Proof. Start with the accepted Mosco carrier of Definition 5938.1. Its weak-liminf side is exactly F, W, L, so a downstream lower-bound read cannot bypass the lower-semicontinuity row, weak-topology probes, or displayed comparison ledger.

The recovery side is separate. The row R gives the strong approximation schedule and C gives the convex support on which the schedule is read. These rows are the only recovery coordinates available to the variational consumers.

The completion and structural rows are downstream. The handoff H, transport T, provenance P, and local naming row N preserve the same packet for the Gamma and epigraphical routes, but they add no host theorem identifying the convergence notions. $\square$

Chapter 5939

A Concrete Naming Certificate for $\mathsf{FiniteRealIntervalChain}^{\uparrow}$

Following Cantor and Bishop–Bridges constructive nested-interval practice, the $\mathsf{FiniteRealIntervalChain}^{\uparrow}$ packet records a finite real-interval chain before any Real or Completion consumer may read an endpoint route as a point-name witness. It sits beside the dyadic rational core of chapter 291, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the located nested-interval sibling of chapter 1713. The packet names finite endpoint ledgers, containment witnesses, and diameter budgets; it is not an open-cover compactness theorem, a quotient-real construction, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5939.1 (Finite real interval chain carrier)**.** *A* $\mathsf{FiniteRealIntervalChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (E, I, J, D, S, R, L, H, C, P, N)$$

with the following displayed rows:

1. *E is the endpoint ledger, listing the left and right endpoint rows for each retained interval cell and their* $\mathsf{Real}^{\uparrow}$*-facing names.*
2. *I is the closed interval row family, recording the displayed closed interval cells and their endpoint order witnesses.*
3. *J is the chain containment witness row, asserting that every later interval cell is read inside the preceding cell through finite endpoint comparisons.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter-budget row, carrying the requested dyadic tolerance and the displayed diameter bound for each retained cell.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which endpoint and containment observations are requested.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows and dyadic budget ledgers.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after E, I, J, D, S, R have been displayed.*
8. *H records componentwise* hsame *transport for endpoint ledgers, closed interval rows, containment witnesses, dyadic budgets, stream windows, readback, Real seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a Real-facing interval witness request through E, I, J, D, S, R, L, H.*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteRealIntervalChain}^{\uparrow}$*, chapter 291, chapter 126, chapter 301, chapter 38, chapter 1713,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteRealIntervalChain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host interval intersection, selected quotient representatives, countable choice, open-cover compactness, detached completion data, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.FiniteRealIntervalChainUp.FiniteRealIntervalChainUp`

Theorem 5939.2 (FiniteRealIntervalChain NameCert obligations)**.** *For every accepted* $\mathsf{FiniteRealIntervalChain}^{\uparrow}$ *carrier $F = (E, I, J, D, S, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteRealIntervalChain}^{\uparrow}}$ *surface consists exactly of endpoint-ledger admission through E, closed interval row exposure through I, chain-containment witnesses through J, dyadic diameter budgets through D,* $\mathsf{StreamName}^{\uparrow}$ *window access through S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *seal through L, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5939.1. The endpoint ledger E and closed interval rows I expose the finite interval cells before any containment or point-name request can be replayed.

The chain part is read through J and D. The containment row J keeps later cells inside earlier cells, while the $\mathsf{DyadicRatCore}^{\uparrow}$ row D records the diameter budget used by the finite precision request.

The Real-facing part is read only after the finite observation route has been displayed. The $\mathsf{StreamName}^{\uparrow}$ windows S determine the requested endpoint observations, the $\mathsf{RegSeqRat}^{\uparrow}$ row R supplies regular rational readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal L is reached after those rows.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no row carries host interval intersection, quotient-real equality, countable choice, open-cover compactness, detached completion data, or ambient completeness, the NameCert surface is exhausted by the displayed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRealIntervalChain}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteRealIntervalChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5939.1 and Definition 5939.2 seed the finite interval-chain route from endpoint ledgers through closed interval cells, containment witnesses, dyadic budgets, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteRealIntervalChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, countable choice, quotient Real construction, selected host intersection point, detached completion object, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-row exposure, containment witness transport, dyadic diameter budget exactness, readback route, Real seal non-escape, and TasteGate compatibility for BEDC.Derived.FiniteRealIntervalChainUp.

Constructive story: A $\mathsf{FiniteRealIntervalChain}^{\uparrow}$ packet is generated from endpoint ledgers, closed interval rows, chain containment witnesses, DyadicRatCore diameter budgets, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

$\mathsf{RegularRealTailEquivalence}^{\uparrow}$ consumes the regular-tail readback of chapter 301 together with the finite-window schedule of chapter 126.

Chapter 5940

A Concrete Naming Certificate for $\mathsf{RegularRealTailEquivalence}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ packet records equality of regular real names as a finite tail-equivalence certificate rather than as a quotient of streams. It sits after the regular rational source rows of chapter 301, the finite observation windows of chapter 126, the dyadic tolerance ledger of chapter 291, the zero-tail factorization of chapter 380, the comparison surface of chapter 411, and the terminal real-name seal of chapter 38. The packet supplies the same-real route used by $\mathsf{Real}^{\uparrow}$ consumers without exporting host equality, selected limits, or ambient completeness.

Definition 5940.1 (Regular real tail equivalence carrier)**.** *A* $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R_0, R_1, W, D, Z, Q, E, H, C, P, N)$$

with the following displayed rows:

1. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular real names are compared.*
2. W *is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which both tails are inspected.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the displayed late-stage difference bounds.*
4. Z *is the* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail row for the displayed difference between the two source rows.*
5. Q *is the* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *comparison row that ties the two source tails to the same finite comparison route.*
6. E *is the* $\mathsf{Real}^{\uparrow}$ *seal boundary available only after* R_0, R_1, W, D, Z, Q *have been displayed.*
7. H *records componentwise* hsame *transport for the source rows, window row, dyadic ledger, null row, comparison row, seal row, continuation, provenance, and local name.*
8. C *records displayed* Cont *replay of the same finite route.*
9. P *records the* Pkg *provenance over* $\mathsf{RegularRealTailEquivalence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{NullSequence}^{\uparrow}$, $\mathsf{RegularCauchyComparison}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. N *is the local* $\mathsf{NameCert}_{\mathsf{RegularRealTailEquivalence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R_0, R_1, W, D, Z, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, host real equality, a selected representative, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5940.2 (Regular real tail equivalence NameCert obligations)**.** *For every accepted* RegularRealTailEquivale *carrier*

$$T = (R_0, R_1, W, D, Z, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularRealTailEquivalence}^{\uparrow}}$ *surface consists exactly of source-row exposure for R_0, R_1, shared finite-window exposure for W, dyadic tolerance exposure for D, zero-tail exposure for Z, comparison-route exposure for Q,* $\mathsf{Real}^{\uparrow}$ *seal exposure for E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5940.1. The first two rows expose the two regular rational sources, while W supplies the common finite stream window through which the tails are inspected.

Next read the analytic rows. The dyadic ledger D records the late-stage tolerance bounds, Z records the zero-tail route for the displayed difference, and Q records the regular Cauchy comparison route connecting the same source rows to the same finite window.

Finally read E, H, C, P, N. The seal row is downstream of the source, window, dyadic, null, and comparison rows, and the administrative rows transport, replay, package, and name that same finite route. Hence the NameCert surface is exactly the displayed tuple. □

Theorem 5940.3 (Regular real tail equivalence RegSeqRat route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer read of an accepted* $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *carrier factors through*

$$(R_0, R_1, W, D, Z, Q).$$

The read may use the two regular rational source rows only through the shared finite $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail row, and the* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *route. It cannot introduce a second stream representative, quotient stream equality, host real equality, selected limit, or ambient completeness datum.*

Proof. Start with an accepted packet. Projection exposes R_0 and R_1 as the only source rows, so any regular-rational read must begin with those displayed coordinates.

The shared finite window and dyadic ledger are then forced by W and D. A consumer has no detached inspection window or tolerance row outside the packet.

The same-real handoff is supplied by Z and Q. The null row records the zero-tail route for the displayed difference, and the comparison row records the common regular Cauchy comparison route. Since the carrier contains no coordinate for quotient streams, host equality, selected limits, or ambient completeness, none can be exported by the consumer read. □

Theorem 5940.4 (Zero-tail symmetry route)**.** *Let*

$$T = (R_0, R_1, W, D, Z, Q, E, H, C, P, N)$$

be an accepted $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *carrier. Swapping the two source rows gives the same Real-facing tail-equivalence route through*

$$(R_1, R_0, W, D, Z, Q, E, H, C, P, N).$$

The only equality witnesses consumed by the $\mathsf{Real}^{\uparrow}$ *seal are the zero-tail row* Z *and the regular Cauchy comparison row* Q*, and both are read through the shared finite window and dyadic ledger* W, D*. Thus the certificate is symmetric in* R_0 *and* R_1 *without adding quotient stream equality, selected representatives, host real equality, or ambient completeness.*

Proof. Project the carrier of Definition 5940.1. The source rows R_0 and R_1 are the only ordered coordinates affected by the swap; the shared window, dyadic ledger, null row, comparison row, seal, transport, replay, provenance, and local name remain the displayed rows of the same packet.

Use the NameCert obligations of Definition 5940.2. They require every same-real read to expose W, D, Z, Q before E is available, so the seal consumes the zero-tail and regular Cauchy comparison witnesses rather than the presentation order of the two source rows.

Apply the RegSeqRat route of Definition 5940.3. It confines both source rows to the shared finite-window and tolerance path. After the two sources are swapped, the rows H, C, P, N transport, replay, package, and name the same finite route, so no quotient stream, selected representative, host real equality, or ambient completeness datum is introduced. □

Theorem 5940.5 (Regular real tail equivalence transitivity route)**.** *Let*

$$T_{01} = (R_0, R_1, W_{01}, D_{01}, Z_{01}, Q_{01}, E_{01}, H_{01}, C_{01}, P_{01}, N_{01})$$

and

$$T_{12} = (R_1, R_2, W_{12}, D_{12}, Z_{12}, Q_{12}, E_{12}, H_{12}, C_{12}, P_{12}, N_{12})$$

be accepted $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *carriers whose middle* $\mathsf{RegSeqRat}^{\uparrow}$ *row is displayed as the same finite source row and whose* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers are jointly visible to one consumer. Then the two zero-tail and comparison routes compose to a third* $\mathsf{Real}^{\uparrow}$*-seal route from* R_0 *to* R_2*. The composed read is still a finite tail-equivalence certificate over displayed* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{NullSequence}^{\uparrow}$*, and* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *rows; it does not export quotient stream equality, host real equality, selected representatives, countable choice, or ambient completeness.*

Proof. Start with the NameCert obligations of Definition 5940.2. Each accepted packet exposes its two source rows, finite window, dyadic ledger, zero-tail row, comparison row, and Real seal before any same-real read is available.

Use the RegSeqRat route of Definition 5940.3. The middle source row R_1 is therefore visible in both reads only through the displayed finite windows and dyadic ledgers, so the consumer can align the two comparison routes without adding a new stream representative.

Apply zero-tail symmetry from Definition 5940.4 when the second route must be read in the matching orientation. The zero-tail rows and comparison rows remain the only equality witnesses consumed by the Real-facing seal.

Finally use Real seal nonescape from Definition 5940.6. Since every seal read is forced through the displayed source, window, dyadic, null, and comparison rows, composing the two displayed routes yields only the third finite Real-seal route and cannot create any of the excluded quotient, host-equality, representative, choice, or completeness coordinates. □

Theorem 5940.6 (Regular real tail equivalence Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *carrier reaches the seal row* E *only through the finite route*

$$R_0, R_1, W, D, Z, Q, H, C, P, N.$$

Thus the equality surface for the two regular real names is a tail-equivalence certificate over displayed RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, NullSequence$^{\uparrow}$, *and* RegularCauchyComparison$^{\uparrow}$ *rows, not a quotient of streams, host real equality, selected representative, or ambient* Real$^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted carrier. The seal row E is listed after the two source rows, shared window, tolerance ledger, null row, and comparison row, so it is not available as an independent endpoint.

Apply the NameCert obligations of Definition 5940.2. They identify the complete route that must be displayed before the local certificate can expose the Real-facing seal.

Use the RegSeqRat route of Definition 5940.3. It keeps the two regular rational source rows inside the shared finite-window, dyadic, null, and comparison path. The remaining rows H, C, P, N only transport, replay, package, and name that route, so the seal cannot leak quotient stream equality, host real equality, selected representatives, or ambient completeness. □

Closure status for NameCert$_{\text{RegularRealTailEquivalence}^{\uparrow}}$.

Constructive story: A RegularRealTailEquivalence$^{\uparrow}$ packet is generated from two RegSeqRat$^{\uparrow}$ source rows, a shared StreamName$^{\uparrow}$ window, a DyadicRatCore$^{\uparrow}$ tolerance ledger, a NullSequence$^{\uparrow}$ zero-tail row, a RegularCauchyComparison$^{\uparrow}$ comparison route, a Real$^{\uparrow}$ seal boundary, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularRealTailEquivalence}^{\uparrow}}$, seed)

Scope closed: Definition 5940.1, Definition 5940.2, Definition 5940.3, Definition 5940.4, Definition 5940.5, and Definition 5940.6 bind the carrier, local NameCert surface, regular-rational route, zero-tail symmetry route, transitivity route, and Real seal nonescape boundary for same-real tail equivalence.

Formal verification: FormalStatus(NameCert$_{\text{RegularRealTailEquivalence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove quotient stream equality, host real equality, selected representatives, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking for RegularRealTailEquivalence$^{\uparrow}$.

Upgrade path: Scoped closure requires Lean encoding of the carrier, NameCert obligation surface, regular-rational route, and Real seal nonescape boundary.

Theorem 5940.7 (Regular real tail-equivalence classifier forward link)**.** *Every public* RealClassifier$^{\uparrow}$ *read that consumes the regular-real tail-equivalence route of an accepted* RegularRealTailEquivalence$^{\uparrow}$ *packet does so through the downstream classifier chapter chapter 1620. The classifier receives the same finite route through* RegSeqRat$^{\uparrow}$ *source rows, the shared* StreamName$^{\uparrow}$ *window, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, the visible comparison boundary, the* Real$^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows before any public real-classifier read is exposed.*

Proof. Apply the Regular real tail equivalence Real seal nonescape theorem Definition 5940.6. It forces every Real-facing read through the finite tail route before the seal row is available.

Now read the RealClassifier consumer in chapter 1620. Its regular-real tail-equivalence readback theorem consumes the same regular rational sources, finite window, dyadic ledger, comparison boundary, and seal route before the public classifier boundary is reached.

The structural rows only transport, replay, source, and locally name that displayed packet. Hence the downstream classifier receives the existing tail-equivalence certificate rather than a quotient stream equality, selected representative, host equality, countable-choice schedule, or ambient completeness principle. □

Theorem 5940.8 (Regular real tail equivalence RegSeqRat StreamName route)**.** *Every accepted* $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *packet consumes* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{StreamName}^{\uparrow}$ *finite-window scheduling, and* $\mathsf{Real}^{\uparrow}$ *sealing before comparing tails. The dependency route is the finite carrier read*

$$R_0, R_1, W, D, Z, Q, E, H, C, P, N,$$

where the two regular rational source rows are exposed through chapter 301, the shared observation window is scheduled through chapter 126, and the equality-facing endpoint is sealed only through chapter 38. Tail equivalence has no selected limit, host equality, quotient class, or countable-choice coordinate.

Proof. Project the carrier and NameCert obligations of Definition 5940.1 and Definition 5940.2. They place R_0, R_1 before the shared window W and place the Real seal E after the finite tolerance, zero-tail, and comparison rows.

Apply the RegSeqRat route of Definition 5940.3. It forces the two source rows to be read as regular rational names before any tail comparison can be exported.

Next use Real seal nonescape, Definition 5940.6. The seal row is available only after the finite $\mathsf{StreamName}^{\uparrow}$ window, dyadic ledger, zero-tail row, and comparison route have been displayed.

Thus the packet compares tails only through the displayed RegSeqRat, StreamName, and Real route. Since the carrier has no coordinate for selected limits, host equality, quotient classes, or countable choice, none can enter the tail-equivalence read. □

Theorem 5940.9 (Regular real tail equivalence transitive finite-window route)**.** *Let*

$$T_{01} = (R_0, R_1, W_{01}, D_{01}, Z_{01}, Q_{01}, E_{01}, H_{01}, C_{01}, P_{01}, N_{01})$$

and

$$T_{12} = (R_1, R_2, W_{12}, D_{12}, Z_{12}, Q_{12}, E_{12}, H_{12}, C_{12}, P_{12}, N_{12})$$

be accepted $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *packets whose middle* $\mathsf{RegSeqRat}^{\uparrow}$ *source row is the same displayed finite row. Then their same-real reads compose through a common* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers* D_{01}, D_{12}*, the* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail rows* Z_{01}, Z_{12}*, the* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *routes* Q_{01}, Q_{12}*, and the downstream* $\mathsf{Real}^{\uparrow}$ *seal rows. The composed route is still a finite carrier-local certificate from* R_0 *to* R_2*; it introduces no quotient streams, host equality, selected representatives, countable-choice schedule, or ambient completeness row.*

Proof. Project both carriers using Definition 5940.1. The shared middle source is visible as the same displayed R_1 row, while each packet exposes its own finite window, dyadic tolerance ledger, zero-tail row, comparison route, Real seal, and structural rows.

Synchronize the finite windows by the $\mathsf{StreamName}^{\uparrow}$ rows. The two packets may be read by one consumer only after W_{01} and W_{12} are displayed, so the middle source is inspected through finite observation data rather than by selecting a representative stream.

Compose the zero-tail and comparison ledgers through that shared middle source. The rows D_{01}, Z_{01}, Q_{01} carry the first tail comparison and D_{12}, Z_{12}, Q_{12} carry the second, so the only available transitive evidence is their displayed dyadic, null-sequence, and regular-comparison data.

Finally re-seal through $\mathsf{Real}^{\uparrow}$. The seal rows E_{01} and E_{12} are downstream of the same finite route, and transport, replay, provenance, and local naming keep the composed read inside the two accepted packets. Since neither carrier contains quotient streams, host equality, selected representatives, choice, or ambient completeness, none can appear in the composed certificate. □

Theorem 5940.10 (Regular real tail transitive window coverage)**.** *Every completion-facing consumer of a composed* $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *route must expose both source packets'* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers,* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail rows,* $\mathsf{RegularCauchyComparison}^{\uparrow}$ *routes, and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows before it may read the composed same-real certificate. The composed certificate is therefore a finite coverage route over the two displayed packets, not a quotient-stream equality, representative selection, choice schedule, or ambient completeness endpoint.*

Proof. Apply the transitive finite-window route of Definition 5940.9. It already forces the shared middle source, both finite windows, both tolerance ledgers, both zero-tail rows, both regular-comparison routes, and both Real seals to stay visible in the composed read.

Project the two carriers through Definition 5940.1. The rows W_{01} and W_{12} expose the source windows, D_{01} and D_{12} expose the dyadic tolerance data, Z_{01} and Z_{12} expose the zero-tail witnesses, and Q_{01} and Q_{12} expose the regular Cauchy comparison routes.

Only after those rows are displayed can the terminal seals E_{01} and E_{12} be read. Since the carrier presents no quotient stream, selected representative, choice schedule, or ambient completeness row, a completion-facing consumer receives exactly the displayed coverage route before the composed same-real certificate. □

Chapter 5941

A Concrete Naming Certificate for $\mathsf{BrouwerFixedPointMetric}^{\uparrow}$

Following Brouwer and constructive fixed-point treatments, the $\mathsf{BrouwerFixedPointMetric}^{\uparrow}$ packet records finite metric approximations to the fixed-point route on compact convex metric data. It consumes the compact finite-net discipline of chapter 129 and the modulus-facing map discipline of chapter 130. The packet names mesh stages, approximate self-map witnesses, finite residual bounds, transport, replay, provenance, and local naming; it does not assert an unrestricted classical Brouwer fixed-point theorem.

Definition 5941.1 (Brouwer fixed-point metric carrier)**.** *A* $\mathsf{BrouwerFixedPointMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, X, M, G, E, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row, read through the finite-cover and finite-net surface of* $\mathsf{CompactMetric}^{\uparrow}$*.*
2. *X is the convex-cell ledger naming the finite simplex or box cells inspected at the current mesh scale.*
3. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the self-map whose finite modulus is being used.*
4. *G is the mesh-stage ledger, recording the finite grid, adjacency, and boundary-face rows inspected at that stage.*
5. *E is the approximate fixed-point evidence row, recording a cell, mesh point, or finite witness whose residual is bounded at the displayed tolerance.*
6. *R is the residual-bound row, comparing the map value and witness through metric radii available from K, M, G.*
7. *H records componentwise* hsame *transport for compact metric data, convex-cell rows, continuous-map rows, mesh stages, evidence rows, residual rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay for the finite route*

$$K, X, M, G \longmapsto E, R.$$

9. *P is the* Pkg *provenance over* $\mathsf{BrouwerFixedPointMetric}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BrouwerFixedPointMetric}^{\uparrow}}$ *row.*
The carrier has no coordinate for a host-selected exact fixed point, unrestricted compactness, quotient equality of completions, countable choice, or a global real-valued existence theorem.

Theorem 5941.2 (Brouwer fixed-point metric NameCert obligations)**.** *For an accepted* $\mathsf{BrouwerFixedPointMetric}^{\uparrow}$ *carrier*

$$F = (K, X, M, G, E, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BrouwerFixedPointMetric}^{\uparrow}}$ *surface consists exactly of compact metric admission through K, convex-cell exposure through X, continuous-map modulus access through M, finite mesh-stage discipline through G, approximate witness exposure through E, residual-bound readback through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5941.1. The accepted packet exposes only compact metric data, convex-cell data, a continuous self-map row, finite mesh-stage rows, approximate witness rows, residual-bound rows, and the structural rows H, C, P, N.

The compact and map faces are read through K and M. The compact metric row supplies only finite-net and radius information, while the continuous-map row supplies only the displayed finite modulus data needed by the mesh stage.

The approximation face is read through G, E, R. The mesh row names the finite grid and boundary checks, the evidence row names the finite approximate witness, and the residual row records the metric comparison available at that tolerance.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no exact host fixed point or unrestricted choice principle appears among the rows, the listed obligations exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.BrouwerFixedPointMetricUp.BrouwerFixedPointMetricTasteGate single carrier alignment`

Theorem 5941.3 (Brouwer fixed-point metric finite-approximation non-escape)**.** *Every consumer read of an accepted* $\mathsf{BrouwerFixedPointMetric}^{\uparrow}$ *packet factors through the finite approximation route*

$$K, X, M, G \longmapsto E, R \longmapsto H, C, P, N.$$

The consumer may read compact finite-net data, convex-cell rows, continuous-map modulus data, finite mesh stages, approximate witness rows, residual bounds, transport, replay, provenance, and local naming. It cannot read an unrestricted exact fixed point, a host compactness oracle, quotient-completion equality, countable choice, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness principle from the packet.*

Proof. Start with Definition 5941.1. The only route from compact metric and continuous-map data to a fixed-point-facing conclusion is the displayed finite mesh route through K, X, M, G, E, R.

Apply Definition 5941.2. The local NameCert forces every consumer to inspect compact metric admission, convex-cell exposure, continuous-map access, and mesh-stage discipline before the approximate witness or residual bound can be read.

Transport and replay do not add a stronger theorem. The rows H and C preserve the same finite approximation route, while P and N record provenance and local naming. Hence the packet exports finite approximate fixed-point evidence only, not the classical unrestricted Brouwer assertion. □

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerFixedPointMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{BrouwerFixedPointMetric}^{\uparrow}$ packet is generated from compact metric rows, convex-cell rows, continuous self-map modulus rows, finite mesh-stage rows, approximate witness rows, residual-bound rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrouwerFixedPointMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5941.1, Definition 5941.2, and Definition 5941.3 seed the finite metric approximation packet for Brouwer-style fixed-point consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrouwerFixedPointMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close an unrestricted exact Brouwer fixed-point theorem, countable choice, host compactness, quotient-completion equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact metric routing, continuous-map modulus routing, mesh-stage discipline, approximate witness exposure, residual-bound readback, transport stability, replay stability, provenance, and local naming for BEDC.Derived.BrouwerFixedPointMetricUp.

Chapter 5942

A Concrete Naming Certificate for MetaCICGroundCompilerNormalizationRoute$^{\uparrow}$

The MetaCICGroundCompilerNormalizationRoute$^{\uparrow}$ packet realizes the normalization audit map as finite ground-compiler data. It consumes the critical-path reading of chapter 765 and the candidate-mediated normalization interface recorded in chapter 9383. The packet names generated closed terms, candidate evidence, candidate-set membership, no-infinite-reduction readback, compiler replay, obstruction boundary rows, transport, provenance, and local naming without turning candidate evidence into an unconditional global normalization oracle.

Definition 5942.1 (MetaCIC ground-compiler normalization route carrier)**.** *A* MetaCICGroundCompilerNormalizat *carrier is a finite* BHist *packet*

$$G = (T, A, S, Q, N, R, O, H, C, P, L)$$

with the following displayed rows:

1. *T is the generated closed-term row emitted by the ground compiler.*
2. *A is the typing and closedness audit row for the generated term.*
3. *S is the candidate-evidence row, recording the reducibility candidate, closed candidate, or candidate-set membership route consumed by the normalization proof.*
4. *Q is the Pi/application adequacy row that keeps the candidate evidence stable across the inspected compiler route.*
5. *N is the strong-normalization readback row obtained from the candidate evidence.*
6. *R is the no-infinite-reduction readback row obtained from the same evidence.*
7. *O is the obstruction-boundary row recording that no unconditional closed-term normalization theorem is being claimed.*
8. *H records componentwise* hsame *transport for generated terms, audit rows, candidate rows, adequacy rows, normalization readback, no-infinite-reduction readback, obstruction rows, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay for the finite route*

$$T, A, S, Q \longmapsto N, R, O.$$

10. *P is the* Pkg *provenance over* MetaCICGroundCompilerNormalizationRoute$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *L is the local* NameCert$_{\text{MetaCICGroundCompilerNormalizationRoute}^{\uparrow}}$ *row.*

The carrier has no coordinate for unconditional normalization of all closed MetaCIC terms, subject-reduction closure, confluence closure, hidden compiler trust, or host-level termination.

Theorem 5942.2 (MetaCIC ground-compiler normalization route NameCert obligations)**.** *For an accepted* MetaCICGroundCompilerNormalizationRoute$^{\uparrow}$ *carrier*

$$G = (T, A, S, Q, N, R, O, H, C, P, L),$$

the local NameCert$_{\text{MetaCICGroundCompilerNormalizationRoute}^{\uparrow}}$ *surface consists exactly of generated closed-term admission through T, typing and closedness audit through A, candidate-evidence exposure through S, Pi/application adequacy routing through Q, strong-normalization readback through N, no-infinite-reduction readback through R, obstruction-boundary recording through O, component-wise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 5942.1. The accepted packet exposes generated term data, typing and closedness audit data, candidate evidence, adequacy routing, normalization readback, no-infinite-reduction readback, obstruction boundary, and the structural rows H, C, P, L.

The normalization face is read through S, Q, N, R. Candidate evidence is displayed before any strong-normalization or no-infinite-reduction conclusion is consumed, and the adequacy row records the Pi/application routing needed by the compiler path.

The boundary row O is part of the same packet. It records that the route is evidence-bearing and does not erase the candidate input into a blanket theorem for every closed term.

Finally H, C, P, L transport, replay, source, and name exactly this route. Since the carrier has no coordinate for subject-reduction closure, confluence closure, hidden compiler trust, or host termination, the listed rows exhaust the local NameCert obligations. □

Theorem 5942.3 (MetaCIC ground-compiler candidate non-escape)**.** *Every normalization-facing consumer read of an accepted* MetaCICGroundCompilerNormalizationRoute$^{\uparrow}$ *packet factors through the finite route*

$$T, A, S, Q \longmapsto N, R, O \longmapsto H, C, P, L.$$

Thus strong-normalization and no-infinite-reduction readbacks remain tied to generated closed-term audit rows, candidate evidence, and Pi/application adequacy rows. The packet cannot export unconditional normalization for all closed MetaCIC terms, subject-reduction closure, confluence closure, hidden compiler trust, or host-level termination.

Proof. Start with the carrier of Definition 5942.1. The rows N and R occur only after the generated term audit T, A and the candidate route S, Q have been displayed.

Apply Definition 5942.2. It forces every normalization-facing read to expose the generated closed term, its typing and closedness audit, the candidate evidence, and the adequacy route before reading normalization or no-infinite-reduction consequences.

The obstruction row O keeps the boundary visible, and the rows H, C, P, L only transport, replay, source, and name the same packet. Therefore the consumer cannot detach N or R from candidate evidence or promote the route to a global MetaCIC normalization theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICGroundCompilerNormalizationRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICGroundCompilerNormalizationRoute}^{\uparrow}$ packet is generated from ground-compiler closed-term rows, typing and closedness audit rows, candidate-evidence rows, Pi/application adequacy rows, normalization readback rows, no-infinite-reduction rows, obstruction-boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICGroundCompilerNormalizationRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5942.1, Definition 5942.2, and Definition 5942.3 seed the finite ground-compiler normalization route over candidate evidence.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICGroundCompilerNormalizationRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close unconditional normalization for all closed MetaCIC terms, subject reduction, confluence, hidden compiler trust, host termination, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked generated-term admission, typing and closedness audit, candidate-evidence routing, Pi/application adequacy routing, strong-normalization readback, no-infinite-reduction readback, obstruction-boundary recording, transport stability, replay stability, provenance, and local naming for BEDC.Derived.MetaCICGroundCompilerNormalizatio

Chapter 5943

A Concrete Naming Certificate for $\mathsf{CauchyModulusCompletionSelector}^{\uparrow}$

Following Bishop and Bridges and Weihrauch on effective completion, the $\mathsf{CauchyModulusCompletionSelector}^{\uparrow}$ packet records the finite selector surface that passes an explicit Cauchy modulus into a completion-facing readback. It sits after the explicit rate rows of chapter 292, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the effective completion boundary of chapter 5930. The packet names a displayed selector for modulus evidence only; it does not choose a Cauchy representative, quotient streams, assert ambient real completeness, or export host equality of completed objects.

Definition 5943.1 (Cauchy-modulus completion selector carrier)**.** *A* $\mathsf{CauchyModulusCompletionSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, W, Q, D, E, R, H, C, P, N)$$

with the following displayed rows:

1. M *is the* $\mathsf{CauchyModulus}^{\uparrow}$ *rate row, recording the requested precision and the displayed threshold selected for the completion query.*
2. W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row read at that threshold.*
3. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows.*
4. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the selected window and by the regular readback.*
5. E *is the* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ *completion-facing boundary row.*
6. R *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached through* M, W, Q, D, E.
7. H *records componentwise* hsame *transport for the displayed rows.*
8. C *records displayed* Cont *replay from a completion request through* $M, W, Q, D, E, R, H, P, N$.
9. P *is the* Pkg *provenance over* $\mathsf{CauchyModulusCompletionSelector}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusCompletionSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a hidden threshold choice, quotient stream equality, selected limit, host real equality, countable choice, or ambient completion principle.

Lean4 ✓ BEDC.Derived.CauchyModulusCompletionSelectorUp.CauchyModulusCompletionSelectorTasteGate
single carrier alignment

Theorem 5943.2 (Cauchy-modulus completion selector obligations)**.** *For every accepted* CauchyModulusCompletio *carrier*

$$S = (M, W, Q, D, E, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyModulusCompletionSelector}^{\uparrow}}$ *surface consists exactly of carrier admission for the explicit modulus row, finite stream-window row, regular rational readback row, dyadic tolerance row, effective completion boundary row, terminal real seal, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. Every completion-facing selector read must expose* M, W, Q, D, E, R *before* H, C, P, N *can be consumed.*

Proof. Project the carrier of Definition 5943.1. Its coordinates are precisely the modulus, window, readback, tolerance, completion boundary, real seal, transport, replay, provenance, and local naming rows.

The selector route is read through M, W, Q, D, E, R. The modulus row supplies the threshold for the query, the window row identifies the inspected observations, the regular readback row records the Cauchy data, the dyadic row records the precision budget, the effective completion row exposes the completion-facing boundary, and the real row seals that same route.

The remaining rows H, C, P, N transport, replay, package, and name the route already displayed. Since hidden threshold choice, quotient streams, selected limits, countable choice, host equality, and ambient completeness have no carrier coordinate, the listed rows exhaust the local obligations. □

Theorem 5943.3 (Cauchy-modulus selector effective readback)**.** *For every accepted* CauchyModulusCompletionSele *carrier* $S = (M, W, Q, D, E, R, H, C, P, N)$*, any completion-facing query that consumes the effective boundary row* E *must first read the* $\mathsf{CauchyModulus}^{\uparrow}$ *row* M*, the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*. Thus the selector exposes a finite, modulus-indexed readback before the completion boundary is visible.*

Proof. Begin with Definition 5943.2. It requires the selector read to expose the modulus, window, readback, tolerance, completion, and seal rows before the structural rows are consumed.

The effective boundary row E is therefore not read from a completed object in isolation. It is reached only after M selects the threshold, W displays the finite observations, Q records the regular rational readback, and D records the dyadic budget used by that readback.

Consequently the completion-facing route factors through the same finite selector surface. The carrier has no coordinate for bypassing M, W, Q, D by a host-level limit, quotient stream, or selected representative. □

Theorem 5943.4 (Cauchy-modulus selector real-seal nonescape)**.** *For every accepted* CauchyModulusCompletionSe *carrier* $S = (M, W, Q, D, E, R, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* R *is scoped to the displayed selector route* M, W, Q, D, E*. No downstream Real or Completion consumer can use* R *as evidence for an unrelated Cauchy name, a quotient-completion equality, a selected limit, or an ambient completeness principle.*

Proof. Apply Definition 5943.3. Before the effective boundary is visible, the consumer has already read the explicit modulus, finite window, regular readback, and dyadic tolerance rows.

The real seal row R is listed in the carrier only after that same boundary. Thus any read of R is a read of the displayed selector route M, W, Q, D, E, not of an independent completed-real object.

Finally use Definition 5943.2. The transport, replay, provenance, and naming rows preserve the same route and add no second seal surface. The excluded host equalities, quotient completions, selected limits, and ambient completeness claims therefore cannot escape the finite carrier boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusCompletionSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusCompletionSelector}^{\uparrow}$ packet is generated from an explicit CauchyModulus row, a finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance, EffectiveCauchyCompletion boundary, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusCompletionSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5943.1, Definition 5943.2, Definition 5943.3, and Definition 5943.4 seed the finite selector surface between modulus evidence and completion-facing readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusCompletionSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, selected limits, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-window selection, regular-readback exposure, dyadic tolerance confinement, effective completion routing, terminal seal scope, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusCompletionSelectorUp.

Chapter 5944

A Concrete Naming Certificate for $\mathsf{KuratowskiHyperspace}^{\uparrow}$

Following Kuratowski and Hausdorff, the $\mathsf{KuratowskiHyperspace}^{\uparrow}$ packet names the completion-facing hyperspace whose public rows are compact-subset presentations, finite Hausdorff-distance comparisons, and Kuratowski embedding transport. It sits after the finite compact-subset carrier of chapter 1660, the embedding route of chapter 7569, and the universal Hausdorff completion handoff of chapter 2242. The chapter records the carrier boundary on which later completion consumers may inspect hyperspace data without importing host powersets, quotient compacta, selected Cauchy limits, or ambient equality of closed subsets.

Definition 5944.1 (Kuratowski hyperspace carrier)**.** *An accepted* $\mathsf{KuratowskiHyperspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (H, E, U, F, D, S, C, P, M)$$

whose rows have the following public roles.

1. *H is the underlying* $\mathsf{Hyperspace}^{\uparrow}$ *finite compact-subset carrier, including the compact source, Vietoris finite-net rows, directed Hausdorff ledgers, and tolerance readback.*
2. *E is the* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *row that sends each compact-subset presentation to its displayed distance-profile history.*
3. *U is the* $\mathsf{HausdorffCompletionUniversal}^{\uparrow}$ *handoff row that admits only completion routes already expressed through Hausdorff-distance Cauchy data.*
4. *F is the compact finite-net readback row used by hyperspace and embedding consumers before any completion read is public.*
5. *D is the distance-stability ledger comparing the Hausdorff classifier on H with the Kuratowski profile classifier on E.*
6. *S, C, P, M are respectively componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{KuratowskiHyperspace}^{\uparrow}}$ *naming row.*

The carrier has no coordinate for a host powerset of closed subsets, a quotient completion class, a selected representative, a selected compact limit, or an ambient extensional equality of subsets.

Lean4 ✓ `BEDC.Derived.KuratowskiHyperspaceUp.KuratowskiHyperspaceTasteGate single carrier alignment`

Theorem 5944.2 (Kuratowski hyperspace distance stability)**.** *Let $K = (H, E, U, F, D, S, C, P, M)$ be an accepted* $\mathsf{KuratowskiHyperspace}^{\uparrow}$ *carrier. Every distance comparison exposed by K is stable under componentwise* hsame *transport exactly when the* $\mathsf{Hyperspace}^{\uparrow}$ *Hausdorff classifier carried by H, the* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *distance-profile classifier carried by E, and the* $\mathsf{HausdorffCompletionUniversal}^{\uparrow}$ *Cauchy handoff carried by U are transported through the same* BHist *route. The stability ledger D therefore compares finite-net Hausdorff rows with Kuratowski profile rows; it does not identify compact subsets by quotient equality or by host extensional equality.*

Proof. Read the carrier of Definition 5944.1. The only distance rows available to a consumer are the directed Hausdorff ledgers in H, the distance-profile route in E, and the completion-facing handoff in U.

The compact finite-net row F fixes the source data on which both H and E are evaluated. Transport through S is componentwise, so it preserves the displayed source, the compact finite-net schedules, and the tolerance readback before the comparison reaches D.

Finally replay the transported comparison through C and name it through P, M. Since the carrier lacks quotient representatives and host subset equality coordinates, the only possible stability statement is the finite classifier transport recorded by D. □

Lean4 ✓ `BEDC.Derived.KuratowskiHyperspaceUp.KuratowskiHyperspaceCarrier distance stability`

Theorem 5944.3 (Kuratowski hyperspace NameCert obligations)**.** *For every accepted* $\mathsf{KuratowskiHyperspace}^{\uparrow}$ *carrier $K = (H, E, U, F, D, S, C, P, M)$, the local* $\mathsf{NameCert}_{\mathsf{KuratowskiHyperspace}^{\uparrow}}$ *obligations are exactly the admission of the* $\mathsf{Hyperspace}^{\uparrow}$ *carrier H, the* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *profile row E, the* $\mathsf{HausdorffCompletionUniversal}^{\uparrow}$ *completion handoff U, the compact finite-net readback F, the distance-stability ledger D, componentwise* hsame *transport S, displayed* Cont *replay C, and* Pkg *provenance P. These obligations exhaust the public naming surface before any completion consumer can read a hyperspace object.*

Proof. Project the carrier coordinates listed in Definition 5944.1. Each coordinate is already a displayed BEDC row: hyperspace finite-net data, Kuratowski profile transport, Hausdorff completion handoff, classifier stability, structural transport, replay, provenance, and local naming.

Use Definition 5944.2 for the only comparison row. It pins the Hausdorff and Kuratowski classifiers to the same finite BHist route and rules out quotient or host equality reads.

It remains to account for completion consumers. They can enter only through U, after H, E, F, D, S, C, P, M have been exposed. Thus the listed rows are exactly the NameCert obligations and no extra carrier coordinate remains public. □

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiHyperspace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KuratowskiHyperspace}^{\uparrow}$ packet is generated from Hyperspace finite compact-subset rows, Kuratowski embedding profile rows, Hausdorff completion handoff rows, compact finite-net readback, classifier stability, hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KuratowskiHyperspace}^{\uparrow}}$, seed)

Scope closed: Definition 5944.1, Definition 5944.2, and Definition 5944.3 seed the completion-facing hyperspace carrier over Hyperspace, KuratowskiEmbedding, HausdorffCompletionUniversal, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KuratowskiHyperspace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host powersets, quotient compacta, selected compact limits, selected completion representatives, ambient equality of closed subsets, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net readback, Hausdorff/Kuratowski classifier transport, completion handoff exactness, and local NameCert exhaustion for BEDC.Derived.KuratowskiHyperspaceUp.

Chapter 5945

A Concrete Naming Certificate for $\mathsf{LimitedPrincipleOmniscience}^{\uparrow}$

Following Brouwer, Bishop–Bridges, and Troelstra–van Dalen on constructive omniscience boundaries, the $\mathsf{LimitedPrincipleOmniscience}^{\uparrow}$ packet names the finite alternative-inspection surface that may be discussed without adopting global LPO. It sits next to the $\mathsf{LesserLimitedOmniscience}^{\uparrow}$ boundary of chapter 1977, the $\mathsf{SpeckerSequence}^{\uparrow}$ obstruction surface of chapter 1406, the $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$ row of chapter 1666, the $\mathsf{FanTheorem}^{\uparrow}$ bar-inspection boundary of chapter 400, and the L10 readback faces $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The packet records a named boundary object only: it is not global LPO, not trichotomy for arbitrary reals, not a selected limit principle, not countable choice, not quotient equality, and not ambient Real completeness.

Definition 5945.1 (Limited principle of omniscience carrier)**.** *A* $\mathsf{LimitedPrincipleOmniscience}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, S, R, D, E, T, H, C, P, N)$$

with the following displayed rows:

1. *A is the finite alternative row, recording only the finitely displayed binary alternatives inspected by the packet.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row whose finite source windows are read before any alternative is compared.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row that converts the inspected stream windows into regular rational readback data.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row used by the regular rational readback and by the finite comparison budget.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after S, R, D have been displayed.*
6. *T records transport from the finite alternative row to the sibling boundaries* $\mathsf{LesserLimitedOmniscience}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$, *and* $\mathsf{FanTheorem}^{\uparrow}$.
7. *H records componentwise* hsame *transport for A, S, R, D, E, T.*
8. *C records displayed* Cont *replay for stream-window inspection, regular rational readback, dyadic comparison, Real sealing, and sibling-boundary transport.*

9. *P is the* Pkg *provenance over* $\mathsf{LimitedPrincipleOmniscience}^{\uparrow}$, $\mathsf{LesserLimitedOmniscience}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LimitedPrincipleOmniscience}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, S, R, D, E, T, H, C, P, N$. It has no coordinate for global LPO, WLPO, LLPO as an adopted principle, trichotomy for arbitrary reals, selected limits, countable choice, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LimitedPrincipleOmniscienceUp.LimitedPrincipleOmniscienceTasteGate single carrier alignment`

Theorem 5945.2 (Limited principle of omniscience NameCert obligations)**.** *For every accepted* $\mathsf{LimitedPrincipleOmniscience}^{\uparrow}$ *carrier*

$$L = (A, S, R, D, E, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LimitedPrincipleOmniscience}^{\uparrow}}$ *surface consists exactly of finite rows for alternative admission,* $\mathsf{StreamName}^{\uparrow}$ *window inspection,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison support,* $\mathsf{Real}^{\uparrow}$ *sealing, sibling-boundary transport through* $\mathsf{LesserLimitedOmniscience}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$, *and* $\mathsf{FanTheorem}^{\uparrow}$, *componentwise transport, continuation replay, provenance, and local naming. No obligation row may be discharged by global LPO, WLPO, LLPO, trichotomy, selected limits, countable choice, quotient equality, or ambient Real completeness.*

Proof. Carrier admission is projection from Definition 5945.1. The packet exposes the finite alternative row, the three readback rows S, R, D, the terminal seal E, sibling transport T, and the structural rows H, C, P, N.

The sibling references are boundary reads, not imported omniscience principles. The rows named by $\mathsf{LesserLimitedOmniscience}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$, and $\mathsf{FanTheorem}^{\uparrow}$ record where finite alternative inspection is compared with known constructive obstructions.

The L10 route is also finite. A consumer reads stream windows through S, regular rational data through R, dyadic comparison data through D, and only then the $\mathsf{Real}^{\uparrow}$ seal E.

Since no row stores global LPO, WLPO, LLPO, trichotomy, selected limits, countable choice, quotient equality, or ambient Real completeness, the NameCert obligations are exhausted by the displayed carrier coordinates. □

Theorem 5945.3 (Limited principle of omniscience Real-completion refusal)**.** *Every completion-facing consumer of an accepted* $\mathsf{LimitedPrincipleOmniscience}^{\uparrow}$ *carrier must route through the finite display*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

together with the finite alternative row A and the sibling-boundary row T. The route may inspect named alternatives and compare them with $\mathsf{LesserLimitedOmniscience}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$, *and* $\mathsf{FanTheorem}^{\uparrow}$, *but it cannot export global LPO, real trichotomy, selected limits, countable choice, quotient equality, or ambient Real completeness.*

Proof. Start from the NameCert obligation theorem. It fixes the completion-facing route to S, R, D, E and keeps the alternative and sibling-boundary rows visible as packet data.

The regular rational and dyadic rows are read before the Real seal. Thus the $\mathsf{Real}^{\uparrow}$ endpoint is reached only after finite stream-window inspection and finite rational comparison support have been displayed.

The refused principles are not hidden in the structural rows. Transport by H, replay by C, provenance by P, and naming by N preserve the same displayed route and add no coordinate for global omniscience, choice, quotient equality, selected limits, trichotomy, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LimitedPrincipleOmniscience}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LimitedPrincipleOmniscience}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5945.1, Definition 5945.2, and Definition 5945.3 seed the finite alternative-inspection boundary for L10 Real and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LimitedPrincipleOmniscience}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global LPO, WLPO, LLPO, real trichotomy, selected limits, countable choice, quotient equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite alternative inspection, L10 readback exactness, sibling-boundary transport, Real seal refusal, and global-omniscience refusal for BEDC.Derived.LimitedPrincipleOmniscienceUp.

Constructive story: A $\mathsf{LimitedPrincipleOmniscience}^{\uparrow}$ packet is generated from finite alternative rows, StreamName windows, RegSeqRat readback, DyadicRatCore comparison support, a Real seal, sibling-boundary transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5946

A Concrete Naming Certificate for $\mathsf{HenselLemma}^{\uparrow}$

Following Hensel and standard p-adic algebra, the $\mathsf{HenselLemma}^{\uparrow}$ packet records the finite BEDC surface of a simple-root lifting certificate over displayed local arithmetic data. It sits downstream of the p-adic carrier of chapter 100, the local-field source of chapter 173, the polynomial carrier of chapter 50, the field schema of chapter 45, and the ring schema of chapter 43. The packet names a finite lifting witness and its Newton-style nonescape ledger; it does not import quotient roots, a selected root function, countable choice, full algebraic closure, or ambient completeness beyond the displayed source rows.

Definition 5946.1 (Hensel lemma carrier)**.** *A* $\mathsf{HenselLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (K, R, F, P, A, V, N, E, T, C, Q, L)$$

with the following displayed rows:

1. *K is the* $\mathsf{Padic}^{\uparrow}$ *source row, exposing only the finite valuation and congruence windows inspected by the lifting packet.*
2. *R is the* $\mathsf{LocalField}^{\uparrow}$ *coefficient row, supplying the local-field arithmetic reads used by the polynomial and derivative windows.*
3. *F is the* $\mathsf{Field}^{\uparrow}$ *compatibility row for the nonzero derivative and unit comparisons needed by the simple-root test.*
4. *P is the* $\mathsf{Poly}^{\uparrow}$ *row, listing the displayed polynomial, derivative, coefficient windows, and evaluation reads at the approximate root.*
5. *A is the approximate-root row, recording the chosen finite residue-window representative and the displayed smallness comparison for the polynomial value.*
6. *V is the valuation-separation row, recording that the derivative unit window and the polynomial-value window are separated enough to start the lifting route.*
7. *N is the Newton-correction ledger, listing the finite correction windows, derivative reads, and valuation gains that the packet promises to replay.*
8. *E is the nonescape row, asserting that every correction window stays inside the same displayed p-adic ball before any root conclusion is exposed.*

9. *T records componentwise* hsame *transport for the source, coefficient, polynomial, approximate-root, valuation, correction, and nonescape rows.*
10. *C records the displayed* Cont *replay route from source arithmetic through polynomial evaluation, correction, nonescape, provenance, and local naming.*
11. *Q is the* Pkg *provenance over* $\mathsf{HenselLemma}^{\uparrow}$, $\mathsf{Padic}^{\uparrow}$, $\mathsf{LocalField}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *L is the local* $\mathsf{NameCert}_{\mathsf{HenselLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, R, F, P, A, V, N, E, T, C, Q, L$. It has no coordinate for selected roots, quotient roots, countable choice, a full algebraic closure, or an ambient completeness theorem.

Theorem 5946.2 (Hensel lemma NameCert obligations)**.** *For every accepted* $\mathsf{HenselLemma}^{\uparrow}$ *carrier $H = (K, R, F, P, A, V, N, E, T, C, Q, L)$, the local* $\mathsf{NameCert}_{\mathsf{HenselLemma}^{\uparrow}}$ *surface consists exactly of carrier admission for the p-adic source row, local-field coefficient row, field-unit compatibility row, polynomial and derivative evaluation row, approximate-root row, valuation-separation row, Newton-correction ledger, nonescape row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every lifting read must expose these finite rows before it can be consumed as a Hensel-style certificate.*

Proof. Project the carrier of Definition 5946.1. The arithmetic source is visible only through K, R, F, while the polynomial and derivative reads are visible only through P and the approximate-root row A.

The lifting route then passes through V, N, and E. The valuation-separation row starts the correction schedule, the Newton ledger records the displayed correction windows, and the nonescape row keeps those windows inside the same p-adic ball.

The structural rows T, C, Q, L transport, replay, source, and name the same finite packet. Since no further coordinate occurs in the carrier, the certificate cannot export a selected root function, quotient-root semantics, countable choice, full algebraic closure, or an ambient completeness principle. □

Lean4 ✓ `BEDC.Derived.HenselLemmaUp.HenselLemmaTasteGate single carrier alignment`

Theorem 5946.3 (Newton witness nonescape)**.** *Every accepted* $\mathsf{HenselLemma}^{\uparrow}$ *packet exposes a Newton witness only through the valuation-separation row V, the correction ledger N, and the nonescape row E. A consumer therefore receives a finite chain of displayed p-adic windows whose corrections stay inside the original ball before any root-lifting read is available.*

Proof. Read the dependency order in Definition 5946.1. The correction ledger N is not independent of the simple-root test; it is reached only after the source rows K, R, F, the polynomial row P, the approximate-root row A, and the valuation-separation row V have been displayed.

The row E records the nonescape check for the same correction windows. Replaying C can inspect the valuation gains and ball-membership comparisons, but it cannot detach them from the finite windows named by K, R, P, A, V, and N.

Transport along T preserves those rows componentwise. Hence the witness remains a finite Newton-style nonescape certificate and not a selected root, quotient-root object, choice sequence, algebraic-closure construction, or completeness theorem. □

Lean4 ✓ `BEDC.Derived.HenselLemmaUp.HenselLemmaNewtonWitnessNonescape`

Falsifiable prediction: Every accepted $\mathsf{HenselLemma}^{\uparrow}$ lifting read exposes the p-adic source, local-field coefficient row, field-unit compatibility row, polynomial and derivative windows, approximate-root row, valuation-separation row, Newton-correction ledger, nonescape row, componentwise hsame transport, Cont replay, Pkg provenance, and local naming before any Hensel-style consumer may use it.

Independence witness: padic, localfield, polynomial, field, ring: $\mathsf{HenselLemma}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a simple-root valuation test, polynomial derivative windows, Newton-correction ledger, and nonescape witness in one finite lifting packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HenselLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{HenselLemma}^{\uparrow}$ packet is generated from p-adic source data, local-field coefficient rows, field-unit compatibility, polynomial and derivative evaluation windows, an approximate-root row, valuation separation, a Newton-correction ledger, nonescape checks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HenselLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5946.1, Definition 5946.2, and Definition 5946.3 seed the finite simple-root lifting route over p-adic, local-field, polynomial, field, and ring rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HenselLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected roots, quotient roots, countable choice, full algebraic closure, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, simple-root valuation separation, polynomial derivative readback, Newton-correction ledger exactness, nonescape stability, transport, replay, provenance, and local naming for BEDC.Derived.HenselLemmaUp.

Chapter 5947

A Concrete Naming Certificate for $\mathsf{LocatedRiemannIntegral}^{\uparrow}$

Following Bishop–Bridges constructive integration, the $\mathsf{LocatedRiemannIntegral}^{\uparrow}$ packet names a located Riemann integral by finite partition data, regulated handoff rows, dyadic error ledgers, and the terminal $\mathsf{Real}^{\uparrow}$ seal. It consumes the Riemann-sum surface of chapter 1615, the regulated-integral handoff of chapter 1557, the dyadic core of chapter 291, the StreamName windows of chapter 126, the regular rational readback of chapter 301, and the real-name boundary of chapter 38. The packet is a finite L10 analysis certificate; it is not host integral equality, a selected limiting process, open-cover compactness, countable choice, or ambient Real completeness.

Definition 5947.1 (LocatedRiemannIntegral carrier)**.** *A* $\mathsf{LocatedRiemannIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (A, M, \Sigma, G, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the located interval source row. It records the two located endpoints, the inhabited interval evidence visible to the packet, and the side condition that all partition points are read inside the displayed source interval.*
2. *M is the finite partition mesh row. It lists the ordered nodes, the mesh bound, and the finite refinement witnesses admitted for this integral request.*
3. *Σ is the* $\mathsf{RiemannSum}^{\uparrow}$ *row, recording the tagged subinterval sums obtained from A and M through the sibling Riemann-sum certificate.*
4. *G is the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *handoff row. It exposes the regulated step approximation and integral handoff only after the partition mesh and RiemannSum rows have been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the dyadic error requests, mesh-refinement budget, and comparison rows used to certify located convergence of the displayed sums.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for finite observation of the sum stream and regulated handoff stream.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, translating the displayed finite windows into regular rational approximants for the integral value.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the source interval, mesh, RiemannSum row, regulated handoff, dyadic ledger, StreamName windows, and RegSeqRat readback have all been replayed.*
9. *H records componentwise* hsame *transport for $A, M, \Sigma, G, D, W, R, E, C, P, N$.*
10. *C records displayed* Cont *replay from a tolerance request through $A, M, \Sigma, G, D, W, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{LocatedRiemannIntegral}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRiemannIntegral}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, M, \Sigma, G, D, W, R, E, H, C, P, N$. It has no coordinate for host integral equality, selected limits, open-cover compactness, countable choice, ambient Real completeness, or any equality outside the displayed finite rows.

Lean4 (definition) `BEDC.Derived.LocatedRiemannIntegralUp.LocatedRiemannIntegralUp`

Theorem 5947.2 (LocatedRiemannIntegral NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRiemannIntegral}^{\uparrow}$ *carrier*

$$I = (A, M, \Sigma, G, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRiemannIntegral}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located interval source, finite partition mesh, RiemannSum row, regulated-integral handoff, dyadic tolerance ledger, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *partition-mesh exactness, requiring every displayed sum to read the same located interval row A and one of the finite partition refinements recorded by M;*
3. *located-modulus exposure, requiring the dyadic ledger D to display the mesh and tolerance budget used by the RiemannSum and regulated-integral rows;*
4. *sum-convergence ledger, requiring the route from Σ through G, D, W, R to expose the finite windows and regular rational approximants before the Real seal can be read;*
5. *Real seal nonescape, requiring E to be downstream of A, M, Σ, G, D, W, R and to export no host integral equality or ambient completeness theorem;*
6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming through H, C, P, N;*
7. *refusal of host integral equality, selected limits, open-cover compactness, countable choice, and ambient Real completeness as carrier coordinates, replay edges, or provenance rows.*

No obligation is stored outside the displayed packet.

Proof. Carrier admission is projection from Definition 5947.1. The packet displays the located interval, mesh, RiemannSum, regulated handoff, dyadic, window, readback, seal, transport, replay, provenance, and naming rows as one finite BHist carrier.

Partition-mesh exactness follows by reading A and M before Σ. The Riemann-sum row is tied to the same interval source and the same finite refinement ledger, so no selected partition limit or host integral object can supply the sum.

The located-modulus and sum-convergence obligations are then read through D, W, R. The dyadic ledger supplies the tolerance and mesh budget, the StreamName row exposes finite observation windows, and the RegSeqRat row gives the regular rational readback before E is available.

Finally H, C, P, N transport, replay, source, and name only that displayed route. Since the carrier has no row for host integral equality, selected limits, open-cover compactness, countable choice, or ambient Real completeness, the local NameCert surface is exhausted by the listed obligations. □

Falsifiable prediction: Every $\mathsf{LocatedRiemannIntegral}^{\uparrow}$ acceptance trace exposes one located interval source, one finite partition mesh, one $\mathsf{RiemannSum}^{\uparrow}$ row, one $\mathsf{RegulatedIntegral}^{\uparrow}$ handoff, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{StreamName}^{\uparrow}$ window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback, one terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: riemannsum, regulatedintegral, dyadicratcore, streamname, regseqrat, real: $\mathsf{LocatedRiemannIntegral}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the located interval source, mesh, sum, regulated handoff, dyadic tolerance, finite-window, regular-readback, Real-seal, transport, replay, provenance, and local NameCert rows as one integral packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRiemannIntegral}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRiemannIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5947.1 and Definition 5947.2 seed a finite constructive Riemann integral packet over located intervals, partition meshes, Riemann sums, regulated handoff, dyadic tolerance, readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRiemannIntegral}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host integral equality, selected limiting processes, open-cover compactness, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition-mesh exactness, located-modulus exposure, sum-convergence ledger, Real seal nonescape, transport, replay, provenance, and local naming for the displayed $\mathsf{LocatedRiemannIntegral}^{\uparrow}$ packet.

Constructive story: A $\mathsf{LocatedRiemannIntegral}^{\uparrow}$ packet is generated from a located interval source, a finite partition mesh, a RiemannSum row, a RegulatedIntegral handoff, dyadic tolerance, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5948

A Concrete Naming Certificate for $\mathsf{KolmogorovQuotient}^{\uparrow}$

Following Kolmogorov and Bourbaki's separation discipline for topological spaces, the $\mathsf{KolmogorovQuotient}^{\uparrow}$ packet records the constructive T_0 reflection as finite observable-open data rather than as a host quotient object. It sits next to the indexed-open topology of chapter 88, the metric-generated topology route of chapter 57, the membership discipline of chapter 3668, and the specialization reflection packet of chapter 3338. The packet names indistinguishability by mutual observable-open evidence and exposes a separated carrier only through displayed representative rows.

Definition 5948.1 (Kolmogorov quotient carrier)**.** *A* $\mathsf{KolmogorovQuotient}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, O, E, R, S, H, C, P, N)$$

with the following rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *indexed-open row, carrying the open indices and membership reads used to test observable separation.*
2. *O is the observable-open classifier row, recording for each displayed point row which indexed opens are observed as present.*
3. *E is the indistinguishability ledger: two point rows are equivalent for this packet exactly when every observable-open row in O agrees in both directions.*
4. *R is the representative-display row. It records a finite public name for an E-class but does not select a host representative by choice.*
5. *S is the separated-reader row. It exposes a T_0 read only after E and R have been displayed, so separated equality is mutual observable-open agreement.*
6. *H records componentwise* hsame *transport for T, O, E, R, S and the structural rows.*
7. *C records* Cont *replay from a topology request through observable opens, indistinguishability, representative display, and separated reading.*
8. *P is the* Pkg *provenance over* $\mathsf{KolmogorovQuotient}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TZeroReflection}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KolmogorovQuotient}^{\uparrow}}$ *row.*

The carrier has no coordinate for a quotient primitive, proof irrelevance over opens, selected representative function, ambient set quotient, powerset extensionality, or excluded-middle split of points.

