThreshold$^{\uparrow}$, *the source theorem of Definition 9462.1699,* BHist, hsame, Cont, Pkg, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $B, S, T, E, D, H, C, P, N$. It has no coordinate for biological mechanism, stochastic evolutionary semantics, quotient codon equality, hidden global enumeration, or an unrecorded trigger oracle.

Theorem 5881.2 (Window-six private/shared decoration obligations)**.** *For every accepted* WindowSixPrivateShared *carrier*

$$W = (B, S, T, E, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}}$ *surface consists exactly of private-block admission through B, shared-row-set admission through S, trigger-coverage exposure through T, decoration-count exposure through E, defect-ledger exposure through D, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5881.1. The private block, shared row set, trigger coverage, decoration count, defect ledger, transport, replay, provenance, and naming data are precisely $B, S, T, E, D, H, C, P, N$.

The rows B, S enforce the private/shared split: each accepted support has a displayed private block, and each shared coordinate is assigned to a row set of size at least two. The trigger-coverage row T then ties those rows to the existing window-six boundary, coverage, closure, and threshold packets.

The rows E, D record the enumeration and defect data used by the source theorem. Finally H, C, P, N preserve, replay, source, and name the same finite route. Since the carrier has no additional coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5881.3 (Window-six private/shared decoration enumeration handoff)**.** *Every accepted* $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ *consumer that reads a private/shared window-six decoration factors through*

$\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$, DNAWindowSixTriggerThres

The exported object is a finite private/shared row-set ledger with trigger-coverage and decoration-count rows. It is not a biological model, a quotient codon space, a hidden enumeration oracle, or an unrestricted trigger-search theorem.

Proof. Read the accepted carrier through Definition 5881.1. The private and shared ledgers B, S supply the displayed row-set split before a decoration count is exposed.

Next use T to route the split through the boundary-tile, six-boundary coverage, boundary-trigger closure, and trigger-threshold siblings. This prevents a decoration request from bypassing the window-six trigger-coverage surface.

The enumeration row E and defect row D then record the finite count and defect-polynomial data from the source theorem. The structural rows H, C, P, N transport, replay, source, and locally name the same rows.

Therefore every accepted consumer receives the finite packet described in the theorem, rather than biological semantics, quotient codon equality, hidden enumeration, or unrestricted trigger search. □

Theorem 5881.4 (Window-six private/shared decoration sibling lattice)**.** *Every accepted* WindowSixPrivateSharedD *packet consumes the sibling lattice*

$\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$, DNAWindowSixTriggerThres

before it exports the private/shared decoration ledger $B, S, T, E, D, H, C, P, N$. The lattice is finite and row-projection based: it displays boundary tiles, six-boundary coverage, trigger closure, and trigger-threshold evidence before the private block, shared row-set, trigger coverage, decoration count, and defect rows are consumed. It is not a biological mechanism, quotient codon semantics, stochastic evolutionary model, or hidden enumeration oracle.

Proof. Project the accepted carrier $W = (B, S, T, E, D, H, C, P, N)$ of Definition 5881.1. The private/shared ledger rows B, S, the trigger row T, the enumeration and defect rows E, D, and the structural rows H, C, P, N are the only exported coordinates.

Apply the enumeration handoff of Definition 5881.3. It forces every private/shared decoration read to pass through the boundary-tile, six-boundary coverage, boundary-trigger closure, and trigger-threshold siblings before $B, S, T, E, D, H, C, P, N$ are consumed.

Thus the dependency is a finite sibling lattice: each sibling supplies a displayed row that is projected before the decoration ledger is exported. Since the carrier has no coordinate for biological mechanism, quotient codon equality, stochastic evolution, or hidden enumeration, none of those interpretations is introduced by the lattice. □

Falsifiable prediction: Every accepted $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ packet must expose private-block, shared-row-set, trigger-coverage, decoration-count, hsame, Cont, Pkg, and NameCert rows before it can export a private/shared window-six decoration read.

Independence witness: dna-window-six-boundary-tile, six-boundary-tile-coverage, dna-boundary-trigger-closure, dna-window-six-trigger-threshold: $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ is not bijective to any listed sibling because the private/shared row-set ledger jointly carries private blocks, shared row sets, trigger coverage, decoration counts, defect rows, transport, replay, provenance, and local naming.

The Lean TasteGate route for `BEDC.Derived.WindowSixPrivateSharedDecorationUp.TasteGate` must provide explicit Nontrivial $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ and FieldFaithful WindowSixPrivateSharedDecora instances preserving $B, S, T, E, D, H, C, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}}$.

Constructive story: A $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ packet is generated from private-block rows, shared-row-set ledgers, trigger-coverage rows, decoration-count rows, defect ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}}$, seed)

Scope closed: Definition 5881.1, Definition 5881.2, and Definition 5881.3 seed the finite private/shared window-six decoration packet over displayed boundary, coverage, closure, threshold, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic evolution, quotient codon equality, hidden global enumeration, unrestricted trigger search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, private-block exposure, shared-row-set arity, trigger-coverage routing, decoration-count exposure, defect-ledger exposure, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.WindowSixPrivateSharedDecorationUp.

Proposition 5881.5 (Window-six private/shared decoration defect forward route)**.** *The private/shared row-set ledger exported by* $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ *is an allowed child route for chapter 7630. Its rows $B, S, T, E, D, H, C, P, N$ supply the private block, shared row set, trigger coverage, enumeration, defect ledger, transport, replay, provenance, and local naming data used by the downstream defect-refined decoration polynomial route.*

Proof. Read the exported packet through Definition 5881.1. The private/shared ledger already separates private blocks from shared row sets and records the defect ledger as a displayed row.

The downstream chapter chapter 7630 consumes exactly that displayed ledger when it forms its defect-refined decoration polynomial route. Because the route is through the named child rows rather than through the hub file, it preserves the hub-only layout and records a genuine forward dependency between the two finite packets. □

Chapter 5882

A Concrete Naming Certificate for $\mathsf{SchurLemma}^{\uparrow}$

Following Schur and the finite-group representation-theory treatments of Serre and Fulton–Harris, the $\mathsf{SchurLemma}^{\uparrow}$ packet records the finite Hom-intertwiner boundary for irreducible representation rows. It sits between the finite representation carrier of chapter 3662, the character-theory trace surface of chapter 245, the representation-ring package of chapter 246, the orthogonality route of chapter 1603, and the character-table consumer of chapter 3574.

Definition 5882.1 (SchurLemma carrier)**.** *A* $\mathsf{SchurLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, V, H, S, T, R, P, N)$$

with the following displayed rows:

1. *U is an irreducible finite representation row over the same finite group source used by Definition 3662.1;*
2. *V is a second irreducible finite representation row over the same finite group source;*
3. *H is the displayed* Hom *and intertwiner row from U to V, recording equivariance rather than all host linear maps;*
4. *S is the scalar-or-zero boundary: when the two irreducible rows are the same finite representation row, accepted endomorphism reads factor through one scalar row, and when they are distinct no nonzero intertwiner row is exported;*
5. *T records componentwise* hsame *transport for the representation rows, Hom row, scalar-or-zero boundary, route, provenance, and naming rows;*
6. *R records displayed* Cont *replay from the finite representation packet through the Hom row into the scalar-or-zero boundary;*
7. *P is the* Pkg *provenance over* $\mathsf{FiniteGroupRepresentation}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, $\mathsf{SchurOrthogonality}^{\uparrow}$, $\mathsf{CharacterTable}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SchurLemma}^{\uparrow}}$ *row.*

The carrier is exactly this finite representation-theory packet. It has no coordinate for a host abelian category, unrestricted module category, global algebra closure, or unrecorded linear-map equality.

Lean4 ✓ `BEDC.Derived.SchurLemmaUp.SchurLemmaTasteGate single carrier alignment`

Theorem 5882.2 (SchurLemma NameCert obligations)**.** *For the carrier of Definition 5882.1, the local* $\mathsf{NameCert}_{\mathsf{SchurLemma}^{\uparrow}}$ *surface consists exactly of carrier admission for* $K = (U, V, H, S, T, R, P, N)$*, irreducible finite representation exposure through* U, V*, Hom-intertwiner exposure through* H*, scalar-or-zero boundary exposure through* S*, componentwise* hsame *transport through* T*, displayed* Cont *replay through* R*, package provenance through* P*, and local naming through* N*.*

Proof. Project the displayed carrier. The packet lists U, V, H, S, T, R, P, N as its whole public surface, so the local certificate cannot introduce a second Hom object, a host representation category, or a hidden linear-map equality relation.

Read the representation rows first. The rows U and V are finite irreducible representation rows of the same group source, and the Hom row H is accepted only as an equivariant row between them.

The scalar-or-zero boundary is then read through S. It records scalar endomorphism reads in the same-row case and zero Hom reads in the distinct-row case. The rows T, R, P, N transport, replay, package, and name only that finite packet. □

Lean4 ✓ `BEDC.Derived.SchurLemmaUp.SchurLemmaCarrier namecert obligations`

Theorem 5882.3 (SchurLemma character-table handoff)**.** *Every accepted* $\mathsf{SchurLemma}^{\uparrow}$ *packet exports to* $\mathsf{CharacterTable}^{\uparrow}$ *only the finite Hom-intertwiner boundary needed by the Schur-orthogonality and character-pairing routes. The handoff reads* U, V, H, S *before* T, R, P, N *and exports no host representation category, unrestricted matrix algebra, quotient computation, or globally chosen basis.*

Proof. Start from Definition 5882.1. The downstream character-table consumer sees exactly the two irreducible representation rows, the displayed Hom-intertwiner row, and the scalar-or-zero boundary.

Use the neighboring representation-theory packets as routing anchors. The finite representation chapter supplies the representation rows, the character-theory and representation-ring chapters supply trace and sum surfaces, and the Schur-orthogonality chapter consumes the scalar-or-zero boundary before the character-table chapter reads pairings.

The structural rows T, R, P, N preserve that same finite packet under transport, replay, provenance, and local naming. Since no host category, unrestricted matrix algebra, quotient computation, or chosen-basis row appears in the carrier, the character-table handoff cannot export one. □

Closure status for $\mathsf{NameCert}_{\mathsf{SchurLemma}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SchurLemma}^{\uparrow}$ packet is generated from two irreducible finite representation rows, a displayed Hom-intertwiner row, a scalar-or-zero boundary row, componentwise transport, displayed continuation replay, package provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SchurLemma}^{\uparrow}}$, seed)

Scope closed: Definition 5882.1, Definition 5882.2, and Definition 5882.3 seed the finite Hom-intertwiner boundary between irreducible representation rows and the character-table consumer.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SchurLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close a host representation category, unrestricted module-category Hom, quotient computation, globally chosen bases, Lean verification, or bridge checking for $\mathsf{SchurLemma}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, irreducible-row exposure, Hom-intertwiner exactness, scalar-or-zero boundary, transport stability, replay stability, and local NameCert nonescape for BEDC.Derived.SchurLemmaUp.

Chapter 5883

A Concrete Naming Certificate for $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$

Following Weierstrass and Bishop–Bridges constructive analysis, the $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$ packet records the interval-minimum half of the compact-real extreme-value route as finite BEDC NameCert data. It sits over the compact interval source of chapter 3986, the closed bounded interval source of chapter 1591, the continuous-map row of chapter 130, the located lower-bound route dual to chapter 1427, and the terminal real-name seal of chapter 38. The packet is minimum-specific: it exposes lower-bound attainment windows without importing open-cover compactness, trichotomy, quotient real equality, selected host extrema, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5883.1 (Compact real interval minimum carrier)**.** *A* $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, K, F, L, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, carrying endpoint order, interval containment, finite endpoint windows, and real endpoint seals.*
2. *K is the compact interval row, read through* $\mathsf{BishopCompactInterval}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$*, exposing only the finite inspection surface admitted for the interval source.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the real-valued map on the displayed compact interval.*
4. *L is the lower-bound and located-supremum-dual row, recording that every inspected value is above a displayed lower-bound candidate and that the candidate is reached through finite located windows rather than by trichotomy.*
5. *W is the finite witness-window row, recording the interval windows in which F and L meet a terminal value seal.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the value and lower-bound comparison windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *value seal row reached only after I, K, F, L, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the interval source, compact source, continuous-map row, lower-bound row, witness windows, regular readbacks, Real seals, replay rows, provenance rows, and local naming rows.*

9. *C records displayed* Cont *replay from minimum-attainment requests through* $I, K, F, L, W, R, E, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{BishopCompactInterval}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRealIntervalMinimum}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for open-cover compactness, arbitrary real trichotomy, quotient real equality, a selected host minimum, a selected host maximum, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CompactRealIntervalMinimumUp.CompactRealIntervalMinimumTasteGate single carrier alignment`

Theorem 5883.2 (Compact real interval minimum NameCert obligations)**.** *For every accepted* $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$ *carrier*

$$M = (I, K, F, L, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactRealIntervalMinimum}^{\uparrow}}$ *surface consists exactly of carrier admission for the closed bounded interval source, compact interval source, continuous-map row, lower-bound and located-supremum-dual row, finite witness-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *value seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No minimum obligation is stored outside these rows.*

Proof. Project the carrier of Definition 5883.1. The interval row I and compact row K expose the only compact-real source windows available to the packet, while F records the continuous real-valued map inspected on those windows.

Read the lower-bound and witness rows next. The row L gives the displayed lower-bound comparison as the dual of the located-supremum route, and W binds that comparison to finite source windows where the map row and bound row meet.

The regular and real-facing rows are downstream. The row R records the regular rational readback of the same finite comparisons, while E seals only those displayed reads as $\mathsf{Real}^{\uparrow}$ values.

The remaining rows H, C, P, N transport, replay, source, and locally name the same route. Since the carrier has no coordinate for open-cover compactness, trichotomy, quotient equality, selected host extrema, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 5883.3 (Compact real interval minimum located attainment)**.** *Every accepted* CompactRealIntervalMinim *consumer that reads a minimum value factors through the displayed route*

$$I, K \longmapsto F, L \longmapsto W \longmapsto R, E \longmapsto H, C, P, N.$$

Thus the compact-real interval-minimum surface exports only a finite witness-window route from a closed bounded compact interval and continuous-map row to a located lower-bound row, regular rational readback, and $\mathsf{Real}^{\uparrow}$ *value seal. It does not export open-cover compactness, trichotomy, quotient real equality, selected host extrema, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the source rows. The closed bounded interval source and compact interval source are displayed as I and K, so every later value comparison is scoped to the same finite compact-real interval windows.

Feed the source into the continuous-map and lower-bound rows. The row F exposes only displayed value reads, while L records the lower-bound comparison through the located-supremum-dual route rather than through a host order decision.

Use the witness-window and readback rows together. The row W records where the compact interval inspection meets the lower-bound comparison, and R repacks those comparisons as $\mathsf{RegSeqRat}^{\uparrow}$ data before the $\mathsf{Real}^{\uparrow}$ seal E is read.

Finally, transport and replay preserve the route through H and C, while P and N provide provenance and local naming. No row supplies open-cover compactness, trichotomy, quotient real equality, selected host extrema, or ambient completeness, so every accepted minimum read remains inside the displayed route. □

Falsifiable prediction: Every $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$ minimum read factors through $\mathsf{ClosedBoundedInterva}$ $\mathsf{BishopCompactInterval}^{\uparrow}$ or $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$-dual lower-bound data, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before reaching finite witness windows and the local $\mathsf{NameCert}_{\mathsf{CompactRealIntervalMinimum}^{\uparrow}}$ row.

Independence witness: bishopcompactinterval, closedboundedinterval, continuousmap, locatedsupremum, real: $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a compact interval source, continuous-map row, located lower-bound route, finite witness-window row, regular readback, Real value seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRealIntervalMinimum}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, a BishopCompactIntervalUp or CompactMetricUp compact source row, a ContinuousMapUp real-valued map row, a lower-bound row dual to LocatedSupremumUp, finite witness windows, RegSeqRatUp readbacks, RealUp value seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRealIntervalMinimum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5883.1, Definition 5883.2, and Definition 5883.3 seed the finite compact-real interval-minimum route over interval, compact-source, continuous-map, lower-bound, witness-window, regular readback, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRealIntervalMinimum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, trichotomy, quotient real equality, selected host extrema, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, finite witness-window exactness, lower-bound routing, regular readback, Real value sealing, replay stability, and nonescape for BEDC.Derived.CompactRealIntervalMinir

Chapter 5884

A Concrete Naming Certificate for $\mathsf{SimpleFunctionApproximation}^{\uparrow}$

Following Caratheodory and Bourbaki measurable approximation, the $\mathsf{SimpleFunctionApproximation}^{\uparrow}$ packet names the finite-range measurable surface by which a measurable real-facing map is approximated without importing completed measure theory or host function equality. It sits after the preimage-ledger map surface of chapter 3461, the event-value rows of chapter 92, the generated-set boundary of chapter 3384, and the terminal real-name seal of chapter 38. The packet records finite range cells, measurable preimage rows, displayed tolerance data, finite observations, transport, replay, provenance, and local naming.

Definition 5884.1 (Simple function approximation carrier)**.** *A* $\mathsf{SimpleFunctionApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, F, R, E, T, O, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Measure}^{\uparrow}$ *row, exposing only the measurable event surface and event-value readback needed by the approximation packet.*
2. *F is the input* $\mathsf{MeasurableFunction}^{\uparrow}$ *row, read through its displayed target-event and preimage ledger rather than through a host function object.*
3. *R is the finite range ledger, listing the displayed* $\mathsf{Real}^{\uparrow}$ *values that the simple approximation may return.*
4. *E is the finite cell ledger, assigning each range row in R to a measurable source cell whose admission is read through* $\mathsf{BorelSet}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, *and the preimage rows of F.*
5. *T is the displayed* $\mathsf{Real}^{\uparrow}$ *tolerance row, naming the approximation budget used by the current consumer.*
6. *O is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row, recording the visible source probes, range reads, and tolerance comparisons exposed to the packet.*
7. *H stores componentwise* hsame *transport for the measure source, measurable-function row, finite range ledger, cell ledger, tolerance row, observation row, provenance, and local naming rows.*
8. *C stores the displayed* Cont *replay from source-event inspection through finite cell selection, range-value readback, tolerance comparison, and observation replay.*

9. *P is the* Pkg *provenance over* $\mathsf{SimpleFunctionApproximation}^{\uparrow}$, $\mathsf{MeasurableFunction}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SimpleFunctionApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, F, R, E, T, O, H, C, P, N$. It has no coordinate for almost-everywhere quotient classes, completed measures, selected representatives, ambient integration theorems, or equality of host functions.

Lean4 ✓ `BEDC.Derived.SimpleFunctionApproximationUp.SimpleFunctionApproximationTasteGate single carrier alignment`

Theorem 5884.2 (Simple function approximation NameCert obligations)**.** *For the carrier of Definition 5884.1, the local* $\mathsf{NameCert}_{\mathsf{SimpleFunctionApproximation}^{\uparrow}}$ *surface consists exactly of carrier admission for the measure source, measurable-function row, finite range ledger, measurable cell ledger, displayed* $\mathsf{Real}^{\uparrow}$ *tolerance row, finite* $\mathsf{StreamName}^{\uparrow}$ *observations, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted approximation consumer must read the finite cells through E, the measurable preimage route through F, the range values through R, and the tolerance comparison through T before any sibling* $\mathsf{Measure}^{\uparrow}$, $\mathsf{BorelSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{StreamName}^{\uparrow}$ *row is exported.*

Proof. Project the carrier $S = (M, F, R, E, T, O, H, C, P, N)$. The measure source M and measurable-function row F are the only rows from which measurable event and preimage information can be read.

Read the finite approximation data. The range ledger R supplies the displayed real values, the cell ledger E ties each range value to a measurable source cell, and the tolerance row T records the visible approximation budget against which the current observations are compared.

Replay the observation and structural rows. The row O records the finite StreamName probes, while H, C, P, N transport, replay, source, and name the same route through the sibling certificates. Since no further coordinate is present, the listed rows exhaust the NameCert obligation surface and cannot export quotient classes, completed measures, selected representatives, ambient integration theorems, or host function equality. □

Theorem 5884.3 (Simple function approximation finite-cell route)**.** *Every accepted* $\mathsf{SimpleFunctionApproximation}^{\uparrow}$ *read factors through the finite route*

$$M, F \longmapsto E \longmapsto R, T \longmapsto O \longmapsto H, C, P, N.$$

Thus a consumer receives a finite measurable partition-by-cells with displayed real values and a displayed tolerance budget, not an almost-everywhere quotient class, completed measure, selected representative, ambient integral, or equality proof for host functions.

Proof. Start with an accepted approximation request. The request first exposes the measure source and the measurable-function row, so every cell read is grounded in the displayed source-event and preimage ledgers.

The cell ledger E is finite. Each displayed cell is paired with a range value from R, and the tolerance row T supplies the visible real-valued budget for the comparison requested by the consumer.

Finally replay the observations and structural rows. The finite StreamName row O records only the exposed probes, while H, C, P, N transport and name the route. No hidden coordinate remains from which a quotient, completion, representative selection, integration theorem, or host equality could be recovered. □

Falsifiable prediction: A $\mathsf{SimpleFunctionApproximation}^{\uparrow}$ consumer that obtains an almost-everywhere quotient class, completed measure, selected representative, ambient integration theorem, or host function equality without first reading $M, F, R, E, T, O, H, C, P, N$ refutes the carrier of Definition 5884.1.

Independence witness: measurablefunction, measure, borelset, real, streamname: no listed sibling supplies the whole ten-row packet $S = (M, F, R, E, T, O, H, C, P, N)$, because each sibling contributes only preimage-ledger, event-value, generated-set, real-name, or finite-observation data while this chapter binds the finite-range approximation surface with tolerance, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SimpleFunctionApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{SimpleFunctionApproximation}^{\uparrow}$ packet is generated from a measure source, a measurable-function preimage ledger, finite range cells, a displayed Real tolerance row, finite StreamName observations, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SimpleFunctionApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5884.1, Definition 5884.2, and Definition 5884.3 seed the finite-range measurable approximation surface over source events, preimage rows, cell ledgers, range values, tolerance rows, observations, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SimpleFunctionApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close almost-everywhere quotient classes, completed measures, selected representatives, ambient integration theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-cell exactness, measurable preimage preservation, Real tolerance replay, StreamName observation stability, and quotient-refusal proofs for BEDC.Derived.SimpleFunctionApproxima

Chapter 5885

A Concrete Naming Certificate for $\mathsf{DyadicModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicModulus}^{\uparrow}$ packet records the finite tolerance-modulus surface by which dyadic precision requests become regular rational readback before the terminal real seal is consumed. It sits between the dyadic tolerance arithmetic of chapter 291, the finite stream windows of chapter 126, the regular rational handoff of chapter 301, the terminal seal boundary of chapter 38, and the Cauchy-modulus route carried by $\mathsf{CauchyModulus}^{\uparrow}$. The packet is a finite NameCert carrier for Real and Completion consumers; it is not a host modulus function, quotient stream equality, selected limit, countable choice, or ambient completeness principle.

Definition 5885.1 (DyadicModulus carrier)**.** *A* $\mathsf{DyadicModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming dyadic scales, finite comparison budgets, rounding windows, and precision requests.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose visible entries are exactly the observations demanded by the tolerance row.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained by reading the stream windows under the dyadic tolerance ledger.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary, available only after D, S, R have been displayed.*
5. *H records componentwise* hsame *transport for tolerance, stream-window, regular-readback, seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from each dyadic precision request through D, S, R, E, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{DyadicModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, S, R, E, H, C, P, N. It has no coordinate for quotient stream equality, selected representatives, host real equality, countable choice, ambient Real completeness, or a detached host-level modulus function.

Lean4 ✓ `BEDC.Derived.DyadicModulusUp.DyadicModulusTasteGate single carrier alignment`

Theorem 5885.2 (DyadicModulus NameCert obligations)**.** *For every accepted* $\mathsf{DyadicModulus}^{\uparrow}$ *carrier* $M = (D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, finite-window exposure, regular rational readback, terminal Real seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Every Real or Completion consumer must read the displayed route

$$D \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

before using the packet as a dyadic tolerance-modulus certificate.

Proof. Project the carrier of Definition 5885.1. The tuple displays exactly the dyadic tolerance row, stream-window row, regular-readback row, terminal seal, transport, replay, provenance, and local name.

The analytic route is forced in order. A precision request first reads D, then the finite stream observations in S, then the regular rational handoff R, and only then reaches the seal boundary E.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no quotient-stream, selected-limit, choice, host-equality, ambient-completeness, or detached-modulus coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 5885.3 (DyadicModulus RegSeqRat handoff)**.** *Let* $M = (D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{DyadicModulus}^{\uparrow}$ *carrier. Any* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or Completion-facing consumer of the modulus row must factor through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* S*, and the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R *before the terminal seal row* E *is read.*

The handoff route is

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

as rows of one BHist *packet, with transport, replay, provenance, and local naming supplied by* H, C, P, N*.*

Proof. Start from Definition 5885.2. It already places every tolerance-modulus consumer on the displayed route D, S, R, E, H, C, P, N.

The regular rational readback is the row R, and R is downstream of both the dyadic tolerance row D and the stream-window row S. Thus a consumer cannot read a regular name, Real seal, or Completion boundary before the finite tolerance and window data have been displayed.

Finally inspect the excluded coordinates of Definition 5885.1. Because no quotient stream, selected representative, host equality, countable-choice schedule, ambient completeness theorem, or detached modulus function is present, the RegSeqRat handoff is exactly the stated finite route. □

Falsifiable prediction: An accepted $\mathsf{DyadicModulus}^{\uparrow}$ consumer is refuted if it reaches $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or a Completion-facing seal without first displaying one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local $\mathsf{NameCert}$ row.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy-modulus: $\mathsf{DyadicModulus}^{\uparrow}$ is not bijective to any listed sibling because the siblings separately provide tolerance arithmetic,

finite windows, regular rational readback, terminal sealing, or threshold scheduling, while this packet binds them into one finite tolerance-modulus handoff route.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicModulus}\uparrow}$.

Constructive story: A $\mathsf{DyadicModulus}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, a StreamName finite-window row, a RegSeqRat handoff row, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicModulus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5885.1, Definition 5885.2, and Definition 5885.3 seed the finite dyadic tolerance-modulus carrier between dyadic precision data and regular rational readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite-window exposure, RegSeqRat handoff, Real seal handoff, structural transport, and non-escape for BEDC.Derived.DyadicModulusUp.

Chapter 5886

A Concrete Naming Certificate for $\mathsf{CauchyFilterSelector}^{\uparrow}$

Following Bishop and Bridges and Kelley filter terminology, the $\mathsf{CauchyFilterSelector}^{\uparrow}$ packet records the finite selector interface by which a Cauchy-filter read can be inspected through named windows before any Real or Completion consumer reads the resulting boundary. It sits after the Cauchy-filter surface of chapter 333, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the completion handoff of chapter 1506. The packet gives the Phase Real and Completion route a finite selector row without quotient filters, host-selected representatives, countable choice, or ambient Real completeness.

Definition 5886.1 (Cauchy filter selector carrier)**.** *A* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row, including its displayed base packets, directed refinement ledger, and Cauchy evidence surface.*
2. *W is the finite selector-window row. It records the displayed filter request, the finite family of inspected base packets, and the chosen window among those already exposed by F.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the selected windows in W.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the filter request, the selector comparison, and the readback radius consumed by R.*
5. *E is the completion-or-Real seal row, read either as a* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff or as the downstream* $\mathsf{Real}^{\uparrow}$ *seal after F, W, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the filter row, selector windows, regular readback, dyadic ledger, seal row, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a Cauchy-filter request through F, W, R, D, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterSelector}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, W, R, D, E, H, C, P, N$. It has no coordinate for quotient filters, host-selected representatives, countable-choice schedules, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyFilterSelectorUp.CauchyFilterSelectorTasteGate single carrier alignment`

Theorem 5886.2 (Cauchy filter selector NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier $S = (F, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source Cauchy-filter data, selector windows, regular readback, dyadic tolerance ledger, completion-or-Real seal, transport, replay, provenance, and local naming row;*
2. *selector-window exactness, requiring the selected window to be one of the finite windows already displayed in W over the source filter row F;*
3. *regular readback handoff, requiring every numeric read to pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R after the selector window is fixed;*
4. *dyadic ledger stability, requiring the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D to govern the selector comparison and the readback radius;*
5. *seal boundary, requiring any* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer to read E only after F, W, R, D have been displayed and replayed;*
6. *nonescape, excluding quotient filters, host-selected representatives, countable choice, host real equality, and ambient Real completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5886.1. The visible packet consists of the source filter row F, selector windows W, regular readback R, dyadic ledger D, seal boundary E, and the structural rows H, C, P, N.

Selector-window exactness is row-local. The selector does not choose from an undisplayed filter; it names one of the finite windows stored in W and read over the already exposed Cauchy-filter row F.

The readback and tolerance obligations are ordered by the carrier. A numeric read reaches R only after W fixes the finite window, and the same dyadic ledger D supplies the tolerance budget for both the selector comparison and the regular readback radius.

The seal boundary is downstream. The replay row C routes every completion-facing or real-facing request through F, W, R, D before E, while H preserves this order under componentwise transport.

Since the carrier contains no quotient-filter coordinate, host-selected representative, choice schedule, host real equality, or Real completeness row, the listed obligations exhaust the local NameCert surface. □

Theorem 5886.3 (Cauchy filter selector RegSeqRat handoff)**.** *Let $S = (F, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier. Every selector read that exports regular numerical data factors through the finite route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}.$$

Concretely, the source filter row F exposes the finite base request, the selector-window row W exposes the inspected $\mathsf{StreamName}^{\uparrow}$ *windows, the readback row R exposes the* $\mathsf{RegSeqRat}^{\uparrow}$ *data, and the dyadic ledger D supplies the tolerance budget used by that readback.*

Proof. Project the accepted carrier. The source request is held in F, but F alone does not expose a regular rational name to downstream consumers.

Replay the selector route by C. The request first reaches the finite selector windows W, and those windows are the only place where the relevant $\mathsf{StreamName}^{\uparrow}$ observations are visible.

After W is fixed, the readback row R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ data. The tolerance row D is then read as the dyadic budget controlling the selector comparison and the regular readback.

Transport by H preserves the same order. Thus the handoff is a finite BEDC route from Cauchy filters to stream windows, regular readbacks, and dyadic tolerances, not a quotient of filters or a selected host representative. □

Theorem 5886.4 (Cauchy filter selector Real and completion seal boundary)**.** *For every accepted* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier* $S = (F, W, R, D, E, H, C, P, N)$*, every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer read exposed by* P *factors through the seal row* E *only after the source Cauchy-filter data, finite selector windows, regular readback, and dyadic tolerance ledger have been displayed. The visible boundary is*

$$F, W, R, D \longmapsto E \longmapsto H, C, P, N.$$

Therefore the packet provides a finite selector interface for the Real and Completion route without exporting quotient filters, host-selected representatives, countable choice, host real equality, or ambient Real completeness.

Proof. Read the seal row in the carrier. The row E is placed after the source filter data, selector windows, regular readback, and dyadic tolerance ledger, so a completion-facing or real-facing consumer cannot reach it from F alone.

The replay row C fixes the same order for every accepted request. It first consumes F, then the selector windows W, then the regular readback R, and then the dyadic tolerance ledger D before the seal row is available.

Componentwise transport by H does not add a new route. It preserves the displayed rows under classifier comparison, while P and N record only the provenance and local naming boundary of that finite route.

The excluded objects are absent from the carrier and from the replay path. Hence the completion-or-Real seal is exactly the displayed downstream boundary, not a quotient filter, selected representative, choice schedule, host equality, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5886.1, Definition 5886.2, Definition 5886.3, and Definition 5886.4 seed the finite selector interface between CauchyFilter, StreamName, RegSeqRat, DyadicRatCore, Real, and MetricCompletion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filters, host-selected representatives, countable choice, host real equality, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Lean closure requires carrier admission, selector-window exactness, RegSeqRat handoff, dyadic ledger stability, and Real or Completion seal boundary for BEDC.Derived.CauchyFilterSelectorUp.

Constructive story: The construction starts from a displayed CauchyFilter row, reads a finite selector window through StreamName observations, extracts RegSeqRat data under a DyadicRatCore tolerance ledger, and exposes Real or MetricCompletion access only through the downstream seal row.

The $\mathsf{Cauchy}^{\uparrow}$ packet is consumed through chapter 301 and chapter 38 before downstream completion or calculus reads inspect the finite Cauchy windows.

Chapter 5887

A Concrete Naming Certificate for $\mathsf{CauchyModulusSpace}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyModulusSpace}^{\uparrow}$ packet records a carrier-space interface for explicit Cauchy modulus schedules. It is anchored in the single-modulus certificate of chapter 292, the finite stream windows of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real seal of chapter 38, and the fast Cauchy sequence route of chapter 2185. The chapter treats a family of modulus schedules as finite naming data, not as a quotient of real sequences or as an ambient completeness theorem.

Definition 5887.1 (Cauchy modulus space carrier)**.** *A* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, S, W, D, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index row for the family of explicit modulus schedules.*
2. *S assigns to each displayed index a* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row, including the monotone precision requests used by the family.*
3. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected by the schedule family.*
4. *D is the dyadic tolerance ledger, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled windows.*
6. *Q records the* $\mathsf{Real}^{\uparrow}$ *seal boundaries at which a scheduled read may leave rational and dyadic data for a real-facing consumer.*
7. *H records componentwise* hsame *transport for $I, S, W, D, R, Q, C, P, N$.*
8. *C records displayed* Cont *replay from an index and precision request through the schedule row, stream window, dyadic tolerance ledger, regular rational readback, and real seal boundary.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusSpace}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and the local naming row.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only after transporting the displayed rows componentwise by hsame*. It has no coordinate for an unscheduled Cauchy oracle, quotient equality of sequences, a selected real limit, countable choice, or an ambient completion theorem.*

Lean4 ✓ `BEDC.Derived.CauchyModulusSpaceUp.CauchyModulusSpaceTasteGate single carrier alignment`

Theorem 5887.2 (Cauchy modulus space NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *carrier*

$$M = (I, S, W, D, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyModulusSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite index family, schedule admission for the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *rows, finite* $\mathsf{StreamName}^{\uparrow}$ *window admission, dyadic tolerance compatibility,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback compatibility,* $\mathsf{Real}^{\uparrow}$ *seal-boundary compatibility, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming for the packet.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusSpaceNameCertObligations`

Proof. Project the accepted carrier of Definition 5887.1. The analytic data are precisely I, S, W, D, R, Q, and the structural rows are precisely H, C, P, N.

Schedule admission is rowwise over I. Each index exposes its explicit modulus schedule before any stream window is inspected, so the packet cannot replace the family by an unscheduled oracle.

The tolerance and readback rows are then forced through D and R. The real boundary row Q is available only after those rational and dyadic ledgers have been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no excluded host object is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 5887.3 (Cauchy modulus space finite route)**.** *Every real-facing comparison of two accepted* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *carriers factors through finite schedule rows, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic tolerance ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seal boundaries, componentwise* hsame*, displayed* Cont*,* Pkg*, and the local* NameCert *rows. The route exports a shared modulus-comparison surface for later diagonal* $\mathsf{Real}^{\uparrow}$ *completion arguments without introducing quotient sequence equality, selected limits, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusSpaceFiniteRoute`

Proof. Open both carriers using Definition 5887.1. A comparison can inspect only the finite index rows, schedule rows, stream windows, tolerance ledgers, readback rows, and seal boundaries.

Componentwise hsame in H transports the two packets to a common finite surface. Displayed Cont replay in C keeps each precision request attached to its schedule, stream window, dyadic tolerance, regular readback, and real seal boundary.

The provenance and naming rows P, N package that finite surface as the local certificate. Thus later diagonal completion routes can share modulus comparison data without receiving any quotient or choice-based object. □

Theorem 5887.4 (CauchyModulusSpace seed interface)**.** *Every accepted* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *packet exports its modulus schedule family to the L10 four-object seal route only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Cauchy}^{\uparrow}$ *root route, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. No consumer of this seed interface can expose quotient stream equality, a selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness as part of the packet surface.*

Proof. Project the carrier of Definition 5887.1. The modulus family is displayed by I, S, and every inspected request is routed through the finite observation rows W, D, R, Q before the structural rows H, C, P, N can name or replay it.

Apply Definition 5887.3. Any real-facing comparison has already factored through finite schedule rows, stream windows, dyadic tolerances, regular rational readbacks, and the terminal Real seal boundary.

The $\mathsf{Cauchy}^{\uparrow}$ root route receives exactly that finite schedule surface. Since the carrier has no coordinate for quotient equality, selected limits, countable choice, or ambient completeness, the seed interface cannot export any of those host objects to L10 Real and Completion consumers. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusSpaceSeedInterface`

Theorem 5887.5 (CauchyModulusSpace tail composition)**.** *For every accepted* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *carrier*

$$M = (I, S, W, D, R, Q, H, C, P, N),$$

two displayed modulus schedules in the family compose only through finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows. The composed tail read is the finite route*

$$I, S, W, D, R, Q \longmapsto H, C, P, N$$

and it exports no quotient sequence equality, selected limit, countable choice, or ambient completeness object.

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusSpaceTailComposition`

Proof. Project the carrier of Definition 5887.1. The two schedules are displayed rows under S indexed by I, and their inspected tails must pass through the same finite window row W.

Apply the finite route and seed interface, Definition 5887.3 and Definition 5887.4. These results force the tolerance ledger D, regular readback R, and Real seal boundary Q to remain visible before the composed tail can be consumed.

Finally replay the structural rows. Componentwise transport H, displayed continuation C, provenance P, and local naming N preserve the same finite schedule surface, so tail composition does not add quotient equality, selected limits, countable choice, or ambient completeness. □

Theorem 5887.6 (CauchyModulusSpace filter handoff)**.** *Every CauchyFilter or CauchyFilterCompletion consumer of an accepted* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *packet receives the modulus family only through the finite handoff*

$$I, S, W, D, R, Q, H, C, P, N.$$

The handoff may be consumed as filter-facing Cauchy evidence, but it cannot be reinterpreted as quotient sequence equality, a selected limit, countable choice, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusSpaceFilterHandoff`

Proof. Begin with a filter-facing read. The seed interface of Definition 5887.4 already routes every scheduled request through finite stream windows, dyadic tolerances, regular rational readback, the Cauchy root route, and the terminal Real seal.

Use tail composition from Definition 5887.5. It shows that composing displayed schedules preserves the same finite route through I, S, W, D, R, Q before structural replay.

The filter consumer therefore receives only the transported and replayed packet named by H, C, P, N. Since the carrier contains no quotient equality coordinate, no selected limit, no

countable-choice schedule, and no ambient completeness row, CauchyFilter and CauchyFilterCompletion may consume only the displayed finite handoff. □

Theorem 5887.7 (CauchyModulusSpace diagonal-family exactness)**.** *A diagonal Real or Completion consumer of an accepted* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *packet may compare schedule families only through the displayed rows*

$$I, S, W, D, R, Q, H, C, P, N.$$

The diagonal request must be routed through finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary before any structural transport, replay, provenance, or local naming row can be consumed. The comparison exports no quotient stream equality, selected limit, countable-choice schedule, or ambient Real completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusSpaceDiagonalFamilyExactness`

Proof. Start with the finite route of Definition 5887.3. It already factors every real-facing comparison of two accepted packets through the finite schedule rows, stream windows, dyadic tolerance ledgers, regular rational readbacks, Real seal boundaries, and the structural rows H, C, P, N.

Apply the seed interface of Definition 5887.4. It binds every L10 request to the schedule family I, S before the finite windows W, tolerance ledger D, readback R, and seal boundary Q are exposed.

Finally use the filter handoff of Definition 5887.6. A diagonal completion consumer is still a consumer of the same finite handoff, so it receives only $I, S, W, D, R, Q, H, C, P, N$ and cannot add quotient equality, selected limits, countable choice, or ambient completeness. □

Falsifiable prediction: A $\mathsf{CauchyModulusSpace}^{\uparrow}$ consumer that compares schedule families while omitting $I, S, W, D, R, Q, H, C, P, N$ refutes the carrier surface of Definition 5887.1.

Independence witness: cauchymodulus, streamname, regseqrat, dyadicratcore, real, fast-cauchy-sequence: no listed sibling binds a family of explicit Cauchy modulus schedules together with finite stream windows, dyadic tolerance ledgers, regular rational readbacks, Real seal boundaries, componentwise transport, replay, provenance, and local naming in one carrier-space packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusSpace}^{\uparrow}$ packet is generated from a finite family of explicit Cauchy modulus schedules, finite StreamName windows, dyadic tolerance ledgers, RegSeqRat readbacks, Real seal boundaries, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5887.1, Definition 5887.2, and Definition 5887.3 seed the carrier-space interface for explicit modulus schedule families and shared finite comparison routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close diagonal Real completion, quotient equality of Cauchy sequences, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule-family exactness, dyadic and regular readback compatibility, Real-seal boundary nonescape, and a Lean carrier formalization for BEDC.Derived.CauchyModulusSpaceUp.

Chapter 5888

A Concrete Naming Certificate for $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$

Following Bishop and Bridges on constructive completion and the finite-limit language of regular category theory, the $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ packet records the boundary where a displayed Cauchy-completion route preserves the finite-limit rows that its source already exposes. It sits beside the Cauchy source route of chapter 3413, the metric-completion universal-property route of chapter 2124, the functorial completion route of chapter 423, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only a finite left-exactness boundary for displayed completion data; it does not assert quotient completions, selected limits, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5888.1 (Cauchy completion left-exactness carrier)**.** *A* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, U, D, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source finite-limit row, recording the displayed terminal, product, equalizer, or kernel-pair data available before completion is read.*
2. *U is the completion unit row, recording the source-to-completion unit reads for every object named by S.*
3. *D is the dense image row, keeping each completed finite-limit comparison tied to the same source rows and unit rows.*
4. *K is the kernel-pair preservation row, recording that equalizer and pullback comparisons are read through the displayed source kernel-pair data rather than through host quotient equality.*
5. *E is the extension ledger, recording the universal-property and functorial completion rows used to transport finite-limit witnesses into completion-facing reads.*
6. *H records componentwise* hsame *transport for S, U, D, K, E, C, P, N.*
7. *C records displayed* Cont *replay from a finite-limit request through S, U, D, K, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionLeftExactness}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion equality, selected representatives, selected finite limits, countable choice, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionLeftExactnessUp.TasteGate.CauchyCompletionLeftExactnessTasteGate single carrier alignment`

Theorem 5888.2 (Cauchy completion left-exactness NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *carrier*

$$L = (S, U, D, K, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionLeftExactness}^{\uparrow}}$ *surface consists exactly of carrier admission for the source finite-limit row, completion unit rows, dense image rows, kernel-pair preservation row, extension ledger, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. Every completion-facing finite-limit read must expose S, U, D, K before E, H, C, P, N can be consumed.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCompletionLeftExactnessNameCertObligations`

Proof. Project the carrier of Definition 5888.1. The source finite-limit row, unit row, dense image row, kernel-pair row, extension ledger, transport, replay, provenance, and local name are exactly the displayed coordinates.

The finite-limit boundary is read through S, U, D, K. The source row supplies the terminal, product, equalizer, or kernel-pair data; the unit row embeds the displayed source names into completion-facing reads; the dense image row keeps those reads tied to source data; and the kernel-pair row confines exactness comparisons to displayed finite rows.

The remaining rows E, H, C, P, N transport and name the same route. Since quotient completion equality, selected representatives, selected finite limits, countable choice, host equality, and ambient completeness have no carrier coordinate, projection of the displayed rows exhausts the NameCert obligations. □

Theorem 5888.3 (Cauchy completion left-exactness carrier admission)**.** *For every accepted* CauchyCompletionLeftE *carrier*

$$L = (S, U, D, K, E, H, C, P, N),$$

the source finite-limit row S, completion unit row U, dense image row D, kernel-pair preservation row K, extension ledger E, componentwise hsame *transport H, displayed* Cont *replay C, provenance row P, and local* NameCert *row N are all admitted as finite coordinates of the same packet. No completion-facing read may treat one of these rows as ambient host data detached from the carrier.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCompletionLeftExactness carrier admission`

Proof. Project the carrier of Definition 5888.1. Its coordinates are exactly $S, U, D, K, E, H, C, P, N$, so each named row is admitted by carrier membership.

Apply Definition 5888.2. The obligation surface requires every completion-facing finite-limit read to expose S, U, D, K before the extension, transport, replay, provenance, and naming rows can be consumed.

Since quotient completion equality, selected representatives, selected finite limits, countable choice, host equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no carrier coordinate, none of the admitted rows can be reread as detached host data. □

Theorem 5888.4 (Cauchy completion left-exactness unit-density route)**.** *Every displayed finite-limit comparison read through an accepted* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *carrier factors first through the source finite-limit row* S*, then through the completion unit row* U*, and then through the dense image row* D *before the extension ledger* E *and structural rows* H, C, P, N *are inspected. This route records the finite source-to-completion passage without selecting representatives of completed objects or invoking countable choice.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCompletionLeftExactnessUnitDensityRoute`

Proof. Begin with the carrier admission theorem Definition 5888.3. It keeps S, U, D as visible coordinates of the same finite packet.

The source row S supplies the finite-limit data before completion is read. The unit row U records the displayed source-to-completion unit for each object named by S, and the dense image row D keeps the resulting completion-facing comparison tied back to the same source and unit rows.

Only after this route is exposed can E, H, C, P, N be consumed. The extension ledger and the structural rows transport, replay, package, and name the source-unit-density passage; they do not add selected representatives, countable choice, or host equality of completed objects. □

Theorem 5888.5 (Cauchy completion left-exactness kernel-pair preservation)**.** *For every accepted* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *carrier* $L = (S, U, D, K, E, H, C, P, N)$*, any equalizer, pullback, or kernel-pair comparison visible after completion is read through the displayed kernel-pair row* K *together with the source finite-limit row* S*, completion unit row* U*, and dense image row* D*. The comparison cannot be exported as quotient completion equality, a selected finite limit, or ambient equality of completed objects.*

Proof. Project the kernel-pair coordinate K from the carrier. By definition, K records equalizer and pullback comparisons through displayed source kernel-pair data rather than through a host quotient.

Use the unit-density route theorem Definition 5888.4. It places every completion-facing finite-limit comparison behind S, U, D, so the kernel-pair row is read as part of the same source-to-completion passage.

Finally apply Definition 5888.2. The rows E, H, C, P, N only extend, transport, replay, package, and name the displayed comparison. They add no coordinate for quotient completion equality, selected finite limits, or ambient equality of completed objects, so preservation remains confined to K and its source, unit, and dense-image context. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCompletionLeftExactnessKernelPairPreservation`

Theorem 5888.6 (Cauchy completion left-exactness regular-limit pullback)**.** *For every accepted* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *carrier* $L = (S, U, D, K, E, H, C, P, N)$*, any regular Cauchy limit read used by a finite-limit comparison factors through the source finite-limit row* S*, the completion unit row* U*, the dense image row* D*, the kernel-pair row* K*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before the extension ledger* E *is consumed. Thus the regular-limit comparison is a pullback of displayed source, unit, dense-image, kernel-pair, regular-readback, and real-seal rows, not a quotient completion or a selected representative of a completed object.*

Proof. Project the accepted carrier. The rows $S, U, D, K, E, H, C, P, N$ are the only admitted coordinates, so a finite-limit comparison cannot begin from a hidden completed object or a host-level limit.

Apply Definition 5888.4. It places every completion-facing finite-limit comparison behind the source finite-limit row, the completion unit row, and the dense image row before the extension ledger and structural rows are inspected.

Next apply Definition 5888.5. Equalizer, pullback, and kernel-pair comparisons remain confined to the displayed kernel-pair row together with the same source, unit, and dense-image context.

The regular Cauchy limit read is then exposed through the sibling $\mathsf{RegSeqRat}^{\uparrow}$ readback surface named in the chapter introduction, and the resulting endpoint is sealed only through the sibling $\mathsf{Real}^{\uparrow}$ boundary. Since those sibling rows are read after S, U, D, K and before E, the comparison has the announced displayed pullback route. No coordinate remains for quotient completion equality, selected representatives, selected finite limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCompletionLeftExactnessRegularLimitPullback`

Theorem 5888.7 (Cauchy completion left-exactness RegSeqRat unit pullback)**.** *For every accepted* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *carrier* $L = (S, U, D, K, E, H, C, P, N)$*, any finite-limit comparison whose completion unit route reaches a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback factors first through the source finite-limit row* S*, completion unit row* U*, dense image row* D*, and kernel-pair row* K*. It then reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *surface and terminal* $\mathsf{Real}^{\uparrow}$ *seal before the extension ledger and structural rows* E, H, C, P, N *are consumed. Componentwise* hsame *transport preserves that order, so the exported comparison contains no quotient completion, selected representative, selected finite limit, host equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCompletionLeftExactnessRegSeqRatUnitPullback`

Proof. Start with the carrier admission theorem Definition 5888.3. It keeps $S, U, D, K, E, H, C, P, N$ as finite coordinates of one accepted packet, so the comparison cannot begin from an external completed object.

Apply the unit-density route theorem Definition 5888.4. This places every completion-facing finite-limit comparison behind S, U, D before the extension ledger and structural rows are inspected.

Next apply the kernel-pair preservation theorem Definition 5888.5. Pullback and equalizer comparisons remain confined to K together with the same source, unit, and dense-image context.

Finally use the regular-limit pullback theorem Definition 5888.6. Its readback route inserts the $\mathsf{RegSeqRat}^{\uparrow}$ surface and the terminal $\mathsf{Real}^{\uparrow}$ seal after S, U, D, K and before E, H, C, P, N. Componentwise hsame transport therefore preserves the displayed order, while the excluded quotient, selection, choice, host-equality, and ambient-completeness rows remain absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionLeftExactness}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ packet is generated from source finite-limit rows, completion unit rows, dense image rows, kernel-pair preservation, an extension ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionLeftExactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5888.1 and Definition 5888.2 seed the finite left-exactness boundary for displayed Bishop-style Cauchy completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionLeftExactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected finite limits, selected representatives, countable choice, host equality of completed objects, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source finite-limit exposure, unit-row exposure, dense image confinement, kernel-pair preservation, extension-ledger confinement, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionLeftExactnessUp.

Theorem 5888.8 (Cauchy root UnaryHistory admission)**.** *Every accepted root* $\mathsf{Cauchy}^{\uparrow}$ *consumer read admits a UnaryHistory-facing presentation before it enters any filter, modulus, or Real-facing route. The admitted packet is the finite row surface*

$$U = (S, Q, D, R, E, H, C, P, N),$$

where S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* Q *is the directed tail-request row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, and* H, C, P, N *are componentwise transport, displayed replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyRootUnaryAdmission`

Proof. Project the root stream and tail-request carriers already displayed for $\mathsf{Cauchy}^{\uparrow}$. Their shared rows expose finite StreamName windows before any tolerance, readback, or terminal seal can be read.

The directed request row supplies the unary admission point. It records one visible later-window request over the same finite stream surface, so the read is a UnaryHistory-facing row rather than a parameter transport over an ambient sequence.

The dyadic, regular readback, Real seal, and structural rows then repack the same finite route. No quotient stream, selected limit, host equality, countable choice, or ambient completeness row is exported. □

Theorem 5888.9 (Cauchy root filter-modulus compatibility)**.** *For every admitted root packet* $U = (S, Q, D, R, E, H, C, P, N)$*, any* $\mathsf{CauchyFilter}^{\uparrow}$ *or finite filter consumer that reads the tail request must use the same modulus-compatible route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{CauchyTailRequest}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

The filter row may refine the visible window named by S *through* Q*, but it cannot replace* D *by an external tolerance oracle or replace* R *by a selected limit.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyRootFilterModulusCompatibility`

Proof. Start with the admitted packet of Definition 5888.8. The stream row S and directed request row Q are read before any filter-facing or modulus-facing datum.

Apply the existing Cauchy filter Real-seal route. It inserts the finite request row before the dyadic tolerance ledger, so a filter consumer reaches D and R only through the displayed tail request.

The structural rows preserve that order under hsame transport and Cont replay. Thus a finite filter may narrow the displayed request, but the modulus and regular readback remain the same BEDC rows. □

Theorem 5888.10 (Cauchy root RegSeqRat Real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-to-*$\mathsf{Real}^{\uparrow}$ *handoff exported by a root* $\mathsf{Cauchy}^{\uparrow}$ *read factors through the finite windows, directed request, dyadic tolerance ledger, and regular rational readback of Definition 5888.9. The Real seal* E *is available only after* S, Q, D, R, H, C, P, N *have been displayed, and it exports no quotient filter, selected real, countable-choice schedule, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Read the filter-modulus compatibility theorem. It places the StreamName window, directed request, dyadic tolerance ledger, and RegSeqRat readback in a fixed order before any Real-facing boundary.

The handoff row is exactly R followed by E. A Real-facing consumer therefore receives rational readback through $\mathsf{RegSeqRat}^{\uparrow}$ first and may inspect the terminal seal only after that readback has been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no quotient filter, selected real, choice schedule, host equality, or ambient completeness coordinate, the handoff remains a finite BEDC route. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyRootRegSeqRatRealHandoff`

The $\mathsf{Cauchy}^{\uparrow}$ packet enters the L10 dependency lattice through its sibling route before completion or filter consumers inspect it. Every such consumer first reads the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular-rational readback of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The Cauchy route is therefore a displayed sibling dependency path, not a floating completion primitive or a host-level filter object.

Theorem 5888.11 (Cauchy L10 sibling dependency route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *consumer in the L10 lattice receives finite observation windows from chapter 126, regular-rational readback from chapter 301, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before any Real-facing approximation is public. The route exports no selected limit, quotient equality, host filter object, or ambient completeness principle.*

Proof. Project the accepted Cauchy packet through its finite observation surface. The first visible rows are the $\mathsf{StreamName}^{\uparrow}$ windows, so downstream readers cannot begin from a host-level limit predicate.

Next read the regular-rational sibling. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the finite regularity readback used by Cauchy consumers before the packet reaches the Real-facing boundary.

Finally expose the $\mathsf{Real}^{\uparrow}$ seal. Since the seal is reached only after the displayed windows and readback rows, the route supplies finite windows and regular-rational data before public approximation, and it leaves no coordinate for selected limits, quotient equality, host filters, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CauchyUp.L10SiblingDependency.CauchyL10SiblingDependencyRoute`

Theorem 5888.12 (Cauchy route RegSeqRat tail inversion)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *consumer that exposes a* $\mathsf{Real}^{\uparrow}$*-facing approximation through the displayed L10 sibling route must first expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational tail row and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. If either row is absent, the consumer has no public* $\mathsf{Real}^{\uparrow}$*-facing approximation route through the* $\mathsf{Cauchy}^{\uparrow}$ *L10 lattice.*

Proof. Start with Definition 5888.11. A public approximation route is visible only after the accepted Cauchy packet has passed through finite $\mathsf{StreamName}^{\uparrow}$ windows, regular-rational readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Read the windows first. They determine which finite observations are available to the consumer, but they do not by themselves supply a regular rational tail or a tolerance account.

Next inspect the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ rows. The regular-rational tail supplies the readback values, while the dyadic ledger supplies the tolerance discipline needed before those values can be read as a Real-facing approximation.

Finally apply the $\mathsf{Real}^{\uparrow}$ seal. Since the seal is reached only after the displayed tail and tolerance rows, deleting either row leaves no public route from the Cauchy consumer to a Real-facing approximation. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyRouteRegSeqRatTailInversion`

Theorem 5888.13 (Cauchy RegSeqRat–Real completion lattice)**.** *Every completion-facing* $\mathsf{Cauchy}^{\uparrow}$ *read factors through the displayed sibling lattice*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before any completion consumer may read a limit row. The StreamName windows are the observation boundary of chapter 126; the regular rational tails are the readback boundary of chapter 301; the metric-completion request is the comparison boundary of chapter 1506; and the terminal seal is the Real boundary of chapter 38. The route exports no quotient stream, selected representative, selected limit, countable-choice schedule, host real equality, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyRegSeqRatRealCompletionLattice`

Proof. Read the hub through its displayed child routes. The finite-window dependency of Definition 3688.8 and the RegSeqRat–StreamName dependency lattice already force every Real-facing Cauchy read to expose $\mathsf{StreamName}^{\uparrow}$ windows before it consumes regular rational readback rows.

Next apply the regular-source completion route of Definition 3688.11. The $\mathsf{MetricCompletion}^{\uparrow}$ boundary receives the same displayed $\mathsf{RegSeqRat}^{\uparrow}$ tail budget, so a completion consumer cannot jump directly from a Cauchy name to a limit row.

Finally use the metric-completion forward lattice. It places the terminal $\mathsf{Real}^{\uparrow}$ seal downstream of the metric-completion comparison, with no quotient stream, selected representative, selected limit, countable-choice schedule, host equality, or ambient completeness coordinate. Thus the public completion read is exactly the four-surface lattice displayed in the statement. □

Theorem 5888.14 (Cauchy public L10 export)**.** *The public* $\mathsf{Cauchy}^{\uparrow}$ *export for L10 consumers is exactly the finite route already established by Definition 3413.1, Definition 5888.16, Definition 5888.18, and Definition 5888.10:* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *route. A public consumer receives no quotient stream equality, selected limit, countable-choice schedule, host real equality, quotient completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyPublicL10Export`

Proof. Start with the carrier boundary. Definition 5888.16 exhausts the accepted Cauchy packet by the Cauchy source row, finite windows, dyadic tolerances, regular readback, Real-facing seal, transport, replay, provenance, and local naming.