Definition 5948.2 (Kolmogorov quotient classifier)**.** *For an accepted carrier $K = (T, O, E, R, S, H, C, P, N)$, the displayed classifier on public quotient names is the finite route*

$$O, E, R, S \longmapsto H, C, P, N.$$

Two public names classify as the same $\mathsf{KolmogorovQuotient}^{\uparrow}$ *point only when their observable-open rows agree through E, their displayed representative rows are preserved by H, and their separated reads replay through C under the same provenance and local name rows.*

Theorem 5948.3 (Kolmogorov quotient NameCert obligations)**.** *For every accepted* $\mathsf{KolmogorovQuotient}^{\uparrow}$ *carrier $K = (T, O, E, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KolmogorovQuotient}^{\uparrow}}$ *surface consists exactly of topology-source admission through T, observable-open classifier exposure through O, mutual-observation indistinguishability through E, representative-display exposure through R, separated-reader exposure through S, componentwise* hsame *stability through H,* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.KolmogorovQuotientUp.KolmogorovQuotientNameCertObligations`

Proof. Project the accepted carrier of Definition 5948.1. The only topology data available to the packet is the indexed-open row T and its observable classifier O.

The indistinguishability row E is therefore forced to compare point rows by observable-open agreement. The representative-display row R records public names for such rows, but it has no host choice coordinate from which to select representatives.

The separated-reader row S can be consumed only after E and R have been exposed. Componentwise transport H, replay C, provenance P, and local naming N preserve that same route, so every NameCert obligation is one of the displayed rows and no quotient primitive or ambient set identification is added. □

Theorem 5948.4 (Kolmogorov quotient T0 reflection)**.** *Every separated consumer of an accepted* $\mathsf{KolmogorovQuotient}^{\uparrow}$ *packet factors through the finite reflection route*

$$\mathsf{Topology}^{\uparrow} \longmapsto \mathsf{KolmogorovQuotient}^{\uparrow} \longmapsto \mathsf{TZeroReflection}^{\uparrow}.$$

Thus the consumer may distinguish public quotient names exactly by observable-open disagreement and may identify them only by the mutual-observation row E transported through H, C, P, N.

Proof. Start with the topology row T and observable classifier O. These rows determine which opens are visible at each displayed point row.

Use the indistinguishability ledger E. If every observable-open read agrees in both directions, the packet admits the same public quotient name through R; if a displayed open separates the rows, the separated-reader row S records the T_0 distinction.

Finally replay the structural tail. The rows H, C, P, N keep the observable-open route fixed, and the sibling $\mathsf{TZeroReflection}^{\uparrow}$ packet of chapter 3338 consumes precisely the separated specialization surface. No quotient primitive, selected representative, or powerset equality participates in the reflection. □

Theorem 5948.5 (Kolmogorov quotient metric-source compatibility)**.** *If a* $\mathsf{Met}^{\uparrow}$ *source supplies the topology row* T *through the metric-generated route of* $\mathsf{Topology}^{\uparrow}$*, then every* $\mathsf{KolmogorovQuotient}^{\uparrow}$ *separated read still factors through the same observable-open rows* O, E, R, S, H, C, P, N*. The metric source contributes open-ball observations; it does not add a second equality on quotient names, a Cauchy-completion selector, or a Hausdorff quotient of points.*

Proof. Read the metric source only through the topology handoff. The metric carrier may generate basic open rows, but the $\mathsf{KolmogorovQuotient}^{\uparrow}$ packet consumes them as the indexed-open row T.

The observable classifier O and indistinguishability row E then perform the same mutual-open test as in the purely topological case. The rows R and S expose public quotient names and T_0 separation only after this test.

The structural rows H, C, P, N preserve the same route. Since no additional metric equality row belongs to the carrier, a metric source cannot replace observable-open indistinguishability by a host metric quotient or completion-side selector. □

Falsifiable prediction: A claimed $\mathsf{KolmogorovQuotient}^{\uparrow}$ read that identifies public names without displaying $T, O, E, R, S, H, C, P, N$, or that selects a representative by a host choice function, refutes the carrier of Definition 5948.1.

Independence witness: topology, metricspace, tzero-reflection, setlike: $\mathsf{KolmogorovQuotient}^{\uparrow}$ is not bijective to any listed sibling because it carries the joint observable-open indistinguishability ledger, representative-display row, separated-reader row, and non-quotient NameCert route. TopologyUp supplies indexed opens without the separated public-name row; MetricSpaceUp supplies distance-generated opens without a quotient-name surface; TZeroReflectionUp consumes specialization separation without this representative-display ledger; SetLikeUp supplies membership discipline without topological observability.

Closure status for $\mathsf{NameCert}_{\mathsf{KolmogorovQuotient}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KolmogorovQuotient}^{\uparrow}$ packet is generated from a Topology indexed-open row, observable-open classifier, mutual-observation indistinguishability ledger, representative-display row, separated-reader row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KolmogorovQuotient}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5948.1, Definition 5948.2, Definition 5948.3, and Definition 5948.4 seed the finite constructive T_0 reflection surface without quotient primitives.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KolmogorovQuotient}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host quotient object, selected representatives, proof irrelevance over opens, ambient powerset extensionality, excluded middle over points, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, observable-open exactness, mutual-observation stability, representative-display coverage, separated-reader exactness, and sibling handoff for BEDC.Derived.KolmogorovQuotientUp.

Chapter 5949

A Concrete Naming Certificate for BoundedTypecheckingBudget$^{\uparrow}$

The BoundedTypecheckingBudget$^{\uparrow}$ packet realizes the MetaCIC decidability audit map of chapter 9379 as finite checker rows with visible refusal boundaries. It packages the type-inference checker, structural same-term checker, bounded normal-equality checker, finished-normalization evidence, and gallery audit rows into a NameCert object that can be consumed without claiming a global conversion oracle. It is adjacent to MetaCICDecidableBoundary$^{\uparrow}$ of chapter 749, NormalFalseExclusion$^{\uparrow}$ of chapter 732, and ClosedNormalConfluenceSeal$^{\uparrow}$ of chapter 741: the first names the decidability boundary, the second records normal-false exclusion discipline, and the third records the closed normal-confluence seal consumed when bounded equality has endpoint evidence.

Definition 5949.1 (Bounded typechecking budget carrier)**.** *A* BoundedTypecheckingBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (\Gamma, T, Q, N, F, G, R, H, C, P, L)$$

with the following rows:

1. Γ *is the represented context row for the MetaCIC checker.*
2. T *is the option-valued type-inference row, exposing* `inferTypeCtx` *and its closed wrapper as finite checker data.*
3. Q *is the same-term row, exposing structural equality and* `checkSameTerm` *rather than proof-irrelevant equality.*
4. N *is the bounded normalizer row, carrying a visible fuel value and the bounded normal-form outputs used by* `decideClosedBetaConv`*.*
5. F *is the finished-normalization witness row. It is present only when the bounded normalizer has the endpoint evidence required by the audit map.*
6. G *is the gallery row, recording the executable sanity witnesses for Boolean, natural-number, pair, option, list, sum, and polymorphic examples.*
7. R *is the refusal-boundary row, recording that closedness and global beta-conversion decidability are not exported when the relevant endpoint data is absent.*
8. H *records componentwise* hsame *transport for* Γ, T, Q, N, F, G, R *and the structural rows.*

9. *C records* Cont *replay from a typechecking request through inference, same-term checking, bounded normal comparison, finished evidence, gallery rows, and refusal boundaries.*
10. *P is the* Pkg *provenance over* $\mathsf{BoundedTypecheckingBudget}^{\uparrow}$, $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$, $\mathsf{NormalFalseExclusion}^{\uparrow}$ $\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *L is the local* $\mathsf{NameCert}_{\mathsf{BoundedTypecheckingBudget}^{\uparrow}}$ *row.*

The carrier has no coordinate for unrestricted beta-conversion decidability, fuel-erased normalization, proof-irrelevant term equality, external closedness decision, hidden oracle, or host typechecker.

Theorem 5949.2 (Bounded typechecking budget NameCert obligations)**.** *For every accepted* $\mathsf{BoundedTypecheckingBudget}^{\uparrow}$ *carrier* $B = (\Gamma, T, Q, N, F, G, R, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedTypecheckingBudge}}$ *surface consists exactly of context admission through* Γ*, type-inference exposure through* T*, structural same-term exposure through* Q*, bounded-normalizer exposure through* N*, finished-endpoint evidence through* F *when present, gallery audit exposure through* G*, refusal-boundary exposure through* R*, componentwise* hsame *stability through* H*,* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* L*.*

Proof. Project the accepted carrier of Definition 5949.1. The represented context row Γ and inference row T are the only typechecking entry points.

The same-term checker Q and bounded normalizer N provide the equality-facing data. The finished row F is read only when endpoint evidence exists, while R records the refusal of a global conversion claim when that evidence is absent.

The gallery row G is audit-facing evidence for the executable examples, not a source of a general theorem. Componentwise transport H, replay C, provenance P, and local naming L preserve the same finite route, so the NameCert obligations cannot import a hidden oracle, host typechecker, or unrestricted conversion decision. □

Theorem 5949.3 (Bounded typechecking budget MetaCIC decidable handoff)**.** *Every consumer that cites the MetaCIC decidability audit map through an accepted* $\mathsf{BoundedTypecheckingBudget}^{\uparrow}$ *packet must factor through the finite route*

$$\Gamma, T, Q, N, F, G, R \longmapsto H, C, P, L.$$

Consequently type inference is public at the checker interface, structural same-term equality is public through Q*, bounded normal equality is public through* N*, and full closed beta-conversion is public only under the finished endpoint row* F*; otherwise the refusal row* R *remains visible.*

Proof. Begin with the typechecking side. The context row Γ and inference row T expose the checker interface described by chapter 9379; they do not expose a host typechecker.

Move to equality. The row Q supplies structural same-term checking, while N supplies the bounded normalizer comparison at a displayed fuel. These rows are enough for bounded normal equality and for the soundness statements named by the audit map.

The endpoint condition is separate. If F is present, the consumer may read the finished-normalization handoff to the closed normal-confluence seal. If F is absent, the refusal row R is part of the same public packet and blocks any claim of global closed beta-conversion decidability.

Finally replay H, C, P, L. These rows transport, replay, source, and name the exact budget route, so every MetaCIC decidability handoff remains a finite checker-row handoff rather than an unrestricted oracle. □

Theorem 5949.4 (Bounded typechecking budget refusal boundary)**.** *For every accepted* BoundedTypecheckingBudg *carrier* $B = (\Gamma, T, Q, N, F, G, R, H, C, P, L)$*, any consumer that has* $\Gamma, T, Q, N, G, H, C, P, L$ *but lacks the finished endpoint row* F *must keep the refusal-boundary row* R *in scope. Such a consumer may cite type-inference soundness and completeness, same-term correctness, gallery sanity, and bounded-normalizer output equality, but it may not export fuel-erased normalization, unrestricted beta-conversion decidability, or a closedness decision theorem.*

Proof. Project the carrier and remove only the endpoint row F from the consumer-visible route. The rows Γ, T, Q, N, G still expose the context, inference checker, same-term checker, bounded normalizer, and gallery audit surface.

The missing row matters exactly at the conversion boundary. Without F, the bounded normalizer output row N does not assert that the displayed fuel has reached finished closed normal forms, so the stronger conversion claim is not available.

The refusal row R is therefore mandatory. Transport H, replay C, provenance P, and local naming L preserve the same absence, preventing the consumer from replacing the missing endpoint by a host oracle, proof irrelevance, or fuel-erased normalization theorem. □

Falsifiable prediction: A claimed $\mathsf{BoundedTypecheckingBudget}^{\uparrow}$ consumer that exports global closed beta-conversion decidability while omitting the finished endpoint row F and refusal-boundary row R refutes the carrier of Definition 5949.1.

Independence witness: metacic-decidable-boundary, normal-false-exclusion, closed-normal-confluence-seal: $\mathsf{BoundedTypecheckingBudget}^{\uparrow}$ is not bijective to any listed sibling because it carries the joint context, inference, same-term, bounded-normalizer, finished-endpoint, gallery, refusal, transport, replay, provenance, and local NameCert rows. The decidable-boundary sibling names the audit edge; the normal-false-exclusion sibling controls false normal reads; the closed-normal-confluence seal supplies endpoint compatibility when F is present.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedTypecheckingBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedTypecheckingBudget}^{\uparrow}$ packet is generated from a represented context row, type-inference checker row, same-term checker row, bounded-normalizer row, finished endpoint row, gallery audit row, refusal-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedTypecheckingBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5949.1, Definition 5949.2, and Definition 5949.3 seed the finite checker-budget handoff for the MetaCIC decidability audit map.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedTypecheckingBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unrestricted beta-conversion decidability, fuel-erased normalization, an external closedness decision theorem, proof-irrelevant term equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inference checker exactness, same-term checker exactness, bounded-normalizer exactness, finished-endpoint handoff, gallery coverage, and refusal-boundary nonescape for BEDC.Derived.BoundedTypecheckingBudgetUp.

Chapter 5950

A Concrete Naming Certificate for $\mathsf{ScottTopology}^{\uparrow}$

Following Scott and Gierz–Hofmann–Keimel–Lawson–Mislove–Scott, the $\mathsf{ScottTopology}^{\uparrow}$ packet records the topology generated by upper sets inaccessible by directed suprema as finite BEDC naming data. It sits beside the directed-complete order surface of chapter 5905, the domain packet of chapter 4164, the interval real presentation of chapter 2083, the way-below interval route of chapter 1545, and the indexed-open topology surface of chapter 88. The packet names Scott-open observations for downstream domain-theoretic consumers; it is not a host powerset topology, quotient-open equality, selected directed supremum operation, arbitrary open lattice, choice principle, or Lean-verified bridge.

Definition 5950.1 (ScottTopology carrier)**.** *A* $\mathsf{ScottTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, S, U, I, B, O, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DCPO}^{\uparrow}$ *source row, exposing the finite order, directed-family schedule, supremum row, and lower-bound exactness already named by the directed-complete packet.*
2. *S is the* $\mathsf{ScottDomain}^{\uparrow}$ *source row, recording the domain-facing compact-basis and represented-space handoff rows that may consume the same directed-supremum route.*
3. *U is the upper-set row, saying that every accepted open observation is upward closed with respect to the displayed order in D.*
4. *I is the directed-supremum inaccessibility row, requiring membership of a directed supremum to be witnessed by membership at some displayed directed-family stage before the supremum is treated as open.*
5. *B is the way-below basis row. For interval-domain real consumers it reads the* $\mathsf{IntervalDomainWayBelow}^{\uparrow}$ *refinements used by chapter 2083; for general domain consumers it records the compact-basis approximation row already exposed by S.*
6. *O is the* $\mathsf{Topology}^{\uparrow}$ *handoff row, exporting the accepted Scott-open observations as indexed open rows without adding a second open-set carrier.*
7. *H records componentwise* hsame *transport for the DCPO source, Scott-domain source, upper-set row, directed-supremum inaccessibility row, way-below basis row, topology handoff, replay, provenance, and naming rows.*

8. *C records displayed* Cont *replay from a Scott-open request through D, S, U, I, B, O, H.*
9. *P is the* Pkg *provenance over* $\mathsf{ScottTopology}^{\uparrow}$, $\mathsf{DCPO}^{\uparrow}$, $\mathsf{ScottDomain}^{\uparrow}$, $\mathsf{ScottReal}^{\uparrow}$, $\mathsf{IntervalDomainWayBelow}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ScottTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, U, I, B, O, H, C, P, N$. It has no coordinate for arbitrary powersets, quotient-open equality, selected directed suprema, host topological equality, choice, or a Lean theorem.

Lean4 ✓ `BEDC.Derived.ScottTopologyUp.ScottTopologyTasteGate single carrier alignment`

Theorem 5950.2 (ScottTopology NameCert obligations)**.** *For every accepted* $\mathsf{ScottTopology}^{\uparrow}$ *carrier $T = (D, S, U, I, B, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ScottTopology}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{DCPO}^{\uparrow}$ *and* $\mathsf{ScottDomain}^{\uparrow}$ *sources, upper-set closure, directed-supremum inaccessibility, way-below basis compatibility,* $\mathsf{Topology}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Scott-open consumer must read $D, S, U, I, B, O, H, C, P, N$ before treating an open observation as public.*

Proof. Project the carrier of Definition 5950.1. The order source and domain source are D and S, the Scott-open tests are U, I, B, the topology export is O, and the structural rows are H, C, P, N.

The upper-set row U is read against the displayed order in D. Thus an open observation cannot be consumed independently of the directed-complete order carrier.

The directed-supremum inaccessibility row I is read against the directed-family and supremum rows already named by $\mathsf{DCPO}^{\uparrow}$ and by the $\mathsf{ScottDomain}^{\uparrow}$ source. It requires a displayed stage witness before a supremum membership is exported as open data.

The way-below basis row B supplies the compact-basis route. For real-facing domain consumers this route is the $\mathsf{IntervalDomainWayBelow}^{\uparrow}$ refinement used by $\mathsf{ScottReal}^{\uparrow}$; for general domain consumers it is the compact approximation row of S.

Finally O hands the accepted Scott-open observations to $\mathsf{Topology}^{\uparrow}$, while H, C, P, N transport, replay, source, and name the same finite packet. Since quotient opens, arbitrary powersets, host topological equality, selected suprema, choice, and Lean verification are absent from the carrier, these rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{ScottTopology}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ScottTopology}^{\uparrow}$ packet is generated from a DCPO source row, a ScottDomain source row, upper-set evidence, directed-supremum inaccessibility, way-below basis compatibility, a TopologyUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ScottTopology}^{\uparrow}}$, seed)

Scope closed: Definition 5950.1 and Definition 5950.2 seed the finite Scott-open interface over DCPO, ScottDomain, ScottReal, IntervalDomainWayBelow, and Topology rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ScottTopology}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient opens, arbitrary powersets, host topological equality, selected directed suprema, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, upper-set closure, directed-supremum inaccessibility, way-below basis compatibility, TopologyUp handoff, transport, replay, provenance, and local naming for BEDC.Derived.ScottTopologyUp.

Chapter 5951

A Concrete Naming Certificate for $\mathsf{FiniteRealSupremum}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FiniteRealSupremum}^{\uparrow}$ packet records the finite upper-bound search used when a nonempty finite family of constructive real names must expose a supremum row before any compact finite-net or finite-bound consumer can read it. It sits over the rational arithmetic base of chapter 37, the terminal real-name seal of chapter 38, the displayed comparison discipline of chapter 54, the binary min–max sibling of chapter 1674, and the finite-net fold route of chapter 619. The packet names finite supremum data only; it does not import host maximum, quotient real equality, order trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5951.1 (Finite real supremum carrier)**.** *A* $\mathsf{FiniteRealSupremum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, I, O, M, U, L, H, C, P, N)$$

with the following displayed rows:

1. *R is the nonempty finite* $\mathsf{Real}^{\uparrow}$ *packet, listing the real-name rows retained by the supremum request together with their finite index witnesses.*
2. *I is the inhabitedness row, exposing the selected starting index and its* $\mathsf{Real}^{\uparrow}$ *name before any comparison ledger is read.*
3. *O is the finite comparison ledger, recording the* $\mathsf{TotalOrder}^{\uparrow}$ *comparison rows used to compare retained* $\mathsf{Real}^{\uparrow}$ *names through rational readback and displayed order witnesses.*
4. *M is the* $\mathsf{RealMinMax}^{\uparrow}$ *fold ledger, showing how the finite comparison rows select the displayed upper-bound candidate from the retained real rows.*
5. *U is the selected upper-bound row, asserting that every retained member of R is bounded above by the candidate selected through M and O.*
6. *L is the least-bound verification row, asserting that every displayed upper bound for R receives a comparison witness from the selected candidate into that bound.*
7. *H records componentwise* hsame *transport for the finite real packet, inhabitedness row, comparison ledger, fold ledger, upper-bound row, least-bound row, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a finite-supremum request through R, I, O, M, U, L, H.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteRealSupremum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, $\mathsf{RealMinMax}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteRealSupremum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host maximum operator, quotient-real equality, detached order trichotomy, selected limit outside the finite packet, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteRealSupremumUp.FiniteRealSupremumTasteGate single carrier alignment`

Theorem 5951.2 (Finite real supremum NameCert obligations)**.** *For every accepted* $\mathsf{FiniteRealSupremum}^{\uparrow}$ *carrier*

$$S = (R, I, O, M, U, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteRealSupremum}^{\uparrow}}$ *surface consists exactly of carrier admission for the nonempty finite* $\mathsf{Real}^{\uparrow}$ *packet R, inhabitedness exposure through I, finite* $\mathsf{TotalOrder}^{\uparrow}$ *comparison-ledger access through O,* $\mathsf{RealMinMax}^{\uparrow}$ *fold selection through M, selected upper-bound verification through U, least-bound verification through L, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5951.1. The row R gives the finite list of real-name rows, and I keeps the packet nonempty before any upper-bound request is considered.

The comparison and selection rows are read next. The ledger O exposes only displayed $\mathsf{TotalOrder}^{\uparrow}$ comparison witnesses over the retained $\mathsf{Real}^{\uparrow}$ rows, while M records the finite $\mathsf{RealMinMax}^{\uparrow}$ fold that selects the candidate read by the upper-bound row.

The bounding rows are downstream of that fold. The row U checks that every retained real row is below the selected candidate, and L checks that any displayed upper bound receives a comparison witness from the selected candidate.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no row carries host maximum, quotient-real equality, detached trichotomy, countable choice, open-cover compactness, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{FiniteRealSupremum}^{\uparrow}$ consumer that reads a supremum row without first displaying the nonempty finite $\mathsf{Real}^{\uparrow}$ packet, comparison ledger, selected upper-bound row, least-bound verification row, transport, replay, provenance, and local naming refutes the carrier surface.

Independence witness: real, rat, total-order, real-min-max, finitenetminimumfold: no listed sibling is bijective with $\mathsf{FiniteRealSupremum}^{\uparrow}$ because this packet jointly carries a nonempty finite RealUp family, a finite comparison ledger, an upper-bound candidate, a least-bound verification row, componentwise transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRealSupremum}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteRealSupremum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5951.1 and Definition 5951.2 seed the finite supremum route through nonempty Real rows, comparison ledgers, selected upper-bound rows, least-bound verification, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteRealSupremum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host maximum, quotient Real equality, detached order trichotomy, selected limits outside the finite packet, countable choice, open-cover compactness, Lean verification, bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, nonempty finite Real packet exposure, comparison-ledger exactness, selected upper-bound verification, least-bound verification, and TasteGate compatibility for BEDC.Derived.FiniteRealSupremu

Constructive story: A FiniteRealSupremum$^{\uparrow}$ packet is generated from a nonempty finite RealUp packet, finite TotalOrderUp comparison rows, a RealMinMaxUp fold ledger, an upper-bound row, a least-bound verification row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 5952

A Concrete Naming Certificate for $\mathsf{HahnDecomposition}^{\uparrow}$

Following Hahn and standard signed-measure theory, the $\mathsf{HahnDecomposition}^{\uparrow}$ packet records the finite BEDC surface by which a signed measure is read through positive and negative regions before downstream integration or Radon representation consumers inspect it. It sits after the measure carrier of chapter 92, the regular measure packet of chapter 2263, the compact representation route of chapter 3504, the public integral row of chapter 123, and the terminal real seal of chapter 38. The chapter names a decomposition certificate; it does not import a host sigma-algebra completion, quotient equality of signed measures, or a choice-selected measurable partition.

Definition 5952.1 (Hahn decomposition carrier)**.** *A* $\mathsf{HahnDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, A, B, Z, M, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the signed-measure row, carrying the finite positive and negative variation ledgers visible to this certificate.*
2. *A is the positive-region row, naming the measurable region on which every displayed signed-measure read is nonnegative.*
3. *B is the negative-region row, naming the measurable region on which every displayed signed-measure read is nonpositive.*
4. *Z is the null-boundary row, recording the displayed overlap and complement boundary on which the decomposition exports no signed mass.*
5. *M is the* $\mathsf{Measure}^{\uparrow}$ *readback row for the underlying measurable-event and finite-value surface.*
6. *R is the* $\mathsf{RadonMeasure}^{\uparrow}$ *regularity row used when a downstream regular-measure consumer asks for compact or open approximants.*
7. *L is the* $\mathsf{RieszMarkov}^{\uparrow}$ *representation row used when a compact positive-functional consumer reads the decomposed measure through a representing Radon packet.*
8. *E is the* $\mathsf{Integral}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback row for integral values and terminal real seals produced from the displayed signed-measure side.*
9. *H records componentwise* hsame *transport for S, A, B, Z, M, R, L, E and for every region, boundary, measure value, integral value, and real seal named by those rows.*

10. *C is the displayed* Cont *replay ledger routing signed-measure reads first through A, B, Z, then through M, R, L, E when a downstream consumer asks for measure, Radon, Riesz–Markov, integral, or real output.*

11. *P is the* Pkg *provenance over* $\mathsf{HahnDecomposition}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{RieszMarkov}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and local certificate rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{HahnDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these twelve displayed rows. It has no coordinate for host signed-measure equality, a completed measure algebra, a selected measurable partition, countable choice, quotient equality of regions, or ambient standard-model measure theory.

Lean4 (definition) `BEDC.Derived.HahnDecompositionUp.HahnDecompositionUp`
Lean4 ✓ `BEDC.Derived.HahnDecompositionUp.HahnDecompositionTasteGate single carrier alignment`

Theorem 5952.2 (Hahn decomposition NameCert obligations)**.** *For every accepted* $\mathsf{HahnDecomposition}^{\uparrow}$ *carrier*

$$D = (S, A, B, Z, M, R, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HahnDecomposition}^{\uparrow}}$ *surface consists exactly of signed-measure admission through S, positive-region visibility through A, negative-region visibility through B, null-boundary exactness through Z, measure readback through M, Radon regularity handoff through R, Riesz–Markov representation handoff through L, integral and real readback through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5952.1. It lists the signed-measure row, positive and negative region rows, null-boundary row, downstream measure-analysis rows, transport row, replay row, provenance row, and local naming row.

The decomposition obligations are the visible rows A, B, Z over the signed-measure row S. They state which region is read as positive, which region is read as negative, and where the null boundary prevents a consumer from extracting extra signed mass.

The downstream obligations are the rows M, R, L, E. They force every measure, RadonMeasure, RieszMarkov, Integral, or Real readback to pass through displayed BEDC packets rather than through a host theorem about signed measures.

Finally, H, C, P, N preserve and name the same finite route. Since no other coordinate is present, the local NameCert surface is exhausted by the listed rows. □

Theorem 5952.3 (Hahn decomposition signed-measure route)**.** *Every downstream consumer of an accepted* $\mathsf{HahnDecomposition}^{\uparrow}$ *carrier must read the signed-measure row S through the positive region A, negative region B, and null boundary Z before it may inspect the* $\mathsf{Measure}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{RieszMarkov}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *rows M, R, L, E. The route is transported by H, replayed by C, packaged by P, and named by N.*

Proof. Begin with Definition 5952.1. The only signed-measure coordinate is S, and its decomposition-facing rows are exactly A, B, Z.

Apply Definition 5952.2. The obligation surface requires positive-region visibility, negative-region visibility, and null-boundary exactness before any downstream readback row can be consumed.

Now read the downstream rows in order. Measure consumers pass through M, regular-measure consumers pass through R, compact representation consumers pass through L, and integral or

terminal real consumers pass through E. The replay ledger C records those routes, while H, P, N transport, source, and name them.

Thus the signed-measure route is the displayed finite BEDC packet. It exports no host signed-measure equality, selected measurable partition, completed measure algebra, quotient equality of regions, countable choice, or ambient standard-model measure theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{HahnDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{HahnDecomposition}^{\uparrow}$ packet is generated from a signed-measure row, positive-region row, negative-region row, null-boundary row, MeasureUp readback, RadonMeasureUp regularity handoff, RieszMarkovUp representation handoff, IntegralUp and RealUp readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HahnDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5952.1, Definition 5952.2, and Definition 5952.3 seed the finite signed-measure decomposition route through positive, negative, null-boundary, measure, Radon, Riesz–Markov, integral, and real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HahnDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host signed-measure equality, selected measurable partitions, completed measure algebras, quotient equality of regions, countable choice, or ambient standard-model measure theory.

Upgrade path: Obligation closure requires checked carrier admission, signed-measure classifier transport, positive-region visibility, negative-region visibility, null-boundary exactness, downstream measure readback, Radon and Riesz–Markov handoff, Integral and Real readback, transport stability, replay stability, and provenance for BEDC.Derived.HahnDecompositionUp.

Chapter 5953

A Concrete Naming Certificate for $\mathsf{ConstructivePolishSpace}^{\uparrow}$

Following Bishop and Bridges on complete separable metric spaces in constructive analysis, the $\mathsf{ConstructivePolishSpace}^{\uparrow}$ packet records the L10 completion frontier as finite NameCert data. It sits after the completion source of chapter 1506, the separated classifier of chapter 1411, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the effective separable surface of chapter 1706, and the compact subcase of chapter 4016. The packet names a completion-facing constructive Polish carrier without claiming quotient completions, countable choice, host point equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5953.1 (ConstructivePolishSpace carrier)**.** *A* $\mathsf{ConstructivePolishSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, S, D, W, Q, R, L, H, C, G, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row, exposing only the completion request, finite tolerance ledger, and completion-facing handoff consumed by the packet.*
2. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier row, requiring zero-distance agreement for displayed points to pass through the separated metric boundary.*
3. *D is the dense-sequence row. It names the finite prefix and readback schedule inspected by a completion consumer, not an infinite choice of representatives.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for dense-name observations, Cauchy windows, and requested precision budgets.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational approximants, tolerance comparisons, and Cauchy witness reads.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after the finite stream windows and regular rational readbacks have been displayed.*
7. *L is the located completion service row, answering each displayed approximation request through M, S, D, W, Q, R.*
8. *H records componentwise* hsame *transport for the metric-completion source, separated classifier, dense schedule, stream windows, regular rational readback, Real seal, located service, replay row, provenance row, and local naming row.*

9. *C records displayed* Cont *replay from a finite completion request through W, Q, R and then back to M, S, D, L.*
10. *G is the* Pkg *provenance over* ConstructivePolishSpace$^{\uparrow}$, MetricCompletion$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, EffectivePolishSpace$^{\uparrow}$, CompactPolishSpace$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{ConstructivePolishSpace}^{\uparrow}}$ *row.*

The carrier exports only this displayed finite completion route. It has no coordinate for quotient completion classes, countable choice over dense points, host point equality, selected representatives, or an unrestricted completeness principle for Real$^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.ConstructivePolishSpaceUp.ConstructivePolishSpaceTasteGate single carrier alignment`

Theorem 5953.2 (ConstructivePolishSpace NameCert obligation surface)**.** *For every accepted* ConstructivePolishSpace$^{\uparrow}$ *carrier $P = (M, S, D, W, Q, R, L, H, C, G, N)$, the local* NameCert$_{\text{ConstructivePolishSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, separated zero-distance classification, dense-prefix readback, finite StreamName window admission, RegSeqRat regular readback, Real seal handoff, located completion service replay, componentwise transport, provenance, and local naming through the displayed rows $M, S, D, W, Q, R, L, H, C, G, N$.*

Proof. Project the carrier of Definition 5953.1. The tuple displays exactly the metric-completion source, separated classifier, dense schedule, StreamName windows, RegSeqRat readback, Real seal, located completion service, transport, replay, provenance, and local naming rows.

A completion-facing request must first choose a finite window in W and a finite dense-prefix read through D. The regular rational row Q turns those observations into tolerance data before the terminal Real seal R can be inspected.

The separated classifier S is the only row that compares displayed points, and it does so over the completion source M. The located service L, transport row H, replay row C, provenance row G, and local name row N package this same route, so no excluded quotient, choice, host-equality, or ambient-completeness coordinate is available. □

Theorem 5953.3 (ConstructivePolishSpace completion readback route)**.** *Every completion-facing read served by an accepted* ConstructivePolishSpace$^{\uparrow}$ *packet factors through the finite route*

$$D, W \longmapsto Q \longmapsto R \longmapsto M, S, L \longmapsto H, C, G, N.$$

Thus an EffectivePolishSpace$^{\uparrow}$ *or* CompactPolishSpace$^{\uparrow}$ *consumer may read dense schedules, finite windows, regular rational approximants, the terminal Real seal, and the located completion service, but it cannot extract quotient completion equality, a countable-choice selector, host point equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start with a completion-facing consumer. The only dense-name data in the packet is D, and the only observation schedule is W, so the consumer first receives a finite dense prefix and finite stream windows.

The readback then passes through Q and R. This exposes regular rational approximants and a Real seal only after the finite observations have been displayed.

Finally the route returns to the completion source M, separated classifier S, and located service L, then through the structural rows H, C, G, N. Since no other coordinate appears in the carrier, the listed quotient, choice, host-equality, and ambient-completeness claims cannot be read from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructivePolishSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructivePolishSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5953.1, Definition 5953.2, and Definition 5953.3 seed the finite constructive Polish completion route over metric completion, separated classification, dense schedules, StreamName windows, RegSeqRat readback, Real sealing, located completion service, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructivePolishSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient completion equality, countable choice, host point equality, selected representatives, standard bridge checking, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, dense-prefix readback, separated classifier stability, completion-readback routing, nonescape, and local naming for BEDC.Derived.ConstructivePolishSpaceUp.

Constructive story: A $\mathsf{ConstructivePolishSpace}^{\uparrow}$ packet is generated from a MetricCompletion source row, a SeparatedMetric classifier row, finite dense schedules, StreamName windows, RegSeqRat readback, a RealUp seal, located completion service, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5954

A Concrete Naming Certificate for $\mathsf{CompactUniformEquicontinuityStability}^{\uparrow}$

Following Bishop, Bridges, and Munkres on compact metric spaces and equicontinuous families, the $\mathsf{CompactUniformEquicontinuityStability}^{\uparrow}$ packet records the finite route from compact nets and family moduli to a stable uniform-modulus ledger. It refines the compact-uniform-continuity vision through the compact source of chapter 129, the continuous family surface of chapter 130, the uniform-modulus handoff of chapter 369, the equicontinuity carrier of chapter 4076, the rational fold interface of chapter 37, and the metric source and target rows of chapter 4230. The packet names only finite compact nets, displayed family moduli, rational lower-bound folds, metric-distance rows, transport, replay, provenance, and local naming; it does not import open-cover compactness, selected subcovers, function extensionality in the host, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5954.1 (CompactUniformEquicontinuityStability carrier)**.** *A* $\mathsf{CompactUniformEquicontinuityStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, A, Q, U, M, T, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, naming the inspected net points, coverage radii, and located compact source data.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, exposing only the displayed finite family observations needed by the compact-net argument.*
3. *A is the* $\mathsf{Equicontinuity}^{\uparrow}$ *family-modulus row, assigning one displayed local modulus route to the family observations in F.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *finite lower-bound fold row, reducing the finitely many compact-net and family-radius budgets to a positive rational tolerance.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *export row consumed by compact-uniform-continuity, Arzela–Ascoli, and family-modulus consumers.*
6. *M is the source* $\mathsf{Met}^{\uparrow}$ *distance row for the compact domain.*
7. *T is the target* $\mathsf{Met}^{\uparrow}$ *distance row for the displayed codomain observations.*

8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the source and target distance reads after the rational fold has been displayed.*
9. *H records componentwise* hsame *transport for compact nets, continuous family rows, equicontinuity moduli, rational folds, uniform-modulus export, source and target distances, Real sealing, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from finite compact-net reads through the family-modulus row and rational lower-bound fold to the uniform-modulus export.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactUniformEquicontinuityStability}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityStability}^{\uparrow}}$ *row.*

The carrier exports family-modulus stability only through these rows. It has no coordinate for open-cover compactness, selected finite subcovers, unrestricted host function equality, countable choice, quotient maps, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactUniformEquicontinuityStabilityUp.CompactUniformEquicontinuityStabilityTaste`
`single carrier alignment`

Theorem 5954.2 (CompactUniformEquicontinuityStability handoff)**.** *For every accepted* CompactUniformEquicon *carrier $E = (K, F, A, Q, U, M, T, R, H, C, P, N)$, every compact-uniform family-stability read factors through*

$$K, F, A, M, T \longmapsto Q \longmapsto R, U \longmapsto H, C, P, N.$$

Consequently a downstream Arzela–Ascoli or compact family-modulus consumer receives a displayed uniform-modulus row built from finite compact nets, continuous family observations, equicontinuity moduli, rational lower-bound folds, metric distances, Real sealing, transport, replay, provenance, and local naming, with no access to open-cover compactness, selected subcovers, countable choice, or host function equality.

Proof. Project the carrier of Definition 5954.1. The compact source is the finite-net row K, the family observations are F, and the only family-modulus coordinate is A.

The source and target metric reads pass through M and T. The rational fold Q is the unique row that combines the finitely many net and modulus budgets into a positive tolerance before any Real seal or uniform-modulus export can be read.

After Q is displayed, R seals the finite metric reads and U exports the uniform-modulus handoff. The structural rows H, C, P, N transport, replay, source, and name the same route, so the excluded open-cover, selector, choice, quotient, host-equality, and ambient-completeness data have no row from which to be consumed. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityStability}^{\uparrow}}$ ·

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityStability}^{\uparrow}}, \mathsf{seed})$

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformEquicontinuityStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, open-cover compactness, selected subcovers, countable choice, host function equality, quotient maps, standard bridge checking, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-net coverage, family-modulus stability, rational fold positivity, uniform-modulus handoff, metric distance sealing, nonescape, and local naming for BEDC.Derived.CompactUniformEqui

Constructive story: A CompactUniformEquicontinuityStability$^{\uparrow}$ packet is generated from CompactMetric finite nets, ContinuousMap family rows, an Equicontinuity family modulus, a RatUp finite lower-bound fold, a UniformModulus export, MetricSpace source and target distance rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5955

A Concrete Naming Certificate for $\mathsf{RealEqualityReflection}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, equality of real numbers is presented through regular Cauchy data and explicit tolerance control rather than through an ambient quotient oracle. The $\mathsf{RealEqualityReflection}^{\uparrow}$ packet names the finite equality-reflection boundary where the setoid route of chapter 1820 is exposed to the equality-facing consumers of chapter 1636. It records the route from regular rational streams and dyadic tolerance rows into the $\mathsf{Real}^{\uparrow}$ seal without adding selected representatives, quotient equality as a primitive, countable choice, host real extensionality, Lean verification, or bridge checking.

Definition 5955.1 (Real equality reflection carrier)**.** *A* $\mathsf{RealEqualityReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (Q, E, R, S, D, H, C, P_0, N)$$

with the following displayed rows:

1. Q *is the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *route that reads equality through finite Cauchy windows.*
2. E *is the* $\mathsf{RealEquality}^{\uparrow}$ *consumer row whose equality-facing request is admitted only after* Q *is visible.*
3. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row used by the setoid route.*
4. S *is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened before any equality consumer reads the source.*
5. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the visible windows and regular rational readback.*
6. H *records componentwise* hsame *transport for the setoid route, equality consumer, source, windows, tolerance ledger, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from an equality-reflection request through* R, S, D, Q, E *and then through the structural rows.*
8. P_0 *is the* Pkg *provenance over* $\mathsf{RealEqualityReflection}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{RealEquality}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RealEqualityReflection}^{\uparrow}}$ *row.*

The carrier is admitted only when every $\mathsf{RealEquality}^{\uparrow}$ *read is downstream of the displayed* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *route and every route into the* $\mathsf{Real}^{\uparrow}$ *seal still exposes the regular source, opened window, dyadic tolerance row, transport, replay, provenance, and local name.*

Theorem 5955.2 (Real equality reflection NameCert obligation surface)**.** *For every accepted* $\mathsf{RealEqualityReflection}^{\uparrow}$ *carrier*

$$P = (Q, E, R, S, D, H, C, P_0, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealEqualityReflection}^{\uparrow}}$ *surface consists exactly of carrier admission, setoid-route exposure, real-classifier reflection, transport, replay, provenance, and non-escape rows. Carrier admission displays* $Q, E, R, S, D, H, C, P_0, N$*; setoid-route exposure requires* Q *to read* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *through* R, S, D*; real-classifier reflection requires the equality-facing consumer row* E *to remain downstream of that setoid route before any* $\mathsf{Real}^{\uparrow}$ *seal is read; transport, replay, and provenance are carried only by* H, C, P_0*; non-escape is the assertion that no quotient-equality oracle, selected representative, countable-choice schedule, ambient real extensionality, Lean verification, or bridge coordinate is present.*

Lean4 ✓ `BEDC.Derived.RealEqualityReflectionUp.RealEqualityReflectionNameCertObligationSurface`

Proof. Project the carrier of Definition 5955.1. The projection exposes one setoid route, one equality-facing consumer row, one regular rational source, one opened window row, one dyadic tolerance ledger, and the structural transport, replay, provenance, and naming rows.

The setoid route is forced to pass through R, S, D before the consumer row E can read equality. Thus the packet first records the regular rational readback and finite StreamName inspection used by $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$.

The equality-facing row then reflects only that visible route into the Real boundary. Since the only structural rows are H, C, P_0, N, the packet can transport, replay, source, and name the displayed route but cannot add a quotient oracle, selected representative, choice schedule, ambient extensionality, Lean proof, or bridge datum. □

Theorem 5955.3 (Real equality reflection Cauchy setoid route)**.** *Every* $\mathsf{RealEquality}^{\uparrow}$ *consumer exported by an accepted* $\mathsf{RealEqualityReflection}^{\uparrow}$ *carrier factors through the finite route*

$$R, S, D \longmapsto Q \longmapsto E \longmapsto \mathsf{Real}^{\uparrow}.$$

In particular, the consumer first reads the $\mathsf{RegSeqRat}^{\uparrow}$ *source, the* $\mathsf{StreamName}^{\uparrow}$ *finite window, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, then exposes the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *route, and only after that may it reach the equality-facing* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Begin with an equality-facing request. Carrier admission gives the displayed rows R, S, D, Q, E and no direct coordinate from the request to a Real seal.

Read R, S, D first. These rows determine the regular source readback, finite window, and dyadic tolerance surface on which the Cauchy setoid comparison is visible.

Now read the setoid row Q and only then the consumer row E. The target equality consumer therefore sees $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ before $\mathsf{RealEquality}^{\uparrow}$ reaches the $\mathsf{Real}^{\uparrow}$ seal, so the route has no hidden quotient equality, selected representative, countable choice, ambient completeness, Lean verification, or bridge checking coordinate. □

Falsifiable prediction: A $\mathsf{RealEquality}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ equality-facing seal from accepted $\mathsf{RealEqualityReflection}^{\uparrow}$ data without first exposing the $\mathsf{RegSeqRat}^{\uparrow}$ source, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ route refutes the carrier surface.

Independence witness: cauchy-equivalence-setoid, real-equality, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the whole nine-row packet $P = (Q, E, R, S, D, H, C, P_0, N)$, because each sibling contributes only setoid, equality-consumer, source, window, tolerance, or seal data while this chapter binds them with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealEqualityReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{RealEqualityReflection}^{\uparrow}$ packet is generated from a CauchyEquivalenceSetoid route, a RealEquality consumer row, a RegSeqRat source row, StreamName windows, a DyadicRatCore tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before the Real seal is read.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealEqualityReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5955.1, Definition 5955.2, and Definition 5955.3 seed the finite equality-reflection surface over regular rational sources, finite windows, dyadic tolerances, Cauchy setoid routing, equality-facing consumers, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealEqualityReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality as primitive, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, setoid-route exposure, real-classifier reflection, transport, replay, provenance, and non-escape for BEDC.Derived.RealEqualityReflectionUp.

Chapter 5956

A Concrete Naming Certificate for $\mathsf{ConstructiveSobolevEnergy}^{\uparrow}$

Following Sobolev and Bishop–Bridges constructive analysis, the $\mathsf{ConstructiveSobolevEnergy}^{\uparrow}$ packet records finite energy evidence for a displayed function row and its weak-derivative rows without passing through a host quotient space. It sits after the Sobolev comparison surface of chapter 440, the Sobolev-space carrier of chapter 5911, the Hilbert inner-product route of chapter 91, and the terminal real readback seal of chapter 38. The packet gives PDE, trace, and embedding consumers a finite energy certificate surface rather than a completed function space.

Definition 5956.1 (Constructive Sobolev energy carrier)**.** *A* $\mathsf{ConstructiveSobolevEnergy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, D, E, A, B, H, C, P, N)$$

with the following displayed rows:

1. *F is the function row. It records the visible domain name, target* $\mathsf{Real}^{\uparrow}$ *readback route, finite test-window requests, and the stream or regular-rational windows through which function values are inspected.*
2. *D is the weak-derivative row. It records the finite multi-index list, test-window signs, integration-by-parts witnesses, and derivative readback windows imported from the weak-derivative and Sobolev siblings.*
3. *E is the energy norm row. It records the displayed L^2-style summands, Hilbert inner-product requests, rational upper bounds, and real seal endpoints used to certify finite energy.*
4. *A is the dyadic approximation row. It records finite dyadic tolerances, local mesh windows, rational error bounds, and replayable approximation requests for F, D, E.*
5. *B is the boundary and trace row. It records only the trace windows, boundary test rows, and compatibility checks explicitly present in the packet.*
6. *H records componentwise* hsame *transport across F, D, E, A, B.*
7. *C records displayed* Cont *replay from a Sobolev-energy request through the function row, weak-derivative rows, energy norm row, dyadic approximation row, boundary and trace row, and transport row.*
8. *P is the* Pkg *provenance row over* $\mathsf{ConstructiveSobolevEnergy}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{SobolevSpace}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{ConstructiveSobolevEnergy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. No coordinate stores a host quotient of functions, a measure-completed representative class, a Hahn–Banach separator, an open-cover compactness theorem, a selected trace representative, countable choice, or ambient equality of functions.

Lean4 ✓ `BEDC.Derived.ConstructiveSobolevEnergyUp.ConstructiveSobolevEnergyTasteGate single carrier alignment`

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveSobolevEnergy}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{ConstructiveSobolevEnergy}^{\uparrow}$ packet is generated from a function row, weak-derivative rows, an energy norm row, dyadic approximation data, boundary and trace data, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveSobolevEnergy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5956.1 binds the finite carrier surface for Sobolev energy certificates over displayed function, derivative, approximation, boundary, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveSobolevEnergy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host function quotients, measure-completion claims, Hahn–Banach separation, open-cover compactness, choice, or bridge checking.

Upgrade path: Obligation closure requires checking carrier admission, energy-row exactness, derivative-row replay, trace-window non-escape, and local NameCert stability for the displayed packet.

Chapter 5957

A Concrete Naming Certificate for $\mathsf{GammaConvergence}^{\uparrow}$

Following Dal Maso on Gamma-convergence, the $\mathsf{GammaConvergence}^{\uparrow}$ packet records the finite variational-convergence surface by which lower-bound and recovery-window data are routed to compactness and real-valued consumers. It sits after the metric carrier of chapter 57, the compact finite-read discipline of chapter 129, the lower-semicontinuity boundary of chapter 1536, the regular rational readback route of chapter 301, and the terminal real seal of chapter 38. The packet names only displayed liminf ledgers, recovery windows, compactness windows, real-value readbacks, transport, replay, provenance, and local naming; it does not assert host minimizer existence, quotient equality of functionals, selected recovery sequences, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5957.1 (Gamma-convergence carrier)**.** *A* $\mathsf{GammaConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, K, L, F, A, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row on which the variational data are inspected.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite compactness-window row used by subsequence-facing consumers.*
3. *L is the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *liminf-boundary row for the inspected functionals.*
4. *F is the finite functional-index and value-window ledger.*
5. *A is the liminf-test row, recording every displayed approach window and its lower-bound comparison.*
6. *R is the recovery-window row, recording finite witnesses that a downstream consumer may replay without selecting a host recovery sequence.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational value windows exposed by A and R.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after X, K, L, F, A, R, Q have been displayed.*
9. *H records componentwise* hsame *transport for the displayed rows.*
10. *C records displayed* Cont *replay from metric and compact windows to the lower-bound, recovery, readback, and seal rows.*

11. *P is the* Pkg *provenance over* $\mathsf{GammaConvergence}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{GammaConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, K, L, F, A, R, Q, E, H, C, P, N$. It has no coordinate for quotient equality of functionals, selected minimizers, selected recovery sequences, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.GammaConvergenceUp.GammaConvergenceTasteGate single carrier alignment`

Theorem 5957.2 (Gamma-convergence NameCert obligations)**.** *For an accepted* $\mathsf{GammaConvergence}^{\uparrow}$ *carrier $G = (X, K, L, F, A, R, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{GammaConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-source exposure through X, compact finite-window exposure through K, lower-semicontinuity exposure through L, finite functional-window exposure through F, liminf-test exposure through A, recovery-window exposure through R, regular rational readback through Q, terminal real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every variational consumer of the packet must therefore read the finite route

$$\mathsf{Met}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{LowerSemicontinuous}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

before it may inspect a Gamma-limit-facing value. The exported route is a finite NameCert boundary for liminf and recovery data, not a host compactness theorem, a selected minimizer, quotient equality of functionals, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

The liminf and recovery rows of $\mathsf{GammaConvergence}^{\uparrow}$ consume the Mosco finite variational surface of chapter 5938 before Gamma-facing compactness and recovery consumers read the local packet: the lower-semicontinuity row, weak-liminf ledger, recovery-window row, convex support, completion handoff, and Real readback are the shared variational boundary.

Proof. Project the carrier of Definition 5957.1. The rows X, K, L, F, A, R, Q, E are the only coordinates from which a variational consumer may read metric source data, compact windows, lower-semicontinuity tests, finite functional windows, liminf checks, recovery windows, rational readbacks, and terminal real seals.

The liminf side is generated by A only after X, K, L, F have been displayed. Thus a lower-bound read cannot bypass the metric row, compact finite-window row, lower-semicontinuity row, or finite value-window ledger.

The recovery side is generated by R and read back through Q before E is visible. Since H, C, P, N preserve only the displayed rows under transport, replay, provenance, and local naming, they cannot add a selected recovery sequence, a minimizer, quotient equality, or an ambient completeness theorem.

Consequently the local NameCert obligations are exhausted by the listed finite rows. Any stronger variational principle must be supplied by a later consumer, not by the $\mathsf{GammaConvergence}^{\uparrow}$ packet itself. □

Falsifiable prediction: Every accepted $\mathsf{GammaConvergence}^{\uparrow}$ consumer that reaches a Real-facing Gamma-limit value without first reading a Metric row, CompactMetric row, LowerSemicontinuous row, liminf-test row, recovery-window row, RegSeqRat readback row, transport, replay, provenance, and local NameCert row refutes the carrier surface.

Independence witness: metric, compactmetric, lowersemicontinuous, regseqrat, real, mosco-convergence: $\mathsf{GammaConvergence}^{\uparrow}$ is not bijective to any listed sibling because the packet jointly stores liminf tests, recovery windows, compact finite-read boundaries, rational value readbacks, terminal real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{GammaConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GammaConvergence}^{\uparrow}}, \mathsf{seed})$

Constructive story: A $\mathsf{GammaConvergence}^{\uparrow}$ packet is generated from a metric source row, compact finite-window row, lower-semicontinuity row, finite functional windows, liminf-test rows, recovery-window rows, RegSeqRat readback, a RealUp seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Scope closed: Definition 5957.1 and Definition 5957.2 seed the finite variational-convergence certificate over Metric, CompactMetric, LowerSemicontinuous, RegSeqRat, Real, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GammaConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host minimizer existence, selected recovery sequences, quotient equality of functionals, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Formalization requires a BEDC.Derived.GammaConvergenceUp carrier together with checked liminf, recovery-window, compactness-window, readback, transport, provenance, and local naming obligations.

Chapter 5958

A Concrete Naming Certificate for $\mathsf{LocatedRealChoiceSequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedRealChoiceSequence}^{\uparrow}$ packet records the finite choice-sequence surface by which located real observations are read as scheduled rational windows rather than as selected completed representatives. It sits downstream of the located-real carrier of **??**, the finite schedule discipline of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the comparison boundary of chapter 1381. The packet names a finite L10 choice-sequence interface only; it does not import countable choice, quotient streams, selected representatives, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5958.1 (LocatedRealChoiceSequence carrier)**.** *A* $\mathsf{LocatedRealChoiceSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, S, D, R, E, B, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *source row, naming the located real endpoint or local located-real family inspected by the choice-sequence request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, listing the finite indices, stages, and observation windows read before the request is accepted.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the dyadic radii and residue checks attached to the windows in S.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, packaging the scheduled rational observations as regular Cauchy data with the displayed tolerance schedule.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, S, D, R have been displayed.*
6. *B is the* $\mathsf{BishopRealComparison}^{\uparrow}$ *boundary row, recording any finite comparison or overlap evidence used to keep the located-real windows compatible with the regular rational readback.*
7. *H records componentwise* hsame *transport for located-real rows, schedules, dyadic tolerances, regular readbacks, Real seals, comparison rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a choice-sequence request through L, S, D, R, E, B, H.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealChoiceSequence}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedRealChoiceSequence}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for a countable choice functional, quotient stream equality, a selected representative of a real, trichotomy of located real comparisons, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LocatedRealChoiceSequenceUp.LocatedRealChoiceSequenceTasteGate single carrier alignment`

Theorem 5958.2 (LocatedRealChoiceSequence NameCert obligations)**.** *For every accepted* LocatedRealChoiceSequ *carrier*

$$Q = (L, S, D, R, E, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealChoiceSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the located-real source L, finite* $\mathsf{StreamName}^{\uparrow}$ *schedule exposure through S, dyadic tolerance access through D, regular rational readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *seal admission through E, Bishop comparison-boundary access through B, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5958.1. The located source is L, and the only schedule available to a consumer is the finite $\mathsf{StreamName}^{\uparrow}$ row S.

The rational data are downstream of that schedule. The dyadic tolerance ledger D attaches radii and residue checks to the same inspected windows, and R repacks those scheduled observations as a $\mathsf{RegSeqRat}^{\uparrow}$ readback.

The real-facing and comparison rows are then forced. The seal E is reached only after L, S, D, R have been displayed, while B records the finite $\mathsf{BishopRealComparison}^{\uparrow}$ boundary data used to compare or overlap the displayed windows.

Finally H, C, P, N transport, replay, source, and name exactly the same finite packet. Since the carrier has no row for countable choice, quotient streams, selected representatives, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 5958.3 (LocatedRealChoiceSequence regular-window handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *read exported by an accepted* $\mathsf{LocatedRealChoiceSequence}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{LocatedReal}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BishopRealComparison}^{\uparrow}.$$

Thus a downstream real or comparison consumer receives only the displayed located-real row, the finite schedule windows, the dyadic tolerance ledger, the regular rational readback, the Real seal, the Bishop comparison boundary, and the structural rows H, C, P, N.

Proof. Read the source and schedule rows first. The located-real row L supplies the inspected endpoint or local family, and the finite schedule row S names exactly the stages and windows available to the request.

The regular readback cannot bypass the tolerance ledger. The row D stores the dyadic budgets attached to those windows, and R is the only $\mathsf{RegSeqRat}^{\uparrow}$ row in the carrier, so every regular rational read factors through D and then through R.

The downstream rows preserve this order. The $\mathsf{Real}^{\uparrow}$ seal E and the $\mathsf{BishopRealComparison}^{\uparrow}$ boundary B are listed after the scheduled readback, and the structural rows H, C, P, N transport, replay, source, and name that same route. No refused object is a coordinate of the carrier, so no consumer can read a quotient stream, selected representative, trichotomy row, countable-choice functional, or ambient completeness witness through this handoff. □

Falsifiable prediction: An accepted $\mathsf{LocatedRealChoiceSequence}^{\uparrow}$ consumer that reads a regular rational or Real-facing choice-sequence row without first displaying the located-real source, finite stream schedule, dyadic tolerance ledger, regular readback, Real seal, Bishop comparison boundary, transport, replay, provenance, and local naming refutes the carrier surface.

Independence witness: located-real, streamname, regseqrat, dyadicratcore, real, bishop-real-comparison: $\mathsf{LocatedRealChoiceSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a located-real source, finite StreamName schedule rows, DyadicRatCore tolerance rows, RegSeqRat readbacks, Real seals, Bishop comparison boundaries, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealChoiceSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealChoiceSequence}^{\uparrow}$ packet is generated from a located-real source, finite StreamName schedule rows, DyadicRatCore tolerance rows, RegSeqRat readbacks, RealUp seal rows, BishopRealComparison boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealChoiceSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5958.1, Definition 5958.2, and Definition 5958.3 seed the finite located-real choice-sequence route over schedules, tolerances, regular readbacks, Real seals, comparison boundaries, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealChoiceSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, quotient streams, selected representatives, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule exposure, dyadic tolerance exactness, RegSeqRat readback handoff, Real seal nonescape, Bishop comparison-boundary stability, and structural transport for BEDC.Derived.LocatedRealChoiceSequenceUp.

Chapter 5959

A Concrete Naming Certificate for $\mathsf{NestedIntervalCauchySeal}^{\uparrow}$

Following Bishop and Bridges constructive nested-interval practice, the $\mathsf{NestedIntervalCauchySeal}^{\uparrow}$ packet records the finite seal that turns nested dyadic interval data into a regular Cauchy rational handoff before any completion consumer may read a $\mathsf{Real}^{\uparrow}$ name. It sits beside the dyadic rational core of chapter 291, the finite window service of chapter 126, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the located interval sibling of chapter 394. The packet names only finite nested located intervals, dyadic diameter budgets, stream windows, regular rational readback, Real handoff, transport, replay, provenance, and local naming; it does not invoke interval intersection, quotient real equality, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5959.1 (NestedIntervalCauchySeal carrier)**.** *A* $\mathsf{NestedIntervalCauchySeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *nested interval ledger, listing the retained interval cells, endpoint windows, and containment witnesses.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter-budget row, carrying the dyadic tolerance requested by the Cauchy read and the displayed diameter bound for each retained cell.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which interval endpoints, containment witnesses, and dyadic tolerances are inspected.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite windows and diameter budgets.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, D, S, R have been displayed.*
6. *H records componentwise* hsame *transport for located intervals, dyadic budgets, stream windows, regular readback, Real sealing, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a Real-facing nested-interval request through I, D, S, R, E, H.*
8. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalCauchySeal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalCauchySeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, R, E, H, C, P, N$. It has no coordinate for host interval intersection, quotient real equality, a selected limiting point, countable choice, detached completion data, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.NestedIntervalCauchySealUp.NestedIntervalCauchySealTasteGate single carrier alignment`

Theorem 5959.2 (NestedIntervalCauchySeal NameCert obligations)**.** *For every accepted* $\mathsf{NestedIntervalCauchySeal}$ *carrier $Z = (I, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalCauchySeal}^{\uparrow}}$ *surface is exhausted by the following five rows:*

1. *located nested-interval admission through I, including endpoint windows and containment witnesses from* $\mathsf{LocatedInterval}^{\uparrow}$*;*
2. *dyadic diameter-budget admission through D, read only as* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data;*
3. *finite observation admission through S and regular Cauchy readback through R, tying the* $\mathsf{StreamName}^{\uparrow}$ *windows to the* $\mathsf{RegSeqRat}^{\uparrow}$ *route;*
4. *terminal handoff through E, exposing a* $\mathsf{Real}^{\uparrow}$ *seal only after I, D, S, R have been displayed;*
5. *structural preservation through H, C, P, N, namely componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming.*

Consequently every Real or Completion consumer of the seal receives a regular Cauchy $\mathsf{Real}^{\uparrow}$ *handoff through finite nested dyadic interval data, and receives no interval-intersection theorem, quotient real equality, selected limit, countable choice, host equality, or ambient completeness principle.*

Proof. Project the carrier of Definition 5959.1. The nested source row is I, and its only precision ledger is the dyadic row D.

The observation route is finite. The $\mathsf{StreamName}^{\uparrow}$ row S selects the endpoint and containment windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R reads the same windows as a regular rational sequence surface.

The Real-facing route starts only after those rows have been exposed. The seal row E is therefore a handoff from finite nested dyadic interval data to the regular Cauchy surface, not a proof of host interval intersection or ambient completeness.

Finally H, C, P, N transport, replay, source, and name exactly the displayed packet. Since the carrier has no row for quotient equality, a selected limiting point, countable choice, detached completion data, or host equality, the five-row NameCert surface is exhausted by the rows listed above. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalCauchySeal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedIntervalCauchySeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5959.1 and Definition 5959.2 seed the finite route from located nested intervals through dyadic diameter budgets, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedIntervalCauchySeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim interval intersection, quotient Real construction, selected host limit, countable choice, detached completion data, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested located-interval containment, dyadic diameter budget exactness, StreamName and RegSeqRat readback, Real seal nonescape, and local naming for BEDC.Derived.NestedIntervalCauc

Constructive story: A $\mathsf{NestedIntervalCauchySeal}^{\uparrow}$ packet is generated from located nested interval rows, DyadicRatCore diameter budgets, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5960

A Concrete Naming Certificate for $\mathsf{Spectrahedron}^{\uparrow}$

Following Boyd–Vandenberghe convex optimization, the $\mathsf{Spectrahedron}^{\uparrow}$ packet records the finite BEDC surface by which an affine section of the semidefinite cone is presented as a convex feasible region. It sits after the matrix carrier of chapter 49, the linear-map row of chapter 48, the vector-space boundary of chapter 47, the semidefinite-cone packet of chapter 310, and the convex-set provenance of chapter 208. The chapter names the affine pencil route; it does not import host spectral calculus, determinant inequalities, quotient equality of matrices, selected feasible points, or ambient analytic closure.

Definition 5960.1 (Spectrahedron carrier)**.** *A* $\mathsf{Spectrahedron}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, L, A, S, K, V, T, C, P, N)$$

with the following displayed rows:

1. *X is the affine-parameter row over the displayed* $\mathsf{VecSpace}^{\uparrow}$ *source.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row carrying the affine pencil direction from parameter rows to symmetric* $\mathsf{Mat}^{\uparrow}$ *rows.*
3. *A is the affine offset matrix row read through* $\mathsf{Mat}^{\uparrow}$*.*
4. *S is the symmetric matrix-pencil row naming the displayed sum $A + L(x)$ for each accepted parameter row.*
5. *K is the* $\mathsf{SemidefiniteCone}^{\uparrow}$ *membership row for the displayed pencil matrix.*
6. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *provenance row that records the accepted parameter rows as a convex feasible subset.*
7. *T records componentwise* hsame *transport for parameter, linear-map, matrix, cone-membership, convex-provenance, replay, package, and local naming rows.*
8. *C records displayed* Cont *replay from parameter reads through the affine pencil, semidefinite-cone membership, and convex-set provenance rows.*
9. *P is the* Pkg *provenance over* $\mathsf{Spectrahedron}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{SemidefiniteCone}^{\uparrow}$*,* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{Spectrahedron}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, L, A, S, K, V, T, C, P, N$. It has no coordinate for eigenvalue decompositions, determinant tests, quotient equality of matrix pencils, selected feasible points, or ambient closed-convex analytic structure.

Theorem 5960.2 (Spectrahedron NameCert obligations)**.** *For every accepted* $\mathsf{Spectrahedron}^{\uparrow}$ *carrier*

$$Q = (X, L, A, S, K, V, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Spectrahedron}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed parameter row X, linear-map row L, offset matrix row A, matrix-pencil row S, semidefinite-cone membership row K, convex-set provenance row V, componentwise* hsame *transport through T, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5960.1. Its coordinates are the parameter, linear-map, offset, matrix-pencil, semidefinite-cone, convex-provenance, transport, replay, package, and local naming rows.

The affine-packet obligations are the rows X, L, A, S. They force every consumer to read the candidate point through a displayed $\mathsf{VecSpace}^{\uparrow}$ parameter row, the $\mathsf{LinMap}^{\uparrow}$ pencil direction, and the $\mathsf{Mat}^{\uparrow}$ offset-and-sum surface.

The feasibility and convexity obligations are the rows K and V. The semidefinite membership row is read through $\mathsf{SemidefiniteCone}^{\uparrow}$, while convex provenance is read through $\mathsf{ConvexSet}^{\uparrow}$ over the same parameter surface.

Finally T, C, P, N transport, replay, source, and name the route. Since no other coordinate is present, the listed rows exhaust the local NameCert surface. □

Theorem 5960.3 (Spectrahedron semidefinite-cone handoff)**.** *Every feasibility-facing consumer of an accepted* $\mathsf{Spectrahedron}^{\uparrow}$ *carrier must factor through the displayed affine pencil route*

$$X, L, A \longmapsto S \longmapsto K \longmapsto V, T, C, P, N.$$

Thus the consumer receives a parameter row, affine matrix-pencil row, semidefinite-cone membership row, convex-set provenance row, transport, replay, package provenance, and local NameCert rather than a host feasible set, spectral selector, determinant criterion, quotient matrix equality, selected feasible point, or ambient analytic closure theorem.

Proof. Begin with a feasibility-facing read of Definition 5960.1. The only route from a parameter row to matrix data is the displayed affine pencil formed by L and A and named by S.

Next read the cone-membership row K. Because K is a $\mathsf{SemidefiniteCone}^{\uparrow}$ row over the displayed matrix pencil, the feasibility read cannot bypass the sibling semidefinite-cone carrier or replace it with a host positivity predicate.

The convex provenance row V then records the accepted parameter surface as a $\mathsf{ConvexSet}^{\uparrow}$ consumer. The route remains tied to the same $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, and $\mathsf{SemidefiniteCone}^{\uparrow}$ rows.

Finally T, C, P, N preserve and name the same finite route under transport and replay. No excluded analytic or host object is stored in the carrier, so every consumer factors through the displayed handoff. □

Theorem 5960.4 (Spectrahedron semidefinite-cone route)**.** *For every accepted* $\mathsf{Spectrahedron}^{\uparrow}$ *carrier*

$$Q = (X, L, A, S, K, V, T, C, P, N),$$

each accepted affine-pencil read must display the $\mathsf{Mat}^{\uparrow}$ *rows* A, S*, the* $\mathsf{LinMap}^{\uparrow}$ *row* L*, the* $\mathsf{VecSpace}^{\uparrow}$ *parameter row* X*, the* $\mathsf{SemidefiniteCone}^{\uparrow}$ *membership row* K*, and the* $\mathsf{ConvexSet}^{\uparrow}$ *provenance row* V *before the local* $\mathsf{NameCert}_{\mathsf{Spectrahedron}^{\uparrow}}$ *row* N *is public. The route exports no host spectral calculus, determinant inequality, quotient matrix equality, selected feasible point, or analytic closure principle.*

Proof. Project the carrier of Definition 5960.1. The affine-pencil read begins at the $\mathsf{VecSpace}^{\uparrow}$ parameter row X, passes through the $\mathsf{LinMap}^{\uparrow}$ row L, reads the $\mathsf{Mat}^{\uparrow}$ offset row A, and names the displayed pencil matrix as S.

Apply the NameCert obligations of Definition 5960.2. They require the semidefinite-cone membership row K and the convex-set provenance row V as local obligations of the same packet, not as external analytic facts.

The semidefinite-cone handoff theorem Definition 5960.3 then forces every feasibility-facing consumer through K and V before the transport, replay, provenance, and naming rows T, C, P, N are read.

Because the carrier contains no coordinate for spectral decomposition, determinant feasibility, quotient equality of matrix pencils, selected feasible points, or analytic closedness, the public route cannot export any of those host objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{Spectrahedron}^{\uparrow}}$.

Constructive story: A $\mathsf{Spectrahedron}^{\uparrow}$ packet is generated from an affine parameter row, LinearMap pencil row, Matrix offset row, matrix-pencil row, SemidefiniteCone membership row, ConvexSet provenance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Spectrahedron}^{\uparrow}}$, seed)

Scope closed: Definition 5960.1, Definition 5960.2, and Definition 5960.3 seed the affine semidefinite-feasibility route through parameter, pencil, cone, convex, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Spectrahedron}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, spectral decomposition, determinant feasibility criteria, quotient equality of matrix pencils, selected feasible points, or ambient analytic closedness of semidefinite sections.

Upgrade path: Obligation closure requires checked carrier admission, affine-parameter visibility, linear-map pencil exactness, matrix offset and pencil replay, semidefinite-cone membership, convex-set provenance, transport stability, replay stability, and local naming for BEDC.Derived.SpectrahedronUp.

The $\mathsf{Spectrahedron}^{\uparrow}$ dossier lattice depends on the concrete sibling route through chapter 310 and chapter 208. A spectrahedron reads a finite affine slice of the semidefinite cone, so its carrier consumes the cone classifier and the convex-set intersection rows before the local NameCert is public. Every $\mathsf{Spectrahedron}^{\uparrow}$ carrier reads its affine-linear matrix inequality through the displayed $\mathsf{SemidefiniteCone}^{\uparrow}$ membership boundary of chapter 310 and the $\mathsf{ConvexSet}^{\uparrow}$ provenance boundary of chapter 208 before exposing the local NameCert. Thus the affine pencil remains a finite forward route from parameter rows to cone membership and convex feasible-surface rows, not a host-level closed semialgebraic set.

Theorem 5960.5 (Spectrahedron sibling dependency route)**.** *Every accepted* $\mathsf{Spectrahedron}^{\uparrow}$ *carrier reads the matrix carrier of chapter 49 as offset rows, the affine pencil rows of chapter 48, vector-space parameter rows from chapter 47, semidefinite cone membership rows from chapter 310, and convex-set provenance rows from chapter 208 before exposing the local spectrahedron* NameCert.

Proof. Project the accepted carrier. Its affine-semidefinite feasibility surface contains a matrix offset row, a linear pencil row, parameter-coordinate rows, positive semidefinite membership, convex provenance, and the local naming row.

The sibling references above exhaust those coordinates. Thus the spectrahedron packet reads the sibling rows as finite provenance before the local NameCert is admitted, rather than importing a host feasible set. □

Chapter 5961

A Concrete Naming Certificate for $\mathsf{NestedRadicalConvergence}^{\uparrow}$

Following Herschfeld and Bishop–Bridges constructive analysis, the $\mathsf{NestedRadicalConvergence}^{\uparrow}$ packet records bounded nested-radical convergence as finite NameCert data. It sits over the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a displayed route from radical coefficients and finite tail bounds to a regular Cauchy handoff without invoking ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient streams, selected limits, or host square-root convergence.

Definition 5961.1 (Nested radical convergence carrier)**.** *A* $\mathsf{NestedRadicalConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, S, D, W, T, Q, H, C, P, N)$$

with the following displayed rows:

1. *A is the radical-coefficient row, listing the finite prefix of nonnegative dyadic or rational coefficients requested by the consumer.*
2. *S is the finite stage row, recording the stagewise radical approximants built by the displayed arithmetic route.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, including the comparison and refinement budgets used to measure adjacent stages.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing only finite windows of the approximation stream.*
5. *T is the tail-control row, recording the Herschfeld-style boundedness and finite tail estimates visible at the requested precision.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, presenting the finite windows and dyadic tolerances as a regular rational sequence.*
7. *H records componentwise* hsame *transport for A, S, D, W, T, Q.*
8. *C records displayed* Cont *replay from coefficient rows through stage construction, tolerance checking, finite windows, tail control, and regular readback.*
9. *P is the* Pkg *provenance over* $\mathsf{NestedRadicalConvergence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedRadicalConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for a host infinite radical, quotient equality of streams, selected limiting representative, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Theorem 5961.2 (Nested radical convergence NameCert obligations)**.** *For every accepted* NestedRadicalConvergenc *carrier*

$$R = (A, S, D, W, T, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NestedRadicalConvergence}^{\uparrow}}$ *surface consists exactly of finite rows for coefficient admission, stage construction, dyadic tolerance checking, StreamName window exposure, tail-control exposure, RegSeqRat readback, componentwise transport, displayed replay, provenance, and local naming. No obligation row may replace T by an unbounded convergence theorem, bypass D and W, or export a completed real without the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Lean4 ✓ `BEDC.Derived.NestedRadicalConvergenceUp.NestedRadicalConvergenceTasteGate single carrier alignment`

Proof. Project the carrier of Definition 5961.1. The coefficient row A and finite stage row S are the only source of radical approximants.

The tolerance and window rows are explicit. The dyadic ledger D supplies the requested comparison budget, while W restricts every read to a finite StreamName window.

The tail row T is the convergence-facing datum. It records the bounded nested-radical estimates used at the requested precision, but it is not a global host theorem about infinite radicals.

Finally Q, H, C, P, N read the finite data as a regular rational sequence, transport the same rows, replay the construction, record provenance, and name the packet. Since every public read factors through those rows, the NameCert surface cannot import quotient streams, selected limits, or ambient completeness. □

Theorem 5961.3 (Nested radical convergence RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{NestedRadicalConvergence}^{\uparrow}$ *carrier must read the finite route*

$$A, S, D, W, T \longmapsto Q \longmapsto H, C, P, N$$

before any $\mathsf{Real}^{\uparrow}$ *seal may be consumed. The handoff exposes radical coefficients, finite stage approximants, dyadic tolerances, StreamName windows, and tail-control rows as a regular rational sequence; it does not assert Real completeness, quotient equality of approximation streams, selected limits, countable choice, trichotomy, or host square-root convergence.*

Proof. Begin with the NameCert obligations of Definition 5961.2. They place coefficient admission, stage construction, dyadic tolerance checking, finite windows, and tail control before the readback row.

The $\mathsf{RegSeqRat}^{\uparrow}$ row Q is therefore downstream of A, S, D, W, T. It can read only the displayed finite approximants and the dyadic tolerance ledger, so it cannot replace the carrier by a quotient stream or by a selected limiting representative.

Transport, replay, provenance, and local naming occur after the handoff. The terminal $\mathsf{Real}^{\uparrow}$ seal can be cited only as a consumer of the regular rational route, not as an ambient completeness principle that creates the route. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedRadicalConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedRadicalConvergence}^{\uparrow}$ packet is generated from radical coefficient rows, finite stage approximants, dyadic tolerance rows, StreamName windows, tail-control estimates, RegSeqRat readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedRadicalConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5961.1, Definition 5961.2, and Definition 5961.3 seed the finite nested-radical route into regular rational readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedRadicalConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient Real completeness, quotient stream equality, selected limits, countable choice, trichotomy, host square-root convergence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stage construction, dyadic tolerance exactness, StreamName window exposure, tail-control replay, RegSeqRat handoff, Real-seal nonescape, transport, provenance, and local naming for BEDC.Derived.NestedRadicalConvergenceUp.

Chapter 5962

A Concrete Naming Certificate for $\mathsf{BoundedNormalizationFuel}^{\uparrow}$

The $\mathsf{BoundedNormalizationFuel}^{\uparrow}$ packet realizes the bounded normalisation endpoint boundary of chapter 9379 as finite checker data. It sits beside the decidability boundary of chapter 749, the budgeted checker route of chapter 5949, the fuel-trace frontier of chapter 5936, and the closed normal-confluence seal consumed when finished endpoints are visible. The packet records fuel-sensitive conversion endpoints without turning bounded computation into unrestricted beta-conversion decidability.

Definition 5962.1 (Bounded normalization fuel carrier)**.** *A* $\mathsf{BoundedNormalizationFuel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (\Gamma, t, u, k, B, E, Z, R, H, C, P, N)$$

with the following displayed rows:

1. Γ *is the represented MetaCIC context row for the checker request.*
2. t, u *are the two closed or context-indexed term rows whose bounded normal forms are compared.*
3. k *is the visible natural fuel row, including the decrement ledger consumed by the normalizer.*
4. B *is the bounded normalizer row, exposing the two computed endpoint terms at fuel* k*.*
5. E *is the equality-check row, comparing the two bounded endpoints by structural same-term checking.*
6. Z *is the finished-normal row, present exactly when both bounded endpoints carry finished-normalisation evidence at the displayed fuel.*
7. R *is the refusal row, recording timeout, missing finished evidence, missing closedness evidence, or attempted fuel erasure.*
8. H *records componentwise* hsame *transport for* $\Gamma, t, u, k, B, E, Z, R$*.*
9. C *records displayed* Cont *replay from the checker request through fuel, bounded endpoints, equality, finished-normal evidence, refusal, and structural rows.*
10. P *is the* Pkg *provenance over* $\mathsf{BoundedNormalizationFuel}^{\uparrow}$*,* $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$*,* $\mathsf{BoundedTypecheckingBu}$ $\mathsf{MetaCICNormalizationFuelBoundary}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
11. N *is the local* $\mathsf{NameCert}_{\mathsf{BoundedNormalizationFuel}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for unrestricted beta-conversion decidability, fuel-erased normalization, proof-irrelevant term equality, quotient syntax equality, host conversion, or closed consistency.

Theorem 5962.2 (Bounded normalization fuel NameCert obligations)**.** *For every accepted* BoundedNormalizationF *carrier*

$$F = (\Gamma, t, u, k, B, E, Z, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedNormalizationFuel}^{\uparrow}}$ *surface consists exactly of finite rows for checker-context admission, term-row admission, fuel-ledger exposure, bounded endpoint computation, structural endpoint comparison, finished-normal evidence when present, refusal visibility, componentwise transport, displayed replay, provenance, and local naming. No obligation row may delete* k*, infer* Z *from* B *alone, hide* R*, or export unrestricted closed beta-conversion.*

Proof. Project the carrier of Definition 5962.1. The checker context, term rows, and fuel row are public before any endpoint comparison is read.

The bounded endpoint row B is fuel-sensitive. It records what the normalizer produced at the displayed fuel k, while the equality row E compares only those bounded outputs.

The finished-normal row Z is separate. When it is present, it justifies the stronger endpoint reading named by the decidability audit map; when it is absent, the refusal row R remains part of the same public packet.

Finally H, C, P, N preserve, replay, source, and name the finite route. Since none of those rows contains an unrestricted normalizer or host conversion oracle, the listed obligations exhaust the local certificate surface. □

Theorem 5962.3 (Bounded normalization fuel finished boundary)**.** *Every public conversion-facing read of an accepted* $\mathsf{BoundedNormalizationFuel}^{\uparrow}$ *carrier factors through*

$$\Gamma, t, u, k, B, E, Z, R \longmapsto H, C, P, N.$$

If Z *is displayed, the consumer may use the finished-normal endpoint handoff attached to the bounded equality row* E*. If* Z *is absent, the refusal row* R *blocks any export of unrestricted beta-conversion decidability, fuel-erased normalization, proof-irrelevant equality, quotient syntax equality, host conversion, or closed consistency.*

Proof. Start with the NameCert obligations in Definition 5962.2. They order the public route through context, terms, visible fuel, bounded endpoint computation, structural comparison, finished evidence, and refusal.

When Z is present, the endpoint evidence is still tied to the displayed fuel k and the bounded endpoint row B. Thus the consumer receives a finished-boundary handoff, not a global conversion oracle.

When Z is absent, R is mandatory. It records the timeout or missing endpoint evidence and prevents E from being read as unrestricted beta-conversion decidability.

Transport, replay, provenance, and local naming preserve the same distinction. The packet therefore has exactly the finite endpoint boundary stated above. □

Theorem 5962.4 (Bounded normalization fuel monotone readback)**.** *If an accepted* $\mathsf{BoundedNormalizationFuel}^{\uparrow}$ *packet is reread at a larger displayed fuel, the public conversion-facing route must still expose the original context row, term rows, visible fuel row, bounded endpoint row, structural equality row, finished-normal row when present, and refusal row when absent. Increasing fuel may refine the bounded endpoint row, but it cannot delete fuel, infer finished evidence from bounded endpoints alone, hide refusal, or export unrestricted beta-conversion decidability.*

Proof. Project the carrier of Definition 5962.1. The reread keeps the same Γ, t, u request surface and replaces only the displayed fuel request by a larger visible fuel row.

Apply Definition 5962.2. The endpoint row may be recomputed at the larger fuel, but the public route still has to display fuel, bounded endpoints, structural equality, finished-normal evidence when present, refusal when absent, and the structural rows.

Now use Definition 5962.3. A refined endpoint row does not by itself create finished-normal evidence; the finished case remains tied to Z, and the nonfinished case remains tied to R.

Thus monotone fuel readback is still a bounded computation route. It can refine what the bounded endpoint row says at the larger fuel, but it cannot become an unrestricted conversion oracle. □

Falsifiable prediction: A $\mathsf{BoundedNormalizationFuel}^{\uparrow}$ consumer that exports unrestricted closed beta-conversion decidability after deleting the fuel row k, the finished-normal row Z, or the refusal row R refutes the carrier of Definition 5962.1.

Independence witness: Nearest siblings: metacicdecidableboundary, bounded-typechecking-budget, metacic-normalization-fuel-boundary, and closed-normal-confluence-seal. $\mathsf{BoundedNormalizationFuel}^{\uparrow}$ is not bijective to any of them because it jointly carries checker context, two term rows, visible fuel, bounded endpoint computation, structural endpoint equality, finished-normal evidence, refusal, transport, replay, provenance, and local naming as one carrier.

The Lean TasteGate follow-up for this packet requires explicit $\mathsf{Nontrivial\ BoundedNormalizationFuel}^{\uparrow}$ and $\mathsf{FieldFaithful\ BoundedNormalizationFuel}^{\uparrow}$ instances in the corresponding TasteGate file. Nontriviality must separate accepted finished endpoint packets from timeout or missing-evidence packets, and field faithfulness must preserve $\Gamma, t, u, k, B, E, Z, R, H, C, P, N$ without erasing fuel or refusal rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedNormalizationFuel}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedNormalizationFuel}^{\uparrow}$ packet is generated from checker-context rows, term rows, visible fuel, bounded endpoint computation, structural endpoint comparison, finished-normal evidence, refusal rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedNormalizationFuel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5962.1, Definition 5962.2, and Definition 5962.3 seed the finite endpoint boundary for bounded normal conversion reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedNormalizationFuel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unrestricted beta-conversion decidability, fuel-erased normalization, proof-irrelevant equality, quotient syntax equality, host conversion, closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fuel-ledger exactness, bounded endpoint computation, structural endpoint comparison, finished-normal boundary, refusal nonescape, TasteGate nontriviality, field faithfulness, and local naming for BEDC.Derived.BoundedNormalizationFuelUp.

Chapter 5963

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedField}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyLocatedField}^{\uparrow}$ packet records the L10 algebra surface available from regular Cauchy real names when every reciprocal and division read is guarded by displayed apartness. It sits over the regular rational source surface of chapter 301, finite stream windows from chapter 126, dyadic endpoint arithmetic from chapter 291, the sum route of chapter 417, the product route of chapter 461, the reciprocal route of chapter 1471, the division route of chapter 1943, the apartness and order boundary of chapter 1710, and the terminal seal of chapter 38. The chapter names a constructive field-operation packet for real-name algebra; it does not identify quotient real equality, trichotomy, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5963.1 (Regular Cauchy located field carrier)**.** *A* $\mathsf{RegularCauchyLocatedField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, W, D, A, M, I, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S lists the* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows for the regular Cauchy names consumed by the algebra packet.*
2. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows opened for every source read and every operation readback.*
3. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows used for rational endpoint arithmetic, tolerance comparison, and finite lower-bound inspection.*
4. *A is the apartness guard row from the* $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ *boundary; it is required before any reciprocal or quotient route can be read.*
5. *M is the additive and multiplicative operation inventory, consisting of* $\mathsf{RegularCauchySum}^{\uparrow}$*,* $\mathsf{RegularCauchyProduct}^{\uparrow}$*, and scalar endpoint rows visible at the same window level.*
6. *I is the guarded reciprocal route from* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$*, read only after A has displayed a positive nonzero-domain witness.*
7. *Q is the guarded division route from* $\mathsf{RegularCauchyDivision}^{\uparrow}$*, factoring quotient reads through the same apartness guard, reciprocal route, product route, and regular readback surface.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal receiving only the displayed regular Cauchy readbacks and their visible operation provenance.*

9. *H records componentwise* hsame *transport for $S, W, D, A, M, I, Q, E, C, P, N$.*
10. *C records displayed* Cont *replay for source inspection, window inspection, dyadic endpoint arithmetic, apartness exposure, sum and product exposure, reciprocal and division handoff, readback, and seal handoff.*
11. *P records* Pkg *provenance over* $\mathsf{RegularCauchyLocatedField}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{RegularCauchyReciprocal}^{\uparrow}$, $\mathsf{RegularCauchyDivision}^{\uparrow}$, $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedField}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the displayed rows $S, W, D, A, M, I, Q, E, H, C, P, N$.

Theorem 5963.2 (Regular Cauchy located field NameCert obligations)**.** *The seed* $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedField}^{\uparrow}}$ *surface for Definition 5963.1 consists exactly of carrier admission, operation exposure, reciprocal and division reads guarded by apartness, regular readback, terminal Real seal nonescape, componentwise transport, displayed continuation replay, package provenance, and the local naming row.*

Proof. Carrier admission is projection from the displayed tuple $F = (S, W, D, A, M, I, Q, E, H, C, P, N)$. The source rows, stream windows, dyadic endpoint arithmetic, apartness guard, operation inventory, reciprocal route, division route, seal, transports, continuations, provenance, and local name are all explicit coordinates.

Operation exposure is finite. Sum and product reads are carried by M, while reciprocal reads are carried by I and quotient reads are carried by Q. The reciprocal and division rows are downstream of A, so no inverse or quotient consumer can bypass the positive apartness guard.

Readback and seal nonescape are terminal. The route reaches $\mathsf{RegSeqRat}^{\uparrow}$ readbacks through the operation rows and then reaches E as a $\mathsf{Real}^{\uparrow}$ seal; the carrier has no coordinate for quotient real equality, trichotomy, selected representatives, countable choice, or ambient completeness.

Transport, replay, and provenance are exactly H, C, P, N. They move and re-expose the same rows componentwise, so the local NameCert surface is exhausted by the displayed packet. □

Theorem 5963.3 (Regular Cauchy located field guarded division scope)**.** *Every reciprocal or quotient read from an accepted* $\mathsf{RegularCauchyLocatedField}^{\uparrow}$ *packet factors through*

$$S, W, D \longmapsto A \longmapsto I, Q \longmapsto E, H, C, P, N.$$

The field-operation packet therefore exposes guarded real-name algebra only through finite regular Cauchy source data, dyadic endpoint arithmetic, apartness evidence, reciprocal and division handoffs, and the terminal $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Project the packet. The rows S, W, D supply the visible regular source data, stream windows, and endpoint arithmetic used by every operation read.

The guard row A is the only coordinate that licenses reciprocal or division access. Hence I and Q can be read only after the apartness boundary has been displayed.

The terminal rows E, H, C, P, N seal and replay that finite route. Since no additional coordinate is present, the carrier cannot export total inversion, trichotomy, quotient equality, selected representatives, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedField}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLocatedField}^{\uparrow}$ packet is generated from RegSeqRat source rows, StreamName windows, DyadicRatCore endpoint arithmetic, RegularCauchySum and RegularCauchyProduct operation rows, apartness-guarded RegularCauchyReciprocal and RegularCauchyDivision rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RegularCauchyLocatedField}^{\uparrow}}$, seed)

Scope closed: Definition 5963.1, Definition 5963.2, and Definition 5963.3 seed the constructive located-field operation boundary over regular Cauchy real names.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchyLocatedField}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, trichotomy, selected representatives, countable choice, total inversion, ambient Real$^{\uparrow}$ completeness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, operation exposure, apartness-guarded reciprocal and division handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyLocatedFieldUp

Chapter 5964

A Concrete Naming Certificate for CompactLipschitzUniformHandoff$^{\uparrow}$

Following Bishop–Bridges style compact metric uniform-continuity, the CompactLipschitzUniformHandoff$^{\uparrow}$ packet records the finite route by which compact finite-net data and a Lipschitz graph row supply a tolerance-only UniformModulus$^{\uparrow}$ consumer. It is grounded in the compact-uniform-continuity vision of chapter 9237; it reads compact metric nets from chapter 129, continuous graph rows from chapter 130, dyadic tolerance rows from chapter 291, rational lower-bound comparison from chapter 37, the uniform-modulus handoff of chapter 369, and the terminal real-name seal of chapter 38. The chapter packages the finite-net, Lipschitz graph, tolerance-fold, and uniform-modulus route without importing choice, open-cover compactness, quotient function equality, or ambient Real$^{\uparrow}$ completeness.

Definition 5964.1 (Compact Lipschitz uniform handoff carrier)**.** *A* CompactLipschitzUniformHandoff$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, G, T, R, U, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *finite-net row, exposing a finite* ProbeBundle *of compact source centers at the requested tolerance scale.*
2. *G is the* ContinuousMap$^{\uparrow}$ *graph row together with its Lipschitz ledger: one rational bound, source and target metric rows, and the graph-distance implication consumed by the uniform estimate.*
3. *T is the* DyadicRatCore$^{\uparrow}$ *tolerance row, carrying endpoint windows for the requested target tolerance and the derived source radius.*
4. *R is the* Rat$^{\uparrow}$ *lower-bound fold over the finite list of compact-net radii and Lipschitz-derived source radii.*
5. *U is the* UniformModulus$^{\uparrow}$ *handoff row exported to downstream compact-continuous consumers.*
6. *E is the terminal* Real$^{\uparrow}$ *seal, reached only after the compact net, graph, tolerance, rational fold, and uniform-modulus rows have been displayed.*
7. *H records componentwise* hsame *transport for $K, G, T, R, U, E, C, P, N$.*
8. *C records displayed* Cont *replay for compact finite-net inspection, graph and Lipschitz inspection, dyadic tolerance comparison, rational lower-bound folding, uniform-modulus handoff, and seal handoff.*

9. *P records* Pkg *provenance over* CompactLipschitzUniformHandoff$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Rat$^{\uparrow}$, UniformModulus$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{CompactLipschitzUniformHandoff}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the rows $K, G, T, R, U, E, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.CompactLipschitzUniformHandoffUp.CompactLipschitzUniformHandoffTasteGate`
`single carrier alignment`

Theorem 5964.2 (Compact Lipschitz uniform handoff NameCert obligations)**.** *The seed* NameCert$_{\text{CompactLipschitzUn}}$ *surface for Definition 5964.1 consists exactly of carrier admission, compact finite-net exposure, continuous graph and Lipschitz ledger exposure, dyadic tolerance inspection, rational lower-bound folding,* UniformModulus$^{\uparrow}$ *handoff, terminal Real seal nonescape, componentwise transport, displayed continuation replay, package provenance, and the local naming row.*

Proof. Carrier admission is projection from $L = (K, G, T, R, U, E, H, C, P, N)$. The compact metric net, graph and Lipschitz row, dyadic tolerance row, rational fold, uniform-modulus handoff, seal, transports, continuations, provenance, and local name are explicit coordinates.

The analytic route is finite. The compact row K supplies only the listed ProbeBundle centers, the graph row G supplies the Lipschitz estimate at those source distances, and the tolerance row T supplies the dyadic scale consumed by the lower-bound fold R.

The uniform-modulus row U is downstream of K, G, T, R. It can therefore be replayed only after the finite-net and Lipschitz ledger have fixed the source precision. The seal E receives this handoff without adding open-cover compactness, selected moduli, quotient function equality, or ambient completeness.

Transport, replay, and provenance are exactly H, C, P, N. Componentwise hsame and displayed Cont rows re-expose the same finite route, so the NameCert obligations are exhausted by the carrier. □

Theorem 5964.3 (Compact Lipschitz uniform consumer route)**.** *Every* UniformModulus$^{\uparrow}$ *consumer of an accepted* CompactLipschitzUniformHandoff$^{\uparrow}$ *packet factors through*

$$K, G, T \longmapsto R \longmapsto U \longmapsto E, H, C, P, N.$$

Thus the exported modulus is a finite compact-net and Lipschitz-ledger handoff, not a choice functional, not an open-cover argument, and not a quotient-function equality principle.

Proof. Read the compact source row K and graph row G first. These rows expose the finite centers, source and target metric data, and Lipschitz bound needed by the consumer route.

Use the dyadic tolerance row T to form the rational comparison scale. The finite lower-bound fold R is computed over the displayed compact-net and Lipschitz-derived radii, so it is a Rat$^{\uparrow}$ ledger rather than an external selector.

The uniform-modulus row U is then the only exported consumer row. The remaining rows E, H, C, P, N seal, transport, replay, source, and name this same finite route, leaving no coordinate for open-cover compactness, countable choice, selected moduli, quotient function equality, or ambient Real$^{\uparrow}$ completeness. □

Closure status for NameCert$_{\text{CompactLipschitzUniformHandoff}^{\uparrow}}$**.**

Constructive story: A CompactLipschitzUniformHandoff$^{\uparrow}$ packet is generated from CompactMetric finite-net rows, a ContinuousMap graph with Lipschitz ledger, DyadicRatCore tolerance rows, a RatUp lower-bound fold, a UniformModulus handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CompactLipschitzUniformHandoff}^{\uparrow}}$, seed)

Scope closed: Definition 5964.1, Definition 5964.2, and Definition 5964.3 seed the finite compact-net and Lipschitz-ledger route into a UniformModulus consumer.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactLipschitzUniformHandoff}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected moduli, countable choice, quotient function equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exposure, Lipschitz graph exposure, tolerance folding, UniformModulus handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactLipschitzUniformHandoffUp.

RegularSequenceSpace$^{\uparrow}$ routes completion-facing sequence reads through chapter 301, chapter 126, chapter 291, and chapter 6003 before the local hub inputs expose the sequence-space certificate.

Chapter 5965

A Concrete Naming Certificate for $\mathsf{RegularSequenceSpace}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy sequences, the $\mathsf{RegularSequenceSpace}^{\uparrow}$ packet records the finite carrier for a displayed space of regular sequence names rather than a single regular sequence certificate. It sits between the stream schedules of chapter 126, the rational regular readbacks of chapter 301, the dyadic rational core of chapter 291, and the value-facing real seal of chapter 38. The same packet also consumes the explicit schedule-family surface of chapter 5887 and the rate ledger of chapter 8037 before tail-filter or completion-facing consumers read the terminal Real seal.

Definition 5965.1 (RegularSequenceSpace carrier)**.** *A* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, T, Q, D, R, H, C, P, N)$$

with the following rows:

1. *X is the displayed index-source row naming the finite family of regular sequence names currently admitted to the space packet.*
2. *T is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row for the inspected tails and precision windows.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational Cauchy names at those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row recording the dyadic tolerance core used by the regularity checks.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *value-facing seal row reached only after X, T, Q, D have stayed visible.*
6. *H records componentwise* hsame *transport for the source, schedule, readback, dyadic scale, value seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a space-level sequence request through the stream schedule, regular rational readback, dyadic tolerance core, and real-facing seal.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularSequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient complete metric space, quotient equality of real names, arbitrary choice of representatives, unrestricted sequence space, or host set of all Cauchy sequences.

Theorem 5965.2 (RegularSequenceSpace NameCert obligations)**.** *For every accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier* $S = (X, T, Q, D, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceSpace}^{\uparrow}}$ *surface consists exactly of space-level carrier admission through* X*, schedule exposure through* T*, regular rational readback through* Q*, dyadic tolerance exposure through* D*, real-facing value seal through* R*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. A consumer therefore reads a regular sequence space only through the finite route*

$$X, T, Q, D \longmapsto R, H, C, P, N.$$

Proof. Project the accepted carrier of Definition 5965.1. The source row X opens the space-level family, while the schedule row T and regular rational readback row Q expose only displayed sequence windows.

The dyadic tolerance core D supplies the regularity scale before the real-facing seal R is consumed. Thus the packet reaches $\mathsf{Real}^{\uparrow}$ only after the stream, rational readback, and dyadic core rows have remained visible.

Finally replay the structural rows. Componentwise transport H, continuation replay C, provenance P, and local naming N preserve the same finite carrier, so no ambient complete space, unrestricted sequence space, quotient of real names, or arbitrary representative choice enters the NameCert surface. □

Lean4 ✓ `BEDC.Derived.RegularSequenceSpaceUp.RegularSequenceSpaceNameCertObligations`

Theorem 5965.3 (RegularSequenceSpace tail-filter handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier* $S = (X, T, Q, D, R, H, C, P, N)$ *factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule* T*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and the regular Cauchy tail-filter route of chapter 1605 before the* $\mathsf{Real}^{\uparrow}$ *seal* R *can be consumed. The accepted space packet therefore exports only the finite regular-name route*

$$X, T, Q, D \longmapsto \mathsf{RegularCauchyTailFilter}^{\uparrow} \longmapsto R, H, C, P, N$$

and no quotient stream, selected limit, countable-choice selector, unrestricted sequence space, or ambient completeness witness.

Proof. Project the carrier of Definition 5965.1. The source row X names the admitted family, while T, Q, D display the stream schedule, rational readback, and dyadic tolerance rows available to a completion-facing consumer.

The schedule row T and dyadic row D are read as the $\mathsf{CauchyModulusSpace}^{\uparrow}$ and $\mathsf{CauchyRateSpace}^{\uparrow}$ budget interface, not as a selected modulus or an ambient complete-space datum.

Apply the NameCert obligations of Definition 5965.2. They require the real-facing seal R to be reached only after X, T, Q, D remain visible in the same packet.

Now route late observations through chapter 1605. Its regular Cauchy tail-filter surface consumes the same stream, readback, and dyadic tolerance data before a Real-facing tail read is available.

Finally H, C, P, N preserve that finite route by transport, replay, provenance, and local naming. Since the carrier has no coordinate for quotient streams, selected limits, countable choice, an unrestricted sequence space, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no completion-facing consumer can escape the displayed tail-filter handoff. □

Theorem 5965.4 (RegularSequenceSpace tail coherence)**.** *Let* $S = (X, T, Q, D, R, H, C, P, N)$ *be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Any two completion-facing reads from* S *that agree on*

the displayed $\mathsf{StreamName}^{\uparrow}$ *schedule* T *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q *also agree on the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D *and on the terminal* $\mathsf{Real}^{\uparrow}$ *seal route* R, H, C, P, N*. This agreement is internal to the displayed carrier and does not use quotient streams, selected representatives, or an ambient complete sequence space.*

Proof. Project the carrier of Definition 5965.1. The tuple $S = (X, T, Q, D, R, H, C, P, N)$ keeps the source family, schedule, regular readback, and dyadic tolerance row visible as separate coordinates.

Use the NameCert obligations of Definition 5965.2. They require any completion-facing read to expose X, T, Q, D before the real-facing seal and structural rows can be consumed.

Route the late observations through the tail-filter handoff of Definition 5965.3. Two reads with the same displayed schedule T and readback Q therefore enter the same regular Cauchy tail-filter surface, where the dyadic tolerance row D is the displayed tolerance coordinate for that route.

Finally H, C, P, N preserve and name the same finite packet. Hence the two reads agree on the dyadic tolerance row and terminal Real seal route without choosing a quotient stream, representative, or external completion object. □

Theorem 5965.5 (RegularSequenceSpace value-seal exhaustion)**.** *Every value-facing read from an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier* $S = (X, T, Q, D, R, H, C, P, N)$ *exposes the source family* X*,* $\mathsf{StreamName}^{\uparrow}$ *schedule* T*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D *before it may consume* R, H, C, P, N*. Consequently the terminal* $\mathsf{Real}^{\uparrow}$ *seal is exhausted by the displayed StreamName, RegSeqRat, DyadicRatCore, transport, replay, provenance, and NameCert route, with no ambient complete sequence space, quotient stream equality, selected representative, or unrestricted sequence object.*

Proof. Use the NameCert obligations of Definition 5965.2. They require every accepted read to keep the source row, schedule row, regular rational readback, and dyadic tolerance row visible before the Real-facing seal and structural rows can be consumed.

Apply the tail-filter handoff of Definition 5965.3. It routes completion-facing and value-facing reads through the same displayed stream schedule, regular rational readback, and dyadic tolerance data before the terminal seal is public.

Finally use tail coherence, Definition 5965.4. Since reads agreeing on T and Q also agree on D and on the terminal seal route R, H, C, P, N, the Real seal is exhausted by the displayed finite route and cannot import an ambient complete space, quotient stream equality, selected representative, or unrestricted sequence object. □

Theorem 5965.6 (RegularSequenceSpace pointwise stream projection)**.** *Every accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *read of a displayed family first exposes the source row* X *and the* $\mathsf{StreamName}^{\uparrow}$ *schedule* T*. It can therefore be projected to a finite PointwiseStreamName-style window, as in chapter 6084, before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and* $\mathsf{Real}^{\uparrow}$ *seal route* R, H, C, P, N *are consumed.*

Proof. Project the carrier of Definition 5965.1. The source row X and stream schedule T are the first two displayed coordinates of every accepted space read.

Apply the NameCert obligations of Definition 5965.2. They require schedule exposure before regular rational readback, dyadic tolerance exposure, and Real-facing sealing.

Use the tail-filter handoff of Definition 5965.3. Since the completion-facing route must pass through the same displayed schedule before Q, D, R, H, C, P, N are available, the read has a finite window that may be routed through the pointwise stream sibling.

The projection therefore consumes only X and T at the pointwise boundary. The later RegSeqRat, DyadicRatCore, and Real rows remain downstream and cannot be inspected before that finite window is displayed. □

Theorem 5965.7 (RegularSequenceSpace finite-window comparison)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Any comparison between two displayed values of S must use the same* $\mathsf{StreamName}^{\uparrow}$ *finite window T,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, tail-filter ledger, dyadic tolerance row D, completion handoff, and transport, replay, provenance, and local naming rows H, C, P, N already exposed by the carrier. Thus a value comparison is a common-window comparison inside the displayed packet and cannot bypass the finite window or introduce quotient stream equality, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the pointwise stream projection of Definition 5965.6. It forces every displayed value read to expose the source row X and the finite stream window T before the readback, dyadic tolerance, and Real-facing seal are consumed.

Use tail coherence, Definition 5965.4. Once two reads share the displayed window and regular rational readback, they also share the dyadic tolerance row and the terminal seal route through R, H, C, P, N.

Finally apply value-seal exhaustion, Definition 5965.5. The terminal Real-facing comparison is exhausted by the displayed StreamName, RegSeqRat, DyadicRatCore, transport, replay, provenance, and NameCert rows, so no comparison can import quotient stream equality, selected limits, or ambient Real completeness. □

Theorem 5965.8 (RegularSequenceSpace obligation scope route)**.** *For every accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier $S = (X, T, Q, D, R, H, C, P, N)$, the carrier admission, tail-filter handoff, tail coherence, value-seal exhaustion, pointwise stream projection, and finite-window comparison obligations are all scoped by the finite rows*

$$\mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{NameCert},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Thus a Real-facing or completion-facing consumer reaches the regular sequence space only through displayed history, componentwise transport, continuation replay, local naming, stream windows, regular rational readback, and the terminal Real seal.

Proof. Project the carrier of Definition 5965.1 and its NameCert obligations in Definition 5965.2. The accepted packet exposes the displayed history row, the componentwise hsame row, the Cont replay row, the local $\mathsf{NameCert}$ row, the $\mathsf{StreamName}^{\uparrow}$ schedule, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal as named coordinates of the same finite carrier.

Apply the tail-filter handoff and tail coherence results, Definition 5965.3 and Definition 5965.4. They keep completion-facing reads inside the same StreamName, RegSeqRat, dyadic tolerance, and Real-seal route.

Finally use value-seal exhaustion, pointwise stream projection, and finite-window comparison, Definition 5965.5, Definition 5965.6, and Definition 5965.7. These rows exhaust the value-facing and comparison obligations, so the scoped route has no coordinate for quotient streams, selected limits, arbitrary representatives, or ambient completeness. □

Theorem 5965.9 (RegularSequenceSpace obligation public interface)**.** *For every accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier $S = (X, T, Q, D, R, H, C, P, N)$, the carrier admission, tail-filter handoff, tail coherence, value-seal exhaustion, pointwise stream projection, and obligation scope route form the public obligation interface for completion-facing consumers. Every such consumer must pass through the*

displayed $\mathsf{StreamName}^{\uparrow}$ *schedule* T, $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q, $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D, *and terminal* $\mathsf{Real}^{\uparrow}$ *seal route* R, H, C, P, N. *The interface has no quotient stream, selected limit, ambient completeness coordinate, unrestricted sequence-space row, or host representative choice.*

Proof. Start with carrier admission and the NameCert obligations of Definition 5965.1 and Definition 5965.2. They expose $X, T, Q, D, R, H, C, P, N$ as the finite public packet and place the stream, readback, dyadic, seal, transport, replay, provenance, and local naming rows in one route.

Use the tail-filter handoff and tail coherence rows, Definition 5965.3 and Definition 5965.4. These keep completion-facing reads downstream of the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ data before any Real-facing read is public.

Next apply value-seal exhaustion and pointwise stream projection, Definition 5965.5 and Definition 5965.6. The terminal seal and every pointwise projection remain attached to the displayed finite window rather than to a quotient stream or chosen representative.

Finally invoke the obligation scope route of Definition 5965.8. The six named obligations therefore form exactly the public interface seen by completion-facing consumers through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with no ambient completeness or unrestricted sequence-space coordinate. □

Theorem 5965.10 (RegularSequenceSpace RegSeqRat Real seal route)**.** *Every endpoint read from an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier factors first through the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row* Q *and then through the* $\mathsf{Real}^{\uparrow}$ *seal row* R, *with the stream schedule* T, *dyadic tolerance row* D, *transport* H, *replay* C, *provenance* P, *and local naming* N *still visible. No endpoint read uses a quotient stream, an ambient complete sequence space, or an unrecorded completeness principle.*

Proof. Use the NameCert obligations of Definition 5965.2. They place the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q before the terminal $\mathsf{Real}^{\uparrow}$ seal R in every accepted value-facing route.

Apply value-seal exhaustion, Definition 5965.5. It states that the Real-facing seal is consumed only after the source, stream schedule, regular rational readback, and dyadic tolerance rows have stayed visible.

Now invoke the obligation scope route of Definition 5965.8. The remaining structural rows H, C, P, N preserve the same finite packet, so endpoint reads cannot pass through quotient streams, ambient completeness, or an unrecorded completion principle before the RegSeqRat classifier and Real seal route is displayed. □

Definition 5965.11 (RegularSequenceSpace Cauchy window)**.** *For an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier*

$$S = (X, T, Q, D, R, H, C, P, N),$$

the Cauchy-window row is the displayed subpacket

$$\mathrm{Win}_{\mathsf{RegularSequenceSpace}^{\uparrow}}(S) = (T, Q, D, R, H, C, P, N).$$

It records the $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, continuation replay, provenance, and local naming rows while omitting only the source family row* X.

Theorem 5965.12 (RegularSequenceSpace Cauchy-window NameCert route)**.** *Let* $S = (X, T, Q, D, R, H, C, P, N)$ *be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Every completion-facing read of* S *factors through the Cauchy-window subpacket* $\mathrm{Win}_{\mathsf{RegularSequenceSpace}^{\uparrow}}(S) = (T, Q, D, R, H, C, P, N)$ *before the* $\mathsf{Real}^{\uparrow}$ *seal is public. The route joins the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$

tolerance row, and terminal $\mathsf{Real}^{\uparrow}$ *seal in one finite NameCert obligation and exports no quotient stream, selected representative, ambient completeness principle, or host real equality.*

Proof. Start with the NameCert obligations of Definition 5965.2. They expose $X, T, Q, D, R, H, C, P, N$ as the finite accepted carrier and place the schedule, readback, tolerance row, and Real seal in the same local certificate surface.

Apply the tail-filter handoff of Definition 5965.3. It routes completion-facing reads through the displayed schedule T, regular rational readback Q, and dyadic tolerance row D before the Real-facing row can be consumed.

Use tail coherence, Definition 5965.4. Once the completion read has entered the displayed window, the later rows R, H, C, P, N remain attached to the same finite route rather than becoming external representatives.

Finally apply the RegSeqRat Real seal route of Definition 5965.10. The terminal $\mathsf{Real}^{\uparrow}$ seal is public only after the $\mathsf{RegSeqRat}^{\uparrow}$ readback and the visible structural rows have been read, so the Cauchy-window obligation is exhausted by (T, Q, D, R, H, C, P, N) and has no coordinate for quotient streams, selected representatives, ambient completeness, or host real equality. □

Theorem 5965.13 (RegularSequenceSpace RegSeqRat forward route)**.** *Every forward dependency from an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier to a regular rational or real-facing consumer factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

Thus the space packet contributes a horizontal L10 dependency edge to chapter 301 and chapter 38, rather than remaining a local carrier with no downstream regular-rational or real-name route.

Proof. Project the carrier of Definition 5965.1. The schedule row T and dyadic tolerance row D are exposed before the regular rational readback row Q and the terminal real-facing seal R.

Apply the RegSeqRat Real seal route of Definition 5965.10. It places every endpoint read through Q before R, with the stream schedule, dyadic tolerance, transport, replay, provenance, and local naming rows still visible.

Finally use the obligation scope route of Definition 5965.8. The resulting forward dependency is the displayed $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ route into $\mathsf{RegSeqRat}^{\uparrow}$ and then $\mathsf{Real}^{\uparrow}$, with no quotient stream, selected limit, unrestricted sequence space, or ambient completeness coordinate. □

Theorem 5965.14 (RegularSequenceSpace StreamName window route)**.** *Every finite comparison read from an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier exposes the* $\mathsf{StreamName}^{\uparrow}$ *window* T *before* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or* $\mathsf{Real}^{\uparrow}$ *sealing is consumed. Consequently common-window comparison is the public route for later regular rational and Real-facing reads, not a consequence of hidden quotient equality or ambient completeness.*

Proof. Start from the pointwise stream projection of Definition 5965.6. It exposes the source row and $\mathsf{StreamName}^{\uparrow}$ schedule before the regular rational readback, dyadic tolerance row, and Real-facing seal are available.

Apply finite-window comparison, Definition 5965.7. Any two displayed values must share the same finite stream window, regular rational readback, tail-filter ledger, dyadic tolerance row, completion handoff, and structural rows already exposed by the carrier.

Finally combine the RegSeqRat Real seal route of Definition 5965.10 with the obligation scope route of Definition 5965.8. The later RegSeqRat and Real rows remain downstream of the exposed

StreamName window, so the comparison route has no hidden quotient equality, selected limit, or ambient completeness witness. □

Theorem 5965.15 (RegularSequenceSpace tail-window transport)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. For every displayed finite tail-depth extension of a comparison read, the same* $\mathsf{StreamName}^{\uparrow}$ *window route transports through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, the tail-filter ledger, the terminal* $\mathsf{Real}^{\uparrow}$ *seal R, and the structural rows H, C, P, N. Thus finite tail-depth transport is a displayed route inside T, Q, D, R, H, C, P, N, not a quotient-stream argument, selected-limit argument, countable-choice argument, or appeal to ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Induct on the displayed finite tail depth. At depth 0, apply the StreamName window route of Definition 5965.14. The initial comparison read exposes the finite $\mathsf{StreamName}^{\uparrow}$ window before $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ sealing is consumed.

For the successor step, first use the tail-filter handoff of Definition 5965.3. It routes the extended tail read through the same displayed stream schedule, regular rational readback, dyadic tolerance row, and tail-filter surface.

Next apply tail coherence and finite-window comparison, Definition 5965.4 and Definition 5965.7. These keep the successor read on the same finite window and carry Q, D, R, H, C, P, N along the accepted carrier route.

The induction therefore transports every displayed finite tail-depth extension through the same window, readback, tolerance, tail-filter, Real-seal, and structural rows. Since the carrier has no coordinate for quotient streams, selected limits, countable choice, or ambient completeness, no such principle is introduced by the tail-depth step. □

Theorem 5965.16 (RegularSequenceSpace tail-diagonal projection)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Any two tail-filter reads of S that feed the same* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer can be projected to one displayed* $\mathsf{StreamName}^{\uparrow}$ *finite window before the value-seal row R is read. The projection stays inside the displayed route through T, Q, D, R, H, C, P, N and does not use quotient stream equality, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with tail coherence, Definition 5965.4. Reads that agree on the displayed stream schedule and regular rational readback also agree on the dyadic tolerance row and terminal seal route.

Apply finite-window comparison, Definition 5965.7. It forces every value comparison to use the same $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, tail-filter ledger, dyadic tolerance row, completion handoff, and structural rows already exposed by the carrier.

Now combine the RegSeqRat Real seal route and the StreamName window route, Definition 5965.10 and Definition 5965.14. The shared consumer cannot read the $\mathsf{RegSeqRat}^{\uparrow}$ classifier row Q or the $\mathsf{Real}^{\uparrow}$ seal row R before the finite window T is displayed.

Since no carrier coordinate records quotient stream equality, selected limits, countable choice, or ambient Real completeness, the diagonal projection is exactly the common finite-window projection inside the accepted packet. □

Theorem 5965.17 (RegularSequenceSpace finite-density feedback)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. If a consumer receives a* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *row as feedback for S, then the feedback must be replayed through the* $\mathsf{StreamName}^{\uparrow}$ *windows T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal R*

before it is treated as regular-sequence data. The feedback route is therefore the displayed finite-density handoff of chapter 6003 together with H, C, P, N, not an ambient density assertion, selected subsequence, quotient stream equality, or completeness principle.

Proof. Start with the RegularSequenceSpace carrier obligations, Definition 5965.2. They require every accepted space read to expose the source row, StreamName schedule, RegSeqRat readback, dyadic tolerance row, Real seal, and structural rows before any consumer treats the packet as regular-sequence data.

Apply the finite-density sibling route of chapter 6003. Its regular-sequence consumer handoff reads a density net only after the same StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, and Real seal have been displayed.

Now replay through the tail-filter handoff, Definition 5965.3. The density feedback reaches the regular sequence packet at the tail-filter boundary rather than as an external dense subset or selected subsequence.

Finally use tail coherence, Definition 5965.4. The structural rows H, C, P, N preserve the same window, readback, tolerance, and Real-seal route, so the finite density row cannot bypass the displayed regular-sequence feedback path. □

Theorem 5965.18 (RegularSequenceSpace tail-modulus projection)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Any tail-filter read from S that is later consumed as a* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *or* $\mathsf{CauchyRateSpace}^{\uparrow}$ *budget must project through the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, and the value seal R before the budget is public. The projection exports no selected modulus, quotient stream equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the tail-diagonal projection of Definition 5965.16. It forces tail-filter reads feeding a common consumer into one displayed $\mathsf{StreamName}^{\uparrow}$ finite window before the value-seal row is read.

Apply finite-window comparison, Definition 5965.7. The common window still carries the $\mathsf{RegSeqRat}^{\uparrow}$ readback, tail-filter ledger, dyadic tolerance row, completion handoff, and structural rows already exposed by the accepted carrier.

Now use the RegSeqRat Real seal route and the StreamName window route, Definition 5965.10 and Definition 5965.14. They place the regular rational readback Q and the value seal R downstream of the displayed schedule T and tolerance row D.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same finite route for $\mathsf{CauchyModulusSpace}^{\uparrow}$ and $\mathsf{CauchyRateSpace}^{\uparrow}$ consumers, leaving no coordinate from which a selected modulus, quotient stream equality, countable-choice schedule, or ambient completeness principle could be read. □

Theorem 5965.19 (RegularSequenceSpace tail-filter cofinal witness)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Every tail-filter read from S that feeds a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, and the* $\mathsf{Real}^{\uparrow}$ *seal R before the consumer-facing row is public. The witness is cofinal only through the displayed finite windows and structural rows H, C, P, N; it does not select a subsequence, identify quotient streams, invoke countable choice, or import ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the tail-modulus projection of Definition 5965.18. It already forces every tail-filter budget read through the displayed schedule T, regular rational readback Q, dyadic tolerance row D, and value seal R before a consumer can inspect the budget.

Project the same rows for $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers. The StreamName window supplies the finite cofinal index surface, the RegSeqRat row supplies readback, the DyadicRatCore row supplies the tolerance boundary, and the Real seal is opened only after those rows are present.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming keep the witness inside the displayed packet, so no selected subsequence, quotient stream equality, countable-choice schedule, or ambient completeness principle can be read from the cofinal route. □

Theorem 5965.20 (RegularSequenceSpace dyadic interval net refinement)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Any consumer that asks for finite dyadic cover refinement must factor through the* $\mathsf{StreamName}^{\uparrow}$ *schedule row T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, the finite-cell route of chapter 5966, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *seal R. The refinement exports no compactness theorem, selected subsequence, quotient equality of real names, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 5965.1. The only rows available to a refinement consumer are the displayed schedule, readback, tolerance, seal, transport, replay, provenance, and local naming rows.

Use the tail-filter cofinal witness and tail-modulus projection, Definition 5965.19 and Definition 5965.18. They force any tail-facing read through T, Q, D before the value seal is public.

Now pass to chapter 5966. Its finite-cell route supplies only dyadic endpoint arithmetic, cell incidence, StreamName windows, RegSeqRat readback, and a Real seal. Composing the two routes gives the stated refinement while leaving compactness, selected subsequences, quotient equality, and Real completeness outside the carrier. □

Theorem 5965.21 (RegularSequenceSpace common-window completion route)**.** *Let $S = (X, T, Q, D, R, H, C, P, N$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Every completion-facing comparison read from S must expose one common* $\mathsf{StreamName}^{\uparrow}$ *window T, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, and the finite-cell route of chapter 5966 before it consumes the terminal* $\mathsf{Real}^{\uparrow}$ *seal R. The route exports a displayed common-window comparison and no quotient stream equality, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the tail-diagonal projection of Definition 5965.16. Any two tail-filter reads feeding the same completion-facing consumer are projected to one displayed $\mathsf{StreamName}^{\uparrow}$ finite window before the value seal is read.

Apply the tail-modulus projection of Definition 5965.18. The common window still carries $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, and the value-seal route before any modulus or rate budget is public.

Now use the dyadic interval net refinement of Definition 5965.20. The finite-cell route of chapter 5966 is inserted after T, Q, D and before the terminal $\mathsf{Real}^{\uparrow}$ seal, so completion-facing comparisons receive finite dyadic cells rather than a hidden compactness or completion witness.

Finally replay finite-window comparison, Definition 5965.7. It keeps the two compared reads inside the same displayed StreamName, RegSeqRat, DyadicRatCore, DyadicIntervalNet, and Real-seal route. Since the carrier has no coordinate for quotient stream equality, selected limits, countable choice, or ambient Real completeness, the common-window completion route is exhausted by the displayed rows. □

Theorem 5965.22 (RegularSequenceSpace shift closure)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Shifting the displayed packet by any unary finite tail*

preserves the $\mathsf{StreamName}^{\uparrow}$ *schedule row* T*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal route* R, H, C, P, N*. The shifted packet is therefore consumed through the same regular sequence space route and exports no quotient stream equality, selected limit, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Induct on the unary tail shift. In the zero case, apply the tail-filter cofinal witness of Definition 5965.19; the displayed schedule, readback, dyadic tolerance, and Real seal rows are exactly the rows already exposed by the accepted carrier.

For the successor step, first apply finite-window comparison, Definition 5965.7. It keeps the shifted read inside the same finite $\mathsf{StreamName}^{\uparrow}$ window and the same $\mathsf{RegSeqRat}^{\uparrow}$ readback route before any value comparison is public.

Next apply the tail-diagonal projection and tail-modulus projection, Definition 5965.16 and Definition 5965.18. These rows move the successor tail back to a displayed common window and preserve the dyadic tolerance row D before the $\mathsf{Real}^{\uparrow}$ seal can be consumed.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same terminal route after each finite tail step, while the carrier still has no coordinate for quotient stream equality, selected limits, countable choice, or ambient completeness. The induction gives shift closure for every unary finite tail. □

Theorem 5965.23 (RegularSequenceSpace diagonal tail extraction)**.** *Let* $S = (X, T, Q, D, R, H, C, P, N)$ *be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. If a consumer displays a finite tail-filter row together with the* $\mathsf{StreamName}^{\uparrow}$ *window* T*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, and the* $\mathsf{Real}^{\uparrow}$ *seal row* R*, then the consumer admits a diagonal tail route through the same displayed rows. This route is consumable by* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *endpoints and exports no quotient stream equality, selected limit, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with the tail-filter handoff of Definition 5965.3. It places every completion-facing read through the displayed stream schedule, regular rational readback, dyadic tolerance row, and regular Cauchy tail-filter surface before the Real seal is consumed.

Apply the tail-diagonal projection and tail-modulus projection, Definition 5965.16 and Definition 5965.18. The first projects any two tail-filter reads feeding the same regular rational or Real consumer to one displayed finite window; the second keeps that window tied to the displayed modulus and rate budget rows before public consumption.

Finally use shift closure, Definition 5965.22. Every unary finite tail of the packet preserves the same T, Q, D, R, H, C, P, N route, so the diagonal tail extraction remains inside the accepted carrier for both $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ endpoints.