Use the scoped filter-modulus route. Definition 5888.18 shows that filter, modulus, Real-facing, and completion-facing consumers all read the same finite path rather than an external completion object.

Finally apply the root readback handoff of Definition 5888.10. It places the $\mathsf{RegSeqRat}^{\uparrow}$ readback and terminal $\mathsf{Real}^{\uparrow}$ seal downstream of the same window and tolerance rows. Thus the public L10 export is the displayed route itself, with no additional host equality, selection, choice, quotient, or completeness principle. □

Theorem 5888.15 (Cauchy forward L10 sum-tail route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *consumer that reaches the regular sum tail-estimate surface must first pass through the regular rational source of chapter 301, the terminal real-name boundary of chapter 38, and the finite tail-estimate packet of chapter 7387. The route is an L10 dependency path through displayed StreamName, DyadicRatCore,*

RegSeqRat, RegularCauchySum, Real, BHist, hsame, Cont, Pkg, *and* NameCert *rows; it exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the $\mathsf{Cauchy}^{\uparrow}$ hub through its child routes. The core carrier exposes finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and the terminal Real-facing seal before any downstream completion or arithmetic consumer is available.

The regular sum tail-estimate chapter consumes exactly that surface twice, once for each regular source row. Its tail-estimate ledger then adds the RegularCauchySum row and finite error budget without creating a detached limit object.

Thus the forward L10 route from the Cauchy hub to the sum-tail packet is the displayed dependency path through RegSeqRat, Real, and the finite tail-estimate surface. Since each row is already a finite NameCert coordinate, no excluded host or choice principle can be read from the hub. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyBaseForwardL10Route`

Theorem 5888.16 (Cauchy seed carrier boundary)**.** *The* $\mathsf{Cauchy}^{\uparrow}$ *seed carrier boundary is exhausted by the displayed Cauchy source row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row. It contains no quotient completion, selected limit, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Read the carrier through Definition 3413.1. The displayed Cauchy packet provides only the source row, finite observation windows, dyadic tolerances, regular readback, the Real-facing seal route, and the structural transport, replay, provenance, and naming rows.

The sibling routes of Definition 3413.4 and Definition 3413.9 keep those rows ordered before any Real-facing consumer reads the packet. Since none of the displayed coordinates is a quotient completion, selected limit, choice schedule, host equality, or ambient completeness proof, the seed carrier boundary exports none of them. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchySeedCarrierBoundary`

Theorem 5888.17 (Cauchy seed NameCert obligation)**.** *For every accepted* $\mathsf{Cauchy}^{\uparrow}$ *seed packet, the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *obligation surface records exactly carrier admission, finite-window exposure, dyadic tolerance exposure, regular-rational readback, Real-seal routing, componentwise transport, continuation replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchySeedNameCertObligation`

Proof. Project the Cauchy packet through the carrier boundary of Definition 5888.16. Every admissible NameCert read is a read of one displayed carrier coordinate or one structural row attached to that coordinate.

Carrier admission supplies the Cauchy source row. Window, tolerance, and readback exposure supply the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows. The terminal route supplies the Real-facing seal, and the remaining rows supply hsame transport, Cont replay, Pkg provenance, and local naming. No further local obligation is available inside the seed packet. □

Theorem 5888.18 (Cauchy filter-modulus scoped route)**.** *Every public* $\mathsf{Cauchy}^{\uparrow}$ *seed read used by a filter, modulus, Real-facing, or completion-facing consumer factors through the displayed finite route consisting of* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row,* BHist *carrier data, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row. The route exports no quotient stream equality, selected limit, countable choice, trichotomy, host real equality, quotient completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyFilterModulusScopedRoute`

Proof. Start from the Cauchy seed boundary of Definition 5888.16. It exhausts the carrier by the Cauchy source row, finite stream windows, dyadic tolerance rows, regular readback, Real-facing seal, transport, replay, provenance, and local naming.

Apply Definition 5888.17. It identifies those same rows as the local NameCert obligation surface, so any filter or modulus consumer reads the seed packet through finite windows, dyadic budgets, regular-rational data, and the Real-facing seal rather than through an external completion object.

The sibling routes of Definition 1981.22, Definition 3688.9, and Definition 3991.15 keep the same packet ordered through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before completion-facing consumers inspect it. Since BHist, hsame, Cont, Pkg, and NameCert only carry, transport, replay, source, and name that route, the excluded quotient, selection, choice, trichotomy, host-equality, and ambient-completeness objects remain outside the scoped boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Cauchy}^{\uparrow}$ seed packet is generated from finite stream windows, DyadicRatCore tolerance rows, RegSeqRat readback, a terminal Real-facing seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 5888.16, Definition 5888.17, Definition 5888.18, and the bridge-facing L10 export of Definition 5888.14 bind the public $\mathsf{Cauchy}^{\uparrow}$ route to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, dyadic tolerance exposure, regular-rational readback, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyUp.

Chapter 5889

A Concrete Naming Certificate for CauchyCompletionEmbeddingReflection$^{\uparrow}$

Following Bishop and Bridges on constructive completions and Bourbaki/Kelley on uniform embeddings, the CauchyCompletionEmbeddingReflection$^{\uparrow}$ packet records the finite route by which a dense completion embedding is reflected through the separated completion interface. It sits over the dense completion embedding of chapter 5893, the dense uniform embedding surface of chapter 1651, the functorial completion route of chapter 1937, the separated reflection boundary of chapter 3543, the finite stream windows of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal real seal of chapter 38. The packet names the completion-embedding reflection route only; it does not select representatives, form a quotient completion outside the displayed certificate, or import ambient completeness.

Definition 5889.1 (CauchyCompletionEmbeddingReflection carrier)**.** *A* CauchyCompletionEmbeddingReflection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (A, G, K, R, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the source approximation row whose metric or uniform histories feed the completion embedding.*
2. *G is the* CauchyCompletionDenseEmbedding$^{\uparrow}$ *row naming the dense completion embedding and its image-window requests.*
3. *K is the* DenseUniformEmbedding$^{\uparrow}$ *row that exposes uniform density before the completion target is read as separated.*
4. *R is the* CauchyCompletionFunctoriality$^{\uparrow}$ *row transporting maps and comparison windows through completion.*
5. *S is the* SeparatedCompletionReflection$^{\uparrow}$ *row that reflects the target route through the separated completion boundary.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row attached to the same finite approximation windows.*
7. *Q is the* RegSeqRat$^{\uparrow}$ *readback row reached after A, G, K, R, S, D have been displayed.*
8. *E is the terminal* Real$^{\uparrow}$ *seal row exposed only after the dense embedding, separated reflection, dyadic tolerance, and regular-rational readback rows are fixed.*

9. *H records componentwise* hsame *transport for the analytic rows and the structural rows.*
10. *C records displayed* Cont *replay of the same embedding-reflection route.*
11. *P is the* Pkg *provenance over* CauchyCompletionEmbeddingReflection$^{\uparrow}$, CauchyCompletionDenseEmbedding$^{\uparrow}$, DenseUniformEmbedding$^{\uparrow}$, CauchyCompletionFunctoriality$^{\uparrow}$, SeparatedCompletionReflection$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{CauchyCompletionEmbeddingReflection}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient-completion equality, selected representatives, countable choice, a detached separated completion, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ BEDC.Derived.CauchyCompletionEmbeddingReflectionUp.TasteGate.CauchyCompletionEmbeddingReflectio
single carrier alignment

Theorem 5889.2 (CauchyCompletionEmbeddingReflection NameCert obligations)**.** *For every accepted* CauchyCompletionEmbeddingReflection$^{\uparrow}$ *carrier* $J = (A, G, K, R, S, D, Q, E, H, C, P, N)$*, the local* NameCert$_{\text{CauchyCompletionEmbeddingReflection}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed approximation row, dense completion embedding row, dense uniform embedding row, completion functoriality row, separated reflection row, dyadic tolerance row, regular-rational readback row, terminal real seal row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every completion-facing read must pass through* $A, G, K, R, S, D, Q, E, H, C, P, N$ *in that order, and no read may bypass the separated reflection boundary.*

Proof. Project the carrier of Definition 5889.1. Its analytic rows are A, G, K, R, S, D, Q, E, followed by the structural rows H, C, P, N.

The dense route begins with A and G. The approximation row supplies the finite source histories, while the CauchyCompletionDenseEmbedding$^{\uparrow}$ row records the image-window requests through which completion consumers may inspect the dense embedding.

The rows K, R, S then bind the same route to dense uniform embedding, functorial completion transport, and separated reflection. A completion-facing consumer therefore reaches the separated target only after the dense route and functorial route have been displayed.

The rows D, Q, E provide dyadic tolerance, regular-rational readback, and the terminal real seal. Finally H, C, P, N transport, replay, source, and name the same packet, so carrier exhaustion blocks every excluded quotient, selector, detached completion, and ambient-completeness route. □

Theorem 5889.3 (CauchyCompletionEmbeddingReflection handoff)**.** *Every downstream consumer of an accepted* CauchyCompletionEmbeddingReflection$^{\uparrow}$ *packet receives the dense completion embedding only through the finite handoff*

$$\text{CauchyCompletionDenseEmbedding}^{\uparrow} \longmapsto \text{DenseUniformEmbedding}^{\uparrow} \longmapsto \text{CauchyCompletionFunctoriality}^{\uparrow} \longmapsto \text{Separat}$$

Thus the consumer obtains a reflected separated-completion route with finite stream windows, dyadic tolerance, regular-rational readback, and a terminal real seal; it does not obtain a quotient-completion representative, a selected dense point, countable choice, or ambient completeness.

Proof. Start with Definition 5889.2. The NameCert surface forces every public read to begin with the approximation row and the dense completion embedding row.

Read the sibling chapters named in the statement along the displayed order. The DenseUniformEmbedding$^{\uparrow}$ row supplies the uniform dense image, CauchyCompletionFunctoriality$^{\uparrow}$ transports the route through

completion, and $\mathsf{SeparatedCompletionReflection}^{\uparrow}$ is the only separated target boundary available to the packet.

The finite observation route is then exposed through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. These rows are exactly the rows D, Q, E together with the stream-window data carried by A, G, K, R, S.

Since the carrier has only $A, G, K, R, S, D, Q, E, H, C, P, N$, the structural rows can preserve and name the handoff but cannot supply a quotient representative, selected dense point, countable-choice schedule, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionEmbeddingReflection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionEmbeddingReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5889.1, Definition 5889.2, and Definition 5889.3 seed the dense completion embedding reflection route through separated completion, finite stream windows, dyadic tolerance, regular-rational readback, real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionEmbeddingReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-completion equality, selected representatives, countable choice, detached separated completions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense completion embedding exposure, dense uniform embedding compatibility, completion functoriality, separated reflection, finite-window readback, dyadic tolerance, regular-rational handoff, real sealing, and nonescape for BEDC.Derived.CauchyCompletionEmbeddingReflectionUp.

Constructive story: A $\mathsf{CauchyCompletionEmbeddingReflection}^{\uparrow}$ packet is generated from a source approximation row, a dense completion embedding row, a dense uniform embedding row, a completion functoriality row, a separated reflection row, dyadic tolerance, regular-rational readback, a terminal real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5890

A Concrete Naming Certificate for $\mathsf{SnakeLemma}^{\uparrow}$

Following Cartan–Eilenberg and Weibel homological algebra, the $\mathsf{SnakeLemma}^{\uparrow}$ packet records the finite diagram chase that turns two exact rows and compatible vertical maps into the connecting boundary route. It sits over the abelian-category carrier of chapter 176, the homology carrier of chapter 98, the spectral-sequence consumer surface that exposes $\mathsf{DerivedFunctor}^{\uparrow}$ rows in chapter 178, and the derived-functor interface of chapter 177. The packet names a displayed exactness boundary; it does not import quotient-object equality, kernel-cokernel object extensionality, or an ambient abelian-category diagram oracle.

Definition 5890.1 (Snake lemma carrier)**.** *A* $\mathsf{SnakeLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, R_0, R_1, V, K, C, E, \partial, H, T, P, L)$$

with the following displayed rows:

1. *A is the* $\mathsf{AbelianCat}^{\uparrow}$ *source row carrying the additive kernel-cokernel surface in which the diagram is read.*
2. *R_0 and R_1 are the upper and lower exact-row ledgers, each exposing three displayed object rows, two morphism rows, and the local image-kernel containment needed for exactness.*
3. *V is the vertical-compatibility row, recording the three displayed vertical morphisms and the two commutative squares that align R_0 with R_1.*
4. *K is the kernel-row ledger for the left and middle vertical maps.*
5. *C is the cokernel-row ledger for the middle and right vertical maps.*
6. *E is the exactness-boundary row, recording that the kernel leg, connecting boundary, and cokernel leg form the displayed exact boundary chain.*
7. *∂ is the connecting-boundary row from the right kernel surface to the left cokernel surface.*
8. *H records componentwise* hsame *transport for the abelian-category source, exact rows, vertical squares, kernel rows, cokernel rows, boundary rows, replay, provenance, and local naming.*
9. *T records displayed* Cont *replay from the two exact rows and vertical squares to $K, C, E, \partial, H, P, L$.*
10. *P is the* Pkg *provenance over* $\mathsf{SnakeLemma}^{\uparrow}$*,* $\mathsf{AbelianCat}^{\uparrow}$*,* $\mathsf{Homology}^{\uparrow}$*,* $\mathsf{DerivedFunctor}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

11. L is the local $\mathsf{NameCert}_{\mathsf{SnakeLemma}^{\uparrow}}$ *row.*

The classifier compares accepted snake-lemma packets only through these rows. It contains no coordinate for host quotient representatives, unbounded diagram search, selected elements outside the displayed histories, or equality of ambient abelian-category objects.

Lean4 ✓ `BEDC.Derived.SnakeLemmaUp.TasteGate.SnakeLemmaTasteGate single carrier alignment`

Theorem 5890.2 (Snake lemma NameCert obligations)**.** *For every accepted* $\mathsf{SnakeLemma}^{\uparrow}$ *carrier*

$$S = (A, R_0, R_1, V, K, C, E, \partial, H, T, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{SnakeLemma}^{\uparrow}}$ *surface consists exactly of abelian-category source exposure through A, upper and lower exact-row exposure through R_0, R_1, vertical-square compatibility through V, kernel-row exposure through K, cokernel-row exposure through C, exact-boundary exposure through E, connecting-boundary exposure through ∂, componentwise transport through H, displayed replay through T, package provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 5890.1. The rows A, R_0, R_1, V expose the ambient additive kernel-cokernel surface, the two exact rows, and the square compatibility before any boundary read is allowed.

The kernel and cokernel ledgers are then read from K and C. They supply the visible source and target surfaces for the connecting row ∂, while E records the exactness statement tying the kernel leg, boundary leg, and cokernel leg into one chain.

Transport, replay, provenance, and local naming preserve this same finite packet through H, T, P, L. Since no excluded quotient representative, host object equality, or unbounded diagram search appears among the coordinates, the listed rows exhaust the local certificate obligations. □

Theorem 5890.3 (Snake lemma exact boundary)**.** *Every downstream* $\mathsf{Homology}^{\uparrow}$ *or* $\mathsf{DerivedFunctor}^{\uparrow}$ *consumer of an accepted* $\mathsf{SnakeLemma}^{\uparrow}$ *packet reads the boundary route*

$$\ker(v_2) \longmapsto \operatorname{coker}(v_0)$$

only through the displayed chain

$$\mathsf{AbelianCat}^{\uparrow} \longmapsto (R_0, R_1, V) \longmapsto (K, C) \longmapsto (\partial, E) \longmapsto (H, T, P, L).$$

Thus the consumer receives one finite exact-boundary packet of abelian-category source rows, exact-row ledgers, vertical-square ledgers, kernel and cokernel rows, the connecting-boundary row, exactness-boundary evidence, transport, replay, provenance, and local naming.

Proof. Start with the abelian-category source row A. The two exact rows R_0, R_1 and the vertical-compatibility row V expose exactly the diagram data on which the classical snake-lemma chase depends.

Read K and C next. These rows identify the displayed kernel and cokernel surfaces that the connecting boundary is permitted to connect, without choosing representatives outside the finite histories.

The boundary row ∂ and exactness row E then supply the only route from the right kernel surface to the left cokernel surface. A homology or derived-functor consumer therefore reads the boundary as a named packet, not as an ambient quotient construction.

Finally H, T, P, L keep the same route stable under componentwise history equality, displayed replay, provenance, and local naming. No quotient-object equality, host diagram oracle, or unbounded element chase is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{SnakeLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{SnakeLemma}^{\uparrow}$ packet is generated from an AbelianCat source row, two exact-row ledgers, vertical-square compatibility rows, kernel-row and cokernel-row ledgers, a connecting-boundary row, an exactness-boundary row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SnakeLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5890.1, Definition 5890.2, and Definition 5890.3 seed the finite snake-lemma packet over abelian-category source rows, exact-row ledgers, vertical-square compatibility, kernel rows, cokernel rows, connecting-boundary rows, exactness-boundary evidence, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SnakeLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient-object equality, host abelian-category equality, unbounded diagram search, or ambient element-chase completeness.

Upgrade path: Obligation closure requires checked carrier admission, exact-row exposure, vertical-square compatibility, kernel-row exposure, cokernel-row exposure, connecting-boundary construction, exactness-boundary preservation, replay stability, provenance exhaustion, and local naming for BEDC.Derived.SnakeLemmaUp.

Chapter 5891

A Concrete Naming Certificate for $\mathsf{RealTailDiameterGauge}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealTailDiameterGauge}^{\uparrow}$ packet records the finite gauge by which a real-facing consumer reads a regular rational tail only after the displayed tail-diameter, dyadic tolerance, stream-window, and readback rows have been exposed. It sits after the tail-diameter witness of chapter 1746, the dyadic tolerance core of chapter 291, the finite window service of chapter 126, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies a non-quotient L10 gauge object for Real and Completion consumers; it is not host real equality, quotient stream equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5891.1 (Real tail-diameter gauge BHist source)**.** *A* $\mathsf{RealTailDiameterGauge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (E, T, D, W, R, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row naming the real-facing boundary that the gauge is allowed to serve.*
2. *T is the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *ledger row, recording the inspected tail threshold, two visible tail indices, and the displayed diameter bound.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row consumed by the same tail-diameter ledger.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that exposes the finite source observations inspected by T.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same window and tolerance data before any real-facing read is accepted.*
6. *H records componentwise* hsame *transport for the seal, tail-diameter ledger, dyadic tolerance, window, readback, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a real-facing gauge request through E, T, D, W, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RealTailDiameterGauge}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealTailDiameterGauge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, T, D, W, R, H, C, P, N$. It has no coordinate for host real equality, quotient stream equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RealTailDiameterGaugeUp.TasteGate.RealTailDiameterGaugeTasteGate single carrier alignment`

Theorem 5891.2 (Real tail-diameter gauge NameCert obligation surface)**.** *For every accepted* $\mathsf{RealTailDiameterGauge}^{\uparrow}$ *carrier*

$$G = (E, T, D, W, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealTailDiameterGauge}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *ledger row* T*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, componentwise transport* H*, displayed replay* C*, package provenance* P*, and local naming* N*.*

Proof. Project the carrier of Definition 5891.1. The analytic rows are the Real seal E, tail-diameter ledger T, dyadic tolerance D, finite window W, and regular rational readback R.

The gauge obligation is read only through T, D, W, R. The tail-diameter ledger records the visible tail request and bound, the dyadic row supplies the tolerance budget, the stream row exposes the inspected finite windows, and the regular row repacks the same data for rational readback.

The structural rows H, C, P, N preserve that route under transport, replay, provenance, and naming. Since the carrier has no coordinate for the excluded host or completion objects, the displayed rows exhaust the local NameCert surface. □

Theorem 5891.3 (Real tail-diameter gauge RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer exported by an accepted* $\mathsf{RealTailDiameterGauge}^{\uparrow}$ *packet factors through*

$$W, D \longmapsto T \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus a Real and Completion route may read the finite stream window, dyadic tolerance ledger, tail-diameter gauge, regular rational handoff, terminal Real seal, transport, replay, provenance, and local naming rows, but it receives no host real equality, quotient stream equality, selected limit, trichotomy decision, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge check.*

Proof. Start with an exported regular-rational or real-facing read. The only finite observations available to the packet are the $\mathsf{StreamName}^{\uparrow}$ row W and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row D.

The tail-diameter ledger T then binds those observations to a displayed tail request and diameter bound. This row is the gauge that prevents a consumer from replacing the finite tail evidence by a quotient stream or a selected limit.

Only after T is displayed does the handoff expose the $\mathsf{RegSeqRat}^{\uparrow}$ row R and the $\mathsf{Real}^{\uparrow}$ seal row E. The readback and seal are therefore downstream from the same finite gauge data.

Finally H, C, P, N transport, replay, source, and name the route. Since the excluded objects do not occur in the carrier, no consumer can bypass the displayed handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealTailDiameterGauge}^{\uparrow}}$.

Constructive story: A $\mathsf{RealTailDiameterGauge}^{\uparrow}$ packet is generated from a RealUp seal row, a CauchyTailDiameterUp ledger, a DyadicRatCore tolerance row, a StreamName window row, a RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealTailDiameterGauge}^{\uparrow}}$, seed)

Scope closed: Definition 5891.1, Definition 5891.2, and Definition 5891.3 seed the finite real-facing tail-diameter gauge for regular rational and completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealTailDiameterGauge}^{\uparrow}}$, unformalized)
Bridge status: none
Not claimed: This chapter does not close host real equality, quotient stream equality, selected limits, trichotomy, countable choice, Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.
Upgrade path: Obligation closure requires checked carrier admission, Real seal confinement, CauchyTailDiameter ledger exactness, DyadicRatCore tolerance readback, StreamName window coverage, RegSeqRat handoff, transport stability, continuation replay, provenance non-escape, and local naming for BEDC.Derived.RealTailDiameterGaugeUp.

This hub routes the EffectiveRealCompactIntervalSearch$^{\uparrow}$ packet through chapter 1250, chapter 1767, and chapter 5899 before the child files expose the compact interval search carrier.

Chapter 5892

A Concrete Naming Certificate for $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ packet records the finite search surface by which a continuous real-valued map on a displayed closed bounded interval is inspected through compact finite nets, uniform-modulus data, and interval bisection rows before a downstream extremum consumer reads a certified bracket. It sits over the real-name seal of chapter 38, the interval endpoint carrier of chapter 1591, the compact-net selector of chapter 914, the graph and pointwise rows of chapter 130, and the tolerance handoff of chapter 369. The packet gives the constructive extreme-value route a finite searchable carrier; it does not assert classical Heine–Borel compactness, choose a host maximum, or identify quotient real functions.

The search packet consumes the compact interval finite-net route before it exports bisection or extreme-value handoffs. Its selector row P is read downstream of the closed-bounded interval net of chapter 1250 and the finite epsilon-net surface of chapter 1767; the bisection ledger then refines those displayed cells instead of introducing an open-cover compactness argument or a selected supremum.

Definition 5892.1 (Effective real compact-interval search carrier)**.** *An* $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, F, U, P, B, V, H, C, Q, N)$$

with the following visible rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *endpoint and containment row whose endpoints are read through* $\mathsf{Real}^{\uparrow}$ *names.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row for a real-valued map over the interval source named by I.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *tolerance handoff for F on the displayed interval source.*
4. *P is the* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *finite-net row that lists the rational mesh cells and selected centers used by the search.*
5. *B is the bisection ledger, a finite prefix tree of interval halves whose cells refine P at the requested tolerance.*
6. *V is the value-comparison ledger storing the displayed* $\mathsf{Real}^{\uparrow}$ *value rows and rational error budgets attached to the cells of B.*

7. *H stores componentwise* hsame *transport for the interval, continuous-map, uniform-modulus, selector, bisection, value-comparison, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from an extremum-search request through $I, F, U, P, B, V, H, Q, N$.*
9. *Q is the* Pkg *provenance over* EffectiveRealCompactIntervalSearch$^{\uparrow}$, Real$^{\uparrow}$, ClosedBoundedInterval$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{EffectiveRealCompactIntervalSearch}^{\uparrow}}$ *row.*

The classifier compares accepted search carriers only through $I, F, U, P, B, V, H, C, Q, N$. No open-cover compactness theorem, selected host maximum, excluded-middle comparison on all real values, quotient function equality, or ambient completeness coordinate is part of the carrier.

Theorem 5892.2 (Effective real compact-interval search obligations)**.** *For every accepted* EffectiveRealCompactInte *carrier $S = (I, F, U, P, B, V, H, C, Q, N)$, the local* NameCert$_{\text{EffectiveRealCompactIntervalSearch}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the closed bounded interval source, continuous-map graph, uniform-modulus handoff, compact-net selector, bisection ledger, value-comparison ledger, transport, replay, provenance, and local naming;*
2. *source agreement, requiring I, F, U, and P to name the same displayed interval source before any cell is searched;*
3. *selector exactness, requiring the search cells in B to refine the finite* ProbeBundle *centers and tolerances exposed by P;*
4. *value-row binding, requiring every value comparison in V to be attached to a cell of B, a displayed graph row of F, and the error budget supplied by U;*
5. *bisection stability, requiring interval refinement to preserve endpoint containment and the selected candidate cell under componentwise* hsame *transport;*
6. *extremum handoff, requiring any lower-bound, upper-bound, near-minimum, or near-maximum read to pass through B, V, H, C, Q, N rather than through a host maximum selector;*
7. *non-escape, excluding open-cover compactness, classical Heine–Borel selection, trichotomy on arbitrary real values, quotient function equality, and ambient* Real$^{\uparrow}$ *completeness from the local packet.*

No effective compact-interval search obligation is stored outside these rows.

Proof. Project the carrier of Definition 5892.1. The interval source is I, the continuous graph is F, the uniform tolerance handoff is U, and the finite selector row is P.

The search may begin only after these rows agree on the same displayed interval source. The bisection ledger B then refines the selector cells supplied by P, so each later comparison is attached to a visible interval cell rather than to an external point choice.

The value ledger V reads graph values from F with the error budget delivered by U. This makes every candidate comparison a finite statement about named cells and rational tolerances.

Finally the extremum-facing read uses H, C, Q, N to replay and name the same route. Since the carrier has no coordinate for open-cover compactness, a host maximum, global real trichotomy, quotient function equality, or ambient completeness, none of those objects can enter the local certificate. □

Theorem 5892.3 (Effective real compact-interval bisection induction)**.** *For an accepted* EffectiveRealCompactInterv *carrier $S = (I, F, U, P, B, V, H, C, Q, N)$, every finite bisection stage in B is obtained by induction from the endpoint row I and the selector row P. The induction step replaces one displayed interval cell by its two named halves, transports the corresponding* ContinuousMap$^{\uparrow}$ *and* UniformModulus$^{\uparrow}$ *reads through H, and extends V only by value rows attached to those halves.*

Proof. The base stage is the interval cell named by I together with the first finite-net read in P. Its value ledger is the corresponding displayed graph read from F with the tolerance supplied by U.

For the induction step, choose the cell already selected by the finite ledger. The midpoint and half-interval endpoints are read as interval rows below I, and the selector exactness obligation identifies their centers with the relevant ProbeBundle entries of P.

Transport along H keeps the continuous-map graph and uniform-modulus handoff on the same source. The new value rows are therefore added to V only for the two displayed halves, so the induction never leaves the finite bisection tree. □

Theorem 5892.4 (Effective real compact-interval extreme-value handoff)**.** *Every extremum-search consumer reading an accepted* EffectiveRealCompactIntervalSearch$^{\uparrow}$ *carrier factors through*

$$I, F, U, P \longmapsto B, V \longmapsto H, C, Q, N.$$

The consumer receives a finite bracket or near-extremal cell family whose error budget is supplied by UniformModulus$^{\uparrow}$ *and whose candidates are selected by* CompactNetModulusSelector$^{\uparrow}$*. It receives no classical maximum point, open-cover compactness proof, quotient equality of functions, global trichotomy on* Real$^{\uparrow}$ *values, or ambient completeness assertion.*

Proof. Begin with the carrier projection. The only source data available to the consumer are the interval row I, continuous graph row F, uniform-modulus row U, and compact-net selector row P.

Apply Definition 5892.3. Every searched cell and every candidate value is produced inside the finite bisection ledger B and value ledger V.

The final handoff reads those ledgers through H, C, Q, N. Applying Definition 5892.2, any route that asks for a host maximum, open-cover compactness, quotient function equality, global real trichotomy, or ambient completeness is outside the accepted packet. □

Theorem 5892.5 (Effective real compact interval search finite-net handoff)**.** *Every accepted* EffectiveRealCompactIntervalSearch$^{\uparrow}$ *search packet reads a compact interval finite-net certificate, a located interval bisection row, and the* Real$^{\uparrow}$ *comparison seal before exporting the extreme-value handoff. The route passes through the closed bounded interval net of chapter 1250 and the finite epsilon-net surface of chapter 1767; it exports no open-cover compactness, selected supremum, host trichotomy, quotient real equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier $S = (I, F, U, P, B, V, H, C, Q, N)$ from Definition 5892.1. The compact interval finite-net data enter through the selector row P, whose cells are read only after the displayed closed bounded interval source I is fixed.

Apply Definition 5892.3. The bisection row B refines the finite cells supplied by P, and every value comparison in V is attached to a displayed graph row of F with the tolerance budget from U.

Apply Definition 5892.4. The final route reads B, V, H, C, Q, N after the finite-net source rows, so the exported extreme-value handoff is a finite search certificate rather than an open-cover compactness, supremum-selection, trichotomy, quotient-equality, or completeness principle. □

Theorem 5892.6 (Effective real compact interval search L10 sibling dependency)**.** *Every accepted* $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ *packet must display the* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *endpoint carrier, the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, the* $\mathsf{UniformModulus}^{\uparrow}$ *tolerance row, the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *finite net, the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *selector, the* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *row, and the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *refinement before exporting any extremum handoff. The route is the finite-net and bisection dependency route of Definition 5892.5, not an isolated kernel-only search packet.*

Proof. Project the carrier definition, Definition 5892.1. The rows I, F, U, P, B, V expose the closed bounded interval source, continuous-map graph, uniform-modulus handoff, compact-net selector, bisection ledger, and value ledger, while the Real-facing seal is read through the displayed interval and value rows.

Apply the finite-net handoff theorem, Definition 5892.5. It forces the search route through the closed bounded interval net and finite epsilon-net surfaces before any bisection or extreme-value consumer can read the packet.

The bisection row B then supplies the located refinement consumed by the extremum handoff. The structural rows H, C, Q, N only transport, replay, source, and name that same sibling-dependent route, so no extremum handoff is exported before the listed L10 siblings are displayed. □

Theorem 5892.7 (Effective real compact interval search inverse modulus bisection)**.** *For an accepted* $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ *carrier* $S = (I, F, U, P, B, V, H, C, Q, N)$*, a displayed* $\mathsf{UniformModulus}^{\uparrow}$ *tolerance row* U *and a* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *finite-net row* P *determine a finite bisection depth in* B *whose dyadic cell diameter is below the requested tolerance. The depth is read only through* P, B, V, H, C, Q, N*: the value ledger* V *attaches comparisons to cells at that depth,* H *transports the same cells under* hsame*,* C *replays the finite request, and* Q, N *package and name the route. The construction exports no open-cover compactness proof, no host maximum, no quotient equality of functions, no trichotomy on* $\mathsf{Real}^{\uparrow}$ *values, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. Project the accepted search carrier. The uniform-modulus row U supplies the requested tolerance, while the selector row P displays the finite mesh data that the search is allowed to refine.

Apply Definition 5892.3. Each step of B replaces a displayed cell by named dyadic halves, so repeated refinement gives a finite depth at which the visible cell diameter is below the tolerance requested by U.

Apply Definition 5892.5. The finite-net row P remains the source of the cells refined by B, and the value ledger V records only comparisons attached to those cells.

Finally H, C, Q, N transport, replay, source, and name the same finite depth-control route. Because the carrier has no open-cover compactness coordinate, host maximum selector, quotient function equality coordinate, trichotomy oracle, or ambient completeness row, the inverse-modulus read remains finite interval-search data. □

Theorem 5892.8 (Effective real compact interval search finite-grid stability)**.** *For an accepted* $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ *carrier* $S = (I, F, U, P, B, V, H, C, Q, N)$*, the displayed finite-net cell selected by* P *and refined by the located bisection ledger* B *is preserved under componentwise* hsame *transport before any extreme-value handoff is exported. Thus every Real-facing extremum consumer reads the same finite cell, value row, and bisection row through* P, B, V, H, C, Q, N*, and receives no open-cover compactness proof, selected host maximum, or* $\mathsf{Real}^{\uparrow}$ *trichotomy.*

Proof. Project the carrier of Definition 5892.1. The finite-net cell is displayed by P, its bisection refinement is recorded in B, and the attached value comparisons are stored in V.

Apply the finite-net handoff theorem, Definition 5892.5. It forces the search route through the closed bounded interval net and finite epsilon-net surfaces before the bisection ledger is consumed.

Apply the inverse-modulus bisection theorem, Definition 5892.7. The bisection depth and the cell read remain tied to P, B, V, while H transports the same displayed rows and C replays the same finite request.

The carrier has no coordinate for open-cover compactness, host maxima, quotient function equality, Real trichotomy, or ambient completeness. The exported extreme-value handoff therefore preserves only the finite-grid cell and located bisection row named by the packet. □

Theorem 5892.9 (Effective real compact interval search Bishop cover link)**.** *Every accepted* $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ *carrier* $S = (I, F, U, P, B, V, H, C, Q, N)$ *reads the Bishop interval-cover finite cover ledger of chapter 5124 before it exports any bisection or extreme-value handoff. The Bishop route supplies the finite interval-cover cells refined by* P *and* B*, while the local search packet preserves the continuous-map, uniform-modulus, value-comparison, transport, replay, provenance, and naming rows. The exported route contains no open-cover compactness theorem, selected supremum, host trichotomy, quotient equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. Project the carrier $S = (I, F, U, P, B, V, H, C, Q, N)$ from Definition 5892.1. The interval source is I, the continuous graph is F, the uniform tolerance handoff is U, the finite selector row is P, the bisection ledger is B, and the value ledger is V.

Apply the finite-net handoff theorem, Definition 5892.5. It forces the search packet to read the closed bounded interval net and finite epsilon-net surfaces before the bisection ledger can be consumed.

Apply the grid-stability theorem, Definition 5892.8. The selected finite cell is preserved through P, B, V, H, C, Q, N, so the Bishop interval-cover ledger supplies interval-cover cells for the same displayed route rather than a separate compactness principle.

The remaining rows H, C, Q, N transport, replay, source, and name the same finite cover-to-search handoff. Since the carrier has no row for open-cover compactness, selected suprema, host trichotomy, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, those principles cannot be exported by the bisection or extreme-value consumer. □

Theorem 5892.10 (Effective real compact interval search RegularCauchyGluing dependency)**.** *Every completion-facing extremum-search read of an accepted* $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ *packet must expose the* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *route of chapter 5899 after the finite bisection and value ledger are displayed and before any* $\mathsf{Real}^{\uparrow}$*-facing seal is consumed. The dependency is read through the finite-net handoff of Definition 5892.5 and the grid-stability route of Definition 5892.8; it is not supplied by quotient stream equality, selected host limits, countable choice, or ambient real completeness.*

Proof. Project the carrier $S = (I, F, U, P, B, V, H, C, Q, N)$ from Definition 5892.1. The completion-facing rows available to the search are the bisection ledger B, the value-comparison ledger V, and the structural replay rows H, C, Q, N.

Apply Definition 5892.5. The finite-net route fixes the displayed interval cells and their Real-valued comparison windows before an extremum consumer can read the packet.

Apply Definition 5892.8. The same finite cell, bisection row, and value row are preserved under componentwise hsame transport, so the completion-facing read has a stable regular-Cauchy window to hand to the gluing sibling.

Route that window through $\mathsf{RegularCauchyGluing}^{\uparrow}$ before the terminal Real-facing seal is consumed. Since the carrier has no quotient stream-equality row, selected host limit, countable-choice

selector, or ambient-completeness coordinate, the gluing dependency is the only completion-facing route available after B and V are displayed. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5892.1, Definition 5892.2, Definition 5892.3, Definition 5892.4, Definition 5892.5, Definition 5892.7, and Definition 5892.8 seed the finite interval-search carrier from displayed Real, closed-bounded-interval, compact-net-selector, continuous-map, finite-net, and uniform-modulus rows to extremum-facing bracket and depth-control handoffs.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close classical Heine–Borel compactness, selected host maxima or minima, quotient equality of functions, global real trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source agreement, selector exactness, value-row binding, bisection stability, extremum handoff, and non-escape for BEDC.Derived.EffectiveRealCompactIntervalSearchUp.

Constructive story: An $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source, ContinuousMapUp graph rows, a UniformModulusUp tolerance handoff, a CompactNetModulusSelectorUp finite-net row, a finite bisection ledger, displayed RealUp value comparisons, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ search packet consumes the closed-bounded interval net of chapter 1250, the finite epsilon-net surface of chapter 1767, the compact-net modulus selector of chapter 914, and the located interval bisection route of chapter 1711 before exporting its extremum handoff. Thus a downstream consumer sees the finite-net and bisection dependencies as displayed route data, not as an open-cover compactness proof or a selected host extremum. The $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ route hands its finite bisection rows, interval-value rows, and compact-window certificates to the compatible-window route of chapter 5899 before any $\mathsf{Real}^{\uparrow}$ seal consumer reads a glued local search window. This dependency keeps each L10 finite-window consumer downstream from the displayed compact search packet, so the gluing step reads certified local windows rather than an ambient completeness or choice principle.

Chapter 5893

A Concrete Naming Certificate for $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$

Following Bishop and Bridges on constructive completions and Bourbaki/Kelley on dense embeddings, the $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$ packet records the finite dense-source route by which a Cauchy completion consumer reads a source object inside its completion boundary. It sits beside the dense uniform embedding surface of chapter 1651, the functorial Cauchy-completion route of chapter 1937, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet supplies dense embedding data for completion consumers without asserting quotient completion equality, selected representatives, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5893.1 (Cauchy completion dense-embedding carrier)**.** *A* $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (A, G, K, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the dense source row. It records the source-side Cauchy observations that a completion consumer may approximate by displayed source data.*
2. *G is the embedding graph row. It records the displayed source-to-completion graph and the finite image-window reads used by dense embedding consumers.*
3. *K is the Cauchy completion row, read through the completion-facing route associated with* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$*.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row exposing the finite request windows inspected by the source and completion sides.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare source-image windows with completion windows.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic tolerances.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after A, G, K, S, D, Q have been displayed.*
8. *H records componentwise* hsame *transport for the dense source, embedding graph, completion, window, tolerance, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a dense-source request through $A, G, K, S, D, Q, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion equality, selected representatives, countable choice, host equality of completion classes, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionDenseEmbeddingUp.CauchyCompletionDenseEmbeddingTasteGate`
`single carrier alignment`

Theorem 5893.2 (Cauchy completion dense-embedding NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$ *carrier*

$$J = (A, G, K, S, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for the dense source row, embedding graph row, Cauchy completion row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing dense read must expose A, G, K, S, D, Q before E, H, C, P, N can be consumed.*

Proof. Project the carrier of Definition 5893.1. The dense source, embedding graph, Cauchy completion row, finite windows, tolerance ledger, regular readback, and Real seal are exactly the displayed analytic coordinates.

The dense-source route is read through A, G, K. A completion consumer first fixes the source row, then the embedding graph row, and only then the completion-facing row associated with the Cauchy completion route.

The finite observation route is read through S, D, Q. The stream windows expose inspected requests, the dyadic ledger supplies the tolerance budget, and the regular rational readback repacks the same observations before any Real-facing seal is visible.

Finally E, H, C, P, N preserve and name the route. Since quotient completion equality, selected representatives, countable choice, host equality, and ambient completeness have no carrier coordinate, the listed rows exhaust the NameCert surface. □

Theorem 5893.3 (Cauchy completion dense-embedding Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion consumer exported by an accepted* $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$ *packet factors through*

$$\mathsf{DenseUniformEmbedding}^{\uparrow},\ \mathsf{CauchyCompletionFunctoriality}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

More precisely, the consumer reads the dense source row A, embedding graph G, Cauchy completion row K, finite windows S, tolerance ledger D, regular readback Q, terminal seal E, componentwise transport H, displayed replay C, provenance P, and local name N before the real-facing boundary is exposed.

Proof. Start with an exported Real-facing or completion-facing read. The NameCert obligations of Definition 5893.2 force the read through A, G, K before the finite observation rows can be consumed.

Read the sibling routes next. The dense source is the $\mathsf{DenseUniformEmbedding}^{\uparrow}$ surface, the completed-map side is routed through $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, and the finite observations are the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows displayed by the carrier.

Only after those rows have been displayed can the terminal $\mathsf{Real}^{\uparrow}$ seal row E be read. The structural rows H, C, P, N transport, replay, source, and name the same route, so the handoff exports no quotient completion equality, selected representative, countable-choice selector, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$ packet is generated from a dense source row, embedding graph row, Cauchy completion row, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5893.1, Definition 5893.2, and Definition 5893.3 seed the dense-source route for Cauchy completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality of completion classes, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense source exposure, embedding graph exactness, Cauchy completion handoff, StreamName window coverage, DyadicRatCore tolerance readback, RegSeqRat handoff, Real seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionDenseEmbeddingUp.

Chapter 5894

A Concrete Naming Certificate for $\mathsf{RiemannRefinementCriterion}^{\uparrow}$

Following Bishop and Bridges on Riemann–Darboux integration, the $\mathsf{RiemannRefinementCriterion}^{\uparrow}$ packet records the finite refinement criterion that lets a tagged Riemann-sum consumer compare upper Darboux rows against a gauge-local partition route. It sits after the tagged partition carrier of chapter 4296, the upper Darboux-sum carrier of chapter 4083, the Riemann sum gauge packet of chapter 4115, and the Cousin cover carrier of chapter 3426. The packet supplies the finite refinement surface consumed by integrability criteria without importing host partitions, selected mesh limits, quotient function equality, choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5894.1 (Riemann refinement criterion carrier)**.** *A* $\mathsf{RiemannRefinementCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, T, U, G, C, M, D, W, E, H, K, P, N)$$

with the following displayed rows:

1. *I is the closed bounded interval row shared by the refinement comparison.*
2. *T is the* $\mathsf{TaggedRealPartition}^{\uparrow}$ *source row, including the finite cell order, tag containment, and mesh exactness visible before refinement is read.*
3. *U is the* ***??*** *row whose upper-sum ledger is compared against the refined tagged route.*
4. *G is the* $\mathsf{RiemannSumGauge}^{\uparrow}$ *row, carrying the positive rational gauge, mesh ledger, and finite tagged-sum handoff.*
5. *C is the* $\mathsf{CousinCover}^{\uparrow}$ *gauge-cover row supplying the finite local cover route that admits the refined cells.*
6. *M is the common-refinement mesh row, listing the displayed refinement map from the tagged partition row into the gauge-cover and upper-sum rows.*
7. *D is the Darboux-gap lock row, recording the finite upper-bound comparison that remains visible after the common refinement has been read.*
8. *W is the window and readback row for interval endpoints, tags, gauges, cover cells, and upper-sum values.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the tagged partition, gauge, Cousin cover, refinement mesh, and Darboux-gap rows are displayed.*

10. *H records componentwise* hsame *transport for interval, partition, upper-sum, gauge, cover, refinement, Darboux-gap, window, seal, replay, provenance, and local naming rows.*
11. *K records displayed* Cont *replay from a refinement request through $I, T, U, G, C, M, D, W, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{RiemannRefinementCriterion}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, *??*, $\mathsf{RiemannSumGauge}^{\uparrow}$, $\mathsf{CousinCover}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannRefinementCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed finite rows. It has no coordinate for host partitions, selected mesh limits, quotient function equality, choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RiemannRefinementCriterionUp.RiemannRefinementCriterionTasteGate single carrier alignment`

Theorem 5894.2 (Riemann refinement criterion NameCert obligations)**.** *For every accepted* RiemannRefinementCr *carrier $R = (I, T, U, G, C, M, D, W, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannRefinementCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the interval, tagged partition, upper Darboux-sum, Riemann sum gauge, Cousin cover, refinement mesh, Darboux-gap lock, window, seal, transport, replay, provenance, and local naming rows.*

Every refinement-facing consumer must read the tagged partition row T from chapter 4296, the upper-sum row U from chapter 4083, the gauge row G from chapter 4115, and the gauge-cover row C from chapter 3426 before the common-refinement mesh row M and Darboux-gap lock row D are available.

Proof. Project the carrier of Definition 5894.1. The tuple displays the only rows available to a refinement consumer: interval source, tagged partition, upper-sum, gauge, Cousin cover, common refinement, Darboux-gap lock, finite windows, terminal seal, transport, replay, provenance, and local naming.

The source rows are T, U, G, C. The tagged partition supplies finite cells and tags, the upper Darboux row supplies the upper-bound ledger, the Riemann sum gauge row supplies the gauge mesh, and the Cousin cover row supplies local gauge cover cells.

The refinement rows are M, D. The mesh row M binds those four source rows into one common finite refinement before the Darboux-gap lock D can be read.

Finally W, E, H, K, P, N preserve the same displayed route through finite windows, the terminal Real seal, transport, replay, provenance, and local naming. Since the carrier has no coordinate for the refused host objects, the listed rows exhaust the local NameCert surface. □

Theorem 5894.3 (Riemann refinement criterion Darboux gap lock)**.** *In every accepted* RiemannRefinementCriterior *packet, the Darboux-gap row D is readable only after the common-refinement mesh row M has already displayed the tagged partition, upper Darboux-sum, Riemann sum gauge, and Cousin cover sources. Thus a Darboux or Riemann-integrability consumer cannot replace the refinement route by host partitions, selected mesh limits, quotient function equality, choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the source rows from Definition 5894.1. The Darboux-gap row is not listed as an independent analytic conclusion; it appears after the tagged partition, upper-sum, gauge, cover, and common-refinement rows.

Apply Definition 5894.2. Its obligation surface requires T, U, G, C to be exposed before M, and M before D.

The structural rows only transport and replay the same finite packet. Therefore the Darboux-gap read is locked to the displayed refinement route and cannot be promoted to any refused host-level principle. □

Theorem 5894.4 (Riemann refinement criterion integral handoff)**.** *Every Riemann-integrability or gauge-integral consumer of an accepted* $\mathsf{RiemannRefinementCriterion}^{\uparrow}$ *packet receives only the finite handoff*

$$\mathsf{TaggedRealPartition}^{\uparrow},\ \textit{??},\ \mathsf{RiemannSumGauge}^{\uparrow},\ \mathsf{CousinCover}^{\uparrow} \longmapsto M \longmapsto D \longmapsto W, E, H, K, P, N.$$

The handoff exports a refinement criterion over displayed finite rows, not an ambient theorem about all host partitions or all mesh limits.

Proof. Start with a consumer read. The packet first exposes the tagged partition, upper Darboux-sum, Riemann sum gauge, and Cousin cover rows through the sibling chapters cited in the carrier.

The common-refinement mesh row M then aligns those sources. The Darboux-gap lock row D is read only along that aligned route, and the window and seal rows W, E expose the Real-facing observations after the finite rows are visible.

Transport, replay, provenance, and local naming through H, K, P, N preserve the same route. No carrier coordinate supplies host partition equality, selected limiting meshes, choice, compactness, quotient function equality, or ambient completeness, so the integral handoff is exactly the displayed finite criterion. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannRefinementCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannRefinementCriterion}^{\uparrow}$ packet is generated from a closed bounded interval row, TaggedRealPartition source, UpperDarbouxSum ledger, RiemannSumGauge mesh row, CousinCover gauge-cover row, common-refinement mesh row, Darboux-gap lock, finite windows, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannRefinementCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5894.1, Definition 5894.2, Definition 5894.3, and Definition 5894.4 seed the finite refinement criterion between tagged partitions, upper Darboux sums, Riemann sum gauges, and Cousin covers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannRefinementCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host partitions, selected mesh limits, quotient function equality, choice, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tagged-partition source lock, upper-sum handoff, gauge mesh exactness, Cousin cover locality, Darboux-gap lock, integral handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RiemannRefinementCriterionUp.

Chapter 5895

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusComposition}^{\uparrow}$

Following the Bishop–Bridges and Heine–Cantor treatment of uniformly continuous maps on compact metric data, the $\mathsf{CompactUniformModulusComposition}^{\uparrow}$ packet records the finite tolerance-only composition surface for two compact-uniform modulus rows. It sits after the compact metric source of chapter 129, the continuous-map carrier of chapter 130, the compact uniform modulus row of chapter 2299, the metric-triangle estimate of chapter 1159, and the stability packet of chapter 5872. The packet supplies the finite composition object used by compact-open and compact-uniform-continuity consumers without exporting a host function space, quotient point equality, selected global modulus, choice schedule, or ambient compactness theorem.

Definition 5895.1 (Compact uniform modulus composition carrier)**.** *A* $\mathsf{CompactUniformModulusComposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, Z, F, G, M_F, M_G, A, T, U, H, C, P, N)$$

with the following displayed rows:

1. *X, Y, Z are compact metric source, middle, and target rows, with finite net and distance ledgers visible at the requested tolerances.*
2. *F and G are* $\mathsf{ContinuousMap}^{\uparrow}$ *rows for the two displayed maps.*
3. *M_F is the first* $\mathsf{CompactUniformModulus}^{\uparrow}$ *row, turning a target tolerance for Y into a source tolerance for X along F.*
4. *M_G is the second* $\mathsf{CompactUniformModulus}^{\uparrow}$ *row, turning a target tolerance for Z into a source tolerance for Y along G.*
5. *A is the tolerance-assembly row, recording that a Z-tolerance request is first read by M_G and that its resulting Y-tolerance request is then read by M_F.*
6. *T is the* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *row that keeps the two transported estimates on the same metric route.*
7. *U is the downstream* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row for the composite map.*
8. *H records componentwise* hsame *transport for compact metric sources, continuous maps, modulus rows, tolerance assembly, triangle estimate, consumer, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a composite tolerance request through $Z, M_G, Y, M_F, X, A, T, U, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulusComposition}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactUniformModulus}^{\uparrow}$, $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusComposition}^{\uparrow}}$ *row.*

The classifier compares accepted composition packets only by these finite rows. It contains no host function-space composition theorem, quotient point equality, selected global modulus, choice schedule, or ambient compactness principle.

Lean4 ✓ `BEDC.Derived.CompactUniformModulusCompositionUp.CompactUniformModulusCompositionTasteGate`
`single carrier alignment`

Theorem 5895.2 (Compact uniform modulus composition NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformModulusComposition}^{\uparrow}$ *carrier $Q = (X, Y, Z, F, G, M_F, M_G, A, T, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusComposition}^{\uparrow}}$ *surface consists exactly of compact source admission through X, Y, Z, continuous-map admission through F, G, first and second compact-uniform modulus reads through M_F, M_G, tolerance assembly through A, metric-triangle transport through T, uniform-modulus export through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5895.1. The compact metric rows, continuous-map rows, compact-uniform modulus rows, assembly row, triangle estimate, uniform-modulus consumer, and structural rows are exactly the displayed coordinates.

The tolerance route is ordered by A. A requested Z-tolerance is consumed by M_G to expose a Y-tolerance, and only that displayed Y-tolerance is then consumed by M_F to expose the source tolerance over X.

The triangle estimate T and consumer row U read the same assembled route. Transport, replay, provenance, and local naming preserve it through H, C, P, N.

Since the carrier has no coordinate for host function-space composition, quotient point equality, selected moduli, choice, or ambient compactness, the listed rows exhaust the NameCert surface. □

Theorem 5895.3 (Compact uniform modulus composition tolerance route)**.** *Every compact-open or compact-uniform-continuity consumer of an accepted* $\mathsf{CompactUniformModulusComposition}^{\uparrow}$ *packet reads the composite modulus only through*

$$M_G \longmapsto A \longmapsto M_F \longmapsto T \longmapsto U.$$

Thus the composite tolerance is assembled from two displayed compact-uniform modulus rows and the metric-triangle ledger, not from a selected host-level modulus for the composite map.

Proof. Begin with the consumer's target tolerance for the Z row. The second modulus row M_G supplies the middle-space tolerance, and the assembly row A records that this is the only tolerance handed to M_F.

The first modulus row M_F returns the source-space tolerance over X. The metric-triangle row T then transports the two displayed estimates into the bound consumed by U.

The structural rows H, C, P, N preserve this route. Since there is no host composition coordinate or selected global modulus in the carrier, every consumer remains on the displayed tolerance chain. □

Theorem 5895.4 (Compact uniform modulus composition nonescape)**.** *No accepted* CompactUniformModulusComp *packet exports quotient point equality, a selected global modulus, a choice schedule, an ambient compactness theorem, or a host function-space composition proof. It exports only the two continuous-map rows, two compact-uniform modulus rows, the tolerance assembly row, the metric-triangle estimate, the uniform-modulus consumer, and the structural NameCert rows.*

Proof. Project the carrier. The only analytic rows are F, G, M_F, M_G, A, T, U over the compact metric sources X, Y, Z.

Apply Definition 5895.2. The local NameCert obligations require the consumer to read the two modulus rows and the tolerance assembly before the uniform-modulus export.

The refused host objects are absent from the carrier and cannot be produced by transport, replay, provenance, or local naming. Therefore the accepted packet exports only the displayed finite composition route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusComposition}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformModulusComposition}^{\uparrow}$ packet is generated from compact metric source, middle, and target rows, two ContinuousMap rows, two CompactUniformModulus rows, a tolerance-assembly row, a MetricTriangleUniformEstimate row, a UniformModulus consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusComposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5895.1, Definition 5895.2, Definition 5895.3, and Definition 5895.4 seed the finite tolerance-only composition route for compact-uniform modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusComposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function-space composition, quotient point equality, selected global moduli, choice schedules, ambient compactness theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact source admission, continuous-map admission, first and second modulus reads, tolerance assembly, metric-triangle transport, uniform-modulus export, replay stability, provenance exhaustion, and local naming for BEDC.Derived.CompactUniformModulusCompositionUp.

Chapter 5896

A Concrete Naming Certificate for $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$

The $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$ packet realizes the private/shared decoration theorem of Definition 9462.1705 inside the boundary-tile source of subsection 9462.28.21. It sits beside the DNA boundary-tile packet of chapter 3393, the trigger-threshold packet of chapter 4217, and the finite trigger algebra route of chapter 3478. The packet records private blocks, shared rows, lift counts, and defect ledgers as finite NameCert data; it is not a biological mechanism, stochastic evolution model, hidden enumeration oracle, or quotient codon semantics.

Definition 5896.1 (PrivateSharedDecorationModel carrier)**.** *A* $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, S, L, D, T, R, P, N)$$

with the following displayed rows:

1. *B is the nonempty private-block row, recording the partition of coordinates that remain private to a single decorated support.*
2. *S is the shared-row ledger, assigning every shared coordinate to a finite row set of size at least two.*
3. *L is the lift-count row, recording the finite ℓ^m lift factor attached to displayed support blocks.*
4. *D is the defect ledger, recording the row-set size contribution to the defect-refined polynomial.*
5. *T records componentwise* hsame *transport for B, S, L, D, R, P, N.*
6. *R records displayed* Cont *replay from a decorated trigger request through the private block, shared rows, lift count, defect ledger, provenance, and local naming rows.*
7. *P is the* Pkg *provenance over* $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, *the source theorem of Definition 9462.1705,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{PrivateSharedDecorationModel}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through B, S, L, D, T, R, P, N. It has no coordinate for biological mechanism, stochastic fitness, quotient codon equality, hidden global semantics, or an unrecorded enumeration oracle.

Theorem 5896.2 (PrivateSharedDecorationModel NameCert obligations)**.** *For every accepted* $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$ *carrier*

$$M = (B, S, L, D, T, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrivateSharedDecorationModel}^{\uparrow}}$ *surface consists exactly of carrier admission for the nonempty private-block row, shared-row ledger, lift-count row, defect ledger, componentwise transport, displayed replay, provenance, and local naming. A decorated trigger read is accepted only after it exposes a nonempty private block and assigns every shared coordinate to at least two rows.*

Proof. Project the carrier of Definition 5896.1. The private block, shared-row ledger, lift count, defect ledger, transport, replay, provenance, and local name are exactly the displayed coordinates.

The private/shared constraint is read through B, S. The row B must display a nonempty private partition, and the ledger S must attach every shared coordinate to a row set of size at least two.

The enumeration and defect data are read through L, D. The lift-count row records the finite lift factor, while the defect ledger records the shared-row contribution used by the source theorem.

Finally T, R, P, N transport, replay, source, and name the same route. Since biological mechanism, stochastic fitness, quotient codon equality, hidden global semantics, and unrecorded enumeration have no carrier coordinate, the listed rows exhaust the NameCert obligations. □

Falsifiable prediction: If a displayed decorated trigger lacks a nonempty private block or assigns a shared coordinate to fewer than two rows, it is rejected by the local NameCert.

Independence witness: dna-window-six-boundary-tile, dna-window-six-trigger-threshold, dna-window-six-translation-boundary: $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$ is not bijective to any listed sibling because this packet jointly carries private-block rows, shared-row ledgers, lift-count rows, defect ledgers, transport, replay, provenance, and local naming.

The Lean TasteGate route for `BEDC.Derived.PrivateSharedDecorationModelUp` must provide explicit $\mathsf{Nontrivial}\ \mathsf{PrivateSharedDecorationModel}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{PrivateSharedDecorationModel}^{\uparrow}$ instances preserving B, S, L, D, T, R, P, N as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{PrivateSharedDecorationModel}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$ packet is generated from a nonempty private-block row, shared-row ledger, lift-count row, defect ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrivateSharedDecorationModel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5896.1 and Definition 5896.2 seed the finite private/shared decoration packet over DNA boundary-tile trigger rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrivateSharedDecorationModel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic evolution, quotient codon equality, hidden global semantics, unrestricted enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, private-block nonemptiness, shared-row arity, lift-count exposure, defect-ledger exposure, transport, replay, provenance, local naming, Nontrivial PrivateSharedDecorationModelUp, and FieldFaithful PrivateSharedDecorationModelUp for BEDC.Derived.PrivateSharedDecorationModelUp.

Chapter 5897

A Concrete Naming Certificate for $\mathsf{BishopLocatedRealFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopLocatedRealFilter}^{\uparrow}$ packet records the finite filter-facing route by which located real brackets are read through dyadic tolerances, stream windows, regular rational readback, and the terminal real seal. It consumes the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the located bracket surface of chapter 1709, and the selector boundary of chapter 5886. The packet gives the L10 Real and Completion route a located filter interface without asserting quotient filter equality, host real equality, selected limit points, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5897.1 (Bishop located real filter carrier)**.** *A* $\mathsf{BishopLocatedRealFilter}^{\uparrow}$ *carrier is a finite packet*

$$S = (F, L, D, W, R, E, B, H, T, P, N)$$

with the following displayed rows:

1. *F is the filter-base row, exposing the finite base request, refinement evidence, and Cauchy-facing filter data that a later completion consumer may inspect.*
2. *L is the located-real bracket row, recording lower and upper bracket reads over* $\mathsf{LocatedRealInterval}^{\uparrow}$ *together with the displayed apartness and containment data used to locate the requested real value.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger governing bracket width, filter-base comparison, stream-window radius, and regular-rational readback.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row attached to the filter request and the located bracket.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the windows in W under the tolerance ledger D.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after F, L, D, W, R have been displayed and replayed.*
7. *B is the* BHist *history row recording the finite route from the filter request through the located bracket, tolerance ledger, stream windows, regular readback, and Real seal.*
8. *H records componentwise* hsame *transport for $F, L, D, W, R, E, B, T, P, N$.*
9. *T records displayed* Cont *replay from every located filter request through $F, L, D, W, R, E, B, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedRealFilter}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{CauchyFilterSelector}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, L, D, W, R, E, B, H, T, P, N$. It has no coordinate for quotient filter equality, host selected representatives, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.BishopLocatedRealFilterUp.BishopLocatedRealFilterUp`

Theorem 5897.2 (Bishop located real filter NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedRealFilter}^{\uparrow}$ *carrier $S = (F, L, D, W, R, E, B, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealFilter}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the filter base, located-real bracket, dyadic tolerance ledger, StreamName windows, RegSeqRat readback, Real seal, history, transport, replay, provenance, and local naming row;*
2. *bracket exactness, requiring each located-real bracket read in L to be witnessed by displayed* $\mathsf{LocatedRealInterval}^{\uparrow}$ *endpoint and containment data;*
3. *filter-base stability, requiring refinements of F to preserve the same located bracket and tolerance ledger through* BHist *and* hsame *transport;*
4. *dyadic ledger stability, requiring D to control the bracket width, stream-window radius, and regular-rational readback without adding an external modulus;*
5. *StreamName and RegSeqRat handoff, requiring every numeric read to pass through W and then R before the terminal seal E can be consumed;*
6. *nonescape, excluding quotient filters, host-selected representatives, countable choice, host real equality, selected limiting points, and ambient Real completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5897.1. The accepted packet displays the filter base, located bracket, dyadic ledger, stream windows, regular readback, Real seal, history, transport, replay, provenance, and local naming rows.

Bracket exactness is row-local. The bracket row L can expose only the endpoint and containment data already carried by $\mathsf{LocatedRealInterval}^{\uparrow}$, so it cannot identify a real by host order equality or by a selected representative.

The filter-base and tolerance rows then fix the route. Refinement of F is transported through B and H, while the same dyadic row D governs bracket width, window radius, and readback precision.

Finally the numeric handoff is ordered by W, R, E. Stream windows are read before regular rational data, and regular rational data are read before the terminal $\mathsf{Real}^{\uparrow}$ seal. Since no excluded host object is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5897.3 (Bishop located real filter L10 handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{BishopLocatedRealFilter}^{\uparrow}$ *packet $S = (F, L, D, W, R, E, B, H, T, P, N)$ must read the finite route*

$$F, L, D, W, R \longmapsto E \longmapsto B, H, T, P, N$$

before it treats the request as Real-facing or completion-facing data. Thus the packet supplies a filter-based located-real handoff to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, *and*

$\mathsf{CauchyFilterSelector}^{\uparrow}$ *consumers without asserting ambient real completeness or quotient equality of filters.*

Proof. Read the carrier rows in order. A consumer first receives the filter base F and the located bracket L, while the dyadic ledger D supplies the common tolerance budget.

The numerical content is then exposed through W and R. The $\mathsf{StreamName}^{\uparrow}$ row records finite observation windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ row records the regular rational readback extracted from those windows.

Only after these rows are displayed can the Real seal E be consumed. The history, transport, replay, provenance, and local naming rows B, H, T, P, N preserve that order for later L10 Real and Completion routes.

The carrier has no quotient-filter equality, selected representative, host real equality, choice schedule, or ambient completeness coordinate. Therefore every downstream handoff factors through the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRealFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRealFilter}^{\uparrow}$ packet is generated from a displayed filter base, a located-real bracket, a dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, a Real seal, BHist history, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5897.1, Definition 5897.2, and Definition 5897.3 seed the finite filter-facing located-real interface for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filter equality, ambient Real completeness, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Lean closure requires carrier admission, bracket exactness, filter-base stability, dyadic ledger stability, StreamName and RegSeqRat handoff, and Real seal boundary for BEDC.Derived.BishopLocatedRealFilterUp.

Chapter 5898

A Concrete Naming Certificate for $\mathsf{TaylorTheorem}^{\uparrow}$

Following Taylor and the validated-numerics treatment of finite Taylor models, the $\mathsf{TaylorTheorem}^{\uparrow}$ packet records the finite theorem-facing route from displayed derivative data to a polynomial jet and a checked remainder envelope. It sits after the Taylor-model enclosure surface of chapter 442, the derivative observation row of chapter 122, the polynomial carrier of chapter 50, the dyadic rational arithmetic core of chapter 291, the regular-rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite Taylor theorem certificate for one displayed center, order, domain window, derivative ledger, polynomial jet, and remainder bound; it does not import analytic convergence, quotient real equality, selected limits, or a host Taylor series.

Definition 5898.1 (Taylor theorem carrier)**.** *A* $\mathsf{TaylorTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, J, P, R, E, Q, H, C, G, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{Derivative}^{\uparrow}$ *row naming the center, finite order, domain window, and derivative observations inspected by the packet.*
2. *J is the finite jet ledger. Each coefficient is read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic and the same derivative window named by D.*
3. *P is the* $\mathsf{Poly}^{\uparrow}$ *row assembled from the displayed finite jet ledger.*
4. *R is the finite remainder-envelope row. It records the derivative-order budget, dyadic interval or ball enclosure, and endpoint window used to bound the residual after P is read.*
5. *E is the* $\mathsf{TaylorModel}^{\uparrow}$ *enclosure row that packages the displayed polynomial part and remainder envelope as a validated finite jet.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback route for polynomial values, derivative observations, and the remainder bound.*
7. *H records componentwise* hsame *transport for derivative, jet, polynomial, remainder, Taylor-model, readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from every Taylor-theorem read through $D, J, P, R, E, Q, H, G, N$.*

9. *G is the* Pkg *provenance over* $\mathsf{TaylorTheorem}^{\uparrow}$, $\mathsf{TaylorModel}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{TaylorTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, J, P, R, E, Q, H, C, G, N$. It has no coordinate for an infinite Taylor series, analytic convergence, quotient equality of real names, selected limiting values, or an ambient smooth-function theorem.

Theorem 5898.2 (Taylor theorem NameCert obligations)**.** *For every accepted* $\mathsf{TaylorTheorem}^{\uparrow}$ *carrier*

$$T = (D, J, P, R, E, Q, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{TaylorTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed derivative row, finite jet ledger, polynomial row, remainder envelope, Taylor-model enclosure, readback route, transport, replay, provenance, and local naming rows;*
2. *derivative-to-jet routing, requiring every coefficient in J to be read from the finite* $\mathsf{Derivative}^{\uparrow}$ *observations in D and through* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic;*
3. *polynomial assembly, requiring P to use exactly the displayed finite coefficient rows in J;*
4. *remainder-envelope exposure, requiring R to bind the next derivative-order budget, the domain window, and the dyadic enclosure before any error bound is exported;*
5. *Taylor-model handoff, requiring E to package only the displayed P and R rows;*
6. *regular and real readback, requiring Q to pass through* $\mathsf{RegSeqRat}^{\uparrow}$ *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is visible;*
7. *non-escape from analytic convergence, quotient real equality, selected limits, and host Taylor series semantics.*

No $\mathsf{TaylorTheorem}^{\uparrow}$ *obligation is stored outside these rows.*

Lean4 ✓ `BEDC.Derived.TaylorTheoremUp.TasteGate.TaylorTheoremTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 5898.1. The theorem-facing data are exactly D, J, P, R, E, Q, and the structural rows are exactly H, C, G, N.

The derivative-to-jet route is finite. Each coefficient read is a displayed entry of J, and the definition of J attaches that entry to the derivative row D and to dyadic rational arithmetic through $\mathsf{DyadicRatCore}^{\uparrow}$.

Polynomial assembly and remainder exposure are then separate rows. The polynomial row P consumes only the coefficients in J, while the remainder row R consumes the derivative-order budget and domain window before any bound is exported.

Finally the Taylor-model and readback rows seal the route. The row E packages the polynomial and remainder as a finite Taylor-model enclosure, and Q sends the same displayed data through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. Since no carrier coordinate names a host Taylor series or a selected limit, the listed rows exhaust the local NameCert surface. □

Theorem 5898.3 (Taylor theorem finite remainder envelope)**.** *Every accepted* $\mathsf{TaylorTheorem}^{\uparrow}$ *carrier exports a remainder claim only through the displayed route*

$$\mathsf{Derivative}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Poly}^{\uparrow} \longmapsto \mathsf{TaylorModel}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

More precisely, a consumer must first read the derivative row D, finite jet ledger J, polynomial row P, remainder-envelope row R, Taylor-model enclosure E, and regular-rational and real readback row Q before it may cite an error bound for the displayed polynomial approximation. The exported envelope is not an analytic convergence theorem, a quotient equality of real functions, a selected limit, or an ambient Taylor-series object.

Proof. Start with an accepted carrier $T = (D, J, P, R, E, Q, H, C, G, N)$. The only source of derivative information is D, and the only coefficient ledger is the finite row J read through $\mathsf{DyadicRatCore}^{\uparrow}$.

Next assemble the approximation. The polynomial row P is built from J, and the remainder row R binds the derivative-order budget, domain window, and dyadic enclosure that measure the residual after that polynomial row has been fixed.

Then pass through the enclosure and readback rows. The Taylor-model row E packages the polynomial and remainder as one finite validated jet, while Q routes the resulting value and bound through $\mathsf{RegSeqRat}^{\uparrow}$ and the terminal $\mathsf{Real}^{\uparrow}$ seal.

The transport, replay, provenance, and local naming rows preserve exactly this route. Because the carrier contains no coordinate for analytic convergence, quotient function equality, selected limits, or host Taylor series semantics, every exported remainder envelope is exhausted by the displayed finite rows. □

Falsifiable prediction: Every accepted $\mathsf{TaylorTheorem}^{\uparrow}$ remainder-envelope read factors through a DerivativeUp row, a DyadicRatCore coefficient ledger, a PolynomialUp row, a TaylorModelUp enclosure, a RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: taylormodel, derivative, polynomial, dyadicratcore, regseqrat, real: $\mathsf{TaylorTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite derivative observations, coefficient arithmetic, polynomial assembly, a theorem-facing remainder envelope, Taylor-model enclosure, regular-rational readback, real sealing, transport, replay, provenance, and local naming in one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{TaylorTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{TaylorTheorem}^{\uparrow}$ packet is generated from a DerivativeUp row, a finite DyadicRatCore coefficient ledger, a PolynomialUp row, a finite remainder envelope, a TaylorModelUp enclosure, RegSeqRatUp and RealUp readback, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TaylorTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5898.1, Definition 5898.2, and Definition 5898.3 seed the finite Taylor theorem route from derivative observations through polynomial jets to displayed remainder envelopes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TaylorTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close analytic convergence, quotient equality of real names, selected limits, host Taylor series semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-to-jet routing, polynomial assembly, finite remainder-envelope exposure, Taylor-model handoff, regular and real readback, and non-escape for BEDC.Derived.TaylorTheoremUp.

$\mathsf{RegularCauchyGluing}^{\uparrow}$ consumes the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance rows of chapter 291, and the terminal Real seal of chapter 38 before routing the child files below.

Chapter 5899

A Concrete Naming Certificate for $\mathsf{RegularCauchyGluing}^{\uparrow}$

Bishop–Bridges style regular Cauchy gluing records the finite route by which two compatible local regular rational windows can be read as one BEDC real-name boundary without passing through quotient representatives or an ambient completeness theorem. The $\mathsf{RegularCauchyGluing}^{\uparrow}$ packet sits after the dyadic tolerance core of chapter 291, the finite observation interface of chapter 126, the regular rational readback of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the reindexing route of chapter 1568.

Definition 5899.1 (Regular Cauchy gluing carrier)**.** *A* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (L, R, D, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the left and right compatible regular Cauchy windows, each carrying finite* $\mathsf{StreamName}^{\uparrow}$ *observations and a local* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row.*
2. *D is the common* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger recording the shared dyadic radii, endpoint comparisons, overlap budgets, and refinement witnesses used by both windows.*
3. *S is the joint* $\mathsf{StreamName}^{\uparrow}$ *observation row, exposing exactly the finite indices inspected on the left window, right window, and overlap.*
4. *Q is the glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained by reading the two local regular rows through the common ledger D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after L, R, D, S, Q have been displayed.*
6. *H records componentwise* hsame *transport for the two windows, common dyadic ledger, finite observations, glued readback, real seal, replay, provenance, and local certificate.*
7. *C records displayed* Cont *replay of the same finite gluing route.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyGluing}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that the two local windows are compatible on the displayed overlap through D, S, Q, H, C, P, N. It has no coordinate for quotient sequence equality, selected representatives, host real equality, countable choice, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 5899.2 (Regular Cauchy gluing classifier)**.** *The* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *classifier compares accepted carriers only through the tuple* $L, R, D, S, Q, E, H, C, P, N$*. Two packets are indistinguishable for this classifier precisely when the left and right window rows, the common dyadic refinement ledger, the finite observation row, the glued regular readback, the terminal real seal, and the transport, replay, provenance, and naming rows are componentwise the same under the displayed* hsame *routes.*

Theorem 5899.3 (Regular Cauchy gluing NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier* $G = (L, R, D, S, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$ *surface consists exactly of carrier admission for the two compatible regular Cauchy windows, common* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement through* D*, finite* $\mathsf{StreamName}^{\uparrow}$ *observation through* S*, glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* Q*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The analytic rows before the seal are exactly the two regular windows L, R, the common dyadic ledger D, the finite observation row S, and the glued regular readback Q.

The overlap obligation is finite. Its comparisons are stored in D and read through the same inspected indices in S, so the two local $\mathsf{RegSeqRat}^{\uparrow}$ rows feed one glued readback row Q without adding a quotient representative.

Transport, replay, provenance, and local naming are supplied by H, C, P, N. Repacking these projections gives the listed $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$ surface, and the carrier definition leaves no hidden row for selected representatives, host equality, countable choice, or ambient completeness. □

Theorem 5899.4 (Regular Cauchy gluing overlap stability)**.** *Let* $G = (L, R, D, S, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier. Any refinement of the displayed overlap that is transported by* H *and replayed by* C *preserves the same glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q *and the same* $\mathsf{Real}^{\uparrow}$ *seal row* E*. Consequently downstream Real and Completion consumers receive only the finite gluing packet and not quotient stream equality, selected representatives, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the displayed overlap ledger. The common dyadic row D records every radius and endpoint comparison used by both local windows, while S records the finite observations on which those comparisons are made.

Apply the classifier of Definition 5899.2. A refinement transported by H and replayed by C can change neither the componentwise ledger coordinates nor the finite observation coordinates exposed to the classifier.

The glued readback row Q is therefore the same row after refinement, and the $\mathsf{Real}^{\uparrow}$ seal E is read only through Q together with H, C, P, N. Since the carrier contains no quotient, selector, host-equality, choice, or completeness coordinate, none of those data can be exported by overlap stability. □

Theorem 5899.5 (Regular Cauchy gluing common-refinement exactness)**.** *Let* $G = (L, R, D, S, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier. Every glued readback exported from* G *must expose the common* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement row* D *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *and the* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The exactness route is transported by* H *and replayed by* C*, and it exports no quotient stream equality, selected representative, host real equality, countable choice, or ambient completeness.*

Proof. Project the accepted carrier. The row D is the common dyadic refinement ledger shared by the two local regular Cauchy windows, while Q is the glued regular readback and E is the terminal Real seal.

Apply overlap stability from Definition 5899.4. Any accepted refinement of the overlap preserves the same Q and E only through the displayed ledger and observation rows, so a glued readback cannot bypass D.

Finally use the Cauchy-reindexing handoff of Definition 5899.7. It reads D, S, Q as the finite reindexing-compatible route before any Real-facing consumer reaches E, with H, C, P, N preserving and naming the same route. □

Theorem 5899.6 (Regular Cauchy gluing overlap induction)**.** *Let $G = (L, R, D, S, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier. For any finite chain of displayed overlap refinements transported by H and replayed by C, the glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E remain unchanged. The resulting route still factors through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{CauchyReindexing}^{\uparrow}$, *and it exports no quotient stream equality, selected representatives, host equality, countable choice, or ambient completeness.*

Proof. Induct on the displayed finite refinement list.

The empty list is the overlap-stability theorem of Definition 5899.4: the common dyadic ledger D and the finite observation row S already determine the same glued readback Q and seal E.

For the step, assume the earlier refinements preserve Q and E. Compose the next displayed refinement with the induction hypothesis, transport the component rows by H, and replay the same finite route by C.

Apply the classifier of Definition 5899.2 componentwise. Since the classifier reads only $L, R, D, S, Q, E, H, C, P, N$ the next refinement cannot add a quotient, representative selector, host equality row, choice schedule, or completeness witness; it only repeats the finite route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchyReindexing}^{\uparrow}$. □

Theorem 5899.7 (Regular Cauchy gluing Cauchy-reindexing handoff)**.** *Every accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier factors its gluing route through the finite* $\mathsf{CauchyReindexing}^{\uparrow}$ *surface recorded in P. The handoff exposes the common dyadic refinement ledger D, the finite observation row S, and the glued regular readback row Q as a reindexing-compatible route, and it exposes no global quotient of regular Cauchy names or ambient completeness principle.*

Proof. Read the package provenance P. It names the route through $\mathsf{CauchyReindexing}^{\uparrow}$ together with $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The carrier rows D, S, Q are exactly the finite data consumed by that route: D supplies the common refinement ledger, S supplies the inspected windows, and Q supplies the regular rational readback after the two local windows agree on the overlap.

The support rows H, C, N transport, replay, and name this same finite path. Thus the handoff is reindexing-compatible BEDC data, not a quotient of regular names, a selected representative, or a completeness theorem. □

Theorem 5899.8 (Regular Cauchy gluing obligation closure handoff)**.** *Every obligation-closure read of an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier must expose the full row tuple*

$$L, R, D, S, Q, E, H, C, P, N.$$

The route factors through the common $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger, the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row, the local* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks and glued readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and*

the $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff named by* P *before any downstream real-name consumer may read the gluing packet.*

Proof. Start with the carrier and NameCert obligations. The accepted packet exposes $L, R, D, S, Q, E, H, C, P, N$, and the obligation surface has no smaller projection that still records the two local windows, their common refinement, and the glued readback.

Use the Cauchy-reindexing handoff of Definition 5899.7. It forces the gluing read through D, S, Q and through the provenance row P naming $\mathsf{CauchyReindexing}^{\uparrow}$, while the carrier rows L, R provide the two regular windows.

The rows E, H, C, N then seal, transport, replay, and name the same finite route. Thus obligation closure reads exactly the displayed tuple and factors through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchyReindexing}^{\uparrow}$. □

Theorem 5899.9 (Regular Cauchy gluing Real seal ordering)**.** *For an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier* $G = (L, R, D, S, Q, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is reachable only after the common dyadic refinement row* D*, the finite observation row* S*, and the glued readback row* Q *have been displayed. The seal-ordering route asserts no quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness.*

Proof. Project the carrier definition. The row E is listed as the terminal $\mathsf{Real}^{\uparrow}$ seal reached only after the two local windows, the common refinement ledger, the finite observations, and the glued readback have been displayed.

Apply the overlap-stability and Cauchy-reindexing handoff theorems. They keep the common dyadic refinement in D, the inspected windows in S, and the glued regular readback in Q visible before any real-name consumer can inspect E.

Since quotient stream equality, selected representatives, host equality, choice schedules, and ambient completeness are not carrier coordinates, the ordering statement cannot export them. It records only the displayed route from D, S, Q to the terminal seal E. □

Theorem 5899.10 (Regular Cauchy gluing local tail compatibility)**.** *For an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier* $G = (L, R, D, S, Q, E, H, C, P, N)$*, the two local regular-Cauchy windows* L *and* R *can be consumed by a* $\mathsf{Real}^{\uparrow}$*-seal reader only after the overlap row, the common-refinement row, and the Cauchy-reindexing row exhibit a shared* $\mathsf{RegSeqRat}^{\uparrow}$ *tail boundary. The compatibility route is the finite route through* D, S, Q, H, C, P, N *supplied by the carrier, and it exports no quotient stream equality, selected representative, or ambient completeness.*

Proof. Project the carrier of Definition 5899.1. The two local windows L, R are not read independently by a Real-facing consumer; the packet first displays their shared dyadic ledger D, finite observations S, and glued readback Q.

Apply overlap stability, Definition 5899.4, and common-refinement exactness, Definition 5899.5. These theorems keep the overlap row and the common refinement visible before Q is consumed, so the two local $\mathsf{RegSeqRat}^{\uparrow}$ tails are compared at the displayed boundary rather than by host stream equality.

Apply overlap induction, Definition 5899.6, to finite chains of displayed refinements, and then use the Cauchy-reindexing handoff, Definition 5899.7. The resulting route makes the shared tail boundary stable under H and replayable by C before E is read.

Since quotient stream equality, selected representatives, and ambient completeness are absent from Definition 5899.1, the compatibility theorem can expose only the finite D, S, Q, H, C, P, N route. □

The local-tail compatibility row is consumed through the $\mathsf{RegSeqRat}^{\uparrow}$ finite-window surface of chapter 301 and the $\mathsf{StreamName}^{\uparrow}$ finite-observation surface of chapter 126. The exact dependency is the common-tail rows displayed by D and Q, together with finite-window readback through S, before the $\mathsf{Real}^{\uparrow}$ seal E is available to any downstream consumer.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyGluing}^{\uparrow}$ packet is generated from two compatible regular Cauchy windows, a common $\mathsf{DyadicRatCore}^{\uparrow}$ refinement ledger, finite $\mathsf{StreamName}^{\uparrow}$ observations, a glued $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}, \mathsf{seed})$

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, countable choice, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exposure, common dyadic-refinement exactness, overlap stability, CauchyReindexing handoff, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyGluingUp.

Theorem 5899.11 (Regular Cauchy gluing L10 sibling route)**.** *Every accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet reads its local gluing route through the L10 sibling lattice before it exports a NameCert row. The route first consumes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows of chapter 291, the* $\mathsf{StreamName}^{\uparrow}$ *finite observation windows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readbacks of chapter 301, the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38, and the Cauchy reindexing handoff of chapter 1568.*

Thus the gluing packet exports only a local finite NameCert route over the displayed dyadic, stream, regular-rational, Real-seal, and reindexing rows. It does not expose quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness.

Proof. Project the carrier of Definition 5899.1. Its visible rows are two local regular windows, the common dyadic ledger, the finite observation row, the glued regular readback, the Real seal, and the transport, replay, provenance, and naming rows.

Apply Definition 5899.3. The local NameCert surface must read exactly those rows, with the dyadic ledger, StreamName windows, RegSeqRat readback, and Real seal appearing before the certificate is exported.

Use Definition 5899.7 for the reindexing component. It identifies the same dyadic, stream, and regular readback rows as a $\mathsf{CauchyReindexing}^{\uparrow}$-compatible route.

Thus the dependency on chapter 1568 is consumed before the $\mathsf{RegSeqRat}^{\uparrow}$ readback and terminal $\mathsf{Real}^{\uparrow}$ seal are available to the gluing certificate.

The exclusions are inherited from the carrier inventory and the overlap stability theorem. Since no coordinate stores quotient stream equality, selected representatives, host real equality, choice, or ambient completeness, the L10 sibling route remains a finite local NameCert route. □

Theorem 5899.12 (Regular Cauchy gluing RegSeqRat route)**.** *Every glued readback row of an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet must pass through the existing* $\mathsf{RegSeqRat}^{\uparrow}$ *sibling surface of chapter 301 and the* $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff of chapter 1568 before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is visible. The local obligations of Definition 5899.3 therefore expose a regular rational readback and a reindexing route before any Real-facing consumer may read the glued value.*

Proof. Start from the local L10 route of Definition 5899.11. It already orders the dyadic ledger, finite StreamName windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{CauchyReindexing}^{\uparrow}$ handoff, and terminal $\mathsf{Real}^{\uparrow}$ seal before the gluing NameCert row is exported.

Apply the local obligations of Definition 5899.3. The glued readback row is one of the displayed certificate rows, so it cannot be consumed without the same regular rational surface and structural support rows.

Use Definition 5899.7. The reindexing handoff keeps the dyadic, stream, and regular readback data aligned before the terminal Real seal appears. Thus a Real-facing read factors through RegSeqRat and CauchyReindexing rather than bypassing them. □

Theorem 5899.13 (Regular Cauchy gluing pasting nonescape)**.** *Every accepted pasting consumer of a* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet must read the finite route of Definition 5899.1, satisfy the local obligations of Definition 5899.3, and pass through the L10 sibling route of Definition 5899.11 before it exports any NameCert row. In particular, the consumer must display the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff, and terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Consequently no such pasting consumer exports quotient stream equality, selected representatives, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness as a coordinate of the* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *read.*

Proof. Project the accepted carrier in Definition 5899.1. Its displayed route already contains the common dyadic ledger, finite StreamName observations, glued RegSeqRat readback, Real seal, and the support rows for transport, replay, provenance, and naming.

Apply Definition 5899.3. A pasting consumer can export a local NameCert row only by preserving exactly those displayed rows, so the consumer has no separate entry point around the dyadic, stream, regular readback, or seal coordinates.

Apply Definition 5899.11. The L10 route orders the same rows through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before export.

The refused objects are absent from the carrier and absent from the sibling route. Thus quotient stream equality, selected representatives, host real equality, countable choice, and ambient completeness cannot be repacked as a pasting consumer of the accepted $\mathsf{RegularCauchyGluing}^{\uparrow}$ packet. □

Theorem 5899.14 (Regular Cauchy gluing separator-use route)**.** *Every accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *consumer that exports an apartness read or a located-comparison read must first pass through the* $\mathsf{RegularSeqApartnessSeparator}^{\uparrow}$ *route of chapter 7930. Ordinary gluing consumers still export only the finite dyadic, stream,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyReindexing}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal rows named by Definition 5899.11.*

Proof. Start with the L10 sibling route of Definition 5899.11. It exposes the dyadic tolerance rows, finite stream windows, regular-rational readback, Cauchy reindexing handoff, and terminal Real seal before the local gluing NameCert row is exported.

For a consumer that reads only gluing data, those rows exhaust the available surface by Definition 5899.13. The carrier has no coordinate for apartness, located comparison, quotient equality, selected representatives, choice, or ambient completeness.

If the same consumer asks for apartness or located comparison, apply the separator sibling dependency of Definition 7930.3. That route requires the stream, regular-rational, dyadic, Real-seal, located-cut, and apartness-field rows to be displayed through $\mathsf{RegularSeqApartnessSeparator}^{\uparrow}$ before such a read is available.

Thus the gluing packet itself remains the ordinary finite route, while apartness-facing or located-comparison-facing reads factor through the separator chapter rather than being smuggled into the gluing carrier. □

Theorem 5899.15 (Regular Cauchy gluing completion consumer route)**.** *Every Bishop-completion or Real-completion consumer of an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet must read the same finite L10 sibling route before exporting a gluing* $\mathsf{NameCert}$ *row. In particular, the consumer first exposes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite observation windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback, the* $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The exported gluing certificate has no coordinate for quotient stream equality, selected representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the L10 sibling route of Definition 5899.11. It already orders the dyadic ledger, stream windows, regular-rational readback, Cauchy reindexing handoff, and terminal Real seal before any local gluing $\mathsf{NameCert}$ row is exported.

Apply the RegSeqRat route of Definition 5899.12. A completion-facing read of the glued value therefore cannot bypass the regular rational surface or the reindexing route on its way to the terminal $\mathsf{Real}^{\uparrow}$ seal.

Apply the pasting nonescape theorem, Definition 5899.13. It keeps every gluing consumer inside the finite carrier route and excludes quotient stream equality, selected representatives, host real equality, countable choice, and ambient completeness as exportable coordinates.

Finally use the separator-use route of Definition 5899.14. Apartness-facing or located-comparison-facing completion reads factor through the separator sibling; ordinary Bishop-completion and Real-completion gluing reads still expose only the dyadic, stream, regular-rational, reindexing, and Real-seal rows before the gluing $\mathsf{NameCert}$ is named. □

Theorem 5899.16 (Regular Cauchy gluing uniform Cauchy criterion route)**.** *Every uniform-Cauchy-criterion consumer of an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet must read the finite sibling route before exporting criterion data. The consumer must expose the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff, the* $\mathsf{BishopRealCompletion}^{\uparrow}$ *consumer rows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal as displayed rows of the gluing route.*

Consequently the criterion consumer exports only the finite BEDC packet obtained from those rows, componentwise hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$ *ledger. It does not export quotient sequence equality, selected representatives, countable choice, host real equality, or ambient completeness.*

Proof. Start with the L10 sibling route of Definition 5899.11. It already places the dyadic tolerance ledger, finite stream windows, regular-rational readback, Cauchy reindexing handoff, and terminal Real seal before any gluing $\mathsf{NameCert}$ row is exported.

Apply the RegSeqRat route of Definition 5899.12 and the completion consumer theorem Definition 5899.15. Together they force a completion-facing criterion read through the regular rational surface, the reindexing handoff, and the Bishop-completion consumer rows before the terminal $\mathsf{Real}^{\uparrow}$ seal can be read.

Finally use the downstream sibling route of Definition 5899.18. It permits only concrete downstream consumers after the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopRealCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows have been displayed. Since the carrier and all cited routes omit quotient sequence equality, selected representatives, countable choice, host real equality, and ambient completeness, none of those objects can be repacked as uniform-Cauchy-criterion data. □

Theorem 5899.17 (Regular Cauchy gluing L10 sibling dependency)**.** *Before any gluing consumer reads the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$ *row, it must display the finite sibling dependency route through the* $\mathsf{RegSeqRat}^{\uparrow}$ *rows of chapter 301, the* $\mathsf{StreamName}^{\uparrow}$ *observation windows of chapter 126,*

the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows of chapter 291, the completion-facing handoff of chapter 3665, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38. The route may also be read by Bishop-completion consumers through the completion consumer theorem Definition 5899.15, but it remains a finite dependency lattice rather than quotient sequence equality, selected representatives, countable choice, host real equality, or ambient real completeness.*

Proof. Start with Definition 5899.11. It already orders the dyadic tolerance rows, stream observation windows, regular-rational readback, Cauchy reindexing handoff, and Real seal before the local $\mathsf{NameCert}$ row is exported.

Apply Definition 5899.15. A Bishop-completion or Real-completion consumer therefore reads the same finite row sequence before it can use the gluing packet as completion-facing data.

The dependency is finite because every cited sibling appears as a displayed row or handoff in the local route. No step asks for quotient sequence equality, a selected representative of a Cauchy class, countable choice over tails, host real equality, or an ambient completeness theorem. □

Theorem 5899.18 (Regular Cauchy gluing downstream sibling route)**.** *Any cofinal, interleaving, or comparison-facing consumer of an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet must first pass through the finite sibling route of Definition 5899.17. After the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopRealCompletion}^{\uparrow}$, *and terminal* $\mathsf{Real}^{\uparrow}$ *rows have been displayed, such a consumer may continue only through a concrete downstream sibling such as chapter 414 or chapter 3514. The gluing packet itself exports no detached cofinal route, no interleaving selector, no quotient equality of Cauchy names, no selected representative, and no ambient completeness theorem.*

Proof. Start with Definition 5899.17. It forces every gluing consumer to display the regular rational rows, finite stream windows, dyadic tolerance rows, Bishop-completion handoff, and terminal Real seal before the local $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$ row is read.

Apply the completion consumer theorem Definition 5899.15. A completion-facing read therefore receives the same finite route, not a quotient stream or selected representative.

For an interleaving-facing read, use the public sibling surface of chapter 414. It supplies the alternating selector and combined modulus ledger only after the relevant $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are displayed.

For a comparison-facing read, use chapter 3514. That packet supplies the even–odd comparison and shared threshold rows as a separate finite consumer surface. Thus any cofinal or interleaving continuation is downstream of the existing L10 sibling dependency, and none of those rows is smuggled into the gluing carrier itself. □

Theorem 5899.19 (Regular Cauchy gluing tail-agreement composition)**.** *Any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer that reads a glued* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet through Definition 5899.18 must continue through the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *route of chapter 699 before treating the glued readback as completion-facing tail agreement. The composed route also reads the Cauchy limit seal of chapter 386; the gluing packet alone exports no ambient tail equality, selected representative, quotient sequence equality, or completeness witness.*

Proof. Start with Definition 5899.18. It permits downstream consumers only after the finite $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopRealCompletion}^{\uparrow}$, and terminal $\mathsf{Real}^{\uparrow}$ rows have been displayed.

A completion-facing tail read then has an additional boundary. The $\mathsf{RealTailAgreementSeal}^{\uparrow}$ chapter supplies the route that turns a Real-facing readback into displayed tail-agreement data, and the $\mathsf{CauchyLimitSeal}^{\uparrow}$ chapter supplies the limit-facing seal used by completion consumers.

Thus the row order is finite: first the local gluing sibling route, then the tail-agreement seal, and finally the Cauchy-limit seal. Because each step only reuses displayed rows, no consumer can replace the route by host tail equality, a selected Cauchy representative, quotient sequence equality, or ambient completeness. □

$\mathsf{RegularCauchyGluing}^{\uparrow}$ consumes its L10 sibling lattice before any gluing read is exported: the $\mathsf{StreamName}^{\uparrow}$ finite windows provide the inspected overlap rows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the regular readback, $\mathsf{DyadicRatCore}^{\uparrow}$ carries the shared tolerance ledger, $\mathsf{Real}^{\uparrow}$ seals the terminal value, and chapter 5544 provides the $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ schedule that keeps the two local Cauchy windows on one displayed budget.

Theorem 5899.20 (Regular Cauchy gluing L10 forward route)**.** *Every accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *consumer reaches Real-facing gluing only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of the local carrier. The route first reads the name certificate construction, then the L10 sibling route, and finally the Bishop-completion consumer route before any gluing conclusion is exported. It refuses quotient stream equality, selected limits, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as coordinates of the gluing read.*

Proof. Project the local carrier and obligations from Definition 5899.1 and Definition 5899.3. The rows available to a consumer are the two compatible windows, the common dyadic ledger, finite observations, glued regular readback, Real seal, transport, replay, provenance, and local naming.

Apply the L10 sibling route of Definition 5899.11. It orders the consumer through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before a local gluing certificate is exported.

Apply the Bishop-completion consumer theorem Definition 5899.22. A Real-facing or Bishop-completion consumer must display the same D, S, Q, E, H, C, P, N route, so the forward path remains finite and local to the accepted packet.

The refused objects are absent from every cited step. The name certificate construction supplies no quotient stream equality; the L10 sibling route supplies no selected limit or countable-choice schedule; and the Bishop-completion consumer route supplies no ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate. Hence every accepted forward gluing read factors through the displayed windows, readbacks, tolerance ledgers, and Real seal. □

Theorem 5899.21 (Regular Cauchy gluing sibling forward link)**.** *Every accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet that is read as a gluing consumer first passes through the L10 sibling route of Definition 5899.11. In particular, the consumer must expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface of chapter 301 and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows of chapter 126 before the local gluing* $\mathsf{NameCert}$ *row is available.*

The forward link is therefore a concrete sibling dependency route rather than a detached hub edge. It also preserves the exclusions already named by the L10 route: no quotient stream equality, selected representative, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness is exported by the gluing read.*

Proof. Start with the carrier and obligation rows of Definition 5899.1 and Definition 5899.3. They display the paired local windows, common dyadic ledger, finite observations, glued regular readback, terminal Real seal, transport, replay, provenance, and local naming rows.

Apply the L10 sibling route of Definition 5899.11. That route orders the same gluing read through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any gluing certificate can be exported.

Thus the hub has a visible child route into the RegSeqRat and StreamName sibling chapters. The refused objects remain absent because neither the local carrier nor the L10 sibling route contains coordinates for quotient stream equality, selected representatives, choice, host equality, or ambient completeness. □

Theorem 5899.22 (Regular Cauchy gluing Bishop completion consumer)**.** *Every* $\mathsf{BishopRealCompletion}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet must first expose the same finite gluing carrier rows already displayed by Definition 5899.1. In particular, before the Bishop completion route may read the terminal* $\mathsf{Real}^{\uparrow}$ *seal, the consumer must display the* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger* D*, the* $\mathsf{StreamName}^{\uparrow}$ *observation row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *glued readback* Q*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, the* $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff recorded in* P*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* NameCert *row* N*.*

Thus the Bishop completion consumer receives the gluing packet only as a finite L10 route over dyadic, stream, regular-rational, Real-seal, reindexing, transport, replay, provenance, and naming data. It receives no quotient stream equality, selected representative, host real equality, countable-choice schedule, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier $G = (L, R, D, S, Q, E, H, C, P, N)$ from Definition 5899.1. The rows that a completion-facing consumer can inspect are exactly the two local windows, the common dyadic ledger, the finite observations, the glued readback, the Real seal, transport, replay, provenance, and local naming.

Apply the L10 sibling route of Definition 5899.11. It orders the gluing packet through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchyReindexing}^{\uparrow}$ before a NameCert row is exported.

Now read the Bishop completion carrier of chapter 3665. Its completion-facing route consumes dyadic precision, finite stream windows, regular rational readback, a Real seal, transport, replay, provenance, and local naming. The gluing rows D, S, Q, E, H, C, P, N are therefore the only rows that can feed such a consumer from $\mathsf{RegularCauchyGluing}^{\uparrow}$.

The exclusions follow from the same carrier inventory. Since neither Definition 5899.1 nor the Bishop completion route supplies quotient stream equality, selected representatives, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness as a coordinate, the consumer cannot export any of those objects from the gluing packet. □

Theorem 5899.23 (Regular Cauchy gluing Real-tail forward route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{Completion}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet that asks for a tail-agreement seal is a forward dependency of the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *route in chapter 699. Concretely, the gluing packet first exposes the common* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger* D*, the paired* $\mathsf{StreamName}^{\uparrow}$ *observation row* S*, the glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and the local* $\mathsf{Real}^{\uparrow}$ *seal* E*; only then may the consumer enter the Real-tail agreement and Cauchy-limit seal route through* $\mathsf{RealTailAgreementSeal}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{Completion}^{\uparrow}$*.*

Proof. Project the accepted gluing carrier $G = (L, R, D, S, Q, E, H, C, P, N)$ from Definition 5899.1. The Real-facing rows available before any tail agreement are exactly the common dyadic ledger D, finite observation row S, glued regular readback Q, terminal seal E, transport row H, replay row C, provenance row P, and local name row N.

Apply the Real seal ordering theorem Definition 5899.9. It forces the route to display D, S, Q before E is readable, so a consumer cannot jump from the two local windows directly to a Real-tail agreement row.

Now use the Real-tail agreement completion-consumer boundary of chapter 699. That boundary receives paired windows, dyadic readback, agreement, Cauchy-limit sealing, and Real or Com-

pletion endpoints as one finite route. Feeding it from $\mathsf{RegularCauchyGluing}^{\uparrow}$ therefore makes the gluing read a forward dependency of that Real-tail route rather than a separate kernel island.

The exclusions are inherited from the two carriers. Neither Definition 5899.1 nor the Real-tail agreement route supplies quotient stream equality, selected representatives, host convergence, countable choice, or ambient completeness as a row, so no such object can be exported by this forward dependency. □

Chapter 5900

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$ packet names the explicit tail-majorant data used when regular rational sequences are read through finite tolerances. It sits between the $\mathsf{RegSeqRat}^{\uparrow}$ source of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ schedule of chapter 126, the dyadic tolerance ledger of chapter 291, the modulus surface of chapter 292, and the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet records a finite threshold service for tail estimates; it is not a completeness theorem, a selected limit operator, or a quotient equality on real names.

Falsifiable prediction: Removing the majorant-threshold row permits a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal to cite a tail estimate without naming the finite stage after which the estimate is valid. Removing the dyadic tolerance row prevents the threshold from being checked against a displayed rational error bound.

Independence witness: Nearest siblings include $\mathsf{RegularCauchyTailBudget}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. None is bijective to $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$ because the budget packet stores observation service, the modulus packet stores a general tolerance schedule, the regular sequence packet stores the source reads, the stream packet stores names, the dyadic packet stores rational tolerances, and the real packet stores a seal rather than the finite tail-majorant threshold binding them.

Definition 5900.1 (Regular Cauchy tail majorant carrier)**.** *A* $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (S, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule naming the inspected regular-sequence tail requests.*
2. *M is the majorant-threshold row assigning to each displayed tolerance request a finite stage after which the tail estimate is accepted.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger whose dyadic entries are the error bounds tested by M.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that exposes the regular rational sequence only through the displayed schedule, threshold, and dyadic tolerance rows.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the scheduled tail-majorant readback has been replayed.*

6. *H records componentwise* hsame *transport for the schedule, majorant threshold, dyadic tolerance, regular readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from schedule requests through the majorant threshold, dyadic tolerance ledger, regular readback, and seal handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailMajorant}^{\uparrow}}$ *row.*

The carrier accepts only packets whose regular Cauchy tail estimates are read through a displayed finite majorant threshold for the requested dyadic tolerance before any $\mathsf{Real}^{\uparrow}$ *seal row is consumed.*

Lean4 ✓ `BEDC.Derived.RegularCauchyTailMajorantUp.RegularCauchyTailMajorantTasteGate single carrier alignment`

Theorem 5900.2 (Regular Cauchy tail majorant NameCert obligations)**.** *For the carrier of Definition 5900.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailMajorant}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$J = (S, M, D, R, E, H, C, P, N),$$

schedule exposure through S, majorant-threshold exposure through M, dyadic tolerance readability through D, regular rational readback through R, seal handoff through E, componentwise hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier. The displayed rows $S, M, D, R, E, H, C, P, N$ are the only coordinates of an accepted $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$ packet.

Read the analytic rows in order. The schedule row S names the inspected tail requests, the threshold row M supplies the finite majorant stage for each displayed request, and the dyadic row D supplies the tolerance being tested.

The readback and seal rows are downstream of that finite service. The $\mathsf{RegSeqRat}^{\uparrow}$ row R may be read only after S, M, D have been displayed, and the $\mathsf{Real}^{\uparrow}$ seal row E consumes that readback rather than creating an ambient limit.

Finally H, C, P, N transport, replay, package, and name the same finite route. Since no carrier coordinate stores quotient real equality, a selected limit, countable choice, or completeness, the local NameCert obligations are exactly the displayed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailMajorant}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyTailMajorant}^{\uparrow}}$, seed)

Scope closed: Definition 5900.1 and Definition 5900.2 bind the seed carrier and local NameCert surface for explicit regular Cauchy tail majorants.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyTailMajorant}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completeness of $\mathsf{Real}^{\uparrow}$, selected limits, quotient equality of real names, countable choice, or Lean verification.

Upgrade path: Formalization requires a Lean carrier for the schedule, dyadic tolerance, regular readback, seal handoff, and finite majorant-threshold rows.

Constructive story: A $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$ packet is generated from a finite stream schedule, displayed majorant thresholds, dyadic tolerance rows, regular readback, a seal handoff, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Chapter 5901

A Concrete Naming Certificate for $\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}$

Following Bishop and Bridges on nested interval principles, the $\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}$ packet records the finite Real-facing window by which nested located intervals are inspected before a real-name seal is read. It sits over the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the nested/Cantor neighbours chapter 320 and chapter 4359. The packet names a finite witness route for Real and Completion consumers; it does not claim open-cover compactness, countable choice, quotient reals, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5901.1 (RealCantorIntersectionFiniteWindow carrier)**.** *A* $\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (I, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the nested located-interval row, carrying the visible interval prefix, the containment witness, and the located endpoint tests read from the nested-interval surface.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter ledger, recording the dyadic width bounds and tolerance requests attached to the displayed prefix.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming exactly the interval and endpoint observations inspected by the consumer.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and the diameter ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after I, D, W, R have been displayed.*
6. *H records componentwise* hsame *transport for the nested interval, diameter, window, readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$I, D \longmapsto W \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{CantorIntersectionMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $I, D, W, R, E, H, C, P, N$ and the displayed replay order. It has no coordinate for an infinite intersection selector, quotient real equality, open-cover compactness, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

`single carrier alignment`

Theorem 5901.2 (RealCantorIntersectionFiniteWindow NameCert obligations)**.** *For every accepted* $\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}$ *carrier*

$$Q = (I, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}}$ *surface consists exactly of carrier admission, nested located-interval exposure, dyadic diameter accounting, finite StreamName window exposure, RegSeqRat readback, Real-seal routing, componentwise transport, displayed continuation replay, package provenance, and local naming. Every Real or Completion consumer read of the packet must pass through the finite nested-window route*

$$I, D \longmapsto W \longmapsto R \longmapsto E$$

before the terminal seal is public.

Proof. Project the carrier of Definition 5901.1. The accepted packet exposes exactly the nested interval row I, dyadic diameter ledger D, finite window row W, regular readback row R, Real seal E, and the structural rows H, C, P, N.

The analytic obligations are read by projection through those rows. The nested located-interval row supplies the visible containment prefix and endpoint locatedness, while the dyadic ledger supplies the diameter budget that makes the inspected prefix usable for a Real-facing read.

Next the window and readback rows fix the finite observation route. The StreamName row W names the inspected observations, and the RegSeqRat row R is the only regular rational readback coordinate generated from them.

Finally the seal and structural rows close the packet. The continuation row places E after I, D, W, R, the transport row preserves the same coordinates, and P, N source and name only this local certificate. Since no further coordinate occurs in the carrier, the listed rows exhaust the NameCert obligations and exclude open-cover compactness, countable choice, quotient reals, selected limits, and ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}}$, seed)

Scope closed: Definition 5901.1 and Definition 5901.2 seed the finite Cantor-intersection window route over nested located intervals, dyadic diameter ledgers, StreamName windows, RegSeqRat readback, and the terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, quotient reals, selected infinite intersections, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested located-interval exposure, diameter accounting, finite-window exposure, regular readback, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RealCantorIntersectionFiniteWindowUp.

Constructive story: A $\mathsf{RealCantorIntersectionFiniteWindow}^{\uparrow}$ packet is generated from nested located intervals, a DyadicRatCore diameter ledger, StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ selector chapter is a structural consumer of chapter 381 and chapter 5899 through its finite selected-window route.

Chapter 5902

A Concrete Naming Certificate for $\mathsf{CauchySubsequenceSelector}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy sequences, the $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ packet records the finite selector schedule by which a regular rational Cauchy name may expose a monotone subsequence corridor before a Real or Completion consumer reads the terminal seal. It sits after the regular rational source of chapter 301, the finite window surface of chapter 126, the terminal real-name boundary of chapter 38, and the Cauchy hub of chapter 406. The packet gives diagonal, tail, and completion-facing chapters a named L10 selector object; it is not a quotient of streams, a selected host limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Any subsequence-selector read must display the $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ route of chapter 4080 and the $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ finite-window schedule of chapter 8091 before reaching $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers. The selector is therefore a visible diagonal-and-window corridor, not a detached subsequence choice. The fast selector route of chapter 1518 consumes this schedule when the cofinal subsequence corridor must be made fast enough for $\mathsf{Real}^{\uparrow}$ completion windows, while chapter 5899 consumes compatible selected windows when the subsequence corridor is glued back into a regular Cauchy route.

Definition 5902.1 (Cauchy subsequence selector carrier)**.** *A* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, W, M, G, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose rational reads are being sampled.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the source observations consumed by the selector.*
3. *M is the monotone selector row, recording a finite schedule of indices and the strict order checks between successive selected positions.*
4. *G is the Cauchy-gap ledger, recording the tail comparison requests that make the selected windows compatible with the source Cauchy evidence.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after R, W, M, G have been displayed.*
6. *H records componentwise* hsame *transport for the source, window, monotone selector, Cauchy-gap, seal, replay, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from a subsequence request through R, W, M, G, E, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, W, M, G, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 5902.2 (Cauchy subsequence selector NameCert obligations)**.** *For every accepted* CauchySubsequenceSel *carrier $S = (R, W, M, G, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelector}^{\uparrow}}$ *surface consists exactly of carrier admission, selector monotonicity,* $\mathsf{StreamName}^{\uparrow}$ *window coverage, Cauchy-gap compatibility,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise transport, displayed replay, package provenance, and local naming. Each obligation is read through the finite route*

$$R, W, M, G \longrightarrow E \longrightarrow H, C, P, N.$$

Proof. Carrier admission is projection from Definition 5902.1. The packet first exposes the regular rational source R, the finite observation windows W, the monotone selector schedule M, and the Cauchy-gap ledger G.

Selector monotonicity is local to M. The window coverage obligation then reads W at precisely the positions displayed by M, so every selected index has a finite $\mathsf{StreamName}^{\uparrow}$ observation before any handoff is consumed.

The $\mathsf{RegSeqRat}^{\uparrow}$ handoff is the source row R restricted along the displayed schedule and checked against the Cauchy-gap ledger G. The terminal seal E is downstream of those rows, and it is only a $\mathsf{Real}^{\uparrow}$ seal for the displayed subsequence corridor.

Transport through H, replay through C, provenance P, and local naming N preserve the same route. Since quotient stream equality, selected limits, host real equality, countable choice, trichotomy, and ambient Real completeness are absent from the carrier coordinates, no obligation can discharge outside the displayed finite packet. □

Theorem 5902.3 (Cauchy subsequence selector real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *packet must first read the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the monotone selector schedule, and the Cauchy-gap ledger. The handoff to E therefore supplies a finite subsequence corridor from regular rational data to Real-facing data, not a host subsequence theorem, not a selected limit, and not a quotient construction.*

Proof. Project an accepted carrier $S = (R, W, M, G, E, H, C, P, N)$. The source row R is the only regular rational input, and W is the only finite observation surface available to a consumer.

The selector row M records the monotone schedule. The Cauchy-gap ledger G records the finite tail comparisons that let the scheduled windows be read as a subsequence corridor of the same source.

Only after R, W, M, G are present may the consumer inspect E as a Real-facing seal. The transport, replay, provenance, and naming rows keep that order visible to downstream chapters.

The carrier contains no coordinate for quotient stream equality, a chosen host subsequence, a selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Thus every Real or Completion handoff factors through the displayed selector rows. □

Theorem 5902.4 (Cauchy subsequence selector sibling lattice route)**.** *Every* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *consumer must pass through* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *and* $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ *before the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows are consumed. The selector route therefore reads the diagonal-selection corridor, the regular Cauchy finite-window induction ledger, the source row R, finite windows W, monotone selector schedule M, Cauchy-gap ledger G, seal row E, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelector}^{\uparrow}}$ *row as one sibling lattice. Before any gluing-facing consumer reads* $\mathsf{RegularCauchyGluing}^{\uparrow}$, *the selected finite windows are certified as regular-Cauchy subsequence data through chapter 381; only then can the gluing route consume the selector rows R, W, M, G before the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

The route exports no detached subsequence choice, quotient stream equality, selected limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project an accepted carrier $S = (R, W, M, G, E, H, C, P, N)$ from Definition 5902.1. The source, window, monotone selector, Cauchy-gap, and seal rows are the only analytic rows available to a consumer, while H, C, P, N are the structural rows that transport, replay, source, and name them.

Apply Definition 5902.2. It forces carrier admission, selector monotonicity, window coverage, Cauchy-gap compatibility, regular-rational handoff, seal non-escape, transport, replay, provenance, and local naming before any consumer can read the selector.

Apply Definition 5902.3. The $\mathsf{Real}^{\uparrow}$ or Completion-facing read reaches E only after R, W, M, G have been displayed, so the diagonal-selection corridor and regular Cauchy window-induction ledger must be upstream of the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows named in the introduction; the same displayed windows are first certified by chapter 381 before $\mathsf{RegularCauchyGluing}^{\uparrow}$ can consume them.

Since the carrier has no coordinate for detached subsequence choice, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, the sibling lattice cannot export any of those principles. □

Theorem 5902.5 (Cauchy subsequence selector diagonal-window readiness)**.** *Every fast-selector or gluing-facing consumer of a* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *packet must expose the* $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ *route and the* $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ *finite schedule before it consumes the selector rows $R, W, M, G, E, H, C, P, N$. In particular, a* $\mathsf{FastCauchySubsequence}^{\uparrow}$ *consumer cannot read the fast cofinal corridor, and a* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *consumer cannot read compatible selected windows, until the diagonal route and finite-window schedule have already displayed the source row, finite windows, monotone selector row, Cauchy-gap ledger, terminal seal, transport, replay, provenance, and local naming rows.*

Proof. Apply Definition 5902.2. It makes $R, W, M, G, E, H, C, P, N$ the full NameCert surface for an accepted selector packet, so a downstream consumer has no row outside that finite display from which to read subsequence data.

Apply Definition 5902.3. The Real or Completion-facing handoff reaches E only after the regular rational source, finite windows, selector schedule, and Cauchy-gap ledger have been displayed.

Now apply Definition 5902.4. It places the $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ corridor and the $\mathsf{RegularCauchyWindowIndu}$ schedule before the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, terminal $\mathsf{Real}^{\uparrow}$, and gluing-facing rows are consumed. Therefore both the fast-selector route and the gluing route must expose the diagonal-window readiness surface before reading $R, W, M, G, E, H, C, P, N$. □

Theorem 5902.6 (Cauchy subsequence selector regular-window handoff)**.** *Every* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *handoff that is later glued or sealed through* $\mathsf{Real}^{\uparrow}$ *first consumes* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *as the finite-window certificate that the selected rows remain regular-Cauchy subsequence data. Thus the selected windows* W *and monotone schedule* M *are certified through chapter 381 before any* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *or terminal* $\mathsf{Real}^{\uparrow}$ *consumer reads* R, W, M, G, E.

Proof. Project the accepted carrier $S = (R, W, M, G, E, H, C, P, N)$. The selected windows W and monotone schedule M are the only rows that can present subsequence data to a downstream consumer.

Use the sibling lattice route of Definition 5902.4. It places the diagonal-selection corridor and regular Cauchy window-induction ledger before the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are consumed.

The regular-window handoff is therefore a finite certification step: W and M are read as regular-Cauchy subsequence data before gluing or sealing can consume R, W, M, G, E. The route has no coordinate for a detached subsequence choice, selected host limit, or ambient completeness principle. □

Theorem 5902.7 (Cauchy subsequence selector forward density route)**.** *Every* $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ *or density-facing completion consumer that reads selected Cauchy subsequence windows from an accepted* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *packet must first pass through* $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal route displayed by the selector. The forward density read therefore consumes the selector rows* $R, W, M, G, E, H, C, P, N$ *as finite regular-Cauchy subsequence data, not as a separate host subsequence, a choice-selected limit, or an ambient completeness principle.*

Proof. Apply the Real handoff theorem, Definition 5902.3. It forces every Real or Completion-facing read through the regular rational source row R, finite windows W, monotone selector schedule M, Cauchy-gap ledger G, and terminal seal row E.

Use the sibling lattice route of Definition 5902.4 together with the regular-window handoff of Definition 5902.6. These place $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{RegularCauchySubsequence}^{\uparrow}$ before any downstream gluing, sealing, or density-facing consumer reads the selected windows.

Thus a $\mathsf{RegularCauchyDenseEmbedding}^{\uparrow}$ consumer receives only the displayed finite selector corridor. Since the carrier has no coordinate for a detached host subsequence, selected limit, quotient stream equality, or ambient completeness, the forward density route cannot bypass the existing selector handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ packet is generated from a RegSeqRat source row, finite StreamName windows, monotone selector schedule, Cauchy-gap ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5902.1, Definition 5902.2, and Definition 5902.3 seed the finite selector corridor from regular rational Cauchy data to a Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, selector monotonicity, StreamName window coverage, Cauchy-gap compatibility, RegSeqRat handoff, Real seal non-escape, transport, replay, provenance, and local naming.