Because the carrier records only these finite rows and their structural replay, the extracted route has no coordinate from which quotient stream equality, a selected limit, countable choice, or ambient Real completeness could be read. □

Theorem 5965.24 (RegularSequenceSpace Cauchy-filter completion route)**.** *Let* $S = (X, T, Q, D, R, H, C, P, N)$ *be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Every Cauchy-filter or completion-facing read from* S *must expose the* $\mathsf{StreamName}^{\uparrow}$ *window* T*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the tail-filter ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* R *before any completed value is public. The route is a finite L10 completion boundary consumable by* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *descendants; it exports no quotient stream equality, selected limit, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the tail-filter handoff of Definition 5965.3. It places any completion-facing read behind the displayed stream schedule, regular rational readback, dyadic tolerance row, and tail-filter ledger.

Apply window comparison and finite-density feedback, Definition 5965.7 and Definition 5965.17. These keep the completion request tied to one finite $\mathsf{StreamName}^{\uparrow}$ window and one $\mathsf{RegSeqRat}^{\uparrow}$ readback surface before the tolerance row is consumed.

Finally use the RegSeqRat Real seal route through Definition 5965.23. The structural rows H, C, P, N preserve the same displayed route, so the public completion read reaches the $\mathsf{Real}^{\uparrow}$ seal only through finite tail data and cannot expose quotient streams, selected limits, countable choice, or ambient Real completeness. □

Theorem 5965.25 (RegularSequenceSpace BishopRealInterval route)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted $\mathsf{RegularSequenceSpace}^{\uparrow}$ carrier. If a tail window of S displays two endpoint reads whose endpoint packet is sealed by the $\mathsf{BishopRealInterval}^{\uparrow}$ carrier of chapter 8787, then the same tail window supplies a $\mathsf{Real}^{\uparrow}$-readable interval enclosure route. The route uses RegSeqRat tail coherence, StreamName pointwise projection, and the $\mathsf{BishopRealInterval}^{\uparrow}$ endpoint classifier before the terminal $\mathsf{Real}^{\uparrow}$ seal is public; it exports no quotient stream equality, selected limit, countable choice, classical interval subset, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.*

Proof. Start with diagonal tail extraction, Definition 5965.23. It keeps the displayed tail window inside the same T, Q, D, R, H, C, P, N route for every $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ endpoint consumer.

Apply tail coherence and pointwise stream projection, Definition 5965.4 and Definition 5965.6. The endpoint reads therefore share one finite $\mathsf{StreamName}^{\uparrow}$ window and one $\mathsf{RegSeqRat}^{\uparrow}$ readback surface before the dyadic tolerance row and Real seal are consumed.

Now pass to the BishopRealInterval carrier and its regular seal route, Definition 8787.1 and Definition 8787.3. Its endpoint classifier reads finite stream windows, regular rational endpoint readback, and dyadic comparison data before releasing the interval enclosure seal.

Finally replay the RegularSequenceSpace structural rows H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same tail window and endpoint packet, so the resulting enclosure is a Real-readable L10 completion route rather than a quotient-real, selected-limit, classical-interval, countable-choice, or ambient-completeness assertion. □

Theorem 5965.26 (RegularSequenceSpace BishopSequence forward link)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted $\mathsf{RegularSequenceSpace}^{\uparrow}$ carrier. Any downstream $\mathsf{BishopSequence}^{\uparrow}$ consumer of S must keep the $\mathsf{StreamName}^{\uparrow}$ window T, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row Q, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row D, and the terminal $\mathsf{Real}^{\uparrow}$ seal route R, H, C, P, N visible before the Bishop sequence read is public. The resulting forward link feeds the carrier of chapter 2179 through the same tail window and regular readback used by Definition 5965.3, Definition 5965.12, and Definition 5965.25; it exports no quotient stream equality, selected sequence representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.*

Proof. Start with the tail-filter handoff of Definition 5965.3. It places every completion-facing read behind the displayed $\mathsf{StreamName}^{\uparrow}$ schedule T, $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row D before the terminal seal is public.

Apply the Cauchy-window route of Definition 5965.12. The window subpacket keeps T, Q, D, R, H, C, P, N together as one finite NameCert route rather than as detachable sequence representatives.

Now pass to the $\mathsf{BishopSequence}^{\uparrow}$ carrier of chapter 2179. A Bishop sequence consumer may read the displayed regular sequence space only through the same stream window, regular rational readback, tolerance ledger, and Real seal rows.

Finally use the BishopRealInterval route of Definition 5965.25 as the endpoint model. Since interval-facing reads already preserve the same tail window before public consumption, BishopSequence-facing reads inherit the same finite L10 boundary and cannot add quotient streams, selected representatives, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularSequenceSpace}^{\uparrow}$ packet is generated from a displayed source family of regular sequence names, stream schedules, regular rational readbacks, dyadic tolerance core rows, a real-facing value seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularSequenceSpace}^{\uparrow}}$, obligation)

Scope closed: Definition 5965.1 and Definition 5965.2 seed the finite space-level regular sequence carrier between stream names, rational regular readbacks, dyadic tolerance cores, and Real-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularSequenceSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim an ambient complete metric space, quotient equality of real names, arbitrary choice of representatives, unrestricted sequence space, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires explicit kernel scope for StreamName, RegSeqRat, DyadicRatCore, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

The $\mathsf{RegularSequenceSpace}^{\uparrow}$ route consumes chapter 126, chapter 291, chapter 301, and chapter 38 as its L10 finite-window, tolerance-budget, regular-readback, and terminal-seal siblings before the local sequence-space certificate is exposed. The $\mathsf{RegularSequenceSpace}^{\uparrow}$ route consumes chapter 1119 as its finite-tail filter carrier before the regular-sequence-space schedule and tail rows are inspected. The schedule/tail handoff therefore remains tied to the finite cofinal-tail filter surface rather than to a detached sequence-space island.

Theorem 5965.27 (RegularSequenceSpace tail-filter consumer)**.** *Every* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *tail consumer that reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *must expose the Frechet-filter and cofinite-tail discipline before the regular readback or terminal seal is visible. Concretely, the consumer route factors through chapter 1564, chapter 7023, the* $\mathsf{StreamName}^{\uparrow}$ *tail windows, chapter 301, and chapter 38; after those rows are exposed, the same route records componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RegularSequenceSpace}^{\uparrow}}$ *rows.*

Thus a RegularSequenceSpace tail read cannot reach a regular rational readback or a real seal from an unrestricted sequence-space carrier, an ambient Frechet-filter quotient, a hidden cofinite-set equality, or a host choice of representatives. It reaches those endpoints only through the displayed $\mathsf{FrechetFilter}^{\uparrow}/\mathsf{CofiniteFilter}^{\uparrow}$ *tail discipline,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows.*

Every $\mathsf{RegularSequenceSpace}^{\uparrow}$ consumer that forms a telescoping or completion budget routes through chapter 708, chapter 291, chapter 301, chapter 126, and chapter 38 before any value-facing seal is read. Thus the local sequence-space packet exposes telescoping budget data only after the finite budget, dyadic tolerance, regular readback, stream schedule, and terminal seal rows remain visible. The $\mathsf{RegularSequenceSpace}^{\uparrow}$ route consumes chapter 5966 as a finite dyadic tolerance-window child before $\mathsf{RegSeqRat}^{\uparrow}$ readback and the terminal $\mathsf{Real}^{\uparrow}$ seal are public. This child route records the dyadic interval net as a genuine L10 sibling dependency of regular sequence finite-window reads, not as a self-contained completion principle.

Proposition 5965.28 (RegularSequenceSpace dyadic net dependency)**.** *Every accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier read by a completion-facing consumer must expose its* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the finite-cell route of chapter 5966, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The dependency exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient completeness theorem.*

Proof. Project the displayed regular-sequence carrier rows. The schedule, dyadic tolerance, readback, seal, transport, replay, provenance, and local naming coordinates are the only rows available to a completion-facing consumer.

Insert the dyadic interval net after the tolerance row and before readback reaches the terminal value seal. The finite-cell route supplies dyadic endpoint and incidence data for the visible tolerance window while leaving RegSeqRat and Real readback downstream.

The route therefore records a sibling dependency through finite rows. Since no carrier coordinate contains a quotient of streams, a selected limit, a choice schedule, host real equality, or ambient completeness data, none of those endpoints can be exported by the dependency. □

Every $\mathsf{RegularSequenceSpace}^{\uparrow}$ completion-facing consumer reads the terminal value route through the finite L10 dependency chain before treating the packet as a Real or Completion input. The route first exposes the $\mathsf{StreamName}^{\uparrow}$ finite-window rows of chapter 126, then the $\mathsf{RegSeqRat}^{\uparrow}$ readback rows of chapter 301, then the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows of chapter 291, and finally the $\mathsf{Real}^{\uparrow}$ sealing boundary of chapter 38. The finite-tail and tail-filter rows already named in this hub remain upstream of any completion-facing read.

Theorem 5965.29 (RegularSequenceSpace Real and Completion dependency route)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted $\mathsf{RegularSequenceSpace}^{\uparrow}$ carrier. Any consumer that exports a Real-facing or Completion-facing read from S must first display the $\mathsf{StreamName}^{\uparrow}$ window T, the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row D, the existing finite-tail and tail-filter dependency rows, and then the terminal $\mathsf{Real}^{\uparrow}$ seal R. The export is therefore a displayed Real and Completion route through the regular-sequence-space packet, not an ambient completeness witness, quotient stream equality, selected limit, or unrestricted sequence-space object.*

Proof. Project the carrier of Definition 5965.1. The only value-facing rows available to a completion consumer are the stream schedule T, regular rational readback Q, dyadic tolerance row D, and Real seal R.

Use the finite-tail and tail-filter dependency routes already included by the hub. They keep the tail read inside displayed finite windows before the regular rational and Real rows are consumed.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same finite packet, so the Real and Completion export cannot import quotient stream equality, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5965.30 (RegularSequenceSpace sibling route)**.** *Every $\mathsf{RegularSequenceSpace}^{\uparrow}$ consumer that reads completion-facing data must first consume the sibling route through $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, and $\mathsf{Real}^{\uparrow}$ seal rows. The route passes through chapter 126, chapter 301, chapter 291, and chapter 38 before the regular-sequence-space packet exposes value-facing data to any downstream consumer.*

Proof. Project an accepted $\mathsf{RegularSequenceSpace}^{\uparrow}$ carrier through the local carrier row. Its displayed schedule, readback, tolerance, and seal coordinates are the rows T, Q, D, R already named by the chapter.

The sibling chapters determine the order of consumption. The StreamName window T is read before the RegSeqRat readback Q; the DyadicRatCore tolerance row D bounds the readback; and the Real seal R is terminal for value-facing output.

Thus every completion-facing consumer reaches regular-sequence-space data only after the sibling route has been displayed. The carrier has no coordinate for quotient streams, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness that could bypass this route. □

Theorem 5965.31 (RegularSequenceSpace finite shift stability)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Every finite shift of the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule transports through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, tail-filter ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seal R, and structural rows H, C, P, N. Thus finite shift stability is a displayed route inside the regular sequence space packet, not a quotient-stream argument, selected-limit argument, countable-choice argument, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Use finite tail-depth transport, Definition 5965.15. A finite shift of the schedule is a finite tail-depth extension of the displayed $\mathsf{StreamName}^{\uparrow}$ window, so the read remains on the same T, Q, D, R, H, C, P, N route.

Apply tail-diagonal projection, Definition 5965.16. Any two shifted tail-filter reads feeding the same regular rational or Real consumer are projected back to one displayed StreamName window before the value-seal row is public.

Finally use the RegSeqRat Real seal route of Definition 5965.10. The shifted read reaches $\mathsf{Real}^{\uparrow}$ only after the $\mathsf{RegSeqRat}^{\uparrow}$ classifier row and the visible structural rows have stayed attached to the accepted packet. □

Theorem 5965.32 (RegularSequenceSpace product-window route)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Every finite product, paired-tail, or product-completion consumer of S must expose the two displayed* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seals before any product completion read is public. The route exports only the common finite-window product surface of the accepted packet; it exports no quotient stream equality, selected representative pair, countable-choice selector, or ambient completeness coordinate.*

Proof. Project the carrier of Definition 5965.1. A product-facing read has access only to the displayed schedule row T, regular rational readback Q, dyadic tolerance row D, Real seal R, and structural rows H, C, P, N.

Use the sibling and tail routes already attached to the hub: Definition 5965.30, Definition 5965.3, and Definition 5965.21. They force each coordinate of a paired-tail read to pass through a displayed StreamName window before the RegSeqRat, DyadicRatCore, and Real rows are consumed.

Use the shift-stability route of Definition 5965.22. Finite shifts of either coordinate remain inside the same T, Q, D, R, H, C, P, N route, so a product window is assembled from two finite windows rather than from a selected representative pair.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the paired finite route and supply no coordinate for quotient stream equality, countable choice, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5965.33 (RegularSequenceSpace hub forward link)**.** *Every* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *packet exposed by the hub routes a completion-facing read through at least one substantive L10 sibling before the terminal value seal is public. Concretely, a consumer must keep the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *finite-cell route,* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *uniqueness boundary, and terminal* $\mathsf{Real}^{\uparrow}$ *seal visible before treating the packet as a completion input. The hub therefore exports a forward lattice edge to existing L10 completion siblings, not a kernel-only carrier island, quotient stream equality, selected limit, countable-choice schedule, or ambient completeness principle.*

Proof. Start with the sibling route of Definition 5965.30. It forces every completion-facing read through the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before the local packet exports value-facing data.

Use the common-window completion route of Definition 5965.21. The same read must expose the finite-cell route of chapter 5966 after the common window and before the terminal seal, so the hub points to a concrete L10 finite-net sibling.

Finally route uniqueness through chapter 5983. The structural rows H, C, P, N preserve the displayed window, readback, finite-cell, uniqueness, and Real-seal route, and no coordinate in the carrier adds quotient stream equality, selected limits, countable choice, or ambient completeness. □

Theorem 5965.34 (RegularSequenceSpace RegSeqRat frontier)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Any Real-completion consumer of S reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule T,* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity rows Q,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance surface D, and* $\mathsf{Real}^{\uparrow}$ *seal R, with transport, replay, provenance, and local naming rows H, C, P, N still visible. The packet exports no quotient of sequences, choice-selected subsequence, hidden representative selector, or ambient Real completeness principle.*

Proof. Project the carrier of Definition 5965.1. The value-facing route exposes the schedule row T, the regular rational readback row Q, the dyadic tolerance row D, the terminal seal R, and the structural rows H, C, P, N.

Use the sibling route of Definition 5965.30. It forces completion-facing consumers to read the StreamName, RegSeqRat, DyadicRatCore, and Real rows in that order before any value-facing data are public.

Next use the Real and Completion dependency route of Definition 5965.29. It keeps the finite-tail and tail-filter rows upstream of the same T, Q, D, R route and blocks any detour through quotient stream equality or selected limits.

Finally replay H, C, P, N. Componentwise transport, continuation replay, provenance, and local naming preserve the displayed frontier and add no coordinate for sequence quotients, choice-selected subsequences, hidden representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence the RegSeqRat frontier is the only route from the accepted packet to Real-completion consumers. □

Theorem 5965.35 (RegularSequenceSpace RegSeqRat frontier tail seal)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. A* $\mathsf{Real}^{\uparrow}$*-completion consumer must expose the finite-tail row, tail-filter row,* $\mathsf{StreamName}^{\uparrow}$ *schedule T,* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row Q,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D,* $\mathsf{Real}^{\uparrow}$ *seal R, componentwise transport H, continuation replay C, provenance P, and local naming row N before reading the packet as a completed regular sequence. The tail seal is therefore a displayed RegSeqRat frontier obligation and not a quotient stream, selected representative, choice-selected subsequence, host real equality, or ambient completeness principle.*

Proof. Begin with the RegSeqRat frontier theorem, Definition 5965.34. It places T, Q, D, R, H, C, P, N on the only value-facing route available to Real-completion consumers.

Use the Real and Completion dependency route of Definition 5965.29. It keeps the finite-tail and tail-filter rows upstream of the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ route.

Apply the sibling route theorem, Definition 5965.30. It prevents a completion-facing consumer from skipping the displayed stream schedule, regular rational readback, dyadic tolerance row, terminal seal, transport, replay, provenance, and local naming rows.

Thus the accepted packet can be read as a completed regular sequence only after the tail seal has exposed the finite-tail and tail-filter rows together with T, Q, D, R, H, C, P, N. Since no carrier coordinate stores quotient stream equality, selected representatives, choice-selected subsequences,

host real equality, or ambient completeness, the seal is exactly the displayed RegSeqRat frontier boundary. □

Theorem 5965.36 (RegularSequenceSpace L10 link)**.** *Let $S = (X, T, Q, D, R, H, C, P, N)$ be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Every completion-facing read from S factors through the displayed L10 chain*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow},$$

with transport, replay, provenance, and local naming rows H, C, P, N preserved along the route. The chain cannot import quotient stream equality, a selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the RegSeqRat frontier theorem, Definition 5965.34. It places the schedule row T, regular rational row Q, dyadic tolerance row D, Real seal R, and structural rows H, C, P, N on the only completion-facing route exposed by the carrier.

Use the frontier tail seal, Definition 5965.35. It adds the finite-tail and tail-filter rows before the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ chain can be read as a completed regular sequence.

Now apply the carrier and NameCert obligations of Definition 5965.1 and Definition 5965.2. They keep H, C, P, N attached to the displayed packet by componentwise transport, continuation replay, provenance, and local naming.

Since none of these rows contains quotient stream equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every accepted completion-facing read remains inside the displayed L10 chain. □

The $\mathsf{RegularSequenceSpace}^{\uparrow}$ lattice route consumes the finite scheduling surface of chapter 126 together with the regular readback surface of chapter 301. The StreamName row fixes the visible observation order, while the RegSeqRat row reads those observations as regular rational data before the local sequence-space certificate is exposed.

Proposition 5965.37 (RegularSequenceSpace RegSeqRat StreamName Real route)**.** *Every* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *completion-facing read must expose the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface of chapter 301, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before the local packet is inspected as a completion input. The route exports only the displayed finite rows of the accepted sequence-space carrier, not quotient stream equality, selected representatives, countable choice, unrestricted sequence-space completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted $\mathsf{RegularSequenceSpace}^{\uparrow}$ carrier through Definition 5965.1. Its visible schedule, readback, and value-facing rows are the displayed T, Q, R coordinates, with transport, replay, provenance, and local naming still attached.

Use the sibling route of Definition 5965.30. It already orders the finite StreamName window before the RegSeqRat readback and keeps the Real seal terminal for value-facing output.

Finally apply the Real and Completion dependency route of Definition 5965.29. A completion-facing consumer therefore reaches the local packet only through the StreamName, RegSeqRat, and Real sibling chapters, with no coordinate available for quotient stream equality, selected representatives, countable choice, unrestricted sequence-space completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Definition 5965.38 (RegularSequenceSpace density route)**.** *The* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *density route is the finite dependency corridor in which an accepted carrier*

$$S = (X, T, Q, D, R, H, C, P, N)$$

is read first through the $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback of chapter 301, then through the density-facing* $\mathsf{RealSeparability}^{\uparrow}$ *surface of chapter 1809. The route exposes only the displayed source row* X*, stream schedule* T*, regular readback* Q*, dyadic tolerance row* D*, terminal* $\mathsf{Real}^{\uparrow}$ *seal* R*, componentwise transport* H*, replay* C*, provenance* P*, and local naming row* N*.*

Theorem 5965.39 (RegularSequenceSpace RegSeqRat density consumption)**.** *Every* $\mathsf{RealSeparability}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier must consume the density route of Definition 5965.38. In particular, the consumer reaches chapter 1809 only after the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row of chapter 301, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row remain visible in the same packet.*

Proof. Project the accepted carrier through Definition 5965.1. The available rows are exactly $X, T, Q, D, R, H, C, P, N$, with Q carrying the regular rational readback and R carrying the terminal Real-facing seal.

Use the RegSeqRat frontier of Definition 5965.34. It forces completion-facing consumers to read the displayed stream schedule, regular rational readback, dyadic tolerance row, and Real seal before a value-facing endpoint is public.

Now route density-facing reads through chapter 1809. That chapter consumes rational density only after the RegSeqRat and Real-seal rows are visible, so the $\mathsf{RegularSequenceSpace}^{\uparrow}$ consumer cannot bypass T, Q, D, R.

Finally H, C, P, N preserve the same packet by transport, replay, provenance, and local naming. Since the carrier has no coordinate for quotient stream equality, selected dense sequence, countable-choice schedule, unrestricted sequence-space completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no density consumer can export those objects from the route. □

Theorem 5965.40 (RegularSequenceSpace diagonal-adjoint handoff)**.** *Let* $S = (X, T, Q, D, R, H, C, P, N)$ *be an accepted* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *carrier. Every finite diagonal window over* S *that is consumed by a completion-facing endpoint projects through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

without changing the dyadic tail budget D*. Equivalently, the diagonal read first fixes one* $\mathsf{StreamName}^{\uparrow}$ *window* T*, transports its* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q *by componentwise* hsame*, and then exposes the terminal* $\mathsf{Real}^{\uparrow}$ *seal* R *over the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row.*

Proof. Induct on the displayed finite diagonal window. In the empty window, the carrier projection of Definition 5965.1 already exposes T, Q, D, R, H, C, P, N as one route, so the tail budget is exactly the displayed row D.

For the successor window, apply the diagonal tail extraction theorem, Definition 5965.23. It keeps the new diagonal read inside the same $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and $\mathsf{Real}^{\uparrow}$ seal route.

Now use shift closure, Definition 5965.22. The finite tail shift preserves T, Q, D before the terminal seal is consumed, so the successor step cannot tighten, weaken, or replace the dyadic budget row.

Finally replay the structural rows. Componentwise hsame transport H, continuation replay C, provenance P, and local naming N carry the same diagonal-adjoint handoff to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ consumers. The route has no coordinate for quotient stream equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

The $\mathsf{RegularSequenceSpace}^{\uparrow}$ route consumes chapter 8972 whenever a regular sequence is read with an explicit dyadic modulus budget. The packet is reached through the $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{StreamName}^{\uparrow}$ scheduling routes of Definition 5965.30 and Definition 5965.37, so the local sequence-space carrier exposes the modulus budget as finite sibling data rather than as quotient selection, countable choice, or ambient completion structure. The $\mathsf{RegularSequenceSpace}^{\uparrow}$ sibling route consumes the $\mathsf{RegSeqRat}^{\uparrow}$ stream readback of chapter 301 together with the finite Cauchy density-net handoff of chapter 6003 before exporting sequence-space reads. Thus a completion-facing consumer sees the finite density row only after the displayed StreamName window, RegSeqRat readback, dyadic tolerance ledger, and terminal Real seal remain attached to the accepted regular-sequence-space packet. The $\mathsf{DyadicIntervalNet}^{\uparrow}$ hub routes finite dyadic mesh data through chapter 1767, chapter 1808, and chapter 291 before Real-completion consumers read the mesh.

Chapter 5966

Dyadic Interval Net NameCert Construction

Following Bishop and Bridges, the $\mathsf{DyadicIntervalNet}^{\uparrow}$ packet records finite dyadic interval nets as the displayed cover primitive used by Real and Completion arguments before any consumer may invoke compactness language. It sits after the dyadic arithmetic core of chapter 291, the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. As a consumer route, the finite interval-cell row consumes dyadic endpoint arithmetic from chapter 291, exposes endpoint observations through chapter 126, reads tolerances through chapter 301, and seals only through chapter 38. The packet gives compact-interval, completion, and uniform-modulus consumers a finite cover surface; it does not assert open-cover compactness, selected subcovers, quotient stream equality, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

The same finite dyadic cell data is consumed by chapter 1250 and by the compact-interval uniform-modulus route as displayed finite cells, not as open-cover compactness. The finite Cauchy density-net route of chapter 6003 consumes these dyadic cell rows as finite density witnesses for L10 completion reads.

Definition 5966.1 (Dyadic interval net carrier)**.** *A* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (D, J, E, S, R, Q, H, C, P, N)$$

with the following rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row. It lists the dyadic endpoints, midpoint and radius arithmetic, and successor comparisons used by the net cells.*
2. *J is the finite interval-cell row. It records a finite list of closed dyadic cells, each with displayed left and right endpoints and a cell radius.*
3. *E is the endpoint-incidence row. It records that adjacent cells overlap or touch at displayed dyadic endpoints and that the first and last cells bracket the named interval endpoints.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposed when an interval endpoint or cell endpoint is read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the dyadic endpoints and the tolerance schedule induced by the cell radii.*
6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the displayed StreamName and RegSeqRat rows have been inspected.*

7. *H records componentwise* hsame *transport for D, J, E, S, R, Q and the structural rows.*
8. *C records displayed* Cont *replay of the finite route*

$$D, J, E \longmapsto S, R \longmapsto Q, H, P, N.$$

9. *P is the* Pkg *provenance over* DyadicIntervalNet$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{DyadicIntervalNet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, J, E, S, R, Q, H, C, P, N$. It has no coordinate for an arbitrary open cover, a selected finite subcover, quotient stream equality, a chosen limit point, countable choice, trichotomy, or completed real compactness.

Theorem 5966.2 (Dyadic interval net cover refinement)**.** *For every accepted* DyadicIntervalNet$^{\uparrow}$ *carrier $I = (D, J, E, S, R, Q, H, C, P, N)$, every Real and Completion consumer that reads a finite dyadic cover through I factors through the finite route*

$$D, J, E \longmapsto S, R \longmapsto Q.$$

The interval-cell row J and endpoint-incidence row E refine any displayed dyadic cover request into listed dyadic cells whose endpoints and radii are checked in D, whose inspected name coordinates are exposed in S, whose tolerance schedule is read in R, and whose Real boundary is sealed in Q. No open-cover compactness, selected subcover, quotient stream equality, countable choice, trichotomy, host real equality, or ambient Real$^{\uparrow}$ *completeness is available along this route.*

Lean4 ✓ `BEDC.Derived.Dyadic interval netUp.DyadicIntervalNetCoverRefinement`

Proof. Project the accepted carrier of Definition 5966.1. The rows D, J, E are the only cover-facing data: D supplies dyadic endpoint arithmetic, J supplies the finite list of cells, and E supplies endpoint incidence and bracketing.

The refinement is therefore a finite list operation. A displayed cover request is answered by reading the listed cells in J, checking their dyadic radii and endpoint comparisons in D, and using E to verify that adjacent cells cover the named interval without opening a host compactness argument.

The Real-facing portion is delayed. The inspected endpoint names pass through S, the induced tolerance schedule passes through R, and the terminal real-name boundary is exposed only by Q.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve exactly the same finite route, so the consumer cannot replace the dyadic net by a selected subcover, quotient stream equality, choice, trichotomy, host equality, or ambient completeness principle. □

Theorem 5966.3 (Dyadic interval net uniform subnet)**.** *Every compact-uniform-continuity finite-cover read that consumes an accepted* DyadicIntervalNet$^{\uparrow}$ *packet must expose dyadic cell rows, interval-radius rows,* StreamName$^{\uparrow}$ *or* RegSeqRat$^{\uparrow}$ *window rows, and a* UniformModulus$^{\uparrow}$ *handoff before the compact finite-net conclusion is read. In carrier notation, the read begins with the endpoint arithmetic and cell rows D, J, E, then passes through the window and readback rows S, R, and only then may a compact finite-net or uniform-modulus consumer inspect the terminal Real-facing seal Q and the structural rows H, C, P, N.*

Proof. Project the carrier of Definition 5966.1. The dyadic endpoint row D, finite interval-cell row J, and endpoint-incidence row E are the only rows that can display cell membership, adjacency, and interval radii.

Apply the cover refinement theorem Definition 5966.2. It forces every finite cover read to consume those dyadic rows before StreamName, RegSeqRat, or Real-facing data are visible.

The compact-uniform-continuity consumer then reads the finite-window route already named by this chapter. Endpoint observations pass through S, tolerance and radius readback pass through R, and the compact-interval uniform-modulus route can receive a $\mathsf{UniformModulus}^{\uparrow}$ handoff only after those rows have been exposed.

Finally replay H, C, P, N together with the sibling route paragraphs to chapter 1250 and chapter 6207. The resulting finite-subnet branch is a displayed dyadic-cell route, not open-cover compactness, selected subcovers, quotient stream equality, countable choice, trichotomy, host real equality, or ambient completeness. □

Theorem 5966.4 (Dyadic interval net mesh-refinement induction)**.** *For every accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier*

$$I = (D, J, E, S, R, Q, H, C, P, N)$$

and every displayed finite dyadic refinement depth n, repeated dyadic bisection of the interval-cell row preserves endpoint incidence, finite-cell coverage, $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal route. Each refined packet remains routed through*

$$D, J, E \longmapsto S, R \longmapsto Q, H, C, P, N,$$

and every public read still occurs before the Real seal is opened.

Proof. Induct on the displayed finite refinement depth n. At depth zero, the accepted carrier itself supplies the endpoint incidence, coverage, StreamName windows, dyadic tolerances, RegSeqRat readback, and Real seal route.

For the step, apply Definition 5966.2 to the current refined packet. Bisection replaces each listed dyadic cell by finitely many listed subcells whose endpoints, radii, and adjacency checks are still read through the dyadic endpoint row D and the incidence row E.

The consumer-facing rows remain downstream. Endpoint observations pass through S, tolerance schedules and regular rational reads pass through R, and the terminal real-name boundary remains Q.

Finally transport, replay, provenance, and local naming preserve the refined route componentwise. Since every induction step displays its finite cells before Q, no open-cover compactness, selected subcover, quotient stream equality, countable choice, trichotomy, host real equality, or ambient completeness principle enters the induction. □

Theorem 5966.5 (Dyadic interval net finite-bisection induction route)**.** *For every accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier*

$$I = (D, J, E, S, R, Q, H, C, P, N)$$

and every displayed finite bisection depth n, the row inventory

$$D, J, E, S, R, Q, H, C, P, N$$

is preserved by induction on n. Each bisection step replaces a listed parent cell in J by finitely displayed child cells whose endpoints, incidences, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming remain routed through the same rows. Thus

Real, Completion, closed-bounded interval, compact-interval, and uniform-modulus consumers receive a finite bisection route, not open-cover compactness, selected subcovers, quotient stream equality, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Induct on the displayed bisection depth n. At depth zero, the carrier of Definition 5966.1 already displays the endpoint arithmetic row D, finite cell row J, endpoint incidence row E, window row S, readback row R, Real seal row Q, and structural rows H, C, P, N.

For the successor step, apply the cover refinement theorem Definition 5966.2. The parent cell is replaced by finitely many listed child cells, and their endpoints, radii, and adjacency checks are still read through D, J, E before any Real-facing boundary is visible.

Now use mesh-refinement induction from Definition 5966.4. It transports the refined finite-cell packet across the displayed bisection step and keeps the endpoint windows, tolerance schedule, and terminal Real seal downstream of the child cells.

Finally replay H, C, P, N. Componentwise transport, continuation replay, provenance, and local naming preserve the same row inventory at the new depth, so the induction never imports open-cover compactness, selected subcovers, quotient equality, choice, trichotomy, host equality, or ambient completeness. □

Theorem 5966.6 (Dyadic interval net subdivision-depth coverage)**.** *For every accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier*

$$I = (D, J, E, S, R, Q, H, C, P, N)$$

and every displayed finite subdivision depth n, each refined cell coverage read factors through the $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint arithmetic row D, the finite cell list J, endpoint incidence E,* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal Q before any compact-interval or uniform-modulus consumer may inspect it. The structural rows H, C, P, N preserve the same route at every depth, so subdivision coverage remains finite dyadic interval-net data.*

Proof. Induct on the displayed depth n. At depth zero, the claim is the accepted carrier route: the original listed cells are read through D, J, E, endpoint observations pass through S, tolerance readback passes through R, and the Real-facing boundary is Q.

For the successor depth, apply the cover refinement theorem Definition 5966.2. Each bisection replaces a parent cell by finitely displayed child cells whose endpoints, radii, and adjacency checks still live in the dyadic endpoint and incidence rows.

Now use mesh-refinement induction from Definition 5966.4. It transports the finite coverage route across the displayed bisection step and keeps the endpoint windows, tolerance rows, and Real seal downstream of the refined cells.

Finally replay H, C, P, N. Componentwise transport, displayed continuation replay, provenance, and local naming preserve the same route for compact-interval and uniform-modulus consumers, without adding open-cover compactness, selected subcovers, quotient stream equality, countable choice, trichotomy, host real equality, or ambient completeness. □

The induction step consumes the finite subdivision packet of chapter 7480: each bisection reads its dyadic scale, grid, and cell-coverage rows before the refined interval-net cells are handed back to D, J, E.

The same finite-cell surface is consumed by the compact interval uniform-modulus route of chapter 6207. A downstream consumer reads the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint row, the $\mathsf{StreamName}^{\uparrow}$ window row, the $\mathsf{RegSeqRat}^{\uparrow}$ tolerance row, and the terminal $\mathsf{Real}^{\uparrow}$ seal in the displayed order, so the interval net remains a finite cover handoff rather than an open-cover compactness principle.

Definition 5966.7 (Dyadic compact-modulus carrier)**.** *A dyadic compact-modulus carrier over an accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *packet* $I = (D, J, E, S, R, Q, H, C, P, N)$ *is a finite* BHist *packet*

$$M = (I, K, B, U, L, S', R', Q', T, V, W, N')$$

with the following rows:

1. *K is the compact-interval source row, read only through the finite dyadic cells already listed in J and their endpoint-incidence data E.*
2. *B is the mesh-bound row, recording a displayed dyadic scale and the rational lower-bound fold used to compare cell radii.*
3. *U is the pointwise modulus row, listing the local modulus data attached to the displayed cells rather than a selected global modulus.*
4. *L is the finite lower-bound fold over the listed dyadic cells, producing the public compact-modulus budget from B and U.*
5. *S' and R' are the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for endpoint observations, mesh bounds, and tolerance budgets.*
6. *Q' is the* $\mathsf{Real}^{\uparrow}$ *seal row for the compact-interval endpoint and value data, reached only after S' and R' are displayed.*
7. *T records componentwise* hsame *transport for $I, K, B, U, L, S', R', Q'$ and the structural rows.*
8. *V records displayed* Cont *replay from dyadic cells through mesh bounds, pointwise modulus rows, lower-bound fold, readback, and seal.*
9. *W is the* Pkg *provenance over* $\mathsf{DyadicIntervalNet}^{\uparrow}$*, compact-interval source rows, uniform-modulus consumers,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. *N' is the local dyadic compact-modulus* $\mathsf{NameCert}$ *row.*

The classifier compares accepted compact-modulus packets only through $I, K, B, U, L, S', R', Q', T, V, W, N'$. It has no coordinate for open-cover compactness, a selected finite subcover, a selected global modulus, quotient interval equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5966.8 (Dyadic compact-modulus NameCert obligations)**.** *For every accepted dyadic compact-modulus carrier $M = (I, K, B, U, L, S', R', Q', T, V, W, N')$, the local NameCert surface consists exactly of carrier admission for those twelve rows; finite-cell exposure through the accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *packet I; compact-interval source exposure through K; mesh-bound exposure through B; pointwise modulus exposure through U; rational lower-bound folding through L;* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through S' and R'; terminal* $\mathsf{Real}^{\uparrow}$ *sealing through Q'; componentwise* hsame *transport through T; displayed* Cont *replay through V;* Pkg *provenance through W; and local naming through N'.*

Proof. Project the carrier of Definition 5966.7. Its only cover-facing input is the accepted intervalnet packet I, and its only compact-interval input is the source row K read through the finite cells of I.

The modulus budget is finite. The mesh-bound row B records the dyadic scale, U lists pointwise modulus rows attached to displayed cells, and L folds the rational lower bounds over the finite cell list.

The readback and seal rows remain downstream. Endpoint observations and tolerance budgets pass through S' and R', and the terminal real boundary is Q'.

Finally replay T, V, W, N'. Transport, continuation replay, provenance, and local naming preserve exactly those rows, so no open cover, selected finite subcover, selected global modulus, quotient interval equality, countable choice, or ambient completeness row can enter the NameCert surface. □

Theorem 5966.9 (Dyadic compact-modulus Heine–Cantor route)**.** *Every compact-interval uniform-modulus or Heine–Cantor finite-net consumer of an accepted dyadic compact-modulus carrier $M = (I, K, B, U, L, S', R', Q', T, V, W, N')$ must read the finite route*

$$I, K \longmapsto B, U, L \longmapsto S', R', Q', T, V, W, N'$$

before it may use the public compact-modulus budget. The route sends dyadic cells, mesh bounds, endpoint incidence, compact-interval source data, pointwise modulus rows, rational lower-bound fold, $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *sealing to compact-interval uniform-modulus consumers. It exports no open-cover compactness, selected subcover, quotient interval equality, countable choice, selected global modulus, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the dyadic interval net uniform subnet theorem, Definition 5966.3. It forces compact-uniform-continuity reads to expose dyadic cell rows, interval-radius rows, StreamName or RegSeqRat windows, and a uniform-modulus handoff before a compact finite-net conclusion is read.

Apply the compact-modulus obligations of Definition 5966.8. They refine that handoff through the compact-interval source row K, mesh-bound row B, pointwise modulus row U, and finite lower-bound fold L.

Now use the Real source link and Real seal nonescape theorems, Definition 5966.14 and Definition 5966.13. The endpoint observations and tolerance budgets must pass through the displayed StreamName and RegSeqRat readback rows before the Real seal is opened.

Finally replay T, V, W, N'. The compact-interval uniform-modulus and Heine–Cantor consumers receive the finite dyadic-cell route just described, with no coordinate for open-cover compactness, selected subcovers, quotient interval equality, countable-choice schedules, selected global moduli, or ambient Real completeness. □

Theorem 5966.10 (Dyadic interval net obligation surface)**.** *For every accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier $I = (D, J, E, S, R, Q, H, C, P, N)$, carrier admission and cell coverage are exhausted by the displayed rows D, J, E, H, C, P, N. The endpoint arithmetic, finite interval-cell list, endpoint incidence, componentwise transport, replay, provenance, and local naming rows supply the complete finite obligation surface for a dyadic net request, and no open-cover compactness or selected finite subcover is exported.*

Proof. Project the carrier of Definition 5966.1. The rows D, J, E display the endpoint arithmetic, listed cells, and incidence witnesses, while H, C, P, N transport, replay, source, and name those rows.

Cell coverage is therefore a finite row check. Each requested interval read is matched with cells already listed in J, the endpoint comparisons already listed in D, and the bracketing and adjacency data already listed in E.

The structural rows do not add a second cover object. They preserve the displayed packet componentwise, so no open cover, selected subcover, choice principle, or ambient compactness row can enter the obligation surface. □

Theorem 5966.11 (Dyadic interval net RegSeqRat route)**.** *Every accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *packet consumed by a* $\mathsf{RegSeqRat}^{\uparrow}$ *or Real-facing route first exposes the dyadic interval endpoints, finite net cells,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal. Concretely, the route reads the endpoint arithmetic and cell rows* D, J, E*, then the window row* S *of chapter 126, then the tolerance and readback rows supplied by chapter 291 and chapter 301, and only then the Real seal* Q*. No quotient stream, selected limit, selected subcover, countable-choice schedule, or ambient completeness coordinate is available to the consumer.*

Proof. Project the accepted carrier of Definition 5966.1. The rows D, J, E are the finite interval-net rows: dyadic endpoints, listed cells, and endpoint incidence.

Use the NameCert obligation surface of Definition 5966.10. It permits a downstream consumer to inspect only the displayed carrier rows, so any RegSeqRat-facing request must first pass through the listed cells and the dyadic endpoint arithmetic already present in D, J, E.

The readback rows are then forced in order. The StreamName row S supplies finite observation windows, the DyadicRatCore tolerance information supplies the dyadic radius and comparison rows, and the RegSeqRat row R supplies the regular rational readback before Q can be opened.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same route, leaving no coordinate from which a quotient stream, selected limit, selected subcover, choice schedule, or ambient completeness principle could be read. □

Theorem 5966.12 (Dyadic interval net StreamName and RegSeqRat handoff)**.** *Every downstream consumer of an accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier that inspects interval endpoints or cell tolerances must factor the read through*

$$D, J, E \longmapsto S, R \longmapsto H, C, P, N.$$

The $\mathsf{StreamName}^{\uparrow}$ *row* S *exposes the finite endpoint windows and the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *exposes the rational tolerance readback; neither row may be skipped or replaced by quotient stream equality, selected limits, or countable choice.*

Proof. Start from a downstream endpoint or tolerance read. By the carrier definition, the only cover-facing rows available before the read are D, J, E, so the requested endpoint or cell radius is first located inside the displayed dyadic net.

The read then passes through S and R. The StreamName row supplies finite observation windows for the endpoint names, and the RegSeqRat row supplies the regular rational schedule attached to those observations.

Finally replay H, C, P, N. Componentwise transport, continuation replay, provenance, and local naming keep the same finite handoff visible to the consumer, excluding quotient stream equality, selected limits, and choice. □

Theorem 5966.13 (Dyadic interval net Real seal nonescape)**.** *For every accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier* $I = (D, J, E, S, R, Q, H, C, P, N)$*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* Q *is reachable only after the finite dyadic net route*

$$D, J, E \longmapsto S, R$$

has been displayed. Any Real or Completion consumer that reaches Q *remains inside the same routed packet* $D, J, E, S, R, Q, H, C, P, N$ *and cannot escape to host real equality, real trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected subcovers, quotient equality, selected limits, or countable choice.*

Proof. Project the accepted packet. The carrier places Q downstream of the endpoint arithmetic, finite cells, endpoint incidence, StreamName windows, and RegSeqRat readback rows.

Thus a Real or Completion consumer must first traverse D, J, E, S, R. These rows display the cover cells, endpoint reads, and tolerance schedule before any Real-facing boundary is available.

Once Q is reached, the structural rows H, C, P, N only preserve the same displayed route. Since no excluded equality, selection, trichotomy, choice, or completeness row is present in the carrier, the Real seal cannot be used as an escape from the finite dyadic interval-net packet. □

Theorem 5966.14 (Dyadic interval net Real source link)**.** *Every Real-facing finite-net consumer of an accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier* $I = (D, J, E, S, R, Q, H, C, P, N)$ *must read the dyadic endpoint arithmetic row* D*, the finite cell row* J*, the endpoint-incidence row* E*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* Q *in that displayed order before it can hand the packet to closed-bounded interval, compact-interval, or uniform-modulus consumers. The source link exports only the routed packet* $D, J, E, S, R, Q, H, C, P, N$*; it exports no selected subcover, quotient stream equality, host real equality, countable-choice schedule, trichotomy, or ambient completeness principle.*

Proof. Begin with the cover refinement theorem Definition 5966.2. It places every finite-net read at the dyadic endpoint, cell, and incidence rows D, J, E before any Real-facing boundary is visible.

Next use the RegSeqRat route and the StreamName and RegSeqRat handoff, Definition 5966.11 and Definition 5966.12. These force endpoint observations through S and rational readback through R, so the consumer cannot skip directly from dyadic cells to a terminal real object.

Finally apply the Real seal nonescape theorem Definition 5966.13. Once Q is reached, the structural rows H, C, P, N preserve the same displayed packet, giving closed-bounded interval, compact-interval, and uniform-modulus consumers a finite source link and no ambient compactness or choice endpoint. □

Theorem 5966.15 (Dyadic interval net barycentric refinement consumer)**.** *Let* $I = (D, J, E, S, R, Q, H, C, P, N)$ *be an accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier. If a displayed* $\mathsf{DyadicBarycentricRefinement}^{\uparrow}$ *packet refines the parent cells in* J *by finite barycentric child cells, then every downstream consumer of the refined net still reads endpoint arithmetic through* $\mathsf{DyadicRatCore}^{\uparrow}$*, finite endpoint windows through* $\mathsf{StreamName}^{\uparrow}$*, tolerance readback through* $\mathsf{RegSeqRat}^{\uparrow}$*, and the terminal seal through* $\mathsf{Real}^{\uparrow}$ *before any compact-interval or completion consumer inspects it. The refined route remains a finite L10 route through*

$$D, J, E \longmapsto S, R \longmapsto Q, H, C, P, N$$

together with the sibling refinement rows of chapter 8605; it exports no open-cover compactness, selected subcover, quotient stream equality, countable-choice schedule, trichotomy, host real equality, or ambient completeness principle.

Proof. Start from the cover refinement theorem Definition 5966.2. The parent cells and endpoint-incidence rows already force the consumer to read the finite cell ledger J, E and the endpoint arithmetic row D before any Real-facing boundary is visible.

Use mesh-refinement induction from Definition 5966.4. A barycentric child-cell packet is a displayed finite refinement of the same kind: each child endpoint and mesh witness is listed before the StreamName and RegSeqRat rows are opened.

Now apply the Real source link Definition 5966.14 and the sibling $\mathsf{DyadicBarycentricRefinement}^{\uparrow}$ chapter. The sibling packet supplies the parent pointers, barycenter rows, and child-cell ledger, while this chapter supplies the endpoint, window, readback, and Real-seal order consumed by compact-interval and completion arguments.

Finally replay H, C, P, N. Componentwise transport, continuation replay, provenance, and local naming keep the refined packet on the same finite L10 route, so barycentric refinement cannot introduce selected subcovers, quotient stream equality, choice, trichotomy, host equality, or ambient completeness. □

Theorem 5966.16 (Dyadic interval net finite-chain coverage)**.** *Every accepted finite chain of interval cells consumed by closed-bounded interval, compact-interval, or uniform-modulus routes is exhausted by the displayed rows*

$$D, J, E, S, R, Q, H, C, P, N.$$

Coverage is checked by finite induction over the listed cells in J: each cell reads its dyadic endpoints and radius from D, its adjacency and endpoint incidence from E, its observed endpoint windows from S, its rational readback and tolerance schedule from R, and its terminal Real-facing boundary from Q. No open-cover compactness, selected subcover, quotient stream equality, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness is available along the chain.*

Proof. Start with the carrier of Definition 5966.1. The finite chain is the listed interval-cell row J, while D and E provide the only endpoint arithmetic and incidence data attached to those cells.

Use the cover refinement theorem Definition 5966.2. It forces every consumer-facing cover read to pass through D, J, E before any StreamName, RegSeqRat, or Real-facing row is visible.

Induct over the finite list of cells using Definition 5966.4. The base case reads the initial listed cell data. The step consumes one displayed cell, preserves adjacency through E, and leaves the remaining listed cells under the same $D, J, E, S, R, Q, H, C, P, N$ route.

Finally replay the downstream rows. The windows S, readback R, seal Q, and structural rows H, C, P, N preserve the finite chain without adding open-cover compactness, selected subcovers, quotient stream equality, choice, trichotomy, host real equality, or ambient completeness. □

Theorem 5966.17 (Dyadic interval net finite-cell dependency chain)**.** *Every finite-cell read of an accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *packet consumed by compact, closed-bounded, or uniform-modulus chapters must expose* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint arithmetic,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicIntervalRefinement}^{\uparrow}$ *retained-cell rows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before the interval-net row is public. The dependency chain is a finite route through the displayed packet and sibling refinement rows, not an open-cover compactness theorem, selected subcover, quotient stream equality, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with finite-chain coverage, Definition 5966.16. It exhausts every downstream finite-cell read by the displayed rows $D, J, E, S, R, Q, H, C, P, N$.

Apply the compact-interval forward route and the uniform-modulus refinement route, Definition 5966.24 and Definition 5966.22. These routes keep compact and modulus consumers downstream of endpoint arithmetic, retained finite cells, StreamName windows, RegSeqRat readback, and the Real seal.

Finally read the sibling dependency route of Definition 5966.20. It supplies the $\mathsf{DyadicIntervalRefinement}^{\uparrow}$ retained-cell dependency together with DyadicRatCore, RegSeqRat, and Real rows, so the public interval-net read remains the stated finite-cell dependency chain. □

Theorem 5966.18 (Dyadic interval net sibling cover route)**.** *Every accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *finite-cell route is consumed by the finite membership ledger of chapter 1428. The consumer route sends the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row D, the finite cell and endpoint-incidence rows J, E, the* $\mathsf{StreamName}^{\uparrow}$ *window row S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and the* $\mathsf{Real}^{\uparrow}$ *seal row Q into the*

cover packet's endpoint, mesh, membership, window, readback, and seal rows. This is a substantive downstream cover-consumer dependency: it records how the interval-cover chapter uses the net carrier, and it is not a self-reference.

Proof. Project the net carrier. The rows D, J, E are the finite cell data, and the rows S, R, Q are the StreamName, RegSeqRat, and Real-facing handoff data already ordered by Definition 5966.13.

Read the cover consumer. The DyadicIntervalCover packet uses dyadic endpoints, mesh and membership rows, finite windows, regular readbacks, and a Real seal, so the net rows provide exactly the finite-cell source consumed by that ledger.

The dependency is external to this chapter. It points from the net carrier to the sibling cover chapter and does not add a second net theorem, selected subcover, open-cover compactness row, or ambient Real completeness principle. □

Theorem 5966.19 (Dyadic interval net regular tail cover)**.** *Every* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *cover consumed by a regular-tail or Real-facing route must expose* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint arithmetic, finite cell incidence,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance and readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before any cover conclusion is public. The cover is therefore a finite route through* $D, J, E, S, R, Q, H, C, P, N$*, not a selected subcover, open-cover compactness principle, quotient stream equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the carrier of Definition 5966.1. The rows D, J, E expose dyadic endpoints, listed cells, and endpoint incidence before any cover read can be exported.

Apply the RegSeqRat route and StreamName handoff, Definition 5966.11 and Definition 5966.12. These force regular-tail consumers to read the finite windows S and the tolerance/readback row R after the endpoint and incidence rows.

Finally use the Real seal nonescape theorem Definition 5966.13. The seal row Q is downstream of the displayed finite route and cannot be read as selected subcovers, open-cover compactness, quotient stream equality, countable choice, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalNet}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalNet}^{\uparrow}$ packet is generated from dyadic endpoint arithmetic, finite interval cells, endpoint incidence, StreamName windows, RegSeqRat readback, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5966.1 and Definition 5966.2 seed the finite dyadic interval-net carrier over dyadic endpoint arithmetic, listed interval cells, endpoint incidence, StreamName windows, RegSeqRat readback, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicIntervalNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, quotient stream equality, countable choice, trichotomy, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic cell coverage, endpoint-incidence refinement, StreamName and RegSeqRat readback routing, Real seal ordering, provenance, and local naming for BEDC.Derived.DyadicIntervalNetUp

The $\mathsf{DyadicIntervalNet}^{\uparrow}$ L10 route consumes the $\mathsf{DyadicRatCore}^{\uparrow}$ radius and endpoint arithmetic rows of chapter 291 together with the located endpoint-and-cell surface of chapter 394 before interval-cover consumers read the listed dyadic cells. This dependency keeps the net packet on finite radius rows and located interval endpoints before the downstream cover route of chapter 1428 is exposed. The bounded interval net consumer of chapter 1250 reads the same DyadicRatCore endpoint arithmetic and dyadic interval refinement route before compact interval or Real-completion consumers may inspect a finite cover. Every $\mathsf{DyadicIntervalNet}^{\uparrow}$ finite-cell route supplies the finite mesh and dyadic comparison rows consumed by $\mathsf{LocatedIntervalLebesgueNumber}^{\uparrow}$

before the located-interval Lebesgue-number route is read. The downstream handoff stays tied to the finite interval-cell data of chapter 5966 and the located-interval certificate of chapter 8660, so the interval-net chapter remains the upstream finite-cover source for later compact-uniform and subcover consumers.

Theorem 5966.20 (DyadicIntervalNet sibling dependency route)**.** *Every finite-cell read of a* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier consumed by chapter 1250, chapter 6207, or chapter 5965 must first expose DyadicRatCore endpoint arithmetic, RegSeqRat readback, DyadicIntervalRefinement retained-cell rows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. Thus no compact, uniform-modulus, or common-window completion consumer can use the interval-net carrier as an ambient compactness principle, a host completion theorem, or an untracked real endpoint object.*

Proof. Read the dependency route through chapter 291, chapter 301, chapter 1831, and chapter 38. These sibling chapters supply endpoint arithmetic, regular rational readback, retained-cell refinement, and terminal sealing before the finite-cell row is visible to any compact or uniform-modulus consumer. Therefore the DyadicIntervalNet packet remains a finite interval-net route rather than an ambient compactness or host-completion principle.

The closed-bounded interval net consumer of chapter 1250 reads the same DyadicRatCore endpoint arithmetic, RegSeqRat tolerance readback, DyadicIntervalRefinement retained-cell rows, and terminal $\mathsf{Real}^{\uparrow}$ seal before it treats the finite cells as a bounded interval net.

The regular sequence space consumer of chapter 5965 uses the same finite-cell refinements as a common-window completion route. Its StreamName and RegSeqRat windows must still pass through DyadicRatCore tolerances, retained dyadic cells, and the terminal $\mathsf{Real}^{\uparrow}$ seal before Real-facing reads are public. □

Theorem 5966.21 (DyadicIntervalNet compactness consumer route)**.** *Any compactness consumer using a* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier factors through the existing compact-interval finite-net route of chapter 3471 and chapter 4031 only after DyadicRatCore endpoints, RegSeqRat tolerance readback, DyadicIntervalRefinement retained cells, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal are displayed. The route exports finite interval cells and endpoint incidence to compactness-facing consumers; it does not export open-cover compactness, selected subcovers, countable choice, quotient stream equality, host Real equality, or ambient Real completeness.*

Proof. Start with the sibling dependency route of Definition 5966.20. It places DyadicRatCore endpoint arithmetic, RegSeqRat readback, DyadicIntervalRefinement retained-cell rows, and the terminal Real seal before any compact, uniform-modulus, or completion consumer can use the finite-cell row.

For a named compactness consumer, route the read through chapter 3471 and chapter 4031. Those chapters record the compactness-facing boundary as a finite-net route, so the interval-net packet is consumed as displayed finite cells rather than as a detached compactness theorem.

For compact-interval finite-net uses, read the finite-net siblings through the compact-interval handoff already cited by the DyadicIntervalNet routes. The same endpoint arithmetic, tolerance readback, retained dyadic cells, and terminal seal remain visible before any finite-net conclusion is public.

Thus both consumer paths preserve the L10 finite-cover route. Since neither path adds a coordinate for open-cover compactness, selected subcovers, countable choice, quotient stream equality, host Real equality, or ambient Real completeness, the DyadicIntervalNet packet remains a finite dependency edge for compactness consumers. □

Theorem 5966.22 (Dyadic interval net uniform-modulus refinement route)**.** *Every* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *mesh-refinement read consumed by* $\mathsf{CompactIntervalUniformModulus}^{\uparrow}$ *or* $\mathsf{FiniteEpsilonNetUniformModulus}^{\uparrow}$ *must first pass through the finite route*

$$D, J, E \longmapsto S, R \longmapsto Q, H, C, P, N$$

of the accepted carrier $I = (D, J, E, S, R, Q, H, C, P, N)$*. The mesh-refinement induction, the* $\mathsf{RegSeqRat}^{\uparrow}$ *route, and the* $\mathsf{StreamName}^{\uparrow}$ *handoff therefore expose dyadic endpoint arithmetic, listed interval cells, endpoint incidence, finite observation windows, regular rational readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming before any uniform-modulus ledger is read.*

Proof. Start with the mesh-refinement induction of Definition 5966.4. It keeps every refined finite cell inside the displayed rows D, J, E and preserves the downstream route through S, R, Q, H, C, P, N at each finite refinement depth.

Next apply the $\mathsf{RegSeqRat}^{\uparrow}$ route of Definition 5966.11 and the $\mathsf{StreamName}^{\uparrow}$ handoff of Definition 5966.12. These rows force endpoint observations through S and rational tolerance readback through R before the terminal Real seal Q is opened.

Now read the consumer rows of chapter 6207 and chapter 8269. A compact-interval or finite-epsilon-net uniform-modulus consumer receives only the routed dyadic packet, so its ledger is downstream of the displayed sequence $D, J, E \longmapsto S, R \longmapsto Q, H, C, P, N$.

The route has no coordinate for open-cover compactness, selected subcovers, quotient stream equality, countable choice, trichotomy, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Thus every uniform-modulus read remains a finite dyadic interval-net refinement read before the modulus ledger is consumed. □

Theorem 5966.23 (Dyadic interval net compact-uniform-continuity forward route)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *packet first reads the dyadic endpoint arithmetic, finite interval cells, endpoint incidence,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal before it folds the finite-net data into a uniform continuity ledger. The route passes through chapter 9237, chapter 6207, and chapter 8269 as a finite cover-refinement handoff, not as open-cover compactness, selected subcovers, quotient stream equality, or countable-choice schedules.*

Proof. Project the accepted $\mathsf{DyadicIntervalNet}^{\uparrow}$ carrier $I = (D, J, E, S, R, Q, H, C, P, N)$. Its cover-refinement rows are the dyadic endpoint arithmetic D, the listed interval cells J, and the endpoint-incidence row E.

Apply the uniform-modulus refinement route Definition 5966.22. It keeps the finite cells on the route

$$D, J, E \longmapsto S, R \longmapsto Q, H, C, P, N$$

before any compact-interval or finite-epsilon-net uniform-modulus consumer can read the packet.

Now read the compact-uniform-continuity capstone and the sibling modulus chapters. The vision site supplies the finite-net fold being consumed, while the two sibling concrete chapters supply the compact-interval and finite-epsilon-net uniform-modulus targets for that fold.

Since the route contains no coordinate for arbitrary open covers, selected subcovers, quotient stream equality, countable-choice schedules, or ambient Real completeness, every compact-uniform-continuity read remains the displayed finite dyadic interval-net handoff. □

Theorem 5966.24 (Dyadic interval net compact interval forward route)**.** *Every compact-interval or closed-bounded-interval consumer of an accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *packet must first read the finite cell row, endpoint incidence,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint arithmetic,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal before compact interval or uniform-modulus rows are public. In particular, consumers routed to chapter 6207 or chapter 1250 receive the interval net only as the displayed finite handoff*

$$D, J, E \longmapsto S, R \longmapsto Q.$$

The route exports no open-cover compactness theorem, selected finite subcover, quotient stream equality, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 5966.1. The finite cell row and endpoint incidence are the rows J, E, while the endpoint arithmetic is read from the $\mathsf{DyadicRatCore}^{\uparrow}$ row D.

Use the cover refinement theorem Definition 5966.2. It places every cover-facing read through the finite cell and endpoint rows before any Real or Completion consumer can inspect the terminal seal.

Next use the StreamName and RegSeqRat handoff of Definition 5966.12. The window row S and regular rational row R are forced between the finite interval-net rows and any compact-interval consumer.

Finally replay the Real-seal nonescape theorem Definition 5966.13. The seal Q remains downstream of D, J, E, S, R, so the compact interval and uniform-modulus routes receive only the finite dyadic handoff and not a host compactness or choice principle. □

The $\mathsf{DyadicIntervalNet}^{\uparrow}$ packet supplies the finite cell route consumed by chapter 8657 and by compact-interval finite-cover consumers. The downstream read receives listed dyadic cells, endpoint incidence, dyadic tolerance rows, StreamName windows, RegSeqRat readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal as displayed packet data, not as open-cover compactness, selected subcovers, countable choice, quotient stream equality, or ambient real completeness.

Theorem 5966.25 (Dyadic interval net compactness forward reference)**.** *The* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *packet is consumed by the finite interval-net compactness route of chapter 8657 through dyadic endpoint rows, finite interval cells,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. In carrier notation, every such compactness-facing read first exposes the dyadic endpoint arithmetic D, the finite cell row J, and endpoint incidence E, then passes through the window and readback rows S, R, and only then reaches the Real seal Q and the structural rows H, C, P, N.*

Proof. Project the carrier of Definition 5966.1. The dyadic endpoint row D, finite interval-cell row J, and endpoint-incidence row E are the only rows that can feed the compactness consumer.

The compactness chapter chapter 8657 reads those rows as finite interval-net data. Its consumer route therefore receives cell coverage from the displayed dyadic rows, not from an ambient open-cover compactness principle.

The analytic readback remains downstream. Endpoint observations are exposed through S, regular rational tolerances are read through R, and the Real-facing boundary is sealed only at Q.

Finally the structural rows H, C, P, N transport, replay, source, and name the same packet. Thus the forward reference records a substantive child route from $\mathsf{DyadicIntervalNet}^{\uparrow}$ to its compactness consumer without adding selected subcovers, countable choice, quotient streams, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5966.26 (Dyadic interval net subdivision closed-bounded route)**.** *Every accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier*

$$I = (D, J, E, S, R, Q, H, C, P, N)$$

used by an interval-lattice consumer factors through the dyadic cell rows of Definition 5966.2, the subdivision carrier of chapter 7480, and the closed-bounded interval net rows of chapter 1250. The route sends D, J, E *to the subdivision scale, grid, and coverage rows, then sends the resulting finite cells to the closed-bounded interval mesh before* S, R, Q *are read. It exports only displayed dyadic cells, subdivision rows, finite mesh coverage, StreamName windows, RegSeqRat readback, and the Real seal; it exports no open-cover compactness theorem, selected finite subcover, quotient stream equality, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the local carrier and cover-refinement rows. The rows D, J, E display dyadic endpoint arithmetic, the listed interval cells, and endpoint incidence, so every interval-net read starts as a finite cell read.

Next pass through dyadic interval subdivision. The subdivision chapter reads closed interval endpoints, dyadic scale, grid rows, cell coverage, and mesh bounds as displayed finite rows. Therefore a lattice consumer can refine J, E only by exposing those subdivision rows, not by invoking an ambient cover or hidden grid selector.

Now attach the closed-bounded interval net. Its carrier reads the located endpoint, mesh, rational and dyadic cell, center, and coverage rows before any Real-facing handoff is public, so the interval net becomes part of the closed-bounded finite mesh route.

Finally read S, R, Q, H, C, P, N. The StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows preserve the same finite route. Since none of the three carriers contains an open-cover compactness, selected-subcover, quotient-stream, countable-choice, host-equality, or ambient-completeness coordinate, the lattice route cannot export one. □

Theorem 5966.27 (Dyadic interval net finite-net sibling dependency route)**.** *Every* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *finite interval-net refinement consumed by a downstream compact or Real-facing route first displays the sibling rows*

$$\mathsf{FiniteLebesgueNumber}^{\uparrow}, \quad \mathsf{CompactMetric}^{\uparrow} \text{ or } \mathsf{CompactInterval}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The finite Lebesgue-number row supplies the mesh threshold, the compact-metric or compact-interval row supplies the bounded interval source, the dyadic row supplies endpoint and radius arithmetic, and the terminal Real row supplies only the seal reached after the finite cells have been listed. Thus the route links chapter 452, chapter 129, the compact-interval surface of chapter 3986, chapter 291, and chapter 38 without exporting an open-cover compactness theorem, selected subcover, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the interval-net carrier through the routed chapter body. Its finite cells are already listed before any Real-facing read is available, so a downstream consumer starts from the displayed mesh threshold and compact source rows.

The dyadic arithmetic row then fixes the endpoint and radius checks for each listed cell. This keeps refinement a finite ledger computation rather than an appeal to a host open-cover compactness principle.

Only after those rows have been displayed may the consumer reach the terminal Real seal. Transport, replay, provenance, and local naming preserve that same finite route, excluding selected subcovers, quotient equality, choice, and ambient completeness. □

Theorem 5966.28 (DyadicIntervalNet finite closed-interval nested-intersection route)**.** *Every* $\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *packet must inspect the finite interval-cell refinement rows before it reaches terminal* $\mathsf{Real}^{\uparrow}$ *seals. The route passes through the local DyadicIntervalNet carrier of chapter 5966 and then through the finite closed-interval nested-intersection packet of chapter 8584; it exports no selected intersection point, quotient real equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the DyadicIntervalNet carrier of Definition 5966.1. The rows D, J, E display dyadic endpoint arithmetic, finite cells, and endpoint incidence before any StreamName, RegSeqRat, or Real-facing seal is visible.

Apply the finite closed-interval nested-intersection carrier of Definition 8584.1. Its cell row reads the same interval-net data before bounded-sequence or nested-intersection consumers receive a Real-facing handoff.

Thus the downstream nested-intersection route is a consumer of displayed finite cell refinement, not a source of completed intersections, selected points, quotient equality, choice, or ambient completeness. □

Every $\mathsf{DyadicIntervalNet}^{\uparrow}$ packet reads the dyadic interval basis of chapter 1916, the finite epsilon-net surface of chapter 1767, and the dyadic rational core of chapter 291 before compactness or Real-completion consumers inspect the mesh. This route keeps the interval cells, finite covering rows, and endpoint arithmetic visible before any downstream compactness, Cauchy, or $\mathsf{Real}^{\uparrow}$ seal argument treats the net as a completed object.

Theorem 5966.29 (Dyadic interval net basis route)**.** *Every accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *read first consumes the dyadic interval basis, finite epsilon-net, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows before any compactness or Real-completion consumer reads the mesh.*

Proof. Project the mesh route through chapter 1916. The interval basis supplies the displayed cells, and chapter 1767 supplies the finite net rows over those cells.

The endpoint and width comparisons are then read through chapter 291. Only after these three sibling rows are visible can a compactness or Real-completion consumer inspect the mesh as a net. □

Theorem 5966.30 (DyadicIntervalNet forward lattice route)**.** *Every compactness, finite-net, or Real-completion consumer of an accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier must expose* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius arithmetic, the listed interval-cell row, endpoint incidence,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before reading compactness or completion rows. The forward lattice is therefore the displayed route*

$$D, J, E \longmapsto S, R \longmapsto Q, H, C, P, N$$

of Definition 5966.1, not an open-cover compactness theorem, selected finite subcover, quotient stream equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the accepted carrier $I = (D, J, E, S, R, Q, H, C, P, N)$ of Definition 5966.1. Endpoint arithmetic and radius comparisons live in D, the listed cells live in J, endpoint incidence lives in E, and the completion-facing rows are downstream in S, R, Q.

Apply the finite-mesh Real-completion route and compact interval forward route, Definition 5966.36 and Definition 5966.24. They force mesh, compact-interval, and completion consumers to display finite cells, endpoint arithmetic, StreamName windows, RegSeqRat readback, and the terminal Real seal in that order.

Apply the regular-Cauchy Real forward route and finite-net sibling dependency route, Definition 5966.34 and Definition 5966.27. These routes keep regular-Cauchy, finite-net, and compactness consumers on the same dyadic endpoint, finite-cell, window, readback, and Real-seal lattice.

Finally replay H, C, P, N. Componentwise transport, continuation replay, provenance, and local naming preserve the finite lattice route and provide no coordinate for open-cover compactness, selected subcovers, quotient stream equality, countable choice, or ambient Real completeness. □

The finite interval-net surface of $\mathsf{DyadicIntervalNet}^{\uparrow}$ is read before the finite coverage consumer of chapter 1767 and the endpoint-radius consumer of chapter 1709. The interval cells D, J, E expose dyadic endpoints and adjacency first; only then may a downstream finite epsilon-net package read centers, tolerances, and coverage rows, or a located real interval package read endpoint, radius, locator, and metric-bracket rows.

Theorem 5966.31 (Dyadic interval net finite-epsilon located-interval dependency)**.** *Every finite-epsilon-net or located-real-interval consumer of an accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *carrier*

$$I = (D, J, E, S, R, Q, H, C, P, N)$$

must read the finite interval-net route

$$D, J, E \longmapsto S, R \longmapsto Q, H, C, P, N$$

before exposing interval coverage, center coverage, or endpoint-radius locatedness. Thus chapter 1767 receives a finite cell surface rather than a host finite subset, and chapter 1709 receives displayed endpoint-radius data rather than host interval equality.

Proof. Project the accepted carrier. The rows D, J, E are the only dyadic interval-net cells, endpoint incidences, and bracketing data available to any consumer.

The finite epsilon-net consumer can therefore read centers and coverage only after the interval cells have been displayed. Its coverage row is downstream of the same finite dyadic route, so it cannot replace the interval net by a host finite subset or selected open-cover proof.

The located real interval consumer is similarly downstream. It may read endpoints, radii, locators, and metric brackets only after the dyadic endpoint and incidence rows have supplied the displayed interval cells.

Finally S, R, Q, H, C, P, N preserve the route through StreamName windows, rational readback, the terminal Real seal, transport, replay, provenance, and local naming. No host interval equality, arbitrary open cover, selected subcover, countable choice, or ambient completeness row is exported. □

$\mathsf{DyadicIntervalNet}^{\uparrow}$ is consumed by chapter 8657 through finite subdivision-depth coverage and endpoint incidence rows. The compactness packet therefore reads the finite net before it exports any interval-cover handoff, and it does not introduce open-cover compactness, selected subcovers, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Theorem 5966.32 (Dyadic interval net finite-density consumer route)**.** *Every completion-facing consumer that reads a* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *packet as finite dyadic cell data may pass that read to* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *only after the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows have been exposed. The handoff cites the finite density packet of chapter 6003 only through dyadic cell incidence, stream windows, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming.*

Proof. Project the dyadic interval-net hub through its L10 sibling routes. The dyadic cells and endpoint incidence are read first through the $\mathsf{DyadicRatCore}^{\uparrow}$ rows, so the consumer has no immediate completion-facing density claim.

The route then exposes the $\mathsf{StreamName}^{\uparrow}$ finite-window row and the $\mathsf{RegSeqRat}^{\uparrow}$ readback row. These rows are the visible bridge from finite dyadic cells to regular rational observations, and they match the stream and readback requirements used by chapter 6003.

Only after those rows are displayed may the consumer read a terminal $\mathsf{Real}^{\uparrow}$ seal and hand the packet to $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$. The same hsame transport, Cont replay, Pkg provenance, and local NameCert rows preserve the displayed route, so no quotient stream, selected representative, ambient completeness theorem, or unrecorded density selector is exported by the dyadic interval net itself. □

The compactness-facing route for $\mathsf{DyadicIntervalNet}^{\uparrow}$ is read by two finite-net siblings before interval compactness consumers inspect a finite subcover ledger. The finite dyadic cells, endpoint incidence rows, and mesh witnesses of the local packet feed the finite-cover carrier of chapter 3471; the same rows are then consumed by the net-compactness packet of chapter 4031 before closed-interval or compact-metric consumers read the retained finite-subcover data.

This dependency is a displayed compactness route, not an ambient open-cover theorem. It keeps the dyadic cell list, finite mesh, Heine–Borel finite-net carrier, Heine–Borel net-compactness carrier, and downstream finite subcover ledger visible as NameCert rows, while refusing selected subcovers, quotient interval equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness. The $\mathsf{DyadicIntervalNet}^{\uparrow}$ finite-net route supplies the finite dyadic endpoints, listed cells, endpoint incidence, and mesh witnesses that a finite-net consumer can read before any compact-interval boundary is exposed. The same route then hands those rows to chapter 3471 for finite-net coverage and to chapter 6207 for compact-interval modulus control. The dependency is horizontal and finite: it records how the dyadic net packet feeds those sibling consumers, and it does not claim open-cover compactness, selected subcovers, quotient interval equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

The displayed endpoint, radius, and cell-incidence rows are also the finite-net surface consumed by chapter 1250; both the closed-bounded interval and compact-interval uniform-modulus routes receive listed dyadic cells, not open-cover compactness.

Theorem 5966.33 (DyadicIntervalNet forward dependency route)**.** *Every* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *finite-cell route consumed by compact interval, finite subcover modulus, or regular-real completion consumers first exposes* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint arithmetic,* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The forward dependency route therefore factors through chapter 291, chapter 126, chapter 301, and chapter 38 before any compactness, finite-subcover, or completion-facing consumer can treat the finite interval net as public.*

Proof. Project the accepted carrier of Definition 5966.1. Its finite-cell data is not public on its own; the endpoint arithmetic is read through the $\mathsf{DyadicRatCore}^{\uparrow}$ row, while endpoint windows and tolerance readback are routed through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$.

Use the existing sibling dependency and compact interval routes for $\mathsf{DyadicIntervalNet}^{\uparrow}$. They place compact interval and finite-subcover consumers downstream of the displayed finite cells, endpoint arithmetic, stream windows, and regular-rational readback.

Finally apply the terminal Real-seal discipline of the same packet. Since the $\mathsf{Real}^{\uparrow}$ seal remains downstream of those rows, regular-real completion consumers receive only the displayed forward dependency route and cannot replace it with an ambient compactness theorem, selected finite subcover, quotient stream equality, host real endpoint, or unrestricted completion principle. □

Theorem 5966.34 (DyadicIntervalNet regular-Cauchy Real forward route)**.** *Every* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *consumer that exports interval windows toward regular-Cauchy or Real-completion routes must first pass through chapter 301, chapter 126, and chapter 38 before any terminal* $\mathsf{Real}^{\uparrow}$ *read is available.*

Proof. Project the accepted carrier of Definition 5966.1. The finite dyadic interval cells expose endpoint and radius data, but they do not by themselves license a regular-Cauchy or Real-facing read.

For completion-facing consumers, route the endpoint windows through the $\mathsf{StreamName}^{\uparrow}$ schedule and the regular rational readback through $\mathsf{RegSeqRat}^{\uparrow}$. Only after those two sibling rows have been displayed may the terminal $\mathsf{Real}^{\uparrow}$ seal be read.

Thus every such consumer factors through the StreamName, RegSeqRat, and Real chapters named above. The route supplies no ambient compactness theorem, selected limit, quotient stream equality, host real endpoint, or unrestricted completion principle. □

Theorem 5966.35 (DyadicIntervalNet regular-Cauchy consumer route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *completion-facing consumer that reads a* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *surface must first expose the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint arithmetic,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows attached to the interval-net packet. The dyadic interval cells therefore enter regular-Cauchy and Real-name consumers only through the finite route named by chapter 291, chapter 126, chapter 301, and chapter 38.*

Proof. Project the accepted $\mathsf{DyadicIntervalNet}^{\uparrow}$ carrier. Its public surface is finite dyadic cell incidence, so endpoint arithmetic is read first through the $\mathsf{DyadicRatCore}^{\uparrow}$ row rather than through host real endpoints.

The same consumer route also serves the finite sign-change bisection path of chapter 3359. The $\mathsf{DyadicIntervalNet}^{\uparrow}$ packet supplies the displayed dyadic cells, while $\mathsf{RealBolzano}^{\uparrow}$ supplies the opposed sign-change row, midpoint read, retained bracket, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal ordering needed by that bisection surface.

The completion-facing read then opens the $\mathsf{StreamName}^{\uparrow}$ finite windows and the $\mathsf{RegSeqRat}^{\uparrow}$ regular-rational readback. These rows are the only route by which the interval cells become regular-Cauchy data for a downstream consumer.

The terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of that readback. Componentwise hsame transport and displayed Cont replay preserve the same finite rows, while Pkg provenance and local NameCert name the packet.

Thus a regular-Cauchy or Real-facing consumer receives the interval-net surface only after the listed rows have been displayed. The route exports no selected limit, quotient stream equality, countable-choice schedule, host real endpoint, ambient completeness theorem, or detached interval-net object. □

Theorem 5966.36 (DyadicIntervalNet finite-mesh Real-completion route)**.** *Every* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *consumer that routes interval cells into finite dyadic mesh and Real-completion data reads the following displayed rows:*

1. *the* $\mathsf{FiniteDyadicMesh}^{\uparrow}$ *mesh row that groups the dyadic interval cells into a finite subdivision;*
2. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row that records endpoint, radius, and containment comparisons;*
3. *the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the displayed mesh request;*
4. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows;*

5. the terminal $\mathsf{Real}^{\uparrow}$ *seal row available only after the preceding rows have been displayed.*

No such consumer may replace these rows by open-cover compactness, a selected limit, quotient stream equality, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted $\mathsf{DyadicIntervalNet}^{\uparrow}$ carrier. Its cells provide finite dyadic interval data, but a Real-completion consumer still needs an explicit mesh row and dyadic arithmetic ledger before a stream window can be opened.

Read the $\mathsf{FiniteDyadicMesh}^{\uparrow}$ row as the finite subdivision surface and the $\mathsf{DyadicRatCore}^{\uparrow}$ row as the endpoint and containment ledger. These rows determine the finite window request sent to $\mathsf{StreamName}^{\uparrow}$.

The $\mathsf{RegSeqRat}^{\uparrow}$ row reads back exactly those windows, and the terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of that readback. The listed rows exhaust the consumer route because the carrier supplies no coordinate for the excluded principles. □

Theorem 5966.37 (DyadicIntervalNet Real-completion route)**.** *Every* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *packet consumed by a Real or regular-Cauchy completion route must expose the finite dyadic interval cells,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint arithmetic,* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before the consumer reads completion data. Thus the dyadic interval net supplies the finite mesh route consumed by chapter 301 and chapter 38, with the same finite-cell discipline used by chapter 6207.*

Proof. Project the accepted $\mathsf{DyadicIntervalNet}^{\uparrow}$ carrier. Its finite cells and endpoint incidences are displayed first, and the endpoint arithmetic is read through $\mathsf{DyadicRatCore}^{\uparrow}$ rather than through host real equality.

The displayed cells open finite $\mathsf{StreamName}^{\uparrow}$ endpoint windows. Those windows are then read as $\mathsf{RegSeqRat}^{\uparrow}$ data, so a completion-facing consumer receives rational tolerance information before any terminal real seal is visible.

Only after this route has exposed cells, dyadic arithmetic, stream windows, regular-rational readback, and the $\mathsf{Real}^{\uparrow}$ seal may the consumer read completion data. The route exports no selected limit, quotient stream equality, countable-choice schedule, host real endpoint, or ambient completeness theorem. □

Theorem 5966.38 (DyadicIntervalNet finite-mesh extraction)**.** *Every* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *finite mesh consumed by a* $\mathsf{RegularCauchySequence}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *completion route factors through the displayed chain*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The extraction first reads dyadic endpoint and containment arithmetic, then opens the finite StreamName windows induced by the mesh, then reads those windows as regular rational data, and finally exposes the terminal Real seal through the existing finite-mesh Real-completion route of Definition 5966.36. It exports no selected limit, quotient stream equality, host real equality, open-cover compactness, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the finite mesh Real-completion route Definition 5966.36. It already places the finite dyadic mesh row, $\mathsf{DyadicRatCore}^{\uparrow}$ arithmetic row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal in the required order.

Now read the regular-Cauchy forward route of Definition 5966.34. A $\mathsf{RegularCauchySequence}^{\uparrow}$ consumer may inspect interval windows only after they have been scheduled as StreamName windows and read back as regular rational data.

Combining the two routes makes finite mesh extraction a displayed dyadic, stream, regular-rational, and Real-seal handoff. Since neither route contains selected limits, quotient stream equality, host real equality, open-cover compactness, countable choice, or ambient completeness as carrier rows, the extraction cannot export those coordinates. □

Theorem 5966.39 (DyadicIntervalNet CauchyFilterSubsequence route)**.** *Every* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *consumer that exports finite dyadic interval windows toward* $\mathsf{CauchyFilterSubsequence}^{\uparrow}$ *must expose the dyadic endpoint and radius cells before the route reaches chapter 8749. The visible handoff factors through the existing* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback before the Cauchy-filter subsequence packet may consume those windows.*

Proof. Project the accepted carrier of Definition 5966.1. The finite net gives only displayed dyadic cells, endpoint comparisons, and radius budgets; it does not by itself select a subsequence or a filter limit.

Route those cells through the dyadic tolerance arithmetic, then through the StreamName schedule and RegSeqRat readback already used by the regular-Cauchy Real forward route. These rows are exactly the visible windows required by chapter 8749.

Thus the Cauchy-filter subsequence consumer receives finite dyadic net windows as displayed BEDC rows. The route exports no hidden subsequence selector, quotient stream equality, countable choice, host interval endpoint, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5966.40 (DyadicIntervalNet BishopCauchyDisplayCertificate route)**.** *Every* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *consumer feeding a* $\mathsf{BishopCauchyDisplayCertificate}^{\uparrow}$ *route must expose the finite dyadic interval-net rows before the display certificate may read* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *seal rows. In carrier notation, the interval-net rows* D, J, E *are displayed first, the endpoint windows and regular readback pass through* S, R*, and only then may the Bishop Cauchy display certificate consume the Real-facing seal* Q *together with the structural rows* H, C, P, N*.*

Proof. Project the accepted carrier of Definition 5966.1. The rows D, J, E are the finite interval-net data: dyadic endpoint arithmetic, the listed cells, and endpoint incidence.

Route those rows into the display-certificate surface of chapter 5151. Its Cauchy display reads finite windows, regular rational readback, dyadic tolerances, and a terminal Real seal, so the interval-net source must first make the finite cells and endpoint bounds visible.

The downstream read therefore passes through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ only after the finite dyadic interval net has been displayed. The route exports no selected limit, quotient stream equality, countable choice, host endpoint equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5966.41 (DyadicIntervalNet RealInterval endpoint route)**.** *Every* $\mathsf{RealInterval}^{\uparrow}$ *endpoint-and-enclosure consumer of an accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *packet must expose the dyadic endpoint row, finite interval-cell row, endpoint incidence row,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and terminal* $\mathsf{Real}^{\uparrow}$ *seal before reading the interval enclosure of chapter 4111. In carrier notation, the read begins with the displayed dyadic net rows* D, J, E*, passes through the window and readback rows* S, R*, reaches the seal row* Q*, and only then may a RealInterval consumer inspect its endpoint-and-enclosure packet.*

Proof. Project the accepted carrier of Definition 5966.1. The dyadic endpoint row D, finite interval-cell row J, and endpoint-incidence row E are the only rows that can provide endpoint and enclosure evidence to a downstream interval consumer.

Apply the Real source link of Definition 5966.14. It requires Real-facing finite-net consumers to read D, J, E, S, R, Q in displayed order before handing the packet to interval or compactness consumers.

Now route the handoff to chapter 4111. Its endpoint-and-enclosure read consumes the same StreamName windows, RegSeqRat readback, and terminal Real seal as interval data, so the Real-Interval packet receives the dyadic net only after D, J, E, S, R, Q have been exposed.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same finite route, excluding selected subcovers, quotient stream equality, host endpoint equality, countable-choice schedules, trichotomy, and ambient $\mathsf{Real}^{\uparrow}$ completeness. □

The $\mathsf{DyadicIntervalNet}^{\uparrow}$ prime forward route exposes a horizontal L10 dependency before arithmetic or Real-facing consumers inspect interval cells: dyadic endpoint and radius arithmetic comes from chapter 291, finite observation windows come from chapter 126, regular rational readback comes from chapter 301, and the terminal seal comes from chapter 38. Thus a prime-window or compact-interval consumer reads a finite dyadic interval net only after those displayed sibling rows are visible, not as an ambient compactness principle or host Real-completion object. The $\mathsf{DyadicIntervalNet}^{\uparrow}$ hub routes finite interval-cell readers through the L10 lattice before compact interval or completion consumers inspect a cell. The dependency first exposes $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint arithmetic from chapter 291, then $\mathsf{StreamName}^{\uparrow}$ finite windows from chapter 126, then $\mathsf{RegSeqRat}^{\uparrow}$ readback from chapter 301, and finally the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. Compact interval and completion-facing consumers therefore read finite interval cells only after those sibling rows are visible, not as ambient compactness, selected limits, quotient interval equality, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness.

Theorem 5966.42 (DyadicIntervalNet sibling anchor)**.** *Every accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *consumer that supplies finite interval-net data must first expose the finite epsilon-net rows of chapter 1767 and the located endpoint rows of chapter 394. The dyadic interval-net packet therefore consumes finite center-radius coverage data together with located interval endpoint evidence before any L10 finite-net consumer may read it as interval-net coverage.*

Proof. Read the finite epsilon-net sibling first. Its rows supply the displayed finite family, radius ledger, and coverage request that a dyadic interval net later specializes to interval cells.

Next read the located interval sibling. Its endpoint rows provide the located lower and upper boundary data needed before a dyadic interval cell can be treated as an interval row rather than a bare dyadic token.

Finally combine the two routes through the local $\mathsf{DyadicIntervalNet}^{\uparrow}$ NameCert rows. The resulting consumer receives finite epsilon-net coverage and located interval endpoint evidence as explicit inputs, and it receives no host compactness theorem, selected subcover, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate. □

Theorem 5966.43 (DyadicIntervalNet interval-arithmetic sibling route)**.** *Every* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *consumer that uses interval arithmetic must expose the* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$*,* $\mathsf{FiniteCover}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal rows before treating the net as a cover witness. The accepted read is the displayed net route together with those sibling rows; it is not a host interval algorithm, a detached finite-cover proof, or an ambient real-completeness claim.*

Proof. Start with the displayed $\mathsf{DyadicIntervalNet}^{\uparrow}$ carrier. Its mesh and endpoint rows provide finite dyadic interval data, but they do not by themselves certify arithmetic closure or real-cover consumption.

Next read the sibling arithmetic route. The $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the rational tolerance ledger, and the $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ row supplies the endpoint-operation surface needed before interval calculations can be consumed.

Finally attach the cover and real-seal rows. The $\mathsf{FiniteCover}^{\uparrow}$ row records the finite cover witness, while the $\mathsf{Real}^{\uparrow}$ seals keep the completed-real boundary visible. Thus an interval-arithmetic consumer receives exactly the displayed net plus its arithmetic, cover, and real-seal siblings. □

Theorem 5966.44 (DyadicIntervalNet interval-exchange dependency route)**.** *Every future* $\mathsf{IntervalExchange}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *packet must first read the dyadic endpoint arithmetic of chapter 291, the finite dyadic interval cells and endpoint-incidence rows of this chapter, the* $\mathsf{StreamName}^{\uparrow}$ *endpoint windows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance and readback rows of chapter 301, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38. Only after that route is displayed may the consumer interpret the finite partition as an interval exchange surface. The dependency exports no invariant measure, minimality claim, unique-ergodicity claim, host interval function, quotient real equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the accepted carrier $I = (D, J, E, S, R, Q, H, C, P, N)$ of Definition 5966.1. The endpoint arithmetic row D and the interval-cell rows J, E are the only finite partition data available before any Real-facing read.

Apply the cover refinement theorem Definition 5966.2. It forces every partition consumer to expose listed dyadic cells, endpoint incidence, and dyadic comparisons before opening StreamName, RegSeqRat, or Real rows.

The interval-exchange consumer then reads the same L10 route used by Real and completion consumers. Endpoint observations pass through S, tolerance and rational readback pass through R, and the terminal real-name boundary is available only at Q.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve that finite dependency route, so an interval-exchange surface cannot import invariant-measure, minimality, host-function, quotient-equality, choice, or ambient-completeness data from the dyadic net. □

The $\mathsf{DyadicIntervalNet}^{\uparrow}$ route reads dyadic mesh cells through chapter 291 and exports finite interval mesh data to the $\mathsf{Real}^{\uparrow}$-facing route of chapter 38. This is a finite net dependency, not compactness, open-cover completeness, or an ambient completeness principle for intervals.

Chapter 5967

Channel Termination Budget Certificate NameCert Construction

The $\mathsf{ChannelTerminationBudgetCertificate}^{\uparrow}$ packet realizes the local channel terminator and global halting-boundary separation of chapter 9369 as finite budget-certificate NameCert data. It sits beside the existing channel boundary packet of chapter 3996, the termination refusal packet of chapter 1197, the certificate compiler surface of chapter 473, and the bounded checker-budget surface of chapter 5949. The packet names a local event-delimiter budget and a refusal ledger for global certificate-level halting; it does not export a total halting classifier, an unbounded parser oracle, a host machine semantics theorem, proof-irrelevant equality, or a standard bridge.

Definition 5967.1 (Channel termination budget-certificate carrier)**.** *A* $\mathsf{ChannelTerminationBudgetCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A, L, Z, F, G, R, H, C, P, N)$$

with the following rows:

1. *A is the active channel alphabet row. It records the binary source glyphs, the body fragments* 0 *and* 10*, and the displayed terminator* 11*.*
2. *L is the legal-event row. It records that a channel event lies in* $(0 \mid 10)^*11$ *and exposes the finite body fragments inspected before the terminator.*
3. *Z is the streaming scan budget row. It lists the finite positions inspected by the decoder until the first channel-level* 11 *is reached.*
4. *F is the local finish row. It certifies that the first displayed* 11 *ends the current legal event and that the body before it decodes to a source event.*
5. *G is the global-halting refusal row. It records that the finite local finish row is not a total classifier for arbitrary* Cont_P*-chains.*
6. *R is the sibling route row through the channel boundary, termination refusal, certificate compiler, and bounded checker-budget packets.*
7. *H records componentwise* hsame *transport for* A, L, Z, F, G, R *and the structural rows.*
8. *C records displayed* Cont *replay of the finite route*

$$A, L, Z \longmapsto F, G, R \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* ChannelTerminationBudgetCertificate$^{\uparrow}$, ChannelTerminationHaltingBoundary$^{\uparrow}$, TerminationRefusalBoundary$^{\uparrow}$, CertificateCompiler$^{\uparrow}$, BoundedTypecheckingBudget$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ChannelTerminationBudgetCertificate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, L, Z, F, G, R, H, C, P, N$. It has no coordinate for global halting decidability, an unbounded parser oracle, fuel-erased evaluation, host machine equality, proof irrelevance, or a bridge field.

Theorem 5967.2 (Channel termination budget-certificate local-global boundary)**.** *For every accepted* ChannelTerminationBudgetCertificate$^{\uparrow}$ *carrier $B = (A, L, Z, F, G, R, H, C, P, N)$, a local channel-event read is certified by the finite route*

$$A, L, Z \longmapsto F$$

while any attempted promotion to certificate-level halting must keep the refusal row G and sibling route row R in scope. Consequently the packet proves only that a legal channel event has a budgeted delimiter endpoint; it does not decide whether an arbitrary $\mathsf{NameCert}_P$ *and history h produce a terminating* Cont_P*-chain.*

Proof. Project the local channel route first. The alphabet row A names the fragments and terminator, L confirms that the inspected event is legal, and Z supplies the finite scan positions leading to the first channel-level 11.

The local finish row F is then read. It certifies the delimiter endpoint for the current event and the body decode before that endpoint, matching the local termination theorem of chapter 9369.

The global boundary is separate. Row G records that this finite delimiter budget is not a total classifier over arbitrary certificate histories, and R routes that refusal through the channel-boundary, termination-refusal, compiler, and bounded-budget sibling packets.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same separation, so no consumer may erase G and read the local delimiter certificate as a global halting decision. □

Falsifiable prediction: A claimed ChannelTerminationBudgetCertificate$^{\uparrow}$ consumer that exports a total certificate-level halting classifier while omitting the global-halting refusal row G and sibling route row R refutes the carrier of Definition 5967.1.

Independence witness: channel-termination-halting-boundary, terminationrefusalboundary, certificatecompiler, bounded-typechecking-budget: ChannelTerminationBudgetCertificate$^{\uparrow}$ is not bijective to any listed sibling because it carries the joint active alphabet, legal-event, finite scan-budget, local finish, global-halting refusal, sibling route, transport, replay, provenance, and local NameCert rows. The channel-boundary sibling separates event and halting strata without the explicit scan-budget certificate; the termination-refusal sibling records refusal visibility without the local delimiter budget; the certificate compiler sibling records compiler graph rows without the channel endpoint budget; the bounded checker-budget sibling records typechecking fuel without the channel terminator route.

Closure status for $\mathsf{NameCert}_{\mathsf{ChannelTerminationBudgetCertificate}^{\uparrow}}$.

Constructive story: A ChannelTerminationBudgetCertificate$^{\uparrow}$ packet is generated from an active channel alphabet row, legal-event row, streaming scan-budget row, local finish row, global-halting refusal row, sibling route row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ChannelTerminationBudgetCertificate}^{\uparrow}}$, seed)

Scope closed: Definition 5967.1 and Definition 5967.2 seed the finite local-delimiter budget certificate and its global-halting refusal boundary.

Formal verification: FormalStatus(NameCert$_{\mathsf{ChannelTerminationBudgetCertificate}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global halting decidability, unbounded parser or evaluator totality, host machine semantics, proof-irrelevant equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, legal-event budget exactness, local finish correctness, global-halting refusal nonescape, sibling route coverage, provenance, and local naming for BEDC.Derived.ChannelTerminationBudgetCerti

Theorem 5967.3 (Channel termination budget-certificate dossier forward link)**.** *Every accepted* $\mathsf{ChannelTerminationBudgetCertificate}^{\uparrow}$ *packet forwards its local delimiter budget and global-halting refusal rows to the sibling surfaces chapter 3996, chapter 1197, chapter 473, and chapter 5949. The forward link reads exactly the rows*

$$A, L, Z, F, G, R, H, C, P, N$$

from Definition 5967.1: A, L, Z, F *certify the local channel delimiter budget,* G *preserves the refusal of global certificate-level halting,* R *exposes the sibling route, and* H, C, P, N *transport, replay, source, and locally name the same dossier.*

Proof. Project the accepted carrier of Definition 5967.1. The rows A, L, Z display the active alphabet, legal-event row, and finite scan budget, while F records the local delimiter endpoint.

Apply Definition 5967.2. It keeps the global-halting refusal row G and sibling route row R in scope whenever a consumer tries to read the local delimiter budget as certificate-level halting data.

Read the sibling route. The row R points to the channel termination halting boundary, termination refusal boundary, certificate compiler, and bounded typechecking budget surfaces, and the rows H, C, P, N preserve that same finite dossier by componentwise transport, displayed replay, provenance, and local naming.

Thus every accepted packet forwards the delimiter and refusal data to the stated sibling surfaces without adding a total halting classifier, unbounded parser oracle, host machine semantics theorem, proof-irrelevant equality, or bridge field. □

The local delimiter budget of $\mathsf{ChannelTerminationBudgetCertificate}^{\uparrow}$ is consumed through chapter 3996, chapter 1197, chapter 473, and chapter 5949. This route records local channel termination together with refusal of global halting; it is not a total halting classifier.

Chapter 5968

A Concrete Naming Certificate for $\mathsf{CadlagRealFunction}^{\uparrow}$

Following Skorokhod and Billingsley on right-continuous paths with left limits, the $\mathsf{CadlagRealFunction}^{\uparrow}$ packet records a real-valued path through finite window data, one-sided regulated fragments, and displayed jump-boundary rows. It sits after the regulated-function interface of chapter 1906, the bounded regulated envelope of chapter 5853, the finite observation schedule of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The certificate exposes a path-space boundary for stochastic-process and Skorokhod-topology consumers without importing selected limits, quotient path equality, measure-theoretic sample spaces, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5968.1 (Cadlag real function carrier)**.** *A* $\mathsf{CadlagRealFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, B, S, R, D, J, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row, exposing finite one-sided regulated windows on the displayed real-domain schedule.*
2. *B is the* $\mathsf{BoundedRegulatedFunction}^{\uparrow}$ *envelope row available on each bounded window requested by a consumer.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule used to name right-hand windows and left-hand approach windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational observations of the displayed windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling window radius, jump comparison, and real-name readback precision.*
6. *J is the cadlag boundary row. It records right-continuity and left-limit availability only as finite window obligations tied to S, R, D.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the regulated source, bounded-window envelope, stream schedule, rational readback, tolerance ledger, and cadlag boundary row have been displayed.*
8. *H records componentwise* hsame *transport for the source, bounded envelope, stream schedule, rational readback, tolerance, cadlag boundary, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a path-window request through $F, B, S, R, D, J, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CadlagRealFunction}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{BoundedRegulatedFunction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CadlagRealFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, B, S, R, D, J, E, H, C, P, N$. It has no coordinate for selected limits, quotient path equality, measure-theoretic sample spaces, trichotomy, host path equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CadlagRealFunctionUp.CadlagRealFunctionTasteGate single carrier alignment`

Theorem 5968.2 (Cadlag real function NameCert obligations)**.** *For every accepted* $\mathsf{CadlagRealFunction}^{\uparrow}$ *carrier $K = (F, B, S, R, D, J, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CadlagRealFunction}^{\uparrow}}$ *surface consists exactly of carrier admission, regulated-source admission, bounded-window envelope admission, finite stream-window exposure, regular rational readback, dyadic tolerance control, right-continuity window obligation, left-limit window obligation, terminal real-seal nonescape, componentwise transport, displayed replay, package provenance, local naming, and ledger refusal for selected limits, quotient path equality, measure-theoretic sample spaces, trichotomy, host path equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The rows F, B, S, R, D, J, E are the only analytic rows before transport, replay, provenance, and local naming are read.

The regulated-source and bounded-window obligations are supplied by the sibling $\mathsf{RegulatedFunction}^{\uparrow}$ and $\mathsf{BoundedRegulatedFunction}^{\uparrow}$ rows. The stream schedule S, rational readback R, and dyadic ledger D provide the finite data on which the cadlag boundary row J can state right-continuity and left-limit obligations.

The terminal seal E is downstream of these rows. Componentwise transport and displayed replay preserve the same finite route, and the provenance and naming rows record it as the local certificate surface.

Since no carrier coordinate stores selected limits, quotient path equality, measure-theoretic sample spaces, trichotomy, host path equality, or ambient real completeness, none of those objects can become a local NameCert obligation. □

Theorem 5968.3 (Cadlag real function regulated-window handoff)**.** *Every path-window consumer of an accepted* $\mathsf{CadlagRealFunction}^{\uparrow}$ *carrier must read the* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row, the* $\mathsf{BoundedRegulatedFunction}^{\uparrow}$ *bounded-window envelope, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger before the cadlag boundary row can export a terminal* $\mathsf{Real}^{\uparrow}$ *seal. The handoff is therefore a finite regulated-window route, not a selected path limit, quotient path equality, measure-theoretic sample-space construction, trichotomy decision, or ambient completeness proof.*

Proof. Let $K = (F, B, S, R, D, J, E, H, C, P, N)$ be accepted. A path-window request first reaches the regulated source row F, then the bounded-window envelope B, then the stream schedule S, rational readback R, and dyadic tolerance ledger D.

Only after those rows are displayed can the cadlag boundary row J be consumed. The row J records right-continuity and left-limit availability as finite window obligations tied to the already displayed schedule and tolerance data.

The terminal $\mathsf{Real}^{\uparrow}$ seal E is downstream of J, and transport through H and replay through C keep the same route visible to downstream consumers. Provenance P and local naming N then certify the route as a $\mathsf{CadlagRealFunction}^{\uparrow}$ packet.

Because selected limits, quotient path equality, measure-theoretic sample spaces, trichotomy, host path equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier coordinates, no consumer can obtain them through the regulated-window handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CadlagRealFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{CadlagRealFunction}^{\uparrow}$ packet is generated from a RegulatedFunction source row, BoundedRegulatedFunction window envelope, StreamName finite schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, cadlag boundary row, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CadlagRealFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5968.1, Definition 5968.2, and Definition 5968.3 seed the finite right-continuous-with-left-limits path route over regulated windows and terminal Real-facing seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CadlagRealFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient path equality, measure-theoretic sample spaces, trichotomy, host path equality, Lean verification, bridge checking, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, regulated-source admission, bounded-window envelope admission, stream-window exposure, rational readback, dyadic tolerance control, cadlag boundary obligations, transport, replay, provenance, and local naming for BEDC.Derived.CadlagRealFunctionUp.

Chapter 5969

A Concrete Naming Certificate for $\mathsf{AlmostPeriodic}^{\uparrow}$

Following Bohr and Besicovitch on almost periodic functions, read through Bishop–Bridges constructive analysis, the $\mathsf{AlmostPeriodic}^{\uparrow}$ packet records relative-density translation data for displayed real-valued function windows as finite BEDC rows. It sits beside the compact-source sup-norm ledger of chapter 3807, the modulus-composition route of chapter 3784, the Dini finite-window route of chapter 5154, the compact-uniform-continuity packet of chapter 388, and the terminal real-name surface of chapter 38. The packet names only finite translation ledgers and displayed sup-norm comparisons; it does not assert host function equality, an infinite hull compactification, Bohr compactification, quotient function-space equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5969.1 (AlmostPeriodic carrier)**.** *An* $\mathsf{AlmostPeriodic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (F, T, N_{\mathrm{rel}}, S, M, U, H, C, P, N)$$

with the following displayed rows:

1. *F is the function-window row, listing the finite source windows and* $\mathsf{Real}^{\uparrow}$*-valued observations of the displayed function.*
2. *T is the translation-budget row, naming the finite translation requests, tolerance budgets, and admissible translated windows.*
3. *N_{rel} is the relatively-dense finite-net row, recording the bounded search interval and the finite list of candidate translations exposed to a consumer.*
4. *S is the sup-norm comparison row, read through the* $\mathsf{ContinuousSupNorm}^{\uparrow}$ *surface and comparing each translated window only by displayed Real-sealed bounds.*
5. *M is the uniform-modulus row, assembled through* $\mathsf{UniformModulusComposition}^{\uparrow}$ *and the compact-uniform-continuity route before any translated read reaches S.*
6. *U is the Dini and compact-uniform handoff row, recording the finite monotone-window and compact-continuity evidence consumed from* $\mathsf{DiniUniformMonotone}^{\uparrow}$ *and* $\mathsf{CompactUniformContinuity}^{\uparrow}$.
7. *H records componentwise* hsame *transport for function windows, translation budgets, relatively-dense nets, sup-norm comparisons, uniform moduli, sibling handoffs, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay from a tolerance request through* $F, T, N_{\mathrm{rel}}, S, M, U, H, P, N$.
9. *P is the* Pkg *provenance over* $\mathsf{AlmostPeriodic}^{\uparrow}$, $\mathsf{ContinuousSupNorm}^{\uparrow}$, $\mathsf{UniformModulusComposition}^{\uparrow}$, $\mathsf{DiniUniformMonotone}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AlmostPeriodic}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, T, N_{\mathrm{rel}}, S, M, U, H, C, P, N$. *It has no coordinate for host-level equality of functions, an infinite translation hull, quotient function spaces, choice-selected periods, open-cover compactness, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.AlmostPeriodicUp.AlmostPeriodicTasteGate single carrier alignment`

Theorem 5969.2 (AlmostPeriodic NameCert obligations)**.** *For every accepted* $\mathsf{AlmostPeriodic}^{\uparrow}$ *carrier* $A = (F, T, N_{\mathrm{rel}}, S, M, U, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{AlmostPeriodic}^{\uparrow}}$ *surface consists exactly of function-window admission, translation-budget accounting, relatively-dense finite-net exposure, sup-norm comparison through displayed Real-sealed bounds, uniform-modulus routing, Dini and compact-uniform sibling handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 5969.1. The function rows, translation rows, relatively-dense net, sup-norm comparison, uniform-modulus handoff, and sibling rows are the only mathematical coordinates before transport, replay, provenance, and naming.

The translation read is finite. A tolerance request first enters T, then opens only the candidates listed in N_{rel}, and then compares translated windows through S.

The comparison is real-facing but not host-functional. The row S reads $\mathsf{ContinuousSupNorm}^{\uparrow}$ and terminal $\mathsf{Real}^{\uparrow}$ seals, while M and U route modulus evidence through chapter 3784, chapter 5154, and chapter 388.

Rows H, C, P, N transport, replay, source, and name exactly the same finite route. Since no excluded hull, quotient, host equality, choice-selected period, compactness, or completeness coordinate appears in the carrier, the listed rows exhaust the NameCert surface. □

Theorem 5969.3 (AlmostPeriodic sup-norm translation stability)**.** *Every accepted* $\mathsf{AlmostPeriodic}^{\uparrow}$ *packet exposes a translation-stability read only through the finite route*

$$F, T, N_{\mathrm{rel}} \longrightarrow M, U \longrightarrow S \longrightarrow H, C, P, N.$$

Thus a consumer may read a translated function window, a displayed translation budget, a relatively-dense finite-net candidate, a uniform-modulus handoff, and a sup-norm comparison row, but it may not replace this route by host equality of functions, an infinite period hull, quotient function-space equality, a choice-selected translation, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the accepted carrier. Rows F, T, N_{rel} determine which function windows and translation candidates can be inspected for the requested tolerance.

The modulus rows are downstream of that inspection. The uniform-modulus composition and Dini or compact-uniform handoff rows M, U must be replayed before a sup-norm comparison is visible.

The comparison row S is the only route to the Real-sealed sup-norm bound. The structural rows H, C, P, N preserve that finite route under transport and replay, so no host function equality, infinite hull, quotient equality, choice-selected translation, compactness principle, or Real completeness theorem is exported. □

Theorem 5969.4 (AlmostPeriodic ledger nonescape)**.** *Every* $\mathsf{AlmostPeriodic}^{\uparrow}$ *consumer read is generated by the rows named in Definition 5969.1. In particular, the packet exports no Bohr compactification, no completed translation hull, no host equality of functions, no quotient function-space equality, no choice-selected period, no open-cover compactness, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project an accepted carrier. Function-window reads pass through F, translation reads pass through T, relatively-dense candidate reads pass through N_{rel}, and every comparison read passes through S after the modulus rows M, U have been replayed.

Transport and replay preserve only those displayed rows. Provenance and local naming record the same packet and do not add analytic coordinates.

The excluded objects are absent from the carrier. They therefore cannot be obtained by projection, componentwise hsame transport, displayed Cont replay, package provenance, or local naming. □

Closure status for $\mathsf{NameCert}_{\mathsf{AlmostPeriodic}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AlmostPeriodic}^{\uparrow}$ packet is generated from function-window rows, translation-budget rows, relatively-dense finite-net rows, sup-norm comparison rows, uniform-modulus rows, Dini and compact-uniform handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlmostPeriodic}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5969.1, Definition 5969.2, Definition 5969.3, and Definition 5969.4 seed the finite almost-periodic translation ledger over displayed sup-norm and uniform-modulus rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlmostPeriodic}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host function equality, infinite translation hull compactness, Bohr compactification, quotient function-space equality, choice-selected periods, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, translation-budget accounting, relatively-dense finite-net exposure, sup-norm comparison stability, uniform-modulus routing, sibling handoff, transport stability, and ledger non-escape for BEDC.Derived.AlmostPeriodicUp.

Chapter 5970

A Concrete Naming Certificate for MetaCICResidualJoinDeterminacy$^{\uparrow}$

The MetaCICResidualJoinDeterminacy$^{\uparrow}$ packet realizes the residual-substitution boundary of chapter 9378 as finite local-join data. It sits beside the confluence-budget witness of chapter 5174, the residual-substitution compatibility boundary of chapter 4370, the local-diamond witness of chapter 3595, the residual envelope of chapter 3921, and the closed parallel-diamond premise ledger of chapter 2325. It names a budgeted local join packet for residual branches; it does not claim full Church–Rosser, unguarded substitution compatibility, global strong normalization, subject reduction, or host reduction semantics.

Definition 5970.1 (MetaCIC residual-join determinacy carrier)**.** *A* MetaCICResidualJoinDeterminacy$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (T, R, B, K, E, S, L, D, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed residual-window row, naming the closed MetaCIC source, the two residual branches, and the inspected redex-frontier fragments.*
2. *R is the residual-budget row, read from the confluence-budget witness and bounding residual addresses, replay fuel, and candidate-join search.*
3. *B is the bounded local-join row, recording the candidate common reduct accepted inside the displayed residual budget.*
4. *K is the determinacy row, requiring any accepted candidate for the same displayed residual branch data to be compared through the same budgeted row B.*
5. *E is the residual-envelope row, preserving the residual branches and the local envelope in which the bounded join is inspected.*
6. *S is the residual-substitution boundary row, recording that substitution compatibility is a guarded input shape, not an unguarded theorem.*
7. *L is the closed-premise ledger row consumed when closed local-diamond evidence is read.*
8. *D is the local-diamond witness row for the displayed peak and its bounded join.*
9. *O is the obstruction row retaining the refusal of full Church–Rosser, full parallel diamond, arbitrary residual substitution compatibility, subject reduction, and host semantics.*

10. *H records componentwise* hsame *transport for typed windows, residual budgets, bounded joins, determinacy rows, envelopes, substitution boundaries, closed-premise ledgers, local diamonds, obstruction rows, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from a residual-join request through $T, R, B, K, E, S, L, D, O, H, P, N$.*
12. *P is the* Pkg *provenance over* MetaCICResidualJoinDeterminacy$^{\uparrow}$, MetaCICConfluenceBudgetWitness$^{\uparrow}$, MetaCICResidualSubstitutionCompatibility$^{\uparrow}$, MetaCICLocalDiamondWitness$^{\uparrow}$, MetaCICConfluenceResidualEnvelope ClosedParallelDiamondPremiseLedger$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{MetaCICResidualJoinDeterminacy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, B, K, E, S, L, D, O, H, C, P, N$. It has no coordinate for full parallel diamond, arbitrary closed Church–Rosser, unguarded substitution compatibility, global strong normalization, subject reduction, or host reduction semantics.

Theorem 5970.2 (MetaCIC residual-join determinacy NameCert obligations)**.** *For every accepted* MetaCICResidualJoinDeterminacy$^{\uparrow}$ *carrier $J = (T, R, B, K, E, S, L, D, O, H, C, P, N)$, the local* NameCert$_{\text{MetaCICResidualJoinDeterminacy}^{\uparrow}}$ *surface consists exactly of typed residual-window admission, residual-budget accounting, bounded local-join exposure, candidate determinacy inside the displayed budget, residual-envelope handoff, guarded residual-substitution boundary visibility, closed-premise ledger handoff, local-diamond handoff, obstruction retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 5970.1. The displayed mathematical rows are $T, R, B, K, E, S, L, D, O$, followed by the structural rows H, C, P, N.

The local join is budgeted before it is deterministic. Rows T and R first bind the residual window and the residual budget; row B then records only the candidate common reduct accepted inside that budget.

The determinacy row K compares accepted candidates for the same displayed residual data through B. It does not supply a global confluence theorem or an unguarded substitution compatibility theorem.

Rows E, S, L, D, O keep the sibling handoffs and the obstruction boundary visible. Rows H, C, P, N transport, replay, source, and name the same finite route, so the listed rows exhaust the local NameCert surface. □

Theorem 5970.3 (MetaCIC residual-join determinacy budgeted local join)**.** *Every accepted* MetaCICResidualJoinD *packet exposes a local join only through the finite route*

$$T, R \longrightarrow B, K \longrightarrow E, S, L, D, O \longrightarrow H, C, P, N.$$

The route may compare bounded candidate joins for the same displayed residual branch data, but it cannot be read as full parallel diamond, arbitrary closed Church–Rosser, unguarded substitution compatibility, global strong normalization, subject reduction, or host reduction semantics.

Proof. Start with the typed residual window T and the residual budget R. These rows determine which branch data and which candidate addresses can be inspected.

The bounded join row B is downstream of that budget, and the determinacy row K compares only candidates accepted for the same displayed data. Thus determinacy is local to the packet.

The envelope, substitution-boundary, closed-premise, local-diamond, and obstruction rows remain visible after the local comparison. The structural rows preserve this finite route without adding endpoint claims. □

Theorem 5970.4 (MetaCIC residual-join determinacy boundary)**.** *Every confluence-facing consumer of* $\mathsf{MetaCICResidualJoinDeterminacy}^{\uparrow}$ *receives only a budgeted residual-local join packet. In particular, the consumer must keep the residual-substitution compatibility row S as a guarded boundary and the obstruction row O as a visible refusal of full Church–Rosser, full parallel diamond, unguarded substitution compatibility, subject reduction, global strong normalization, and host reduction semantics.*

Proof. Read the carrier and apply Definition 5970.3. The route exposes typed residual windows, a residual budget, bounded candidate joins, and local determinacy before any sibling handoff is consumed.

The substitution boundary is not discharged by this packet. It is stored as row S, while the obstruction row O records the endpoint claims that remain unavailable to the consumer.

Transport, replay, provenance, and naming preserve the displayed rows only. Hence the consumer obtains a finite residual-local join boundary, not an endpoint confluence theorem. □

Falsifiable prediction: A $\mathsf{MetaCICResidualJoinDeterminacy}^{\uparrow}$ packet that omits the residual-budget row R, the bounded local-join row B, the guarded residual-substitution boundary row S, or the obstruction row O is rejected even if it carries typed residual windows and local-diamond evidence.

Independence witness: metacic-confluence-budget-witness, metacic-residual-substitution-compatibility, metacic-local-diamond-witness, metacic-confluence-residual-envelope, closed-parallel-diamond-premise-ledger: $\mathsf{MetaCICResidualJoinDeterminacy}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds typed residual windows, residual budgets, bounded local joins, determinacy rows, residual envelopes, guarded substitution-boundary rows, closed-premise ledgers, local-diamond evidence, obstruction retention, transport, replay, provenance, and local NameCert data.

The Lean-side hardening surface requires future Nontrivial and FieldFaithful instances for the residual-join determinacy packet. The nontrivial witness separates an accepted packet with displayed residual-budget, bounded-join, guarded-boundary, and obstruction rows from a refused packet missing one of those rows; field faithfulness compares $T, R, B, K, E, S, L, D, O, H, C, P, N$ componentwise so that equal displayed fields are indistinguishable to the local NameCert classifier.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinDeterminacy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MetaCICResidualJoinDeterminacy}^{\uparrow}$ packet is generated from typed residual-window rows, residual-budget rows, bounded local-join rows, determinacy rows, residual-envelope rows, guarded residual-substitution boundary rows, closed-premise ledger rows, local-diamond rows, obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinDeterminacy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5970.1, Definition 5970.2, Definition 5970.3, and Definition 5970.4 seed the finite residual-local join determinacy boundary for MetaCIC confluence consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinDeterminacy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full parallel diamond, arbitrary closed Church–Rosser, unguarded substitution compatibility, subject reduction, global strong normalization, host reduction semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual-budget accounting, bounded local-join exposure, candidate determinacy, residual-envelope handoff, guarded substitution-boundary visibility, local-diamond handoff, obstruction retention, and Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.MetaCICResidualJoinDeterminacyUp.

Chapter 5971

A Concrete Naming Certificate for $\mathsf{BrownianBridge}^{\uparrow}$

Following Doob's treatment of Brownian bridge conditioning, the $\mathsf{BrownianBridge}^{\uparrow}$ packet records the finite BEDC route by which a Brownian path segment is conditioned to meet a displayed endpoint without importing a host conditional-law object. It sits between the Brownian motion carrier of chapter 191, the transition-row discipline of chapter 189, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives stochastic-process consumers one named bridge-conditioning route before a filtration, regular conditional probability, quotient path law, selected endpoint representative, or ambient Gaussian process theorem is available.

Definition 5971.1 (BrownianBridge carrier)**.** *A* $\mathsf{BrownianBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (W, T, E, K, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{Brownian}^{\uparrow}$ *source row, exposing only the finite path-window and step-difference data read by the bridge.*
2. *T is the displayed time-window row, including the initial time, terminal time, and inspected intermediate time coordinates.*
3. *E is the endpoint row, carrying the terminal* $\mathsf{Real}^{\uparrow}$ *target value and the endpoint observation window to which the path is conditioned.*
4. *K is the Markov-transition conditioning row, read through the adjacent finite transition surface of* $\mathsf{MarkovChain}^{\uparrow}$ *rather than through a host conditional distribution.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selecting path observations, endpoint windows, and conditioning requests.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row for the displayed bridge values, time gaps, and endpoint comparisons.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by stochastic-process or completion-facing consumers after S and Q have been displayed.*
8. *H stores componentwise* hsame *transport for Brownian source, time, endpoint, transition, stream, regular, Real seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from a bridge-conditioning request through the same finite rows.*
10. *P is the* Pkg *provenance over* $\mathsf{BrownianBridge}^{\uparrow}$, $\mathsf{Brownian}^{\uparrow}$, $\mathsf{MarkovChain}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BrownianBridge}^{\uparrow}}$ *row.*

The classifier compares accepted bridge packets only through these rows. It has no coordinate for a host Brownian bridge process, a filtration, a regular conditional probability, quotient path equality, selected path representative, Gaussian density theorem, or ambient stochastic-process completion.

Lean4 ✓ `BEDC.Derived.BrownianBridgeUp.BrownianBridgeTasteGate single carrier alignment`

Theorem 5971.2 (BrownianBridge NameCert obligations)**.** *For every accepted* $\mathsf{BrownianBridge}^{\uparrow}$ *carrier* $B = (W, T, E, K, S, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BrownianBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for the Brownian source, displayed time and endpoint rows, Markov-transition conditioning row, StreamName windows, RegSeqRat readback, Real seal, componentwise transport, displayed replay, provenance, and local naming. Every bridge-conditioning read is exhausted by those rows and exports no filtration, regular conditional probability, quotient path law, selected endpoint representative, or host Gaussian-process object.*

Proof. Project the carrier of Definition 5971.1. The visible rows are exactly $W, T, E, K, S, Q, R, H, C, P, N$, so any local certificate obligation must be read from one of those displayed coordinates.

The stochastic source is W, T, E, K. The Brownian row supplies the finite path-window data, the time and endpoint rows bind the bridge request, and the Markov-transition row records the conditioning surface without creating a separate host conditional-law object.

The numerical and structural reads are S, Q, R, H, C, P, N. StreamName windows and RegSeqRat readback expose finite observations before the Real seal is visible, while transport, replay, provenance, and local naming keep the same packet stable for downstream consumers. □

Theorem 5971.3 (BrownianBridge conditioning route)**.** *Every Brownian-path, Markov-transition, Real, or Completion consumer of an accepted* $\mathsf{BrownianBridge}^{\uparrow}$ *packet factors through the displayed route*

$$W, T, E \longmapsto K \longmapsto S, Q \longmapsto R, H, C, P, N.$$

Thus the bridge endpoint is read first as finite Brownian and time-window data, then through the Markov conditioning row, and only then through StreamName windows, regular rational readback, and the terminal Real seal.

Proof. Begin with the Brownian source and endpoint data. The rows W, T, E determine the inspected Brownian path windows, the time interval, and the terminal endpoint request; they do not yet expose a completed path law.

Next read the conditioning row K. This row is the only bridge-specific transition surface and is tied to the Markov-chain dependency of chapter 189, so a consumer cannot replace it by a regular conditional probability or a host filtration.

Finally pass through the numerical route. The StreamName row S and RegSeqRat row Q expose finite bridge observations and rational comparisons before the Real seal R is consumed, and H, C, P, N transport, replay, source, and name the same finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BrownianBridge}^{\uparrow}}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrownianBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5971.1, Definition 5971.2, and Definition 5971.3 seed the finite Brownian bridge route over Brownian source windows, time and endpoint rows, Markov conditioning, StreamName windows, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{BrownianBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, filtrations, regular conditional probabilities, quotient path laws, selected endpoint representatives, Gaussian density theorems, standard bridge checking, or ambient stochastic-process completion.

Upgrade path: Obligation closure requires checked carrier admission, Brownian source exposure, endpoint conditioning, Markov-transition routing, StreamName windows, RegSeqRat readback, Real sealing, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BrownianBridgeUp.

Constructive story: A BrownianBridge$^{\uparrow}$ packet is generated from Brownian source windows, displayed time and endpoint rows, a Markov-transition conditioning row, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5972

A Concrete Naming Certificate for $\mathsf{CauchyModulusFunctor}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyModulusFunctor}^{\uparrow}$ packet records the finite modulus-transport object used when a completion argument must move from dyadic tolerances and stream windows to regular rational readback and a terminal real-name seal. It sits between the dyadic rational core of chapter 291, the finite observation surface of chapter 126, the regular rational sequence packet of chapter 301, and the real-name seal of chapter 38. The packet is a finite carrier for modulus schedules, not a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 5972.1 (Cauchy modulus functor carrier)**.** *A* $\mathsf{CauchyModulusFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, S, R, E, A, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger naming the dyadic precision requests consumed by the modulus schedule.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row on which the schedule is inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows and dyadic tolerances.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, S, R have been displayed.*
5. *A is the admissible-modulus row, recording the finite assignment from requested precision to a displayed window bound.*
6. *T is the transport row, recording how the same assignment is reused by completion-facing consumers without asserting host function equality.*
7. *H records componentwise* hsame *transport for tolerance ledgers, windows, readbacks, Real seals, modulus assignments, transport rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a completion request through D, S, R, E, A, T, H.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusFunctor}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusFunctor}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient real equality, a selected limit, a global choice function, trichotomy, host function extensionality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusFunctorUp.CauchyModulusFunctorTasteGate single carrier alignment`

Theorem 5972.2 (Cauchy modulus functor NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusFunctor}^{\uparrow}$ *carrier* $M = (D, S, R, E, A, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusFunctor}^{\uparrow}}$ *surface consists exactly of dyadic tolerance admission through* D*, finite StreamName window admission through* S*, regular rational readback through* R*, terminal Real seal admission through* E*, admissible-modulus assignment through* A*, completion-facing transport through* T*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 5972.1. Its numeric source rows are D, S, R: dyadic precision requests, finite observation windows, and regular rational readbacks.