The fast selector route of chapter 1518 consumes the $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ monotone schedule when the subsequence corridor must be made fast enough for $\mathsf{Real}^{\uparrow}$ completion windows. The $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ route is consumed by chapter 1518 when a cofinal fast subsequence schedule must be displayed before a completion-facing read, and by chapter 5899 when selected finite windows are glued back into a regular Cauchy route. Thus the selector sits in the L10 dependency lattice between finite StreamName windows, regular rational source rows, fast subsequence scheduling, and regular Cauchy gluing, rather than floating as a kernel-only carrier.

Theorem 5902.8 (CauchySubsequenceSelector regular Cauchy gluing forward route)**.** *Every* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *packet must first read the source regular-rational row R, the selected finite windows W, the monotone selector schedule M, and the Cauchy-gap ledger G before gluing compatible selected windows back into a regular Cauchy route. The handoff to chapter 5899 therefore remains a displayed finite-window route rather than a selected representative, quotient stream equality, countable-choice schedule, or ambient Real-completeness principle.*

Proof. Project the selector carrier described in chapter 5902. Its gluing-facing data are the source row R, finite selected windows W, monotone selector schedule M, and Cauchy-gap ledger G.

Only after those rows are visible can a gluing consumer inspect compatible windows. The $\mathsf{RegularCauchyGluing}^{\uparrow}$ route then supplies its own regular-Cauchy compatibility and terminal Real-seal boundary, so the selector packet is a forward dependency of gluing rather than a replacement for the gluing certificate.

Since neither the selector rows nor the gluing route contain quotient stream equality, selected representatives, countable choice, or ambient Real completeness, the composed route exports only the finite selected-window data and the downstream regular Cauchy gluing surface. □

Theorem 5902.9 (Cauchy subsequence selector finite-window forward link)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *read factors through the finite-window route*

$$\mathsf{FiniteStream}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{CauchyDiagonalSelection}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

before the terminal seal is available. The consumer therefore reads the selector carrier rows as displayed finite windows and diagonal-selection data, not as a quotient subsequence, selected limit, countable-choice schedule, host real equality, or ambient completeness principle.

Proof. Project the selector carrier from Definition 5902.1. Its source row, finite windows, monotone schedule, Cauchy-gap ledger, real seal, transport, replay, provenance, and local naming rows are the only coordinates available to a downstream read.

Use the real handoff of Definition 5902.3. It forces every seal consumer to pass through the regular rational source row, the $\mathsf{StreamName}^{\uparrow}$ finite windows, the selector schedule, and the Cauchy-gap ledger before reading the terminal $\mathsf{Real}^{\uparrow}$ row.

Now read the sibling lattice route of Definition 5902.4. The lattice places the selector between $\mathsf{CauchyDiagonalSelection}^{\uparrow}$, $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$, finite window data, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally identify the forward consumer rows: $\mathsf{FiniteStream}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ provide the finite observations, $\mathsf{CauchyDiagonalSelection}^{\uparrow}$ supplies the displayed diagonal corridor, $\mathsf{RegSeqRat}^{\uparrow}$ reads the regular rational name, and $\mathsf{DyadicRatCore}^{\uparrow}$ records the tolerance row before the terminal seal. Since all of these rows are explicit carrier-local reads, no refused quotient, choice, selected-limit, host-equality, or ambient-completeness endpoint can enter the route. □

The selector packet also consumes the regular-Cauchy subsequence surface of chapter 381. Its monotone selector row, finite windows, and Cauchy-gap ledger are read as a route inside the same regular-Cauchy finite-window surface before the terminal $\mathsf{Real}^{\uparrow}$ seal is available. Thus a downstream completion consumer sees the selected subsequence as displayed regular-Cauchy data, not as a detached host subsequence or a separate choice principle. The selector dependency route is consumed by both the fast subsequence handoff of chapter 1518 and the regular-Cauchy gluing route of chapter 301. Thus a downstream Cauchy consumer reads the same displayed selector schedule, finite windows, and gap ledger before treating the selected route as fast enough for completion-facing readback.

Theorem 5902.10 (Cauchy subsequence selector orphan lattice route)**.** *Every selector read consumed by* $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ *must preserve the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ *witness row, and the* $\mathsf{Real}^{\uparrow}$ *terminal seal before any subsequence extraction is public. Thus the extractor-facing selector route is the finite lattice*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegularCauchyMinModulus}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

inside the accepted $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *packet, not a detached subsequence choice or quotient stream selection.*

Proof. Project the selector carrier of Definition 5902.1. The available selector rows are the source row R, finite windows W, monotone selector schedule M, Cauchy-gap ledger G, terminal seal E, transport, replay, provenance, and local naming.

Use the selector dependency route and the cofinal subsequence dependency route. They force every extractor-facing read to pass through the displayed selector schedule before the extraction row can be consumed as finite subsequence data.

Finally read the regular-Cauchy minimum-modulus forward link. It keeps the $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ witness visible alongside the $\mathsf{RegSeqRat}^{\uparrow}$ source row and $\mathsf{StreamName}^{\uparrow}$ finite windows before the terminal $\mathsf{Real}^{\uparrow}$ seal is public. Hence the selector exports only the stated finite lattice to the extractor and no separate host-side subsequence selection. □

Chapter 5903

A Concrete Naming Certificate for RiemannIntegrationCompletion$^{\uparrow}$

Following Riemann and Bishop–Bridges constructive integration, the RiemannIntegrationCompletion$^{\uparrow}$ packet records the finite Cauchy-sum completion data visible when an integration consumer treats Riemann sums as a regular real-valued completion route. It sits after the integrability witness of chapter 1960, the tagged-sum gauge surface of chapter 4115, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names the boundary object that completion-facing integration consumers can inspect without importing host function quotients, selected refining partitions, measure completion, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 5903.1 (Riemann integration completion carrier)**.** *A* RiemannIntegrationCompletion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, G, S, Q, R, E, H, C, P, N)$$

with the following rows.

- *I is the* RiemannIntegrable$^{\uparrow}$ *row displaying finite Darboux-gap or integrability evidence for the inspected integrand and interval.*
- *G is the* RiemannSumGauge$^{\uparrow}$ *row carrying tagged partitions, gauge windows, mesh control, and finite sum observations.*
- *S is the finite Cauchy-sum schedule row: it records only displayed pairs of gauge windows and their rational comparison tolerances.*
- *Q is the dyadic or rational comparison row used to compare two displayed Cauchy-sum observations at a stated tolerance.*
- *R is the* RegSeqRat$^{\uparrow}$ *readback row reached from the finite Cauchy-sum schedule and comparison rows.*
- *E is the terminal* Real$^{\uparrow}$ *seal row for the completed integration value read.*
- *H is componentwise* hsame *transport for I, G, S, Q, R, E.*
- *C is displayed* Cont *replay of the same finite route.*
- *P is* Pkg *provenance over* RiemannIntegrationCompletion$^{\uparrow}$, RiemannIntegrable$^{\uparrow}$, RiemannSumGauge$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

- *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegrationCompletion}^{\uparrow}}$ *row.*

The carrier predicate asserts that these rows form one displayed finite Cauchy-sum completion history. It has no coordinate for a host function quotient, a selected refining sequence of partitions, a completed measure object, countable choice, or an ambient real-completeness principle.

Lean4 ✓ `BEDC.Derived.RiemannIntegrationCompletionUp.RiemannIntegrationCompletionTasteGate`
`single carrier alignment`

Theorem 5903.2 (Riemann integration completion NameCert obligations)**.** *For every accepted* $\mathsf{RiemannIntegrationCompletion}^{\uparrow}$ *carrier* $K = (I, G, S, Q, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegrationCompletio}}$ *surface consists exactly of carrier admission, integrability-source exposure through I, tagged-sum gauge exposure through G, finite Cauchy-sum schedule exposure through S, tolerance comparison through Q, regular rational readback through R, terminal Real seal non-escape through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5903.1. The only integration rows available to the certificate are I and G, and the only completion-facing rows are the finite schedule S, comparison row Q, regular rational readback R, and Real seal E.

The source rows are already named by chapter 1960 and chapter 4115. Their use here is by displayed BHist rows, not by a host-level function space or by quotient equality between integrands.

The completion side is constrained by the regular rational and Real boundaries of chapter 301 and chapter 38. Therefore the local certificate can expose only $I, G, S, Q, R, E, H, C, P, N$, with H, C, P, N supplying transport, replay, provenance, and naming for the same finite route. □

Theorem 5903.3 (Riemann integration completion Cauchy-sum handoff)**.** *Every completion-facing read of an accepted* $\mathsf{RiemannIntegrationCompletion}^{\uparrow}$ *packet must pass from the* $\mathsf{RiemannIntegrable}^{\uparrow}$ *source row I through the* $\mathsf{RiemannSumGauge}^{\uparrow}$ *row G, finite Cauchy-sum schedule S, tolerance comparison row Q, and* $\mathsf{RegSeqRat}^{\uparrow}$ *row R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is read. The handoff exports finite Cauchy-sum comparison data only; it exports no selected sequence of tagged partitions, quotient integrand equality, measure completion, or countable-choice selector.*

Proof. Start with the source rows. The integrability row I supplies the displayed finite evidence that a Riemann integration route is being named, while G supplies the finite tagged-gauge and sum observations available to downstream consumers.

The Cauchy-sum schedule S can only compare displayed observations through Q. Once a comparison has been displayed at a stated tolerance, the regular rational handoff R packages the finite Cauchy behavior as a $\mathsf{RegSeqRat}^{\uparrow}$-facing read.

Finally the terminal seal E is read only after R. The excluded selected partition sequence, quotient integrand equality, measure completion, and countable-choice selector have no coordinate in K, so no completion-facing read can bypass the route I, G, S, Q, R, E. □

Theorem 5903.4 (Riemann integration completion Real seal non-escape)**.** *For every accepted* $\mathsf{RiemannIntegrationCompletion}^{\uparrow}$ *packet, any* $\mathsf{Real}^{\uparrow}$*-facing integration value read is sealed by the displayed finite Cauchy-sum route $I, G, S, Q, R, E, H, C, P, N$. The Real seal cannot be used as a detached integral value, an ambient completeness witness, a host-level equality of integrands, or a measure-theoretic completion object.*

Proof. Apply Definition 5903.3. It places the terminal Real read after the integrability source, tagged-sum gauge surface, finite Cauchy-sum schedule, tolerance comparison, and regular rational readback.

Use Definition 5903.2 for the structural rows. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row all replay the same finite route and add no detached Real coordinate.

Thus the seal E remains a terminal observation of the finite Cauchy-sum packet. A consumer may inspect the displayed integration completion route, but cannot extract host equality, selected representatives, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness from this chapter. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannIntegrationCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannIntegrationCompletion}^{\uparrow}$ packet is generated from a $\mathsf{RiemannIntegrable}^{\uparrow}$ source row, a $\mathsf{RiemannSumGauge}^{\uparrow}$ tagged-sum gauge row, a finite Cauchy-sum schedule row, a dyadic or rational comparison row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannIntegrationCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5903.1, Definition 5903.2, Definition 5903.3, and Definition 5903.4 seed the finite Cauchy-sum completion boundary over $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{RiemannSumGauge}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannIntegrationCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected refining partitions, quotient integrand equality, measure completion, countable choice, ambient Real completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite Cauchy-sum comparison, regular rational handoff, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.RiemannIntegrationCompletionUp.

Chapter 5904

A Concrete Naming Certificate for $\mathsf{CauchySchwarzCompletion}^{\uparrow}$

Following Riesz and Bishop–Bridges constructive analysis, the $\mathsf{CauchySchwarzCompletion}^{\uparrow}$ packet records the finite completion-stable route by which a Cauchy–Schwarz estimate is carried from displayed real-vector inequality data into Cauchy-window and complete-metric handoff rows. It sits after the finite inequality certificate of chapter 1684, the Cauchy-window surface of chapter 406, the complete-metric boundary of chapter 128, and the terminal real-name seal of chapter 38. The packet names only the displayed finite route through regular rational readback, stream schedules, completion handoff, transport, replay, provenance, and local naming; it does not import a host Hilbert completion, quotient stream equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5904.1 (Cauchy–Schwarz completion carrier)**.** *A* $\mathsf{CauchySchwarzCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, W, M, Q, S, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{CauchySchwarzReal}^{\uparrow}$ *inequality row, including the displayed finite-vector source, inner-product read, norm-square rows, and dyadic square comparison already sealed for real-analysis consumers.*
2. *W is the* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *Cauchy-window row, carrying the common finite windows through which the inequality row is inspected as a completion-facing sequence of estimates.*
3. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff row, recording the displayed completeness request and the finite nonescape boundary for the estimate route.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from the Cauchy-window observations and the dyadic tolerance comparisons attached to R.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row that exposes the finite observation windows shared by R, W, Q, and M.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the estimate value after the Cauchy-window and complete-metric handoff rows have been displayed.*
7. *H records componentwise* hsame *transport for $R, W, M, Q, S, E, C, P, N$.*

8. *C records displayed* Cont *replay from the finite Cauchy–Schwarz inequality row through the Cauchy-window, regular-readback, stream-schedule, complete-metric, and Real-seal rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchySchwarzCompletion}^{\uparrow}$, $\mathsf{CauchySchwarzReal}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySchwarzCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for host Hilbert completion, quotient equality of Cauchy names, selected completed representatives, countable choice, detached real limits, or ambient completeness.

Theorem 5904.2 (Cauchy–Schwarz completion NameCert obligations)**.** *For every accepted* CauchySchwarzComple *carrier $K = (R, W, M, Q, S, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySchwarzCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, Cauchy–Schwarz real-inequality exposure through R, Cauchy-window exposure through W, complete-metric handoff exposure through M, regular rational readback through Q, shared stream scheduling through S, terminal Real seal non-escape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6898.1. The only inequality source is the displayed $\mathsf{CauchySchwarzReal}^{\uparrow}$ row R, whose finite vector, inner-product, norm-square, and dyadic square-comparison data are already part of the accepted packet.

The completion-facing route is then forced by W, M, Q, S, E. The Cauchy-window row W exposes the common finite windows, the complete-metric row M records the displayed handoff request, the regular rational row Q reads the finite observations, the stream row S schedules those observations, and the terminal Real row E seals the same route.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no row for host Hilbert completion, quotient Cauchy-name equality, selected completed representatives, countable choice, detached real limits, or ambient completeness, the listed rows exhaust the local NameCert obligation surface. □

Theorem 5904.3 (Cauchy–Schwarz completion limit handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchySchwarzCompletion}^{\uparrow}$ *packet must first read the finite route*

$$\mathsf{CauchySchwarzReal}^{\uparrow}, \mathsf{CauchySequenceSpace}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow} \longmapsto R, W, M, Q, S, E, H, C, P, N.$$

In particular, the Cauchy–Schwarz estimate is available at a completion boundary only after the Cauchy-window row, complete-metric handoff row, regular rational readback, stream schedule, terminal Real seal, transport, replay, provenance, and local naming rows have all been displayed.

Proof. Start from an accepted packet $K = (R, W, M, Q, S, E, H, C, P, N)$. The estimate source is R, so every inequality read already factors through the finite real-vector and dyadic comparison rows named by chapter 1684.

The estimate can then enter completion only through the visible Cauchy-window route. The row W supplies the inspected Cauchy windows, S schedules the finite observations, and Q records the regular rational readback attached to those windows.

The handoff row M is the only complete-metric coordinate, and the Real seal E is downstream of R, W, M, Q, S. Thus a consumer cannot read a completion-stable estimate without first displaying the Cauchy-window, complete-metric, readback, schedule, and seal rows.

Finally, H, C, P, N keep the handoff attached to the same packet by transport, replay, provenance, and local naming. The route exports a finite completion-stable estimate boundary, not a

host Hilbert completion, quotient stream equality, selected limit, countable choice principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Falsifiable prediction: An accepted $\mathsf{CauchySchwarzCompletion}^{\uparrow}$ read is refuted if a completion-facing consumer obtains the estimate boundary without first displaying the CauchySchwarzRealUp inequality row, CauchySequenceSpaceUp window row, CompleteMetricUp handoff row, RegSeqRatUp readback, StreamNameUp schedule, RealUp seal, transport, replay, provenance, and local NameCert rows.

Independence witness: cauchy-schwarz-real, cauchysequence-space, completemetric, regseqrat, streamname, real: $\mathsf{CauchySchwarzCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an inequality row, Cauchy-window row, complete-metric handoff row, regular readback, stream schedule, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySchwarzCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySchwarzCompletion}^{\uparrow}$ packet is generated from a CauchySchwarzRealUp inequality row, CauchySequenceSpaceUp windows, a CompleteMetricUp handoff row, RegSeqRatUp readback, StreamNameUp schedules, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySchwarzCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6898.1, Definition 6898.2, and Definition 6898.3 seed the finite completion-stable Cauchy–Schwarz estimate route over displayed Cauchy windows and complete-metric handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySchwarzCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Hilbert completion, quotient equality of Cauchy names, selected completed representatives, countable choice, detached real limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy–Schwarz inequality exposure, Cauchy-window exposure, complete-metric handoff, regular rational readback, stream scheduling, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchySchwarzCompletionUp.

Chapter 5905

A Concrete Naming Certificate for $\mathsf{DCPO}^{\uparrow}$

Following Scott domain theory and standard order theory, the $\mathsf{DCPO}^{\uparrow}$ packet records the directed-complete partial-order surface as finite BEDC naming data. It sits after the directed-index substrate of chapter 1607, the separated order surface of chapter 53, the Moore–Smith net route of chapter 3403, the directed-filter corridor of chapter 3898, and the Cauchy-net completion boundary of chapter 589. It is also the order-theoretic neighbour of the displayed directed-supremum packet in chapter 4164. The packet names finite directed-supremum evidence for completion routes; it is not a host powerset lattice, not a quotient order, not a selected lub operator, and not an ambient completeness theorem.

Definition 5905.1 (DCPO carrier)**.** *A* $\mathsf{DCPO}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (O, I, W, S, M, F, Q, L, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Poset}^{\uparrow}$ *order row, exposing the displayed comparison relation and the antisymmetry witness accepted by the packet.*
2. *I is the* $\mathsf{DirectedSet}^{\uparrow}$ *index row for a directed family whose inspected addresses are available to completion consumers.*
3. *W is the finite directed-window row, listing the displayed subfamilies of the directed diagram that a consumer may request.*
4. *S is the supremum row, recording the displayed least-upper-bound read attached to the directed windows in W.*
5. *M is the* $\mathsf{MooreSmithNet}^{\uparrow}$ *handoff row, reading the same directed family as a finite net route before any convergence or completion consumer is reached.*
6. *F is the* $\mathsf{DirectedFilter}^{\uparrow}$ *handoff row, translating the same directed-tail ledger into a filter-base corridor.*
7. *Q is the* $\mathsf{CauchyNet}^{\uparrow}$ *and completion-facing row, available only after O, I, W, S, M, F have been displayed.*
8. *L is the lower-bound exactness row, recording that a candidate receiving every displayed upper-bound comparison from S is already above the named supremum by the order row O.*

9. *H records componentwise* hsame *transport for the order, directed-family, supremum, handoff, exactness, replay, provenance, and naming rows.*
10. *C records displayed* Cont *replay from a directed-supremum request through $O, I, W, S, M, F, Q, L, H$.*
11. *P is the* Pkg *provenance over* $\mathsf{DCPO}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{DirectedFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{ScottDomain}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DCPO}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, I, W, S, M, F, Q, L, H, C, P, N$. It has no coordinate for arbitrary joins, quotient-order equality, selected least-upper-bound functions, global choice over directed families, host powersets, or ambient order completeness.

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoCarrier field projection round trip`

Theorem 5905.2 (DCPO NameCert obligations)**.** *For every accepted* $\mathsf{DCPO}^{\uparrow}$ *carrier $D = (O, I, W, S, M, F, Q, L,$ the local* $\mathsf{NameCert}_{\mathsf{DCPO}^{\uparrow}}$ *surface consists exactly of order admission, directed-index admission, finite directed-window coverage, directed-supremum readability, Moore–Smith net handoff, directed-filter handoff, CauchyNet and completion-facing handoff, lower-bound exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every directed-supremum consumer must read the rows O, I, W, S, L before treating the supremum as public, and no obligation is stored outside $O, I, W, S, M, F, Q, L, H, C, P, N$.*

Proof. Project the carrier of Definition 5905.1. The order and directed-family rows are O, I, W, S, L, while the completion-facing handoff rows are M, F, Q and the structural rows are H, C, P, N.

Order admission is read from O. Directed-index admission and window coverage are read from I and W, so a consumer cannot ask for a directed supremum before the inspected directed family has been displayed.

The supremum row S supplies the named upper-bound endpoint, and the exactness row L records the leastness comparison back through the same order row O. Thus a lower-bound or completion consumer receives a displayed directed-supremum certificate rather than a host lub selector.

The sibling rows M, F, Q expose the same directed family to Moore–Smith nets, directed filters, and Cauchy-net completion routes. Transport and replay through H and C preserve the displayed rows, while P, N source and name the same finite carrier. Since none of the excluded host objects appears as a coordinate, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoCarrier local namecert surface`

Theorem 5905.3 (DCPO directed-supremum handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{DCPO}^{\uparrow}$ *carrier must factor its directed-supremum read through*

$$\mathsf{Poset}^{\uparrow}, \mathsf{DirectedSet}^{\uparrow}, W, S, L \longmapsto \mathsf{MooreSmithNet}^{\uparrow}, \mathsf{DirectedFilter}^{\uparrow}, \mathsf{CauchyNet}^{\uparrow} \longmapsto H, C, P, N.$$

The route exposes the order row, the directed index row, finite directed windows, the named supremum, and lower-bound exactness before any Moore–Smith net, directed-filter, or CauchyNet consumer is read. It does not export arbitrary joins, quotient-order equality, global directed-choice data, host powersets, or ambient completeness.

Proof. Begin with an accepted carrier $D = (O, I, W, S, M, F, Q, L, H, C, P, N)$. The directed-supremum data are not supplied by an external order-completion object; the only available order and directed-family evidence is the displayed row family O, I, W, S, L.

The Moore–Smith route M and directed-filter route F are downstream of those rows. Each therefore receives the same finite directed-tail ledger and cannot replace it by a selected cofinal net, quotient filter, or host-level directed diagram.

The CauchyNet and completion-facing row Q is downstream of M and F. It may consume the directed-supremum handoff, but it cannot read an ambient completion witness before the finite order, directed-window, supremum, and leastness rows have been displayed.

Finally, componentwise transport and continuation replay through H and C preserve this row order, and P, N record provenance and local naming for the same packet. Since arbitrary joins, quotient equality, directed-choice data, host powersets, and ambient completeness are absent from the carrier, every public completion read remains inside the displayed handoff. □

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoCarrier directed supremum handoff`

Theorem 5905.4 (DCPO Scott-domain compatibility)**.** *The* $\mathsf{ScottDomain}^{\uparrow}$ *consumer of an accepted* $\mathsf{DCPO}^{\uparrow}$ *carrier reads only the displayed directed-supremum route* O, I, W, S, L *and the structural rows* H, C, P, N*. Compact-basis, Scott-open, and represented-space observations may be attached downstream by chapter 4164, but the* $\mathsf{DCPO}^{\uparrow}$ *packet itself exports only the directed-complete order substrate.*

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoScottDomainCompatibility`

Proof. Apply Definition 5905.2. The DCPO obligation surface exposes the order row, directed-index row, directed windows, supremum row, and lower-bound exactness row before any sibling consumer is reached.

The Scott-domain packet of chapter 4164 adds basis, Scott-open, and represented-space rows on top of a displayed directed-supremum route. When it consumes a $\mathsf{DCPO}^{\uparrow}$ carrier, those rows can only be attached after O, I, W, S, L have been read.

Apply Definition 5905.3. Transport, replay, provenance, and local naming remain componentwise, so the Scott-facing route cannot turn the DCPO packet into a host domain, quotient order, selected basis enumeration, or ambient semantic-completeness claim. □

Theorem 5905.5 (DCPO carrier directed obligations)**.** *For every accepted* $\mathsf{DCPO}^{\uparrow}$ *carrier*

$$D = (O, I, W, S, M, F, Q, L, H, C, P, N),$$

the carrier-admission and directed-window obligations are exactly the displayed rows O, I, W*. A directed-supremum consumer must first read the* $\mathsf{Poset}^{\uparrow}$ *order row* O*, the* $\mathsf{DirectedSet}^{\uparrow}$ *index row* I*, and the finite directed-window row* W *before any supremum, net, filter, or completion-facing row is public.*

Proof. Project the carrier of Definition 5905.1. The row O is the only order-admission coordinate, and the row I is the only directed-index coordinate.

The finite windows are stored in W. Since the carrier has no coordinate for a host directed family, global choice over indices, quotient-order equality, or ambient powerset lattice, a consumer cannot bypass I and W when asking for directed coverage.

The later rows $S, M, F, Q, L, H, C, P, N$ are therefore downstream of O, I, W. They may consume the directed-window surface, but they cannot supply carrier admission or directed-window coverage in place of those rows. □

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoCarrier carrier directed obligations`

Theorem 5905.6 (DCPO supremum ledger obligations)**.** *For every accepted* $\mathsf{DCPO}^{\uparrow}$ *carrier*

$$D = (O, I, W, S, M, F, Q, L, H, C, P, N),$$

the public supremum ledger is the row pair S, L *read over the order and directed-window rows* O, I, W*. The row* S *supplies the named directed-supremum read, and* L *supplies lower-bound exactness for every displayed upper-bound comparison exposed through* O*.*

Proof. Begin with the directed rows O, I, W from Definition 5905.5. These rows determine which order and directed-window data are visible to the supremum reader.

Read S next. It records the named supremum endpoint attached to the displayed directed windows, so the supremum is public only as a row of the finite carrier.

Finally read L. This lower-bound exactness row sends every displayed upper-bound comparison back through O, forcing leastness to remain an order-row obligation rather than a selected least-upper-bound operator or an ambient completeness theorem. □

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoCarrier supremum ledger obligations`

Theorem 5905.7 (DCPO continuity scope obligations)**.** *For every accepted* $\mathsf{DCPO}^{\uparrow}$ *carrier*

$$D = (O, I, W, S, M, F, Q, L, H, C, P, N),$$

the Moore–Smith, directed-filter, and CauchyNet consumers can read the directed-complete order surface only through the finite handoff route

$$O, I, W, S, L \longmapsto M, F, Q \longmapsto H, C, P, N.$$

The rows H, C, P, N *preserve componentwise transport, displayed replay, provenance, and local naming for this route; they do not add ambient continuity, host completion, arbitrary joins, or selected suprema.*

Proof. First read the directed-supremum ledger of Definition 5905.6. It exposes the order row, directed-index row, finite windows, named supremum, and lower-bound exactness as the only public directed-complete substrate.

Next pass to M, F, Q. The Moore–Smith row, directed-filter row, and CauchyNet row consume that substrate in sequence; none of them can introduce a new directed family, quotient equality, host powerset, arbitrary join operation, or ambient completion witness.

Finally use H, C, P, N. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{DCPO}^{\uparrow}}$ row preserve the same finite route, so the continuity-facing scope remains exactly the displayed carrier route. □

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoCarrier continuity scope obligations`

Theorem 5905.8 (DCPO directed-window coverage)**.** *For every accepted* $\mathsf{DCPO}^{\uparrow}$ *carrier*

$$D = (O, I, W, S, M, F, Q, L, H, C, P, N),$$

the finite directed-window row W *is the only coverage surface available to a directed-supremum consumer. A consumer must read* O, I, W *before reading* S, L *and before using the handoff of Definition 5905.3; no arbitrary join family, host powerset of directed subsets, global choice over indices, quotient-order equality, selected least-upper-bound function, or ambient completeness coordinate is exported.*

Proof. Project the carrier of Definition 5905.1. The rows O and I expose the order and directed-index data, while W is the finite window row attached to those data.

Apply Definition 5905.3. Its displayed route places O, I, W before S, L and before the Moore–Smith, directed-filter, and CauchyNet rows M, F, Q.

The remaining rows H, C, P, N only transport, replay, source, and name that same carrier. Since the carrier has no coordinate for arbitrary joins, host powersets, quotient-order equality, global directed choice, selected lub functions, or ambient completeness, directed-window coverage is exactly the displayed row W over O, I. □

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoCarrier directed window coverage`

Theorem 5905.9 (DCPO lower-bound exactness)**.** *For every accepted* $\mathsf{DCPO}^{\uparrow}$ *carrier*

$$D = (O, I, W, S, M, F, Q, L, H, C, P, N),$$

the lower-bound exactness row L is read only after the order row O, directed-index row I, finite-window row W, and supremum row S have been displayed. It records leastness through the same order row used by Definition 5905.3, and it does not introduce arbitrary joins, quotient-order equality, selected lub functions, global choice, host powersets, or ambient completeness.

Proof. Begin with the public supremum ledger of Definition 5905.6. It identifies S, L as the supremum and lower-bound exactness rows read over O, I, W.

The exactness row L therefore cannot be detached from the displayed order row. It sends lower-bound comparisons back through O after the directed windows in W and the named supremum in S have been exposed.

Apply Definition 5905.3. The downstream rows M, F, Q, H, C, P, N consume this exactness route; they do not supply a selected least-upper-bound function, quotient-order equality, arbitrary join operation, global choice schedule, host powerset, or ambient completeness theorem. □

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoCarrier lower bound exactness`

Theorem 5905.10 (DCPO completion-facing handoff)**.** *For every accepted* $\mathsf{DCPO}^{\uparrow}$ *carrier*

$$D = (O, I, W, S, M, F, Q, L, H, C, P, N),$$

the completion-facing route is exactly the finite handoff

$$O, I, W, S, L \longmapsto M, F, Q \longmapsto H, C, P, N.$$

The CauchyNet row Q is public only after the Moore–Smith row M and directed-filter row F have consumed the displayed directed-window and lower-bound exactness rows named in Definition 5905.3. The route exports no arbitrary joins, quotient-order equality, selected lub functions, global choice, host powersets, or ambient completeness.

Proof. Read O, I, W, S, L first. By Definition 5905.8 and Definition 5905.9, these rows provide the order, directed index, finite windows, named supremum, and leastness comparisons.

Apply Definition 5905.3. The Moore–Smith row M, directed-filter row F, and CauchyNet row Q are downstream consumers of that displayed directed-complete order surface.

Finally inspect H, C, P, N. Componentwise transport, displayed replay, provenance, and local naming preserve the same route and cannot add arbitrary joins, quotient-order equality, selected lub functions, global choice, host powersets, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoCarrier completion facing handoff`

Theorem 5905.11 (DCPO directed-supremum scope)**.** *For every accepted* $\mathsf{DCPO}^{\uparrow}$ *carrier*

$$D = (O, I, W, S, M, F, Q, L, H, C, P, N),$$

every scoped directed-supremum read factors through the route

$$O, I, W, S, L \longmapsto M, F, Q \longmapsto H, C, P, N.$$

The read first exposes the $\mathsf{Poset}^{\uparrow}$ *order row,* $\mathsf{DirectedSet}^{\uparrow}$ *index row, finite directed-window row, named supremum row, and lower-bound exactness row; only then may it reach the Moore–Smith, directed-filter, and CauchyNet handoff rows, followed by componentwise transport, displayed replay, provenance, and local naming. The scope exports no arbitrary joins, quotient equality, host powersets, selected lub operator, global directed choice, or ambient completeness.*

Proof. Project the carrier of Definition 5905.1. The only rows available to a directed-supremum reader before handoff are O, I, W, S, L.

Apply Definition 5905.8 and Definition 5905.9. The first theorem forces every directed read to pass through the finite window row W over O, I, and the second attaches leastness to S, L over the same order row.

Finally apply Definition 5905.10. It places M, F, Q after the displayed directed-supremum route and leaves H, C, P, N as transport, replay, provenance, and naming rows. Since the carrier has no coordinate for arbitrary joins, quotient equality, host powersets, selected lubs, global directed choice, or ambient completeness, the displayed route is the whole scoped directed-supremum surface. □

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoCarrier directed supremum scope`

Theorem 5905.12 (DCPO obligation-closure package)**.** *For every accepted* $\mathsf{DCPO}^{\uparrow}$ *carrier*

$$D = (O, I, W, S, M, F, Q, L, H, C, P, N),$$

the directed-window coverage, supremum ledger, continuity scope, and completion-facing handoff obligations jointly exhaust the obligation *surface over* $\mathsf{Poset}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{DirectedFilter}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *The package consists exactly of the order row O, directed-index row I, finite directed-window row W, supremum row S, lower-bound exactness row L, Moore–Smith handoff M, directed-filter handoff F, CauchyNet handoff Q, transport row H, replay row C, provenance row P, and local naming row N; it exports no selected lub operator, host powerset, quotient order, global directed-choice schedule, or ambient completeness claim.*

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoCarrier obligation closure package`

Proof. Start with carrier admission and directed coverage. Theorems 5905.5 and 5905.8 identify O, I, W as the whole order, directed-index, and finite directed-window surface available before any supremum consumer is public.

Next read the supremum ledger. Theorems 5905.6 and 5905.9 place S and L over the same O, I, W rows, so leastness remains a displayed order-row obligation rather than a selected least-upper-bound function or an ambient completeness theorem.

Now pass to the continuity and completion rows. The continuity scope theorem Definition 5905.7 and the completion-facing handoff theorem Definition 5905.10 force M, F, Q to consume the route O, I, W, S, L before any Moore–Smith, directed-filter, or CauchyNet read is public.

Finally use H, C, P, N. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming preserve the same finite route and add no new carrier coordinate. Therefore the listed rows jointly exhaust the obligation-closure surface, while selected lubs, host powersets, quotient orders, directed-choice schedules, and ambient completeness remain outside the package. □

Theorem 5905.13 (DCPO obligation-closure record)**.** *For every accepted* $\mathsf{DCPO}^{\uparrow}$ *carrier* $D = (O, I, W, S, M, F, Q, L, H, C, P, N)$*, the displayed rows* $O, I, W, S, L, M, F, Q, H, C, P, N$ *form the complete obligation record consumed by* $\mathsf{ScottDomain}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{DirectedFilter}^{\uparrow}$, *and* $\mathsf{CauchyNet}^{\uparrow}$. *The record exposes order admission, directed-index admission, finite directed-window coverage, directed-supremum readability, lower-bound exactness, Moore–Smith handoff, directed-filter handoff, CauchyNet handoff, transport, replay, provenance, and local naming, and it exports no arbitrary joins or selected least-upper-bound functions.*

Lean4 ✓ `BEDC.Derived.DcpoUp.DcpoCarrier obligation closure record`

Proof. Start with directed-window coverage and the supremum ledger, Definition 5905.8 and Definition 5905.6. They identify O, I, W, S as the visible order, directed-index, finite-window, and supremum rows that every downstream order consumer must read.

Next apply lower-bound exactness, Definition 5905.9. It attaches L to the same O, I, W, S route, so leastness remains a displayed order-row obligation rather than a selected lub operation.

Finally use continuity scope and completion-facing handoff, Definition 5905.7 and Definition 5905.10. These theorems force $\mathsf{ScottDomain}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{DirectedFilter}^{\uparrow}$, and $\mathsf{CauchyNet}^{\uparrow}$ consumers to receive the same finite route through M, F, Q, H, C, P, N. Since the carrier contains no rows for arbitrary joins, host powersets, quotient-order equality, global directed choice, or selected lubs, the listed rows are the complete obligation record. □

Closure status for $\mathsf{NameCert}_{\mathsf{DCPO}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DCPO}^{\uparrow}$ packet is generated from a Poset order row, DirectedSet index row, finite directed windows, a directed-supremum row, MooreSmithNet and DirectedFilter handoffs, a CauchyNet completion-facing row, lower-bound exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DCPO}^{\uparrow}}$, scopedClosed)

Scope closed: Definition 5905.1, Definition 5905.2, Definition 5905.3, Definition 5905.5, Definition 5905.6, Definition 5905.7, and Definition 5905.13 bind the DCPO carrier, order, directed-index, finite-window, supremum, lower-bound, BHist, hsame, Cont, Pkg, and NameCert obligations as the displayed scope consumed by completion and domain-theoretic readers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DCPO}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary joins, quotient-order equality, selected least-upper-bound functions, global choice over directed families, host powersets, ambient order completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires binding the displayed obligation record to a checked kernel route for carrier admission, directed-window coverage, supremum readability, lower-bound exactness, MooreSmithNet handoff, DirectedFilter handoff, CauchyNet handoff, transport, replay, provenance, and local naming.

Chapter 5906

A Concrete Naming Certificate for $\mathsf{CauchyDedekindGapRouter}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, the $\mathsf{CauchyDedekindGapRouter}^{\uparrow}$ packet records the finite route by which a regular Cauchy real presentation and a located Dedekind-cut boundary are compared without selecting a host limit or quotient representative. It sits over the dyadic tolerance cells of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the located-cut completion surface of chapter 5554, and the Cauchy–Dedekind boundary of chapter 1745. The router is a finite NameCert carrier for the comparison gap; it is not a construction of $\mathsf{Real}^{\uparrow}$ from primitive cuts and not an ambient completeness theorem.

Definition 5906.1 (Cauchy–Dedekind gap-router carrier)**.** *A* $\mathsf{CauchyDedekindGapRouter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, S, R, E, L, B, J, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the positive dyadic gaps, refinements, and comparison cells used by both sides of the route.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the observed Cauchy name and the observed cut-boundary probes.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, binding the Cauchy-facing windows in S to regular rational observations.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, S, R have been displayed.*
5. *L is the* $\mathsf{LocatedCut}^{\uparrow}$ *lower-and-upper cut ledger addressed by the same dyadic and stream windows.*
6. *B is the* $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$ *boundary row comparing the displayed regular readback with the displayed located-cut ledger.*
7. *J is the gap-routing judgment row. It records, for each public comparison request, which dyadic gap cell in D routes the request through R toward E or through L, B toward the boundary surface.*
8. *H records componentwise* hsame *transport for the dyadic, stream, readback, real-seal, located-cut, boundary, judgment, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the comparison route*

$$D, S \longmapsto R, E \qquad \textit{and} \qquad D, S \longmapsto L, B, J.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyDedekindGapRouter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{DedekindCutCauchyBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyDedekindGapRouter}^{\uparrow}}$ *row.*

The classifier accepts only packets displaying exactly these rows. It has no coordinate for quotient stream equality, primitive Dedekind-cut equality, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyDedekindGapRouterUp.CauchyDedekindGapRouterTasteGate single carrier alignment`

Theorem 5906.2 (Cauchy–Dedekind gap-router NameCert obligations)**.** *For an accepted* CauchyDedekindGapRout *carrier*

$$G = (D, S, R, E, L, B, J, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyDedekindGapRouter}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the dyadic tolerance ledger, stream-window schedule, regular rational readback, real seal, located-cut ledger, Cauchy–Dedekind boundary row, gap-routing judgment, transport, replay, provenance, and local naming rows;*
2. *window exactness, requiring every public comparison request to be addressed by S before either the Cauchy-facing readback R or the located-cut ledger L can be inspected;*
3. *dyadic gap exactness, requiring every routed comparison to consume a displayed positive dyadic cell from D;*
4. *Cauchy-side handoff, requiring the* $\mathsf{Real}^{\uparrow}$ *seal E to be downstream of D, S, R;*
5. *cut-side handoff, requiring the boundary row B to compare only the displayed R and L rows;*
6. *routing determinacy, requiring J to name the gap cell and side of the comparison without adding a second equality principle;*
7. *classifier transport and replay, requiring H and C to preserve exactly the listed rows;*
8. *non-escape, excluding quotient stream equality, primitive cut equality, selected limits, trichotomy, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 5906.1. The accepted packet exposes the dyadic, stream, regular readback, real-seal, located-cut, boundary, judgment, and structural rows as one finite display.

Window exactness follows from the shared row S. A public request cannot reach either the Cauchy-facing row R or the located-cut row L until its finite observation window has been named.

Dyadic gap exactness is supplied by D. The same positive dyadic cell is the comparison budget used by the regular readback and by the located boundary row, so the router cannot introduce an unbudgeted comparison.

The Cauchy-side handoff reaches E only after D, S, R have been displayed. The cut-side handoff reaches B only after D, S, L and the common readback row have been displayed.

The routing row J then records which displayed gap cell and side of the comparison is used. Since J is a row of the carrier rather than an external equality principle, it cannot export quotient stream equality or primitive cut equality.

Finally H, C, P, N transport, replay, source, and name only the listed rows. The excluded completeness and choice principles have no carrier coordinate and therefore cannot become local obligations. □

Theorem 5906.3 (Cauchy–Dedekind gap-router L10 handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CauchyDedekindGapRouter}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{LocatedCut}^{\uparrow},\ \mathsf{DedekindCutCauchyBoundary}^{\uparrow}.$$

The exported comparison is a displayed gap route between regular Cauchy readback and located Dedekind boundary data, not a quotient stream, primitive cut equality, selected host limit, trichotomy split, countable-choice construction, or ambient completeness theorem.

Proof. Project the public rows from Definition 5906.1. The dyadic ledger D and stream schedule S are read before either comparison side is public.

On the Cauchy-facing side, R reads the finite windows as regular rational observations and E seals that route as a $\mathsf{Real}^{\uparrow}$ boundary. On the cut-facing side, L exposes only located lower-and-upper tests and B compares those tests with the same regular readback.

The judgment row J attaches each comparison request to a displayed gap cell. Thus a consumer can move between the Cauchy and Dedekind presentations only through D, S, R, E, L, B, J.

The structural rows H, C, P, N preserve and name that route. Since no excluded principle appears as a carrier coordinate, the handoff exports only the finite BEDC comparison surface. □

Falsifiable prediction: Every accepted $\mathsf{CauchyDedekindGapRouter}^{\uparrow}$ comparison request factors through displayed DyadicRatCore, StreamName, RegSeqRat, RealUp, LocatedCut, DedekindCut-CauchyBoundary, routing judgment, transport, replay, provenance, and local naming rows.

Independence witness: dyadicratcore, streamname, regseqrat, real, located-cut-completion, cauchy-dedekind-boundary: $\mathsf{CauchyDedekindGapRouter}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the shared dyadic gap ledger, finite observation windows, regular readback, Real seal, located-cut ledger, boundary comparison row, routing judgment, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyDedekindGapRouter}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyDedekindGapRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5906.1, Definition 5906.2, and Definition 5906.3 seed the finite Cauchy–Dedekind gap route over DyadicRatCore, StreamName, RegSeqRat, RealUp, LocatedCut, DedekindCutCauchyBoundary, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyDedekindGapRouter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, primitive cut equality, selected host limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exactness, dyadic gap exactness, Cauchy-side handoff, cut-side handoff, routing determinacy, classifier transport, replay, and non-escape for BEDC.Derived.CauchyDedekindGap

Constructive story: A $\mathsf{CauchyDedekindGapRouter}^{\uparrow}$ packet is generated from DyadicRatCore gap cells, StreamName finite windows, RegSeqRat readback, a RealUp seal, a LocatedCut ledger, a DedekindCutCauchyBoundary comparison row, a routing judgment, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5907

A Concrete Naming Certificate for $\mathsf{SequentCalculus}^{\uparrow}$

Following Gentzen's sequent calculi for structural proof theory, the $\mathsf{SequentCalculus}^{\uparrow}$ packet records sequents, inference rows, structural rules, proof trees, and cut-free boundary data as finite BEDC naming evidence. It sits beside the first-order syntax surface of chapter 197, the model-theory satisfaction packet of chapter 198, and the MetaCIC critical-path route of chapter 765. The packet supplies a proof-calculus substrate for later proof-theoretic consumers; it is not host proof syntax, a quotient of derivations, a global cut-elimination theorem, or a semantic completeness principle.

Definition 5907.1 (Sequent calculus carrier)**.** *A* $\mathsf{SequentCalculus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, \Gamma, \Delta, R, T, K, H, C, P, N)$$

with the following displayed rows:

1. *F is the formula-source row, read through the first-order syntax surface before any sequent endpoint is public.*
2. *Γ is the antecedent-context row, listing the finite left-hand formula window of each displayed sequent.*
3. *Δ is the succedent-context row, listing the finite right-hand formula window of each displayed sequent.*
4. *R is the rule-ledger row, naming the initial, logical, and structural rule entries accepted by the packet.*
5. *T is the proof-tree row, recording finite inference trees whose leaves and conclusions are sequents formed from F, Γ, Δ, R.*
6. *K is the cut-boundary row, recording which displayed trees are read as cut-free and which trees still contain an explicit cut occurrence.*
7. *H records componentwise* hsame *transport for formula, context, rule, tree, cut-boundary, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a proof-calculus request through $F, \Gamma, \Delta, R, T, K, H$.*
9. *P is the* Pkg *provenance over* $\mathsf{SequentCalculus}^{\uparrow}$, $\mathsf{FirstOrder}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{SequentCalculus}^{\uparrow}}$ *row.*
The carrier has no coordinate for host derivation equality, proof-term quotation, quotienting of derivations, semantic validity, completeness, global cut elimination, or normalization.

Lean4 ✓ `BEDC.Derived.SequentCalculusUp.SequentCalculusTasteGate single carrier alignment`

Theorem 5907.2 (Sequent calculus NameCert obligations)**.** *For every accepted* $\mathsf{SequentCalculus}^{\uparrow}$ *carrier* $S = (F, \Gamma, \Delta, R, T, K, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SequentCalculus}^{\uparrow}}$ *surface consists exactly of formula-source admission, antecedent-context display, succedent-context display, rule-ledger admission, proof-tree readability, cut-boundary visibility, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every proof-calculus consumer must read the rows* $F, \Gamma, \Delta, R, T, K$ *before exporting any sequent derivation route.*

Proof. Project the carrier of Definition 5907.1. The formula and context rows F, Γ, Δ determine the sequents that may be inspected, while R determines the finite rule ledger available to proof-tree consumers.

Read T only after those rows. A proof tree is public as a displayed finite inference tree over the visible sequents and rule entries, not as host syntax or an unrecorded derivation object.

Finally read K, H, C, P, N. The cut-boundary row keeps cut occurrences explicit, while transport, replay, provenance, and local naming preserve the same packet. Since semantic validity, completeness, quotient derivation equality, and global cut elimination are absent coordinates, the listed rows exhaust the NameCert obligations. □

Theorem 5907.3 (Sequent calculus cut-free scope)**.** *For every accepted* $\mathsf{SequentCalculus}^{\uparrow}$ *carrier* $S = (F, \Gamma, \Delta, R, T, K, H, C, P, N)$*, a cut-free read is scoped to the displayed proof-tree row* T *and the cut-boundary row* K*. If* K *marks a tree as cut-free, downstream consumers may use that tree only through the same formula, context, rule, transport, replay, provenance, and naming rows* $F, \Gamma, \Delta, R, H, C, P, N$*. The packet does not transform arbitrary cut-containing trees into cut-free trees and does not assert global cut elimination.*

Proof. Start with the NameCert obligations of Definition 5907.2. They force every proof-calculus read to pass through the formula source, antecedent and succedent contexts, rule ledger, proof-tree row, and cut-boundary row.

The cut-free claim is therefore a scope claim about an already displayed row of the carrier. A consumer may replay the cut-free marking only together with the same tree and rule ledger; it cannot infer a cut-free replacement for another tree.

Transport and continuation replay through H and C preserve the displayed rows componentwise, while P, N source and name the same packet. Since the carrier contains no global cut-elimination coordinate, no semantic completeness row, and no quotient of derivations, the public cut-free surface remains exactly the finite boundary recorded by K over T. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentCalculus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SequentCalculus}^{\uparrow}$ packet is generated from first-order formula rows, finite antecedent and succedent context rows, a rule ledger, proof-tree rows, a cut-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SequentCalculus}^{\uparrow}}$, seed)

Scope closed: Definition 5907.1, Definition 5907.2, and Definition 5907.3 seed the finite proof-calculus carrier and its cut-free read boundary for later proof-theoretic consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SequentCalculus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove cut elimination, proof normalization, semantic completeness, quotient derivation equality, host proof-term adequacy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rule-ledger exactness, proof-tree readability, cut-boundary visibility, transport, replay, provenance, and local naming for BEDC.Derived.SequentCalculusUp.

Chapter 5908

A Concrete Naming Certificate for $\mathsf{CauchyDedekindEquivalence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyDedekindEquivalence}^{\uparrow}$ packet names the bidirectional finite handoff between regular Cauchy reads and located-cut completion reads on the L10 Real and Completion route. It is anchored in the one-way bridge of chapter 2346, the located-cut completion surface of chapter 5554, the regular rational route of chapter 301, the finite observation discipline of chapter 126, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet records equivalence as two displayed certificate routes, not as quotient equality of completed real names or as an ambient completeness principle.

Definition 5908.1 (Cauchy-Dedekind equivalence carrier)**.** *A* $\mathsf{CauchyDedekindEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, W, D, L, B, E_0, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy readback row exposed before any cut-facing comparison is consumed.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule controlling every source, comparison, and return read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger shared by the regular Cauchy side and the located-cut side.*
4. *L is the* $\mathsf{LocatedCutCompletion}^{\uparrow}$ *bracket-completion row, carrying lower and upper located evidence through the same finite windows and dyadic refinements.*
5. *B is the forward* $\mathsf{CauchyDedekindBridge}^{\uparrow}$ *row from R, W, D into the located-cut-facing comparison route.*
6. *E_0 is the reverse located-cut-to-regular-Cauchy row. It reads the displayed L, W, D brackets back into the regular rational route R before any terminal real seal is exposed.*
7. *H records componentwise* hsame *transport for the regular row, window schedule, dyadic ledger, located completion row, forward bridge, reverse row, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay of the two routes*

$$R, W, D \longmapsto B, L \qquad \textit{and} \qquad L, W, D \longmapsto E_0, R.$$

9. *P is the* Pkg *provenance over* $\mathsf{CauchyDedekindEquivalence}^{\uparrow}$, $\mathsf{CauchyDedekindBridge}^{\uparrow}$, $\mathsf{LocatedCutCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyDedekindEquivalence}^{\uparrow}}$ *row.*

The classifier accepts only packets displaying both directions. It has no coordinate for quotient equality of real names, a selected representative, countable choice, trichotomy, primitive Dedekind cuts outside the displayed rows, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyDedekindEquivalenceUp.CauchyDedekindEquivalenceTasteGate single carrier alignment`

Theorem 5908.2 (Cauchy-Dedekind equivalence NameCert obligations)**.** *For every accepted* CauchyDedekindEquiv *carrier*

$$E = (R, W, D, L, B, E_0, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyDedekindEquivalence}^{\uparrow}}$ *surface consists exactly of carrier admission, regular Cauchy readback, finite-window scheduling, dyadic tolerance compatibility, located-cut completion exposure, forward bridge exposure, reverse located-cut-to-regular-Cauchy exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from the excluded host principles.*

Proof. Project the accepted carrier of Definition 5908.1. The regular side is R, the common finite observation and tolerance surface is W, D, and the located-cut completion side is L.

The forward handoff is exactly the row B. It is read as the bridge from the regular Cauchy data into the located-cut-facing comparison surface already named by chapter 2346.

The reverse handoff is exactly the row E_0. It reads the displayed lower and upper located-cut completion evidence back through the same finite windows and dyadic tolerances into the regular rational route, so it cannot introduce a selected limit or a quotient representative.

Finally H, C, P, N transport, replay, source, and name the two routes as one packet. Since no excluded host principle occurs as a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 5908.3 (Cauchy-Dedekind equivalence two-way handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{CauchyDedekindEquivalence}^{\uparrow}$ *packet factors through the paired finite routes*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyDedekindBridge}^{\uparrow},\ \mathsf{LocatedCutCompletion}^{\uparrow}$$

and

$$\mathsf{LocatedCutCompletion}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

Thus the packet exports a named two-way handoff between regular Cauchy reads and located-cut completion reads before the terminal $\mathsf{Real}^{\uparrow}$ *seal, without exposing quotient stream equality, selected limits, countable choice, trichotomy, primitive host cuts, or ambient completeness.*

Proof. Open an accepted carrier $E = (R, W, D, L, B, E_0, H, C, P, N)$. The forward route is forced through R, W, D and then through B, L because those are the only rows connecting regular Cauchy readback to located-cut completion evidence.

The reverse route is forced through L, W, D and then through E_0, R. The same finite window schedule and dyadic ledger are reused, so the return direction stays inside displayed packet data.

Rows H and C preserve the two routes under componentwise transport and replay. Rows P and N record the provenance and local naming of the paired handoff. Since the terminal $\mathsf{Real}^{\uparrow}$

seal is downstream of these rows, the consumer receives an equivalence interface rather than an ambient real-completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{CauchyDedekindEquivalence}^{\uparrow}$ consumer that claims a two-way Cauchy–Dedekind handoff while omitting one of $R, W, D, L, B, E_0, H, C, P, N$ refutes the carrier surface of Definition 5908.1.

Independence witness: cauchy-dedekind-bridge, located-cut-completion, regseqrat, streamname, dyadicratcore, real: $\mathsf{CauchyDedekindEquivalence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a forward bridge row and a reverse located-cut-to-regular-Cauchy row over the same finite windows, dyadic tolerance ledger, transport, replay, provenance, and local naming surface.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyDedekindEquivalence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyDedekindEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5908.1, Definition 5908.2, and Definition 5908.3 seed the bidirectional finite handoff between regular Cauchy readback and located-cut completion reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyDedekindEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, trichotomy, primitive host cuts, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, forward bridge exposure, reverse located-cut-to-regular-Cauchy exposure, shared finite-window and dyadic tolerance exactness, transport and replay stability, provenance non-escape, and TasteGate field faithfulness for BEDC.Derived.CauchyDedekindEquivalenceUp.

Constructive story: A $\mathsf{CauchyDedekindEquivalence}^{\uparrow}$ packet is generated from RegSeqRat readback, StreamName finite windows, DyadicRatCore tolerances, a LocatedCutCompletion row, a CauchyDedekindBridge row, a reverse located-cut-to-regular-Cauchy row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

$\mathsf{LuenbergerObserver}^{\uparrow}$ reads the state-transition row from chapter 329, the observability row from chapter 294, and the matrix and linear-map rows before the local observer correction packet is consumed.

Chapter 5909

A Concrete Naming Certificate for $\mathsf{LuenbergerObserver}^{\uparrow}$

Following Luenberger's observer construction for finite-dimensional linear systems, the $\mathsf{LuenbergerObserver}^{\uparrow}$ packet records a deterministic state-estimate correction row rather than a stochastic filter. It consumes the observed-output surface of $\mathsf{ControlObservability}^{\uparrow}$ in chapter 294, the reachability-side finite-control surface of $\mathsf{ControlControllability}^{\uparrow}$ in chapter 297, the finite dual readback of $\mathsf{ObservabilityGramian}^{\uparrow}$ in chapter 5787, the estimator boundary of $\mathsf{KalmanFilter}^{\uparrow}$ in chapter 5102, and the linear-map carrier of $\mathsf{LinMap}^{\uparrow}$ in chapter 48. The chapter names the displayed observer ledger used by downstream estimator and observer-based-control packets; it does not identify the deterministic observer with a Kalman update.

Definition 5909.1 (LuenbergerObserverUp BHist carrier)**.** *A* $\mathsf{LuenbergerObserver}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, C, Y, G, R, E, H, T, P, N).$$

Here A is the plant-dynamics row, read as the finite transition surface shared with $\mathsf{LinMap}^{\uparrow}$ *and the control-system certificates; C is the output-map row consumed through* $\mathsf{ControlObservability}^{\uparrow}$*; Y is the displayed measured-output and predicted-output comparison row; G is the observer-gain row, with its finite matrix or linear-map provenance separated from any Kalman covariance update; R is the residual row naming $y - C\widehat{x}$ as a finite output discrepancy; E is the error-propagation ledger recording the closed observer error route governed by the displayed plant, output, and gain rows; H is componentwise* hsame *transport for all observer rows; T is displayed* Cont *replay for residual formation and error-propagation reads; P is the* Pkg *provenance over* $\mathsf{LuenbergerObserver}^{\uparrow}$, $\mathsf{ControlObservability}^{\uparrow}$, $\mathsf{ControlControllability}^{\uparrow}$, $\mathsf{ObservabilityGramian}^{\uparrow}$, $\mathsf{KalmanFilter}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*; and N is the local* $\mathsf{NameCert}_{\mathsf{LuenbergerObserver}^{\uparrow}}$ *row.*

The classifier compares observer packets only through $A, C, Y, G, R, E, H, T, P, N$. It has no coordinate for stochastic covariance recursion, optimal filtering, asymptotic convergence rate, pole-placement completeness, unobserved trajectory semantics, or a hidden analytic state space.

Theorem 5909.2 (LuenbergerObserverUp NameCert obligations)**.** *For every accepted* $\mathsf{LuenbergerObserver}^{\uparrow}$ *carrier $L = (A, C, Y, G, R, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LuenbergerObserver}^{\uparrow}}$ *surface consists exactly of plant-dynamics admission through A, output-map admission through C, measured/predicted output comparison through Y, observer-gain admission through G, residual formation through R, error-propagation exposure through E, componentwise transport through H, displayed continuation replay through T, package provenance through P, and local naming through N.*

A downstream deterministic estimator, observer-based controller, or control-diagnostic packet may read this surface only after the plant dynamics, output map, observer gain, residual, and error-propagation ledger have all been displayed. The packet exports no Kalman covariance update, no stochastic innovation law, no host convergence theorem, no pole-placement theorem, and no analytic state-trajectory object.