The Real-facing boundary is the seal row E. Since E is displayed only after D, S, R, the packet exports a finite handoff route and not a detached completeness principle.

The modulus data are A and T. Row A records the precision-to-window assignment, while T records the reuse route seen by completion consumers. Neither row asserts equality of host functions or selects a limiting real.

Finally H, C, P, N transport, replay, source, and name the same rows. Because the carrier contains no coordinate for quotient equality, selected limits, choice, trichotomy, host function extensionality, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Theorem 5972.3 (Cauchy modulus functor completion handoff)**.** *Every Real-and-Completion consumer that reads a* $\mathsf{CauchyModulusFunctor}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

through the displayed rows $D, S, R, E, A, T, H, C, P, N$*. The handoff may transport a modulus schedule into diagonal-limit or Real-seal arguments, but it does not provide Real completeness, quotient real equality, selected limits, countable choice, trichotomy, or host function extensionality.*

Proof. Use Definition 5972.2. The obligation theorem exposes the dyadic tolerance ledger, StreamName window, RegSeqRat readback, and Real seal as the ordered source of every accepted packet.

The completion-facing rows are then forced through A and T. They record the finite modulus assignment and its transport route, so a diagonal-limit consumer can reuse the same schedule without importing an unrecorded host function.

The structural rows H, C, P, N preserve and name exactly that route. Since no refused coordinate is present in the carrier, the handoff is the displayed finite modulus-transport object and not a proof of $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusFunctor}^{\uparrow}$ packet is generated from DyadicRatCore tolerance ledgers, StreamName windows, RegSeqRat readback rows, a RealUp seal, admissible modulus assignments, completion-facing transport, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyModulusFunctor}^{\uparrow}}$, seed)

Scope closed: Definition 5972.1, Definition 5972.2, and Definition 5972.3 seed the finite modulus-transport handoff from $\mathsf{DyadicRatCore}^{\uparrow}$ through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ to a terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyModulusFunctor}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Real completeness, quotient real equality, selected limits, countable choice, trichotomy, host function extensionality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exactness, StreamName window admission, RegSeqRat readback, Real seal nonescape, modulus assignment transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusFunctorUp.

Chapter 5973

A Concrete Naming Certificate for $\mathsf{FiniteModulusCompactUniformEquicontinuity}^{\uparrow}$

Following Bishop and Bridges on compact metric uniform continuity and equicontinuous families, the $\mathsf{FiniteModulusCompactUniformEquicontinuity}^{\uparrow}$ packet records the finite-modulus route from compact source nets to one family-level uniform equicontinuity ledger. It realizes the compact-uniform-continuity pressure of chapter 9237 over the compact metric source of chapter 129, continuous-map observations from chapter 130, metric distance rows from chapter 57, finite observation windows from chapter 126, regular rational readback from chapter 301, and the terminal real-name seal of chapter 38. The packet exposes finite moduli and compact-net rows only; it does not import open-cover compactness, selected subcovers, host function equality, quotient map equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5973.1 (FiniteModulusCompactUniformEquicontinuity carrier)**.** *A* FiniteModulusCompactUniformEqui *carrier is a finite* BHist *packet*

$$E = (K, F, M, U, D, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, carrying inspected centers, coverage radii, and located compact source data.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, exposing the displayed finite family observations used by the equicontinuity request.*
3. *M is the finite-modulus row assigning local source-distance budgets to the family observations at the compact-net centers.*
4. *U is the compact-uniform equicontinuity export row, giving one displayed uniform modulus for all members of the inspected family.*
5. *D is the* $\mathsf{Met}^{\uparrow}$ *distance row for source and target comparisons used by the finite-modulus test.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selecting compact-net centers, family observations, modulus requests, and distance reads.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for radii, distances, and modulus comparisons.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for compact-uniform consumers after S and Q have been displayed.*

9. *H records componentwise* hsame *transport for compact nets, continuous family rows, finite moduli, uniform export, metric distances, stream windows, regular readback, Real sealing, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from compact-net and family-modulus requests to the uniform equicontinuity export.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteModulusCompactUniformEquicontinuity}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusCompactUniformEquicontinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an open-cover proof, selected subcover, unrestricted host function equality, quotient map equality, countable choice, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.FiniteModulusCompactUniformEquicontinuityUp.FiniteModulusCompactUniformEquicontinu`
`single carrier alignment`

Theorem 5973.2 (FiniteModulusCompactUniformEquicontinuity NameCert obligations)**.** *For every accepted* $\mathsf{FiniteModulusCompactUniformEquicontinuity}^{\uparrow}$ *carrier* $E = (K, F, M, U, D, S, Q, R, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusCompactUniformEquicontinuity}^{\uparrow}}$ *surface consists exactly of compact finite-net admission through K, continuous-family observations through F, finite-modulus control through M, compact-uniform export through U, metric-distance inspection through D, StreamName windows, RegSeqRat readback, Real sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5973.1. The compact source row K, family row F, finite-modulus row M, export row U, and metric row D are the only mathematical coordinates available to the local certificate.

The numerical route is finite. Rows S and Q display the selected observation windows and rational comparisons before R seals the Real-facing distance reads.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no row for open covers, selected subcovers, host function equality, quotient map equality, countable choice, or ambient Real completeness, none of those objects is part of the obligation surface. □

Theorem 5973.3 (Finite-modulus compact-uniform equicontinuity route)**.** *Every compact-uniform or Arzela–Ascoli consumer of an accepted* $\mathsf{FiniteModulusCompactUniformEquicontinuity}^{\uparrow}$ *packet factors through*

$$K, F, D \longmapsto M \longmapsto S, Q \longmapsto R, U \longmapsto H, C, P, N.$$

Thus the consumer reads compact finite nets, continuous family observations, and metric distances before the finite modulus is exported, and reaches the Real seal and uniform equicontinuity row only after StreamName windows and regular rational readback are visible.

Proof. Start with the compact source, family, and metric rows. The compact-net data in K, the continuous-family observations in F, and the distance comparisons in D determine the finite family-modulus requests.

Next read the finite-modulus row M. It is the only coordinate that binds the finitely many compact-net and family observations to a common source-distance budget, so it cannot be replaced by open-cover compactness or a selected subcover.

Finally pass through S, Q, R, U, H, C, P, N. StreamName windows and RegSeqRat readback expose the numerical comparisons before the Real seal and uniform export are consumed, and the structural rows keep the route inside the same finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteModulusCompactUniformEquicontinuity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteModulusCompactUniformEquicontinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5973.1, Definition 5973.2, and Definition 5973.3 seed the finite-modulus compact-uniform equicontinuity route over compact metric nets, continuous family observations, metric distances, StreamName windows, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteModulusCompactUniformEquicontinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, open-cover compactness, selected subcovers, host function equality, quotient map equality, countable choice, standard bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-net coverage, continuous-family observation, finite-modulus control, compact-uniform export, metric-distance inspection, StreamName windows, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformEquicontinuityUp.

Constructive story: A $\mathsf{FiniteModulusCompactUniformEquicontinuity}^{\uparrow}$ packet is generated from CompactMetric finite nets, ContinuousMap family observations, a finite modulus row, a compact-uniform equicontinuity export, Metric distance rows, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5974

A Concrete Naming Certificate for $\mathsf{RealCompletionBoundaryWitness}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealCompletionBoundaryWitness}^{\uparrow}$ packet records the finite boundary data used by a regular-sequence completion proof at the moment where diagonal-limit convergence and uniqueness are read back as a Real-facing handoff. It is anchored in the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet witnesses the boundary that a completion proof may consume; it does not assert a global completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 5974.1 (Real completion boundary witness carrier)**.** *A* $\mathsf{RealCompletionBoundaryWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (D, S, R, E, L, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the diagonal-limit comparison.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected prefixes of the source streams.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational sequence obtained from those windows.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row read only after D, S, R have been displayed.*
5. *L is the convergence-boundary row, recording the finite diagonal-limit evidence available to the completion proof.*
6. *U is the uniqueness-boundary row, recording the finite same-limit comparison available at the same boundary.*
7. *H records componentwise* hsame *transport for tolerance ledgers, windows, readbacks, Real seals, convergence boundary, uniqueness boundary, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a completion-boundary request through D, S, R, E, L, U, H.*
9. *P is the* Pkg *provenance over* $\mathsf{RealCompletionBoundaryWitness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionBoundaryWitness}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient completeness theorem, a quotient-real equality principle, countable choice, a selected representative stream, trichotomy, or host-level limit selection.

Lean4 (definition) `BEDC.Derived.RealCompletionBoundaryWitnessUp.RealCompletionBoundaryWitnessUp`
Lean4 ✓ `BEDC.Derived.RealCompletionBoundaryWitnessUp.RealCompletionBoundaryWitnessTasteGate`
`single carrier alignment`

Theorem 5974.2 (Real completion boundary witness NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionBoundaryWitness}^{\uparrow}$ *carrier* $W = (D, S, R, E, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealCompletionBoundaryW}}$ *obligations are exactly dyadic tolerance admission through* D*, finite StreamName window admission through* S*, RegSeqRat readback through* R*, Real seal admission through* E*, convergence-boundary display through* L*, uniqueness-boundary display through* U*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 5974.1. The source of the boundary is the finite triple D, S, R: dyadic tolerances, stream windows, and regular rational readback.

The Real-facing row E seals only that displayed readback. It therefore supplies a boundary handoff to $\mathsf{Real}^{\uparrow}$ without adding ambient completeness or quotient equality.

Rows L and U are the two boundary witnesses. The first records convergence evidence for the diagonal-limit route, and the second records the uniqueness comparison available at the same finite boundary.

Finally H, C, P, N preserve, replay, source, and name those rows. Since the carrier has no coordinate for completeness, quotient equality, choice, representative selection, trichotomy, or host-level limit selection, the listed obligations exhaust the certificate surface. □

Theorem 5974.3 (Real completion boundary witness seal handoff)**.** *Every completion proof that consumes a* $\mathsf{RealCompletionBoundaryWitness}^{\uparrow}$ *packet reads convergence and uniqueness only through the displayed route*

$$D, S, R, E, L, U, H, C, P, N.$$

In particular, the packet hands a diagonal-limit boundary to $\mathsf{Real}^{\uparrow}$ *consumers after the DyadicRatCore, StreamName, and RegSeqRat rows are displayed, and it refuses ambient Real completeness, quotient real equality, countable choice, selected representatives, trichotomy, and host-level limit selection.*

Proof. Apply Definition 5974.2. The theorem lists the only rows available to a consumer of the packet, with dyadic tolerance, StreamName window, and RegSeqRat readback preceding the Real seal.

The boundary rows L and U are then read under the same seal. They expose convergence and uniqueness evidence as finite carrier data rather than as an external completeness theorem.

The structural rows H, C, P, N keep this route invariant under transport, replay, provenance, and local naming. Because no refused coordinate occurs in the carrier, the seal handoff is exactly the displayed finite boundary route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionBoundaryWitness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealCompletionBoundaryWitness}^{\uparrow}$ packet is generated from DyadicRatCore tolerance ledgers, StreamName windows, RegSeqRat readback rows, a RealUp seal, convergence-boundary rows, uniqueness-boundary rows, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealCompletionBoundaryWitness}^{\uparrow}}$, seed)

Scope closed: Definition 5974.1, Definition 5974.2, and Definition 5974.3 seed the finite diagonal-limit convergence and uniqueness boundary consumed before a RealUp seal is read.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealCompletionBoundaryWitness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim ambient Real completeness, quotient real equality, countable choice, selected representative streams, trichotomy, host-level limit selection, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exactness, StreamName window admission, RegSeqRat readback, Real seal nonescape, convergence and uniqueness boundary exactness, replay, provenance, and local naming for BEDC.Derived.RealCompletionBoundaryWitnessUp.

Chapter 5975

A Concrete Naming Certificate for $\mathsf{RegularCauchyMeshGluing}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy approximation and finite common refinements, the $\mathsf{RegularCauchyMeshGluing}^{\uparrow}$ packet records the mesh-gluing route by which regular Cauchy mesh cofinality, finite Cauchy gluing budgets, and the cofinal modulus seal meet in one displayed NameCert surface. It is grounded in chapter 5839, chapter 1113, and chapter 1198. The packet supplies a finite common-refinement route for Real-completeness consumers without quotient streams, hidden subnets, selected limits, countable choice, host real equality, or ambient completeness.

Definition 5975.1 (Regular Cauchy mesh-gluing carrier)**.** *A* $\mathsf{RegularCauchyMeshGluing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, G, Q, B, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ *row exposing the cofinal finite mesh route.*
2. *G is the* $\mathsf{FiniteCauchyGluingBudget}^{\uparrow}$ *row exposing the finite gluing budget, synchronizer, and completion-seal route.*
3. *Q is the* $\mathsf{CofinalModulusSeal}^{\uparrow}$ *row that records the cofinal modulus seal reached by the shared route.*
4. *B is the common-refinement budget aligning the precision request, cofinal mesh depth, gluing synchronizer, and modulus-seal threshold.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the common budget.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row over those windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the readback.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, G, Q, B, S, R, D have been displayed.*
9. *H stores componentwise* hsame *transport for every displayed row.*
10. *C stores displayed* Cont *replay from the incoming precision request through*

$$M, G, Q \longmapsto B \longmapsto S, R, D \longmapsto E.$$

11. *P is the* Pkg *provenance over* RegularCauchyMeshGluing$^{\uparrow}$, RegularCauchyMeshCofinality$^{\uparrow}$, FiniteCauchyGluingBud CofinalModulusSeal$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{RegularCauchyMeshGluing}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, G, Q, B, S, R, D, E, H, C, P, N$. It has no coordinate for quotient streams, hidden subnets, selected limits, countable-choice schedules, host real equality, trichotomy, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.RegularCauchyMeshGluingUp.RegularCauchyMeshGluingTasteGate single carrier alignment`

Theorem 5975.2 (Regular Cauchy mesh-gluing NameCert obligations)**.** *For every accepted* RegularCauchyMeshGlu *carrier*

$$K = (M, G, Q, B, S, R, D, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyMeshGluing}^{\uparrow}}$ *surface consists exactly of carrier admission, cofinal mesh exposure through M, finite gluing-budget exposure through G, cofinal modulus-seal exposure through Q, common-refinement alignment through B, StreamName window exposure through S, RegSeqRat readback through R, DyadicRatCore tolerance visibility through D, terminal Real seal admission through E, transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 5975.1. The accepted packet displays exactly the mesh cofinality, gluing budget, cofinal modulus seal, common budget, windows, readback, tolerance, Real seal, transport, replay, provenance, and naming rows.

The three source rows M, G, Q are read before any Real-facing seal. The budget row B is the single meeting point for the mesh depth, gluing synchronizer, and modulus threshold.

Rows S, R, D, E are downstream of that budget, and H, C, P, N preserve and name the route. Since no additional coordinate exists, the listed rows exhaust the local NameCert surface. □

Theorem 5975.3 (Regular Cauchy mesh-gluing common-refinement handoff)**.** *Every Real-completeness or diagonal-limit consumer of an accepted* RegularCauchyMeshGluing$^{\uparrow}$ *carrier receives its seal-facing data only through the finite route*

$$M, G, Q \longmapsto B \longmapsto S, R, D \longmapsto E, H, C, P, N.$$

Thus the consumer must pass through mesh cofinality, finite Cauchy gluing, the cofinal modulus seal, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, and the RealUp seal before exporting a completion-facing conclusion.

Proof. Start from a Real-completeness consumer request. The carrier exposes no direct seal row until the continuation route has displayed M, G, Q.

The common budget B aligns the cofinal mesh, gluing synchronizer, and modulus-seal threshold. This forces the StreamName windows S, RegSeqRat readback R, and Dyadic tolerance row D to share the same finite refinement.

Only then can the Real seal E be read. Transport, replay, provenance, and local naming preserve the same route, while quotient streams, hidden subnets, selected limits, and choice-based completion objects are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMeshGluing}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMeshGluing}^{\uparrow}$ packet is generated from regular Cauchy mesh cofinality, a finite Cauchy gluing budget, a cofinal modulus seal row, a common-refinement budget, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, a RealUp seal, transport, replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshGluing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5975.1, Definition 5975.2, and Definition 5975.3 seed the finite common-refinement route from mesh cofinality and gluing budgets to the cofinal modulus seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshGluing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, hidden subnets, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal mesh exposure, finite gluing-budget exposure, cofinal modulus-seal exposure, common-refinement alignment, finite readback, tolerance visibility, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMeshGluingUp.

Chapter 5976

A Concrete Naming Certificate for $\mathsf{BrouwerSpreadBar}^{\uparrow}$

Following Brouwer and Bishop on spreads, bars, and finite choice-sequence observation, the $\mathsf{BrouwerSpreadBar}^{\uparrow}$ packet records the finite route by which an admitted spread prefix, a decidable bar row, and a lawless boundary read are handed to Real and Completion-facing consumers. It sits between the spread carrier of chapter 1677, the barred-spread induction surface of chapter 1675, and the finite observation boundary of chapter 1495. The packet names finite bar/spread data only; it does not select an infinite branch, assert countable choice, identify quotient stream tails, close fan compactness, or supply ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5976.1 (Brouwer spread-bar carrier)**.** *A* $\mathsf{BrouwerSpreadBar}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, B, R, L, W, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the accepted* $\mathsf{BrouwerSpread}^{\uparrow}$ *finite prefix row, including its decidable prefix-tree admission and StreamName scheduling.*
2. *B is the finite bar row over the prefixes displayed by S, with explicit* $\mathsf{Bool}^{\uparrow}$ *bar decisions and monotone extension checks.*
3. *R is the barred-spread replay row inherited from* $\mathsf{BrouwerBarInduction}^{\uparrow}$*, restricted to the finite children displayed in S.*
4. *L is the lawless boundary row. It records only finite observed prefixes and refuses a law selecting all future answers.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window opened by the common spread/bar/lawless route.*
6. *A is the analytic handoff row through* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal when a Real or Completion consumer reads the packet.*
7. *H stores componentwise* hsame *transport for the spread prefix, bar decision, induction replay, lawless boundary, window, analytic handoff, continuation, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a finite prefix request through*

$$S, B, R, L \longmapsto W \longmapsto A.$$

9. *P is the* Pkg *provenance over* $\mathsf{BrouwerSpreadBar}^{\uparrow}$, $\mathsf{BrouwerSpread}^{\uparrow}$, $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{LawlessSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerSpreadBar}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, R, L, W, A, H, C, P, N$. It has no coordinate for completed branches, countable-choice selectors, quotient stream equality, fan compactness, selected limits, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.BrouwerSpreadBarUp.BrouwerSpreadBarTasteGate single carrier alignment`

Theorem 5976.2 (Brouwer spread-bar NameCert obligations)**.** *For every accepted* $\mathsf{BrouwerSpreadBar}^{\uparrow}$ *carrier*

$$K = (S, B, R, L, W, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BrouwerSpreadBar}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed spread prefix, finite bar row, barred-spread replay, lawless boundary row, StreamName window, analytic handoff, transport, continuation, provenance, and local naming rows; classifier agreement on the same rows; and non-escape requiring every public read to factor through $S, B, R, L, W, A, H, C, P, N$.*

Proof. Carrier admission is the tuple of Definition 5976.1. The accepted packet exposes only the spread prefix, bar decision, barred-spread replay, lawless boundary, window, handoff, transport, continuation, provenance, and local naming rows.

Classifier agreement is therefore rowwise agreement over the same tuple. The spread component is read through chapter 1677, the bar replay through chapter 1675, and the lawless boundary through chapter 1495.

The non-escape clause follows from the absence of any additional coordinate. Since the carrier does not store a completed branch, a choice selector, quotient stream equality, compactness, selected limits, or ambient completeness, the listed rows exhaust the local certificate surface. □

Theorem 5976.3 (Brouwer spread-bar finite bar handoff)**.** *Every Real or Completion-facing read of an accepted* $\mathsf{BrouwerSpreadBar}^{\uparrow}$ *carrier must first display the finite route*

$$S, B, R, L \longmapsto W \longmapsto A, H, C, P, N.$$

Thus the consumer receives only a finite barred-prefix handoff from the spread row, bar row, barred-spread replay row, and lawless boundary row before any $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *seal is read.*

Proof. Start with a public read of the packet. The only route to the analytic handoff row A passes through the continuation row C.

Replay C. It first exposes the spread prefix S, then the finite bar decisions B, the barred-spread replay R, and the lawless boundary row L. Only after these rows are displayed can the read open the StreamName window W and the analytic handoff A.

Transport and provenance are supplied by H, P, N. Since the carrier lacks any branch-selection or quotient-stream coordinate, the handoff is exactly the finite route stated above. □

Theorem 5976.4 (Brouwer spread-bar lawless boundary)**.** *The lawless component of an accepted* $\mathsf{BrouwerSpreadBar}^{\uparrow}$ *carrier is boundary data for finite observations only. It may certify that the currently displayed prefixes meet the bar route, but it cannot be used to construct a law for all future values, a completed spread branch, a countable-choice schedule, or a Real-completeness witness.*

Proof. Read the lawless row L inside the carrier. By definition it contains only the finite observed prefixes already synchronized with the spread row S and bar row B.

Use the finite handoff theorem, Definition 5976.3. Every downstream read must pass from S, B, R, L to the finite StreamName and analytic rows before exporting a Real or Completion-facing conclusion.

The packet has no coordinate for a future-value law, completed branch, countable-choice schedule, or completeness witness. Therefore the lawless component is a finite boundary row and not a generator of the excluded data. □

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerSpreadBar}\uparrow}$.

Constructive story: A $\mathsf{BrouwerSpreadBar}^{\uparrow}$ packet is generated from a Brouwer spread finite prefix row, a finite bar row, barred-spread replay, a lawless finite-observation boundary, StreamName windows, analytic handoff rows, componentwise transport, displayed continuation replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrouwerSpreadBar}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5976.1, Definition 5976.2, Definition 5976.3, and Definition 5976.4 seed the finite spread-bar route from Brouwer spread prefixes and bar replay to lawless finite observations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrouwerSpreadBar}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed branches, countable choice, quotient stream equality, fan compactness, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier agreement, finite bar handoff, lawless-boundary nonescape, transport, continuation, provenance, and local naming for BEDC.Derived.BrouwerSpreadBarUp.

Chapter 5977

A Concrete Naming Certificate for $\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}$ packet records the finite stability surface needed when a located Cauchy completion proof is replayed through dyadic tolerances, stream windows, regular rational readback, locatedness evidence, and the terminal real seal. It is anchored in the DyadicRatCore ledger of chapter 291, the finite StreamName surface of chapter 126, the RegSeqRat readback of chapter 301, the LocatedReal observation row of chapter 1933, the terminal Real seal of chapter 38, and the located-real completion route of chapter 3488. The packet witnesses stability of displayed completion data; it does not introduce quotient streams, host limits, choice, trichotomy, or ambient completeness.

Definition 5977.1 (Bishop located Cauchy completion stability carrier)**.** *A* $\mathsf{BishopLocatedCauchyCompletionStabili}$ *carrier is a finite* BHist *packet*

$$Q = (D, S, R, L, E, T, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-window ledger naming the radii and comparison budgets used by the stability check.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected at those tolerances.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy readback row obtained from the same displayed windows.*
4. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *locatedness row attached to that readback.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, S, R, L have been displayed.*
6. *T records componentwise* hsame *transport for tolerance windows, stream windows, readback rows, locatedness rows, the Real seal, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from each stability request through D, S, R, L, E, T, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient-stream representatives, host-level limits, selected representatives, countable choice, trichotomy, apartness by host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.BishopLocatedCauchyCompletionStabilityUp.BishopLocatedCauchyCompletionStab`

Theorem 5977.2 (Bishop located Cauchy completion tolerance-window stability)**.** *For every accepted* $\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}$ *carrier* $Q = (D, S, R, L, E, T, C, P, N)$*, any replay of a completion request keeps the DyadicRatCore tolerance row* D *fixed before reading the StreamName window* S*, the RegSeqRat readback* R*, the LocatedReal row* L*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*.*

Proof. Project the carrier of Definition 5977.1. The first displayed analytic row is the tolerance ledger D, and every later analytic row is indexed by the same completion request.

Apply the located-real completion route of Definition 3488.3. It identifies the order D, S, R, L, E for displayed completion data.

The stability packet adds T, C, P, N only for transport, replay, provenance, and local naming. Since none of those rows contains a second tolerance ledger or a host limit selector, replay cannot change the tolerance window while preserving the same packet. □

Theorem 5977.3 (Bishop located Cauchy completion readback stability)**.** *For every accepted* $\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}$ *carrier* $Q = (D, S, R, L, E, T, C, P, N)$*, the regular Cauchy readback exposed to a completion consumer is the row* R *read from the displayed* D, S *window route. No consumer can replace* R *by a quotient-stream representative, selected host limit, or ambient equality witness while remaining inside the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}}$ *surface.*

Proof. Read D and S from the carrier and then the readback row R. These are finite rows of the same BHist packet.

Apply Definition 3488.5. The Bishop located-real completion chapter exposes its Cauchy representation only through D, S, R, L before the terminal seal.

The stability rows T, C, P, N preserve and replay that displayed readback. Because the carrier has no quotient-stream, selected-limit, or host-equality coordinate, replacing R by such data would change the packet rather than witnessing stability. □

Theorem 5977.4 (Bishop located Cauchy completion locatedness preservation)**.** *For every accepted* $\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}$ *carrier* $Q = (D, S, R, L, E, T, C, P, N)$*, locatedness is preserved only as the displayed row* L *attached to the same* D, S, R *readback route. A replay may transport* L *through* T *and* C*, but it cannot derive locatedness from trichotomy, host apartness, choice, or an external order-completeness principle.*

Proof. Project L from the carrier after the tolerance, window, and readback rows. The row is part of the same finite packet and is not a detached located-real object.

Apply Definition 3488.4. It forces every located-real completion consumer through D, S, R, L before the Real seal.

Rows T and C transport and replay that row, while P and N source and name it. The refused trichotomy, host apartness, choice, and external completeness objects are absent from the carrier, so they cannot supply locatedness inside the certificate. □

Theorem 5977.5 (Bishop located Cauchy completion Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}$ *packet factors through the finite route* $D, S, R, L, E, T, C, P, N$*. The seal exports stability of the displayed located Cauchy completion data, but it exports no quotient stream, selected host limit, host real equality test, countable-choice selector, trichotomy split, apartness shortcut, or ambient Real completeness theorem.*

Proof. Project the carrier and isolate the terminal seal row E. It occurs after the displayed tolerance, window, readback, and locatedness rows.

Apply Definition 3488.6. The underlying located-real completion seal cannot be read as quotient equality, selected host limits, choice, trichotomy, or ambient completeness.

The stability packet preserves the same seal through T, C, P, N. Since no refused object has a carrier coordinate, the exported $\mathsf{Real}^{\uparrow}$ row remains the finite stability seal for D, S, R, L. □

Theorem 5977.6 (Bishop located Cauchy completion transport replay provenance)**.** *For every accepted* $\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}$ *carrier* $Q = (D, S, R, L, E, T, C, P, N)$*, all stability claims are invariant only through the displayed transport row* T*, continuation replay row* C*, package provenance row* P*, and local naming row* N*. These rows preserve the finite route* D, S, R, L, E *and do not add analytic content beyond the displayed completion data.*

Proof. Project the structural rows T, C, P, N from the carrier. They are listed after the analytic rows and are therefore read as preservation, replay, provenance, and naming data for D, S, R, L, E.

Apply the preceding four stability theorems. Each one identifies the analytic route that must be preserved: fixed tolerances, regular readback, locatedness, and the terminal Real seal.

Thus T, C, P, N certify replay of the same finite route rather than a broader completion theorem. Any additional quotient, host-limit, choice, trichotomy, apartness, or ambient-completeness claim would require a carrier coordinate not present in Q. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}$ packet is generated from DyadicRatCore tolerance windows, StreamName finite windows, RegSeqRat regular Cauchy readback, LocatedReal locatedness rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5977.1, Definition 5977.2, Definition 5977.3, Definition 5977.4, Definition 5977.5, and Definition 5977.6 seed the finite stability route from displayed located Cauchy completion data to the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyCompletionStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient-stream completion, host-level limits, selected representatives, countable choice, trichotomy, host apartness, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-window stability, regular Cauchy readback stability, locatedness preservation, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedCauchyCompletionStabilityUp.

Chapter 5978

CauchyMatrixUp NameCert Construction

Following Bishop and Bridges, the $\mathsf{CauchyMatrix}^{\uparrow}$ packet records a two-index Cauchy matrix certificate for the L10 Real and Completion route. It sits after the dyadic tolerance core of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet names row and column regularity, diagonal extraction, transport, replay, provenance, and local naming as finite BHist data; it does not assert quotient equality of completed real names, select a limiting row, use countable choice, or invoke ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5978.1 (Cauchy matrix carrier)**.** *A* $\mathsf{CauchyMatrix}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R, C, W, D, Q, E, H, K, P, N)$$

with the following displayed rows:

1. *R is the row-regularity ledger, recording the finite row windows whose tails are read as regular rational Cauchy data.*
2. *C is the column-regularity ledger, recording the finite column windows whose tails satisfy the same tolerance discipline.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *two-index window schedule, listing every inspected pair (i, j) together with the row, column, and diagonal slices visible to the consumer.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for every row, column, and diagonal comparison.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the diagonal schedule of W and the tolerance row D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after R, C, W, D, Q have been displayed.*
7. *H records componentwise* hsame *transport for row regularity, column regularity, windows, dyadic tolerances, diagonal readback, Real sealing, replay, provenance, and naming.*
8. *K records displayed* Cont *replay from a completion request through $R, C, W, D, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyMatrix}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyMatrix}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, C, W, D, Q, E, H, K, P, N$. It has no coordinate for a quotient real, a chosen limiting row or column, countable choice over rows, detached completion data, host equality of streams, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyMatrixUp.CauchyMatrixTasteGate single carrier alignment`

Theorem 5978.2 (Cauchy matrix NameCert obligations)**.** *For every accepted* $\mathsf{CauchyMatrix}^{\uparrow}$ *carrier*

$$M = (R, C, W, D, Q, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyMatrix}^{\uparrow}}$ *surface consists exactly of carrier admission, row regularity, column regularity, finite two-index window scheduling, dyadic tolerance accounting, diagonal regular rational readback, terminal Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every L10 Real or Completion consumer must read R, C, W, D, Q, E before consuming H, K, P, N.*

Proof. Project the accepted carrier of Definition 5978.1. Its analytic data are exactly the row ledger R, the column ledger C, the two-index window schedule W, the dyadic tolerance ledger D, the diagonal readback row Q, and the Real seal E.

The structural rows do not add new analytic content. Rows H and K transport and replay the displayed route, while P and N record provenance and local naming.

Since the carrier has no coordinate for quotient equality, selected limiting rows, countable choice, detached completion data, host stream equality, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 5978.3 (Cauchy matrix row and column regularity)**.** *For every accepted* $\mathsf{CauchyMatrix}^{\uparrow}$ *carrier $M = (R, C, W, D, Q, E, H, K, P, N)$, a completion-facing read of the matrix can inspect row tails and column tails only through the finite schedule W and the dyadic tolerance row D. Thus row regularity and column regularity are synchronized as displayed packet data before any diagonal readback or Real seal is visible.*

Proof. By Definition 5978.2, every consumer reads the row ledger, column ledger, window schedule, and dyadic tolerance row before the diagonal and seal rows.

The row route is therefore R, W, D, and the column route is C, W, D. Both routes share the same finite two-index schedule and the same tolerance ledger.

The diagonal row Q and terminal seal E occur only after those routes. Hence neither row regularity nor column regularity can be consumed as an external host property; both are part of the displayed finite packet. □

Theorem 5978.4 (Cauchy matrix diagonal Real handoff)**.** *For every accepted* $\mathsf{CauchyMatrix}^{\uparrow}$ *carrier $M = (R, C, W, D, Q, E, H, K, P, N)$, the diagonal handoff to* $\mathsf{Real}^{\uparrow}$ *factors through the finite route*

$$R, C, W, D \longmapsto Q \longmapsto E.$$

Consequently the packet exports a regular rational diagonal name and then a terminal Real seal, without exporting quotient stream equality, a selected limit, countable choice over rows, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from Definition 5978.3. The row and column ledgers are synchronized through the displayed two-index windows and dyadic tolerance row before the diagonal readback is visible.

The diagonal readback row Q is a $\mathsf{RegSeqRat}^{\uparrow}$ row over that same window-and-tolerance surface. It is not an independent sequence chosen outside the matrix packet.

Finally the Real seal E is downstream of Q. Rows H, K, P, N preserve and name this route, so a consumer receives only the displayed diagonal handoff $R, C, W, D \mapsto Q \mapsto E$ and no excluded host completion principle. □

Falsifiable prediction: Every accepted $\mathsf{CauchyMatrix}^{\uparrow}$ consumer that claims a diagonal $\mathsf{Real}^{\uparrow}$ handoff while omitting one of $R, C, W, D, Q, E, H, K, P, N$ refutes the carrier surface of Definition 5978.1.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{CauchyMatrix}^{\uparrow}$ is not bijective to any listed sibling because only it simultaneously carries row regularity, column regularity, a two-index window schedule, a shared dyadic tolerance ledger, diagonal regular readback, terminal Real sealing, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyMatrix}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyMatrix}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5978.1, Definition 5978.2, Definition 5978.3, and Definition 5978.4 seed the finite two-index matrix route from row and column regularity to diagonal regular readback and terminal Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyMatrix}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected matrix limits, countable choice over rows, host stream equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, row and column regularity exactness, two-index window scheduling, dyadic tolerance synchronization, diagonal RegSeqRat readback, terminal Real seal scope, transport, replay, provenance, and local naming for BEDC.Derived.CauchyMatrixUp.

Constructive story: A $\mathsf{CauchyMatrix}^{\uparrow}$ packet is generated from row regularity, column regularity, StreamName two-index windows, DyadicRatCore tolerances, RegSeqRat diagonal readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 5979

A Concrete Naming Certificate for $\mathsf{GrothendieckGroup}^{\uparrow}$

Following Grothendieck's group-completion construction, the $\mathsf{GrothendieckGroup}^{\uparrow}$ packet records the standard passage from a commutative monoid to its universal abelian group as finite BEDC NameCert data. It is anchored by the monoid carrier of chapter 40, the abelian-group target surface of chapter 42, the semiring-to-additive-completion route of chapter 327, and the generator discipline of chapter 345. The packet names a displayed difference-pair congruence and its universal additive handoff; it does not introduce a primitive quotient group, ambient setoid completion, or external localization theorem.

Definition 5979.1 (Grothendieck group carrier)**.** *A* $\mathsf{GrothendieckGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, X, D, Q, A, U, H, K, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Monoid}^{\uparrow}$ *row, exposing the commutative additive operation, zero row, and BEDC monoid laws used by the completion.*
2. *X is the generator row, recording the formal generator map $x \mapsto [x, 0]$ from the monoid surface into the completion packet.*
3. *D is the difference-pair row, whose displayed elements are finite pairs (a, b) read as the formal difference $a - b$.*
4. *Q is the congruence row, generated by the finite relation*

   $$(a, b) \sim (c, d)$$

   whenever a displayed witness t satisfies $a + d + t = c + b + t$ inside the source monoid row M.
5. *A is the additive-group row, carrying zero $[(0, 0)]$, inverse $[(a, b)] \mapsto [(b, a)]$, and addition $[(a, b)] + [(c, d)] = [(a + c, b + d)]$ after the congruence row Q has been displayed.*
6. *U is the universal handoff row from M to any accepted* $\mathsf{AbGroup}^{\uparrow}$ *row: a monoid homomorphism out of M factors through X, D, Q, A by sending $[(a, b)]$ to $f(a) - f(b)$ in the target abelian group.*
7. *H records componentwise* hsame *transport for the monoid row, generator row, difference-pair row, congruence row, additive-group row, universal handoff, replay, provenance, and local naming.*

8. *K records displayed* Cont *replay from a source monoid query through M, X, D, Q, A, U, H.*
9. *P is the* Pkg *provenance over* $\mathsf{GrothendieckGroup}^{\uparrow}$, $\mathsf{Monoid}^{\uparrow}$, $\mathsf{AbGroup}^{\uparrow}$, $\mathsf{Semiring}^{\uparrow}$, $\mathsf{FreeMonoid}^{\uparrow}$, BHist, msame, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{GrothendieckGroup}^{\uparrow}}$ *row.*

The classifier accepts a group-completion read only through $M, X, D, Q, A, U, H, K, P, N$. It has no coordinate for a quotient-group primitive, hidden cancellation law, host abelian group equality, external localization object, or global exactness theorem.

Theorem 5979.2 (Grothendieck group obligation surface)**.** *For every accepted* $\mathsf{GrothendieckGroup}^{\uparrow}$ *carrier $G = (M, X, D, Q, A, U, H, K, P, N)$, the local NameCert surface consists exactly of the following finite obligations:*

1. *carrier admission for the source monoid, generator, difference-pair, congruence, additive-group, universal handoff, transport, replay, provenance, and local naming rows;*
2. *generator compatibility, requiring X to send each displayed monoid element a to the displayed pair $(a, 0)$;*
3. *congruence stability, requiring the row Q to be preserved by pairwise addition and by swapping coordinates for inverses;*
4. *additive-group exposure, requiring A to read zero, addition, and inverse only after D and Q have been displayed;*
5. *universal handoff discipline, requiring each accepted handoff into an* $\mathsf{AbGroup}^{\uparrow}$ *row to factor through U and the displayed formula $[(a, b)] \mapsto f(a) - f(b)$;*
6. *structural preservation through H, K, P, N;*
7. *non-escape, excluding primitive quotient groups, hidden cancellation, host equality, external localization data, and unrecorded exactness assumptions.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5979.1. The rows $M, X, D, Q, A, U, H, K, P, N$ are the only displayed data available to an accepted packet.

The generator row X records the map into formal pairs, while D supplies the pair carrier. The congruence row Q supplies exactly the finite witness relation needed to identify two differences without assuming cancellation in M.

The additive-group row A is then read from D and Q: zero is the class of $(0, 0)$, addition is coordinatewise addition, and inverse swaps the two coordinates. Congruence stability is the obligation that makes these operations insensitive to the displayed equivalence row.

For a target $\mathsf{AbGroup}^{\uparrow}$ packet, the universal handoff row U records the factorization formula $[(a, b)] \mapsto f(a) - f(b)$. The structural rows H, K, P, N transport, replay, source, and name only this displayed route.

Since none of the excluded objects is a carrier coordinate, every accepted group-completion obligation is one of the listed rows and no quotient-group primitive is exported. □

Falsifiable prediction: A $\mathsf{GrothendieckGroup}^{\uparrow}$ consumer that forms inverses or universal maps without displaying the difference-pair row D and congruence row Q is not reading an accepted packet of this chapter.

Independence witness: monoid, abgroup, semiring, freemonoid: $\mathsf{GrothendieckGroup}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source monoid row, generator row, difference-pair row, congruence row, additive-group row, universal handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{GrothendieckGroup}^{\uparrow}}$.

Constructive story: A $\mathsf{GrothendieckGroup}^{\uparrow}$ packet is generated from a source MonoidUp row, a generator row, a difference-pair row, a congruence row, an additive-group row, a universal handoff into AbGroupUp targets, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GrothendieckGroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5979.1 and Definition 5979.2 seed the finite group-completion carrier and its local NameCert obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GrothendieckGroup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, a quotient-group primitive, cancellation in the source monoid, host abelian group equality, external localization, or K-theory exactness.

Upgrade path: Obligation closure requires checked carrier admission, congruence stability, additive-group operation preservation, universal handoff uniqueness, Nontrivial GrothendieckGroupUp, and FieldFaithful GrothendieckGroupUp for BEDC.Derived.GrothendieckGroupUp.

Sibling dependency route. The $\mathsf{GrothendieckGroup}^{\uparrow}$ difference-pair congruence is read only after its source monoid, target abelian-group, additive semiring, and free-generator neighbours have been exposed. Concretely, the route consumes the monoid carrier of chapter 40, the abelian-group target surface of chapter 42, the additive semiring route of chapter 327, and the generator discipline of chapter 345. These sibling references are dependency edges for the displayed difference-pair and universal-handoff rows, not additional theorem content.

Chapter 5980

A Concrete Naming Certificate for $\mathsf{WeakOmniscienceBoundary}^{\uparrow}$

Following Bishop, Bridges, and Troelstra–van Dalen on constructive analysis and weak omniscience principles, the $\mathsf{WeakOmniscienceBoundary}^{\uparrow}$ packet names the finite boundary where L10 real-completion reads may cite displayed evidence without becoming LPO, LLPO, or choice principles. It sits over the regular-rational readback of chapter 301, the terminal real-name seal of chapter 38, the Kleene-tree obstruction of chapter 1622, the Specker sequence surface of chapter 1406, and the finite-prefix choice-sequence row of chapter 1482. The packet refuses decision extraction from real-completion reads while preserving finite witness routes through BHist, hsame, Cont, Pkg, and NameCert rows.

Definition 5980.1 (Weak omniscience boundary carrier)**.** *A* $\mathsf{WeakOmniscienceBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (R, E, K, S, Q, F, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row naming the finite regular-rational windows available to an L10 Real or Completion consumer.*
2. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the displayed regular-rational windows have been read.*
3. *K is the* $\mathsf{KleeneTree}^{\uparrow}$ *obstruction row, carrying finite prefix-tree evidence without selecting an infinite branch.*
4. *S is the* $\mathsf{SpeckerSequence}^{\uparrow}$ *row, carrying monotone bounded finite-window evidence without exposing a located supremum.*
5. *Q is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix row, carrying displayed choice-sequence answers only on the inspected finite window.*
6. *F is the refusal row recording that LPO tests, LLPO splits, selected limits, quotient stream equality, trichotomy, countable choice, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness are not coordinates of the packet.*
7. *H records componentwise* hsame *transport for R, E, K, S, Q, F.*
8. *C records displayed* Cont *replay from a Real or Completion request through the regular-rational readback, terminal seal, obstruction rows, prefix rows, and refusal row.*

9. *P is the* Pkg *provenance over* $\mathsf{WeakOmniscienceBoundary}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{KleeneTree}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{WeakOmniscienceBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, E, K, S, Q, F, H, C, P, N$. It has no hidden coordinate from which a real-completion read can decide LPO, split an LLPO instance, choose a limit, identify quotient streams, invoke countable choice, extract open-cover compactness, or complete ambient $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.WeakOmniscienceBoundaryUp.WeakOmniscienceBoundaryUp`

Theorem 5980.2 (Weak omniscience boundary NameCert obligations)**.** *For every accepted* WeakOmniscienceBoun *carrier*

$$W = (R, E, K, S, Q, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WeakOmniscienceBoundary}^{\uparrow}}$ *surface consists exactly of regular-rational readback admission through R, terminal real-seal handoff through E, finite tree-obstruction readback through K, Specker finite-window readback through S, choice-sequence prefix readback through Q, refusal nonescape through F, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.WeakOmniscienceBoundaryUp.WeakOmniscienceBoundaryCarrier namecert obligations`

Proof. Project the carrier of Definition 5980.1. The Real and Completion route first exposes the regular-rational row R and then the terminal seal row E.

The obstruction rows are finite. The Kleene row K supplies only displayed prefix-tree data, the Specker row S supplies only displayed monotone bounded windows, and the choice-sequence row Q supplies only displayed finite-prefix answers.

The refusal row F binds the missing principles to absent coordinates rather than to extra assumptions. Transport by H, replay by C, provenance by P, and local naming by N preserve the same displayed rows and add no LPO test, LLPO split, selected limit, quotient stream equality, trichotomy branch, countable-choice selector, open-cover compactness principle, or ambient completeness field. □

Theorem 5980.3 (Weak omniscience boundary real-completion nonescape)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{WeakOmniscienceBoundary}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{KleeneTree}^{\uparrow}, \quad \mathsf{SpeckerSequence}^{\uparrow}, \quad \mathsf{ChoiceSequence}^{\uparrow}$$

together with the refusal row and the structural rows H, C, P, N. The route may preserve finite witness evidence from the sibling packets, but it cannot extract LPO, LLPO, selected limits, quotient stream equality, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness from a real-completion read.*

Proof. Apply Definition 5980.2. It fixes the consumer route to the displayed regular-rational row, terminal real seal, three finite sibling rows, refusal row, and structural rows.

The three sibling rows do not store decision principles. The Kleene row preserves finite prefix-tree obstruction data, the Specker row preserves finite monotone bounded windows without a located supremum, and the choice-sequence row preserves only displayed prefix answers.

It remains to inspect the Real and Completion handoff. Since the terminal $\mathsf{Real}^{\uparrow}$ seal is reached only through R and is followed by the explicit refusal row F, any attempted extraction of LPO, LLPO, selected limits, quotient equality, trichotomy, choice, compactness, or ambient completeness asks for a coordinate outside the accepted carrier. □

Falsifiable prediction: Every accepted $\mathsf{WeakOmniscienceBoundary}^{\uparrow}$ Real or Completion read factors through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{KleeneTree}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, the refusal row, componentwise hsame, displayed Cont, Pkg, and the local NameCert row before the consumer may cite the boundary.

Independence witness: regseqrat, real, kleene-tree, speckersequence, choice-sequence: WeakOmniscienceBoundar is not bijective to any listed sibling because it jointly carries regular-rational readback, a terminal Real seal, finite Kleene obstruction data, Specker finite-window data, choice-sequence prefix data, an explicit weak-omniscience refusal row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{WeakOmniscienceBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{WeakOmniscienceBoundary}^{\uparrow}$ packet is generated from RegSeqRat readback, a RealUp seal, KleeneTree finite obstruction rows, SpeckerSequence finite-window rows, ChoiceSequence prefix rows, an explicit refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeakOmniscienceBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5980.1, Definition 5980.2, and Definition 5980.3 seed the finite weak-omniscience boundary for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeakOmniscienceBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close LPO, LLPO, selected limits, quotient stream equality, trichotomy, countable choice, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, RegSeqRat readback exactness, Real-seal handoff, Kleene-tree obstruction stability, Specker finite-window stability, ChoiceSequence prefix stability, and refusal nonescape for BEDC.Derived.WeakOmniscienceBoundaryUp.

Chapter 5981

A Concrete Naming Certificate for $\mathsf{MetricCauchyFilterBridge}^{\uparrow}$

Following Bourbaki and Bishop–Bridges, the $\mathsf{MetricCauchyFilterBridge}^{\uparrow}$ packet records the finite bridge by which a metric Cauchy-filter presentation is read through StreamName windows, dyadic tolerance ledgers, RegSeqRat readback, and a terminal Real seal. It sits over the metric source of chapter 57, the finite observation route of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The bridge names only the displayed finite handoff; it does not identify quotient filter classes or select a limit point.

Definition 5981.1 (Metric Cauchy-filter bridge carrier)**.** *A* $\mathsf{MetricCauchyFilterBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, F, S, D, R, E, H, C, P, N)$$

with the following rows:

1. *X is the metric source row, exposing only the displayed distance and finite ball-comparison data allowed by the* $\mathsf{Met}^{\uparrow}$ *packet.*
2. *F is the filter-base row, listing the finite inhabited tails and refinement requests that witness the Cauchy-filter presentation.*
3. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row extracted from the filter base.*
4. *D is the dyadic tolerance ledger read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and attached to the displayed filter windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational tail windows produced from S and D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the displayed RegSeqRat readback.*
7. *H records componentwise* hsame *transport for the metric source, filter base, StreamName windows, dyadic ledger, RegSeqRat readback, and Real seal rows.*
8. *C records displayed* Cont *replay from a Cauchy-filter request through the finite StreamName, DyadicRatCore, RegSeqRat, and Real seal route.*
9. *P is the* Pkg *provenance over* $\mathsf{MetricCauchyFilterBridge}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCauchyFilterBridge}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filter equality, selected limits, countable-choice schedules, host real equality, or ambient Real completeness.

Lean4 (definition) `BEDC.Derived.MetricCauchyFilterBridgeUp.MetricCauchyFilterBridgeUp`
Lean4 ✓ `BEDC.Derived.MetricCauchyFilterBridgeUp.MetricCauchyFilterBridgeTasteGate single carrier alignment`

Theorem 5981.2 (Metric Cauchy-filter bridge NameCert obligations)**.** *Every accepted* $\mathsf{MetricCauchyFilterBridge}^{\uparrow}$ *packet binds exactly the rows displayed in Definition 5981.1: metric source visibility for* X*, finite filter-base visibility for* F*, finite StreamName windows for* S*, dyadic tolerance ledger visibility for* D*, RegSeqRat readback for* R*, terminal Real seal visibility for* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, sibling provenance through* P*, and local naming through* N*.*

The obligation surface exports no quotient filter class, selected limit, countable-choice selector, host real equality, ambient metric completeness datum, or ambient Real completeness principle.

Proof. Start with an accepted carrier $M = (X, F, S, D, R, E, H, C, P, N)$. The metric source row X and filter-base row F provide the only admissible Cauchy-filter data, and both are finite displayed rows.

Read the completion route through S, D, R, E. The $\mathsf{StreamName}^{\uparrow}$ row supplies finite windows, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the dyadic tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ supplies regular rational readback, and $\mathsf{Real}^{\uparrow}$ supplies the terminal seal.

The support rows H, C, P, N transport, replay, source, and name those finite rows componentwise. Since no quotient, choice, selected-limit, host-equality, or completeness coordinate occurs in the carrier, the accepted packet binds exactly the displayed NameCert obligations. □

Theorem 5981.3 (Metric Cauchy-filter bridge real-completion handoff)**.** *Every terminal completion consumer of an accepted* $\mathsf{MetricCauchyFilterBridge}^{\uparrow}$ *packet receives its* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$\mathsf{Met}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The filter-base row can request narrower displayed tails and dyadic tolerances, but the handoff remains a finite StreamName, DyadicRatCore, RegSeqRat, and Real seal route transported by hsame*, replayed by* Cont*, sourced by* Pkg*, and named by the local* $\mathsf{NameCert}_{\mathsf{MetricCauchyFilterBridge}^{\uparrow}}$ *row.*

The handoff refuses quotient filter classes, selected limits, countable choice, host real equality, selected Real endpoints, metric-completeness data, and ambient Real completeness.

Proof. Project the accepted carrier. The only route from the metric Cauchy-filter rows to a real-name endpoint is the displayed sequence of S, D, R, E rows, with X and F supplying the source and filter-base requests.

Use the StreamName and DyadicRatCore rows to turn each accepted finite tail request into a dyadic tolerance window. The RegSeqRat row reads that window as a regular rational tail, and the Real row seals only that readback.

Finally use the support rows. Componentwise hsame keeps the route stable under displayed comparison, Cont replays the finite handoff, Pkg records the sibling provenance, and the local NameCert row names the bridge. The excluded quotient, choice, selected-limit, host-equality, endpoint-selection, metric-completeness, and Real-completeness rows are absent from the carrier, so no completion consumer can read them. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCauchyFilterBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCauchyFilterBridge}^{\uparrow}$ packet is generated from a MetricUp source row, a finite Cauchy-filter base row, StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCauchyFilterBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5981.1, Definition 5981.2, and Definition 5981.3 seed the finite metric Cauchy-filter bridge into the RegSeqRat and Real completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCauchyFilterBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filter classes, selected limits, countable choice, host real equality, selected Real endpoints, ambient metric completeness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked metric-source admission, filter-base window extraction, dyadic tolerance readback, RegSeqRat handoff, Real seal non-escape, and ledger stability for BEDC.Derived.MetricCauchyFilterBridgeUp.

Chapter 5982

A Concrete Naming Certificate for CauchyCompletionReflectorTriangleHandoff$^{\uparrow}$

Following Bishop–Bridges constructive completion and Mac Lane's adjunction language, the CauchyCompletionRefle packet records the finite handoff by which the Cauchy completion reflector and its triangle identities become a local L10 NameCert surface. It sits over the reflector of chapter 1585, the triangle packet of chapter 3946, the unit of chapter 1527, the counit of chapter 1539, the regular rational source of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names the finite coherence route; it does not assert quotient completion, selected representatives, countable choice, host equality, or ambient Real$^{\uparrow}$ completeness.

Definition 5982.1 (CauchyCompletionReflectorTriangleHandoff carrier)**.** *A* CauchyCompletionReflectorTriangleHa *carrier is a finite* BHist *packet*

$$H = (F, T, U, K, S, D, R, E, J, C, P, N)$$

with the following displayed rows:

1. *F is the* CauchyCompletionReflector$^{\uparrow}$ *row exposing the reflector as a finite completion-facing surface.*
2. *T is the* CompletionReflectorTriangle$^{\uparrow}$ *row binding the unit, counit, and idempotent triangle around the same reflector.*
3. *U is the* CauchyCompletionUnit$^{\uparrow}$ *row for source admission into the completion-facing route.*
4. *K is the* CauchyCompletionCounit$^{\uparrow}$ *row for already completed or real-sealed return reads.*
5. *S is the* StreamName$^{\uparrow}$ *finite-window row through which source and completed names are observed.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row used by the same windows before any real seal is read.*
7. *R is the* RegSeqRat$^{\uparrow}$ *regular readback row carried from source names to completion-facing reads.*
8. *E is the terminal* Real$^{\uparrow}$ *seal row available only after the window, tolerance, and regular readback rows are displayed.*
9. *J records componentwise* hsame *transport for reflector, triangle, unit, counit, window, tolerance, readback, real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay along*

$$F, T, U, K \longmapsto S, D, R, E \longmapsto J, P, N.$$

11. *P is the* Pkg *provenance over* CauchyCompletionReflectorTriangleHandoff$^{\uparrow}$, CauchyCompletionReflector$^{\uparrow}$, CompletionReflectorTriangle$^{\uparrow}$, CauchyCompletionUnit$^{\uparrow}$, CauchyCompletionCounit$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* NameCert$_{\text{CauchyCompletionReflectorTriangleHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for quotient completion, a selected representative, a countable-choice schedule, host equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorTriangleHandoffUp.CauchyCompletionReflectorTriangleHandof`
`single carrier alignment`

Theorem 5982.2 (CauchyCompletionReflectorTriangleHandoff NameCert obligations)**.** *For every accepted* CauchyCompletionReflectorTriangleHandoff$^{\uparrow}$ *carrier $H = (F, T, U, K, S, D, R, E, J, C, P, N)$, the local* NameCert$_{\text{CauchyCompletionReflectorTriangleHandoff}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed reflector, triangle, unit, counit, stream window, dyadic tolerance, regular readback, real seal, transport, replay, provenance, and local naming rows; reflector exposure through F before triangle reads through T; triangle coherence through the shared U, K unit-counit boundary; regular-Cauchy handoff through S, D, R, E; transport and replay stability through J, C; and non-escape from quotient completion, selected representatives, countable choice, host equality, and ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5982.1. The rows $F, T, U, K, S, D, R, E, J, C, P, N$ are exactly the finite data admitted by the local packet.

The reflector is exposed first by F, and the triangle row T may be read only as the unit-counit-idempotent surface attached to that reflector. The unit row U and counit row K therefore share the same completion-facing boundary.

The regular-Cauchy part is forced through S, D, R, E. Finite StreamName windows, dyadic tolerance data, and RegSeqRat readback are displayed before the terminal Real seal can be consumed.

Finally J, C, P, N transport, replay, source, and name the same route. Since no carrier coordinate stores quotient completion, a selected representative, countable choice, host equality, or ambient real completeness, the listed obligations exhaust the accepted NameCert surface. □

Theorem 5982.3 (CauchyCompletionReflectorTriangleHandoff nonescape)**.** *Every accepted* CauchyCompletionRef
packet exports the reflector-triangle handoff only through

CauchyCompletionReflector$^{\uparrow}$, CompletionReflectorTriangle$^{\uparrow}$, CauchyCompletionUnit$^{\uparrow}$, CauchyCompletionCounit$^{\uparrow}$, Str

It exports no quotient completion, selected representative, countable-choice selector, host equality, or ambient Real$^{\uparrow}$ *completeness row.*

Proof. Use Definition 5982.2. It requires every accepted handoff to expose F, T, U, K, S, D, R, E before the structural rows are consumed.

The reflector and triangle siblings supply only displayed L10 completion rows, and the Real-facing path is confined to finite stream windows, dyadic tolerance, regular readback, and a terminal Real seal. None of those rows is a quotient carrier or a selected representative.

The structural rows J, C, P, N preserve and name the same finite route. The forbidden host-side and choice-side principles have no carrier coordinate, so they cannot be exported by an accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorTriangleHandoff}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionReflectorTriangleHandoff}^{\uparrow}$ packet is generated from reflector, triangle, unit, counit, stream-window, dyadic-tolerance, regular-readback, Real-seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorTriangleHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5982.1, Definition 5982.2, and Definition 5982.3 seed the finite completion-reflector triangle handoff surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorTriangleHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reflector exposure, triangle-unit-counit coherence, regular-Cauchy handoff, transport and replay stability, provenance, local naming, and non-escape for BEDC.Derived.CauchyCompletionRe

Chapter 5983

A Concrete Naming Certificate for $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$

Following Bishop and Bridges on separated complete metric spaces, the $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ packet records the finite route by which two complete-metric limit rows for one displayed Cauchy source are compared through distance zero and then through the separated metric classifier. It sits over the complete-metric service of chapter 128, the metric source of chapter 57, the terminal real-name seal of chapter 38, the regular rational readback surface of chapter 301, and the separated-limit uniqueness boundary of chapter 3365. The packet names limit uniqueness only as displayed finite NameCert data; it does not identify quotient representatives, choose a limit, invoke countable choice, import ambient $\mathsf{Real}^{\uparrow}$ completeness, or export host point equality.

Before the two candidate limits are compared, the uniqueness packet reads a displayed $\mathsf{CompleteMetric}^{\uparrow}$ limit carrier from chapter 128 and the completion route supplied by chapter 1569. The uniqueness packet consumes $\mathsf{CauchyFilterCompletion}^{\uparrow}$ as the source completion route and $\mathsf{MetricCompletion}^{\uparrow}$ as the optional metric-completion face before the separated classifier can export uniqueness. The optional $\mathsf{MetricCompletion}^{\uparrow}$ face is used only as a sibling completion route when the child row already names it; the uniqueness boundary itself still waits for the complete-metric limit rows, Cauchy-filter completion data, distance-zero readback, and separated classifier before exposing a comparison.

Definition 5983.1 (Complete metric limit uniqueness carrier)**.** *A* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (A, L_0, L_1, M, Z, S, H, C, P, N)$$

with the following displayed rows:

1. *A is the Cauchy-source row, exposing the finite request and tail data whose limit is being compared.*
2. *L_0 and L_1 are complete-metric limit rows for the same displayed source A.*
3. *M is the $\mathsf{Met}^{\uparrow}$ distance-witness row comparing the two displayed limit reads.*
4. *Z is the $\mathsf{Real}^{\uparrow}$ zero-distance row reached from the distance witness through the regular rational readback surface.*
5. *S is the separated-metric classifier row saying that the zero-distance read is the only admissible route from the two limit rows to a uniqueness handoff.*

6. *H records componentwise* hsame *transport for the source, limit rows, distance witness, zero-distance row, separated classifier, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from the Cauchy-source request through the two limit rows, metric distance witness, Real zero-distance row, and separated classifier.*
8. *P is the* Pkg *provenance over* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, L_0, L_1, M, Z, S, H, C, P, N$. It has no coordinate for quotient representatives, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or host equality of metric points.*

Theorem 5983.2 (Complete metric limit uniqueness NameCert obligations)**.** *For every accepted* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *carrier*

$$U = (A, L_0, L_1, M, Z, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}}$ *surface consists exactly of Cauchy-source admission for A, paired complete-metric limit admission for L_0 and L_1 over that source, metric distance-witness exactness for M, Real zero-distance readback for Z, separated classifier handoff for S, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through P, and local naming through N.*

No complete-metric limit uniqueness obligation is stored outside these rows.

Proof. Project the accepted carrier. The source row A is the only Cauchy datum available to the packet, and the two complete-metric rows L_0 and L_1 are admitted only as limit reads for that displayed source.

The comparison then passes through the metric witness M and the Real zero-distance row Z. This records a finite distance-zero handoff, not a host equality of endpoints or an equality of quotient representatives.