Lean4 ✓ `BEDC.Derived.LuenbergerObserverUp.LuenbergerObserverCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 5909.1. The rows A, C, Y, G, R, E are the observer-facing data, while H, T, P, N transport, replay, source, and name the same finite packet.

The output row is read through $\mathsf{ControlObservability}^{\uparrow}$ and the transition/gain rows through the displayed finite linear-map surface. The observability Gramian and controllability packets can be used only as named provenance for finite control rows; they do not add an unrecorded analytic observer theorem.

The Kalman-filter sibling is present only as an estimator boundary. Since the carrier separates the deterministic gain row G and residual row R from any covariance update, a consumer cannot reinterpret the observer certificate as stochastic filtering data.

Thus the listed rows exhaust the local NameCert surface. Any read that demands a convergence theorem, pole-placement completeness theorem, covariance recursion, or host trajectory semantics leaves the accepted carrier. □

Falsifiable prediction: Every future consumer of $\mathsf{LuenbergerObserver}^{\uparrow}$ must expose the plant row, output row, observer-gain row, residual row, and error-propagation ledger before it reads a deterministic observer handoff; no consumer may obtain a Kalman covariance update from this packet.

Independence witness: controlobservability, controlcontrollability, observability-gramian, kalman-filter, linearmap: none is bijective to $\mathsf{LuenbergerObserver}^{\uparrow}$ because the observer packet jointly carries plant dynamics, output map, observer gain, residual, deterministic error propagation, transport, replay, provenance, and local NameCert rows while excluding stochastic covariance update and host convergence semantics.

Closure status for $\mathsf{NameCert}_{\mathsf{LuenbergerObserver}^{\uparrow}}$.

Constructive story: A $\mathsf{LuenbergerObserver}^{\uparrow}$ packet is generated from displayed plant dynamics, output map, observer gain, measured/predicted output comparison, residual, deterministic error-propagation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LuenbergerObserver}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5909.1 and Definition 5909.2 seed the deterministic observer carrier and its local NameCert obligation surface over displayed control and linear-map rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LuenbergerObserver}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not prove observer convergence, pole-placement completeness, stochastic optimality, Kalman covariance update laws, analytic trajectory semantics, Lean verification, or a bridge-checked public schema.

Upgrade path: Obligation closure requires checked carrier admission, plant-dynamics exposure, output-map exposure, observer-gain exactness, residual exactness, error-propagation ledger coverage, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.LuenbergerObserverUp.

Theorem 5909.3 (LuenbergerObserverUp control sibling dependency route)**.** *Every deterministic observer correction read of an accepted* $\mathsf{LuenbergerObserver}^{\uparrow}$ *packet consumes the control sibling route through chapter 294, chapter 297, chapter 5787, chapter 5102, and chapter 48 before any observer-interface row is treated as public. The route exposes the plant-dynamics row, output-map row, observer-gain row, residual row, deterministic error-propagation ledger, componentwise* hsame

transport, displayed Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{LuenbergerObserver}^{\uparrow}}$*; it exports no stochastic covariance update, pole-placement theorem, observer convergence theorem, or hidden analytic state trajectory.*

Proof. Project the accepted carrier of Definition 5909.1. Its rows $A, C, Y, G, R, E, H, T, P, N$ name the deterministic observer interface and the structural transport, replay, provenance, and local naming records.

The output row is read through $\mathsf{ControlObservability}^{\uparrow}$, the finite control provenance through $\mathsf{ControlControllability}^{\uparrow}$, the dual readback through $\mathsf{ObservabilityGramian}^{\uparrow}$, the estimator boundary through $\mathsf{KalmanFilter}^{\uparrow}$, and the transition and gain rows through $\mathsf{LinMap}^{\uparrow}$. These sibling chapters must therefore be displayed before a consumer treats the observer correction as public.

Since the carrier contains no covariance recursion, pole-placement completeness row, convergence theorem, or host trajectory semantics, the public observer-interface read is exactly the displayed control sibling route. □

Theorem 5909.4 (Luenberger observer control-system route)**.** *Every accepted* $\mathsf{LuenbergerObserver}^{\uparrow}$ *read that exposes observer-error feedback data first consumes the control-system state-transition row through* $\mathsf{DynSystem}^{\uparrow}$*, the finite observation row through* $\mathsf{ControlObservability}^{\uparrow}$*, and the state-space carrier through* $\mathsf{StateSpaceModel}^{\uparrow}$*. The public route is the displayed plant dynamics, observation map, state carrier, measured-output comparison, observer gain, residual row, deterministic error-propagation ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{LuenbergerObserver}^{\uparrow}}$*; it exports no hidden trajectory semantics, stochastic covariance recursion, pole-placement theorem, or convergence claim.*

Proof. Project the carrier of Definition 5909.1. The plant-dynamics row A, output row C, comparison row Y, observer-gain row G, residual row R, and error-propagation row E are displayed before transport, replay, provenance, and local naming are read.

The state-transition part of A is a control-system read through $\mathsf{DynSystem}^{\uparrow}$, while the state carrier is routed through $\mathsf{StateSpaceModel}^{\uparrow}$. The output row C and the observation-facing part of the residual ledger are routed through $\mathsf{ControlObservability}^{\uparrow}$ before any observer-error feedback is public.

The structural rows H, T, P, N preserve exactly those displayed dependencies. Since no carrier coordinate stores a host trajectory, covariance update, pole-placement theorem, or convergence result, every observer-error feedback read factors through the stated control-system route. □

Theorem 5909.5 (LuenbergerObserverUp control-observability forward route)**.** *Every accepted* $\mathsf{LuenbergerObserver}^{\uparrow}$ *deterministic correction read consumes the finite observer rows supplied by chapter 294 and the estimator boundary of chapter 5102 before the residual and error-propagation rows are public. The route keeps the output-map, measured/predicted comparison, gain, residual, and deterministic error ledger attached to the carrier of Definition 5909.1; it exports no covariance recursion, stochastic innovation law, pole-placement theorem, or hidden trajectory semantics.*

Proof. Project the accepted carrier $L = (A, C, Y, G, R, E, H, T, P, N)$ from Definition 5909.1. The public correction read depends on the output row C, comparison row Y, gain row G, residual row R, and error-propagation row E.

The observability sibling supplies the finite row by which C, Y, R, E are inspected as observer-facing data. The Kalman-filter boundary sibling supplies only estimator comparison data, so the deterministic rows remain A, C, Y, G, R, E rather than covariance or innovation coordinates.

The structural rows H, T, P, N preserve the same finite route under transport, replay, provenance, and local naming. Thus the observer packet is routed through control and observability

siblings before its correction interface is public, without becoming a stochastic filter or analytic convergence theorem. □

Theorem 5909.6 (LuenbergerObserverUp Kalman filter boundary route)**.** *Every deterministic observer read of an accepted* $\mathsf{LuenbergerObserver}^{\uparrow}$ *carrier may cite chapter 5102 only as an estimator boundary. The read must keep the plant row, output row, observer-gain row, residual row, and error-propagation row visible as the carrier coordinates*

$$A, C, G, R, E$$

of Definition 5909.1, together with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{LuenbergerObserver}^{\uparrow}}$ *naming. It exports no covariance recursion, stochastic innovation law, optimal-filtering theorem, or hidden probabilistic state row.*

Proof. Project the accepted carrier $L = (A, C, Y, G, R, E, H, T, P, N)$. The plant, output, gain, residual, and error-propagation rows are the deterministic observer data, while H, T, P, N preserve and name that finite packet.

The control sibling route of Definition 5909.3 already displays the control, observability, Gramian, Kalman-boundary, and linear-map chapters before the observer correction becomes public. The observability route of Definition 5909.10 keeps the output, residual, gain, and error ledger attached to the same finite carrier.

The Kalman-filter citation is therefore boundary information for estimator comparison. Since no covariance coordinate, stochastic innovation coordinate, or probabilistic state coordinate occurs in L, the deterministic observer route cannot export a Kalman-filter law. □

Theorem 5909.7 (LuenbergerObserverUp Kalman filter dependency boundary)**.** *The* $\mathsf{LuenbergerObserver}^{\uparrow}$ *route consumes* $\mathsf{KalmanFilter}^{\uparrow}$ *only as an estimator-boundary sibling. The plant, output, observer-gain, residual, and error-propagation rows remain deterministic carrier data in* A, C, G, R, E*, and the structural rows* H, T, P, N *preserve that deterministic packet without adding covariance, innovation, probability-space, or optimality coordinates.*

Proof. Use Definition 5909.6. It already places every Kalman-filter citation outside the carrier coordinates that generate the deterministic observer read.

The displayed carrier rows of Definition 5909.1 are therefore the complete dependency surface for plant evolution, output comparison, gain application, residual formation, and error propagation. Since $\mathsf{KalmanFilter}^{\uparrow}$ appears only through the boundary citation, no stochastic row can be imported into the deterministic observer packet. □

Theorem 5909.8 (LuenbergerObserverUp Kalman filter dependency route)**.** *Every* $\mathsf{KalmanFilter}^{\uparrow}$ *or observer-controller consumer of an accepted* $\mathsf{LuenbergerObserver}^{\uparrow}$ *carrier must first expose the state-space row, observability row, output-error row, observer-gain row, replay row, provenance row, and local* $\mathsf{NameCert}_{\mathsf{LuenbergerObserver}^{\uparrow}}$ *row of the displayed packet. The Kalman-filter side is read only through chapter 5102, and the observation side is read only through the* $\mathsf{ControlObservability}^{\uparrow}$ *and* $\mathsf{ObservabilityGramian}^{\uparrow}$ *rows already named by chapter 294 and chapter 5787. Thus no consumer may treat the deterministic observer correction as a hidden covariance update, stochastic innovation law, selected state trajectory, or host convergence theorem.*

Proof. Project the accepted carrier $L = (A, C, Y, G, R, E, H, T, P, N)$ of Definition 5909.1. The plant and state-space information is carried by A, the observability and output rows by C and Y, the gain and output-error data by G, R, E, and the structural replay by H, T, P, N.

Apply the Kalman boundary route of Definition 5909.6. It keeps every Kalman-filter citation outside the deterministic carrier coordinates that generate the observer read.

Apply the observability dependency route and observer-controller forward route, Definition 5909.10 and Definition 5909.9. These routes force the consumer to display the observation, residual, gain, error-propagation, replay, provenance, and naming rows before any controller or estimator handoff is public.

Since the carrier has no covariance recursion, stochastic innovation, selected trajectory, or host convergence coordinate, the Kalman-filter and observer-controller consumers can read only the displayed deterministic dependency route. □

Theorem 5909.9 (LuenbergerObserverUp observer-controller forward route)**.** *Every downstream deterministic observer-controller read of an accepted* $\mathsf{LuenbergerObserver}^{\uparrow}$ *packet must consume the observer only through the displayed plant, output, gain, residual, error-propagation, transport, replay, provenance, and local NameCert rows of Definition 5909.1. The route may then pass to the closest deterministic control-system siblings chapter 294, chapter 297, chapter 5787, and chapter 48; it exports no stochastic covariance update, pole-placement theorem, host convergence theorem, or hidden analytic state trajectory.*

Proof. Project the accepted carrier $L = (A, C, Y, G, R, E, H, T, P, N)$ from Definition 5909.1. The observer-controller read can use only the plant row A, output row C, comparison row Y, gain row G, residual row R, and error-propagation row E before the structural rows are exposed.

Use the control sibling dependency route of Definition 5909.3 and the control-observability forward route of Definition 5909.5. They keep the deterministic control and observability siblings visible before the observer correction is public.

The rows H, T, P, N preserve, replay, source, and name the same finite packet. Since no covariance recursion, pole-placement completeness row, convergence theorem, or host trajectory row occurs in the carrier, every observer-controller consumer remains inside the displayed deterministic route. □

Theorem 5909.10 (LuenbergerObserverUp observability dependency route)**.** *Every observer-error ledger read of an accepted* $\mathsf{LuenbergerObserver}^{\uparrow}$ *packet must pass through chapter 294 and chapter 5787 before the residual row and observer-gain row are exposed. Concretely, the read projects the carrier rows*

$$(C, Y, G, R, E)$$

from Definition 5909.1: C supplies the observed-output map, Y compares measured and predicted outputs, G supplies the deterministic observer gain, R names the residual, and E records the observer-error propagation ledger. The route exports no Kalman covariance recursion, pole-placement theorem, or host trajectory semantics.

Proof. Project the accepted carrier $L = (A, C, Y, G, R, E, H, T, P, N)$. The observer-error ledger E can be read only after the output-map row C, the measured/predicted comparison row Y, the gain row G, and the residual row R are visible.

The output-map row is the observability-facing entry point. It is therefore routed through $\mathsf{ControlObservability}^{\uparrow}$ before the observer-error ledger is public, and the finite dual readback required by the same output surface is routed through $\mathsf{ObservabilityGramian}^{\uparrow}$.

After those two sibling routes are displayed, the residual and gain rows may be exposed as the deterministic observer interface. The carrier still has no coordinate for Kalman covariance, pole placement, or host trajectory semantics, so the read remains an observability dependency route rather than a stochastic or analytic observer theorem. □

Theorem 5909.11 (Luenberger observer state-space dependency route)**.** *Every accepted* $\mathsf{LuenbergerObserver}^{\uparrow}$ *packet consumes the finite state-space carrier of chapter 329, the linear-map evolution row of chapter 48, the observability row routed through Definition 5909.10, the Kalman-filter boundary route of chapter 5102, and the observer-controller forward route of Definition 5909.9 before exporting estimator-error dynamics. The exported read is the displayed tuple of plant dynamics, output map, measured/predicted output comparison, observer gain, residual, deterministic error propagation, transport, replay, provenance, and local naming rows; it is not a hidden analytic state trajectory, stochastic covariance recursion, pole-placement theorem, or host convergence claim.*

Proof. Project the carrier of Definition 5909.1. The plant row A and output row C are meaningful only after the state-space and linear-map substrates have been displayed.

Next read the observability dependency route. It exposes the output-map, residual, observer-gain, and error-ledger rows through the accepted observability and Gramian surfaces before the deterministic observer interface is public.

Finally compose the Kalman-filter boundary route and the observer-controller forward route. These sibling routes keep stochastic covariance and controller synthesis outside the observer carrier while allowing the estimator-error ledger E to be consumed as deterministic state-space data.

The structural rows H, T, P, N transport, replay, source, and name exactly this route. Since the carrier has no coordinate for hidden state trajectories, covariance recursion, pole placement, or host convergence, every estimator-error export factors through the displayed state-space dependency route. □

Every observer-error feedback read of an accepted $\mathsf{LuenbergerObserver}^{\uparrow}$ packet factors through the displayed $\mathsf{StateSpaceModel}^{\uparrow}$ row, $\mathsf{ControlObservability}^{\uparrow}$ row, observer-gain row, residual row, deterministic error-propagation ledger, and the existing anchors chapter 329 and chapter 294 before it can be consumed by estimator or observer-controller routes. The lattice route exports the finite plant, observation, gain, residual, error, transport, replay, provenance, and local naming rows only; it exports no hidden trajectory semantics, stochastic covariance recursion, pole-placement theorem, or host convergence claim.

Theorem 5909.12 (Luenberger observer state-space realization forward link)**.** *Every accepted* $\mathsf{LuenbergerObserver}^{\uparrow}$ *packet that reads the observer gain, plant state, output row, and innovation replay consumes the finite* $\mathsf{StateSpaceModel}^{\uparrow}$ *and* $\mathsf{TransferFunctionStateSpaceRealization}^{\uparrow}$ *realization rows before any observer-controller or Kalman handoff. The forward link exports only the displayed plant, output, gain, innovation, realization, transport, replay, provenance, and local naming rows; it exports no hidden analytic transfer-function equality, stochastic covariance recursion, pole-placement theorem, or host convergence claim.*

Proof. Project the carrier of Definition 5909.1. The observer gain, plant state, output row, and innovation replay are visible only as displayed finite rows of the accepted packet.

Read the state-space dependency route of Definition 5909.11. It forces the observer packet through the finite $\mathsf{StateSpaceModel}^{\uparrow}$ and $\mathsf{LinMap}^{\uparrow}$ surfaces before the estimator-error ledger is public.

Now use the realization surface of chapter 9117. The observer can pass to observer-controller or Kalman handoff rows only after the transfer readback and state-space realization compatibility rows have been displayed.

The structural rows transport, replay, source, and name exactly this route. Since neither the observer packet nor the realization packet contains analytic transfer-function equality, stochastic covariance recursion, pole placement, or host convergence, the forward link remains a finite NameCert dependency. □

Theorem 5909.13 (Luenberger observer transportability dependency route)**.** *Every accepted* $\mathsf{LuenbergerObserver}^{\uparrow}$ *packet used as an externally valid observer-state reconstruction route must first read the selection-domain row of* $\mathsf{Transportability}^{\uparrow}$ *through chapter 9055, the finite state-transition carrier of* $\mathsf{StateSpaceModel}^{\uparrow}$ *through chapter 329, the deterministic control-system rows through Definition 5909.4, the observability row through chapter 294, and the estimator boundary through chapter 5102. Only after those sibling rows are displayed may a consumer treat the observer correction, residual ledger, and error-propagation row as portable between source and target systems. The route exports no hidden domain-selection oracle, stochastic covariance update, host state equality, or ambient external-validity theorem.*

Proof. Project the accepted carrier of Definition 5909.1. Its observer rows $A, C, Y, G, R, E, H, T, P, N$ expose plant dynamics, output, comparison, gain, residual, deterministic error propagation, transport, replay, provenance, and local naming.

The transportability read supplies the source and target selection-domain row before those observer rows are used outside their original system. The state-space, control-system, observability, and Kalman-filter boundary siblings then keep the plant carrier, output route, and estimator boundary visible.

Since the Luenberger carrier contains no domain-selection oracle, host state equality, covariance recursion, or external-validity theorem, observer-state transfer is public only along the displayed transportability and control sibling route. □

Theorem 5909.14 (LuenbergerObserver observer-control lattice route)**.** *Every deterministic* $\mathsf{LuenbergerObserver}^{\uparrow}$ *correction read consumes the observer/control dependency lattice before it exposes the observer row. The route must display* $\mathsf{ControlObservability}^{\uparrow}$ *for the output-map read,* $\mathsf{ControlControllability}^{\uparrow}$ *for the finite control-side reachability boundary,* $\mathsf{ObservabilityGramian}^{\uparrow}$ *for the dual observability ledger,* $\mathsf{KalmanFilter}^{\uparrow}$ *as the stochastic-estimator boundary,* $\mathsf{LinMap}^{\uparrow}$ *for the plant and gain rows, and* $\mathsf{StateSpaceModel}^{\uparrow}$ *for the finite state-space carrier before the rows of Definition 5909.1 are public.*

Proof. Start from the carrier of Definition 5909.1. Its plant, output, observer-gain, residual, and error-propagation rows are not standalone data; each is displayed against a control or state-space sibling.

The observability and controllability packets supply the finite output and control lattice. The observability Gramian records the dual readback, while the Kalman-filter packet marks the estimator boundary that this deterministic observer does not internalize.

The remaining rows come from the displayed linear and state-space carriers. $\mathsf{LinMap}^{\uparrow}$ names the plant and gain maps, and $\mathsf{StateSpaceModel}^{\uparrow}$ supplies the state-space row through which those maps are read. Thus a consumer reaches the public $\mathsf{LuenbergerObserver}^{\uparrow}$ row only after the full observer/control dependency lattice is visible. □

Chapter 5910

A Concrete Naming Certificate for $\mathsf{BinaryTree}^{\uparrow}$

Following Knuth and Cormen–Leiserson–Rivest–Stein, the binary-tree packet treats a tree node as a finite record with at most one left branch and at most one right branch. The certificate is a finite-data neighbor of $\mathsf{List}^{\uparrow}$ (chapter 36), $\mathsf{Tree}^{\uparrow}$ (chapter 119), $\mathsf{Graph}^{\uparrow}$ (chapter 118), and $\mathsf{FinSet}^{\uparrow}$ (chapter 112): it uses list-style finite spines for node positions, graph-style incidence rows for branches, and tree-style rooted transport without importing a host datatype.

5910.1 Carrier definition

Definition 5910.1 (BinaryTree finite carrier)**.** *A* $\mathsf{BinaryTree}^{\uparrow}$ *carrier row is a finite* BHist *packet*

$$\mathsf{BinaryTreePacket}(h)$$

with the following displayed rows:

1. *a root history* r *carried by the same* Pkg *provenance as* h*;*
2. *a finite-node position carrier* $\mathsf{NodePos}(h)$ *with readback* $\mathsf{node}_h : \mathsf{NodePos}(h) \to \mathsf{BHist}$ *and root position* p_r *satisfying* $\mathsf{node}_h(p_r)\mathsf{hsame}r$*;*
3. *partial branch classifiers* left_h *and* right_h *from node positions to node positions, each represented by a finite incidence row rather than by a host function;*
4. *a branch classifier saying that any displayed branch row is either left or right and that a node has at most one displayed left target and at most one displayed right target up to* hsame *transport;*
5. hsame *transport rows for the root, every node position, and every left/right branch row;*
6. Cont *replay rows that read the same packet after transporting along the displayed* hsame *witnesses;*
7. Pkg *provenance for the root, node spine, branch rows, and local certificate rows;*
8. *local* $\mathsf{NameCert}$ *rows for the carried root, node-position spine, and left/right incidence classifiers.*

The carrier exports exactly these finite rows. It does not export a host recursive datatype, a hidden traversal order, or an unrecorded quotient of node labels.

Lean4 ✓ `BEDC.Derived.BinaryTreeUp.BinaryTreeTasteGate single carrier alignment`

5910.2 Obligation surface

Theorem 5910.2 (BinaryTree NameCert obligation surface)**.** *The* $\mathsf{BinaryTree}^{\uparrow}$ *certificate obligations are exactly the carrier, classifier, and ledger obligations displayed in Definition 5910.1. Carrier coverage says that an accepted history exposes a root, a finite node-position spine, finite left/right branch rows,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows. Classifier stability says that two accepted packets classify together precisely when their roots, node positions, and left/right branch rows are transported componentwise by the displayed* hsame *witnesses. Ledger exactness says that branch-choice evidence, finite-node enumeration evidence, and replay evidence remain ledger rows and never become host equality.*

Proof. Read an accepted packet through Definition 5910.1. The carrier projection gives the root, node-position spine, left/right branch incidence rows, transport rows, replay rows, provenance rows, and local naming rows.

For classifier stability, compare two packets componentwise. The root comparison is the displayed hsame row, node comparisons use the finite-position readback, and branch comparisons use the left/right incidence rows transported along the same provenance.

For ledger exactness, isolate the data that justifies the visible rows: branch-choice witnesses, finite enumeration witnesses, and replay witnesses. Since each of these is consumed only to justify or transport a visible row, none is exported as host equality or as a hidden traversal order. This is exactly the carrier/classifier/ledger surface claimed above. □

Theorem 5910.3 (BinaryTree induction readback)**.** *Let* $\mathsf{BinaryTreePacket}(h)$ *be an accepted* $\mathsf{BinaryTree}^{\uparrow}$ *carrier row. If a predicate* Q *on displayed node positions holds at the root position and is stable under each displayed left and right branch row, then* Q *holds at every node position in* $\mathsf{NodePos}(h)$*. Equivalently, structural induction over a binary tree is read back from the finite root and branch rows of the packet.*

Proof. Induct over the displayed finite node-position spine. The root case is the supplied root witness $Q(p_r)$.

For a node reached by a displayed left branch, apply the left-branch stability clause to the predecessor position and transport the resulting witness along the branch classifier row. The right-branch case is identical with the right-branch stability clause.

Every position in the finite packet is either the root position or appears as the target of a finite sequence of displayed left/right branch rows from the root, because the packet is accepted only after the branch incidence ledger has been replayed through the rooted $\mathsf{Tree}^{\uparrow}$ and finite $\mathsf{Graph}^{\uparrow}$ rows. Repeatedly applying the two branch steps therefore yields Q at the chosen position. Componentwise hsame transport carries the witness across equivalent packet presentations. □

Closure status for $\mathsf{NameCert}_{\mathsf{BinaryTree}^{\uparrow}}$**.**

Constructive story: A binary tree is accepted only after a visible finite packet records a root row, finite node-position rows, left and right branch incidence rows, classifier transport, replay, provenance, and local naming rows. The construction reads ordinary binary-tree branching as displayed BHist data: root and branch rows are public, while traversal choices and replay witnesses remain ledger data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BinaryTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: The chapter names the finite carrier, classifier, induction readback, and ledger boundary for binary-tree packets over BHist rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BinaryTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a checked Lean implementation, a standard bridge, balancing invariants, search-order invariants, or host recursive tree equality.

Upgrade path: A checked carrier namespace and finite branch-row induction theorem would raise the verification axis.

Chapter 5911

A Concrete Naming Certificate for $\mathsf{SobolevSpace}^{\uparrow}$

Following Sobolev and Adams–Fournier, the $\mathsf{SobolevSpace}^{\uparrow}$ packet records a finite constructive-analysis surface for functions whose weak derivatives and norm budgets are visible as named BEDC rows. It sits downstream of the weak-derivative interface of chapter 2210, the norm carrier of chapter 89, the metric-completion boundary of chapter 1506, and the real seal of chapter 38. The packet supplies PDE, variational, and compactness-facing consumers with a displayed Sobolev-space carrier rather than a host function quotient, an ambient Banach theorem, or a selected completion point.

Definition 5911.1 (SobolevSpace carrier)**.** *A* $\mathsf{SobolevSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, D, N_0, I, M, R, H, C, P, L)$$

with the following displayed rows:

1. *F is the source-function row, listing the finite function-name windows, domain probes, boundary tags, and scalar readbacks exposed to this Sobolev-space packet.*
2. *D is the* $\mathsf{WeakDerivative}^{\uparrow}$ *row, recording the displayed weak derivative actions, derivative-coordinate tags, test-action windows, and candidate derivative readbacks attached to F.*
3. *N_0 is the* $\mathsf{Norm}^{\uparrow}$ *budget row. It binds the source-function row and each displayed weak-derivative row to the finite integrability, exponent, and seminorm ledger used by the carrier.*
4. *I is the integrability and local-domain budget row, naming the finite measurable-window, power-budget, and comparison data that justify the accepted norm reads.*
5. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row, available only after F, D, N_0, I have been displayed and only for the completion route named by this carrier.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row for norm values, integrability budgets, weak-derivative action values, and completion-facing estimates.*
7. *H stores componentwise* hsame *transport for source-function, weak-derivative, norm, integrability, completion, Real readback, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from every Sobolev-space request through $F, D, N_0, I, M, R, H, P, L$.*
9. *P is the* Pkg *provenance over* $\mathsf{SobolevSpace}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. *L is the local* $\mathsf{NameCert}_{\mathsf{SobolevSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, D, N_0, I, M, R, H, C, P, L$. It has no coordinate for quotient equality of functions, a host distribution space, global measurability completion, countable choice, compact embedding, trace theory, PDE solvability, or an ambient Banach-space theorem.

Lean4 ✓ `BEDC.Derived.SobolevSpaceUp.SobolevSpaceTasteGate single carrier alignment`

Theorem 5911.2 (SobolevSpace NameCert obligations)**.** *For every accepted* $\mathsf{SobolevSpace}^{\uparrow}$ *carrier*

$$S = (F, D, N_0, I, M, R, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{SobolevSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source-function, weak-derivative, norm-budget, integrability, completion-handoff, Real readback, transport, replay, provenance, and local naming rows;*
2. *weak-derivative coverage, requiring every derivative read to pass through the displayed* $\mathsf{WeakDerivative}^{\uparrow}$ *row D before it can contribute to a Sobolev-space norm budget;*
3. *norm and integrability exactness, requiring every norm, exponent, and local-domain budget read to factor through N_0, I before it reaches the* $\mathsf{Real}^{\uparrow}$ *row R;*
4. *completion nonescape, requiring the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row M to be downstream of F, D, N_0, I, R and not detachable as a selected completion point;*
5. *structural stability under H, C, P, L, which transports, replays, sources, and names only the displayed finite route.*

No $\mathsf{SobolevSpace}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Project the carrier of Definition 5911.1. The analytic data visible to the classifier are exactly the source row F, weak-derivative row D, norm-budget row N_0, integrability row I, completion handoff M, and Real readback R.

The weak-derivative obligation is forced before any norm read. A consumer cannot inspect a derivative budget unless it first reads D, and D exposes only the finite test-action and candidate derivative surface inherited from $\mathsf{WeakDerivative}^{\uparrow}$.

The norm and integrability obligations are then attached to N_0, I, R. Norm values, exponent budgets, and local-domain comparisons reach the Real seal only through those displayed rows, so they cannot be replaced by quotient function equality or global measurability completion.

Finally read H, C, P, L. These rows transport, replay, source, and name the same finite packet, while M remains downstream of the displayed analytic rows. Hence the listed rows exhaust the local NameCert surface. □

Theorem 5911.3 (SobolevSpace completion handoff)**.** *Every completion-facing read exported by an accepted* $\mathsf{SobolevSpace}^{\uparrow}$ *carrier factors through the finite route*

$$F, D, N_0, I \longmapsto R \longmapsto M \longmapsto H, C, P, L.$$

The handoff supplies only displayed source-function windows, weak-derivative actions, norm and integrability budgets, Real readbacks, completion routing, transport, replay, provenance, and local naming. It does not supply a quotient of functions, a selected equivalence class, a global distribution dual, compact embedding, trace theory, PDE solvability, countable choice, or an ambient Banach-space completeness theorem.

Proof. Begin with a completion-facing request for an accepted carrier. The request must first expose the source-function row F and the weak-derivative row D, because those rows determine which function windows and derivative actions can enter the Sobolev norm.

Next the request reads N_0 and I. These rows bind the norm, exponent, and local integrability budgets to the same displayed function and derivative data, and the Real readback row R is the only scalar seal available to the route.

The completion handoff M is read after those rows. Transport and replay through H, C preserve the route, while P, L record provenance and local naming. Since the excluded host objects are not carrier coordinates, no completion-facing consumer can bypass the displayed route. □

Theorem 5911.4 (SobolevSpace dual test-action handoff)**.** *Every dual-facing consumer of an accepted* $\mathsf{SobolevSpace}^{\uparrow}$ *carrier*

$$S = (F, D, N_0, I, M, R, H, C, P, L)$$

must first read $F, D, N_0, I, R, H, C, P, L$ *before it can expose a test-action value or dual budget. Consequently a dual-facing route exported from this packet cannot bypass the displayed source-function windows, weak-derivative actions, norm and integrability budgets, scalar seal, transport, replay, provenance, and local naming.*

Proof. Project the accepted carrier. The source row F names the function windows available to any dual-facing request, and D supplies the weak derivative actions and test-action coordinates that the request may inspect.

Next the route reads N_0 and I. These rows bind the norm, exponent, and integrability budgets to the same source and derivative data; the Real row R is the only scalar seal for action values and budget comparisons.

Finally read H, C, P, L. These rows transport, replay, source, and name the finite route without adding host distribution spaces, quotient function equality, Hahn–Banach extension, countable choice, compact embedding, or PDE solvability. □

Falsifiable prediction: An accepted $\mathsf{SobolevSpace}^{\uparrow}$ completion-facing read that reaches $\mathsf{MetricCompletion}^{\uparrow}$ without first exposing source-function windows, WeakDerivativeUp rows, NormUp and integrability budgets, RealUp readbacks, hsame transport, Cont replay, Pkg provenance, and local naming refutes the carrier surface of Definition 5911.1.

Independence witness: weak-derivative, norm, metric-completion, real: no listed sibling is bijective to $\mathsf{SobolevSpace}^{\uparrow}$ because this packet jointly binds source-function windows, weak-derivative actions, norm and integrability budgets, completion handoff, Real readback, transport, replay, provenance, and local naming in one Sobolev-space carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{SobolevSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{SobolevSpace}^{\uparrow}$ packet is generated from source-function windows, WeakDerivativeUp rows, NormUp and integrability budgets, MetricCompletionUp handoff data, RealUp readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SobolevSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5911.1, Definition 5911.2, and Definition 5911.3 seed the finite Sobolev-space carrier downstream of weak derivatives, norm budgets, completion handoff, and Real readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SobolevSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of functions, global measurability completion, distribution duality, compact embedding, trace theory, PDE solvability, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, weak-derivative coverage, norm and integrability exactness, completion nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SobolevSpaceUp.

Chapter 5912

A Concrete Naming Certificate for $\mathsf{MetricCompletionSeparableCore}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley on metric completion, the MetricCompletionSeparableCor packet records the finite L10 handoff by which countable dense data remains visible to completion consumers. It reads the metric carrier of chapter 57, the indexed dense rows of chapter 1566, the separability surface of chapter 1458, the completion interface of chapter 1506, the dense-image packet of chapter 1985, the dense embedding of chapter 3351, the finite windows of chapter 126, the regular-rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet is a displayed separability-to-completion core; it does not use quotient completion equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a host dense-image theorem.

Definition 5912.1 (Metric completion separable core carrier)**.** *A* $\mathsf{MetricCompletionSeparableCore}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, D, W, E, I, J, Q, R, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row, carrying the finite distance comparisons used by dense and completion-facing reads.*
2. *D is the* $\mathsf{CountableDenseSubset}^{\uparrow}$ *and* $\mathsf{SeparableMetric}^{\uparrow}$ *dense enumeration row over M.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the source indices and completion entries inspected by the current consumer.*
4. *E is the* $\mathsf{MetricCompletion}^{\uparrow}$ *entry row, exposing completion names only as displayed finite Cauchy-entry data.*
5. *I is the* $\mathsf{DenseImageCompletion}^{\uparrow}$ *row, recording that displayed source entries approximate the completion read.*
6. *J is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *row, tying the dense image to the source metric and separated comparison route.*
7. *Q is the separated comparison row, recording zero-distance and apartness-facing comparisons only through finite displayed tolerances.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational observations opened by W.*

9. *L is the* $\mathsf{Real}^{\uparrow}$ *tolerance ledger, sealing the finite distance and approximation budgets read by R.*
10. *H records componentwise* hsame *transport for the metric, dense enumeration, completion-entry, dense-image, dense-embedding, separated comparison, readback, tolerance, replay, provenance, and naming rows.*
11. *C records displayed* Cont *replay from source metric inspection through dense enumeration windows, completion-entry reads, dense-image exposure, separated comparison, rational readback, and Real tolerance sealing.*
12. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionSeparableCore}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CountableDenseSubset}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{DenseImageCompletion}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionSeparableCore}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion equality, a selected dense subsequence, countable-choice enumeration, an ambient completed metric object, or Real completeness outside the displayed tolerance ledger.

Lean4 ✓ `BEDC.Derived.MetricCompletionSeparableCoreUp.MetricCompletionSeparableCoreTasteGate`
`single carrier alignment`

Theorem 5912.2 (Metric completion separable core NameCert obligations)**.** *For every accepted* $\mathsf{MetricCompletionSeparableCore}^{\uparrow}$ *carrier $S = (M, D, W, E, I, J, Q, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletio}}$ *surface consists exactly of carrier admission for the source metric row, dense enumeration row, finite stream windows, completion entry row, dense-image row, dense-embedding row, separated comparison row, regular-rational readback, Real tolerance ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing separability read must expose $M, D, W, E, I, J, Q, R, L, H, C, P, N$ before it can be consumed.*

Proof. Project the carrier of Definition 5912.1. The only source and density coordinates are M, D, W, so a separability read cannot inspect completion data before the metric and dense enumeration windows are displayed.

The completion-facing rows are then read in order. The entry row E exposes completion names as finite Cauchy-entry data, while I and J expose the dense-image and dense-embedding routes that keep the source metric visible to completion consumers.

The comparison and readback rows are downstream of the same windows. The row Q records separated comparison data, R reads the regular rational observations opened by W, and L seals the resulting Real tolerance ledger.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no other coordinate occurs in the carrier, the local NameCert surface cannot import quotient completion equality, countable choice, selected limits, ambient Real completeness, or a host dense-image theorem. □

Theorem 5912.3 (Metric completion separable core density handoff)**.** *Let $S = (M, D, W, E, I, J, Q, R, L, H, C, P,$ be an accepted* $\mathsf{MetricCompletionSeparableCore}^{\uparrow}$ *carrier. Every* $\mathsf{MetricCompletion}^{\uparrow}$ *consumer that asks for separability of the completion receives the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{CountableDenseSubset}^{\uparrow},\ \mathsf{SeparableMetric}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{DenseImageCompletion}^{\uparrow},\ \mathsf{M}$$

Thus the completion-side dense read is generated by displayed source dense data, finite observation windows, regular-rational readback, Real tolerance ledgers, dense-image exposure, and dense-embedding comparison rows, not by quotient representatives, selected completion points, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a completion-facing density request. The source of dense data is D over the metric row M, and the only observations available to the request are the finite stream windows W.

Read those windows through R and L. Regular-rational readback supplies the finite rational observations, and the Real tolerance ledger records the approximation budgets used by the completion-side consumer.

The handoff to completion is through E, I, J, Q. The completion entry row opens the finite target entry, the dense-image row records the source approximation, the dense-embedding row keeps the source and target tied to one metric route, and the separated comparison row records only displayed tolerances.

The structural rows H, C, P, N preserve this route. Consequently the completion consumer receives a finite separability handoff from the source dense enumeration to the completion read, with no coordinate for quotient equality, selected limits, countable-choice enumeration, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{MetricCompletionSeparableCore}^{\uparrow}$ completion-facing density read factors through the source metric, countable dense schedule, finite StreamName windows, completion entry row, dense-image row, dense-embedding row, separated comparison, RegSeqRat readback, Real tolerance ledger, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: metric, countable-dense-subset, separablemetric, metriccompletion, dense-image-completion, metric-completion-dense-embedding, streamname, regseqrat, real: MetricCompletionSeparableCo is not bijective to any listed sibling because it carries the complete separability-to-completion handoff in one packet, with dense enumeration, completion entry, dense image, separated comparison, readback, and tolerance rows visible together.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionSeparableCore}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionSeparableCore}^{\uparrow}$ packet is generated from a source Metric row, CountableDenseSubset and SeparableMetric dense enumeration rows, finite StreamName windows, MetricCompletion entry rows, DenseImageCompletion and MetricCompletionDenseEmbedding rows, separated comparison rows, RegSeqRat readback, Real tolerance ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionSeparableCore}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5912.1, Definition 5912.2, and Definition 5912.3 seed the finite separability-to-completion route from countable dense source data to completion-facing dense consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionSeparableCore}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense enumeration window replay, completion-entry routing, dense-image exactness, separated comparison stability, regular-rational readback, Real tolerance exactness, transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionSeparableCoreUp.

Chapter 5913

A Concrete Naming Certificate for $\mathsf{BaireMeasurableFunction}^{\uparrow}$

Following classical descriptive set theory, the $\mathsf{BaireMeasurableFunction}^{\uparrow}$ packet records a real-facing Baire-measurable map by finite inverse-image ledgers for Baire-cylinder generators. It sits between the cylinder rows of chapter 1685, the pointwise-limit ledger of chapter 1604, the prefix source of chapter 334, and the measurable preimage discipline of chapter 3461. The packet names generator-level Baire measurability only through displayed preimage rows; it does not add sigma-algebra completion, quotient equality of functions, a selected representative, or a choice principle.

Definition 5913.1 (BaireMeasurableFunction carrier)**.** *A* $\mathsf{BaireMeasurableFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Y, B, G, R, O, H, C, P, N)$$

with the following displayed rows:

1. *X is the source-context row, read through* $\mathsf{BaireSpace}^{\uparrow}$ *prefixes or through a real-facing Baire source supplied by* $\mathsf{RealBaireCylinder}^{\uparrow}$*.*
2. *Y is the target real-observation row, exposing only displayed real-value windows and Baire-cylinder target events.*
3. *B is the Baire-cylinder generator ledger, listing the target* $\mathsf{RealBaireCylinder}^{\uparrow}$ *rows whose inverse images are inspected.*
4. *G is the graph-observation row tying displayed source windows to displayed target real windows.*
5. *R is the inverse-image ledger assigning each displayed generator in B to a displayed source event row over X.*
6. *O is the Baire-one handoff row, recording when the same finite preimage route is supplied by a* $\mathsf{BaireOneFunction}^{\uparrow}$ *approximation ledger.*
7. *H records componentwise* hsame *transport for the source, target, generator, graph, inverse-image, handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a target generator request through B, R, X, G, O.*
9. *P is the* Pkg *provenance over* $\mathsf{BaireMeasurableFunction}^{\uparrow}$*,* $\mathsf{RealBaireCylinder}^{\uparrow}$*,* $\mathsf{BaireOneFunction}^{\uparrow}$*,* $\mathsf{BaireSpace}^{\uparrow}$*,* $\mathsf{MeasurableFunction}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireMeasurableFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for a completed sigma algebra, countable union closure beyond displayed generator ledgers, almost-everywhere equality, selected representatives, or ambient function-space equality.

Lean4 ✓ `BEDC.Derived.BaireMeasurableFunctionUp.BaireMeasurableFunctionTasteGate single carrier alignment`

Theorem 5913.2 (BaireMeasurableFunction NameCert obligations)**.** *For every accepted* $\mathsf{BaireMeasurableFunction}^{\uparrow}$ *carrier* $F = (X, Y, B, G, R, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BaireMeasurableFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for* F*, target Baire-cylinder generator admission through* B*, inverse-image ledger exposure through* R*, source-event readback through* X*, graph-observation compatibility through* G*, Baire-one handoff compatibility through* O*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. Every measurable-map sibling read must factor through the displayed generator-to-preimage route before it may cite* $\mathsf{MeasurableFunction}^{\uparrow}$*.*

Proof. Project the carrier of Definition 5913.1. The target generators available to the packet are exactly the rows in B, and each such row is a finite $\mathsf{RealBaireCylinder}^{\uparrow}$ read rather than an ambient Borel family.

Read the inverse-image ledger R. It assigns each displayed target generator to a displayed source event over X, while the graph row G supplies the finite observation compatibility between source windows and target real windows.

The Baire-one row O is only a handoff for the same displayed route. It can replay a $\mathsf{BaireOneFunction}^{\uparrow}$ approximation ledger, but it cannot add a separate function-space representative or a sigma-algebra completion.

Finally replay H, C, P, N. These structural rows transport, replay, source, and name the same finite generator ledger. Since no other coordinate is present, the NameCert surface exports no host inverse-image operation, no completion principle, no quotient of functions, and no choice of representatives. □

Theorem 5913.3 (Baire measurable generator route)**.** *Every accepted target-generator read of a* $\mathsf{BaireMeasurableFunction}^{\uparrow}$ *packet factors through the finite route*

$$B \longmapsto R \longmapsto X, G, O \longmapsto H, C, P, N.$$

Thus the public Baire-measurability claim is an inverse-image ledger for displayed Baire-cylinder generators, not a sigma-algebra completion theorem and not an ambient measurable-function quotient.

Proof. Start with a target request. By Definition 5913.1, the request enters through the displayed generator ledger B and not through a host collection of all Baire sets.

The inverse-image row R then supplies the source-side event row. The source context X and graph row G keep the source and target observations paired, while O records only the Baire-one handoff cases that use the same finite route.

The structural rows H, C, P, N preserve and replay this route. Therefore every public read remains a finite generator-ledger read and cannot export sigma-algebra completion, choice of representatives, almost-everywhere equality, or ambient function equality. □

Falsifiable prediction: A $\mathsf{BaireMeasurableFunction}^{\uparrow}$ consumer that claims Baire measurability without displaying target Baire-cylinder generators, inverse-image rows, source-event readback,

graph compatibility, componentwise hsame, Cont, Pkg, and local NameCert rows refutes the carrier of Definition 5913.1.

Independence witness: realbairecylinder, baireonefunction, bairespace, measurablefunction: $\mathsf{BaireMeasurableFunction}^{\uparrow}$ is not bijective to any listed sibling because it binds target Baire-cylinder generators, inverse-image ledgers, source prefix rows, graph observations, Baire-one handoff rows, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BaireMeasurableFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireMeasurableFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5913.1, Definition 5913.2, and Definition 5913.3 seed the finite Baire-measurable inverse-image ledger over displayed Baire-cylinder generators.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireMeasurableFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close sigma-algebra completion, quotient equality of functions, almost-everywhere equality, selected representatives, full Borel measurability, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, Baire-cylinder generator exposure, inverse-image exactness, graph compatibility, Baire-one handoff compatibility, componentwise transport, and measurable-function sibling nonescape for BEDC.Derived.BaireMeasurableFunctionUp.

Constructive story: A $\mathsf{BaireMeasurableFunction}^{\uparrow}$ packet is generated from source-context, target-observation, Baire-cylinder generator, graph-observation, inverse-image, Baire-one handoff, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows.

Chapter 5914

A Concrete Naming Certificate for $\mathsf{DiscoveryPipelineCalculus}^{\uparrow}$

The $\mathsf{DiscoveryPipelineCalculus}^{\uparrow}$ packet realizes the automated theory-discovery pipeline of chapter 9410 as a finite NameCert surface. It sits beside theorem-DNA scoring in chapter 9408, theorem-genome lineage in chapter 9409, theory-stability admission in chapter 9459, and the compiler audit inventory of chapter 9407. The packet names discovery only when finite theory-state, automation-record, genome, score, lineage, classifier-shift, gate, and refusal rows are visible.

Definition 5914.1 (DiscoveryPipelineCalculus carrier)**.** *A* $\mathsf{DiscoveryPipelineCalculus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (T, A, G, S, L, Q, K, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the certified theory-state row, displaying source, pattern, ledger, classifier, and semantic NameCert coordinates.*
2. *A is the automation-record row, listing generated material without identifying raw record growth with discovery.*
3. *G is the theorem-genome extractor row, exposing theorem-DNA completeness before a theorem-like object is scored or selected.*
4. *S is the score-certificate row, carrying public weights, budget values, and the displayed comparison used by the pipeline.*
5. *L is the lineage ledger row, recording parent, child, and transition-kind edges.*
6. *Q is the classifier-shift row, separating classifier change from record growth, score compression, and recombination.*
7. *K is the discovery-gate row, admitting only claims whose kind matches the displayed evidence.*
8. *R is the refusal and demotion row, naming unpaid discovery, DNA-incomplete, unscored, unledgered, and prose-only attempts as non-admitted.*
9. *H records componentwise* hsame *transport for the state, automation, genome, score, lineage, classifier, gate, refusal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a pipeline claim through A, G, S, L, Q, K, R and back to the certified theory-state row T.*

11. *P is the* Pkg *provenance over* $\mathsf{DiscoveryPipelineCalculus}^{\uparrow}$*, chapter 9410, chapter 9408, chapter 9409, chapter 9459, chapter 9407,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DiscoveryPipelineCalculus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for self-certified discovery, prose-only novelty, raw output volume, hidden scoring weights, unledgered lineage, or a carrier map that bypasses classifier-shift evidence.

Theorem 5914.2 (DiscoveryPipelineCalculus NameCert obligations)**.** *For every accepted* DiscoveryPipelineCalculus *carrier $D = (T, A, G, S, L, Q, K, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DiscoveryPipelineCalculus}^{\uparrow}}$ *surface consists exactly of certified theory-state admission through T, automation-record exposure through A, theorem-genome extraction through G, score-certificate exposure through S, lineage-ledger exposure through L, classifier-shift evidence through Q, discovery-gate admission through K, refusal and demotion through R, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. A discovery claim is admitted only after classifier-shift evidence and the gate row are both visible.*

Proof. Project the carrier of Definition 5914.1. The certified theory-state row T fixes the state coordinates, while A records generated material without changing the classifier by itself.

The theorem-genome and scoring rows G, S expose the theorem-DNA completeness and public weight account needed for scored claims. The lineage row L records the parent-child route, so selection cannot be read as an unledgered assertion.

The classifier-shift row Q is the discovery-facing boundary. The gate row K consumes Q together with G, S, L and the certified state data before a discovery claim is admitted, while R records the non-admitted cases.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no row identifies raw record growth, score reduction, or prose novelty with discovery, the local NameCert surface is exactly the listed finite ledger. □

Theorem 5914.3 (Discovery admission requires classifier shift)**.** *Every accepted discovery read from a* $\mathsf{DiscoveryPipelineCalculus}^{\uparrow}$ *packet factors through*

$$A, G, S, L, Q, K, R \longmapsto H, C, P, N.$$

In particular, classifier-shift rows Q, not raw automation-record growth in A, are necessary for discovery admission.

Proof. Read the automation-record row A first. It lists generated material, but by Definition 5914.1 it has no coordinate that changes the certified classifier state.

The genome, score, and lineage rows G, S, L supply the audit account for theorem-like objects and their transitions. These rows make a claim reproducible, but they still do not identify record growth with discovery.

The discovery-facing test reaches the classifier-shift row Q and then the gate row K. Only after Q is visible can K admit a discovery claim; the refusal row R records attempts that omit the shift, score, lineage, genome, certificate, or boundary evidence.

The structural rows H, C, P, N preserve this dependency order. Thus discovery admission requires classifier-shift evidence and cannot be obtained from raw record growth alone. □

Theorem 5914.4 (DiscoveryPipelineCalculus audit-map route)**.** *Every accepted discovery claim in a* $\mathsf{DiscoveryPipelineCalculus}^{\uparrow}$ *packet $D = (T, A, G, S, L, Q, K, R, H, C, P, N)$ routes its classifier-shift row Q and discovery-gate row K through the concrete audit-map surfaces of chapter 836 and*

chapter 806 before it is read as a pipeline admission. The audit-map route is a concrete NameCert *dependency carried by P and replayed by C, not a prose-only methodology reference.*

Proof. Project the carrier of Definition 5914.1. The classifier-shift row Q and the discovery-gate row K are read only after the certified theory-state, automation, genome, score, and lineage rows T, A, G, S, L have been displayed.

Apply the admission theorem Definition 5914.3. It forces every accepted discovery read to pass through Q, K, R and then through the structural rows H, C, P, N.

Now read the provenance row P and replay row C against the concrete siblings. The Ground-Compiler audit-map packet of chapter 836 supplies compiler-facing theorem inventory and audit rows, while the audit-map interface of chapter 806 supplies the common audit-map surface. Thus classifier-shift and gate admission are routed through concrete NameCert dependencies before the pipeline reads the claim as admitted. □

Falsifiable prediction: A $\mathsf{DiscoveryPipelineCalculus}^{\uparrow}$ admission trace that accepts discovery from automation-record growth alone, without a classifier-shift row and discovery-gate row, refutes the carrier of Definition 5914.1.

Independence witness: theorem_dna_complexity_scoring, theorem_genome_evolution, theory_stability_taste_gate, groundcompiler_audit_map: $\mathsf{DiscoveryPipelineCalculus}^{\uparrow}$ is not bijective to these siblings because it jointly binds certified theory-state rows, automation records, theorem-genome extraction, public score certificates, lineage, classifier-shift evidence, discovery-gate admission, refusal ledgers, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DiscoveryPipelineCalculus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiscoveryPipelineCalculus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5914.1, Definition 5914.2, and Definition 5914.3 seed the finite admission calculus for automated discovery claims.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiscoveryPipelineCalculus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close automated theorem proving, self-certified discovery, proof generation, hidden scoring, unledgered lineage, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, theorem-genome extraction, public scoring, lineage acyclicity, classifier-shift admission, gate soundness, refusal exactness, and TasteGate compatibility for BEDC.Derived.DiscoveryPipelineCalculusUp.

Constructive story: A $\mathsf{DiscoveryPipelineCalculus}^{\uparrow}$ packet is generated from certified theory-state, automation-record, theorem-genome, score-certificate, lineage, classifier-shift, discovery-gate, refusal, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows.

Chapter 5915

A Concrete Naming Certificate for $\mathsf{LipschitzRetraction}^{\uparrow}$

Following Banach and Bishop–Bridges metric fixed-point and retraction theory, the $\mathsf{LipschitzRetraction}^{\uparrow}$ packet records the finite certificate by which a metric source retracts onto a displayed subcarrier through a Lipschitz graph and an identity-on-subcarrier row. It sits on the L10 metric and complete-space boundary beside the metric source of chapter 57, the complete-service surface of chapter 128, the continuous-map graph route of chapter 130, and the located-apartness Real comparison route of chapter 3564. The packet names a constructive finite retraction certificate; it does not assert a selected nearest point, quotient equality of subspaces, ambient completeness of the source, or a classical choice principle.

Definition 5915.1 (Lipschitz retraction carrier)**.** *A* $\mathsf{LipschitzRetraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, A, K, G, I, M, L, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{Met}^{\uparrow}$ *source row supplying all source-distance witnesses.*
2. *A is the subcarrier row, displaying membership, inclusion into X, and the inherited distance reads used by the retraction.*
3. *K is the Lipschitz-constant ledger, recording a rational bound together with the source and target distance reads compared by that bound.*
4. *G is the retraction graph row, whose source observations lie in X and whose values are admitted by A.*
5. *I is the retraction-identity row, requiring every point already admitted by A to replay through G as the same displayed subcarrier point.*
6. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row available to consumers that later read Cauchy or endpoint data on the subcarrier.*
7. *L is the* $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ *comparison row used when a distance inequality is inspected through located Real and completion readbacks.*
8. *E is the* $\mathsf{ContinuousMap}^{\uparrow}$ *replay row tying the graph G to the finite continuity route induced by the Lipschitz ledger K.*

9. *H records componentwise* hsame *transport for the metric source, subcarrier, Lipschitz ledger, graph, identity, complete-metric service, located-apartness comparison, continuous-map replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a retraction request through $X, A, K, G, I, M, L, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{LipschitzRetraction}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzRetraction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a selected best approximation, quotient subspace equality, ambient completeness theorem, global fixed-point theorem, or classical real-order decision.

Lean4 (definition) `BEDC.Derived.LipschitzRetractionUp.LipschitzRetractionUp`
Lean4 ✓ `BEDC.Derived.LipschitzRetractionUp.LipschitzRetractionTasteGate single carrier alignment`

Theorem 5915.2 (Lipschitz retraction NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzRetraction}^{\uparrow}$ *carrier $R = (X, A, K, G, I, M, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LipschitzRetraction}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tuple, metric-source visibility through X, subcarrier admission and inherited-distance visibility through A, Lipschitz-constant readback through K, graph admission through G, retraction identity through I, complete-metric service access through M, located-apartness Real comparison through L, continuous-map replay through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5915.1. The displayed tuple lists exactly the metric source, subcarrier, Lipschitz ledger, graph, identity, complete-service, located-apartness, continuous-map, transport, replay, provenance, and naming rows.

The source-facing obligations are exhausted by X, A, K, G, I. The metric row supplies distance witnesses, the subcarrier row supplies admissible values, the Lipschitz ledger supplies the bound, the graph row supplies the finite retraction observations, and the identity row forces admitted subcarrier points to replay unchanged.

The consumer-facing obligations are exhausted by M, L, E. A complete-space consumer can inspect only the displayed $\mathsf{CompleteMetric}^{\uparrow}$ service row, a Real comparison can inspect only the $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ row, and a continuity consumer can inspect only the $\mathsf{ContinuousMap}^{\uparrow}$ replay induced by the Lipschitz ledger.

Finally H, C, P, N transport, replay, package, and name this same finite route. Since the carrier has no selected nearest point, quotient equality, ambient completeness theorem, global fixed-point theorem, or classical comparison branch, no such obligation is present in the local certificate. □

Theorem 5915.3 (Lipschitz retraction metric factorization)**.** *Every* $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, *or* $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ *consumer of an accepted* $\mathsf{LipschitzRetraction}^{\uparrow}$ *carrier factors through the finite route*

$$X, A \longmapsto K, G, I \longmapsto E, L, M \longmapsto H, C, P, N.$$

Thus source distances are read in the ambient metric row X, subcarrier values are admitted through A, the Lipschitz graph and identity rows are checked before any continuous-map or complete-service handoff, and located Real inequalities are exposed only through the displayed $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ *comparison route. The factorization exports a Lipschitz retraction certificate, not a choice-selected projection, quotient subspace equality, or ambient completeness claim.*

Proof. Start with the NameCert obligations of Definition 5915.2. Any consumer first receives the metric source row X and the subcarrier row A, since these are the only rows that can supply source distances and admitted retraction values.

The retraction data then pass through K, G, I. The Lipschitz ledger bounds graph distances, the graph row records the finite observations, and the identity row verifies that points already in the subcarrier replay as themselves.

Only after those rows are displayed can a consumer read E, L, M. The continuous-map row is induced by the same Lipschitz ledger, the located-apartness comparison row reads Real-facing inequalities through the finite readback bridge, and the complete-metric service row is a displayed downstream service rather than an ambient completeness theorem.

Transport, replay, provenance, and local naming are then carried by H, C, P, N. These rows preserve the factorization but add no selected projection, quotient equality, host equality, or classical branch. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzRetraction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzRetraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5915.1, Definition 5915.2, and Definition 5915.3 seed the finite Lipschitz retraction route over metric source, subcarrier, graph, identity, continuous-map replay, located-apartness comparison, and complete-service rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LipschitzRetraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected nearest points, quotient subspace equality, ambient completeness, global fixed-point existence, Lean verification, bridge checking, or classical real-order decision.

Upgrade path: Obligation closure requires checked carrier admission, metric-source visibility, subcarrier admission, Lipschitz-ledger readback, graph admission, retraction identity, continuous-map replay, located-apartness comparison, complete-metric service access, transport, replay, provenance, and local naming for BEDC.Derived.LipschitzRetractionUp.

Constructive story: A $\mathsf{LipschitzRetraction}^{\uparrow}$ packet is generated from a MetricSpace source row, a subcarrier row, a Lipschitz-constant ledger, a retraction graph, a retraction identity row, a CompleteMetric service row, a LocatedApartnessRealBridge comparison row, a ContinuousMap replay row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

$\mathsf{FiniteStream}^{\uparrow}$ routes finite request rows from chapter 36 into the finite-window discipline of chapter 126, before RegSeqRat and Real-facing consumers inspect the child files below.

Chapter 5916

A Concrete Naming Certificate for $\mathsf{FiniteStream}^{\uparrow}$

Following Bishop and Bridges on finite sequences and finite observation records, the $\mathsf{FiniteStream}^{\uparrow}$ packet records the finite schedule object that sits between $\mathsf{List}^{\uparrow}$ spine data and the countable-name windows of $\mathsf{StreamName}^{\uparrow}$. It packages only the finitely requested observations needed by downstream regular-rational and real-name consumers. The chapter is a finite observation-schedule neighbour of chapter 36, chapter 126, chapter 301, chapter 291, and chapter 38; it does not export an infinite stream, quotient stream equality, a selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5916.1 (FiniteStream carrier)**.** *A* $\mathsf{FiniteStream}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (Q, L, W, R, D, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite request row in* BHist*, recording the ordered observation indices and payload requests actually inspected by the consumer.*
2. *L is the* $\mathsf{List}^{\uparrow}$ *prefix spine that stores those requests as a finite constructor-generated list rather than as a host array or hidden stream segment.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window handoff row, exposing exactly the window generated from Q and L.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback boundary available to regular-rational consumers only after the finite window W has been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the displayed dyadic radii, comparison cells, and finite precision budget attached to the window.*
6. *H records componentwise* hsame *transport for the request row, list prefix spine, StreamName window, RegSeqRat readback boundary, DyadicRatCore tolerance row, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a finite request through Q, L, W, R, D, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteStream}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{FiniteStream}^\uparrow}$ *row.*
The classifier compares accepted packets only through the rows $Q, L, W, R, D, H, C, P, N$. No coordinate stores a completed stream, host stream equality, selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 5916.2 (FiniteStream NameCert obligations)**.** *For every accepted* $\mathsf{FiniteStream}^\uparrow$ *carrier*

$$F = (Q, L, W, R, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteStream}^\uparrow}$ *surface consists exactly of carrier admission for the finite request row,* $\mathsf{List}^\uparrow$ *prefix spine,* $\mathsf{StreamName}^\uparrow$ *finite-window handoff,* $\mathsf{RegSeqRat}^\uparrow$ *readback boundary,* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The finite-window exactness clause requires W to expose only the observations listed by Q and represented by L. The StreamName handoff clause requires every downstream countable-name read to pass through W before it can reach R or D. The RegSeqRat and Real nonescape clause requires every regular-rational or* $\mathsf{Real}^\uparrow$*-facing consumer to remain downstream from $Q, L, W, R, D, H, C, P, N$. The provenance exhaustion clause requires P and N to name only this finite route.*

Lean4 ✓ `BEDC.Derived.FiniteStreamUp.FiniteStreamCarrier namecert obligations`

Proof. Project the carrier of Definition 5916.1. Its displayed inventory is exactly the finite request row, the finite list spine, the StreamName window, the regular-rational readback boundary, the dyadic tolerance row, and the structural rows H, C, P, N.

Finite-window exactness is read from Q, L, W. The request row lists the observations, the list spine represents them as finite constructor data, and the StreamName handoff exposes precisely that finite window.

The regular-rational and dyadic rows are downstream. A consumer may reach the $\mathsf{RegSeqRat}^\uparrow$ readback boundary R or the $\mathsf{DyadicRatCore}^\uparrow$ tolerance row D only after the finite window W has already been displayed.

Transport, replay, and provenance preserve the same route. Since the carrier contains no completed stream, quotient stream equality, selected limit, countable-choice row, trichotomy branch, or ambient $\mathsf{Real}^\uparrow$ completeness coordinate, no Real-facing consumer can escape the finite packet. □

Theorem 5916.3 (FiniteStream section sibling lock)**.** *Every* $\mathsf{Real}^\uparrow$*-facing consumer of an accepted* $\mathsf{FiniteStream}^\uparrow$ *packet reads the* $\mathsf{StreamName}^\uparrow$ *window W,* $\mathsf{RegSeqRat}^\uparrow$ *boundary R,* $\mathsf{DyadicRatCore}^\uparrow$ *tolerance row D, and downstream* $\mathsf{Real}^\uparrow$ *seal rows only over the same finite request row Q and* $\mathsf{List}^\uparrow$ *spine L. In particular, no sibling packet can replace Q or L while preserving the displayed route*

$$Q, L, W, R, D, H, C, P, N.$$

Proof. Project the carrier of Definition 5916.1. The rows W, R, D are not free-standing analytic objects; they are displayed after the finite request row Q and the finite list spine L.

The displayed Cont replay row C then fixes the request coordinate used by the downstream consumer. Replaying the packet with a different finite request row would leave the listed carrier rows and hence would leave the accepted $\mathsf{FiniteStream}^\uparrow$ packet.

The componentwise hsame transport row H preserves the same coordinate rather than identifying it with an unlisted sibling. Thus any $\mathsf{Real}^\uparrow$-facing read that reaches W, R, D or a Real seal remains locked to the original Q, L route named by P, N. □

Theorem 5916.4 (FiniteStream StreamName dependency route)**.** *Every accepted* $\mathsf{FiniteStream}^{\uparrow}$ *packet consumed by a* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *reader must expose the finite request row* Q*, the* $\mathsf{List}^{\uparrow}$ *prefix spine* L*, and the* $\mathsf{StreamName}^{\uparrow}$ *window* W *before the read can reach the downstream rows*

$$R, D, H, C, P, N.$$

The substantive dependency edge is therefore the finite request/list route into the StreamName window of chapter 126, as displayed by the carrier of Definition 5916.1.

The same finite request row, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and $\mathsf{Real}^{\uparrow}$ seal boundary are consumed by $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ when equality of regular real names is read through finite tail data in chapter 5940.

Proof. Project the carrier of Definition 5916.1. Its first exposed consumer rows are Q, L, W, and the remaining rows R, D, H, C, P, N are displayed only as downstream readback, tolerance, transport, replay, provenance, and naming data.

Use Definition 5916.3. A Real-facing read that reaches W, R, D or a Real seal remains locked to the original Q, L route, so a StreamName, RegSeqRat, DyadicRatCore, or Real reader cannot replace the finite request/list surface with an unlisted sibling.

Thus the dependency is not an ambient infinite-stream dependency. It is the displayed finite route from Q and L into the $\mathsf{StreamName}^{\uparrow}$ window W, after which the downstream rows may be consumed.

The same finite request/list/window route is the route consumed by chapter 8396 before cluster-witness readback can reach $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$. That consumer therefore receives the displayed Q, L, W boundary as an actual dependency row, not as a replaceable narrative shortcut. □

Theorem 5916.5 (FiniteStream StreamName route)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteStream}^{\uparrow}$ *packet must display the finite request row* Q*, the* $\mathsf{List}^{\uparrow}$ *prefix spine* L*, and the finite-window row* W *before it can reach any* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *row. The only admissible route is*

$$Q, L, W \longmapsto R, D, H, C, P, N,$$

so the downstream regular-rational, dyadic-tolerance, and real-seal rows remain locked to the same finite request/list packet.

Proof. Project the carrier of Definition 5916.1. The rows Q, L, W are the finite request, list-spine, and StreamName-window data; the rows R, D, H, C, P, N are downstream readback, tolerance, transport, replay, provenance, and naming data.

Apply Definition 5916.3. It prevents a downstream $\mathsf{Real}^{\uparrow}$-facing read from replacing Q or L while keeping the displayed route.

Now apply Definition 5916.4. It forces any StreamName, RegSeqRat, DyadicRatCore, or Real reader to pass through Q, L, W before the downstream rows are consumed. Therefore every StreamName consumer sees the finite route rather than an ambient infinite stream or an unlisted sibling packet. □

Theorem 5916.6 (FiniteStream Real-seal forward link)**.** *Every* $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteStream}^{\uparrow}$ *packet must read the finite request row* Q*,* $\mathsf{List}^{\uparrow}$ *spine* L*,* $\mathsf{StreamName}^{\uparrow}$ *window* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary in that order, with transport, replay, provenance, and local naming supplied*

only by H, C, P, N. The downstream sibling route is the regular-tail equality surface of chapter 5940, which consumes finite request windows rather than an ambient completed stream.

Proof. Project the carrier of Definition 5916.1. Its Real-facing rows are downstream from the displayed finite request, list spine, StreamName window, regular-rational readback, and dyadic tolerance rows.

Use the StreamName route of Definition 5916.5. It forces every StreamName-facing read to expose Q, L, W before R, D, H, C, P, N can be consumed.

Apply the finite-window factorization of Definition 5916.11. The factorization identifies the same ordered route as the only admissible path toward RegSeqRat or Real-facing finite-window data. Therefore a $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer receives a finite request-window seal, not quotient equality of real names, a selected limit, countable choice, or ambient Real completeness. □

Theorem 5916.7 (FiniteStream prefix-window Real handoff)**.** *An accepted* $\mathsf{FiniteStream}^{\uparrow}$ *prefix packet can be consumed by a Real-facing route only after the* $\mathsf{List}^{\uparrow}$ *finite row L, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary have all been displayed over the same finite request row Q. The handoff preserves componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming through H, C, P, N, and it exports no infinite stream, quotient stream equality, selected limit, countable choice, trichotomy, or ambient Real completeness.*

Proof. Project the carrier of Definition 5916.1. Its Real-facing route is the displayed packet $Q, L, W, R, D, H, C, P, N$, with the Real seal available only downstream from the finite request, list spine, StreamName window, regular readback, and dyadic tolerance rows.

Use the pointwise stream forward route, Definition 5916.8. It forces any pointwise or StreamName consumer of the finite prefix to expose Q, L, W before readback can reach RegSeqRat, DyadicRatCore, or Real-facing rows.

Apply the Real-seal forward link, Definition 5916.6, and the finite-window factorization, Definition 5916.11. Together they keep R and D downstream from the finite prefix window and keep the terminal Real boundary downstream from the displayed readback route. Thus a Real-facing consumer receives a finite prefix-window handoff rather than an ambient completed stream or selected limit. □

Theorem 5916.8 (FiniteStream pointwise stream forward route)**.** *Every pointwise stream consumer of an accepted* $\mathsf{FiniteStream}^{\uparrow}$ *packet, in particular a* $\mathsf{PointwiseStreamName}^{\uparrow}$ *reader of chapter 6084, must first expose the finite request row Q, the* $\mathsf{List}^{\uparrow}$ *spine L, and the* $\mathsf{StreamName}^{\uparrow}$ *finite window W. Only after that displayed window route is public may the readback reach* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *rows.*

Proof. Project the carrier of Definition 5916.1. Its finite observation surface begins with Q, L, W, so a pointwise reader has no entry point into the downstream rows before the request row, list spine, and window row are visible.

Use the StreamName route of Definition 5916.5. It forces every StreamName-facing consumer to display the same Q, L, W route before any regular-rational readback, dyadic tolerance row, or Real seal can be consumed.

Finally compare with the pointwise stream carrier of Definition 6084.1. A $\mathsf{PointwiseStreamName}^{\uparrow}$ read starts from a certified StreamName source and requested finite point windows; when that source is supplied by $\mathsf{FiniteStream}^{\uparrow}$, those windows are exactly the displayed finite request/list/window

route. Thus the pointwise consumer receives finite BEDC window data, not an ambient infinite stream, quotient stream equality, selected representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5916.9 (FiniteStream window concatenation)**.** *Let*

$$F_i = (Q_i, L_i, W_i, R_i, D_i, H_i, C_i, P_i, N_i)$$

for $i = 0, 1$ be accepted $\mathsf{FiniteStream}^{\uparrow}$ *packets whose endpoint window rows match, so the final displayed row of W_0 is the initial displayed row of W_1 under the componentwise* hsame *transport. Then the concatenated finite observation schedule is accepted as a* $\mathsf{FiniteStream}^{\uparrow}$ *packet whose* $\mathsf{StreamName}^{\uparrow}$ *consumer reads the first finite window, then the second finite window, before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal is exposed. The concatenated route remains finite:*

$$Q_0, Q_1, L_0, L_1, W_0, W_1 \longmapsto R, D, H, C, P, N.$$

Proof. Project the two carrier rows. The request rows Q_i, list spines L_i, and StreamName windows W_i are the only schedule data available before downstream readback.

Use the matching endpoint window rows to compose the finite lists. Concatenate the displayed request rows and their $\mathsf{List}^{\uparrow}$ spines, identifying the shared endpoint only through the given componentwise hsame transport.

The downstream rows are replayed componentwise. The transport row preserves the two windows, the displayed Cont replay reads W_0 and then W_1, and the provenance and local naming rows record the same finite route.

Thus the consumer reaches any $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ seal only after both finite windows have been displayed. No infinite stream, selected limit, quotient stream equality, or ambient completeness row is exposed by the concatenation. □

Theorem 5916.10 (FiniteStream product window)**.** *Given two accepted* $\mathsf{FiniteStream}^{\uparrow}$ *packets over displayed rows*

$$F_i = (Q_i, L_i, W_i, R_i, D_i, H_i, C_i, P_i, N_i)$$

for $i = 0, 1$, a product finite-window read is admissible only by exposing both request rows Q_0, Q_1, both $\mathsf{List}^{\uparrow}$ *spines L_0, L_1, and the componentwise* $\mathsf{StreamName}^{\uparrow}$ *product window $W_0 \times W_1$ before any downstream row is consumed. The product route then reads the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, componentwise* hsame *transports, displayed* Cont *replays,* Pkg *provenance rows, and local* NameCert *rows for the same two finite packets. It exports no host product stream, no quotient stream equality, no selected limit, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the two carriers from Definition 5916.1. Each carrier exposes its own finite request row, list spine, StreamName window, regular-rational readback, dyadic tolerance row, transport, replay, provenance, and local naming.

Apply Definition 5916.3 separately to the two packets. The lock prevents either downstream read from replacing Q_i or L_i while keeping the displayed StreamName, RegSeqRat, DyadicRatCore, or Real-facing route.

Next use Definition 5916.4 and Definition 5916.5. They require each component window to pass through Q_i, L_i, W_i before its readback and tolerance rows are consumed.

The product window is therefore formed only after both component routes are visible. Pair the two displayed StreamName windows componentwise, then read R_0, R_1, D_0, D_1, H_0, H_1, C_0, C_1, P_0, P_1, and N_0, N_1 along the same finite request/list routes. Since neither carrier contains a host product stream, quotient stream equality, selected limit, or ambient completeness coordinate, the paired read remains a finite product-window route. □

Theorem 5916.11 (FiniteStream finite-window factorization)**.** *Every accepted* $\mathsf{FiniteStream}^{\uparrow}$ *packet consumed by a* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *finite-window route factors through the list-indexed finite request surface*

$$Q, L, W, R, D, H, C, P, N.$$

The factorization first exposes the finite request row Q *and* $\mathsf{List}^{\uparrow}$ *prefix spine* L*, then the displayed* $\mathsf{StreamName}^{\uparrow}$ *window* W*, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback boundary* R *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and finally the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. It exports no infinite stream, quotient stream equality, countable choice, selected limit, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows from Definition 5916.1. The packet inventory gives $Q, L, W, R, D, H, C, P, N$ and no coordinate outside that finite list.

Use the StreamName route of Definition 5916.5. It forces every StreamName-facing consumer to display Q, L, W before the downstream rows are available.

Next use the product-window theorem, Definition 5916.10, in the singleton component case. The same argument that blocks a product read from bypassing its two request/list surfaces blocks a one-window read from bypassing its single request/list surface.

It remains to identify the unavailable coordinates. The carrier contains no completed stream, quotient stream equality, countable-choice schedule, selected limit, or ambient Real completeness row, so the finite-window route factors exactly through the displayed request, window, readback, transport, replay, provenance, and naming rows. □

Falsifiable prediction: Every accepted $\mathsf{FiniteStream}^{\uparrow}$ read is refuted if it reaches a $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer without displaying the finite request row, $\mathsf{List}^{\uparrow}$ prefix spine, finite-window handoff, regular-rational readback boundary, dyadic tolerance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: list, streamname, regseqrat, dyadicratcore, real: $\mathsf{FiniteStream}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite request row, a List prefix spine, a StreamName window handoff, RegSeqRat readback boundary, DyadicRatCore tolerance row, transport, replay, provenance, and local naming as one finite schedule packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteStream}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteStream}^{\uparrow}$ packet is generated from finite BHist request rows, a ListUp prefix spine, a StreamName finite-window handoff, a RegSeqRat readback boundary, a DyadicRatCore tolerance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteStream}^{\uparrow}}$, seed)

Scope closed: Definition 5916.1, Definition 5916.2, Definition 5916.3, and Definition 5916.4 seed the finite observation-schedule route between List spines and StreamName finite windows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteStream}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite stream equality, selected limits, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite request admission, List prefix exactness, StreamName handoff exactness, RegSeqRat and DyadicRatCore boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteStreamUp.

Theorem 5916.12 (FiniteStream pointwise metric forward route)**.** *Every* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *consumer that reads a* $\mathsf{FiniteStream}^{\uparrow}$ *packet must first consume the finite request row, list prefix spine, and finite-window handoff of Definition 5916.1. The route then reaches chapter 4139 only through the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows. Thus the pointwise metric read receives finite stream windows as finite BEDC data and does not import an*

infinite stream, quotient stream equality, selected representative, countable choice, or ambient Real completeness.

Proof. Project the finite stream carrier of Definition 5916.1. The rows $Q, L, W, R, D, H, C, P, N$ display the finite request, list prefix, StreamName window, regular-rational readback, dyadic tolerance row, and structural evidence before any downstream consumer is visible.

Use the section sibling lock of Definition 5916.3. It keeps every Real-facing read attached to the same finite request row and list spine.

The pointwise metric chapter consumes exactly that finite-window route. Since the accepted packet has no coordinate for an infinite stream, quotient stream equality, selected representative, choice schedule, or ambient completeness, the forward route exports only the finite window surface. □

Theorem 5916.13 (FiniteStream prefix-cover determinacy)**.** *Every* $\mathsf{FiniteStream}^{\uparrow}$ *prefix-cover read offered to a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer first exposes the finite request row* Q*, the* $\mathsf{List}^{\uparrow}$ *prefix spine* L*, the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the local structural rows* H, C, P, N *of Definition 5916.1. The dependency route is read through chapter 126, chapter 301, chapter 291, and chapter 38; no downstream consumer receives an ambient stream, selected limit, quotient stream equality, countable-choice schedule, or detached real-completeness witness.*

Proof. Project the accepted $\mathsf{FiniteStream}^{\uparrow}$ carrier of Definition 5916.1. Its finite request row Q and $\mathsf{List}^{\uparrow}$ prefix spine L name the prefix-cover domain before any window is exported.

Read the StreamName, RegSeqRat, and DyadicRatCore rows next. The window row W is the only StreamName surface available to the consumer, the readback row R supplies the regular-rational interpretation, and the tolerance row D fixes the dyadic comparison budget.

Finally apply the existing NameCert obligations and sibling routes in the chapter. The structural rows H, C, P, N preserve the same finite route through the cited StreamName, RegSeqRat, DyadicRatCore, and Real chapters, so a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer cannot bypass the prefix cover or replace it with an ambient completed stream. □

Theorem 5916.14 (FiniteStream prefix-refinement window exhaustion)**.** *Every accepted* $\mathsf{FiniteStream}^{\uparrow}$ *packet consumed by a* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *reader factors through the same finite request row* Q *and list prefix row* L*. Any refinement of the requested window must display the prefix inclusion before downstream rows* W, R, D, H, C, P, N *are consumed. The route is read through chapter 126, chapter 301, chapter 291, and chapter 38; it is not an ambient infinite stream, quotient equality, selected limit, or Real completeness fact.*

Proof. Project the finite stream carrier of Definition 5916.1. The accepted packet exposes the finite request row and list spine before any StreamName or Real-facing rows are available.

Use the section sibling lock, Definition 5916.3. It prevents a downstream consumer from replacing Q or L while preserving the same StreamName, RegSeqRat, DyadicRatCore, or Real-facing route.

Now apply the StreamName dependency route, Definition 5916.4. A reader that reaches W, R, D, H, C, P, N must first pass through the displayed finite schedule. A refined window therefore has to show its prefix inclusion against the original L before those downstream rows can be consumed.

The sibling chapters supply only the named downstream surfaces: StreamName gives the finite window, RegSeqRat gives the regular readback, DyadicRatCore gives tolerance data, and Real

gives the terminal seal. None supplies a second request row or an unlisted list prefix, so the accepted read is exhausted by the displayed prefix-refinement route. □

Theorem 5916.15 (FiniteStream countable-name prefix route)**.** *Every countable-name consumer of an accepted* $\mathsf{FiniteStream}^{\uparrow}$ *finite prefix observation must pass through the displayed finite request row Q, the list prefix row L, the prefix-refinement window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the* $\mathsf{StreamName}^{\uparrow}$ *row W, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{FiniteStream}^{\uparrow}}$ *row before exporting a countable-name observation. The route is local to the finite prefix and does not claim an ambient infinite stream, quotient stream equality, selected real limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First project the existing prefix-refinement window of Definition 5916.14. It forces the consumer to read the same finite request row Q and list prefix row L before any downstream countable-name surface is available.

Next apply prefix-cover determinacy, Definition 5916.13, together with the section sibling lock of Definition 5916.3. These keep the read attached to the displayed prefix and prevent replacement by a second request row, a second list prefix, or an ambient infinite stream.

The remaining rows are then routed through the named dependency children. The $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{StreamName}^{\uparrow}$ window are consumed through Definition 5916.4; the DyadicRatCore tolerance and Real seal are the downstream sibling surfaces named in chapter 291 and chapter 38. Componentwise transport, replay, provenance, and the local NameCert row carry the same finite-prefix route to the exported countable-name observation. □

Finite $\mathsf{FiniteStream}^{\uparrow}$ windows are consumed by the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301 before the downstream $\mathsf{Real}^{\uparrow}$ seal of chapter 38 is available. The dependency route is the displayed finite observation row W together with the carrier rows Q, L, R, D, H, C, P, N of Definition 5916.1; it records no completed stream, quotient stream equality, selected real limit, or ambient real-completeness datum.

Theorem 5916.16 (FiniteStream regular-real tail forward route)**.** *Any* $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteStream}^{\uparrow}$ *packet must expose the finite request row Q, the* $\mathsf{List}^{\uparrow}$ *spine L, the* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback boundary R, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D before reading the regular-real tail-equivalence boundary of chapter 5940. The forward route is therefore*

$$Q, L, W, R, D \longmapsto H, C, P, N,$$

with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row supplied only after the finite request window has been displayed.*

Proof. Project the $\mathsf{FiniteStream}^{\uparrow}$ carrier of Definition 5916.1. The accepted packet stores exactly the finite request row Q, list spine L, StreamName window W, RegSeqRat readback boundary R, DyadicRatCore tolerance row D, and structural rows H, C, P, N.

Apply the StreamName route of Definition 5916.5. It forces any downstream StreamName, RegSeqRat, DyadicRatCore, or Real-facing read to expose Q, L, W before the readback, tolerance, transport, replay, provenance, or naming rows are consumed.

Now read chapter 5940 as the downstream consumer. Its same-real tail boundary consumes regular rational sources through a finite StreamName window and dyadic tolerance ledger, so a $\mathsf{FiniteStream}^{\uparrow}$ source must provide Q, L, W, R, D before that boundary is available. The route supplies finite request-window data only; it does not export quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5916.17 (FiniteStream Real seal dependency route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{FiniteStream}^{\uparrow}$ *packet must expose the carrier rows*

$$Q, L, W, R, D, H, C, P, N$$

from Definition 5916.1 before any terminal $\mathsf{Real}^{\uparrow}$ *seal is consumed. The row* W *is read through the* $\mathsf{StreamName}^{\uparrow}$ *window,* R *through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback boundary, and* D *through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance route. The downstream seal is the* $\mathsf{Real}^{\uparrow}$ *consumer of chapter 38; the route asserts neither ambient* $\mathsf{Real}^{\uparrow}$ *completeness nor quotient stream equality.*

Proof. Project the accepted carrier of Definition 5916.1. Its displayed inventory is exactly $Q, L, W, R, D, H, C, P, N$, with no hidden completed stream or selected limit coordinate.

Apply the NameCert obligations of Definition 5916.2. They force the finite request row Q and $\mathsf{List}^{\uparrow}$ spine L to appear before the $\mathsf{StreamName}^{\uparrow}$ window W, and they place the $\mathsf{RegSeqRat}^{\uparrow}$ boundary R and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row D downstream of that window.

Now name $\mathsf{Real}^{\uparrow}$ as the downstream seal consumer. Since the carrier exposes only the finite request, window, readback, tolerance, transport, replay, provenance, and naming rows, the Real seal can be consumed only after those rows are visible, and the argument supplies no Real completeness theorem or quotient stream equality. □

Theorem 5916.18 (FiniteStream uniform Real seal route)**.** *Every family of accepted* $\mathsf{FiniteStream}^{\uparrow}$ *packets consumed by a common* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-window reader uses the same displayed request, list, and window route* Q, L, W *before reaching* R, D, H, C, P, N*. Componentwise* hsame *transport and displayed* Cont *replay preserve that route uniformly across the family. The route exports no quotient stream equality, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier inventory of Definition 5916.1. Each accepted packet exposes the same row pattern $Q, L, W, R, D, H, C, P, N$, so a common finite-window reader can compare packets only through those displayed rows.

Apply Definition 5916.2. The request row Q and list row L must be visible before the $\mathsf{StreamName}^{\uparrow}$ window W, and the readback and tolerance rows R, D are downstream from that window.

Use Definition 5916.3 to keep sibling section reads on the same finite route. Then apply Definition 5916.17; any Real-facing consumer reaches the terminal seal only after $Q, L, W, R, D, H, C, P, N$ are displayed.

The componentwise transport row H and displayed replay row C preserve the route uniformly for the whole family, while P, N source and name it. Since none of the packets carries quotient stream equality, selected limits, countable choice, or ambient Real completeness, the common reader receives only the uniform finite-window route. □

Every $\mathsf{FiniteStream}^{\uparrow}$ read consumed by chapter 301 or chapter 38 first passes through the finite-observation surface of chapter 126. The packet therefore exposes its request row, list spine, and StreamName window before the RegSeqRat readback boundary or the Real seal can be inspected; no consumer receives an ambient infinite stream or a selected real limit outside the displayed finite route.

The finite-window source is the StreamName naming certificate itself, where each exported observation is a bounded request against a named stream window, while the regular-Cauchy readback source is chapter 301, where the window is consumed as rational sequence data rather than as an ambient sequence object. Thus the sibling lattice for $\mathsf{FiniteStream}^{\uparrow}$ has two visible dependency

faces: chapter 126 supplies the window discipline, and chapter 301 supplies the regular-rational readback discipline used by later completion consumers.

Theorem 5916.19 (FiniteStream sibling dependency route)**.** *For every accepted* $\mathsf{FiniteStream}^{\uparrow}$ *carrier, any downstream finite-stream consumer that reads a prefix window toward* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *first consumes the same finite observation lattice*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

through the StreamName finite-window discipline of chapter 126, the regular-rational readback route of chapter 301, and the Real seal of chapter 38. The dependency is sibling-visible because each stage is named by the carrier's BHist, hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{FiniteStream}^{\uparrow}}$ *rows before the prefix window is exported to any later finite-stream consumer.*

The downstream packets $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ and $\mathsf{RegularSequenceClusterWitness}^{\uparrow}$ consume the same finite request/list/window route before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ seal read; for instance, chapter 5940 reads equality of regular real names through that displayed finite tail data. The $\mathsf{FiniteStream}^{\uparrow}$ dependency route reads finite-window names through chapter 126, the regular-sequence rational route of chapter 301, and the real-name seal of chapter 38 before any Real-facing consumer inspects a displayed finite window. Thus a finite stream is visible to downstream L10 consumers only after its stream-name row, rational regular-sequence row, and $\mathsf{Real}^{\uparrow}$ readback route have all been exposed inside the same dependency lattice.

Chapter 5917

A Concrete Naming Certificate for $\mathsf{PoincareDiskGeodesicProjection}^{\uparrow}$

Following classical Poincare disk geometry, the $\mathsf{PoincareDiskGeodesicProjection}^{\uparrow}$ packet records the finite route by which displayed disk points are projected onto a boundary-determined geodesic before metric and phase-transport consumers read the result. It sits after the disk carrier of chapter 377, the hyperbolic metric rows of chapter 3474, the geodesic-boundary packet of chapter 3491, the boundary-fixed transport packet of chapter 3500, and the disk phase-transport route of chapter 3455. The packet names a finite geodesic projection surface; it is not a completed hyperbolic plane, quotient ideal boundary, selected nearest point, host minimizer, physical horizon, or global compactification.

Definition 5917.1 (Poincare disk geodesic projection carrier)**.** *A* $\mathsf{PoincareDiskGeodesicProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, B, M, T, J, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-point row, recording the finite disk coordinates and source observations to be projected.*
2. *B is the boundary-geodesic row, recording the two displayed boundary endpoints or boundary-incidence data that determine the geodesic arc.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *comparison row, exposing the metric reads used to compare the disk point with the geodesic boundary data.*
4. *T is the* $\mathsf{PoincareBoundaryFixedTransport}^{\uparrow}$ *row, carrying the boundary-fixed transport that preserves the displayed geodesic endpoints during the projection read.*
5. *J is the projection-join row, tying D, B, M, T to the same finite source surface before any projected point or phase-transport consumer can read the packet.*
6. *H records componentwise* hsame *transport for disk points, boundary-geodesic data, hyperbolic-metric comparisons, boundary-fixed transport, projection join, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a projection request through D, B, M, T, J, H, P, N.*

8. *P is the* Pkg *provenance over* PoincareDiskGeodesicProjection$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicGeodesicBoundary$^{\uparrow}$, PoincareBoundaryFixedTransport$^{\uparrow}$, PoincareDiskPhaseTransport$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{PoincareDiskGeodesicProjection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, B, M, T, J, H, C, P, N$. It has no coordinate for a completed disk, quotient boundary equality, selected nearest point, host minimizer, physical horizon, or global hyperbolic compactification.

Lean4 ✓ `BEDC.Derived.PoincareDiskGeodesicProjectionUp.PoincareDiskGeodesicProjectionTasteGate`
`single carrier alignment`

Theorem 5917.2 (Poincare disk geodesic projection NameCert obligations)**.** *For every accepted* PoincareDiskGeodesicProjection$^{\uparrow}$ *carrier*

$$G = (D, B, M, T, J, H, C, P, N),$$

the local NameCert$_{\text{PoincareDiskGeodesicProjection}^{\uparrow}}$ *surface consists exactly of disk-point admission, boundary-geodesic admission, hyperbolic-metric comparison, boundary-fixed transport, projection-join exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every projection consumer must read*

$$D, B, M, T \longmapsto J \longmapsto H, C, P, N$$

before it can pass projected geodesic data to a phase-transport or metric consumer.

Proof. Project the carrier of Definition 5917.1. The only visible source rows are the disk point row D, boundary-geodesic row B, hyperbolic-metric comparison row M, boundary-fixed transport row T, and the structural rows J, H, C, P, N.

The geodesic projection read is forced through D, B, M, T. Disk coordinates provide the source point, boundary-geodesic data provide the target arc, metric comparisons provide the displayed hyperbolic reading, and boundary-fixed transport preserves the endpoints while the request is replayed.

The projection-join row J binds those four rows to one finite source surface. Componentwise transport and displayed replay then preserve that same packet through H and C.

Finally P and N exhaust provenance and local naming. Since no completed disk, quotient boundary equality, selected nearest point, host minimizer, physical horizon, or global compactification row appears in the carrier, the projection remains a finite NameCert route. □

Falsifiable prediction: An accepted PoincareDiskGeodesicProjection$^{\uparrow}$ read is refuted if a consumer obtains projected geodesic data without displaying the disk-point row, boundary-geodesic row, HyperbolicMetric comparison row, boundary-fixed transport row, projection join, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: unitdisk, hyperbolic-metric, hyperbolic-geodesic-boundary, poincare-boundary-fixed-transport, poincare-disk-phase-transport: no listed sibling is bijective to PoincareDiskGeodesicProjec because this packet jointly carries disk points, boundary-geodesic data, metric comparisons, boundary-fixed transport, projection joining, transport, replay, provenance, and local naming as one finite route.

Closure status for NameCert$_{\text{PoincareDiskGeodesicProjection}^{\uparrow}}$.

Constructive story: A PoincareDiskGeodesicProjection$^{\uparrow}$ packet is generated from UnitDisk point rows, boundary-geodesic rows, HyperbolicMetric comparison rows, PoincareBoundaryFixedTransport rows, projection joining, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PoincareDiskGeodesicProjection}^{\uparrow}}$, seed)

Scope closed: Definition 5917.1 and Definition 5917.2 seed the finite disk-point, boundary-geodesic, hyperbolic-metric, and phase-transport projection route.

Formal verification: FormalStatus(NameCert$_{\text{PoincareDiskGeodesicProjection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic-plane geometry, quotient ideal-boundary equality, selected nearest points, host minimizers, physical horizons, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-point admission, boundary-geodesic admission, hyperbolic-metric comparison, boundary-fixed transport, projection-join exactness, transport, replay, provenance, and local naming for BEDC.Derived.PoincareDiskGeodesicProjectionUp.

Theorem 5917.3 (Poincare disk geodesic projection hyperbolic route)**.** *Every public* PoincareDiskGeodesicProjectio *projection read factors through the hyperbolic geodesic and phase-transport siblings before export. For an accepted carrier*

$$G = (D, B, M, T, J, H, C, P, N),$$

the consumer first reads the boundary-geodesic data through chapter 3491, then the metric comparison row through chapter 3474, and then the phase-transport route through chapter 3455. Only after those sibling rows have been exposed may the local projection join J be exported as projected disk-geodesic data.

Proof. Project the accepted carrier through Definition 5917.1. The rows B, M, and T are visible coordinates of the same finite packet, and the projection join J is downstream of those rows.

Apply Definition 5917.2. Its NameCert surface requires every projection consumer to read

$$D, B, M, T \longmapsto J \longmapsto H, C, P, N$$

before phase-transport or metric export.

The boundary-geodesic row B is therefore read through chapter 3491; the metric row M is read through chapter 3474; and the outgoing transport consumer is read through chapter 3455. Since J is not available before those sibling rows are displayed, the projection read cannot float independently of the hyperbolic and phase-transport route. □

Theorem 5917.4 (Poincare disk geodesic projection sibling lattice)**.** *Every accepted* PoincareDiskGeodesicProjectior *route reads the disk-carrier, boundary row, metric/geodesic row, transport row, replay row, provenance row, and local* NameCert *row before any projection consumer inspects the projected route. The sibling lattice runs through the disk carrier of chapter 377, the hyperbolic metric surface of chapter 3474, the geodesic-boundary packet of chapter 3491, the boundary-fixed transport route of chapter 3500, and the outgoing phase-transport route of chapter 3455.*

Proof. Project an accepted carrier

$$G = (D, B, M, T, J, H, C, P, N)$$

through Definition 5917.1. The rows D, B, M, T, H, C, P, N are visible before the projection join J can be exported.

Apply Definition 5917.2. It forces every projection consumer to read the disk row, boundary-geodesic row, hyperbolic metric row, boundary-fixed transport row, projection join, componentwise transport, replay, provenance, and local naming in that order.

Thus the route is horizontal rather than kernel-only: D is anchored in chapter 377, M in chapter 3474, B in chapter 3491, T in chapter 3500, and the downstream projection consumer in chapter 3455. Since J is unavailable until those rows have been displayed, no projection read floats apart from its disk and hyperbolic siblings. $\square$

Chapter 5918

A Concrete Naming Certificate for $\mathsf{CalkinWilfTree}^{\uparrow}$

Following Calkin–Wilf and Hardy–Wright, the $\mathsf{CalkinWilfTree}^{\uparrow}$ packet records the finite binary tree route by which positive rational presentations are generated from 1/1 through the child rules $a/b \mapsto a/(a+b)$ and $a/b \mapsto (a+b)/b$. It sits between the rational carrier of chapter 37, the determinant-one tree boundary of chapter 1704, the adjacent rational ledger of chapter 1759, and the breadth-first stream surface of chapter 1474. The packet names a finite address-to-rational tree carrier; it is not a host enumeration of rational numbers, a quotient-rational equality theorem, a selected representative principle, or an ambient completion claim.

Definition 5918.1 (Calkin–Wilf tree carrier)**.** *A* $\mathsf{CalkinWilfTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, Q, L, R, S, F, H, C, P, N)$$

with the following displayed rows:

1. *A is the binary address row, recording the finite left/right word from the root address to the inspected node.*
2. *Q is the positive* $\mathsf{Rat}^{\uparrow}$ *readback row at the inspected address, stored as displayed numerator and denominator histories.*
3. *L is the left-child row, recording the displayed transition from a/b to $a/(a+b)$.*
4. *R is the right-child row, recording the displayed transition from a/b to $(a+b)/b$.*
5. *S is the* $\mathsf{SternBrocot}^{\uparrow}$ *comparison row, sending the inspected address to the sibling finite tree boundary and mediant route.*
6. *F is the* $\mathsf{FareySequence}^{\uparrow}$ *comparison row, recording the adjacent determinant-one rational window through which the inspected presentation is compared with Farey neighbors.*
7. *H stores componentwise* hsame *transport for the address, rational readback, child-step, Stern–Brocot comparison, Farey comparison, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from an address request through child-step inspection, rational readback, Stern–Brocot comparison, Farey-neighbor comparison, and downstream handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{CalkinWilfTree}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{FareySequence}^{\uparrow}$, $\mathsf{CalkinWilfEnumeration}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CalkinWilfTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, Q, L, R, S, F, H, C, P, N$. The carrier has no coordinate for host enumeration, quotient rational equality, selected representatives, signed-rational coverage, real order, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CalkinWilfTreeUp.CalkinWilfTreeUp`

Theorem 5918.2 (Calkin–Wilf tree NameCert obligations)**.** *For every accepted* $\mathsf{CalkinWilfTree}^{\uparrow}$ *carrier*

$$T = (A, Q, L, R, S, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CalkinWilfTree}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed binary address, positive rational readback, child-step, Stern–Brocot comparison, Farey comparison, transport, replay, provenance, and local naming rows;*
2. *root admission, requiring the empty address in A to expose the displayed positive rational row $1/1$ in Q;*
3. *child-step exactness, requiring every left edge to be read through L as $a/b \mapsto a/(a+b)$ and every right edge to be read through R as $a/b \mapsto (a+b)/b$;*
4. *Stern–Brocot comparison, requiring S to compare the addressed node through the finite rational-tree route of chapter 1704;*
5. *Farey comparison, requiring F to expose the adjacent determinant-one rational window before any consumer treats Q as rational comparison data;*
6. *enumeration handoff, requiring the breadth-first stream packet of chapter 1474 to read only the displayed A, Q, L, R route when it consumes tree nodes;*
7. *non-escape, stating that host enumeration, quotient rational equality, selected representatives, signed-rational coverage, real order, and ambient completion are absent from the packet.*

Proof. Carrier admission is projection from Definition 5918.1. The accepted tuple exposes exactly the address row, rational readback row, two child-step rows, sibling comparison rows, and structural rows listed in the statement.

Root admission is the base case of the displayed address row. At the empty address, the packet reads the positive $\mathsf{Rat}^{\uparrow}$ presentation $1/1$ from Q, with no external enumeration or quotient comparison.

For the successor step, inspect the next bit of A. A left bit uses L and a right bit uses R; in both cases the numerator-denominator presentation remains positive and is written back to Q as finite BHist data.

The sibling comparison obligations are then read from S and F. The Stern–Brocot row compares the addressed node with the finite tree boundary route, while the Farey row records the adjacent determinant-one window before rational comparison data can be consumed.

Finally H, C, P, N transport, replay, package, and name the same finite inventory. Because the inventory has no coordinate for host enumeration, quotient rational equality, selected representatives, signed coverage, real order, or ambient completion, the listed rows exhaust the local certificate. □

Theorem 5918.3 (Calkin–Wilf tree rational-enumeration handoff)**.** *Every* $\mathsf{CalkinWilfEnumeration}^{\uparrow}$ *read of an accepted* $\mathsf{CalkinWilfTree}^{\uparrow}$ *carrier factors through the finite route*

$$A \longmapsto L, R \longmapsto Q \longmapsto S, F \longmapsto H, C, P, N.$$

Consequently the enumeration sibling receives positive $\mathsf{Rat}^{\uparrow}$ *presentations generated by the displayed address row and child-step rows, while Stern–Brocot and Farey comparison data remain available as finite neighbor checks. The handoff does not export host rational enumeration, quotient equality, selected representatives, signed-rational coverage, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Induct on the displayed address row A. The empty address exposes $1/1$ through Q, and the enumeration sibling may read that root as the first positive rational presentation.

For a successor address, the induction hypothesis supplies the parent presentation through the earlier prefix of A. The next bit selects exactly one of L or R, so the child presentation is again computed inside the finite carrier before it is written to Q.

The comparison rows are read after the child presentation is present. Row S routes the same address to the Stern–Brocot boundary surface, and row F records the Farey-neighbor comparison window for the displayed rational presentation.

The enumeration handoff is therefore a projection of finite rows, not a separate enumeration principle. Transport, replay, provenance, and local naming preserve this route through H, C, P, N, so downstream rational-enumeration consumers receive no quotient equality, host selector, signed coverage, real order, or completion coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CalkinWilfTree}^{\uparrow}}$.

Constructive story: A $\mathsf{CalkinWilfTree}^{\uparrow}$ packet is generated from a finite binary address row, a positive RatUp readback row, displayed left and right child-step rows, SternBrocot and FareySequence comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CalkinWilfTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5918.1, Definition 5918.2, and Definition 5918.3 seed the finite Calkin–Wilf binary-tree packet between Rat, SternBrocot, FareySequence, and CalkinWilfEnumeration rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CalkinWilfTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not claim host rational enumeration, quotient rational equality, selected representatives, signed-rational coverage, real order, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, root admission, child-step exactness, Stern–Brocot comparison, Farey comparison, enumeration handoff, transport, replay, provenance, and local naming for BEDC.Derived.CalkinWilfTree

Chapter 5919

A Concrete Naming Certificate for $\mathsf{TarskiFixedPoint}^{\uparrow}$

Following Tarski's fixed point theorem for monotone maps on complete lattices, the $\mathsf{TarskiFixedPoint}^{\uparrow}$ packet records the finite BEDC route by which a lattice self-map certificate exposes prefixpoint, postfixpoint, iteration, and fixed-row data to downstream order-theoretic consumers. It is grounded in the finite order surfaces of chapter 55, chapter 53, and chapter 1378, and it hands its iteration ledger to chapter 2383. The packet is a naming certificate for a displayed monotone fixed-row route, not a host theorem asserting ambient complete-lattice semantics or unrestricted fixed-point existence.

Definition 5919.1 (Tarski fixed-point carrier)**.** *A* $\mathsf{TarskiFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (L, P, O, F, A, B, I, X, H, C, G, N)$$

with the following displayed rows:

1. *L is the finite* $\mathsf{Lattice}^{\uparrow}$ *source row, exposing meet, join, bound, and finite comparison data only through the carried lattice certificate.*
2. *P is the* $\mathsf{Poset}^{\uparrow}$ *row underneath L, recording reflexive, transitive, and antisymmetric comparison reads for the same displayed endpoints.*
3. *O is the* $\mathsf{Order}^{\uparrow}$ *row used by arithmetic and ledger consumers to inspect the finite comparison branches without importing a host order.*
4. *F is the monotone self-map row. It stores source membership, target membership, and the displayed implication from $x \leq y$ to $F(x) \leq F(y)$ for the carried rows.*
5. *A is the prefixpoint ledger, listing finite rows whose displayed comparison reads certify $F(x) \leq x$.*
6. *B is the postfixpoint ledger, listing finite rows whose displayed comparison reads certify $x \leq F(x)$.*
7. *I is the* $\mathsf{FixedPointIteration}^{\uparrow}$ *chain row, recording the finite orbit, comparison phase, and stabilization checks read by iteration consumers.*
8. *X is the fixed-row witness. It is available only after A, B, I are displayed and records the paired comparisons $F(x) \leq x$ and $x \leq F(x)$ as local ledger rows.*
9. *H records componentwise* hsame *transport for the lattice, poset, order, self-map, prefixpoint, postfixpoint, iteration, fixed-row, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from order reads through the monotone self-map, prefixpoint and postfixpoint ledgers, iteration chain, fixed-row witness, transport, provenance, and naming rows.*
11. *G is the* Pkg *provenance over* $\mathsf{TarskiFixedPoint}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{FixedPointIteration}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{TarskiFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, P, O, F, A, B, I, X, H, C, G, N$. It has no coordinate for host complete-lattice semantics, quotient function equality, unrestricted choice, or ambient standard-model fixed points.

Lean4 (definition) `BEDC.Derived.TarskiFixedPointUp.TarskiFixedPointUp`

Theorem 5919.2 (Tarski fixed-point NameCert obligations)**.** *For every accepted* $\mathsf{TarskiFixedPoint}^{\uparrow}$ *carrier*

$$T = (L, P, O, F, A, B, I, X, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{TarskiFixedPoint}^{\uparrow}}$ *surface consists exactly of the finite lattice source, poset comparison, order readback, monotone self-map, prefixpoint ledger, postfixpoint ledger, iteration chain, fixed-row witness, componentwise transport, continuation replay, package provenance, and local naming rows of Definition 5919.1. A valid obligation read must display the sibling route*

$$\mathsf{Order}^{\uparrow} \longmapsto \mathsf{Poset}^{\uparrow} \longmapsto \mathsf{Lattice}^{\uparrow} \longmapsto \mathsf{FixedPointIteration}^{\uparrow}$$

before the fixed-row witness is exported. No obligation may call on host complete-lattice semantics, quotient equality of self-maps, an unrestricted-choice selector, or a standard-model fixed point outside the packet.

Proof. Project the carrier of Definition 5919.1. The accepted packet exposes only the rows $L, P, O, F, A, B, I, X, H, C$

The order-theoretic source is read first. The $\mathsf{Order}^{\uparrow}$ row supplies finite comparison branches, the $\mathsf{Poset}^{\uparrow}$ row supplies comparison stability, and the $\mathsf{Lattice}^{\uparrow}$ row supplies meet, join, and bound data for the same displayed endpoints.

The monotone self-map row F is then interpreted over that carried source. Prefixpoint rows in A and postfixpoint rows in B can be checked only by replaying the displayed comparison implications from F together with the source rows.

The iteration chain I and fixed-row witness X consume those ledgers. Since X stores only the paired local comparisons $F(x) \leq x$ and $x \leq F(x)$, it is a packet witness rather than a host fixed point.

The remaining rows H, C, G, N transport, replay, source, and name the same route. No excluded complete-lattice, quotient-function, unrestricted-choice, or ambient fixed-point principle is present as a carrier coordinate. □

Theorem 5919.3 (Tarski fixed-point lattice-iteration handoff)**.** *Every downstream consumer of an accepted* $\mathsf{TarskiFixedPoint}^{\uparrow}$ *packet reads the fixed-row witness only after the* $\mathsf{Lattice}^{\uparrow}$ *source,* $\mathsf{Poset}^{\uparrow}$ *comparison surface,* $\mathsf{Order}^{\uparrow}$ *branch ledger, monotone self-map row, prefixpoint and postfixpoint ledgers, and* $\mathsf{FixedPointIteration}^{\uparrow}$ *chain have been displayed. The handoff exports the finite rows*

$$L, P, O, F, A, B, I, X, H, C, G, N$$

and nothing that identifies quotient self-maps, selects arbitrary lattice elements, or asserts a host standard-model fixed point.

Proof. Start with a downstream consumer of the accepted packet. The only consumer-facing route is the replay row C, and its first dependencies are the finite order, poset, and lattice rows O, P, L.

The self-map row F is available only as a monotone row over those displayed comparisons. The prefixpoint ledger A and postfixpoint ledger B therefore record finite comparison checks rather than semantic least or greatest fixed-point arguments.

The iteration chain I consumes the same ledgers and exports only its displayed finite chain. The fixed-row witness X is downstream of I and stores paired comparisons for one named row.

Transport, provenance, and local naming preserve that ordering. Thus every consumer receives the lattice-iteration handoff and no larger complete-lattice theorem, quotient-function equality, unrestricted-choice selector, or ambient fixed-point object. □

Closure status for $\mathsf{NameCert}_{\mathsf{TarskiFixedPoint}\uparrow}$.

Constructive story: A $\mathsf{TarskiFixedPoint}^{\uparrow}$ packet is generated from a finite LatticeUp source, PosetUp comparison surface, OrderUp branch ledger, monotone self-map row, prefixpoint and postfixpoint ledgers, FixedPointIterationUp chain, fixed-row witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TarskiFixedPoint}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5919.1, Definition 5919.2, and Definition 5919.3 seed the finite Tarski fixed-point naming route over displayed order, lattice, monotone-map, ledger, iteration, witness, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TarskiFixedPoint}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host complete-lattice semantics, quotient function equality, unrestricted choice, ambient standard-model fixed points, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lattice and poset source coverage, monotone self-map stability, prefixpoint and postfixpoint ledger coverage, iteration-chain replay, fixed-row witness coverage, transport, replay, provenance, and local naming for BEDC.Derived.TarskiFixedPointUp.

Chapter 5920

A Concrete Naming Certificate for $\mathsf{LocatedRealCompletionUniversal}^{\uparrow}$

Following Bishop and Bridges, the constructive universal property of the located real completion is read here as a finite extension surface rather than as a quotient completion theorem. The $\mathsf{LocatedRealCompletionUniversal}^{\uparrow}$ packet sits downstream of the rational core of chapter 291, the stream-name route of chapter 126, the regular rational sequence carrier of chapter 301, the real-name seal of chapter 38, the located completion functor of chapter 3531, and the Cauchy completion universal property of chapter 2319. It records only displayed rational probes, regular Cauchy windows, located modulus data, extension rows, uniqueness comparisons, transport, replay, provenance, and local naming; it refuses quotient classes, choice-selected limits, and ambient completeness.

Definition 5920.1 (LocatedRealCompletionUniversal carrier)**.** *A* $\mathsf{LocatedRealCompletionUniversal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, S, R, E, L, F, X, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row, naming the finite rational probes and dyadic tolerance budgets inspected by the completion route.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, displaying the finite stream windows on which regular names are read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, packaging the stream observations as regular rational Cauchy data with the displayed modulus and tolerance schedule.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from D, S, R and from no other source.*
5. *L is the located comparison row, recording the finite locatedness tests and apartness witnesses used by the extension route.*
6. *F is the* $\mathsf{LocatedCompletionFunctor}^{\uparrow}$ *handoff row, carrying the displayed source map and located completion action on the finite rows already exposed.*
7. *X is the extension row, naming the candidate map on completed real names as a route through D, S, R, E, L, F.*

8. *Q is the* CauchyCompletionUniversalProperty$^{\uparrow}$ *comparison row, recording uniqueness only as a displayed comparison between two extension routes that agree on the dense rational source rows.*
9. *H records componentwise* hsame *transport for dyadic probes, stream windows, regular rational readbacks, Real seals, located comparisons, functor handoffs, extension rows, universal-property comparisons, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from every universal-property request through $D, S, R, E, L, F, X, Q, H, P, N$.*
11. *P is the* Pkg *provenance over* LocatedRealCompletionUniversal$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, LocatedCompletionFunctor$^{\uparrow}$, CauchyCompletionUniversalProperty$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{LocatedRealCompletionUniversal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient classes of Cauchy names, choice-selected limits, ambient completeness of a host real line, global equality of completed objects, or an unrestricted extension theorem detached from the displayed located route.

Lean4 ✓ `BEDC.Derived.LocatedRealCompletionUniversalUp.LocatedRealCompletionUniversalTasteGate`
`single carrier alignment`

Theorem 5920.2 (LocatedRealCompletionUniversal NameCert obligations)**.** *For every accepted* LocatedRealCompletionUniversal$^{\uparrow}$ *carrier*

$$U = (D, S, R, E, L, F, X, Q, H, C, P, N),$$

the local NameCert$_{\text{LocatedRealCompletionUniversal}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for dyadic rational probes, stream windows, regular rational readbacks, Real seals, located comparisons, located completion functor handoffs, extension rows, universal-property comparison rows, transport, replay, provenance, and local naming;*
2. *rational-source density, requiring every extension request to expose D, S, R before the terminal* Real$^{\uparrow}$ *seal E can be consumed;*
3. *located functoriality, requiring F to read the displayed located comparison row L together with the same rational-source and Real-seal rows;*
4. *extension formation, requiring X to be built from D, S, R, E, L, F and not from a quotient class or selected completion point;*
5. *uniqueness comparison, requiring Q to compare extension routes only after agreement on the displayed dense rational source has been named;*
6. *structural stability under H, C, P, N, which transports, replays, sources, and names only the displayed packet.*

No obligation is stored outside these rows.

Proof. Project the carrier of Definition 5920.1. The source-facing rows are D, S, R, E: dyadic probes, stream windows, regular rational readback, and the Real seal.

The located route is then read through L and F. The located comparison row supplies the finite tests used by the functor handoff, and F cannot act before the source-facing rows have been displayed.

The extension row X is downstream of those data. Since the carrier has no quotient-class or selected-limit coordinate, an accepted extension route is a displayed route through D, S, R, E, L, F rather than a host completion map.

Finally read the comparison and structural rows. The row Q compares extension routes only by their displayed agreement on the dense rational source, while H, C, P, N transport, replay, source, and name the same finite packet. These projections exhaust the listed NameCert obligations. □

Theorem 5920.3 (LocatedRealCompletionUniversal extension route)**.** *Every extension read exported by an accepted* $\mathsf{LocatedRealCompletionUniversal}^{\uparrow}$ *carrier factors through the finite route*

$$D, S, R \longmapsto E \longmapsto L, F \longmapsto X, Q \longmapsto H, C, P, N.$$

The route exposes dyadic rational probes, finite stream windows, regular rational Cauchy readbacks, a terminal Real seal, located comparisons, the located completion functor handoff, extension data, uniqueness comparison, transport, replay, provenance, and local naming. It does not export quotient classes of Cauchy names, choice-selected limits, ambient completeness, global equality of completed objects, or an extension principle outside the displayed packet.

Proof. Begin with an extension request. By carrier admission the only rational source available to the request is the displayed triple D, S, R, and the only real-facing endpoint attached to that source is E.

The located part of the request is read next. The row L supplies the finite located comparisons, and the $\mathsf{LocatedCompletionFunctor}^{\uparrow}$ handoff F consumes that row together with the already displayed rational and Real data.

The extension and uniqueness rows are downstream. The row X records the extension route built from the finite source and located functor rows, while Q compares two such routes only through displayed agreement on the dense rational source, as in the $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$ packet.

Transport through H, replay through C, provenance through P, and local naming through N preserve the same route. Since none of the refused objects is a coordinate of the carrier, no extension read can bypass the displayed finite surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealCompletionUniversal}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealCompletionUniversal}^{\uparrow}$ packet is generated from DyadicRatCore probes, StreamName windows, RegSeqRat readbacks, a RealUp seal, located comparison rows, a LocatedCompletionFunctor handoff, extension rows, universal-property comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealCompletionUniversal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5920.1, Definition 5920.2, and Definition 5920.3 seed the constructive located Real completion universal-property carrier over displayed rational and located rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealCompletionUniversal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient classes of Cauchy names, choice-selected limits, ambient completeness, global equality of completed objects, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational-source density, located functoriality, extension formation, uniqueness comparison, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealCompletionUniversal

Chapter 5921

A Concrete Naming Certificate for $\mathsf{NiemytzkiPlane}^{\uparrow}$

Following Niemytzki's classical tangent-disc topology, the $\mathsf{NiemytzkiPlane}^{\uparrow}$ packet records the upper half-plane together with its boundary-line neighbourhood discipline as finite NameCert data. It reads the open-set carrier of chapter 88, the metric-neighbourhood interface of chapter 1655, the real-coordinate seal of chapter 38, the coordinate-pair route of chapter 2000, and the separated-point surface of chapter 1925. The packet names the tangent-disc boundary route only; it does not assert metrizability, separability, compactness, classical choice principles, or a completed continuum beyond displayed real-coordinate rows.

Definition 5921.1 (Niemytzki plane carrier)**.** *A* $\mathsf{NiemytzkiPlane}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (U, B, T, R, Q, H, C, P, L)$$

with the following displayed rows:

1. *U is the upper-half-plane point row, presenting points with positive second coordinate through displayed* $\mathsf{Real}^{\uparrow}$ *coordinate reads.*
2. *B is the boundary-line point row, presenting points with zero second coordinate and a displayed first-coordinate readback.*
3. *T is the tangent-disc neighbourhood row, recording for a boundary point the basic neighbourhood consisting of that boundary point together with an open Euclidean disc tangent to the boundary line at that point.*
4. *R is the product-real coordinate readback row, routing all point and disc-center coordinates through* $\mathsf{Real}^{\uparrow}$ *and the product-topology surface before any topology consumer reads the packet.*
5. *Q is the classifier row, comparing accepted neighbourhood packets by upper-half-plane membership, boundary-line membership, tangent-disc incidence, and coordinate readback only.*
6. *H records componentwise* hsame *transport for point, boundary, tangent-disc, coordinate-readback, classifier, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a neighbourhood request through U, B, T, R, Q, H, P, L.*
8. *P is the* Pkg *provenance over* $\mathsf{NiemytzkiPlane}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{MetricTopology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ProductTopology}^{\uparrow}$, $\mathsf{HausdorffSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. L is the local $\mathsf{NameCert}_{\mathsf{NiemytzkiPlane}^{\uparrow}}$ *row.*
The classifier has no coordinate for a global metric inducing the topology, a countable base, compactness, selected centres by choice, or host equality of real pairs.