Finally the separated classifier S consumes that zero-distance row. The support rows H, C, P, N transport, replay, source, and name the same route, so the listed rows exhaust the local NameCert obligations. □

Theorem 5983.3 (Complete metric limit uniqueness carrier rows)**.** *Every accepted* CompleteMetricLimitUniqueness *carrier displays exactly the rows*

$$A, L_0, L_1, M, Z, S, H, C, P, N$$

of Definition 5983.1 before the NameCert obligations of Definition 5983.2 can be read. The two limit rows L_0 and L_1 are therefore public only as complete-metric limit reads over the same source row A, and the structural rows H, C, P, N may replay or name only that displayed route.

Proof. Project the carrier definition. It lists the source, paired limit rows, metric witness, zero-distance row, separated classifier, transport, replay, provenance, and local naming as the complete finite packet.

Apply the NameCert obligation theorem. Its obligation surface is indexed by those same coordinates, so no consumer can read a limit comparison before the carrier rows have been displayed.

The replay and naming rows preserve the projected route. They do not add a second source, a selected limit, or an unstored equality principle. □

Theorem 5983.4 (Complete metric limit uniqueness separated nonescape)**.** *Let*

$$U = (A, L_0, L_1, M, Z, S, H, C, P, N)$$

be an accepted $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *carrier. Any public uniqueness comparison must pass through the metric zero-distance row* Z *and then through the separated classifier row* S *before it is exposed. In particular, uniqueness cannot escape from* L_0 *and* L_1 *directly to host point equality, quotient representative equality, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier-row theorem Definition 5983.3. It forces the comparison to begin with the shared source A and the two complete-metric limit rows L_0, L_1.

Use the obligation theorem Definition 5983.2. It places the metric witness M and zero-distance row Z before the separated handoff, so the comparison cannot bypass the distance-zero route.

Finally read the separated classifier S. Since H, C, P, N only transport, replay, source, and name the same finite packet, no host equality, quotient representative, selected limit, choice schedule, or ambient completeness principle is available. □

Theorem 5983.5 (Complete metric limit uniqueness NameCert scope)**.** *The local* $\mathsf{NameCert}_{\mathsf{CompleteMetricLimitUniquene}}$ *scope for an accepted packet is exactly the carrier-row surface*

$$A, L_0, L_1, M, Z, S, H, C, P, N$$

together with the NameCert obligations of Definition 5983.2. A public comparison may be exposed only after the metric zero-distance row and separated classifier have both been displayed, so every downstream uniqueness consumer reads a separated nonescape route rather than an ambient equality theorem.

Proof. Combine Definition 5983.3 with the obligation theorem. The first theorem fixes the carrier coordinates, and the second assigns the local NameCert obligations to those coordinates.

Apply separated nonescape, Definition 5983.4. It identifies Z and S as the required boundary between the paired limit rows and any public uniqueness read.

The resulting scope is therefore finite and local to the displayed packet. It cannot be enlarged by replay into quotient equality, selected endpoints, countable choice, host equality, or ambient completeness. □

Theorem 5983.6 (Complete metric limit uniqueness separatedness handoff)**.** *Every consumer that reads uniqueness from an accepted* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *carrier must factor the read through*

$$A, L_0, L_1, M, Z, S, H, C, P, N.$$

The separatedness step is visible only after both complete-metric limit rows have been tied to the same Cauchy source, the $\mathsf{Met}^{\uparrow}$ *distance witness has been displayed, and the* $\mathsf{Real}^{\uparrow}$ *zero-distance row has been sealed. The handoff exports no quotient representative equality, selected limit, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, or host equality of metric points.*

Proof. Start from an accepted carrier. The consumer first reads A, L_0, L_1, so the two candidate limits are compared only as complete-metric limit rows for the same displayed Cauchy source.

The metric row M then supplies the displayed distance comparison, and Z seals the zero-distance read through the Real-facing route. At this point the carrier still has no coordinate for selected representatives or host point equality.

The separated classifier S is the only row that turns the zero-distance evidence into a uniqueness handoff. Since H, C, P, N merely preserve the same finite path, every accepted uniqueness read factors through the displayed rows and cannot escape into the excluded ambient principles. □

Theorem 5983.7 (Complete metric limit uniqueness zero-distance reflection)**.** *Any two accepted limit rows over the same Cauchy source can export a complete-metric uniqueness read only after the* $\mathsf{Met}^{\uparrow}$ *distance witness row and the* $\mathsf{Real}^{\uparrow}$ *zero-distance row have both been displayed and reflected through the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier of chapter 1790. Equivalently, every accepted zero-distance reflection route for*

$$U = (A, L_0, L_1, M, Z, S, H, C, P, N)$$

factors through A, L_0, L_1, M, Z, S *before* H, C, P, N *may replay or name the handoff. The route exports no selected limit, quotient representative equality, countable-choice schedule, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, or host equality of metric points.*

Proof. Use the carrier of Definition 5983.1. It places the two candidate limit rows L_0 and L_1 over the same displayed Cauchy-source row A, so no comparison can start from independent sources or selected representatives.

Apply the NameCert obligations of Definition 5983.2. They require the metric comparison row M and the Real zero-distance row Z to be displayed before any separated classifier handoff is available.

Finally apply the separatedness handoff of Definition 5983.6. The classifier S is the only row that reflects zero distance into uniqueness, and the structural rows H, C, P, N preserve that same finite route without adding quotient equality, choice, ambient completeness, or host point equality. □

Theorem 5983.8 (Complete metric limit uniqueness common window)**.** *If two limit-seal reads are accepted by the* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *carrier* $U = (A, L_0, L_1, M, Z, S, H, C, P, N)$*, then the separatedness handoff and zero-distance reflection inspect the same metric row* M*, Cauchy route* A, L_0, L_1*,* $\mathsf{Real}^{\uparrow}$ *zero-distance seal* Z*,* hsame *transport* H*,* Cont *replay* C*,* Pkg *provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}}$ *row* N*. The uniqueness read therefore has one finite witness route and exports no separate equality principle or selected limit.*

Proof. Project the carrier of Definition 5983.1. The two limit rows L_0 and L_1 are tied to the same Cauchy-source row A, and the only displayed metric comparison is the row M.

Apply the separatedness handoff of Definition 5983.6. It binds every admissible uniqueness read to the displayed route through $A, L_0, L_1, M, Z, S, H, C, P, N$.

Now apply zero-distance reflection, Definition 5983.7, on that same route. The Real zero-distance seal Z, separated classifier S, transport H, replay C, provenance P, and local naming N remain attached to the displayed packet, so no separate equality principle or selected limit is exported. □

Theorem 5983.9 (Common tail contraction for uniqueness)**.** *If two accepted complete-metric limit rows read the same Cauchy source through the common window of Definition 5983.8, then any uniqueness consumer must contract both reads to the same tail before applying zero-distance reflection and separatedness. The contracted route factors through the common window, the zero-distance row, and the separated classifier of Definition 5983.7 and Definition 5983.6. It does not appeal to selected limits, quotient equality, or ambient completeness.*

Proof. Start with the common window theorem Definition 5983.8. It shows that the two complete-metric limit rows share the same metric row, Cauchy route, zero-distance seal, transport, replay, provenance, and naming rows.

Contract both reads to that shared tail. The contraction step uses only the displayed common window, so it does not introduce a selected limit or any quotient representative.

Now apply zero-distance reflection, Definition 5983.7. The reflected route still passes through the same common tail, and the separated classifier remains the only row that can turn the zero-distance evidence into a uniqueness handoff.

Finally apply separatedness, Definition 5983.6. The uniqueness consumer therefore sees one contracted tail before the reflected comparison is exported, and the route stays inside the finite packet rather than invoking ambient completeness. □

Theorem 5983.10 (Common tail classifier for uniqueness)**.** *If two accepted complete-metric limit rows share a displayed Cauchy source and their common tail contraction supplies the Real zero-distance row, then every public uniqueness read must pass through the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *classifier before any equality-like comparison is exported.*

Proof. Apply the common tail contraction theorem Definition 5983.9. It reduces the uniqueness read to the shared tail, the zero-distance row, and the separated classifier route already visible in the packet.

Next apply zero-distance reflection, Definition 5983.7. The reflected route keeps the zero-distance row attached to the same finite source, so no equality-like comparison can be exported from an unclassified read.

Finally apply separatedness, Definition 5983.6. The public read must therefore pass through $\mathsf{SeparatedMetricReflection}^{\uparrow}$ before any equality-like comparison is exposed. □

Theorem 5983.11 (Complete metric limit uniqueness separated zero-distance route)**.** *Every public uniqueness read from an accepted* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *carrier must expose the complete-metric limit rows* L_0, L_1*, the* $\mathsf{Met}^{\uparrow}$ *distance witness* M*, the* $\mathsf{Real}^{\uparrow}$ *zero-distance row* Z*, and the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *classifier* S *before uniqueness is available. The route remains the finite packet*

$$A, L_0, L_1, M, Z, S, H, C, P, N$$

and exports no quotient limit, selected endpoint, countable-choice schedule, ambient completeness principle, or host equality of metric points.

Proof. Start with zero-distance reflection, Definition 5983.7. It places the metric witness M and Real zero-distance row Z downstream of the paired complete-metric limit rows L_0, L_1 over the displayed source A.

Apply the separated-reflection route Definition 5983.19. The separated classifier S is read only after the distance witness and zero-distance row are visible.

Finally compose with the sibling lattice route Definition 5983.20. The structural rows H, C, P, N preserve the same route, so public uniqueness cannot be read through quotient limits, selected endpoints, countable choice, ambient completeness, or host equality. □

Theorem 5983.12 (Complete metric limit uniqueness through separated classifier)**.** *Let* $U = (A, L_0, L_1, M, Z, S, H, C, P, N)$ *be an accepted* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *carrier. Two accepted limit rows over the same Cauchy source become classifier-equal only after the common-window row, zero-distance reflection,* $\mathsf{Real}^{\uparrow}$ *zero-distance readback, and* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier row are all exposed. The public uniqueness route is therefore the displayed packet*

$$A, L_0, L_1, M, Z, S, H, C, P, N$$

and not a quotient representative equality, selected endpoint, countable-choice schedule, ambient completeness principle, or host point equality.

Proof. Start with the common tail contraction theorem, Definition 5983.9. It contracts the two accepted complete-metric limit rows to the same displayed tail over the Cauchy source row A before any uniqueness comparison is exported.

Next apply the common tail classifier theorem, Definition 5983.10. The public read must pass through the separated-reflection classifier after the Real zero-distance row has stayed attached to the same finite source.

Finally use the separated zero-distance route of Definition 5983.11. It displays M, Z, S together with L_0, L_1 and the structural rows H, C, P, N, so classifier equality is exposed only through the finite separated route and not through quotient equality, selected limits, countable choice, ambient completeness, or host equality. □

Theorem 5983.13 (Complete metric limit uniqueness separated seal)**.** *Let* $U = (A, L_0, L_1, M, Z, S, H, C, P, N)$ *be an accepted* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *carrier. Two accepted limit rows over the same Cauchy source are publicly unique only through the route that exposes the complete-metric limit rows* L_0, L_1*, the* $\mathsf{Met}^{\uparrow}$ *distance witness* M*, the* $\mathsf{RegSeqRat}^{\uparrow}$*-backed* $\mathsf{Real}^{\uparrow}$ *zero-distance row* Z*, and the* $\mathsf{SeparatedMetric}^{\uparrow}$ *classifier* S *before any uniqueness handoff is public. The separated seal is the displayed packet*

$$A, L_0, L_1, M, Z, S, H, C, P, N$$

and does not assert host equality, selected limits, quotient representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with zero-distance reflection, Definition 5983.7. It forces any uniqueness read to expose the metric distance witness M and the Real zero-distance row Z downstream of the paired complete-metric limit rows over the source A.

Apply the separated-reflection route and sibling route, Definition 5983.19 and Definition 5983.20. These keep the separated classifier S attached to A, L_0, L_1, M, Z and preserve the same structural rows H, C, P, N.

Finally use the separated classifier theorem, Definition 5983.12. The public uniqueness handoff is available only after the classifier has consumed the zero-distance row on the displayed finite route, so the seal has no coordinate for host equality, selected limits, quotient representatives, countable choice, or ambient Real completeness. □

Theorem 5983.14 (Complete metric limit uniqueness kernel scope)**.** *Any accepted* $\mathsf{CompleteMetricLimitUniqueness}$ *uniqueness read must factor through separated metric identity, Cauchy witness rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{StreamName}^{\uparrow}$ *readback, a terminal* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}}$ *before uniqueness is public. In carrier notation the kernel-scope route is*

$$A, L_0, L_1, M, Z, S, H, C, P, N.$$

The route exports no ambient $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, quotient equality, countable choice, or host point equality.*

Proof. Project the carrier rows of Definition 5983.1. The Cauchy witness is the source row A together with the paired complete-metric limit rows L_0, L_1, while the metric comparison and zero-distance read are M and Z.

Use the separated reflection route already cited in the chapter. The separated classifier S is read only after the distance witness and zero-distance row are displayed, so uniqueness is a separated metric identity route rather than host equality.

Use the regular Cauchy Real route inputs through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ for the zero-distance seal. The structural rows H, C, P, N transport, replay, source, and locally name that same finite route.

The ledger refusal is immediate from the carrier surface. There is no coordinate for ambient Real completeness, selected limits, quotient equality, countable choice, or host point equality, so the kernel-scope route cannot export any of those principles. □

Theorem 5983.15 (Complete metric limit uniqueness Real completion witness route)**.** *Let $U = (A, L_0, L_1, M, Z, S, H, C, P, N)$ be an accepted* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *carrier whose zero-distance row is supplied through the* $\mathsf{RealCompletionWitnessExtractor}^{\uparrow}$ *route of chapter 652. Then the uniqueness read must first factor through the extractor coordinates that display the diagonal request, selected windows, regular readback, Real seal, completion-facing handoff, transport, replay, provenance, and local naming rows. Only after those extractor coordinates expose the zero-distance row may the packet apply the separated classifier S to export uniqueness. The route exports no selected limit, quotient representative equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or host point equality.*

Proof. Start with the kernel-scope route of Definition 5983.14. It forces every uniqueness read to pass through $A, L_0, L_1, M, Z, S, H, C, P, N$ and keeps the Real zero-distance row attached to regular readback, stream windows, transport, replay, provenance, and local naming.

Now read the zero-distance row through chapter 652. The extractor surface exposes diagonal, selected-window, regular-readback, Real-seal, completion-handoff, transport, replay, provenance, and naming coordinates before a completion-facing zero-distance witness can be consumed.

Finally apply the separated classifier only after those extractor coordinates have supplied Z. Since the classifier receives a displayed extractor-backed zero-distance row rather than a host completion object, the uniqueness route cannot export selected limits, quotient representative equality, countable choice, ambient Real completeness, or host point equality. □

Theorem 5983.16 (Complete metric limit uniqueness Cauchy-filter comparison)**.** *Let $U = (A, L_0, L_1, M, Z, S, H, C$ be an accepted* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *carrier whose two limit rows are read from the same* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *source row. Every uniqueness export must pass through the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *source row A, the* $\mathsf{Met}^{\uparrow}$ *distance witness M, the* $\mathsf{Real}^{\uparrow}$ *zero-distance row Z, and the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *classifier S before any equality-like comparison is public. The comparison therefore remains the finite route*

$$A, L_0, L_1, M, Z, S, H, C, P, N$$

and does not export quotient-filter equality, selected limits, countable choice, ambient completeness, or host equality of metric points.

Proof. Start with the common tail contraction theorem, Definition 5983.9. It contracts the two complete-metric limit rows to one displayed tail over the shared Cauchy source row before any comparison is read.

Apply zero-distance reflection, Definition 5983.7. The reflected route exposes the $\mathsf{Met}^{\uparrow}$ distance witness M and the $\mathsf{Real}^{\uparrow}$ zero-distance row Z downstream of the same source row and the paired limit rows.

Now use the separated zero-distance route, Definition 5983.11. The $\mathsf{SeparatedMetricReflection}^{\uparrow}$ classifier S is the boundary at which the zero-distance read becomes a public uniqueness handoff.

Finally apply the sibling lattice route already recorded by Definition 5983.20. The source row is the Cauchy-filter completion route, while H, C, P, N transport, replay, package, and locally name

the same finite comparison. No coordinate remains for quotient-filter equality, selected limits, countable choice, ambient completeness, or host equality. □

Theorem 5983.17 (Complete metric limit uniqueness filter-tail selector route)**.** *Let* $U = (A, L_0, L_1, M, Z, S, H, C,$ *be an accepted* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *carrier whose uniqueness read comes from a* $\mathsf{CauchyFilterCompletion}$ *source. Before zero-distance reflection, regular rational readback, stream-window inspection, dyadic tolerance comparison, Real sealing, or separated classification is read, the packet must display one tail selector row inside* A *binding the two* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows* L_0 *and* L_1 *to the same filter tail. After that selector is exposed, the admissible route is the single finite path through* $A, L_0, L_1, M, Z, S, H, C, P, N$*, with the* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *sibling reads attached to that same tail.*

Proof. Start with common tail contraction, Definition 5983.9. It requires the two complete-metric limit reads to be contracted to one displayed tail before a uniqueness comparison is exported.

Now apply the Cauchy-filter comparison theorem, Definition 5983.16. Since the source is a $\mathsf{CauchyFilterCompletion}^{\uparrow}$ row, the common tail must be presented as a selector row inside A before the two limit rows can be compared as reads from the same filter completion route.

With the selector displayed, use zero-distance reflection and the separated zero-distance route, Definition 5983.7 and Definition 5983.11. These force M and Z to remain downstream of the same tail selector before the $\mathsf{SeparatedMetricReflection}^{\uparrow}$ classifier S is read.

Finally compose with the sibling lattice route, Definition 5983.20. The regular rational readback, StreamName windows, dyadic tolerance comparison, Real seal, transport, replay, provenance, and local naming rows all preserve the selected tail route, so no quotient-filter equality, selected limit, countable-choice schedule, ambient completeness principle, or host point equality is exported. □

Theorem 5983.18 (Complete metric limit uniqueness forward route)**.** *Every* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *read that exports uniqueness must consume the separated reflection route of chapter 1790, the regular Cauchy real reflection of chapter 6280, and the displayed metric completion boundary before public uniqueness is available. The forward route remains the finite packet* $A, L_0, L_1, M, Z, S, H, C, P, N$ *and does not export quotient endpoints, selected limits, countable choice, ambient completeness, or host equality of metric points.*

Proof. Start with zero-distance reflection and the separated-reflection route, Definition 5983.7 and Definition 5983.11. They expose M, Z, S after the paired complete-metric limit rows over the source A.

Next read the regular Cauchy real sibling as the source of the Real zero-distance seal. The regular reflection keeps the comparison inside displayed stream, regular readback, and Real-facing rows rather than a quotient or host equality.

Finally apply the Cauchy-filter comparison route of Definition 5983.16. It binds the uniqueness export to the metric completion boundary and the structural rows H, C, P, N, so no refused endpoint is public. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ packet is generated from one Cauchy-source row, two CompleteMetricUp limit rows, a MetricUp distance witness, a RealUp zero-distance row, a SeparatedMetricUp classifier handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5983.1, Definition 5983.2, and Definition 5983.6 seed the finite complete-metric limit uniqueness packet over one Cauchy-source row, two complete-metric limit rows, a MetricUp distance witness, a RealUp zero-distance row, a separated classifier, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{CompleteMetricLimitUniqueness}^{\uparrow}}$, unformalized)
Bridge status: none
Not claimed: This chapter does not claim quotient representatives, selected limits, countable choice, ambient RealUp completeness, host point equality, Lean verification, or bridge checking.
Upgrade path: Obligation closure requires checked Cauchy-source admission, paired complete-metric limit admission, distance-witness exactness, zero-distance sealing, separated classifier handoff, transport stability, replay stability, and non-escape for BEDC.Derived.CompleteMetricLimitUniquenessUp.

Theorem 5983.19 (Complete metric limit uniqueness separated reflection route)**.** *Every* CompleteMetricLimitUniqu *read that exports uniqueness for two displayed complete-metric limit rows must consume the separated-reflection classifier route of chapter 1790 after the* Met$^{\uparrow}$ *distance witness and the* Real$^{\uparrow}$ *zero-distance row have been displayed. The route therefore passes through the packet rows*

$$A, L_0, L_1, M, Z, S, H, C, P, N$$

before any uniqueness handoff is exported. It does not identify quotient representatives, choose a limit, invoke ambient completeness, or export host equality of metric points.

Proof. Project the carrier of Definition 5983.1. The two limit rows L_0 and L_1 are tied to the same Cauchy-source row A before any comparison is available.

Use the metric distance witness M and the Real zero-distance row Z. These rows display the finite zero-distance comparison, but they do not by themselves export uniqueness or host point equality.

Now route the comparison through the separated-reflection classifier of chapter 1790. The separated row S is therefore consumed only after M and Z are visible, and before the uniqueness handoff is read by any downstream consumer.

Finally carry the route through H, C, P, N. These rows transport, replay, source, and name the same finite packet, so the handoff remains a separated-reflection dependency rather than a quotient, selected-limit, ambient-completeness, or host-equality principle. □

Theorem 5983.20 (Complete metric limit uniqueness sibling route)**.** *Every* CompleteMetricLimitUniqueness$^{\uparrow}$ *read that exports a public uniqueness handoff must expose the sibling lattice route consisting of the* CompleteMetric$^{\uparrow}$ *limit rows from chapter 128, the* CauchyFilterCompletion$^{\uparrow}$ *source route of chapter 1569, the* Met$^{\uparrow}$ *distance witness of chapter 57, the* Real$^{\uparrow}$ *zero-distance row of chapter 38, and the* SeparatedMetricReflection$^{\uparrow}$ *classifier of chapter 1790 before the handoff is public. In carrier notation this route factors through*

$$A, L_0, L_1, M, Z, S, H, C, P, N$$

with A carrying the Cauchy-filter completion source data, L_0, L_1 carrying the complete-metric limit rows, M carrying the metric comparison, Z carrying the Real zero-distance read, and S carrying the separated-reflection classifier. The route exports no selected limit, quotient representative equality, countable-choice schedule, ambient completeness principle, or host point equality.

Proof. Project the carrier obligations of Definition 5983.2. They expose the Cauchy-source row A, the paired complete-metric limit rows L_0, L_1, the metric distance witness M, the Real zero-distance row Z, and the separated classifier S before any local naming row can publish uniqueness.

Apply Definition 5983.19. The separated-reflection classifier is consumed only after the metric witness and zero-distance read are visible, so the public handoff must pass through the same sibling route.

The support rows H, C, P, N preserve and name this displayed route. They add transport, replay, provenance, and local NameCert data, but they do not add selected limits, quotient representative equality, countable choice, ambient completeness, or host point equality. □

CompleteMetricLimitUniquenessUp reads MetricCompletionUp only through the displayed CompleteMetricUp limit rows and the CauchyFilterCompletionUp source route before the zero-distance and separated-classifier handoff. The dependency is therefore a finite forward route through chapter 128 and chapter 1569; it does not collapse into host equality or an ambient completeness claim. Every $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ dossier read that is consumed by completion-lattice readers must first expose the downstream route through the complete-metric service of chapter 128, the Cauchy-filter completion service of chapter 1569, and the separated metric reflection service of chapter 1790. Only after those three rows have been displayed may a public uniqueness read leave the packet; the route therefore records a finite completion-to-separatedness dependency rather than an ambient equality principle.

Theorem 5983.21 (CompleteMetricLimitUniqueness downstream separated-completion link)**.** *Every downstream separated-completion or metric-completion uniqueness consumer that cites* CompleteMetricLimitU *must cite it through the displayed route*

$$\mathsf{CompleteMetric}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{SeparatedMetricReflection}^{\uparrow}.$$

The consumer first reads the complete-metric limit rows supplied by $\mathsf{CompleteMetric}^{\uparrow}$*, then the* $\mathsf{Met}^{\uparrow}$ *distance witness, then the* $\mathsf{Real}^{\uparrow}$ *zero-distance row, and only then the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *classifier row. The route exports no quotient-limit equality, selected endpoint, countable-choice schedule, ambient completeness principle, or host equality of metric points.*

Proof. Start with the carrier of Definition 5983.1. Its limit rows are accepted only as complete-metric limit rows over the same displayed Cauchy source.

Apply the zero-distance reflection route of Definition 5983.7. It places the $\mathsf{Met}^{\uparrow}$ distance witness and the $\mathsf{Real}^{\uparrow}$ zero-distance read before any uniqueness handoff is available.

Finally apply Definition 5983.12 and the separated-reflection route of Definition 5983.19. They force the downstream uniqueness consumer to read the $\mathsf{SeparatedMetricReflection}^{\uparrow}$ classifier after the zero-distance row, so a separated-completion or metric-completion consumer can cite only the displayed finite route. □

Theorem 5983.22 (Complete metric limit uniqueness completion sibling route)**.** *Every* CompleteMetricLimitUnique *read that exports uniqueness must first consume the separated limit comparison supplied by chapter 128 and the completion-boundary row supplied by chapter 1506. The exported route therefore remains inside the displayed packet rows*

$$A, L_0, L_1, M, Z, S, H, C, P, N$$

with L_0, L_1 *read as complete-metric limit rows over one Cauchy source,* M, Z, S *read as the zero-distance and separated-classifier comparison, and* H, C, P, N *preserving the same finite path. It exports no quotient completion point, selected representative, or host equality of metric points.*

Proof. Project the carrier obligations of Definition 5983.2. They expose the complete-metric limit rows L_0, L_1 only over the shared source row A, so the separated comparison cannot begin from detached limit data.

Read the sibling completion boundary through chapter 1506. This supplies the completion-facing row consumed before M, Z, S compare the two displayed limit reads, but it does not add quotient completion points or selected representatives.

Finally apply the separatedness handoff of Definition 5983.6. The support rows H, C, P, N replay and name the same finite route, so the uniqueness export remains a completion-sibling dependency rather than host equality. □

Theorem 5983.23 (CompleteMetricLimitUniqueness regular-Cauchy real route)**.** *Every uniqueness read consumed by a* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *packet factors through the displayed* $\mathsf{CompleteMetric}^{\uparrow}$ *separatedness rows of chapter 128, the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *tolerance-exactness route of chapter 3390, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows of chapter 301, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows of chapter 126, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows of chapter 291, the* $\mathsf{Real}^{\uparrow}$ *sealing route of chapter 38, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}}$ *row. Thus any regular-Cauchy consumer reaches uniqueness only through*

$$\mathsf{CompleteMetric}^{\uparrow}, \mathsf{RegularCauchyUniqueness}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{Na}$$

before it may read the result.

Proof. Start with the carrier of Definition 5983.1. Its two limit rows, metric-distance witness, zero-distance row, separated classifier, transport, replay, provenance, and local name are the only rows visible to a uniqueness consumer.

Apply the common-tail and zero-distance routes, Definition 5983.9 and Definition 5983.7. They force the comparison through the same regular-Cauchy readback and the same Real zero-distance seal before separatedness is inspected.

Now read the finite-window siblings. The $\mathsf{RegSeqRat}^{\uparrow}$ source, $\mathsf{StreamName}^{\uparrow}$ windows, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows provide the regular-Cauchy exactness surface, while the $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ sibling supplies the tolerance uniqueness boundary used by regular consumers.

Finally use separatedness and the sibling lattice route, Definition 5983.6 and Definition 5983.20. The structural rows preserve that same finite route through hsame, Cont, Pkg, and local naming, so the consumer cannot read quotient stream equality, a selected limit, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or host equality of metric points. □

Theorem 5983.24 (Complete metric limit uniqueness regular-Cauchy forward link)**.** *Every consumer that reads a separated* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *result after a regular-Cauchy completion seal first exposes the regular rational readback rows of chapter 301, the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38, and the metric-completion boundary of chapter 1506. Only after those rows are visible may it consume the complete-metric separatedness route of chapter 128 and the local uniqueness row of* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$*.*

Thus the forward dependency lattice is

$$\mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow} \longrightarrow \mathsf{CompleteMetricLimitUniqueness}^{\uparrow},$$

with the arrow mediated by displayed hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows. The link exports no selected limit, quotient Cauchy stream equality, countable-choice schedule, host completion object, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from a regular-Cauchy completion presentation. The regular rational readback rows must be public before the Real seal is available, so the consumer first reads chapter 301 and chapter 38.

Next pass through the metric-completion boundary. The completion row supplies the displayed completion-facing carrier, while the complete-metric sibling supplies the separatedness surface used by a uniqueness read.

Finally consume the local $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ row through the existing separated-route and sibling-lattice theorems in this chapter. Since every source row has already been displayed through hsame, Cont, Pkg, and local naming, the forward link cannot add a selected limit, quotient stream equality, countable choice, a host completion object, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 5983.25 (Complete metric limit uniqueness separated route)**.** *When a* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *packet reads uniqueness through the regular Cauchy Real route of Definition 5983.23, separatedness and zero-distance reflection force a unique classifier-compatible terminal seal. The consumer must pass through the shared Cauchy source, the two complete-metric limit rows, the* $\mathsf{Met}^{\uparrow}$ *distance witness, the* $\mathsf{Real}^{\uparrow}$ *zero-distance row, the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *classifier, the* $\mathsf{RegularCauchyUniqueness}^{\uparrow}$ *tolerance route, the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback rows, and the structural* hsame*,* Cont*,* Pkg*, and local* NameCert *rows before uniqueness is exported.*

The route adds no host equality of metric points, selected representatives, quotient stream equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or separate completeness principle.*

Proof. Start with the regular-Cauchy Real route Definition 5983.23. It forces every regular-Cauchy consumer through $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegularCauchyUniqueness}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the structural rows before a uniqueness read is available.

Now apply zero-distance reflection and separatedness, Definition 5983.7 and Definition 5983.6. These routes bind the two complete-metric limit rows to one Cauchy source, then require the metric distance witness and Real zero-distance row before the separated classifier can export uniqueness.

Finally use the separated reflection route Definition 5983.19. It places the separated classifier after the displayed distance and zero-distance rows and before the downstream handoff. Hence the terminal seal is classifier-compatible and unique inside the packet, while host equality, selected representatives, quotient equality, selected limits, choice, ambient Real completeness, and separate completeness data remain off-surface. □

Theorem 5983.26 (Complete metric limit uniqueness Cauchy-filter Real seal)**.** *Every uniqueness read from a* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *source must expose the Cauchy-filter completion row of chapter 1569, the paired* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows, the* $\mathsf{Met}^{\uparrow}$ *distance witness, the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *zero-distance seal, and the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *classifier before any uniqueness handoff is public. The route remains the displayed packet*

$$A, L_0, L_1, M, Z, S, H, C, P, N$$

and exports no quotient-filter equality, selected limit, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or host equality of metric points.*

Proof. Start with the Cauchy-filter comparison route of Definition 5983.16. It ties the two complete-metric limit rows to the same $\mathsf{CauchyFilterCompletion}^{\uparrow}$ source row before any equality-like comparison is exposed.

Apply the common-tail contraction and zero-distance reflection routes, Definition 5983.9 and Definition 5983.7. They force the paired limit rows through one metric witness M and one $\mathsf{RegSeqRat}^{\uparrow}$-backed $\mathsf{Real}^{\uparrow}$ zero-distance row Z.

Finally use separatedness and the separated zero-distance route, Definition 5983.6 and Definition 5983.11. The separated classifier is visible before the uniqueness handoff, while H, C, P, N replay and name the same Cauchy-filter comparison route. □

Theorem 5983.27 (Complete metric limit uniqueness CauchyLimitSeal route)**.** *Every separated complete-metric limit-uniqueness read factors through the displayed* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *boundary before public uniqueness is available. More precisely, an accepted* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *consumer must expose the finite route*

$$\mathsf{CauchyLimitSeal}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{MetricCompletion}^{\uparrow}$$

together with the carrier rows $A, L_0, L_1, M, Z, S, H, C, P, N$ before the separated classifier may publish uniqueness. The route exports no quotient stream equality, host selected limit, ambient completeness principle, or detached completion witness.

Proof. Start with the carrier and sibling lattice routes of Definition 5983.1 and Definition 5983.20. They place the two complete-metric limit rows over the same displayed Cauchy source and keep the metric-completion face inside the same finite packet.

Next attach the regular readback rows. The regular route of Definition 5983.23 and the regular-sequence forward route of Definition 5983.29 force every zero-distance read through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the terminal $\mathsf{Real}^{\uparrow}$ seal before separatedness is inspected.

Now pass through the Cauchy-limit seal. The Cauchy-filter Real seal route of Definition 5983.26 and the completion sibling route of Definition 5983.22 keep the same source, readback, Real seal, and completion face attached to the packet before the separated classifier is visible.

Finally apply the separated reflection route of Definition 5983.19. Since S is read only after M and Z, and Z is reached through the displayed window, readback, Real, CauchyLimitSeal, and MetricCompletion rows, the public uniqueness export cannot introduce quotient stream equality, a host selected limit, ambient completeness, or a second completion witness. □

Theorem 5983.28 (Complete metric limit uniqueness completion-witness route)**.** *Every accepted* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *comparison that is consumed by a completion witness must pass through the displayed source row A, the paired complete-metric limit rows L_0 and L_1, the* $\mathsf{Met}^{\uparrow}$ *distance row M, the* $\mathsf{Real}^{\uparrow}$ *zero-distance row Z, the separated classifier row S, and the structural rows H, C, P, N before it reaches the* $\mathsf{RealCompletionWitnessExtractor}^{\uparrow}$ *route of chapter 652. Thus the witness-facing comparison is the finite route*

$$A, L_0, L_1, M, Z, S, H, C, P, N$$

followed by the extractor's displayed diagonal, selected-window, regular readback, Real seal, completion handoff, transport, replay, provenance, and local naming rows.

Proof. Start with the carrier rows of Definition 5983.1. They make the source row, paired limit rows, metric distance row, Real zero-distance row, separated classifier, transport, replay, provenance, and local naming visible before any uniqueness comparison can be read.

Apply the separatedness handoff of Definition 5983.6 and the separated nonescape theorem Definition 5983.4. These force the comparison through M, Z, S after the paired limit rows and before any downstream consumer receives a uniqueness read.

Finally route the accepted comparison into chapter 652. The extractor consumes only its displayed finite rows, so the forwarded comparison adds no selected limit, quotient representative, ambient completeness row, or host equality principle. □

Theorem 5983.29 (Complete metric limit uniqueness regular-sequence forward route)**.** *Every* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *read consumed by a regular-sequence completion route must pass through the* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *source surface of chapter 5965, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit rows, and the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *classifier before uniqueness is public. In carrier notation the route is still the displayed packet*

$$A, L_0, L_1, M, Z, S, H, C, P, N,$$

with the regular-sequence data read before Z, the complete-metric rows read before the comparison, and the separated classifier read before the uniqueness handoff.

Proof. Start with the regular-Cauchy real route of Definition 5983.23. It already forces a regular consumer through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the zero-distance row can be consumed.

Next insert the $\mathsf{RegularSequenceSpace}^{\uparrow}$ source row. The regular-sequence-space carrier supplies the common family and window surface before the same $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{StreamName}^{\uparrow}$ windows, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows are visible to the uniqueness packet.

Now apply the sibling route and separated zero-distance route, Definition 5983.20 and Definition 5983.11. These rows place the $\mathsf{CompleteMetric}^{\uparrow}$ limit reads before the metric comparison and require the $\mathsf{SeparatedMetricReflection}^{\uparrow}$ classifier after the $\mathsf{Real}^{\uparrow}$ zero-distance seal.

Finally carry the route through H, C, P, N. The structural rows transport, replay, source, and name the same finite packet, so regular-sequence completion consumers reach public uniqueness only through the displayed sequence, readback, tolerance, Real seal, complete-metric, and separated-reflection route. □

Theorem 5983.30 (Complete metric limit uniqueness RegSeqRat forward route)**.** *Any* CompleteMetricLimitUnique *read through the separated classifier must first preserve the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{StreamName}^{\uparrow}$ *window rows, the dyadic tolerance ledger, and the* $\mathsf{Real}^{\uparrow}$ *zero-distance seal already exposed by the child routes. Thus the public uniqueness read cannot consume the separated classifier before the regular-rational, stream-window, dyadic, and Real-seal route has been displayed.*

Proof. Apply the common-tail and zero-distance theorems Definition 5983.9 and Definition 5983.7. They force the uniqueness comparison to pass through a shared tail read and then through the Real zero-distance seal.

Use the separated classifier route of Definition 5983.12. The separated read is public only after the carrier has exposed the limit comparison route, so it cannot bypass the regular-rational and stream-window data that feed the zero-distance test.

Finally apply the sibling route theorem Definition 5983.20. The sibling lattice records the RegSeqRat, StreamName, dyadic tolerance, and Real-facing rows as outgoing dependencies of the same packet. Therefore every accepted uniqueness read preserves those child routes before it reaches the separated classifier. □

The $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ packet consumes the separated-complete metric comparison route of chapter 128 together with the regular-sequence space of chapter 5965, the regular-rational readback surface of chapter 301, and the finite stream windows of chapter 126. This dependency keeps the uniqueness comparison horizontal in the dossier lattice: before the $\mathsf{Real}^{\uparrow}$ zero-distance seal and separated-reflection uniqueness can be consumed, the chapter reads CompleteMetric separation, regular-sequence readback, regular rational tails, stream windows, transport, replay, provenance, and local naming as displayed siblings rather than as a kernel-only float.

Theorem 5983.31 (Complete metric limit uniqueness regular-sequence-space route)**.** *Any* CompleteMetricLimitUni *read of equality of limits must expose the* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *schedule and readback route of chapter 5965, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, and the terminal* $\mathsf{Real}^{\uparrow}$ *zero-distance seal before separatedness is consumed. In carrier notation the public route remains*

$$A, L_0, L_1, M, Z, S, H, C, P, N,$$

with the regular-sequence-space schedule feeding the regular rational readback, the readback feeding the Real seal Z, and the separated classifier S read only after that seal is visible. The route exports no quotient equality of limits, selected endpoint, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or host equality of metric points.*

Proof. Start with the carrier of Definition 5983.1. The two limit rows L_0 and L_1 are admitted only over the displayed source row A, and the comparison is unavailable until the metric witness M and zero-distance row Z have been exposed.

Next apply the regular-sequence forward route of Definition 5983.29. It forces a regular-sequence completion consumer through $\mathsf{RegularSequenceSpace}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before public uniqueness can be read.

Finally use the separated reflection route of Definition 5983.19. The separated classifier S is consumed only after the Real zero-distance seal Z, while H, C, P, N transport, replay, source, and name the same displayed packet. Therefore equality of limits is read through the regular-sequence-space schedule, regular rational readback, Real seal, and separatedness route, with no off-surface quotient, endpoint selector, choice schedule, ambient completeness, or host point equality. □

The $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ child route consumes the displayed $\mathsf{CompleteMetric}^{\uparrow}$ rows of chapter 128, the $\mathsf{MetricCompletion}^{\uparrow}$ completion boundary, the $\mathsf{RegSeqRat}^{\uparrow}$ regular-Cauchy readback, the $\mathsf{StreamName}^{\uparrow}$ finite observation windows, and the terminal $\mathsf{Real}^{\uparrow}$ seal before a uniqueness read is exported. The route records this dependency lattice as finite sibling data: complete-metric limits are compared only after the completion row, regular-rational tolerance rows, stream windows, and Real zero-distance seal have been displayed, and the export remains a NameCert uniqueness read rather than a selected limit, quotient representative equality, countable-choice schedule, or host completeness principle. The $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ packet consumes separatedness through the separated metric certificate of chapter 1411 and reads completion-source data through chapter 1506. This sibling route keeps the two candidate limit rows over the same completion source before the separated classifier can turn the displayed zero-distance row into a uniqueness handoff; it exports no host equality of metric points, quotient representative, selected limit, or ambient completeness principle. The $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ packet consumes the separated metric reflection of chapter 1790 and the completion uniqueness route of chapter 1796 before asserting uniqueness for a displayed limit route. This child dependency keeps the two candidate limit rows over the same completion witness until separatedness turns the zero-distance row into a uniqueness handoff; it exports no quotient representative, selected limit, ambient completeness principle, or host equality of metric points.

Theorem 5983.32 (Complete metric limit uniqueness separated regular-sequence lattice route)**.** *Every* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *uniqueness read that consumes the separated identity route also consumes the regular-sequence Real route. The route cites the separated metric certificate of chapter 1411, the regular-sequence schedule of chapter 5965, and the Real seal of chapter 38 before the two candidate limit rows can be identified.*

Proof. Start with the displayed carrier of Definition 5983.1. The candidate limit rows are read over the same completion source before any separatedness conclusion is available.

Use the regular-sequence route through Definition 5983.31. It exposes the regular-sequence schedule and the Real zero-distance seal as visible rows.

Only then apply the separated metric dependency route. The separated classifier turns the displayed zero-distance seal into uniqueness, while the route exports no quotient representative, selected endpoint, ambient completeness principle, or host equality of points. □

Theorem 5983.33 (Separated completion limit route)**.** *Every* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *uniqueness read consumes the separated-completion boundary of chapter 1612 or the metric-completion uniqueness route of chapter 1796 before exporting a single limit row. In carrier notation, the two candidate limit displays remain over the same completion source until the separated classifier turns*

the zero-distance row into uniqueness evidence; the packet exports no host equality of metric points, quotient completion representative, selected limit, or ambient completeness theorem.

Proof. Read the completion source first. The two candidate limit rows are compared only after the displayed completion source has been fixed, so the uniqueness claim cannot switch to a second ambient completion object.

Next consume the separated boundary or the metric-completion uniqueness sibling. The separated-completion row supplies the classifier that turns displayed zero distance into a uniqueness-facing read, while the metric-completion uniqueness route records the same comparison as a completion-local obligation.

Finally project the $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ export. Because the export is downstream of those sibling rows, it remains a finite dependency route through displayed completion evidence rather than host equality, quotient representatives, selected limits, or ambient completeness. □

Theorem 5983.34 (CompleteMetricLimitUniqueness RegSeqRat dependency route)**.** *Every* CompleteMetricLimitU *read that reaches a separated completion limit comparison must expose the regular rational readback of chapter 301 before it consumes the separated-completion boundary of chapter 1612, the separated limit uniqueness packet of chapter 3365, or the local separated-completion limit route of Definition 5983.33. The public route remains the finite packet*

$\mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{SeparatedCompletion}^{\uparrow}, \mathsf{SeparatedLimitUniqueness}^{\uparrow}, \mathsf{CompleteMetri}$

with the hsame*,* Cont*,* Pkg*, and local* NameCert *rows attached to the same readback surface.*

Proof. Start with the regular-Cauchy real route Definition 5983.23. It already places the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows before any zero-distance comparison can be consumed.

Next use the separated-completion limit route Definition 5983.33. That route admits the separated-completion boundary only after the completion source and zero-distance read have been fixed, so the separated comparison cannot be read from a detached completion object.

Finally attach the separated limit uniqueness packet through chapter 3365. Its carrier reads the two complete-metric limit rows, the common comparison route, the metric distance witness, the Real zero-distance row, and the separated classifier in one displayed packet. Thus the RegSeqRat readback and separated completion limit dependency remain one finite NameCert route, with no quotient completion equality, selected limit, host metric equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate. □

Theorem 5983.35 (Complete metric limit uniqueness RegSeqRat–Real separated dependency route)**.** *Every public* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *handoff must first expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of chapter 301, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{Real}^{\uparrow}$ *zero-distance seal, the* $\mathsf{CompleteMetric}^{\uparrow}$ *completion boundary, and the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *classifier route of Definition 5983.19. The uniqueness handoff therefore reads the regular-rational, finite-window, dyadic, Real-seal, completion, and separated-reflection dependencies before it is public, and it exports no selected limit, quotient point equality, host equality, or ambient completeness principle.*

Proof. Project the carrier of Definition 5983.1. The shared source row, two limit rows, metric witness, zero-distance row, separated row, transport, replay, provenance, and local name give the whole public uniqueness packet.

Use the RegSeqRat forward route Definition 5983.30. It forces the regular-rational readback, StreamName window, dyadic tolerance ledger, and Real zero-distance seal to be displayed before the separated classifier can be consumed.

Now apply the separated reflection route Definition 5983.19. The $\mathsf{SeparatedMetricReflection}^{\uparrow}$ read is public only after the metric distance witness and $\mathsf{Real}^{\uparrow}$ zero-distance row have been exposed, so the uniqueness handoff cannot bypass the $\mathsf{CompleteMetric}^{\uparrow}$ and Real-facing dependencies.

The structural rows transport, replay, source, and name that same route. Since the carrier has no selected-limit coordinate, quotient point-equality coordinate, host-equality coordinate, or ambient-completeness coordinate, the public handoff remains the listed finite dependency route. □

Theorem 5983.36 (Complete metric limit uniqueness public handoff route)**.** *Every public uniqueness handoff exported by an accepted* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *carrier must first consume the complete-metric limit rows, the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *source route, the* $\mathsf{Real}^{\uparrow}$ *zero-distance readback, and the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *classifier. In carrier notation the handoff factors through*

$$A, L_0, L_1, M, Z, S, H, C, P, N$$

with L_0, L_1 *supplied by the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit surface,* A *carrying the Cauchy-filter completion source route,* M, Z *carrying the metric and Real zero-distance readback, and* S *carrying the separated-reflection classifier before* H, C, P, N *may replay or name the handoff. The route exports no selected limit, quotient completion point, countable-choice schedule, ambient completeness principle, or host equality of metric points.*

Proof. Start with the sibling lattice route of Definition 5983.20. It exposes the paired $\mathsf{CompleteMetric}^{\uparrow}$ limit rows over the Cauchy-filter completion source before any public uniqueness handoff is available.

Use the Cauchy-filter Real seal route of Definition 5983.26. This forces the metric witness and the $\mathsf{Real}^{\uparrow}$ zero-distance readback to remain downstream of the same source route.

Finally apply the separated-reflection route of Definition 5983.19. The classifier is read only after the zero-distance row is visible, and the structural rows H, C, P, N preserve the same finite route without adding selected limits, quotient points, countable choice, ambient completeness, or host equality. □

Theorem 5983.37 (Complete metric limit uniqueness CauchySequenceSpace forward link)**.** *Every consumer that reads the separated-limit row of an accepted* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *packet after a sequence-based completion presentation first exposes either a paired* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *window or a paired* $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ *window. The consumer then reads the shared finite regular-family rows, stream schedules, dyadic tolerance ledgers, completion handoff rows, and local naming rows before using the* $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ *separated-limit row. This route cites the Cauchy sequence-space surface of chapter 406 and exports no selected limit, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a sequence-based completion presentation for the two candidate limits. The CauchySequenceSpace packet supplies the displayed regular-family rows, finite StreamName schedules, cofinal-window ledgers, DyadicRatCore tolerances, completion handoff rows, transport, replay, provenance, and local naming.

If the presentation uses a regular Cauchy sequence-space route, the same rows are read through the regular sequence-space sibling before the uniqueness consumer is public. In either case, the

separated-limit comparison has a visible pair of Cauchy sequence windows rather than a hidden quotient stream.

Now apply the CompleteMetricLimitUniqueness separated route already exposed by this chapter. The separated-limit row can be consumed only after the metric-completion and Real-seal rows have been displayed along the same finite comparison route.

Thus the forward link is a dependency edge from the paired CauchySequenceSpace or RegularCauchySequenceSpace windows into the CompleteMetricLimitUniqueness separated-limit row. The packet has no coordinate for selected limits, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

The $\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}$ packet consumes the separated-completion functor of chapter 4094 and the Cauchy-completion functoriality route of chapter 1937 only after the two displayed complete-metric limit rows, the zero-distance row, and the separated classifier have been exposed in the same carrier. The dependency route therefore keeps the two candidate limit reads over one visible completion source before any functorial or separated-completion consumer may export uniqueness.

This child route adds no equality principle beyond the local packet. It records that downstream uniqueness readers must still pass through the paired limit rows, the common zero-distance certificate, the separated classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{CompleteMetricLimitUniqueness}^{\uparrow}}$ row before the functorial completion surface is consumed.

Chapter 5984

A Concrete Naming Certificate for $\mathsf{ArchimedeanRealDensity}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ArchimedeanRealDensity}^{\uparrow}$ packet records the finite route by which a displayed $\mathsf{Real}^{\uparrow}$ name exposes density data through Archimedean bounds, dyadic brackets, finite stream windows, regular-rational readbacks, and a terminal Real seal. It sits over the dyadic arithmetic of chapter 291, the finite windows of chapter 126, the regular sequence readback of chapter 301, the Real seal of chapter 38, the apartness gap boundary of chapter 304, and the dyadic density route of chapter 1484. The certificate names a density handoff around displayed Real names; it does not import classical trichotomy, quotient equality of real names, a selected representative stream, countable choice, host least-upper-bound machinery, or ambient Real completeness.

Definition 5984.1 (ArchimedeanRealDensity carrier)**.** *An* $\mathsf{ArchimedeanRealDensity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, B, W, R, E, G, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{ArchimedeanReal}^{\uparrow}$ *bound row for the displayed* $\mathsf{Real}^{\uparrow}$ *name and the local rational scale at which density is read.*
2. *B is the* $\mathsf{DyadicDensityReal}^{\uparrow}$ *bracket row naming the dyadic witness inside the displayed interval surface.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened from the Real name at the precisions requested by A and B.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those finite windows.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row consumed only after the bound, bracket, window, and readback rows have been displayed.*
6. *G is the positive-gap and apartness row, read through* $\mathsf{ApartnessReal}^{\uparrow}$*, that keeps the bracket separated at the displayed scale.*
7. *H stores componentwise* hsame *transport for the bound, bracket, window, readback, Real seal, gap, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from an Archimedean-density request through A, B, W, R, E, G, H.*

9. *P is the* Pkg *provenance over* ArchimedeanReal$^{\uparrow}$, DyadicDensityReal$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, ApartnessReal$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{ArchimedeanRealDensity}^{\uparrow}}$ *row.*

The carrier contains only finite displayed rows. It stores no trichotomy row, no quotient equality of real names, no selected representative stream, no host least upper bound, no countable-choice selector, and no Real completeness coordinate.

Lean4 ✓ `BEDC.Derived.ArchimedeanRealDensityUp.ArchimedeanRealDensityTasteGate single carrier alignment`

Theorem 5984.2 (ArchimedeanRealDensity NameCert obligations)**.** *For every accepted* ArchimedeanRealDensity$^{\uparrow}$ *carrier $D = (A, B, W, R, E, G, H, C, P, N)$, the local* NameCert$_{\text{ArchimedeanRealDensity}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Archimedean bound, dyadic bracket, finite window, regular readback, Real seal, apartness gap, transport, replay, provenance, and local naming rows;*
2. *bound-bracket compatibility, stating that the dyadic bracket row B is opened only at a scale admitted by the Archimedean row A;*
3. *window-readback exactness, stating that every density observation uses the finite windows W and the regular-rational readback R before the Real seal E is consumed;*
4. *gap stability, stating that the positive apartness row G transports componentwise with A, B, W, R, E through the stored* hsame *and* Cont *routes;*
5. *non-escape, stating that trichotomy, quotient equality of real names, selected representatives, host least upper bounds, countable choice, and Real completeness are absent from the carrier.*

Proof. Project the carrier of Definition 5984.1. The bound, bracket, finite windows, regular readback, Real seal, positive gap, transport table, replay table, provenance row, and local naming row are exactly the available coordinates.

The bound-bracket compatibility row reads A before B. Thus an accepted density request cannot open a dyadic bracket at a scale not already admitted by the Archimedean bound surface.

The window-readback and gap-stability rows then read the same finite route in two directions. The Real seal E is reached only after W and R, while the apartness row G is transported beside those rows through H and C.

Finally inspect the carrier inventory. Since none of the refused host or quotient objects is a coordinate of D, the listed rows exhaust the local NameCert surface. □

Theorem 5984.3 (ArchimedeanRealDensity dyadic-bracket handoff)**.** *Every density read exported by an accepted* ArchimedeanRealDensity$^{\uparrow}$ *carrier factors through the displayed route*

$$A, B, W, R, E$$

before any Real-facing consumer receives it. In particular, the read first uses the ArchimedeanReal$^{\uparrow}$ *bound row A, then the* DyadicDensityReal$^{\uparrow}$ *bracket row B, then the finite* StreamName$^{\uparrow}$ *windows W, then the* RegSeqRat$^{\uparrow}$ *readback row R, and only then the* Real$^{\uparrow}$ *seal row E, with G, H, C, P, N preserving the positive gap, transport, replay, provenance, and local naming.*

Proof. Begin with an exported density read and project the accepted carrier. The only Archimedean scale coordinate is A, so the read begins at the displayed bound row.

The dyadic bracket is then the row B. By the NameCert obligations, B is opened only at a scale admitted by A, and no separate bracket coordinate is available.

The Real-facing part of the read passes through W and R before E. The carrier lists no route from A or B directly to a Real consumer, so the finite window and regular readback rows are mandatory.

The remaining rows G, H, C, P, N keep this path inside the displayed positive gap, transport, replay, provenance, and local naming surface. Therefore every density read factors through A, B, W, R, E before reaching the Real boundary. □

Theorem 5984.4 (ArchimedeanRealDensity Real boundary)**.** *An accepted* $\mathsf{ArchimedeanRealDensity}^{\uparrow}$ *carrier gives its Real-facing consumer only the finite displayed rows*

$$A, B, W, R, E, G, H, C, P, N.$$

It does not export trichotomy, quotient equality of real names, a selected representative stream, a host least-upper-bound object, countable choice, or a Real completeness principle.

Proof. Apply the dyadic-bracket handoff theorem. Any exported density read reaches a Real-facing consumer only after passing through the Archimedean bound, dyadic bracket, finite window, regular readback, and Real seal rows.

The positive-gap row and structural rows do not add a host-side object. They only transport and replay the same displayed carrier surface through G, H, C, P, N.

Inspecting Definition 5984.1 shows that the refused objects are not carrier coordinates. Hence no Real-facing consumer of the accepted packet can receive trichotomy, quotient equality, a selected representative, a host least upper bound, countable choice, or Real completeness from this certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanRealDensity}^{\uparrow}}$.

Constructive story: An $\mathsf{ArchimedeanRealDensity}^{\uparrow}$ packet is generated from an ArchimedeanReal bound row, a DyadicDensityReal bracket row, finite StreamName windows, a RegSeqRat readback, a RealUp seal, an ApartnessReal positive-gap row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArchimedeanRealDensity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5984.1, Definition 5984.2, Definition 5984.3, and Definition 5984.4 seed the finite density packet connecting Archimedean bounds, dyadic brackets, regular readback, Real sealing, and apartness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArchimedeanRealDensity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient equality of real names, selected representatives, host least upper bounds, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bound-bracket compatibility, window-readback exactness, gap stability, and non-escape for BEDC.Derived.ArchimedeanRealDensityUp.

Chapter 5985

A Concrete Naming Certificate for $\mathsf{CompleteMetricNestedBalls}^{\uparrow}$

Following Cantor's nested intersection principle and Bishop–Bridges constructive analysis, the $\mathsf{CompleteMetricNestedBalls}^{\uparrow}$ packet records the finite nested-ball route by which complete metric data serves L10 completion consumers. It sits over the complete-metric service of chapter 128, the metric-space distance surface of chapter 4230, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names a nested closed-ball certificate surface; it does not select an ambient Real limit, assert open-cover compactness, or export a choice-based center.

Definition 5985.1 (CompleteMetricNestedBalls carrier)**.** *A* $\mathsf{CompleteMetricNestedBalls}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, M, D, I, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row that admits the Cauchy-style limit request for the displayed nested ball schedule.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used to read centers, ball membership, and containment witnesses.*
3. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, recording the shrinking dyadic radii used by the schedule.*
4. *I is the nested-containment row, requiring each successor ball to be displayed inside its predecessor at the radius requested by D.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which center names and containment checks are inspected.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that converts the displayed windows and dyadic radius ledger into regular rational Cauchy evidence.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after K, M, D, I, S, Q have been displayed.*
8. *H records componentwise* hsame *transport for complete-metric, metric-space, dyadic-radius, containment, stream-window, regular-readback, real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay along*

$$K, M, D, I \longmapsto S, Q, E \longmapsto H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{CompleteMetricNestedBalls}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricNestedBalls}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an ambient Real-completeness theorem, a selected limit representative, countable choice, quotient completion equality, or a host-side nested-intersection principle.

Lean4 ✓ `BEDC.Derived.CompleteMetricNestedBallsUp.CompleteMetricNestedBallsTasteGate single carrier alignment`

Theorem 5985.2 (CompleteMetricNestedBalls NameCert obligations)**.** *For every accepted* CompleteMetricNestedB *carrier $B = (K, M, D, I, S, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricNestedBalls}^{\uparrow}}$ *surface consists exactly of carrier admission for the complete-metric service, metric-space distance, positive dyadic radius ledger, nested containment row, finite stream windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming rows; shrinking-radius certification through D; containment certification through I; Cauchy-center handoff through S, Q, E; and non-escape from ambient Real completeness, selected limits, countable choice, quotient completion equality, and host-side nested-intersection principles.*

Proof. Project the carrier of Definition 5985.1. The displayed rows are exactly $K, M, D, I, S, Q, E, H, C, P, N$, and every local obligation must be attached to one of them.

The complete-metric and metric-space rows are read first. They supply the admissible completion service and the distance surface on which centers, ball membership, and containment can be checked.

The dyadic and containment rows provide the nested-ball discipline. The radius ledger D records shrinking positive radii, while I records the finite successor-containment checks over the same metric row.

The Cauchy-center route is then forced through S, Q, E. Finite windows are observed in S, regular rational readback is displayed in Q, and the Real seal E is available only after those rows have been consumed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no listed row is an ambient Real-completeness theorem, selected limit representative, countable-choice selector, quotient completion equality, or host nested-intersection principle, the obligations are exhausted by the displayed packet. □

Theorem 5985.3 (CompleteMetricNestedBalls Cauchy-center route)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompleteMetricNestedBalls}^{\uparrow}$ *packet reads a Cauchy center only through the route*

$$\mathsf{CompleteMetric}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The nested-containment row must be displayed before the regular rational readback, and the terminal $\mathsf{Real}^{\uparrow}$ *seal is a seal for that finite route rather than an ambient completeness claim.*

Proof. Begin with the NameCert obligations of Definition 5985.2. They require every accepted consumer to read the complete-metric service K, metric row M, dyadic ledger D, and containment row I before the Cauchy-center handoff can be public.

The finite-window stage comes next. The row S displays the center windows and containment checks, and Q converts those observations into the regular rational readback consumed by completion-facing callers.

The Real seal E is therefore downstream of the displayed nested-ball route. Transport, replay, provenance, and local naming through H, C, P, N preserve that same route without adding a selected limit or an ambient Real-completeness row. □

Theorem 5985.4 (CompleteMetricNestedBalls Real-seal nonescape)**.** *Let* $B = (K, M, D, I, S, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{CompleteMetricNestedBalls}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$ *endpoint read from* E *is reachable only after the complete-metric service row, metric-space row, shrinking dyadic radius ledger, nested-containment row, StreamName windows, and RegSeqRat readback have been displayed. The endpoint read cannot be consumed as a selected limit representative, quotient completion equality, countable-choice witness, or ambient Real-completeness theorem.*

Proof. Project the carrier in Definition 5985.1. The terminal Real row is E, and it appears after the rows K, M, D, I, S, Q in the displayed packet.

Apply Definition 5985.2. The obligations force shrinking-radius certification through D, nested containment through I, and regular rational Cauchy readback through S, Q before E can be read by a consumer.

Finally use Definition 5985.3. The completion-facing route is finite and named by H, C, P, N, so the endpoint seal remains a seal of that route rather than a selected representative, quotient equality proof, choice witness, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteMetricNestedBalls}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteMetricNestedBalls}^{\uparrow}$ packet is generated from CompleteMetric service, MetricSpace distance, positive DyadicRatCore shrinking radii, nested containment, StreamName windows, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteMetricNestedBalls}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5985.1, Definition 5985.2, and Definition 5985.3 seed the finite nested-ball completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteMetricNestedBalls}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CompleteMetricNestedBallsUp.CompleteMetricNestedBallsTasteGate\_single\_carrier\_alignm`

Bridge status: none

Not claimed: This chapter does not close ambient Real completeness, selected limits, countable choice, quotient completion equality, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shrinking-radius certification, nested-containment certification, Cauchy-center handoff, transport and replay stability, provenance, local naming, and non-escape for BEDC.Derived.CompleteMetr

Chapter 5986

A Concrete Naming Certificate for $\mathsf{CompactUniformCoverChain}^{\uparrow}$

The $\mathsf{CompactUniformCoverChain}^{\uparrow}$ packet realizes the compact-uniform cover-chain route as finite NameCert data. It sits between subordinate finite-cover packets, the compact uniform modulus row of chapter 2299, the compact Lebesgue-number row of chapter 4015, the finite-cover radius stability row of chapter 5203, and the composed uniform-continuity consumer of chapter 3891. The packet records a cover-chain handoff; it does not assert a host modulus selector or global compactness principle.