Theorem 5921.2 (Niemytzki plane NameCert obligations)**.** *For every accepted* $\mathsf{NiemytzkiPlane}^{\uparrow}$ *carrier*

$$N = (U, B, T, R, Q, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{NiemytzkiPlane}^{\uparrow}}$ *surface consists exactly of upper-half-plane point admission through U, boundary-line point admission through B, tangent-disc neighbourhood admission through T, product-real coordinate readback through R, classifier transport through Q, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through L.*

Lean4 ✓ `BEDC.Derived.NiemytzkiPlaneUp.NiemytzkiPlaneNameCertObligations`
↪ variant `BEDC.Derived.NiemytzkiPlaneUp.NiemytzkiPlaneTasteGate single carrier alignment`

Proof. Project the carrier of Definition 5921.1. The accepted packet exposes upper-half-plane points, boundary-line points, tangent-disc neighbourhoods, coordinate readback, classifier transport, replay, provenance, and local naming as separate rows.

The topology-facing rows are U, B, T. Upper-half-plane points are ordinary displayed coordinate pairs above the boundary, while boundary points obtain their basic neighbourhoods only through the tangent-disc row.

The coordinate and classifier rows are downstream of those point rows. The row R forces every coordinate read through $\mathsf{Real}^{\uparrow}$ and $\mathsf{ProductTopology}^{\uparrow}$, and Q compares packets only through visible incidence and coordinate data.

Finally H, C, P, L transport, replay, source, and name the same finite route. Since no row supplies a global metric, countable base, compactness witness, selected centre, or host pair equality, the listed rows exhaust the local NameCert surface. □

Theorem 5921.3 (Niemytzki tangent-disc boundary route)**.** *Every boundary-neighbourhood read exported by an accepted* $\mathsf{NiemytzkiPlane}^{\uparrow}$ *packet must pass through the boundary-line row B, the tangent-disc neighbourhood row T, and the product-real coordinate readback row R before it can be consumed as a* $\mathsf{Topology}^{\uparrow}$ *or* $\mathsf{HausdorffSpace}^{\uparrow}$ *neighbourhood. Thus the boundary topology is read as a finite tangent-disc certificate, not as an ordinary metric-ball neighbourhood, a chosen countable basis, a compactness claim, or a classical-choice selection.*

Proof. Start with the boundary-line row. It identifies a displayed point on the real boundary and separates it from upper-half-plane reads.

Next read the tangent-disc row. The neighbourhood of a boundary point is supplied by the boundary point together with a displayed tangent Euclidean disc, so the certificate does not reduce the boundary read to an ordinary product-open rectangle.

The coordinate row R then routes the centre, radius, tangent point, and incident upper-half-plane points through $\mathsf{Real}^{\uparrow}$ and $\mathsf{ProductTopology}^{\uparrow}$. Transport and replay preserve this order before provenance or local naming is inspected.

Consequently a topology or Hausdorff consumer receives only the displayed tangent-disc route. It receives no metrizability theorem, countable-base witness, compactness witness, selected family of discs, or hidden real-pair equality. □

Falsifiable prediction: Every accepted $\mathsf{NiemytzkiPlane}^{\uparrow}$ boundary-neighbourhood read displays a boundary-line row, a tangent-disc neighbourhood row, product-real coordinate readback, classifier transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: topology, metric-topology, real, product-topology, hausdorffspace: $\mathsf{NiemytzkiPlane}^{\uparrow}$ is not bijective to any listed sibling because it binds ordinary upper-half-plane coordinate reads and boundary tangent-disc neighbourhood reads into one finite topology packet.

Closure status for $\mathsf{NameCert}_{\mathsf{NiemytzkiPlane}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NiemytzkiPlane}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5921.1, Definition 5921.2, and Definition 5921.3 seed the finite upper-half-plane, boundary-line, tangent-disc, product-real, classifier, transport, replay, provenance, and local naming route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NiemytzkiPlane}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim metrizability, separability, compactness, classical choice principles, selected tangent-disc families, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tangent-disc neighbourhood exactness, product-real coordinate readback, classifier transport, replay, provenance, and local naming for BEDC.Derived.NiemytzkiPlaneUp.

Constructive story: A $\mathsf{NiemytzkiPlane}^{\uparrow}$ packet is generated from upper-half-plane point rows, boundary-line point rows, tangent-disc neighbourhood rows, product-real coordinate readback, classifier transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{RationalCauchyTelescope}^{\uparrow}$ hub routes completion-facing reads through chapter 1585 before exposing the dyadic, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Chapter 5922

A Concrete Naming Certificate for $\mathsf{RationalCauchyTelescope}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy real names, the $\mathsf{RationalCauchyTelescope}^{\uparrow}$ packet records the finite telescoping route by which rational step rows become a regular Cauchy readback before any completed-real assertion is available. It sits after rational rows from chapter 37, the dyadic tolerance core of chapter 291, the finite observation windows of chapter 126, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite L10 route for Real and Completion consumers; it does not assert quotient streams, selected limits, trichotomy, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5922.1 (RationalCauchyTelescope carrier)**.** *A* $\mathsf{RationalCauchyTelescope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (Q, D, W, R, M, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite* $\mathsf{Rat}^{\uparrow}$ *rational-step ledger, indexed by the same observation stages that the downstream stream window reads.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that bounds the visible tail of the rational step rows.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the observation stages used by Q and D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained by summing the displayed rational step rows over the windows in W.*
5. *M is the telescoping modulus row saying that every accepted tail comparison is discharged by the dyadic budget in D.*
6. *H records componentwise* hsame *transport for Q, D, W, R, M, C, P, N.*
7. *C records displayed* Cont *replay of the finite telescoping computation and its tail comparisons.*
8. *P is the* Pkg *provenance over* $\mathsf{RationalCauchyTelescope}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalCauchyTelescope}^{\uparrow}}$ *row.*

The carrier contains no quotient stream equality, selected limit, trichotomy decision, choice principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Theorem 5922.2 (RationalCauchyTelescope NameCert obligations)**.** *For every accepted* $\mathsf{RationalCauchyTelescope}^{\uparrow}$ *carrier*

$$T = (Q, D, W, R, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalCauchyTelescope}^{\uparrow}}$ *surface consists exactly of rational-step admission, dyadic tolerance visibility, finite-window exposure, regular rational readback, telescoping-modulus discharge, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obligation is read through the finite route*

$$\mathsf{Rat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Proof. Project the carrier of Definition 5922.1. The only mathematical rows available to a consumer are Q, D, W, R, M together with the structural rows H, C, P, N.

The rational-step ledger Q supplies the finite addends, while W supplies the observation stages on which those addends may be read. The dyadic row D fixes the tolerance budget for tail comparisons on the same windows.

The readback row R is obtained by displayed finite summation over Q and W. The modulus row M then records that every accepted telescoping tail comparison is bounded by the dyadic budget from D.

Transport, replay, provenance, and local naming are confined to H, C, P, N. Since no quotient-stream, selected-limit, trichotomy, choice, or completeness coordinate occurs in the packet, the listed rows exhaust the NameCert obligation surface. □

Theorem 5922.3 (RationalCauchyTelescope RegSeqRat factorization)**.** *Every Real-facing or Completion-facing read of an accepted* $\mathsf{RationalCauchyTelescope}^{\uparrow}$ *packet factors through the displayed chain*

$$Q \longmapsto W \longmapsto D \longmapsto M \longmapsto R,$$

before it can expose a $\mathsf{Real}^{\uparrow}$ *seal. Thus the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is sourced by finite rational step rows, finite StreamName windows, and a dyadic telescoping modulus, not by quotient streams, selected representatives, trichotomy, choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from an accepted carrier $T = (Q, D, W, R, M, H, C, P, N)$. The rational step rows Q can be inspected only through the finite windows W, and the same windows carry the dyadic tolerance row D.

The telescoping modulus M is read after Q, W, D. It is the row that converts finite step sums into tail comparisons suitable for the regular rational readback.

Finally the readback row R is the only $\mathsf{RegSeqRat}^{\uparrow}$ coordinate in the packet. Any Real-facing seal therefore receives its regular rational name through R after the finite telescoping route has been displayed.

Because the carrier has no further coordinate for quotient stream equality, selected representatives, trichotomy, choice, or ambient completeness, no completion consumer can bypass the displayed factorization. □

Theorem 5922.4 (RationalCauchyTelescope dyadic budget composition)**.** *Let*

$$T_i = (Q_i, D_i, W_i, R_i, M_i, H_i, C_i, P_i, N_i)$$

for $i = 0, 1$ *be accepted* $\mathsf{RationalCauchyTelescope}^{\uparrow}$ *packets whose rational telescope segments are adjacent along the displayed finite window boundary. Their composition is accepted by concatenating the rational step rows, adding only the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget rows, and preserving the*

$\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff before the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The composed readback still factors through*

$$Q_0, Q_1 \longmapsto W_0, W_1 \longmapsto D_0, D_1 \longmapsto M \longmapsto R.$$

Proof. Project the two telescope carriers. Each packet exposes finite rational step rows, a dyadic tolerance ledger, a finite StreamName window, a RegSeqRat readback, a telescoping modulus, and the structural rows.

Use the shared finite window boundary to concatenate the rational step rows. The composed row is still a finite $\mathsf{Rat}^{\uparrow}$ ledger, and the observation stages remain those displayed by W_0 followed by W_1.

Combine the dyadic tolerance ledgers through the displayed budget coordinate. The composed modulus row records only the sum of the visible $\mathsf{DyadicRatCore}^{\uparrow}$ budgets needed for the adjacent segments.

Finally replay Definition 5922.3 for the composed packet. The $\mathsf{RegSeqRat}^{\uparrow}$ readback is reached after the finite rational rows, StreamName windows, dyadic budgets, and telescoping modulus have been displayed, so no quotient stream, selected representative, trichotomy, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate enters the composition. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalCauchyTelescope}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalCauchyTelescope}^{\uparrow}$ packet is generated from RatUp rational step rows, a DyadicRatCoreUp tolerance ledger, StreamName finite windows, a RegSeqRatUp readback, a telescoping modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RationalCauchyTelescope}^{\uparrow}}$, seed)

Scope closed: Definition 5922.1, Definition 5922.2, and Definition 5922.3 seed the finite telescoping route from rational step rows to regular rational readback.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RationalCauchyTelescope}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected limits, trichotomy, choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked rational-step admission, dyadic tolerance stability, finite-window exposure, regular rational readback, telescoping-modulus discharge, and ledger non-escape for BEDC.Derived.RationalCauchyTelescopeUp.

Every $\mathsf{RationalCauchyTelescope}^{\uparrow}$ completion-facing consumer reads the rational step rows through chapter 1585 after the dyadic, StreamName, RegSeqRat, and RealUp rows of Definition 5922.1, and before any terminal Real-facing seal is public. This route keeps the completion-reflector dependency on the displayed telescope surface: $Q, D, W, R, M, H, C, P, N$ remain the only rows available to the consumer, and no quotient stream equality, selected limit, choice principle, trichotomy decision, or ambient $\mathsf{Real}^{\uparrow}$ completeness row is exported by the hub.

Chapter 5923

A Concrete Naming Certificate for $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$ packet records the finite diagonal-tail telescope by which a family of regular Cauchy rational readbacks is inspected along a displayed tail before the terminal real-name seal is available. It refines the rational telescoping route of chapter 5922 through the dyadic tolerance core of chapter 291, the finite observation windows of chapter 126, the regular rational handoff of chapter 301, and the Real seal boundary of chapter 38. The packet is a finite L10 diagonal-tail route for Real and Completion consumers; it is not quotient stream equality, a selected host limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5923.1 (Bishop diagonal Cauchy telescope carrier)**.** *A* $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, D, W, G, M, L, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RationalCauchyTelescope}^{\uparrow}$ *source row naming the finite rational telescoping schedule being diagonalized.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic budget for each accepted diagonal-tail comparison.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the observed tail windows and the diagonal index at which each window begins.*
4. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the windows in W and the rational telescope row R.*
5. *M is the displayed diagonal modulus row, saying that later diagonal requests move to weakly later windows and preserve the same dyadic budget discipline.*
6. *L is the finite tail-link ledger tying each accepted diagonal step to the preceding telescope row and the next regular rational readback.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, D, W, G, M, L have been displayed.*
8. *H records componentwise* hsame *transport for the telescope, dyadic, window, readback, diagonal modulus, tail-link, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route from R through D, W, G, M, L to E.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$, $\mathsf{RationalCauchyTelescope}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, D, W, G, M, L, E, H, C, P, N$. It contains no coordinate for quotient equality of streams, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5923.2 (Bishop diagonal Cauchy telescope NameCert obligations)**.** *For every accepted* $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$ *carrier $T = (R, D, W, G, M, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopDiagonalCauch}}$ *surface consists exactly of rational telescope admission, dyadic tolerance exposure, finite tail-window exposure, regular rational readback, diagonal-modulus exactness, finite tail-link composition, Real seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer must read the displayed route*

$$\mathsf{RationalCauchyTelescope}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before using the diagonal-tail telescope as evidence for a completed real name.

Proof. Project the carrier of Definition 5923.1. The rows R, D, W, G, M, L are the only pre-seal mathematical data, and they respectively expose the rational telescope, dyadic budget, finite tail windows, regular rational readback, diagonal modulus, and tail-link ledger.

The diagonal step is finite. A consumer reads R through the windows W, measures the displayed tail by D, and then obtains the regular rational row G. The modulus row M restricts later requests to weakly later windows, while L records the finite chain of accepted tail links.

The seal row E is downstream of those displayed rows. The structural rows H, C, P, N only transport, replay, source, and name the same route, so the local NameCert surface has no remaining coordinate from which quotient streams, selected representatives, countable choice, host real equality, or ambient completeness could be read. □

Theorem 5923.3 (Bishop diagonal Cauchy telescope tail route)**.** *Every diagonal-tail read exported by an accepted* $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$ *packet factors through the finite route*

$$R, D, W, G, M, L \longmapsto E \longmapsto H, C, P, N.$$

Thus a Real or Completion consumer receives a $\mathsf{RationalCauchyTelescope}^{\uparrow}$ *source row, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, one* $\mathsf{StreamName}^{\uparrow}$ *finite tail-window row, one* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, a displayed diagonal modulus, a finite tail-link ledger, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, replay, provenance, and local naming before it may use the diagonal-tail telescope. The route exports no quotient stream equality, selected representative, selected host limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted carrier $T = (R, D, W, G, M, L, E, H, C, P, N)$. The rational telescope row R is not readable as a Real-facing object until the dyadic row D and the finite window row W have displayed the inspected tail.

The regular rational readback G is then obtained on those same windows. The diagonal modulus M keeps later reads on weakly later windows, and the link ledger L records the finite composition of the accepted tail steps.

Apply the NameCert obligations of Definition 5923.2. They force the Real seal E and the structural rows H, C, P, N to remain downstream of the displayed tail route. Since the carrier contains no further coordinate, no downstream consumer can replace the route by quotient stream equality, selected representatives, selected limits, countable choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$ Real or Completion consumer factors through one RationalCauchyTelescope source row, one DyadicRatCore tolerance ledger, one StreamName finite tail-window row, one RegSeqRat readback row, one diagonal-modulus row, one finite tail-link ledger, one RealUp seal handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert before it may use a diagonal-tail telescope.

Independence witness: rationalcauchytelescope, dyadicratcore, streamname, regseqrat, real: $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$ is not bijective to any listed sibling because the siblings separately supply rational telescoping, tolerance budgets, finite windows, regular rational readback, and terminal Real sealing, while this packet uniquely binds them into one finite diagonal-tail route.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$ packet is generated from a RationalCauchyTelescope source row, a DyadicRatCore tolerance ledger, StreamName finite tail windows, a RegSeqRat readback row, a diagonal modulus, a finite tail-link ledger, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5923.1, Definition 5923.2, and Definition 5923.3 seed the finite diagonal-tail telescope route through RationalCauchyTelescope, DyadicRatCore, StreamName, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected representatives, selected host limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite tail-window readback, RegSeqRat handoff, diagonal-modulus exactness, finite tail-link composition, Real seal handoff, structural transport, and ledger non-escape for BEDC.Derived.BishopDiagonalCauchyTelescopeUp.

Theorem 5923.4 (Bishop diagonal Cauchy telescope RegSeqRat route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$ *packet must read the rational telescope route,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal in that order before the diagonal tail is public. In carrier notation, the consumer reads*

$$R, \quad D, \quad W, \quad G, \quad E$$

inside $T = (R, D, W, G, M, L, E, H, C, P, N)$*, with the diagonal modulus* M*, tail-link ledger* L*, transport* H*, replay* C*, provenance* P*, and local* NameCert *row* N *preserving the same route.*

Proof. Project the carrier from Definition 5923.1. The rational telescope row R, dyadic tolerance ledger D, finite-window row W, regular rational readback G, and terminal real seal E are the only Real-facing analytic rows available to the packet.

Apply the NameCert obligation surface of Definition 5923.2. It forces any Real or Completion consumer to expose the rational telescope, dyadic tolerance, finite tail windows, RegSeqRat readback, diagonal modulus, and finite tail-link composition before using the completed real-name seal.

Finally read the tail route of Definition 5923.3. The structural rows H, C, P, N transport, replay, source, and name that ordered route, so no quotient stream equality, selected host limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness is available to the consumer. □

Theorem 5923.5 (Bishop diagonal Cauchy telescope regular readback forward link)**.** *Every accepted* $\mathsf{BishopDiagonalCauchyTelescope}^{\uparrow}$ *packet reads its regular rational component through chapter 301 before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is available. Consequently every downstream Real or Completion consumer inherits the dependency on the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* G *inside the carrier* $T = (R, D, W, G, M, L, E, H, C, P, N)$.

Proof. Project the carrier of Definition 5923.1. The row G is explicitly the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, and the seal row E is listed only after the rational telescope, dyadic budget, finite windows, readback, diagonal modulus, and tail-link ledger.

Apply Definition 5923.4. It forces Real and Completion consumers to read R, D, W, G, E in order, with the remaining rows preserving that same route.

Thus the regular rational component is not an optional sibling citation. It is a forward dependency carried by every accepted diagonal-tail packet before any terminal $\mathsf{Real}^{\uparrow}$ seal or Completion-facing consequence may be consumed. □

Chapter 5924

A Concrete Naming Certificate for $\mathsf{HausdorffReflectionCompletionCounit}^{\uparrow}$

Following Bishop–Bridges completion and the Kelley–Bourbaki language of Hausdorff reflection, the $\mathsf{HausdorffReflectionCompletionCounit}^{\uparrow}$ packet records the finite return map from a Hausdorff-reflected completion surface back to its separated completion read. It consumes the unit row of chapter 1527, the counit row of chapter 1539, the reflection row of chapter 403, and the separated-completion boundary of chapter 1612. The chapter names the local counit interface only as displayed BEDC rows; it does not add quotient representatives, host equality of completed points, selected limits, countable choice, or ambient completeness.

Definition 5924.1 (Hausdorff reflection completion counit carrier)**.** *A* $\mathsf{HausdorffReflectionCompletionCounit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, V, R, S, W, Q, D, E, H, C, P, N)$$

with the following visible rows:

1. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *admission row for the displayed source entering the completion surface.*
2. *V is the* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *return row for already displayed completion reads.*
3. *R is the* $\mathsf{CompletionReflection}^{\uparrow}$ *row that reflects completion-facing consumers through the separated boundary.*
4. *S is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row inspected before Hausdorff equality is exported.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened before rational observations are read.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the finite windows and readback comparisons.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the separated completion read has passed through W, D, Q.*
9. *H records componentwise* hsame *transport for U, V, R, S, W, Q, D, E and the structural rows.*
10. *C records displayed* Cont *replay for consumers that inspect the reflected counit, the separated boundary, or the terminal real-facing route.*

11. *P is the* Pkg *provenance over* HausdorffReflectionCompletionCounit$^{\uparrow}$, CauchyCompletionUnit$^{\uparrow}$, CauchyCompletionCounit$^{\uparrow}$, CompletionReflection$^{\uparrow}$, SeparatedCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{HausdorffReflectionCompletionCounit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient-completion equality, selected completion representatives, host equality of completed objects, countable choice, or an ambient completeness theorem.

Lean4 ✓ BEDC.Derived.HausdorffReflectionCompletionCounitUp.HausdorffReflectionCompletionCounitTasteGate
single carrier alignment

Theorem 5924.2 (Hausdorff reflection completion counit obligations)**.** *For an accepted* HausdorffReflectionComplet *carrier $K = (U, V, R, S, W, Q, D, E, H, C, P, N)$, the local* NameCert$_{\text{HausdorffReflectionCompletionCounit}^{\uparrow}}$ *surface consists exactly of the carrier admission row, unit admission row, counit return row, completion-reflection row, separated-completion boundary, finite-window row, regular-rational readback, dyadic tolerance ledger, terminal real seal, componentwise transport, continuation replay, package provenance, and local naming row.*

Proof. Project the carrier of Definition 5924.1. Its coordinates are exactly $U, V, R, S, W, Q, D, E, H, C, P, N$.

The completion-facing part is the route through U, V, R, S. The unit row admits the source into the completion surface, the counit row returns displayed completion reads, the reflection row routes the read through the Hausdorff boundary, and the separated-completion row is the boundary at which equality can be consumed.

The real-facing part is the finite route W, Q, D, E. These rows expose stream windows, regular-rational readback, dyadic tolerances, and the terminal real seal as data of the same packet.

Finally, H, C, P, N transport, replay, source, and name the displayed rows. Since no further coordinate exists, the local certificate exports no quotient completion, selected representative, host equality, countable-choice schedule, or ambient completeness principle. □

Theorem 5924.3 (Hausdorff reflection completion counit compatibility)**.** *Let $K = (U, V, R, S, W, Q, D, E, H, C, P,$ be an accepted* HausdorffReflectionCompletionCounit$^{\uparrow}$ *carrier. Every consumer of the reflected completion counit factors through the displayed route*

$$U, V \longmapsto R \longmapsto S \longmapsto W, Q, D \longmapsto E \longmapsto H, C, P, N.$$

Thus the counit read is compatible with both the CompletionReflection$^{\uparrow}$ *route and the* SeparatedCompletion$^{\uparrow}$ *boundary: it returns the same finite real-facing seal that the counit row already exposes, and it does not replace that seal by quotient representatives, host equality, selected limits, countable choice, or ambient completeness.*

Proof. Start with the unit and counit rows U, V. They are the only coordinates that admit a displayed source into the completion surface and return an already displayed completion read.

Next pass through the reflection row R. The carrier makes the reflected completion consumer read R before any separated equality boundary can be inspected, so the reflected counit remains attached to the same completion-facing data as U and V.

Now inspect the separated boundary S and the real-facing route W, Q, D, E. The finite-window row, regular-rational readback, dyadic tolerance ledger, and terminal real seal are coordinates of the same carrier, so the reflected counit reaches the same displayed seal as the original counit read.

The structural rows H, C, P, N preserve and name this route. They do not add quotient classes, selected representatives, host equality, countable choice, or ambient completeness; therefore every consumer factors through the displayed counit-compatible route. □

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffReflectionCompletionCounit}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffReflectionCompletionCounit}^{\uparrow}$ packet is generated from CauchyCompletionUnit admission, CauchyCompletionCounit return, CompletionReflection routing, SeparatedCompletion boundary, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffReflectionCompletionCounit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5924.1, Definition 5924.2, and Definition 5924.3 seed the finite Hausdorff-reflected completion counit surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffReflectionCompletionCounit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-completion equality, selected completion representatives, host equality of completed objects, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, public bridge evidence, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, reflected counit compatibility, separated-boundary exactness, non-escape, and a Lean carrier formalization for BEDC.Derived.HausdorffReflectionCompletionCounitUp.

Chapter 5925

A Concrete Naming Certificate for MetaCICCandidateStrongNormalization$^{\uparrow}$

The MetaCICCandidateStrongNormalization$^{\uparrow}$ packet realizes the candidate-mediated boundary of chapter 9370 as finite MetaCIC evidence. It sits beside the normalization frontier of chapter 892, the decidability boundary of chapter 749, the closed-term substitution boundary of chapter 527, the authorized-generator recursor of chapter 525, and the normalization audit packet of chapter 750. The packet keeps candidate data, fuel, normal-form endpoints, refusal rows, transport, replay, provenance, and local naming visible before any strong-normalization read is accepted.

Definition 5925.1 (MetaCIC candidate strong-normalization carrier)**.** *A* MetaCICCandidateStrongNormalization$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, K, F, E, R, A, H, C, P, N, G)$$

with the following displayed rows:

1. *T is the closed typed MetaCIC term row, recording the term, context boundary, and closedness data consumed by the candidate route.*
2. *K is the candidate row, naming the reducibility candidate, closed-candidate wrapper, or candidate-set membership evidence used by the strong-normalization read.*
3. *F is the fuel row, displaying the finite reduction budget or staged descent ledger attached to the candidate read.*
4. *E is the normal-form endpoint row, recording the normal endpoint reached by the fuel-and-candidate route.*
5. *R is the refusal row, rejecting evidence-free strong normalization, missing-fuel endpoints, subject-reduction erasure, substitution erasure, global confluence, and closed-consistency shortcuts.*
6. *A is the audit-boundary row, reading* MetaCICNormalizationFrontier$^{\uparrow}$, MetaCICDecidableBoundary$^{\uparrow}$, ClosedTermSubstitutionBoundary$^{\uparrow}$, AuthorizedGeneratorRecursor$^{\uparrow}$, *and* MetaCICNormalizationAudit$^{\uparrow}$ *as sibling sources.*
7. *H records componentwise* hsame *transport for term, candidate, fuel, endpoint, refusal, audit-boundary, replay, provenance, TasteGate, and local naming rows.*
8. *C records displayed* Cont *replay from the strong-normalization request through $T, K, F, E, R, A, H, P, N, G$.*

9. *P is the* Pkg *provenance over* $\mathsf{MetaCICCandidateStrongNormalization}^{\uparrow}$*, the five sibling anchors,* BHist*,* hsame*,* Cont*, and* NameCert*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICCandidateStrongNormalization}^{\uparrow}}$ *row.*
11. *G is the TasteGate obligation row requiring Lean support in* `TasteGate.lean` *for* Nontrivial *and* FieldFaithful *instances of the carrier.*

The classifier compares accepted packets only through $T, K, F, E, R, A, H, C, P, N, G$. It has no coordinate for evidence-free strong normalization, an endpoint without fuel, hidden subject reduction, global confluence, quotient syntax equality, host evaluator soundness, or completed closed consistency.

Theorem 5925.2 (MetaCIC candidate strong-normalization NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICCandidateStrongNormalization}^{\uparrow}$ *carrier*

$$S = (T, K, F, E, R, A, H, C, P, N, G),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICCandidateStrongNormalization}^{\uparrow}}$ *surface consists exactly of closed typed term admission through T, candidate evidence through K, fuel visibility through F, normal-form endpoint readback through E, refusal exactness through R, sibling audit-boundary anchoring through A, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, local naming through N, and TasteGate nontriviality and field faithfulness through G.*

Lean4 ✓ `BEDC.Derived.MetaCICCandidateStrongNormalizationUp.MetaCICCandidateStrongNormalizationCarrier namecert obligations`

Proof. Project the carrier of Definition 5925.1. The accepted packet displays the closed typed term, candidate evidence, fuel, endpoint, refusal, audit-boundary, transport, replay, provenance, local naming, and TasteGate rows.

The positive route begins with T, K, F, E. A strong-normalization read reaches a normal-form endpoint only after candidate evidence and a fuel ledger have both been displayed.

The refusal and audit rows are part of the same surface. The row R rejects missing-candidate, missing-fuel, and endpoint-only reads, while A preserves the normalization frontier, decidability boundary, closed-term substitution boundary, authorized-generator recursor, and normalization audit packet as named sibling sources.

Finally H, C, P, N, G transport, replay, source, name, and guard the carrier. Because G requires Nontrivial and FieldFaithful instances, a Lean realization must distinguish evidence-bearing packets from endpoint-only packets and preserve the displayed field order. □

Theorem 5925.3 (MetaCIC candidate strong-normalization endpoint refusal)**.** *Every strong-normalization read exported by an accepted* $\mathsf{MetaCICCandidateStrongNormalization}^{\uparrow}$ *packet must display both a fuel row and a refusal row before the normal-form endpoint row can be consumed. Any claimed candidate strong-normalization read that omits fuel endpoint evidence or omits the refusal boundary is outside the carrier.*

Proof. Read the positive route through Definition 5925.2. The endpoint row E is downstream of the closed typed term, candidate, and fuel rows T, K, F.

Now read the negative route. The refusal row R remains visible alongside the endpoint row and rejects any route that bypasses candidate evidence, fuel, subject-reduction boundaries, substitution boundaries, confluence boundaries, or closed-consistency boundaries.

Transport and replay do not alter the route. The rows H, C, P, N, G preserve the same ordered packet, so a consumer cannot turn the endpoint into an evidence-free theorem or a fuel-free normal-form claim. □

Theorem 5925.4 (MetaCIC candidate strong-normalization fuel-refusal determinacy)**.** *For every accepted* $\mathsf{MetaCICCandidateStrongNormalization}^{\uparrow}$ *carrier*

$$S = (T, K, F, E, R, A, H, C, P, N, G),$$

if two strong-normalization reads expose the same closed typed term row T, candidate row K, fuel row F, endpoint row E, and refusal row R, then their exported finite endpoint surface is the same displayed packet route through A, H, C, P, N, G. No such read can split into an evidence-free endpoint, omit the refusal boundary, or export a different endpoint surface while keeping T, K, F, E, R fixed.

Proof. Project the accepted carrier of Definition 5925.1. The rows T, K, F, E, R are the only displayed term, candidate, fuel, endpoint, and refusal coordinates available to a strong-normalization read.

Compare the two reads on those five rows. Since the closed typed term, candidate evidence, fuel ledger, endpoint row, and refusal row are the same, both reads consume the same finite positive route and the same refusal boundary before any endpoint surface is public.

It remains to inspect the structural rows. The audit row A names the same sibling frontier, decidability, substitution, recursor, and normalization-audit sources; H transports the same components; C replays the same displayed route; P records the same provenance; N binds the same local name; and G enforces the same TasteGate field order.

Therefore the exported endpoint surface is componentwise identical through A, H, C, P, N, G. An evidence-free endpoint or a missing-refusal endpoint would require a coordinate outside S, and no such coordinate exists in the carrier. □

Theorem 5925.5 (MetaCIC candidate strong-normalization candidate-fuel endpoint descent)**.** *Let $S = (T, K, F, E, R, A, H, C, P, N, G)$ be an accepted* $\mathsf{MetaCICCandidateStrongNormalization}^{\uparrow}$ *carrier. Any accepted carrier read exposing the same closed typed term row T, candidate row K, and fuel row F reaches the endpoint row E only through the displayed descent ledger and the refusal row R. Decreasing or replaying the fuel ledger preserves the same endpoint boundary through A, H, C, P, N, G and cannot yield evidence-free strong normalization, global confluence, or subject reduction.*

Proof. Project the carrier of Definition 5925.1. The positive route displays the closed typed term, candidate evidence, fuel ledger, and endpoint rows T, K, F, E in that order.

Read the refusal route at the same time. The row R rejects any endpoint read that omits candidate evidence, omits fuel, or turns the endpoint into an evidence-free strong-normalization theorem.

Now compare a decreased or replayed fuel ledger with the original accepted read. The structural rows A, H, C, P, N, G preserve the sibling audit boundary, componentwise transport, replay, provenance, local naming, and TasteGate field order without adding confluence or subject-reduction coordinates.

Apply Definition 5925.4 to rule out an alternate endpoint surface once T, K, F, E, R are fixed. Hence every accepted descent-facing read reaches the same endpoint boundary through the displayed ledger and refusal rows. □

Theorem 5925.6 (MetaCIC candidate strong-normalization TasteGate boundary)**.** *Lean support for* MetaCICCandidateStrongNormalization$^{\uparrow}$ *must provide* Nontrivial *and* FieldFaithful *instances in* `TasteGate.lean`*. Nontriviality distinguishes a carrier with candidate, fuel, endpoint, and refusal rows from a closed-term endpoint without those rows; field faithfulness preserves the field order*

$$T \longmapsto K \longmapsto F \longmapsto E \longmapsto R \longmapsto A \longmapsto H, C, P, N, G$$

before any carrier-alignment theorem can count as the Lean realization.

Proof. Nontriviality is forced by the carrier boundary: deleting K, F, or R leaves a closed typed term and an endpoint-like read, but not an accepted candidate strong-normalization packet.

Field faithfulness is the route-preservation condition. If a projection erases or permutes $K, F, E, R, A, H, C, P, N$ the displayed carrier no longer records the candidate-mediated strong-normalization boundary of Definition 5925.1. □

Falsifiable prediction: Any claimed MetaCICCandidateStrongNormalization$^{\uparrow}$ read that reaches a normal-form endpoint without both the fuel row and the refusal row refutes the carrier.

Independence witness: metacicnormalizationfrontier, metacicdecidableboundary, closedtermsubstitutionboundary, authorizedgeneratorrecursor, metacicnormalizationaudit: MetaCICCandidateStrongNormalizatio is not bijective to any listed sibling because it jointly carries candidate evidence, fuel, normal-form endpoint, refusal, sibling audit route, transport, replay, provenance, TasteGate, and local NameCert rows.

Closure status for NameCert$_{\text{MetaCICCandidateStrongNormalization}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICCandidateStrongNormalization}^{\uparrow}}$, seed)

Scope closed: Definition 5925.1, Definition 5925.2, Definition 5925.3, Definition 5925.4, and Definition 5925.6 seed the candidate-mediated finite strong-normalization boundary over term, candidate, fuel, endpoint, refusal, audit, transport, replay, provenance, TasteGate, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICCandidateStrongNormalization}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.MetaCICCandidateStrongNormalizationUp.MetaCICCandidateStrongNormalizationCarrier\_namec`

Bridge status: none

Not claimed: This chapter does not close unconditional strong normalization for all closed MetaCIC terms, unrestricted subject reduction, arbitrary substitution preservation, global confluence, closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate visibility, fuel endpoint exactness, refusal exactness, sibling audit anchoring, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICCandidateStrongNormalizationUp.

Constructive story: A MetaCICCandidateStrongNormalization$^{\uparrow}$ packet is generated from a closed typed term row, candidate evidence, fuel row, normal-form endpoint row, refusal row, sibling audit-boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, TasteGate obligations, and a local NameCert row.

Chapter 5926

A Concrete Naming Certificate for $\mathsf{RealDiagonalModulus}^{\uparrow}$

Following Bishop–Bridges style constructive diagonal arguments, the $\mathsf{RealDiagonalModulus}^{\uparrow}$ packet records the rank-one modulus row used when a regular rational diagonal route is read as a real-name construction. It sits between the finite selector packet of chapter 375, the finite stream surface of chapter 126, the regular rational readback of chapter 301, the dyadic observation core of chapter 291, and the terminal real-name seal of chapter 38. The packet isolates the single displayed modulus schedule consumed by regular-Cauchy and $\mathsf{Real}^{\uparrow}$ completion routes without quotient streams, selected host representatives, countable choice, or ambient completeness.

Definition 5926.1 (Real diagonal modulus carrier)**.** *A* $\mathsf{RealDiagonalModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (n, \mu, S, R, D, E, H, C, Q, N)$$

with the following displayed rows:

1. *n is the unary precision-request row submitted by a* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer;*
2. *μ is the accepted* $\mathsf{DiagonalModulus}^{\uparrow}$ *selector row naming the threshold inspected for that request;*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the selected threshold;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed window S;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radius, endpoint comparison, and diagonal-budget cells read by R;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, R, D have been displayed;*
7. *H is the componentwise* hsame *transport ledger for n, μ, S, R, D, E and for their finite subrows;*
8. *C is the* Cont *route ledger from precision request to modulus threshold, stream window, regular readback, dyadic tolerance, and real seal;*
9. *Q is the* Pkg *provenance row over* $\mathsf{RealDiagonalModulus}^{\uparrow}$, $\mathsf{DiagonalModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealDiagonalModulus}^{\uparrow}}$ *naming row.*

The classifier on such packets is componentwise transport through H with replay along C. It never compares hidden streams, quotient representatives, host real endpoints, selected limits, or ambient complete spaces.

Lean4 ✓ `BEDC.Derived.RealDiagonalModulusUp.RealDiagonalModulusTasteGate single carrier alignment`

Theorem 5926.2 (RealDiagonalModulusUp NameCert obligations)**.** *For every accepted* $\mathsf{RealDiagonalModulus}^{\uparrow}$ *carrier* $P = (n, \mu, S, R, D, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealDiagonalModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, classifier transport through* H*, route replay through* C*, selector visibility through* μ*, stream-window visibility through* S*, regular-rational readback through* R*, dyadic tolerance exactness through* D*, real-seal non-escape through* E*, package provenance through* Q*, and local naming through* N*.*

Proof. Carrier admission is Definition 5926.1. It lists the precision request, modulus selector, stream window, regular readback, dyadic ledger, real seal, transport ledger, continuation ledger, provenance row, and local naming row.

The selector and readback obligations are inherited by projection. The row μ is the only $\mathsf{DiagonalModulus}^{\uparrow}$ selector coordinate, S is the only $\mathsf{StreamName}^{\uparrow}$ window coordinate, R is the only $\mathsf{RegSeqRat}^{\uparrow}$ readback coordinate, and D is the only $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance coordinate.

The transport and route obligations are exactly H and C. Any consumer that moves the packet must move each displayed row componentwise and then replay the same route from n through μ, S, R, D to E.

Finally, Q and N close the local naming surface. Since no other coordinate occurs in the carrier, the certificate cannot export quotient stream equality, selected host representatives, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5926.3 (RealDiagonalModulusUp real-seal route)**.** *Let* $P = (n, \mu, S, R, D, E, H, C, Q, N)$ *be an accepted* $\mathsf{RealDiagonalModulus}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the seal row* E *first reads the displayed precision request* n*, the* $\mathsf{DiagonalModulus}^{\uparrow}$ *selector* μ*, the* $\mathsf{StreamName}^{\uparrow}$ *finite window* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, with transport and provenance supplied by* H, C, Q, N*. Thus the real-facing handoff is a finite diagonal-modulus route rather than a quotient stream, selected representative, choice sequence, host equality proof, or ambient completeness principle.*

Proof. Start with the carrier projection. The only row whose type can feed a terminal real-name read is E, and the carrier places it after the displayed diagonal route n, μ, S, R, D.

Replay the route ledger C. A precision request opens the $\mathsf{DiagonalModulus}^{\uparrow}$ selector, the selector opens the finite $\mathsf{StreamName}^{\uparrow}$ window, the window is read back by R, and the dyadic tolerance data in D records the comparison budget before E is exposed.

Transport is controlled by H, while Q and N record the package and local certificate names. Therefore every real-seal consumer factors through the same finite route and cannot read a quotient stream, selected host representative, choice sequence, host equality proof, or ambient complete space. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealDiagonalModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealDiagonalModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5926.1, Definition 5926.2, and Definition 5926.3 seed the rank-one diagonal-modulus route from $\mathsf{DiagonalModulus}^{\uparrow}$ through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealDiagonalModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close quotient stream equality, selected representatives, countable choice, host real equality, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, selector visibility, stream readback, dyadic tolerance exactness, real-seal non-escape, and package provenance for the same packet.

Constructive story: The construction starts from a displayed precision request, reads one diagonal modulus selector, opens one finite stream window, reads the regular rational row and dyadic tolerance ledger, and then exposes the real seal as finite NameCert data.

Chapter 5927

A Concrete Naming Certificate for $\mathsf{CompactUniformHomeomorphism}^{\uparrow}$

Following the compact-metric uniform-continuity theorem as presented in Munkres and in Bishop–Bridges, the $\mathsf{CompactUniformHomeomorphism}^{\uparrow}$ packet records the finite certificate surface that turns a displayed compact metric homeomorphism into an inverse-uniform-continuity route. It consumes the finite cover and total-boundedness rows of chapter 129 and chapter 127, the function and continuity rows of chapter 130, the distance interface of chapter 57, and the terminal real-name seal of chapter 38. The inverse modulus is read from finite-net and separated-target rows; it is not read from choice, open-cover compactness, host equality, or ambient Real completeness.

Definition 5927.1 (CompactUniformHomeomorphism carrier)**.** *A* $\mathsf{CompactUniformHomeomorphism}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, Y, M, T, F, G, A, B, E, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. X, Y *are the source and target* $\mathsf{Met}^{\uparrow}$ *carrier rows.*
2. M *is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-cover row for the source metric space.*
3. T *is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row read from* M *at each displayed dyadic scale.*
4. F *is the forward* $\mathsf{ContinuousMap}^{\uparrow}$ *row and* G *is the displayed inverse map row on the same named carrier windows.*
5. A *records the finite graph-window agreement that* $G(F(x))$ *and* $F(G(y))$ *return to the displayed source and target windows through componentwise classifier reads.*
6. B *is the separated-target ledger: for every finite net row and positive target separation request it displays the finite list of source cells whose forward images are classifier-separated in* Y*.*
7. E *is the inverse-modulus row obtained by refining* T *until the separated-target ledger* B *accepts the target tolerance.*
8. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for source and target observations.*
9. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational metric observations exposed by* S*.*
10. R *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for all distance and tolerance rows.*

11. *H records componentwise* hsame *transport for the metric, compact, totally bounded, continuity, graph-agreement, separated-target, inverse-modulus, stream, regular-rational, Real, replay, provenance, and local naming rows.*

12. *C records displayed* Cont *replay through*

$$X, Y, M, T, F, G, A, B, E, S, Q, R \longmapsto \mathsf{NameCert}_{\mathsf{CompactUniformHomeomorphism}^{\uparrow}}.$$

13. *P is the* Pkg *provenance over* $\mathsf{CompactUniformHomeomorphism}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformHomeomorphism}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, M, T, F, G, A, B, E, S, Q, R, H, C, P, N$. The carrier has no coordinate for open-cover compactness, selected nearest net points, quotient equality of functions, host equality, an ambient inverse map, choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactUniformHomeomorphismUp.CompactUniformHomeomorphismTasteGate single carrier alignment`

Theorem 5927.2 (CompactUniformHomeomorphism NameCert surface)**.** *For every accepted* CompactUniformHon *carrier*

$$U = (X, Y, M, T, F, G, A, B, E, S, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformHomeomorphism}^{\uparrow}}$ *surface consists exactly of the metric-space rows X, Y, the compact-metric finite-cover row M, the totally-bounded finite-net row T, the forward and inverse graph rows F, G, A, the separated-target ledger B, the inverse-modulus row E, the finite stream and regular-rational rows S, Q, the terminal Real seal R, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local name N.*

Consequently every inverse-uniform-continuity read exported by the packet must pass through the sibling $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before any consumer may inspect the inverse modulus. The surface exports no open-cover compactness theorem, no selected finite subcover, no quotient equality of maps, no host equality, no choice function, and no ambient Real-completeness witness.*

Lean4 ✓ `BEDC.Derived.CompactUniformHomeomorphismUp.CompactUniformHomeomorphismNameCertSurface`

Proof. Project the accepted carrier. Its public rows are precisely the metric, compact, total-boundedness, continuity, graph-agreement, separation, modulus, stream, regular-rational, Real, transport, replay, provenance, and local naming rows listed in Definition 5927.1.

The finite-net rows are read from M through T, while the map rows are read from F, G, A. The separated-target ledger B compares finite target cells using only the metric classifier rows in Y and the displayed forward graph row.

The inverse-modulus row E is downstream of those finite rows. Transport, replay, provenance, and local naming are then supplied by H, C, P, N without adding another compactness or equality coordinate. □

Theorem 5927.3 (CompactUniformHomeomorphism inverse modulus)**.** *Let U be an accepted* $\mathsf{CompactUniformHomeomorphism}^{\uparrow}$ *packet and let ε be a positive target tolerance row displayed through the target* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal. Then U displays a finite source tolerance row δ such that every pair of target observations whose source representatives are read through the accepted*

inverse graph row and whose target distance is below δ has source distance below ε on the displayed finite windows.

The row δ is obtained by refining the $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row of the* $\mathsf{CompactMetric}^{\uparrow}$ *source until the separated-target ledger accepts the target tolerance. It preserves the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph rows,* $\mathsf{Met}^{\uparrow}$ *distance rows,* $\mathsf{Real}^{\uparrow}$ *tolerance seal, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *support. The construction does not use choice, open-cover compactness, host equality, quotient equality of maps, selected limits, or ambient Real completeness.*

Proof. Start with the positive target tolerance row and open the finite-net row T supplied by the compact-metric source row M. Each refinement remains a displayed finite BEDC row with the same metric, stream, regular-rational, and Real seal support.

Use the separated-target ledger B to test the images of the finitely many source cells. When the ledger accepts the requested target separation, it records a finite source radius that prevents two distinct source cells from being identified by the inverse graph read.

Read that accepted radius as the inverse-modulus row E. The forward and inverse graph rows F, G, A then transport the finite target comparison back to the source metric rows, and H, C, P, N preserve the same route under transport, replay, provenance, and local naming.

Since every step uses displayed finite-net rows and separated-target rows, the modulus is not extracted from a choice operator, an open-cover compactness proof, host equality, quotient map equality, selected limits, or ambient Real completeness. □

Falsifiable prediction: Every $\mathsf{CompactUniformHomeomorphism}^{\uparrow}$ inverse-modulus read factors through one CompactMetric finite-cover row, one TotallyBounded finite-net row, ContinuousMap graph rows, MetricSpace distance rows, RealUp tolerance seals, separated-target rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compactmetric, continuousmap, metricspace, totallybounded, real: CompactUniformHom is not bijective to any listed sibling because it jointly carries finite-net refinement, separated-target comparison, inverse graph agreement, inverse-modulus extraction, Real tolerance sealing, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformHomeomorphism}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformHomeomorphism}^{\uparrow}$ packet is generated from source and target MetricSpace rows, CompactMetric finite-cover data, TotallyBounded finite-net rows, ContinuousMap graph rows, separated-target comparison, inverse graph agreement, inverse-modulus extraction, stream and regular-rational readback, Real tolerance seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformHomeomorphism}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5927.1, Definition 5927.2, and Definition 5927.3 seed the finite compact-uniform-homeomorphism carrier, certificate, and inverse-modulus packet boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformHomeomorphism}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected finite subcovers, quotient equality of functions or maps, host equality, choice functions, ambient inverse maps, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net refinement exactness, separated-target ledger exactness, inverse graph agreement, inverse-modulus extraction and non-escape, Real tolerance sealing, transport, replay, provenance, local NameCert coverage, package non-escape, and a Lean carrier formalization for BEDC.Derived.CompactUniformHomeom

Chapter 5928

A Concrete Naming Certificate for $\mathsf{LocatedMonotoneLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedMonotoneLimit}^{\uparrow}$ packet records the finite route by which a located upper bound and a displayed monotone real sequence supply a regular Cauchy seal without importing a classical supremum, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. It sits after the reusable upper-bound witness of chapter 3396, the located-supremum monotone handoff of chapter 1427, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38.

Definition 5928.1 (LocatedMonotoneLimit carrier)**.** *A* $\mathsf{LocatedMonotoneLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, U, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the monotone real-sequence row, carrying the inspected finite sequence windows and the displayed increasing comparison ledger.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to those finite windows.*
3. *U is the* $\mathsf{LocatedUpperBound}^{\uparrow}$ *row, naming the located upper-bound witness consumed by the sequence window.*
4. *W is the common precision-window row, recording the finite index at which the monotone window and upper-bound ledger are read together.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from S, D, U, W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the regular readback R and from no other source.*
7. *H records componentwise* hsame *transport for the monotone sequence, dyadic tolerance, located upper bound, common window, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from every limit request through $S, D, U, W, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedMonotoneLimit}^{\uparrow}$, $\mathsf{LocatedUpperBound}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedMonotoneLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host supremum, a selected limit point, quotient real equality, trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LocatedMonotoneLimitUp.LocatedMonotoneLimitTasteGate single carrier alignment`

Theorem 5928.2 (LocatedMonotoneLimit NameCert obligations)**.** *For every accepted* $\mathsf{LocatedMonotoneLimit}^{\uparrow}$ *carrier*

$$M = (S, D, U, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedMonotoneLimit}^{\uparrow}}$ *surface consists exactly of carrier admission, monotone-window exposure, located-upper-bound extraction, common-window compatibility, regular Cauchy readback, terminal Real-seal routing, componentwise transport, displayed replay, provenance, and local naming for the same finite packet.*

Proof. Project the carrier of Definition 5928.1. The analytic rows visible before the seal are exactly the monotone sequence row S, dyadic tolerance row D, located upper-bound row U, common precision window W, and regular readback row R.

The located-upper-bound and monotone-window obligations are read before R. Thus the regular Cauchy readback is built from displayed finite rows rather than from a host supremum theorem or a selected limit.

Finally read the structural rows H, C, P, N. They transport, replay, source, and name the same packet componentwise, so the listed obligations exhaust the local certificate surface. □

Theorem 5928.3 (LocatedMonotoneLimit upper-bound extraction)**.** *Every accepted* $\mathsf{LocatedMonotoneLimit}^{\uparrow}$ *carrier exposes its upper-bound information only through the displayed* $\mathsf{LocatedUpperBound}^{\uparrow}$ *row* U *and the common precision window* W*. A completion-facing consumer must read* S, D, U, W *before it can inspect the regular readback* R *or the terminal Real seal* E*.*

Proof. The upper-bound coordinate of the carrier is the row U. By definition it is paired with the monotone sequence and tolerance rows through the window W, so no consumer can read an upper-bound witness detached from the inspected sequence window.

The readback row R is downstream of S, D, U, W. Therefore any completion-facing request that reaches R or E has already exposed the located upper-bound witness and the finite precision window that binds it to the monotone sequence. □

Theorem 5928.4 (LocatedMonotoneLimit regular Cauchy seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{LocatedMonotoneLimit}^{\uparrow}$ *carrier factors through the finite route*

$$S, D, U, W \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

The route records the constructive monotone-limit handoff as a regular rational Cauchy seal, not as a quotient completion, selected supremum, or ambient completeness theorem.

Proof. Start with the displayed monotone sequence, dyadic tolerance ledger, located upper-bound row, and common precision window. These rows are the only pre-readback coordinates of the carrier.

The row R repacks those finite rows as regular rational Cauchy data. The terminal row E is then a $\mathsf{Real}^{\uparrow}$ seal for that readback, and H, C, P, N preserve the same route under transport, replay, provenance, and naming.

Since the carrier has no quotient-completion, selected-supremum, or ambient-completeness coordinate, the exported seal is exactly the displayed regular Cauchy route. □

Theorem 5928.5 (LocatedMonotoneLimit nonescape)**.** *No accepted* $\mathsf{LocatedMonotoneLimit}^{\uparrow}$ *consumer can extract a classical least upper bound, trichotomy decision, countable-choice selector, quotient representative, host sequence equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle from the packet. Every observable limit-facing row remains a read of* $S, D, U, W, R, E, H, C, P, N$*.*

Proof. Inspect the carrier coordinates. They list only the monotone sequence windows, dyadic tolerance ledger, located upper-bound witness, common precision window, regular readback, terminal seal, and structural rows.

The refused objects are absent from this list. Componentwise transport through H and replay through C preserve existing rows but do not add new coordinates, and provenance plus local naming record the same finite packet.

Consequently any accepted consumer remains inside the route $S, D, U, W, R, E, H, C, P, N$ and cannot export the refused classical or ambient data. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedMonotoneLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedMonotoneLimit}^{\uparrow}$ packet is generated from monotone real-sequence windows, a DyadicRatCore tolerance ledger, a LocatedUpperBound witness, a common precision window, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedMonotoneLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5928.1, Definition 5928.2, Definition 5928.3, Definition 5928.4, and Definition 5928.5 seed the finite constructive monotone-limit handoff from located upper-bound data to a regular Cauchy Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedMonotoneLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close classical supremum existence, trichotomy, countable choice, quotient representatives, host sequence equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window exposure, located-upper-bound extraction, common-window compatibility, regular Cauchy readback, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.LocatedMonotoneLimitUp.

Chapter 5929

A Concrete Naming Certificate for $\mathsf{HopfRinowFiniteGeodesic}^{\uparrow}$

Following Hopf and Rinow, the $\mathsf{HopfRinowFiniteGeodesic}^{\uparrow}$ packet records the finite BEDC surface on which a compact complete Riemannian metric presentation exposes geodesic segments only as named rows. It reads the complete-metric handoff of chapter 128, the geodesic metric surface of chapter 2213, the Riemannian metric row of chapter 133, the compact metric row of chapter 129, and the Real readback boundary of chapter 38. The packet is a finite geodesic NameCert neighbour for completion data; it does not assert classical compactness theorems, select minimizing geodesics globally, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5929.1 (Hopf–Rinow finite geodesic carrier)**.** *A* $\mathsf{HopfRinowFiniteGeodesic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (C, M, R, K, S, Q, A, H, T, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row exposing the Cauchy-limit service used by finite geodesic endpoint reads.*
2. *M is the* $\mathsf{GeodesicMetric}^{\uparrow}$ *row naming the displayed geodesic segment incidence surface.*
3. *R is the* $\mathsf{RiemannianMetric}^{\uparrow}$ *row whose tangent-fibre metric data supplies the local length ledger.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *row whose finite-net and coverage witnesses bound the inspected endpoint windows.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row listing the endpoint, subdivision, and observation windows opened by the packet.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational length, radius, and tolerance observations exposed by S.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *seal for the finite distance and length comparisons read through Q.*
8. *H records componentwise* hsame *transport for the complete, geodesic, Riemannian, compact, stream, readback, Real, replay, provenance, and naming rows.*
9. *T records displayed* Cont *replay from endpoint windows through geodesic incidence, finite length comparisons, compact coverage, and complete-metric handoff.*

10. *P is the* Pkg *provenance over* HopfRinowFiniteGeodesic$^{\uparrow}$, CompleteMetric$^{\uparrow}$, GeodesicMetric$^{\uparrow}$, RiemannianMetric$^{\uparrow}$, CompactMetric$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{HopfRinowFiniteGeodesic}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an open-cover compactness theorem, a global minimizing-geodesic selector, quotient path equality, an unbounded Hopf–Rinow equivalence, or ambient Real$^{\uparrow}$ *completeness outside the displayed finite readback route.*

Lean4 ✓ `BEDC.Derived.HopfRinowFiniteGeodesicUp.HopfRinowFiniteGeodesicTasteGate single carrier alignment`

Theorem 5929.2 (Hopf–Rinow finite geodesic NameCert obligations)**.** *For every accepted* HopfRinowFiniteGeodesic *carrier $G = (C, M, R, K, S, Q, A, H, T, P, N)$, the local* NameCert$_{\text{HopfRinowFiniteGeodesic}^{\uparrow}}$ *surface consists exactly of carrier admission for the complete-metric row, geodesic-metric incidence row, Riemannian metric row, compact-metric row, finite stream windows, regular-rational readback, Real comparison seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every finite geodesic read must expose $C, M, R, K, S, Q, A, H, T, P, N$ before it can be consumed by a completion or metric-geometry neighbour.*

The packet exports no classical Hopf–Rinow equivalence, no chosen minimizing geodesic for arbitrary endpoints, no open-cover compactness principle, no quotient path completion, and no ambient completeness theorem for Real$^{\uparrow}$.

Proof. Project the carrier of Definition 5929.1. The complete, geodesic, Riemannian, and compact faces occur only as the rows C, M, R, K, so a downstream reader cannot replace them by host compactness or a global geodesic theorem.

Read the finite observations through S, Q, A. The stream row displays the endpoint and subdivision windows, the regular-rational row reads the length and radius comparisons opened by those windows, and the Real row seals only those finite comparisons.

The structural rows H, T, P, N then transport, replay, source, and name the same packet. Since no other coordinate occurs in the carrier, the local NameCert obligations cannot import open-cover compactness, a selected minimizing-geodesic function, quotient path equality, an unbounded Hopf–Rinow equivalence, or ambient Real completeness. □

Falsifiable prediction: Every accepted HopfRinowFiniteGeodesic$^{\uparrow}$ finite geodesic read factors through displayed CompleteMetricUp, GeodesicMetricUp, RiemannianMetricUp, CompactMetricUp, StreamNameUp, RegSeqRatUp, RealUp, hsame, Cont, Pkg, and local NameCert rows.

Independence witness: completemetric, geodesic-metric, riemannianmetric, compactmetric, streamname, regseqrat, real: HopfRinowFiniteGeodesic$^{\uparrow}$ is not bijective to any listed sibling because it carries the finite geodesic endpoint route together with completion, compact coverage, Riemannian length, rational readback, and local naming rows in one packet.

Closure status for NameCert$_{\text{HopfRinowFiniteGeodesic}^{\uparrow}}$.

Constructive story: A HopfRinowFiniteGeodesic$^{\uparrow}$ packet is generated from CompleteMetricUp handoff rows, GeodesicMetricUp incidence rows, RiemannianMetricUp length rows, CompactMetricUp finite-net rows, StreamName endpoint windows, RegSeqRat readback, RealUp comparison seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{HopfRinowFiniteGeodesic}^{\uparrow}}$, seed)

Scope closed: Definition 5929.1 and Definition 5929.2 seed the finite geodesic NameCert surface over completion, compactness, Riemannian metric, and rational readback rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{HopfRinowFiniteGeodesic}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim the classical Hopf–Rinow theorem, global minimizing geodesic selection, open-cover compactness, quotient path completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite endpoint-window replay, geodesic incidence stability, Riemannian length readback, compact coverage routing, complete-metric handoff, Real comparison exactness, transport, replay, provenance, and local naming for BEDC.Derived.HopfRinowFiniteGeodesicUp.

EffectiveCauchyCompletion$^{\uparrow}$ reads its completion route through chapter 126, chapter 301, chapter 291, and chapter 38; the child files below keep the carrier and L10 dependency rows separate.

Chapter 5930

A Concrete Naming Certificate for $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges and Weihrauch on constructive completion, the $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ packet records the finite L10 route by which regular rational Cauchy data becomes a completion-facing name without quotienting streams or selecting representatives. It sits after the dyadic tolerance core of chapter 291, the finite window discipline of chapter 126, the regular rational readback of chapter 301, the functorial Cauchy-completion route of chapter 423, and the terminal real-name seal of chapter 38. The certificate names the displayed effective completion surface only; it does not assert ambient completeness of $\mathsf{Real}^{\uparrow}$, quotient equality of Cauchy names, countable choice, selected limits, or host equality of completed objects.

The completion dependency is substantive: $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ consumes the $\mathsf{RealCauchyCompletion}^{\uparrow}$ seal route of chapter 360 and the $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ handoff of chapter 423 only through the visible $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{StreamName}^{\uparrow}$ finite-window rows. The consumed NameCert rows are the carrier rows W, R, D, F, S below: finite observation window, regular rational readback, dyadic tolerance, functorial completion route, and terminal $\mathsf{Real}^{\uparrow}$ seal. Thus the packet records a completion-lattice dependency rather than a kernel-only shortcut.

Definition 5930.1 (Effective Cauchy completion carrier)**.** *An* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, W, R, D, F, S, H, C, P, N)$$

with the following displayed rows:

1. *Q is the rational source row, recording the finite rational object or rational metric source being completed.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing the finite observation schedule used by completion consumers.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the regular rational Cauchy data visible on each requested window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, storing the dyadic error budget that certifies regularity and comparison.*
5. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *functorial route row, recording the displayed map from source data into completion-facing names.*

6. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row, recording the terminal real-name boundary consumed by downstream L10 readers.*
7. *H records componentwise* hsame *transport for $Q, W, R, D, F, S, C, P, N$.*
8. *C records displayed* Cont *replay from a completion request through $Q, W, R, D, F, S, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveCauchyCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion equality, selected stream representatives, selected limits, countable choice, host equality of completed objects, or ambient real completeness.

Theorem 5930.2 (Effective Cauchy completion NameCert obligations)**.** *For every accepted* EffectiveCauchyComple *carrier*

$$E = (Q, W, R, D, F, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveCauchyCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the rational source row, finite stream-window row, regular rational readback row, dyadic tolerance row, functorial completion route, terminal real-name seal, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. Every effective completion read must expose Q, W, R, D, F, S before H, C, P, N can be consumed.*

Proof. Project the carrier of Definition 5930.1. Its displayed coordinates are exactly the rational source, stream-window, regular-readback, dyadic-tolerance, functorial-completion, real-seal, transport, replay, provenance, and local naming rows.

The effective completion route is read through Q, W, R, D, F, S. The source row supplies the rational object, the window row supplies finite access, the regular readback row supplies Cauchy data, the dyadic row supplies the error budget, the functorial row records the completion passage, and the seal row presents the terminal real-name boundary.

The remaining rows H, C, P, N transport, replay, package, and name the same displayed route. Since quotient equality, selected representatives, selected limits, countable choice, host equality, and ambient completeness have no carrier coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 5930.3 (Effective Cauchy completion regular readback)**.** *For every accepted* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ *carrier $E = (Q, W, R, D, F, S, H, C, P, N)$, any completion-facing query that asks for a regular Cauchy name must read the finite* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D before it can consume the functorial completion route F or the terminal real-name seal S. The readback is therefore finite, dyadic, and regular before any completed-real boundary is visible.*

Proof. Begin with Definition 5930.2. It requires every effective completion read to expose the source, window, readback, tolerance, functorial, and seal rows before the structural rows are consumed.

The requested regular Cauchy name is not a host-level limit. It is the displayed triple W, R, D: finite windows determine what is observed, regular rational data supplies the Cauchy values, and the dyadic tolerance row records the budget that makes the read regular.

Only after this triple is visible can the functorial route F and the real seal S be consumed. Thus the completed boundary is reached through finite regular readback rather than through quotient completion or selected representatives. □

Theorem 5930.4 (Effective Cauchy completion window telescope)**.** *For every accepted* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ *carrier* $E = (Q, W, R, D, F, S, H, C, P, N)$*, any finite chain of completion-facing window refinements exposes the same route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyCompletionFunctor}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The later seal row factors through the earlier displayed windows, regular readbacks, dyadic tolerance rows, and functorial completion rows. No refinement step adds quotient completion equality, a selected stream representative, countable choice, or an ambient completeness coordinate.

Proof. Project the carrier of Definition 5930.1. The only refinement-facing rows are the finite window row W, the regular rational readback row R, the dyadic tolerance row D, the functorial route row F, and the terminal seal row S.

Apply Definition 5930.2. Each completion-facing read must expose those rows in order before H, C, P, N are consumed, so a later finite window refinement can only refine data already displayed by W, R, D, F, S.

Apply Definition 5930.3. Regular readback is visible before the functorial completion route and the real seal, and the dyadic tolerance row remains the only error-budget coordinate.

Therefore the finite telescope is componentwise: later rows factor through earlier displayed windows by hsame transport and displayed Cont replay. Since the carrier contains no quotient, choice, selected-representative, or ambient-completeness coordinate, none can appear in the refined seal. □

Theorem 5930.5 (Effective Cauchy completion rational telescope route)**.** *For every accepted* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ *carrier* $E = (Q, W, R, D, F, S, H, C, P, N)$*, every finite window refinement consumed by* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ *may be read through the rational telescope sibling of chapter 5922 before the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *row* F *and the* $\mathsf{Real}^{\uparrow}$ *seal row* S *are consumed. The route exposes* Q, W, R, D *as rational source, stream window, regular rational readback, and dyadic tolerance data, then passes through the telescope boundary before the functorial completion and terminal real-name rows are read.*

Proof. Project the carrier of Definition 5930.1. The finite completion-facing route is displayed as $Q, W, R, D, F, S, H, C, P, N$, so the rational source, window, regular readback, and tolerance rows are visible before the functorial and seal rows.

Apply Definition 5930.4. Any finite window refinement factors through the same stream-window, regular-readback, dyadic-tolerance, functorial-completion, and real-seal route. Apply Definition 5930.3. Regular rational readback is already exposed before the functorial completion route and the terminal seal are consumed.

The rational telescope sibling is finite, so inserting its read between Q, W, R, D and F, S does not add a quotient completion, a selected representative, a selected limit, countable choice, or host equality of completed objects. The support rows H, C, P, N then transport, replay, source, and name the same displayed route. □

Theorem 5930.6 (Effective Cauchy completion real seal scope)**.** *For every accepted* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ *carrier* $E = (Q, W, R, D, F, S, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *row* S *seals only the displayed regular-Cauchy route over* Q, W, R, D, F*. It does not identify all Cauchy names by quotient equality, does not choose a canonical representative, and does not supply ambient completeness for unrelated real-name consumers.*

Proof. Apply Definition 5930.3. The seal row is consumed only after the finite window, regular rational readback, dyadic tolerance, and functorial completion rows have been exposed.

This confines the seal to the same displayed route. The carrier has no row for quotienting all Cauchy names, selecting a canonical representative, or proving an ambient completeness principle for arbitrary real-name consumers.

Finally use Definition 5930.2. The structural rows H, C, P, N transport, replay, package, and name the route already bounded by Q, W, R, D, F, S; they do not add a second completion surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveCauchyCompletion}^{\uparrow}}$.

Constructive story: An $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ packet is generated from a rational source row, finite stream-window row, regular rational readback row, dyadic tolerance row, functorial Cauchy-completion route, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveCauchyCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5930.1, Definition 5930.2, Definition 5930.3, and Definition 5930.6 seed the finite effective-completion surface for L10 real and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveCauchyCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, selected limits, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, regular-readback exposure, dyadic tolerance confinement, functorial completion routing, terminal seal scope, transport, replay, provenance, and local naming for BEDC.Derived.EffectiveCauchyCompletionUp.

Theorem 5930.7 (Effective Cauchy completion L10 dependency route)**.** *Every* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ *completion read consumes its L10 dependency lattice before it exports completion evidence: finite windows from chapter 126, regular rational Cauchy readback from chapter 301, terminal real-name sealing from chapter 38, and the isometry-facing completion route from chapter 2036. These sibling rows must be visible before the packet presents* $Q, W, R, D, F, S, H, C, P, N$ *as an effective completion surface.*

Proof. Read the carrier through Definition 5930.1. The rows W, R, S are exactly the finite-window, regular-rational, and terminal real-name entries, while F is the completion-facing route row.

Apply Definition 5930.2. It requires the source, window, readback, tolerance, completion route, and real seal to be exposed before transport, replay, provenance, and naming are consumed.

Thus the L10 siblings are not optional commentary. They are the dependency route through which completion evidence becomes visible, and no quotient completion, selected representative, selected limit, or ambient completeness row is exported outside that route. □

Chapter 5931

A Concrete Naming Certificate for $\mathsf{EdelsteinContraction}^{\uparrow}$

Following Edelstein and Bishop–Bridges constructive metric practice, the $\mathsf{EdelsteinContraction}^{\uparrow}$ packet records the strict compact-metric contraction surface before any fixed-point endpoint is read. It sits after the metric source of chapter 57, the compact-metric finite inspection surface of chapter 129, the contraction comparison discipline of chapter 1418, the displayed Picard orbit route of chapter 2359, and the endpoint consumer of chapter 4298. The packet names only the compact source, a self-map graph, the Picard-style orbit, strict distance-decrease rows, sequential-continuity transport, componentwise history transport, continuation replay, provenance, and local naming; it does not select a fixed point, assert a Banach contraction ratio, import quotient completion equality, or use host choice.

Definition 5931.1 (EdelsteinContraction carrier)**.** *An* $\mathsf{EdelsteinContraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, K, F, O, D, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row carrying the inspected point and distance classifier;*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *row exposing only the finite compact-metric inspection data used by the strict-decrease consumer;*
3. *F is the self-map graph row over the same metric carrier;*
4. *O is the* $\mathsf{PicardIteration}^{\uparrow}$*-style orbit row generated from the self-map graph and an initial displayed point;*
5. *D is the strict distance-decrease row, recording that every displayed non-diagonal comparison in the orbit is sent to a strictly smaller displayed distance;*
6. *S is the* $\mathsf{SequentialContinuity}^{\uparrow}$ *transport row carrying convergent subsequence and image-cluster reads for the same graph;*
7. *H records componentwise* hsame *transport for the metric, compact-metric, graph, orbit, strict-decrease, sequential-continuity, replay, provenance, and local naming rows;*
8. *C records displayed* Cont *replay for the finite strict-contraction route;*
9. *P is the* Pkg *provenance over* $\mathsf{EdelsteinContraction}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{EdelsteinFixedPoint}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{EdelsteinContraction}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected fixed point, a uniform Lipschitz constant, a quotient completion representative, host function extensionality, open-cover compactness, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.EdelsteinContractionUp.EdelsteinContractionTasteGate single carrier alignment`

Theorem 5931.2 (EdelsteinContraction NameCert obligations)**.** *For every accepted* $\mathsf{EdelsteinContraction}^{\uparrow}$ *carrier $E = (X, K, F, O, D, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EdelsteinContraction}^{\uparrow}}$ *surface consists exactly of metric carrier admission through X, compact-metric finite inspection through K, self-map graph exposure through F, Picard-style orbit exposure through O, strict distance-decrease exposure through D, sequential-continuity transport through S, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5931.1. The rows $X, K, F, O, D, S, H, C, P, N$ are the only rows available to the local certificate, so each admissible read must begin with the displayed metric, compact-metric, graph, orbit, strict-decrease, sequential-continuity, transport, replay, provenance, and naming coordinates.

The compactness service is read only through K, and the distance service is read only through X. The self-map and orbit service is therefore constrained to the same source carrier before the strict decrease row D can be consumed.

Finally repack the rows through H, C, P, N. Componentwise transport, displayed replay, provenance, and local naming preserve exactly the listed rows and add no endpoint coordinate or host contraction principle. □

Theorem 5931.3 (EdelsteinContraction compact-metric route)**.** *Every fixed-point-facing consumer of an accepted* $\mathsf{EdelsteinContraction}^{\uparrow}$ *packet must read the route*

$$\mathsf{Met}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{ContractionMapping}^{\uparrow}, \mathsf{PicardIteration}^{\uparrow}, \mathsf{EdelsteinContraction}^{\uparrow}$$

through $X, K, F, O, D, S, H, C, P, N$ before the $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ *endpoint packet may be cited. In particular, the strict compact-metric contraction surface supplies a standalone dependency route and cannot be replaced by a Banach ratio row, a selected endpoint, quotient completion equality, host choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $E = (X, K, F, O, D, S, H, C, P, N)$. The metric and compact-metric rows X and K supply the only distance and compactness reads, so any endpoint-facing consumer first exposes the same source carrier and finite inspection surface.

Read the self-map graph F and the Picard-style orbit O next. The strict distance-decrease row D is meaningful only for those displayed graph and orbit rows, while S transports the sequential image and cluster reads along the same finite route.

The endpoint packet $\mathsf{EdelsteinFixedPoint}^{\uparrow}$ can therefore cite the contraction surface only through H, C, P, N after the metric, compact-metric, graph, orbit, strict-decrease, and sequential-continuity rows have been displayed. Since no Banach ratio, selected endpoint, quotient completion representative, host choice operator, or ambient real-completeness row appears in the carrier, none is exported by the route. □

Falsifiable prediction: Every $\mathsf{EdelsteinContraction}^{\uparrow}$ read factors through one MetricUp source row, one CompactMetricUp finite inspection row, one self-map graph row, one PicardIterationUp-style orbit row, one strict distance-decrease row, one SequentialContinuityUp transport row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any EdelsteinFixedPointUp endpoint consumer is available.

Independence witness: metric, compactmetric, contractionmapping, picard-iteration, edelstein-fixed-point: $\mathsf{EdelsteinContraction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a compact-metric source, a self-map graph, an orbit row, a strict pointwise distance-decrease row, sequential-continuity transport, and endpoint-facing provenance without carrying an endpoint itself.

Closure status for $\mathsf{NameCert}_{\mathsf{EdelsteinContraction}^{\uparrow}}$.

Constructive story: An $\mathsf{EdelsteinContraction}^{\uparrow}$ packet is generated from a MetricUp source row, a CompactMetricUp finite inspection row, a self-map graph, a PicardIterationUp-style orbit row, a strict distance-decrease row, a SequentialContinuityUp transport row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EdelsteinContraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5931.1, Definition 5931.2, and Definition 5931.3 seed the strict compact-metric contraction surface feeding the Edelstein fixed-point endpoint route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EdelsteinContraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close endpoint existence, endpoint uniqueness, Banach contraction ratios, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-metric inspection, self-map graph exposure, orbit exposure, strict distance-decrease preservation, sequential-continuity transport, replay, provenance, and local naming for BEDC.Derived.EdelsteinContractionUp.

Chapter 5932

A Concrete Naming Certificate for $\mathsf{BerkovichClosedDisc}^{\uparrow}$

Following Berkovich's closed-disc analytic viewpoint, the $\mathsf{BerkovichClosedDisc}^{\uparrow}$ packet records the finite BEDC surface of a closed non-Archimedean analytic disc as local-field source data, an ultrametric radius ledger, polynomial probes, and bounded multiplicative seminorm reads. It sits downstream of the p-adic carrier of chapter 100, the local-field source of chapter 173, the ultrametric space boundary of chapter 1535, and the polynomial probe family of chapter 50. The packet names the closed-disc seminorm interface; it does not claim full rigid analytic geometry, a completed adic space theory, a generic-point topology, or a global affinoid-category theorem.

Definition 5932.1 (Berkovich closed disc carrier)**.** *A* $\mathsf{BerkovichClosedDisc}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, a, \rho, U, Q, E, V, H, C, P, N)$$

with the following displayed rows:

1. *K is the local-field source row, exposing only the finite coefficient, valuation, residue, and completeness reads needed by the disc packet.*
2. *a is the centre row, read through the same local-field source and not as a selected host point outside the displayed packet.*
3. *ρ is the ultrametric radius ledger, recording the closed bound $|x - a| \leq \rho$ and the finite tolerance comparisons used by downstream consumers.*
4. *U is the* $\mathsf{UltrametricSpace}^{\uparrow}$ *route that keeps radius comparison non-Archimedean and componentwise.*
5. *Q is the polynomial probe-family row, listing the finite polynomial names and coefficient windows inspected by the current analytic read.*
6. *E is the bounded multiplicative-seminorm read row, recording the values assigned to the displayed probes and the bound imposed by the closed radius ledger.*
7. *V is the valuation compatibility row, requiring products, sums, and scalar coefficients to be consumed only through the displayed local-field and polynomial rows.*
8. *H records componentwise* hsame *transport for K, a, ρ, U, Q, E, V and for the replay, provenance, and local naming rows.*

9. *C records the displayed* Cont *route from local-field inspection through ultrametric radius comparison, polynomial probe readback, bounded seminorm evaluation, and valuation compatibility.*
10. *P is the* Pkg *provenance over* $\mathsf{BerkovichClosedDisc}^{\uparrow}$, $\mathsf{Padic}^{\uparrow}$, $\mathsf{LocalField}^{\uparrow}$, $\mathsf{UltrametricSpace}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BerkovichClosedDisc}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, a, \rho, U, Q, E, V, H, C, P, N$. It has no coordinate for a full Berkovich spectrum, a rigid analytic atlas, an adic point space, a completed structure sheaf, a quotient of analytic functions, or a host compactness theorem.

Lean4 ✓ `BEDC.Derived.BerkovichClosedDiscUp.BerkovichClosedDiscTasteGate single carrier alignment`

Theorem 5932.2 (Berkovich closed disc NameCert obligations)**.** *For every accepted* $\mathsf{BerkovichClosedDisc}^{\uparrow}$ *carrier $D = (K, a, \rho, U, Q, E, V, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BerkovichClosedDisc}^{\uparrow}}$ *surface consists exactly of carrier admission for the local-field source row, centre row, ultrametric radius ledger, ultrametric comparison route, polynomial probe family, bounded multiplicative-seminorm reads, valuation compatibility, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every closed-disc analytic read must expose $K, a, \rho, U, Q, E, V, H, C, P, N$ before it can be consumed.*

Proof. Project the carrier of Definition 5932.1. The source of coefficients and the centre of the disc are visible only through K and a, while the closed-radius constraint is recorded by the ultrametric ledger ρ and route U.

The analytic read then reaches only the displayed probe surface. The polynomial row Q supplies the finite family being inspected, and the bounded multiplicative-seminorm row E records values for those probes under the bound enforced by ρ.

Valuation compatibility is supplied by V, so products, sums, and scalar coefficients remain tied to the local-field and polynomial rows. The structural rows H, C, P, N transport, replay, source, and name the same finite packet.

Since no further coordinate occurs in the carrier, the certificate cannot export a full spectrum, rigid atlas, adic point space, structure sheaf, analytic-function quotient, or host compactness theorem. □

Falsifiable prediction: Every accepted $\mathsf{BerkovichClosedDisc}^{\uparrow}$ analytic read exposes the local-field source, centre, ultrametric radius ledger, polynomial probe family, bounded multiplicative seminorm values, valuation compatibility, componentwise hsame transport, Cont replay, Pkg provenance, and local naming before any closed-disc consumer may use it.

Independence witness: padic, localfield, ultrametricspace, polynomial: $\mathsf{BerkovichClosedDisc}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a local-field source, a closed ultrametric radius ledger, polynomial probe windows, and bounded multiplicative-seminorm reads in one finite analytic-disc packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BerkovichClosedDisc}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BerkovichClosedDisc}^{\uparrow}$ packet is generated from local-field source data, a centre row, an ultrametric closed-radius ledger, polynomial probe windows, bounded multiplicative-seminorm reads, valuation compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BerkovichClosedDisc}^{\uparrow}}$, seed)

Scope closed: Definition 5932.1 and Definition 5932.2 seed the finite closed-disc seminorm route over local-field, ultrametric, and polynomial probe rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BerkovichClosedDisc}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full rigid analytic geometry, completed adic space theory, a Berkovich spectrum topology, structure sheaf exactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius-ledger exactness, polynomial-probe readback, bounded multiplicative-seminorm compatibility, valuation stability, transport, replay, provenance, and local naming for BEDC.Derived.BerkovichClosedDiscUp.

The BoundedRealVariation$^{\uparrow}$ hub reads its partition-variation certificate through chapter 38, chapter 301, chapter 1863, chapter 291, and chapter 1757.

Chapter 5933

Bounded Real Variation NameCert Construction

Following Jordan's finite-variation analysis and the Bishop–Bridges constructive treatment of real functions by explicit rational names, the $\mathsf{BoundedRealVariation}^{\uparrow}$ packet records bounded real variation as finite BEDC ledger data. It sits between the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic partition surface of chapter 1863, the dyadic arithmetic ledger of chapter 291, and the bounded-set control of chapter 1757. The packet is a finite partition-variation certificate; it is not a host function quotient, an equality principle for completed reals, an open-cover compactness theorem, a variation measure, a supremum over all partitions, or a selected limiting partition.

Definition 5933.1 (Bounded real variation carrier)**.** *A* $\mathsf{BoundedRealVariation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (I, \Pi, E, R, D, B, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *interval-source row naming the displayed domain endpoints only through terminal real seals.*
2. *Π is the finite partition row, recording the ordered endpoint windows and adjacency data inspected by the variation request.*
3. *E is the endpoint-read row. For every cell boundary in Π, it records the finite source coordinate by which the real-valued input is read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the endpoint values displayed by E.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *variation-bound ledger. It stores the rational absolute-difference rows, finite partial-sum rows, and the displayed dyadic upper bound for the partition variation.*
6. *B is the* $\mathsf{BoundedSet}^{\uparrow}$ *control row asserting that the endpoint reads used by Π stay inside the displayed bounded real window consumed by the ledger D.*
7. *H records componentwise* hsame *transport for the interval source, partition rows, endpoint reads, regular rational readbacks, dyadic variation ledger, bounded-window row, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from partition exposure through endpoint readback, dyadic variation accounting, bounded-window control, and the terminal real-name route.*

9. *P is the* Pkg *provenance over* $\mathsf{BoundedRealVariation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BoundedSet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedRealVariation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, \Pi, E, R, D, B, H, C, P, N$. It has no coordinate for host real equality, arbitrary open covers, countable choice, a completed function-space quotient, a variation measure, or a supremum over unlisted partitions.

Lean4 ✓ `BEDC.Derived.BoundedRealVariationUp.BoundedRealVariationTasteGate single carrier alignment`

Theorem 5933.2 (Bounded real variation NameCert obligations)**.** *For every accepted* $\mathsf{BoundedRealVariation}^{\uparrow}$ *carrier*

$$V = (I, \Pi, E, R, D, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedRealVariation}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed real interval source I, finite partition exposure through Π, endpoint reads through E,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through R, dyadic variation-bound accounting through D, bounded-window control through B, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5933.1. Carrier admission is the assertion that the packet exposes only the rows $I, \Pi, E, R, D, B, H, C, P, N$.

The analytic rows are finite. The partition row Π lists the cells to be inspected, the endpoint-read row E names the finite coordinates used at each cell boundary, and R converts those reads into regular rational data before the dyadic ledger can sum any displayed difference.

The variation-bound obligation is exactly D, with bounded-window control supplied by B. Transport, replay, provenance, and local naming are the structural rows H, C, P, N over that same finite ledger.

Since no carrier coordinate stores host real equality, open-cover compactness, a selected limiting partition, a function-space quotient, a variation measure, or a supremum over all partitions, the listed rows exhaust the NameCert obligation surface. □

Theorem 5933.3 (Bounded real variation RegSeqRat handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{BoundedRealVariation}^{\uparrow}$ *carrier reads endpoint values only through the finite route*

$\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, Na

In particular, the consumer must expose the partition row Π, endpoint-read row E, regular rational readback row R, variation-bound ledger D, and bounded-window row B before the terminal real-name row I can be used as a bounded-variation certificate.

Proof. Start with a consumer read of an accepted packet. By Definition 5933.1, the only displayed partition data are the ordered cells in Π, so every endpoint request is tied to that finite row.

Endpoint values are then read through E and R. The row E selects the finite source coordinates, while R provides the $\mathsf{RegSeqRat}^{\uparrow}$ readback visible to arithmetic consumers.

The variation certificate is obtained only after the dyadic ledger D and bounded-window row B have been displayed. Thus a Real or Completion consumer receives a finite partition-variation route rather than host real equality, open-cover compactness, a selected limiting partition, a function-space quotient, or an ambient completeness principle. □

Theorem 5933.4 (Bounded real variation compactness refusal)**.** *An accepted* $\mathsf{BoundedRealVariation}^{\uparrow}$ *packet exports no open-cover compactness, no host real equality, and no supremum principle over all finite partitions. Its public boundary is only the displayed partition ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *variation-bound ledger, bounded-window control, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{BoundedRealVariation}^{\uparrow}}$ *row.*

Proof. Inspect the carrier coordinates in Definition 5933.1. None of $I, \Pi, E, R, D, B, H, C, P, N$ is an open cover, a cover-refinement choice function, a host-real equality witness, a quotient of real-valued functions, or a supremum construction.

The rows that can be consumed downstream are therefore the finite rows already named by the carrier: partition exposure, endpoint readback, dyadic variation accounting, bounded-window control, transport, replay, provenance, and naming. Any compactness or equality principle would require an additional coordinate, and the classifier ignores all such data. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRealVariation}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BoundedRealVariation}^{\uparrow}}$, seed)

Scope closed: Definition 5933.1, Definition 5933.2, Definition 5933.3, and Definition 5933.4 seed the finite bounded-real-variation route over partition rows, RegSeqRat endpoint reads, DyadicRatCore variation ledgers, bounded-window control, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BoundedRealVariation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host real equality, open-cover compactness, a completed function-space quotient, a variation measure, a supremum over all finite partitions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, RegSeqRat endpoint handoff, dyadic variation-bound exactness, bounded-window control, refusal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BoundedRealVariationUp.

Constructive story: A $\mathsf{BoundedRealVariation}^{\uparrow}$ packet is generated from a RealUp interval-source row, finite DyadicPartition endpoint rows, RegSeqRat readbacks, a DyadicRatCore variation-bound ledger, BoundedSet control, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5934

A Concrete Naming Certificate for $\mathsf{ProfiniteCompletion}^{\uparrow}$

Following Serre and Bourbaki-style profinite completion, the $\mathsf{ProfiniteCompletion}^{\uparrow}$ packet records a residually finite completion surface as finite inverse-limit quotient data rather than as a host topological group. It consumes the projection-window discipline of chapter 2168, the binary compact readback of chapter 1475, the finite observation windows of chapter 126, and the compact metric witness surface of chapter 129. The packet names only finite quotient stages, finite projection checks, compact totally disconnected readbacks, transport, replay, provenance, and local naming; it refuses quotient completion, Haar measure, selected infinite points, host equality, and choice.

Definition 5934.1 (Profinite completion carrier)**.** *A* $\mathsf{ProfiniteCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (Q, \Pi, W, B, K, H, C, P, N)$$

with the following displayed rows:

1. *Q is the quotient-stage ledger. Each row names a visible finite quotient stage, its finite kernel witness, and the finite comparison data admitted at that stage.*
2. *Π is the projection-compatibility ledger. It records only finite bonding maps between named quotient stages and the checked compatibility rows consumed by the inverse-limit surface.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row by which consumers ask for finitely many quotient stages and finitely many projection comparisons.*
4. *B is the* $\mathsf{CantorSpace}^{\uparrow}$ *readback row for the compact totally disconnected binary presentation obtained from the displayed finite windows.*
5. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *readback row, sealing the compact metric surface reached through the same finite quotient and projection data.*
6. *H records componentwise* hsame *transports for quotient stages, projection compatibility rows, stream windows, Cantor-space readbacks, compact metric readbacks, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay of the route*

$$Q \longmapsto \Pi \longmapsto W \longmapsto B \longmapsto K.$$

8. *P is the* Pkg *provenance over* ProfiniteCompletion$^{\uparrow}$, InverseLimitMetric$^{\uparrow}$, CantorSpace$^{\uparrow}$, StreamName$^{\uparrow}$, CompactMetric$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{ProfiniteCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion, Haar measure, selected infinite points, host equality, or choice.

Theorem 5934.2 (Profinite completion NameCert obligations)**.** *For every accepted* ProfiniteCompletion$^{\uparrow}$ *carrier $F = (Q, \Pi, W, B, K, H, C, P, N)$, the local* NameCert$_{\text{ProfiniteCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed quotient-stage ledger, finite projection-compatibility ledger,* StreamName$^{\uparrow}$ *finite windows,* CantorSpace$^{\uparrow}$ *compact totally disconnected readback,* CompactMetric$^{\uparrow}$ *readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public read must pass through those rows in the order displayed by C.*

Proof. Project the accepted carrier in Definition 5934.1. The only mathematical rows available to a consumer are the finite quotient stages Q, the projection-compatibility ledger Π, the finite window schedule W, the Cantor-space readback B, and the compact metric readback K.

The replay row C fixes the inspection route. A public read first selects finitely many quotient stages, then verifies finite projection compatibility, then reads the StreamName window, and only then reaches the CantorSpace and CompactMetric readback rows.

The rows H, P, N transport, source, and name exactly that surface. Since the carrier has no coordinate for quotient completion, Haar measure, selected infinite points, host equality, or choice, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.ProfiniteCompletionUp.ProfiniteCompletionTasteGate single carrier alignment`

Theorem 5934.3 (Profinite completion inverse-limit route)**.** *Every inverse-limit-facing read exported by an accepted* ProfiniteCompletion$^{\uparrow}$ *carrier factors through the displayed route*

$$Q, \Pi, W, B, K, H, C, P, N.$$

The quotient-stage ledger Q supplies finite stage data, Π supplies finite bonding compatibility, W supplies the StreamName$^{\uparrow}$ *window discipline, B supplies the* CantorSpace$^{\uparrow}$ *compact totally disconnected readback, and K supplies the* CompactMetric$^{\uparrow}$ *readback. The rows H, C, P, N provide transport, replay, provenance, and local naming for the same route.*

Proof. Start with the carrier of Definition 5934.1. Its inverse-limit content is not a host object; it is the displayed finite route from quotient stages and projection checks to finite windows and compact readbacks.

Apply the NameCert surface of Definition 5934.2. The consumer must inspect Q and Π before reading W, and W is the only access path to the CantorSpace row B and the CompactMetric row K.

Transport by H and replay by C preserve the same finite route, while P and N record provenance and local naming. Therefore every inverse-limit-facing read factors through $Q, \Pi, W, B, K, H, C, P, N$ and exports no quotient completion, Haar measure, selected infinite point, host equality, or choice principle. □

Closure status for NameCert$_{\text{ProfiniteCompletion}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{ProfiniteCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 5934.1, Definition 5934.2, and Definition 5934.3 seed the finite profinite-completion packet over quotient stages, projection compatibility, StreamName windows, CantorSpace readback, CompactMetric readback, transport, replay, provenance, and naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{ProfiniteCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, Haar measure, selected infinite points, host equality, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite quotient-stage routing, projection compatibility, StreamName window routing, CantorSpace readback, CompactMetric readback, transport stability, provenance, and local naming for BEDC.Derived.ProfiniteCompletionUp.

Constructive story: A ProfiniteCompletion$^{\uparrow}$ packet is generated from finite quotient-stage rows, projection-compatibility rows, StreamName finite-window rows, CantorSpace compact totally disconnected readback rows, CompactMetric readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 5935

A Concrete Naming Certificate for $\mathsf{SequentialCompactReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SequentialCompactReal}^{\uparrow}$ packet records the real-sequence compactness route as finite BEDC data. It sits beside the finite-window compactness surface of chapter 2372, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a non-quotient route from displayed sequence windows to a compact interval cluster read; it is not countable choice, not open-cover compactness, and not a selected infinite subsequence supplied by the host.

Definition 5935.1 (SequentialCompactReal carrier)**.** *A* $\mathsf{SequentialCompactReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, W, Q, I, S, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the real-sequence source row, naming the sequence request and the finite indices inspected by the compactness consumer.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite source windows, requested index windows, and observation schedule.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the rational approximants and tail budgets visible inside W.*
4. *I is the compact interval and finite-net row. It records the displayed interval bound, finite net scale, and interval membership witnesses used by the compactness route.*
5. *S is the subsequence-window row, recording only the displayed selected finite windows, their monotone index ledger, and the cluster-window comparison cells.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, compact interval row, and subsequence-window row have been exposed.*
7. *H records componentwise* hsame *transport for A, W, Q, I, S, E.*
8. *C records displayed* Cont *replay from the sequence source through stream windows, regular rational readback, compact interval nets, subsequence windows, and the real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{SequentialCompactReal}^{\uparrow}$, $\mathsf{SequentialCompact}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCompactReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, W, Q, I, S, E, H, C, P, N$. It has no coordinate for quotient stream equality, a host-selected infinite subsequence, countable choice, open-cover compactness, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.SequentialCompactRealUp.SequentialCompactRealTasteGate single carrier alignment`

Theorem 5935.2 (SequentialCompactReal NameCert obligations)**.** *For every accepted* $\mathsf{SequentialCompactReal}^{\uparrow}$ *carrier*

$$R = (A, W, Q, I, S, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialCompactReal}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *real-sequence source admission through A and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in W;*
2. $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q, with rational observations restricted to the displayed windows and tail budgets;*
3. *compact interval and finite-net admission through I, before any cluster read can be public;*
4. *subsequence-window and cluster comparison through S, followed by the terminal* $\mathsf{Real}^{\uparrow}$ *seal E;*
5. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N.*

No obligation row may be discharged by quotient stream equality, countable choice, a host-selected infinite subsequence, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 5935.1. The packet exposes exactly the real-sequence source, stream windows, regular rational readback, compact interval net, subsequence window, real seal, transport, replay, provenance, and local naming rows.

The source and rational data are finite. The rows A, W, Q name only requested sequence windows and their rational readbacks, so a consumer cannot replace them by a quotient stream or a full sequence object.

The compactness data enter through I and S. The interval and finite-net row is displayed before any cluster comparison, and the subsequence row records only finite selected windows with a monotone index ledger.

Finally E, H, C, P, N seal, transport, replay, source, and name that same packet. Since the excluded host principles are absent from the carrier, the five displayed obligation rows exhaust the local NameCert surface. □

Theorem 5935.3 (SequentialCompactReal regular rational route)**.** *Every public subsequence, cluster, or compact-interval read of an accepted* $\mathsf{SequentialCompactReal}^{\uparrow}$ *packet factors through*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{SequentialCompact}^{\uparrow}$$

before it reaches a downstream real-completion consumer. More concretely, the read first opens the finite windows W, then reads the regular rational row Q, then reaches the real-name seal E, and only then may cite the sequential compactness surface through I, S, H, C, P, N. The route exports no quotient stream equality, host-selected infinite subsequence, countable choice, open-cover compactness theorem, or ambient real completeness principle.

Proof. Start from Definition 5935.1. A public read can inspect only $A, W, Q, I, S, E, H, C, P, N$.

Apply Definition 5935.2. The source row opens finite $\mathsf{StreamName}^{\uparrow}$ windows before the $\mathsf{RegSeqRat}^{\uparrow}$ readback row can be consumed, and the real seal remains downstream of those rational observations.

The compactness part is then read through the sibling route of chapter 2372. The compact interval row I and subsequence-window row S play the same finite-window role for real sequences that the $\mathsf{SequentialCompact}^{\uparrow}$ packet plays for compactness consumers.

The structural rows H, C, P, N preserve and name this route. Since no excluded host coordinate occurs among the displayed rows, every public subsequence or cluster read factors through the stated sequence of finite interfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCompactReal}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialCompactReal}^{\uparrow}$ packet is generated from a real-sequence source row, finite StreamName windows, RegSeqRat rational readbacks, compact interval finite-net rows, subsequence-window ledgers, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialCompactReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5935.1, Definition 5935.2, and Definition 5935.3 seed the finite real-sequence compactness route through StreamName, RegSeqRat, Real, and SequentialCompact rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialCompactReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, countable choice, host-selected infinite subsequences, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exactness, RegSeqRat readback, compact interval finite-net admission, subsequence-window monotonicity, Real seal nonescape, and selector-refusal proofs for BEDC.Derived.SequentialCompactRealUp.

Chapter 5936

A Concrete Naming Certificate for MetaCICNormalizationFuelBoundary$^{\uparrow}$

The MetaCICNormalizationFuelBoundary$^{\uparrow}$ packet realizes the candidate-mediated bounded-fuel reading of chapter 9383 as finite NameCert data. It sits beside the normalization-candidate socket of chapter 3566, the candidate router of chapter 5210, the critical-path packet of chapter 765, and the normalization frontier of chapter 892. The packet records bounded inspection of candidate evidence; it does not promote a fuel trace into global strong normalization.

Definition 5936.1 (MetaCIC normalization fuel-boundary carrier)**.** *A* MetaCICNormalizationFuelBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, K, B, L, R, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed-term row, naming the typed closed MetaCIC term and the finite observations requested by the audit.*
2. *K is the candidate row, carrying candidate, closed-candidate, or candidate-set evidence before any strong-normalization read is allowed.*
3. *B is the bounded-fuel row, recording the natural fuel budget, decrement ledger, and stopping boundary for the inspected trace.*
4. *L is the finite trace row, listing the inspected beta steps and the local normal-endpoint status reached within the budget.*
5. *R is the closedness-preservation row, requiring every inspected trace endpoint to keep the displayed closed-term boundary before it is replayed.*
6. *O is the obstruction row, recording timeout, missing candidate evidence, subject-reduction dependence, and evidence-erasure refusal as visible outcomes.*
7. *H records componentwise* hsame *transport for T, K, B, L, R, O.*
8. *C records displayed* Cont *replay from the closed term through candidate evidence, fuel, trace, closedness preservation, obstruction, and structural rows.*
9. *P is the* Pkg *provenance over* MetaCICNormalizationFuelBoundary$^{\uparrow}$, NormalizationCandidateSocket$^{\uparrow}$, MetaCICCandidateNormalizationRouter$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationFuelBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, K, B, L, R, O, H, C, P, N$. It has no coordinate for evidence-erased strong normalization, erased subject reduction, host conversion equality, quotient syntax equality, or closed consistency.

Theorem 5936.2 (MetaCIC normalization fuel-boundary NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICNormalizationFuelBoundary}^{\uparrow}$ *carrier*

$$F = (T, K, B, L, R, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationFuelBoundary}^{\uparrow}}$ *surface consists exactly of finite rows for closed-term admission, candidate-evidence admission, bounded-fuel ledger exposure, trace inspection, closedness-preservation replay, obstruction visibility, componentwise transport, displayed continuation replay, provenance, and local naming. No obligation row may erase K, widen B into an unbounded normalizer, discharge the subject-reduction boundary, or export closed consistency.*

Proof. Project the carrier of Definition 5936.1. The displayed packet exposes a closed term, candidate evidence, bounded fuel, a finite trace, closedness preservation, obstruction, transport, replay, provenance, and local naming.

The candidate row is consumed before any normalization read. A public consumer may inspect K as evidence for the candidate-mediated route, but it cannot delete K and retain the same conclusion.

The fuel and trace rows are bounded. The row B supplies a finite budget and decrement ledger, while L records only the inspected steps within that budget.

The rows R and O keep the boundary visible. Closedness preservation is replayed only for the inspected trace endpoints, and missing candidate evidence, timeout, or subject-reduction dependence remain obstruction outcomes rather than hidden assumptions.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no evidence-erased normalizer or closed-consistency row, the listed obligations exhaust the local NameCert surface. □

Theorem 5936.3 (MetaCIC normalization fuel-boundary candidate route)**.** *Every public bounded-fuel normalization audit read of an accepted* $\mathsf{MetaCICNormalizationFuelBoundary}^{\uparrow}$ *packet factors through the candidate row K, the fuel row B, the finite trace row L, the closedness-preservation row R, and the visible obstruction row O before any replay through H, C, P, N. The route may report a bounded normal endpoint or a visible obstruction, but it cannot export evidence-erased strong normalization, unbounded normalization, erased subject reduction, host conversion equality, quotient syntax equality, or closed consistency.*

Proof. Begin with Definition 5936.2. It orders the public rows as closed-term admission, candidate evidence, bounded fuel, finite trace, closedness preservation, obstruction, transport, replay, provenance, and local naming.

The candidate-mediated siblings supply the front of the route. The normalization-candidate socket and candidate-normalization router provide the evidence row K and route it into the bounded trace without turning candidate evidence into an erased premise.

The critical-path and frontier siblings supply the boundary. They keep subject-reduction dependence, unfinished global normalization, and closed-consistency use outside the exported packet unless the displayed rows name them.

Thus a consumer can read only a bounded trace under candidate evidence, together with its visible obstruction status. The packet has no coordinate for the excluded host conclusions, so the candidate route is the whole public audit surface. □

Falsifiable prediction: A bounded normalization audit read that exports strong normalization after deleting the candidate row K and the fuel ledger B falsifies $\mathsf{MetaCICNormalizationFuelBoundary}^{\uparrow}$; the rejected evidence-erased fuel-to-SN route is not an accepted packet read.

Independence witness: Nearest siblings: normalization-candidate-socket, metacic-candidate-normalization-router, metaciccriticalpath, and metacicnormalizationfrontier. The fuel-boundary packet is not bijective to any of them because it jointly carries closed-term data, candidate evidence, bounded fuel, a finite trace, closedness preservation, visible obstruction, transport, replay, provenance, and local naming as one carrier.

The Lean TasteGate follow-up for this packet requires explicit $\mathsf{Nontrivial}\ \mathsf{MetaCICNormalizationFuelBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{MetaCICNormalizationFuelBoundary}^{\uparrow}$ instances in `TasteGate.lean`. The nontrivial boundary must separate accepted candidate-mediated bounded traces from timeout or missing-candidate packets, and field faithfulness must preserve $T, K, B, L, R, O, H, C, P, N$ without erasing the candidate or fuel rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationFuelBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICNormalizationFuelBoundary}^{\uparrow}$ packet is generated from a closed MetaCIC term row, candidate evidence, bounded fuel, finite trace rows, closedness-preservation replay, visible obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationFuelBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5936.1, Definition 5936.2, and Definition 5936.3 seed the candidate-mediated bounded-fuel normalization audit boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationFuelBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim evidence-erased strong normalization, unbounded normalization, erased subject reduction, host conversion equality, quotient syntax equality, closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked closed-term admission, candidate-evidence admission, fuel-ledger exactness, trace inspection, closedness-preservation replay, obstruction visibility, TasteGate nontriviality, field faithfulness, and local naming for BEDC.Derived.MetaCICNormalizationFuelBoundaryUp.

Chapter 5937

A Concrete Naming Certificate for $\mathsf{CompactIntervalModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactIntervalModulus}^{\uparrow}$ packet records the finite modulus route for compact intervals as displayed NameCert data. It refines the compact interval source of chapter 3986, consumes the finite compactness surface of chapter 3969, and terminates through the real-name seal of chapter 38. The packet supplies a choice-free L10 route from interval compactness to modulus readback for downstream Completion, LocatedMetric, and separated-reflection consumers without asserting open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5937.1 (Compact interval modulus carrier)**.** *A* $\mathsf{CompactIntervalModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, K, F, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{BishopCompactInterval}^{\uparrow}$ *source row, exposing the constructive interval endpoint, locatedness, finite-net, dyadic, stream, regular, and Real-facing data of the compact interval route.*
2. *K is the* $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ *compactness row over the same interval source.*
3. *F is the finite-net handoff row, recording the inspected mesh, radius ledger, and coverage comparison used by modulus consumers.*
4. *T is the dyadic tolerance row for requested output precision.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the interval and finite-net data.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the finite windows and tolerance ledger.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint and modulus readback.*
8. *H records componentwise* hsame *transport for source interval, compactness, finite-net, tolerance, stream, regular, Real, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from interval inspection through compact finite-net handoff, tolerance request, finite windows, regular readback, and Real sealing.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalModulus}^{\uparrow}$, $\mathsf{BishopCompactInterval}^{\uparrow}$, ClosedBoundedIntervalCompact $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalModulus}^{\uparrow}}$ *row.*

The classifier accepts only packets with these displayed rows. It has no coordinate for arbitrary open covers, selected finite subcovers, quotient real equality, countable-choice schedules, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactIntervalModulusUp.CompactIntervalModulusTasteGate single carrier alignment`

Theorem 5937.2 (Compact interval modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactIntervalModulus}^{\uparrow}$ *carrier* $M = (I, K, F, T, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, Bishop compact interval source exposure through* I*, closed-bounded compactness exposure through* K*, finite-net handoff through* F*, dyadic tolerance control through* T*, finite window exposure through* W*, regular rational readback through* R*, terminal Real sealing through* E*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Carrier admission is projection from Definition 5937.1. The tuple lists the interval source, compactness row, finite-net handoff, tolerance row, stream windows, regular readback, Real seal, and structural rows.

The interval source is read first through I and K. These rows bind the Bishop compact interval route to the closed-bounded compactness surface before a modulus consumer can inspect any mesh or tolerance data.

The modulus handoff is finite. The row F records the mesh and coverage comparison, while T, W, R route each precision request through dyadic tolerance, finite stream windows, and regular rational readback.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no open-cover, selected-subcover, quotient, choice, representative, or ambient-completeness coordinate, the listed rows exhaust the local certificate surface. □

Theorem 5937.3 (Compact interval modulus finite-net handoff)**.** *Every modulus-facing consumer of an accepted* $\mathsf{CompactIntervalModulus}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{BishopCompactInterval}^{\uparrow} \longmapsto \mathsf{ClosedBoundedIntervalCompact}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}$$

The handoff exposes only the compact interval source, closed-bounded compactness row, finite-net mesh, dyadic tolerance, finite windows, regular readback, Real sealing, transport, replay, provenance, and local naming; it exports no open-cover compactness theorem, selected subcover, quotient real equality, countable-choice schedule, selected representative, or ambient Real completeness principle.

Proof. Project the accepted carrier $M = (I, K, F, T, W, R, E, H, C, P, N)$. The compact interval source is I, the compactness row is K, and the finite-net handoff is F.

Read a modulus request through T, W, R. The dyadic tolerance row fixes the requested precision, the stream row exposes the finite windows permitted by the interval and net data, and the regular row gives the rational readback.

The terminal route reaches E only after those displayed rows have been consumed. The structural rows H, C, P, N preserve the same order for downstream consumers.

Because the carrier lacks open-cover, selected-subcover, quotient, choice, representative, and ambient-completeness coordinates, no stronger compactness or Real principle can be read from the handoff. □

Theorem 5937.4 (Compact interval modulus completion readback)**.** *Any* Completion$^{\uparrow}$ *or* LocatedMetric$^{\uparrow}$ *consumer reading a modulus from an accepted* CompactIntervalModulus$^{\uparrow}$ *packet receives the displayed rows* $I, K, F, T, W, R, E, H, C, P, N$ *and no additional equality, selection, or completeness data. A* SeparatedMetric$^{\uparrow}$ *consumer may later transport the distance or readback rows through its own reflection surface, but this packet itself does not turn compact interval modulus evidence into host equality, quotient equality, selected representatives, selected subcovers, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start with the carrier of Definition 5937.1. Its completion-facing data are exactly the compact interval source, compactness row, finite-net handoff, tolerance row, stream row, regular readback, Real seal, and structural rows.

Apply Definition 5937.2. The obligation surface forces source exposure through I, K, handoff through F, tolerance and readback through T, W, R, and terminal sealing through E.

Apply Definition 5937.3. The theorem orders the same rows as the finite route from compact interval data to modulus readback.

Thus Completion and LocatedMetric consumers may consume the displayed distance and readback data only through this route. A later SeparatedMetric consumer must add its own reflection rows before any identity interpretation is available, and all refused open-cover, selection, quotient, choice, representative, and ambient-completeness objects remain absent. □

Falsifiable prediction: Every accepted CompactIntervalModulus$^{\uparrow}$ read passes through BishopCompactIntervalUp, ClosedBoundedIntervalCompactUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, transport, replay, provenance, and local naming rows before any modulus output is visible.

Independence witness: bishop-compact-interval, closed-bounded-interval-compact, compact-interval-modulus-bridge, compact-interval-choice-free, uniformmodulus: CompactIntervalModulus$^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact interval source rows, closed-bounded compactness rows, finite-net handoff, dyadic tolerance, stream windows, regular readback, terminal Real sealing, transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{CompactIntervalModulus}^{\uparrow}}$.

Constructive story: A CompactIntervalModulus$^{\uparrow}$ packet is generated from BishopCompactIntervalUp, ClosedBoundedIntervalCompactUp, finite-net handoff, DyadicRatCoreUp tolerance, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactIntervalModulus}^{\uparrow}}$, seed)

Scope closed: Definition 5937.1, Definition 5937.2, Definition 5937.3, and Definition 5937.4 seed the finite compact-interval modulus route over compact interval, closed-bounded compactness, dyadic, stream, regular, and Real rows.

Formal verification: FormalStatus(NameCert$_{\text{CompactIntervalModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, quotient real equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact interval source exposure, finite-net handoff, tolerance routing, readback, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.CompactIntervalModu

Chapter 5938

A Concrete Naming Certificate for $\mathsf{MoscoConvergence}^{\uparrow}$

Following Mosco's variational convergence theorem, the $\mathsf{MoscoConvergence}^{\uparrow}$ packet records the finite certificate surface by which lower-semicontinuous convex functionals converge through weak-liminf and strong-recovery clauses. It sits downstream of the weak-topology route of chapter 5192, the convex-support surface of chapter 208, the completion handoff of chapter 1506, and the terminal real readback of chapter 38. Its weak-liminf and recovery rows feed the explicit variational witness ledger of chapter 6745 before that sibling exposes recovery schedules, value readbacks, and completion handoffs. The packet is a NameCert for variational convergence data, not a host Hilbert-space theorem, a selected minimizer, quotient equality of functionals, compactness by choice, or an ambient dual-space completion principle.

Definition 5938.1 (MoscoConvergence carrier)**.** *A* $\mathsf{MoscoConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, W, L, R, C, H, T, P, N)$$

with the following displayed rows:

1. *F is the lower-semicontinuity row for the source functionals, exposing only finite sublevel probes, scalar readbacks, and closedness checks.*
2. *W is the weak-topology row, naming the finite weak neighborhoods and convergence probes used by liminf consumers.*
3. *L is the weak-liminf ledger, recording each lower-bound comparison through F, W and the terminal real readback.*
4. *R is the strong recovery-sequence row, displaying the finite approximation schedule, strong convergence probes, and scalar upper-bound witnesses.*
5. *C is the convex-set support row, binding the admissible-domain and sublevel convexity data used by both L and R.*
6. *H is the completion handoff row, available only after F, W, L, R, C have been displayed and only for the completion route named by this packet.*
7. *T stores componentwise* hsame *transport for lower-semicontinuity, weak topology, liminf, recovery, convex support, completion, provenance, and local naming rows.*

8. *P is the* Pkg *provenance over* $\mathsf{MoscoConvergence}^{\uparrow}$*, weak topology, convex support, completion handoff, lower-semicontinuity, recovery-sequence,* BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{MoscoConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, W, L, R, C, H, T, P, N$. It has no coordinate for host epigraph convergence, a selected minimizer, quotient equality of functionals, global compactness, countable choice, or ambient Hilbert-space completeness.

Theorem 5938.2 (MoscoConvergence NameCert obligations)**.** *For every accepted* $\mathsf{MoscoConvergence}^{\uparrow}$ *carrier*

$$M = (F, W, L, R, C, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MoscoConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the lower-semicontinuity row F, weak-topology row W, weak-liminf ledger L, recovery-sequence row R, convex support row C, completion handoff H, componentwise transport T, package provenance P, and local naming N.*

Proof. Project the carrier of Definition 5938.1. The convergence data visible to the classifier are precisely the lower-semicontinuity row F, weak-topology row W, weak-liminf ledger L, recovery row R, convex support row C, and completion handoff H.

The liminf obligation is forced through F, W, L. A consumer cannot read a weak lower-bound comparison until the weak neighborhood probes and lower-semicontinuity readbacks have both been displayed.

The recovery obligation is separate and positive. The row R supplies only finite strong-approximation schedules and scalar upper-bound witnesses, while C records the convex support on which those schedules are allowed to live.

Finally read H, T, P, N. These rows route completion handoff, transport, provenance, and local naming for the same finite packet. Since no host convergence theorem or selected minimizer is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 5938.3 (MoscoConvergence liminf-limsup scope)**.** *Every variational-convergence consumer of an accepted* $\mathsf{MoscoConvergence}^{\uparrow}$ *packet must read the weak-liminf route through F, W, L and the recovery route through R, C before it may use the completion handoff H or the structural rows T, P, N. The packet supplies a finite liminf–recovery certificate; it does not supply epi-convergence as a host theorem, Gamma-convergence equivalence, selected minimizers, quotient equality of functionals, compactness by countable choice, or ambient Hilbert-space completeness.*

Proof. Begin with the weak-liminf request. The only available lower-bound route is F, W, L, so the request must expose lower-semicontinuity probes, weak-topology neighborhoods, and the displayed real-valued comparison ledger.

Next read the recovery side. The row R supplies finite strong-approximation data, and C records the convex support needed to keep those approximants inside the admissible packet.

The completion handoff H is downstream of both routes. Transport, provenance, and local naming through T, P, N preserve the same displayed rows but add no global variational-convergence theorem. Thus the packet closes only the finite Mosco liminf–limsup scope named by the carrier. □

The same weak-liminf and recovery rows are consumed by chapter 5957 and **??** through the shared $F, W, L, R, C, H, T, P, N$ carrier before epigraphical or Gamma-facing consumers read completion data, so the local Mosco packet sits on the variational dependency lattice rather than as an isolated witness ledger.

Theorem 5938.4 (MoscoConvergence subspace topology route)**.** *Let $M = (F, W, L, R, C, H, T, P, N)$ be an accepted* $\mathsf{MoscoConvergence}^{\uparrow}$ *carrier. Any Gamma-convergence, epigraphical-limit, or subspace-topology consumer of the Mosco data must first display the lower-semicontinuity row F, weak-topology row W, recovery-sequence row R, convex-support row C, and completion handoff H, together with the weak-liminf ledger L and the structural rows T, P, N. In particular, consumers routed through chapter 5957,* **??***, or chapter 5993 receive the same finite variational packet before reading an induced topology or variational comparison conclusion.*

Proof. Project the carrier of Definition 5938.1. The rows F, W, L, R, C, H are the only analytic data available before transport, provenance, and local naming.

Apply Definition 5938.2. The lower-semicontinuity and weak-topology rows must precede the weak-liminf ledger, while the recovery and convex-support rows must precede any strong recovery read.

Next apply Definition 5938.3. It keeps the completion handoff downstream from both variational sides, so Gamma-facing, epigraphical, and subspace-topology consumers cannot read H or an induced-topology conclusion before F, W, L, R, C are displayed.

The structural rows T, P, N preserve the same finite packet. Since no carrier coordinate stores host epigraph convergence, quotient equality of functionals, selected minimizers, global compactness, or countable choice, the sibling lattice route is exactly the displayed row order. □

Closure status for $\mathsf{NameCert}_{\mathsf{MoscoConvergence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MoscoConvergence}^{\uparrow}$ packet is generated from lower-semicontinuity rows, weak-topology probes, a weak-liminf ledger, recovery-sequence data, convex support, completion handoff, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MoscoConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5938.1, Definition 5938.2, and Definition 5938.3 seed the finite Mosco convergence carrier through lower-semicontinuity, weak topology, recovery, convex support, completion handoff, and the recovery-ledger route of chapter 6745.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MoscoConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host epigraph convergence, Gamma-convergence equivalence, selected minimizers, quotient equality of functionals, global compactness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-semicontinuity visibility, weak-liminf exactness, recovery-sequence coverage, convex-support routing, completion handoff, transport, provenance, and local naming for BEDC.Derived.MoscoConvergenceUp.

Theorem 5938.5 (Mosco-to-Gamma variational dependency route)**.** *Every Γ-convergence or epigraphical-limit consumer that uses a* $\mathsf{MoscoConvergence}^{\uparrow}$ *packet may read the Mosco data only through the displayed carrier rows*

$$F, W, L, R, C, H, T, P, N.$$

The weak-liminf request is therefore routed through F, W, L, the recovery request through R, C, and any completion handoff through H after those two variational rows have been displayed. Consequently the sibling routes of chapter 5957 and **??** *consume a shared finite variational lattice rather than a host equivalence between Mosco, epigraphical, and Γ convergence.*