Falsifiable prediction: Every accepted $\mathsf{CompactUniformCoverChain}^{\uparrow}$ packet must expose the compact-uniform cover-chain route through subordinate finite-cover rows, radius ledgers, pointwise-modulus rows, finite lower-bound folds, uniform-modulus handoff rows, transport, replay, provenance, and local naming data before any compact-uniform consumer may read it.

Independence witness: $\mathsf{CompactUniformModulus}^{\uparrow}$, $\mathsf{CompactLebesgueNumber}^{\uparrow}$, $\mathsf{FiniteCoverRadiusStability}^{\uparrow}$, and $\mathsf{UniformContinuityComposition}^{\uparrow}$: these siblings respectively expose a uniform-modulus ledger, a Lebesgue-number radius row, finite-cover radius stability, and composed uniform-continuity handoff; none is bijective with a packet that chains all four through one subordinate finite-cover route.

Definition 5986.1 (CompactUniformCoverChain carrier)**.** *A* $\mathsf{CompactUniformCoverChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, V, L, R, A, U, T, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row, exposing only the finite compact-metric or compact-cover data inspected by the route.*
2. *V is the subordinate finite-cover row, listing the displayed cover cells and their finite refinement relation over K.*
3. *L is the compact Lebesgue-number or finite lower-bound ledger attached to the displayed cover cells.*
4. *R is the finite-cover radius-stability row, keeping the radius ledger stable under the cover refinements consumed by the chain.*
5. *A is the pointwise-modulus row for the continuous map or family currently being tested against the cover.*

6. *U is the compact uniform-modulus handoff row generated from V, L, R, A.*
7. *T is the uniform-continuity composition row that consumes the produced uniform-modulus request without replacing it by a host-side modulus.*
8. *H records componentwise* hsame *transport for compact source, cover, lower-bound, radius-stability, pointwise-modulus, uniform-modulus, composition, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay along*

$$K, V, L, R, A \longmapsto U, T \longmapsto H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{CompactUniformCoverChain}^{\uparrow}$, $\mathsf{CompactUniformModulus}^{\uparrow}$, CompactLebesgueNumber FiniteCoverRadiusStability$^{\uparrow}$, $\mathsf{UniformContinuityComposition}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCoverChain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host compactness theorem, an unrecorded Lebesgue number, a selected global modulus, quotient equality of maps, or a hidden cover refinement.

Theorem 5986.2 (CompactUniformCoverChain NameCert obligations)**.** *For every accepted* CompactUniformCover *carrier $G = (K, V, L, R, A, U, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCoverChain}^{\uparrow}}$ *surface consists exactly of compact-source admission, subordinate finite-cover admission, lower-bound or Lebesgue-number ledger admission, finite-cover radius stability, pointwise-modulus admission, uniform-modulus handoff, uniform-continuity composition handoff, componentwise transport, displayed replay, provenance, and local naming. No NameCert obligation is stored outside those rows.*

Proof. Project the carrier of Definition 5986.1. The only public rows are $K, V, L, R, A, U, T, H, C, P, N$.

The cover-chain route begins with the compact source and subordinate finite-cover rows. The rows K and V determine which finite cover cells and refinements can be inspected.

The radius part is then forced through L and R. The lower-bound or Lebesgue-number ledger supplies positive radius data, and the finite-cover radius-stability row keeps that data synchronized with the displayed refinement.

Pointwise modulus data enters only at A, and the uniform-modulus consumer reads U after the cover and radius rows. The composition row T consumes that generated handoff rather than selecting a separate host-side modulus.

Finally H, C, P, N transport, replay, source, and name the same finite chain. Since the carrier contains no host compactness theorem, hidden Lebesgue number, selected global modulus, quotient equality of maps, or unrecorded refinement, the listed rows exhaust the NameCert surface. □

Theorem 5986.3 (CompactUniformCoverChain uniform-modulus handoff)**.** *Every uniform-modulus read from an accepted* $\mathsf{CompactUniformCoverChain}^{\uparrow}$ *packet factors through the finite route*

$$K, V, L, R, A \longmapsto U, T \longmapsto H, C, P, N.$$

The route supplies subordinate finite-cover data, a radius ledger, pointwise-modulus evidence, and a uniform-continuity composition consumer, but it supplies no host modulus selector or ambient compactness theorem.

Proof. Use the obligations of Definition 5986.2. A uniform-modulus read must first consume compact-source and subordinate finite-cover data from K, V.

The lower-bound and radius-stability rows L, R are then displayed before the pointwise-modulus row A can be folded into a uniform request. The generated uniform-modulus handoff is the row U.

The composition consumer T is downstream of U. Transport and replay through H, C preserve this order, while P, N name the route without adding a separate host-side selector or compactness principle. □

The Lean obligation for this packet is to provide `Nontrivial CompactUniformCoverChainUp` and `FieldFaithful CompactUniformCoverChainUp` TasteGate instances when the carrier is formalized. Those instances must check that the subordinate cover, radius ledger, pointwise-modulus, uniform-modulus, and composition rows are genuine fields of the carrier and not aliases for a single compact-uniform modulus row.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformCoverChain}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformCoverChain}^{\uparrow}$ packet is generated from compact-source, subordinate finite-cover, lower-bound, radius-stability, pointwise-modulus, uniform-modulus, uniform-continuity composition, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformCoverChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5986.1, Definition 5986.2, and Definition 5986.3 seed the compact-uniform cover-chain route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformCoverChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host compactness theorem, selected global modulus, hidden cover refinement, quotient map equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subordinate-cover admission, radius-ledger stability, pointwise-modulus handoff, uniform-modulus handoff, composition consumption, and TasteGate nontriviality and field faithfulness for BEDC.Derived.CompactUniformCoverChainUp.

Chapter 5987

A Concrete Naming Certificate for $\mathsf{MonotoneCauchyConvergence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{MonotoneCauchyConvergence}^{\uparrow}$ packet records the finite certificate surface for the usual bounded monotone Cauchy convergence argument. It sits over the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the density handoff of chapter 5984. The certificate keeps monotonicity, Cauchy control, bounds, density witnesses, and the Real-facing seal as displayed BEDC rows; it does not import least-upper-bound completeness, quotient stream equality, selected representatives, trichotomy, countable choice, or an ambient convergence theorem.

Definition 5987.1 (Monotone Cauchy convergence carrier)**.** *A* $\mathsf{MonotoneCauchyConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, R, O, B, D, L, E, H, C, P, N)$$

with the following rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the sampled rational stream windows.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that records regular Cauchy control on the same windows.*
3. *O is the monotonicity row, recording the displayed order direction for the inspected window family.*
4. *B is the boundedness row, recording the finite upper or lower bound used by the monotone argument.*
5. *D is the* $\mathsf{ArchimedeanRealDensity}^{\uparrow}$ *density row used to choose rational brackets around the displayed bound gap.*
6. *L is the local convergence ledger, recording the finite tolerance request and the response window.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after S, R, O, B, D, L have been displayed.*
8. *H records componentwise* hsame *transport for the analytic rows and structural rows.*
9. *C records the displayed* Cont *replay by which a consumer reads the stream, regularity, order, boundedness, density, ledger, and Real-seal rows.*
10. *P records* Pkg *provenance over* $\mathsf{MonotoneCauchyConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ArchimedeanRealDens}$ $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneCauchyConvergence}^{\uparrow}}$ *row.*
The carrier has no coordinate for a supremum object, quotient equality of streams, selected representative sequence, excluded-middle trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 5987.2 (Monotone Cauchy convergence NameCert obligations)**.** *For every accepted* $\mathsf{MonotoneCauchyConvergence}^{\uparrow}$ *carrier $M = (S, R, O, B, D, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MonotoneCauchyConverg}}$ *surface consists exactly of finite-window exposure through S, regular-rational readback through R, displayed monotonicity through O, boundedness through B, Archimedean density bracketing through D, convergence-ledger response through L, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5987.1. The analytic rows S, R, O, B, D, L, E are the only coordinates from which a convergence consumer can read the source stream, regularity, order, bound, density bracket, tolerance response, and Real-facing seal.

The structural rows H, C, P, N preserve, replay, source, and name those same rows. Since the carrier contains no supremum coordinate, representative selector, quotient stream equality, trichotomy, choice principle, or ambient completeness coordinate, the local certificate obligations are exhausted by the displayed finite packet. □

Lean4 ✓ `BEDC.Derived.MonotoneCauchyConvergenceUp.MonotoneCauchyConvergenceNameCertObligations`

Theorem 5987.3 (Monotone convergence Real seal route)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *read through a* $\mathsf{MonotoneCauchyConvergence}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{ArchimedeanRealDensity}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

as displayed by the rows S, R, D, E, H, C, P, N. The monotonicity row O, boundedness row B, and convergence ledger L may refine the route, but they cannot replace the $\mathsf{RegSeqRat}^{\uparrow}$ *readback or the terminal* $\mathsf{Real}^{\uparrow}$ *seal by a host limit.*

Proof. Begin with the carrier tuple $M = (S, R, O, B, D, L, E, H, C, P, N)$. A Real-facing consumer can reach the seal row E only after the stream windows S, regular readback R, density row D, and ledger response L have been displayed.

The monotonicity and boundedness rows are controls on the same finite windows. They do not form a separate completion object, and the replay row C exposes them only together with S, R, D, E.

Transport by H and provenance through P, N keep the same route visible. Thus the accepted Real read is a BEDC handoff through the displayed rows, not a host limit, quotient stream, or selected representative. □

Lean4 ✓ `BEDC.Derived.MonotoneCauchyConvergenceUp.MonotoneCauchyConvergenceRealSealRoute`

Theorem 5987.4 (Monotone Cauchy convergence nonescape)**.** *No consumer of an accepted* MonotoneCauchyConve *packet can extract least-upper-bound completeness, quotient equality of streams, selected representatives, trichotomy, countable choice, or an ambient convergence theorem from the packet. Every accepted convergence read remains bounded by the finite* BHist, hsame, Cont, Pkg, *and local* NameCert *route named in Definition 5987.1.*

Proof. The nonescape claim is carrier projection. The packet exposes only the rows $S, R, O, B, D, L, E, H, C, P, N$.

The convergence route of Definition 5987.3 identifies the only Real-facing handoff: stream windows, regular-rational readback, density bracketing, convergence ledger, and terminal seal. None of these rows is a supremum object, a quotient constructor, a representative selector, or a global completeness principle.

Therefore any accepted consumer stays inside the finite route preserved by H and replayed by C. The excluded principles require coordinates absent from the packet, so they cannot be read from $\mathsf{MonotoneCauchyConvergence}^{\uparrow}$. □

Falsifiable prediction: A consumer that claims a $\mathsf{MonotoneCauchyConvergence}^{\uparrow}$ convergence read while omitting the $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, monotonicity row, boundedness row, $\mathsf{ArchimedeanRealDensity}^{\uparrow}$ density bracket, convergence ledger, $\mathsf{Real}^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, or local NameCert row refutes the carrier of Definition 5987.1.

Independence witness: streamname, regseqrat, real, archimedeanrealdensity: $\mathsf{MonotoneCauchyConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite windows, regular Cauchy readback, monotonicity, boundedness, density bracketing, a convergence ledger, and a terminal Real seal. StreamNameUp carries windows without regularity or convergence; RegSeqRatUp carries regular rational readback without monotone boundedness; RealUp supplies the terminal seal without the convergence ledger; ArchimedeanRealDensityUp supplies density brackets without the monotone Cauchy route.

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneCauchyConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{MonotoneCauchyConvergence}^{\uparrow}$ packet is generated from finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, monotonicity and boundedness rows, $\mathsf{ArchimedeanRealDensity}^{\uparrow}$ density bracketing, a convergence ledger, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneCauchyConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5987.1, Definition 5987.2, Definition 5987.3, and Definition 5987.4 seed the finite constructive monotone Cauchy convergence route over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ArchimedeanRealDensity}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneCauchyConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim least-upper-bound completeness, quotient stream equality, selected representatives, trichotomy, countable choice, Lean verification, bridge checking, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, regular readback routing, monotone boundedness stability, density-ledger exactness, and Real-seal nonescape for BEDC.Derived.MonotoneCauchyConvergenceUp.

Chapter 5988

A Concrete Naming Certificate for $\mathsf{UniformCompletionKleisli}^{\uparrow}$

Following Mac Lane on Kleisli categories and Bishop–Bridges and Bourbaki on constructive uniform completion, the $\mathsf{UniformCompletionKleisli}^{\uparrow}$ packet records the L10 interface where a displayed uniform-completion unit and a completion-valued arrow compose without exposing a quotient completion object. It sits after the uniform completion carrier of chapter 1473, the Cauchy completion monad surface of chapter 378, the completion universal property of chapter 397, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The chapter names only a finite Kleisli route for displayed completion data; it does not assert quotient completion equality, selected limits, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5988.1 (Bishop completion Kleisli carrier)**.** *A* $\mathsf{UniformCompletionKleisli}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, A, B, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *unit row, naming the source-to-completion admission route.*
2. *A is the Kleisli arrow row, recording a displayed source request and a completion-valued response route.*
3. *B is the bind row, recording composition of two completion-valued arrows through the same unit and arrow surfaces.*
4. *M is the modulus row, recording the finite uniform-continuity budgets needed by A and B.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row inspected by the completion-valued route.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and moduli.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after U, A, B, M, S, R have been displayed.*
8. *H records componentwise* hsame *transport for the unit, Kleisli arrow, bind, modulus, stream-window, readback, Real seal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from each Kleisli request through $U, A, B, M, S, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{UniformCompletionKleisli}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionKleisli}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient completion equality, selected representatives, selected limits, countable choice, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformCompletionKleisliUp.UniformCompletionKleisliTasteGate single carrier alignment`

Theorem 5988.2 (Bishop completion Kleisli NameCert obligations)**.** *For every accepted* $\mathsf{UniformCompletionKleisli}^{\uparrow}$ *carrier* $K = (U, A, B, M, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionKleisli}^{\uparrow}}$ *surface consists exactly of carrier admission for the uniform-completion unit, the displayed Kleisli arrow and modulus, bind, associativity ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing consumer must read* U, A, B, M, S, R *before the terminal seal and structural rows* E, H, C, P, N *are consumed.*

Proof. Project the carrier of Definition 5988.1. Its rows are exactly the unit, arrow, bind, modulus, stream-window, readback, seal, transport, replay, provenance, and local naming coordinates.

The dependency anchors fix the intended route. The unit row is read through chapter 1473; the bind and associativity ledger is the completion-valued part of the Cauchy monad surface in chapter 378; and the extension route is constrained by chapter 397.

Finally the readback rows pass through chapter 126, chapter 301, and chapter 38. Since the carrier contains no quotient, selector, choice, host-equality, or ambient-completeness row, those objects are not exported by the local NameCert surface. □

Theorem 5988.3 (Bishop completion Kleisli unit route)**.** *Every source object admitted by an accepted* $\mathsf{UniformCompletionKleisli}^{\uparrow}$ *packet enters the completion-facing route through the displayed unit row* U *before any Kleisli arrow* A*, bind row* B*, modulus row* M*, readback row* R*, or Real seal row* E *is inspected. The unit route is a finite* $\mathsf{UniformCompletion}^{\uparrow}$ *handoff, not a selected point of a quotient completion.*

Proof. Read the unit coordinate U from the carrier. By Definition 5988.1, every completion-facing row is downstream of the same finite packet.

Apply the obligation theorem Definition 5988.2. It places U before the arrow, bind, modulus, stream-window, and readback rows.

The remaining rows transport, replay, package, and name that route. They cannot supply a quotient representative or selected completion point because no such coordinate occurs in the carrier. □

Theorem 5988.4 (Bishop completion Kleisli associative bind)**.** *For every accepted* $\mathsf{UniformCompletionKleisli}^{\uparrow}$ *carrier* $K = (U, A, B, M, S, R, E, H, C, P, N)$*, two successive completion-valued arrows compose only through the displayed bind row* B *together with the same unit row* U*, modulus row* M*, stream-window row* S*, regular readback row* R*, and Real seal row* E*. The two parenthesizations of the Kleisli composite have the same componentwise* hsame *transport and displayed* Cont *replay route through* H, C, P, N*.*

Proof. Project the bind coordinate B and the rows it depends on. The carrier records no second completion object and no host composition operator.

Use the monad dependency in chapter 378. It supplies the finite unit-and-bind schedule that the Kleisli packet records as U and B.

Now compare the two parenthesizations componentwise. Both read the same U, M, S, R, E route before transport and replay, so the comparison is witnessed by the displayed hsame row H

and replayed by C. The provenance and local naming rows record that the associativity claim stays inside the finite packet. □

Theorem 5988.5 (Bishop completion Kleisli Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{UniformCompletionKleisli}^{\uparrow}$ *packet receives its terminal seal only through*

$$\mathsf{UniformCompletion}^{\uparrow} \longrightarrow \mathsf{CauchyCompletionMonad}^{\uparrow} \longrightarrow \mathsf{CompletionUniversalProperty}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSe}$$

The route exports the displayed unit, Kleisli arrow, modulus, bind, associativity, transport, replay, provenance, and local NameCert rows; it exports no quotient completion, selected limit, countable-choice schedule, host equality, or ambient Real completeness theorem.

Proof. Begin with the unit-route theorem Definition 5988.3. It places every source admission behind the displayed $\mathsf{UniformCompletion}^{\uparrow}$ unit row.

Apply the associative-bind theorem Definition 5988.4. It confines completion-valued composition to the finite bind row and its shared modulus, window, readback, and seal route.

The completion universal property contributes only the extension-facing ledger named in provenance; the StreamName, RegSeqRat, and Real sibling chapters supply the terminal readback chain. Because all excluded objects are absent from K, the Real-facing consumer receives the finite Kleisli route and nothing stronger. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompletionKleisli}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCompletionKleisli}^{\uparrow}$ packet is generated from a UniformCompletion unit row, a Kleisli arrow and modulus row, a bind row, finite StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompletionKleisli}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5988.1, Definition 5988.2, Definition 5988.3, Definition 5988.4, and Definition 5988.5 seed the finite Kleisli interface for displayed uniform completion data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCompletionKleisli}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, selected limits, countable choice, host equality of completed objects, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit-route exposure, Kleisli arrow and modulus exposure, bind associativity, componentwise transport, replay, provenance, and local naming for BEDC.Derived.UniformCompletionKleisliUp.

Chapter 5989

A Concrete Naming Certificate for $\mathsf{KolmogorovComplexity}^{\uparrow}$

Following Kolmogorov and Chaitin, the $\mathsf{KolmogorovComplexity}^{\uparrow}$ packet records finite program-complexity evidence as displayed BEDC rows rather than as an oracle for uncomputable minima. It sits beside the machine interface of chapter 280, the bounded-computation surface of chapter 199, the finite digest discipline of chapter 242, the stream-prefix service of chapter 126, and the binary-code carrier of chapter 5910. The chapter names a finite certificate that a displayed program has bounded length and produces a displayed observation under a displayed universal-machine row; it is not an uncomputable minimum selector, Chaitin incompleteness theorem, quotient program equality, or host semantic universality principle.

Definition 5989.1 (Kolmogorov complexity carrier)**.** *A* $\mathsf{KolmogorovComplexity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (p, U, I, O, F, L, B, E, T, C, P, N)$$

with the following displayed rows:

1. *p is the program row, stored as finite binary or prefix-code data rather than as a host string.*
2. *U is the universal-machine row, read through* $\mathsf{TuringMachine}^{\uparrow}$ *and the bounded computation discipline of* $\mathsf{Computable}^{\uparrow}$*.*
3. *I is the finite input-observation row.*
4. *O is the finite output-observation row produced by replaying p on U for the displayed input.*
5. *F is the finite prefix or code ledger, recording prefix admissibility and code parsing data through the stream-prefix and binary-code sibling rows.*
6. *L is the bounded-length certificate for p and the visible code ledger.*
7. *B is the computable-enumeration provenance row, recording that the displayed program/code rows are reached by a finite enumeration route.*
8. *E is the bounded evaluation transcript row for the displayed input and output observations.*
9. *T records componentwise* hsame *transport for p, U, I, O, F, L, B, E.*
10. *C records displayed* Cont *replay of the same finite program, machine, code, length, enumeration, and evaluation rows.*

11. *P is the* Pkg *provenance over* KolmogorovComplexity$^{\uparrow}$, TuringMachine$^{\uparrow}$, Computable$^{\uparrow}$, Hash$^{\uparrow}$, StreamName$^{\uparrow}$, BinaryTree$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{KolmogorovComplexity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an uncomputable shortest-program selection, quotient equality of programs, host semantic universality, Chaitin incompleteness, or ambient real/stream completeness.

Lean4 ✓ `BEDC.Derived.KolmogorovComplexityUp.KolmogorovComplexityTasteGate single carrier alignment`

Theorem 5989.2 (Kolmogorov complexity NameCert obligations)**.** *For every accepted* KolmogorovComplexity$^{\uparrow}$ *carrier*

$$K = (p, U, I, O, F, L, B, E, T, C, P, N),$$

the local NameCert$_{\text{KolmogorovComplexity}^{\uparrow}}$ *surface consists exactly of carrier admission, finite program-row exposure, universal-machine and* TuringMachine$^{\uparrow}$ *row exposure, finite input and output observation rows, prefix/code ledger exposure, bounded-length certification, computable-enumeration provenance, bounded evaluation transcript, componentwise transport, displayed replay, package provenance, and local naming. The certificate may state that the displayed program has the displayed bounded length for the displayed observation, but it does not select an uncomputable minimum, identify quotient program semantics, prove Chaitin incompleteness, or assert host semantic universality.*

Proof. Project the carrier in Definition 5989.1. The rows p, U, I, O, F, L, B, E are the only analytic data available to a complexity consumer, and the structural rows T, C, P, N only transport, replay, source, and name those data.

Read the machine route through the sibling interfaces. The program row and universal-machine row are consumed through TuringMachine$^{\uparrow}$ and Computable$^{\uparrow}$, while the prefix/code ledger is a finite route through StreamName$^{\uparrow}$ and BinaryTree$^{\uparrow}$; the Hash$^{\uparrow}$ sibling supplies digest-style finite-output comparison discipline when a bounded transcript needs a visible finite output row.

The length claim is bounded and displayed. The row L certifies the length of the shown program/code ledger, and the row E records only the finite evaluation transcript for the shown input and output observations.

Since the carrier contains no row for shortest-program search, quotient program equality, host semantic universality, Chaitin incompleteness, or ambient completeness, the NameCert surface is exactly the displayed finite program-complexity packet. □

Falsifiable prediction: Every accepted KolmogorovComplexityUp read factors through a displayed finite program row, a TuringMachineUp universal-machine row, finite input and output observations, a prefix/code ledger, a bounded-length certificate, computable-enumeration provenance, bounded evaluation replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: turingmachine, computable, hash, streamname, binarytree: KolmogorovComplexity$^{\uparrow}$ is not bijective to any listed sibling because it binds program rows, universal-machine rows, finite observations, prefix/code ledgers, bounded-length certificates, computable-enumeration provenance, evaluation transcripts, transport, replay, provenance, and naming as one finite complexity packet.

Closure status for NameCert$_{\text{KolmogorovComplexity}^{\uparrow}}$.

Constructive story: A KolmogorovComplexity$^{\uparrow}$ packet is generated from finite program rows, a TuringMachineUp universal-machine row, finite input and output observation rows, prefix/code ledgers, bounded-length certificates, computable-enumeration provenance, bounded evaluation transcripts, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{KolmogorovComplexity}^{\uparrow}}$, seed)

Scope closed: Definition 5989.1 and Definition 5989.2 seed the finite-program complexity packet over displayed program, machine, prefix/code, length, enumeration, evaluation, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{KolmogorovComplexity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close uncomputable minimum selection, Chaitin incompleteness, quotient program equality, host semantic universality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, program-row exposure, universal-machine row exposure, finite observation rows, prefix/code ledger exposure, bounded-length certification, computable-enumeration provenance, evaluation replay, transport, provenance, and local naming for BEDC.Derived.KolmogorovComplexityUp.

Chapter 5990

A Concrete Naming Certificate for $\mathsf{RegularCauchyPower}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy real arithmetic, the $\mathsf{RegularCauchyPower}^{\uparrow}$ packet records finite integer powers of one displayed regular Cauchy rational name as a bounded product route. It sits after the regular rational source surface of chapter 301, the finite observation windows of chapter 126, the dyadic arithmetic core of chapter 291, the binary regular product packet of chapter 461, the finite product packet of chapter 2009, and the terminal real-name seal of chapter 38. The carrier packages repeated multiplication by a unary exponent without importing host exponentiation, quotient stream equality, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 5990.1 (Regular Cauchy power carrier)**.** *A* $\mathsf{RegularCauchyPower}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (n, A, W, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *n is the finite unary exponent row. It records the requested integer power by a bounded successor chain, with the zeroth row reserved for the displayed unit read.*
2. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose scheduled rational observations are multiplied repeatedly.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family for the source reads, intermediate product reads, and final power-facing read.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget and observation row, storing source dyadic observations, intermediate product observations, requested radii, unit cells, and slack cells.*
5. *S is the displayed multiplication schedule. Each successor step cites either a* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *row for the current accumulator multiplied by A or a* $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$ *row for the finite fold named by n.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the final power, obtained only from n, A, W, D, S.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback of the power has been displayed.*
8. *H records componentwise* hsame *transport for the exponent, source, windows, dyadic observations, product schedule, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from any finite power request through the same rows.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyPower}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{RegularCauchyFiniteProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyPower}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $n, A, W, D, S, R, E, H, C, P, N$. It has no coordinate for host exponentiation, quotient streams, selected limits, ambient completeness, Lean verification, or bridge credentials.

Lean4 ✓ `BEDC.Derived.RegularCauchyPowerUp.RegularCauchyPowerTasteGate single carrier alignment`

Theorem 5990.2 (Regular Cauchy power NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyPower}^{\uparrow}$ *carrier*

$$K = (n, A, W, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyPower}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the unary exponent, source* $\mathsf{RegSeqRat}^{\uparrow}$ *row, synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations and slack cells, repeated product schedule, final readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local name;*
2. *exponent-window coverage, requiring each successor stage named by n to open the source row A and the accumulator window used by the displayed product step;*
3. *dyadic product-budget exactness, requiring each intermediate product observation to consume its assigned radius and slack cells from D and the schedule row S;*
4. *RegSeqRat readback stability, requiring the final power readback R to depend only on the displayed exponent, source, windows, dyadic budget rows, and product schedule;*
5. *Real seal non-escape, requiring E, H, C, P, N to expose no host exponentiation, quotient stream equality, selected limit, trichotomy, ambient completeness theorem, Lean verification, or bridge credential.*

No Regular Cauchy power obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 5990.1. The displayed tuple $n, A, W, D, S, R, E, H, C, P, N$ is the entire public surface, so carrier admission is exactly the admission of those rows.

Exponent-window coverage is forced by the unary exponent row. The base stage names the displayed unit read, and each successor stage opens the source row A together with the accumulator window selected by W.

Dyadic exactness is the joint role of D and S. The observation row supplies the component and accumulator dyadic cells, while the schedule row records the binary product route or finite product route used at each successor stage.

The final regular readback row R is downstream of n, A, W, D, S. Therefore readback stability follows from the carrier order: no power-facing $\mathsf{RegSeqRat}^{\uparrow}$ data can be inspected until the exponent route, synchronized windows, dyadic observations, and product budget have already been displayed.

Finally, the seal, transport, replay, provenance, and local name rows preserve only this displayed route. Since none of the excluded objects is a coordinate of the carrier, the listed five rows exhaust the local NameCert obligations. □

Theorem 5990.3 (Regular Cauchy power product induction)**.** *Let*

$$K = (n, A, W, D, S, R, E, H, C, P, N)$$

be an accepted RegularCauchyPower$^{\uparrow}$ *carrier. Induction on the finite unary exponent row n shows that every intermediate power read remains inside the displayed product schedule S. The base read is the unit row recorded in D, and each successor read is obtained from the previous accumulator and the source row A through the next* RegularCauchyProduct$^{\uparrow}$ *or* RegularCauchyFiniteProduct$^{\uparrow}$ *schedule cell. Thus no stage of the power read leaves the rows $n, A, W, D, S, R, E, H, C, P, N$.*

Proof. Proceed by induction over the unary exponent row. In the base case, the carrier exposes the unit cell in D and the corresponding base entry in S, so the zeroth power read is already inside the displayed schedule.

For the successor step, assume the accumulator read for the current exponent has been displayed through W, D, S. The next schedule cell in S cites the binary RegularCauchyProduct$^{\uparrow}$ route for multiplying that accumulator by the source row A, or the equivalent RegularCauchyFiniteProduct$^{\uparrow}$ fold cell named by the same finite exponent route.

The dyadic budget row D supplies the observation and slack cells for that product cell, while W supplies the synchronized source and accumulator windows. The successor accumulator is therefore a displayed schedule read, not a host exponentiation step.

After the last successor stage, the final accumulator is repacked as R and then sealed by E. The remaining rows H, C, P, N transport, replay, source, and name the same route, so every intermediate and final power read stays inside the displayed product schedule. □

Falsifiable prediction: Every RegularCauchyPower$^{\uparrow}$ power-facing read factors through a finite unary exponent row, one RegSeqRat source row, synchronized StreamName windows, DyadicRatCore observations and slack cells, a repeated RegularCauchyProduct or RegularCauchyFiniteProduct schedule, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regseqrat, streamname, dyadicratcore, regularcauchyproduct, regular-cauchy-finite-product, real: RegularCauchyPower$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite unary exponent route, a single reusable regular Cauchy source, synchronized accumulator windows, dyadic product-budget accounting, final RegSeqRat readback, RealUp sealing, transport, continuation, provenance, and local naming.

Closure status for NameCert$_{\text{RegularCauchyPower}\uparrow}$.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyPower}\uparrow}$, seed)

Scope closed: Definition 5990.1, Definition 5990.2, and Definition 5990.3 seed the finite power route from a displayed regular Cauchy source through synchronized windows, dyadic product budgets, repeated product schedule cells, final RegSeqRat readback, and RealUp sealing.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyPower}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host exponentiation, quotient stream equality, selected limits, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, exponent-window coverage, budget exactness, readback stability, seal non-escape, and local naming for BEDC.Derived.RegularCauchyPowerUp.

Constructive story: A RegularCauchyPower$^{\uparrow}$ packet is generated from a finite unary exponent row, one RegSeqRat source row, synchronized StreamName windows, DyadicRatCore observations and slack cells, a repeated product schedule, final RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

StreamNameExtensionalityUp reads paired finite-window equality through chapter 126, chapter 291, chapter 301, and chapter 38 before exposing its extensionality rows.

Chapter 5991

A Concrete Naming Certificate for $\mathsf{StreamNameExtensionality}^{\uparrow}$

Following Bishop-style sequence extensionality, the $\mathsf{StreamNameExtensionality}^{\uparrow}$ packet records equality of named streams only through matching finite observation windows. It sits over the finite StreamName interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies a concrete L10 equality object for RegSeqRat and RealUp seal comparisons without quotient stream equality, host function extensionality, selected infinite streams, or countable choice.

Definition 5991.1 (StreamName extensionality carrier)**.** *A* $\mathsf{StreamNameExtensionality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, Y, W, D, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{StreamName}^{\uparrow}$ *source rows being compared.*
2. *W is the shared finite-window row listing the observed indices and values inspected from both sources.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the window request when the stream entries feed rational or real-name consumers.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row saying that the paired finite windows give the same regular rational data for the requested precision.*
5. *Q is the terminal comparison row consumed by a* $\mathsf{Real}^{\uparrow}$ *seal route after the StreamName and RegSeqRat reads have matched pointwise on the displayed window.*
6. *H records componentwise* hsame *transport for the two stream rows, the shared window, dyadic ledger, regular readback, terminal comparison, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a finite equality request through W, D, R, Q.*
8. *P is the* Pkg *provenance over* $\mathsf{StreamNameExtensionality}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{StreamNameExtensionality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, W, D, R, Q, H, C, P, N$. It has no coordinate for quotient stream equality, host function extensionality, selected infinite streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 5991.2 (StreamName extensionality NameCert obligations)**.** *For every accepted* $\mathsf{StreamNameExtensional}$ *carrier*

$$E = (X, Y, W, D, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StreamNameExtensionality}^{\uparrow}}$ *surface consists exactly of paired StreamName admission for* X *and* Y*, pointwise finite-window agreement for* W*, dyadic tolerance ledger visibility for* D*, RegSeqRat readback agreement for* R*, terminal Real-facing comparison for* Q*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, sibling provenance through* P*, and local naming through* N*.*

No StreamName extensionality obligation is stored outside these rows.

Proof. Project the accepted carrier. The two stream names enter only as X and Y, and the only equality-facing observation is the displayed finite window W.

The dyadic ledger D and regular rational readback R consume that same window before any Real-facing comparison can be read. Thus the packet records pointwise finite-window agreement, not quotient equality of streams.

The terminal row Q is downstream of the StreamName, DyadicRatCore, and RegSeqRat rows. Transport, replay, provenance, and local naming through H, C, P, N preserve the same route, so the displayed rows exhaust the NameCert obligations. □

Theorem 5991.3 (StreamName extensionality seal route)**.** *Every accepted* $\mathsf{StreamNameExtensionality}^{\uparrow}$ *packet exports equality evidence to* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers only through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The route reads paired stream sources, a shared finite window, dyadic tolerance data, regular rational readback, and the terminal comparison row, then preserves the same packet through hsame*,* Cont*,* Pkg*, and the local* $\mathsf{NameCert}_{\mathsf{StreamNameExtensionality}^{\uparrow}}$ *row. It exports no quotient stream equality, host function extensionality, selected infinite stream, countable-choice selector, or ambient Real completeness theorem.*

Proof. Begin with the paired stream rows X, Y. A comparison request can inspect them only through the finite window row W, so the equality surface is pointwise and bounded by the displayed request.

The tolerance ledger D and regular readback R turn the same finite window into the data consumed by RegSeqRat-facing routes. The terminal comparison row Q is therefore a seal over a displayed finite-window readback, not an independent infinite-stream equality.

Finally H, C, P, N transport, replay, source, and name that route. Since the excluded quotient, function-extensionality, selected-stream, choice, and completeness coordinates are absent from the carrier, every RegSeqRat or RealUp equality read factors through the stated finite route. □

Theorem 5991.4 (StreamName extensionality finite-window symmetry)**.** *Let*

$$E = (X, Y, W, D, R, Q, H, C, P, N)$$

be an accepted $\mathsf{StreamNameExtensionality}^{\uparrow}$ *carrier. Swapping the two* $\mathsf{StreamName}^{\uparrow}$ *source rows* X *and* Y *preserves the shared finite window* W*, dyadic tolerance ledger* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, terminal* $\mathsf{Real}^{\uparrow}$ *seal comparison* Q*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{StreamNameExtensionality}^{\uparrow}}$ *row* N*.*

Thus the equality evidence exported to RegSeqRat and RealUp consumers is symmetric at the finite-window level and introduces no quotient stream equality, host function extensionality, selected infinite stream, countable-choice selector, or ambient Real completeness theorem.

Proof. Project the carrier of Definition 5991.1. The only ordered coordinates are the two source rows X and Y; the shared window, tolerance ledger, readback, seal comparison, transport, replay, provenance, and local naming rows are displayed independently of that order.

Exchange X and Y while keeping W, D, R, Q, H, C, P, N fixed. The NameCert obligation theorem Definition 5991.2 says that these rows are exactly the local certificate surface, so no hidden equality datum changes under the exchange.

The seal-route theorem Definition 5991.3 then forces every RegSeqRat or RealUp consumer to read the same finite route. Since the carrier has no quotient, function-extensionality, selected-stream, choice, or completeness coordinate, the swapped packet exports only the symmetric finite-window evidence. □

Theorem 5991.5 (StreamName extensionality transitive window route)**.** *Let*

$$E_0 = (X, Y, W_0, D_0, R_0, Q_0, H_0, C_0, P_0, N_0) \quad \textit{and} \quad E_1 = (Y, Z, W_1, D_1, R_1, Q_1, H_1, C_1, P_1, N_1)$$

be accepted $\mathsf{StreamNameExtensionality}^{\uparrow}$ *packets sharing the middle* $\mathsf{StreamName}^{\uparrow}$ *row* Y *and compatible finite windows. A transitive equality read from* X *to* Z *may compose the packets only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *source rows, finite windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, terminal* $\mathsf{Real}^{\uparrow}$ *seal rows, componentwise* hsame *transports, displayed* Cont *replays,* Pkg *provenance rows, and local* NameCert *rows. It exports no quotient stream equality, host function extensionality, selected infinite stream, countable-choice selector, or ambient Real completeness theorem.*

Proof. Apply the NameCert obligations, Definition 5991.2, to E_0 and E_1. They expose the paired StreamName rows, finite windows, dyadic ledgers, regular readbacks, terminal Real-facing comparisons, transport, replay, provenance, and local names as the whole certificate surface.

Use the seal route, Definition 5991.3. It forces each equality read to pass through the finite StreamName-to-DyadicRatCore-to-RegSeqRat-to-Real route before any RegSeqRat or Real consumer may use the comparison.

Finally apply finite-window symmetry, Definition 5991.4, to align the middle row when the two packets are read in opposite orientations. The shared Y row is therefore used only as a displayed finite-window coordinate, and the composed X to Z route retains both sets of ledgers, readbacks, seals, transports, replays, provenance rows, and names. Since neither carrier contains a quotient, host-extensionality, selected-stream, choice, or completeness coordinate, transitivity remains a finite BEDC route. □

Closure status for $\mathsf{NameCert}_{\mathsf{StreamNameExtensionality}^{\uparrow}}$.

Constructive story: A $\mathsf{StreamNameExtensionality}^{\uparrow}$ packet is generated from two StreamNameUp source rows, a shared finite-window row, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a terminal RealUp comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StreamNameExtensionality}^{\uparrow}}$, obligation)

Scope closed: Definition 5991.1, Definition 5991.2, Definition 5991.3, and Definition 5991.4 enumerate the paired StreamName admission, finite-window agreement, dyadic ledger, RegSeqRat readback, terminal Real seal comparison, transport, replay, provenance, and local NameCert obligations.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{StreamNameExtensionality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, host function extensionality, selected infinite streams, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked paired StreamName admission, finite-window agreement, dyadic tolerance readback, RegSeqRat handoff, Real seal non-escape, transport stability, replay stability, and non-escape for BEDC.Derived.StreamNameExtensionalityUp.

Theorem 5991.6 (StreamName extensionality finite-window determinacy)**.** *Let* $E = (X, Y, W, D, R, Q, H, C, P, N$ *and* $E' = (X', Y', W', D', R', Q', H', C', P', N')$ *be accepted* $\mathsf{StreamNameExtensionality}^{\uparrow}$ *packets. Suppose the two packets display the same finite request index, the same point certificate, and componentwise* hsame *agreement on the inspected window rows. Then every public observation route through* Cont, Pkg*, and the local* $\mathsf{NameCert}_{\mathsf{StreamNameExtensionality}^{\uparrow}}$ *row exposes the same finite-window comparison data for the two packets.*

The determinacy claim is only a finite observation claim. It does not identify host functions, select infinite streams, assert quotient stream equality, or compare completed stream representatives outside the displayed window.

Proof. Project both accepted carriers. The only equality-facing rows available before any public observation are the paired StreamName rows, the finite window rows, the dyadic tolerance ledgers, the RegSeqRat readbacks, and the terminal Real-facing comparison rows.

Use the shared request index and point certificate to align the two window reads. Componentwise hsame agreement then identifies the displayed entries of W and W' at precisely the inspected finite indices, without making any claim about uninspected stream coordinates.

Apply the NameCert obligation theorem of Definition 5991.2. The dyadic ledger, RegSeqRat readback, and terminal comparison rows are downstream of that same finite window, so the aligned window determines the public comparison data available to the packet.

Finally use the seal route of Definition 5991.3. The Cont, Pkg, and local NameCert rows replay, source, and name only the displayed finite route. Therefore two accepted packets with the same request, point certificate, and componentwise window agreement expose the same public observation route, while host function equality and selected infinite stream equality remain outside the packet. □

Theorem 5991.7 (StreamName extensionality RegSeqRat forward link)**.** *Every accepted finite-window determinacy read accepted by a* $\mathsf{StreamNameExtensionality}^{\uparrow}$ *packet passes through the sibling* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of chapter 301 and then through the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before any public comparison data is exposed. The route is finite-window data first, regular rational readback second, and Real-facing seal last; it does not expose host stream equality, quotient stream representatives, or a selected infinite comparison stream.*

Proof. Start from Definition 5991.6. The only comparison data available after aligning the request, point certificate, and componentwise window rows is the finite observation route carried by the accepted packets.

Use Definition 5991.2 to read the downstream rows of that route. The RegSeqRat readback is part of the same finite window ledger, so the public comparison cannot bypass it or replace it by a host rational sequence.

Finally apply Definition 5991.3. The Real-facing comparison rows are exposed only after the seal route has replayed the finite window and regular rational readback, which gives the stated forward link to the sibling RegSeqRat and Real chapters. □

Theorem 5991.8 (StreamName extensionality tail reindex)**.** *Let* $E = (X, Y, W, D, R, Q, H, C, P, N)$ *and* $E' = (X', Y', W', D', R', Q', H', C', P', N')$ *be accepted* $\mathsf{StreamNameExtensionality}^{\uparrow}$ *packets. Suppose* W' *displays the same finite request window as* W *after a tail shift and reindexing of the two* $\mathsf{StreamName}^{\uparrow}$ *source rows, and suppose the shifted window has componentwise* hsame *agreement on the displayed entries, dyadic tolerance rows, regular rational readback rows, terminal comparison rows, replay rows, provenance rows, and local naming rows. Then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and the* $\mathsf{Real}^{\uparrow}$*-facing seal route expose the same finite comparison data for* E *and* E'*.*

The conclusion is only a displayed tail-window stability claim. It does not identify quotient streams, host functions, selected infinite streams, countable-choice schedules, or completed real representatives.

Proof. Project the two accepted packets. The tail shift changes only the displayed request indices for the two source rows; the hypothesis supplies the reindexed window W' and the componentwise hsame witnesses comparing it with W.

Apply finite-window determinacy, Definition 5991.6, to the shifted window. The theorem identifies the public observation data available from the aligned windows, because the request, point certificate, and inspected entries agree after reindexing.

Use the NameCert obligation theorem Definition 5991.2. It forces the dyadic ledger, regular rational readback, terminal comparison, transport, replay, provenance, and local naming rows to be read from the same finite window data, so the tail shift cannot introduce a second comparison source.

Finally apply the seal route and the RegSeqRat forward link, Definition 5991.3 and Definition 5991.7. They route the aligned finite window through $\mathsf{RegSeqRat}^{\uparrow}$ and then through the $\mathsf{Real}^{\uparrow}$-facing seal before public comparison data is exposed. Since no quotient stream equality, host function extensionality, selected infinite stream, countable choice, or Real completeness coordinate appears in the carrier, the reindexed tail exposes exactly the same finite comparison data. □

Chapter 5992

A Concrete Naming Certificate for $\mathsf{CaratheodoryMeasureExtension}^{\uparrow}$

Following Caratheodory and the standard extension theorem for premeasures, the $\mathsf{CaratheodoryMeasureExtension}^{\uparrow}$ packet records the finite BEDC route by which displayed premeasure event-value rows are handed through an outer-measure boundary and returned as $\mathsf{Measure}^{\uparrow}$ rows. It sits after the measurable-event schedule of chapter 5186, the outer-measure boundary of chapter 3385, and the root premeasure rows of chapter 92. The packet names only the finite carrier data required to replay the extension read; it does not assert a completed measure space, a host powerset, quotient event equality, countable choice, or Lebesgue completion.

Definition 5992.1 (Caratheodory measure-extension carrier)**.** *A* $\mathsf{CaratheodoryMeasureExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (A, S, O, M, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the premeasure event-value row, including the displayed event family, the finite disjoint-union ledgers already accepted by the* $\mathsf{Measure}^{\uparrow}$ *root premeasure surface, and the* $\mathsf{Real}^{\uparrow}$ *value names attached to those events.*
2. *S is the* $\mathsf{SigmaAlgebra}^{\uparrow}$ *schedule row that records which generated measurable-event rows are admissible before the extension read reaches the target measure row.*
3. *O is the* $\mathsf{OuterMeasure}^{\uparrow}$ *boundary row that carries the cover-valued outer-measure read and the visible handoff from premeasure event values to outer-measure approximants.*
4. *M is the* $\mathsf{Measure}^{\uparrow}$ *target value row exposed after the schedule and outer-measure boundary have been read.*
5. *E is the extension exactness ledger, stating that every accepted target value read agrees with the displayed premeasure row on the admitted source events and with the outer-measure boundary on generated measurable events.*
6. *H records componentwise* hsame *transport for the premeasure, schedule, outer-measure, target-value, exactness, replay, provenance, and local name rows.*
7. *C records displayed* Cont *replay from an extension request through A, S, O, M, E, H.*

8. *P is the* Pkg *provenance over* $\mathsf{OuterMeasure}^{\uparrow}$, $\mathsf{SigmaAlgebra}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and sibling* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CaratheodoryMeasureExtension}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a completed measure space, a host powerset of events, quotient event equality, a countable-choice selector, or Lebesgue completion.

Lean4 ✓ `BEDC.Derived.CaratheodoryMeasureExtensionUp.CaratheodoryMeasureExtensionTasteGate`
`single carrier alignment`

Theorem 5992.2 (Caratheodory measure-extension NameCert obligations)**.** *For every accepted* $\mathsf{CaratheodoryMeasureExtension}^{\uparrow}$ *carrier* $X = (A, S, O, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CaratheodoryMeasureExtension}}$ *surface consists exactly of carrier admission, premeasure compatibility, sigma-algebra schedule admission, outer-measure boundary handoff,* $\mathsf{Measure}^{\uparrow}$ *nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 5992.1. The displayed rows are precisely the premeasure event-value row A, the sigma-algebra schedule S, the outer-measure boundary O, the target value row M, the exactness ledger E, and the structural rows H, C, P, N.

Premeasure compatibility is read from A and E: the ledger compares target values only against source events already displayed in the premeasure row. Schedule admission is read from S, so generated measurable-event requests cannot bypass the sigma-algebra schedule.

The handoff to outer measure is the row O. It is consumed before M, and E records the agreement between the outer-measure boundary and the target $\mathsf{Measure}^{\uparrow}$ value row. Thus a consumer cannot obtain a measure-extension read without the premeasure, schedule, and outer-measure rows already visible.

Finally replay H, C, P, N. These rows transport, continue, source, and locally name the same finite packet. Since no carrier coordinate stores completed measure spaces, host powersets, quotient event equality, countable choice, or Lebesgue completion, the listed rows exhaust the NameCert obligations. □

Theorem 5992.3 (Caratheodory measure-extension outer-measure handoff)**.** *Every accepted* CaratheodoryMeasure *extension read passes through* $\mathsf{OuterMeasure}^{\uparrow}$, $\mathsf{SigmaAlgebra}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows. No accepted read can be completed by a completed measure space, host powerset, quotient event equality, countable choice, or Lebesgue completion.*

Proof. Start from an accepted extension read. Carrier projection exposes the premeasure event-value row A, whose event and value names are read through $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and the finite BHist rows already present in the packet.

The generated-event part of the read is then routed through the $\mathsf{SigmaAlgebra}^{\uparrow}$ schedule row S and the $\mathsf{OuterMeasure}^{\uparrow}$ boundary row O. The target measure value M is not public until those two rows and the extension exactness ledger E have been displayed.

The structural route is fixed by H, C, P, N. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve exactly the same finite handoff. Therefore every accepted read passes through the listed BEDC rows and cannot appeal to any absent completion, host-powerset, quotient-equality, choice, or Lebesgue-completion coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CaratheodoryMeasureExtension}^{\uparrow}}$ ·

Constructive story: A CaratheodoryMeasureExtension$^{\uparrow}$ packet is generated from a displayed premeasure event-value row, a SigmaAlgebra schedule, an OuterMeasure boundary row, a Measure target row, an extension exactness ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\text{CaratheodoryMeasureExtension}^{\uparrow}}$, seed)

Scope closed: Definition 5992.1, Definition 5992.2, and Definition 5992.3 seed the finite extension carrier from premeasure rows through SigmaAlgebra, OuterMeasure, Measure, Real, StreamName, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{CaratheodoryMeasureExtension}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CaratheodoryMeasureExtensionUp.CaratheodoryMeasureExtensionTasteGate\_single\_carrier\_`

Bridge status: none

Not claimed: This chapter does not claim completed measure spaces, host powersets, quotient event equality, countable choice, Lebesgue completion, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, premeasure compatibility, sigma-algebra scheduling, outer-measure handoff, Measure nonescape, extension exactness, transport, replay, provenance, and local naming for BEDC.Derived.CaratheodoryMeasureExtensionUp.

Chapter 5993

A Concrete Naming Certificate for $\mathsf{SubspaceTopology}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{SubspaceTopology}^{\uparrow}$ packet records the induced topology on a displayed carrier inside an ambient topological space as finite BEDC naming data. It sits between the indexed-open topology surface of chapter 88, the metric-subspace restriction packet of chapter 1519, and the existing BHist subspace-open surface in Definition 88.69. The packet gives compact-subspace, restriction-of-continuity, and relative-open consumers a general topology-level carrier, without forcing them through metric distance rows, host powersets, quotient subset equality, or selected ambient points.

Before a subspace open is exported, the carrier consumes the ambient $\mathsf{Topology}^{\uparrow}$ open-row discipline of chapter 88 and the inclusion-facing admission classifier carried by its own row A. Thus every relative-open read is already anchored in the ambient indexed-open ledger and the displayed inclusion surface, rather than being a free-standing host subset or an independent topology replacement.

Definition 5993.1 (SubspaceTopology carrier)**.** *A* $\mathsf{SubspaceTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, A, O, R, B, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{Topology}^{\uparrow}$ *row, exposing the point classifier, indexed-open ledger, finite-intersection rows, arbitrary-union rows, boundary opens, and visible open-membership stability.*
2. *A is the displayed admission row for the subspace carrier. A point is available to the subspace packet only when it passes the ambient point classifier of X and the admission row A.*
3. *O is the relative-open row. Each accepted subspace open is displayed as an ambient open row of X together with restriction to admitted points.*
4. *R is the restriction-exactness row, recording that membership in a relative open is read only as simultaneous admission by A and ambient membership in the corresponding open row of X.*
5. *B is the boundary and closure ledger, recording empty, whole-of-subspace, finite-intersection, and arbitrary-union rows obtained by restricting the corresponding ambient topology rows.*
6. *H records componentwise* hsame *transport for the ambient topology, admission row, relative-open row, restriction exactness, boundary and closure ledger, replay, provenance, and local naming rows.*

7. *C records displayed* Cont *replay from a relative-open request through X, A, O, R, B, H.*
8. *P is the* Pkg *provenance over* $\mathsf{SubspaceTopology}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, *Definition 88.69,* BHist, hsame, Cont, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SubspaceTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, A, O, R, B, H, C, P, N$. It has no coordinate for host powersets, quotient subset equality, selected ambient representatives, independent open selectors, metric distance data, or a replacement topology.

Theorem 5993.2 (SubspaceTopology NameCert obligations)**.** *For every accepted* $\mathsf{SubspaceTopology}^{\uparrow}$ *carrier $S = (X, A, O, R, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SubspaceTopology}^{\uparrow}}$ *surface consists exactly of carrier admission for the ambient topology and admission rows, relative-open exposure, restriction exactness, boundary and closure rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every relative-open consumer must read the route*

$$\mathsf{Topology}^{\uparrow}, A, O, R, B, H, C, P, N$$

before treating a subspace open as public.

Proof. Carrier admission is projection from Definition 5993.1. The available rows are the ambient topology X, admission predicate A, relative-open row O, restriction exactness R, boundary and closure ledger B, and the structural rows H, C, P, N.

Relative-open exposure is the role of O and R. A public subspace membership read is not a host subset membership; it is the displayed conjunction of the admission row A and an ambient open-membership row of X.

The boundary and closure rows are inherited from the ambient topology. Empty and whole-of-subspace opens are obtained by restricting the corresponding boundary opens of X, finite intersections restrict the ambient meet row, and arbitrary unions restrict the ambient union row while keeping the same admission predicate.

Transport and replay preserve the same route. The row H aligns the ambient classifier and admission predicate, C replays relative-open requests through the displayed rows, and P, N source and name the packet.

Since host powersets, quotient subset equality, selected representatives, independent open selectors, metric distance data, and replacement topologies are absent from the carrier, no local NameCert obligation can export them. □

Theorem 5993.3 (SubspaceTopology neighbour compatibility)**.** *Every* $\mathsf{SubspaceTopology}^{\uparrow}$ *packet refines the ambient* $\mathsf{Topology}^{\uparrow}$ *row by restriction to admitted points, and every* $\mathsf{MetricSubspace}^{\uparrow}$ *topology consumer may read the same admission row through this topology-level packet before invoking metric distance data. In particular, the relative-open route factors as*

$$X, A \longmapsto O, R, B \longmapsto H, C, P, N,$$

so compact subspace, continuity restriction, and metric-subspace consumers can share the same displayed subspace carrier while keeping metric distances outside the general topology certificate.

Proof. Start with an accepted $\mathsf{SubspaceTopology}^{\uparrow}$ carrier and project the ambient topology row X and admission row A. These two rows determine the carrier on which all relative-open reads take place.

Use Definition 5993.2. It forces every relative-open read through O, R, B after the admission row has been displayed, and it keeps transport, replay, provenance, and local naming in H, C, P, N.

A $\mathsf{MetricSubspace}^{\uparrow}$ consumer supplies a compatible admission row and an inherited distance ledger, but those metric rows are not needed to form the relative opens. The topology-level packet can therefore be read first, and metric distance data can be invoked only by consumers that explicitly require it.

Thus the packet is the common neighbour of the ambient topology and metric-subspace surfaces: it restricts opens by admission, names the induced topology, and does not add an independent metric or host subset coordinate. □

Theorem 5993.4 (SubspaceTopology continuity restriction)**.** *Let $S = (X, A, O, R, B, H, C, P, N)$ be an accepted* $\mathsf{SubspaceTopology}^{\uparrow}$ *carrier. Any* $\mathsf{ContinuousMap}^{\uparrow}$ *route whose source is the ambient* $\mathsf{Topology}^{\uparrow}$ *row X restricts to admitted subspace points only after the consumer reads $X, A, O, R, B, H, C, P, N$ in order: ambient opens from X, admission from A, relative opens from O, restriction exactness from R, inherited boundary and closure rows from B, transport from H, replay from C, provenance from P, and local naming from N.*

The restricted continuity read is therefore a relative-open route through the displayed subspace packet. It introduces no metric rows, host subset equality, selected ambient representatives, independent open selectors, or replacement topology.

Proof. Project the carrier of Definition 5993.1. A subspace point is available only when the ambient point classifier in X and the admission row A have both been displayed.

Apply the neighbour compatibility theorem Definition 5993.3. It factors every relative-open read through X, A before O, R, B, so the preimage test for a restricted continuous route can inspect only admitted points and ambient open rows.

The restriction-exactness row R supplies the needed membership reading: a point belongs to a relative open exactly through the displayed admission row and the corresponding ambient open-membership row. Thus continuity on the subspace is checked by pulling the ambient open request back through the same relative-open route.

Finally H, C, P, N preserve, replay, source, and name that route. Since no metric distance row, host subset equality, selected representative, independent selector, or replacement topology is present in the carrier, none can be exported by the restricted continuity read. □

Theorem 5993.5 (SubspaceTopology downstream Kelleyfication route)**.** *Let $S = (X, A, O, R, B, H, C, P, N)$ be an accepted* $\mathsf{SubspaceTopology}^{\uparrow}$ *carrier. Any* $\mathsf{Kelleyfication}^{\uparrow}$ *or compactly generated reflection consumer that reads the topology induced on the displayed subspace must first pass through the ambient* $\mathsf{Topology}^{\uparrow}$ *row X, the admission row A, the relative-open row O, the restriction-exactness row R, and the transport and replay rows H, C before the compact-window tests of chapter 6830 may consume the result.*

Proof. Project the carrier in Definition 5993.1. The rows X, A, O, R, H, C are the only displayed route by which an accepted subspace packet exposes its ambient topology, admitted carrier, relative opens, restriction exactness, componentwise transport, and replay.

Apply Definition 5993.3. It factors every relative-open route through X, A before O, R, B and then through H, C, P, N, keeping metric distance data and host subset coordinates outside the general topology certificate.

A $\mathsf{Kelleyfication}^{\uparrow}$ consumer reads compact-window tests from a topology source. Therefore its downstream request must receive the induced topology only after the subspace packet has exposed the ambient topology, admission, relative-open, restriction-exactness, transport, and replay rows.

This is exactly the route displayed by S, so the compactly generated reflection gains no independent topology replacement. □

Closure status for $\mathsf{NameCert}_{\mathsf{SubspaceTopology}^\uparrow}$.

Constructive story: A $\mathsf{SubspaceTopology}^\uparrow$ packet is generated from an ambient TopologyUp row, displayed admission row, relative-open row, restriction-exactness row, boundary and closure ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubspaceTopology}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 5993.1, Definition 5993.2, and Definition 5993.3 seed the finite induced-topology interface over ambient topology, admission, relative opens, restriction exactness, closure rows, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubspaceTopology}^\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host powerset topologies, quotient subset equality, selected ambient representatives, independent open selectors, metric distance construction, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, relative-open exposure, restriction exactness, inherited boundary and closure rows, neighbour compatibility with MetricSubspaceUp, transport, replay, provenance, and local naming for BEDC.Derived.SubspaceTopologyUp.

Theorem 5993.6 (SubspaceTopology topology forward route)**.** *Every relative-open read of an accepted* $\mathsf{SubspaceTopology}^\uparrow$ *packet first consumes the ambient* $\mathsf{Topology}^\uparrow$ *indexed-open ledger of chapter 88. Only after the ambient point classifier, indexed-open row, finite-intersection row, arbitrary-union row, admission row, relative-open row, restriction-exactness row, transport, replay, provenance, and local naming rows are visible may a* $\mathsf{MetricSubspace}^\uparrow$ *or* $\mathsf{Kelleyfication}^\uparrow$ *consumer use the induced topology. The route is a displayed topology-forward dependency; it does not export a host powerset topology, quotient subset equality, selected ambient representative, metric distance row, or independent open selector.*

Proof. Project the carrier of Definition 5993.1. The ambient topology row X and admission row A appear before the relative-open row O and restriction-exactness row R, so every relative-open read starts with the same displayed $\mathsf{Topology}^\uparrow$ source.

Use the NameCert obligations of Definition 5993.2. They require the indexed-open ledger, finite-intersection row, arbitrary-union row, admission row, relative-open row, restriction-exactness row, transport, replay, provenance, and local naming rows to remain visible before a subspace open is public.

Apply the neighbour compatibility theorem, Definition 5993.3, and the downstream Kelleyfication route, Definition 5993.5. These routes let $\mathsf{MetricSubspace}^\uparrow$ and $\mathsf{Kelleyfication}^\uparrow$ consume the induced topology only after the ambient $\mathsf{Topology}^\uparrow$ ledger has been exposed. Hence the subspace packet supplies a topology-forward dependency and not an independent host topology. □

Theorem 5993.7 (SubspaceTopology topology sibling route)**.** *Every accepted* $\mathsf{SubspaceTopology}^\uparrow$ *read that exports a subspace-open row consumes the ambient* $\mathsf{Topology}^\uparrow$ *carrier row of chapter 88, the subcarrier classifier, restriction and replay rows,* BHist, hsame, Cont, Pkg, *and the local* $\mathsf{NameCert}_{\mathsf{SubspaceTopology}^\uparrow}$ *row. The route is a sibling dependency on the displayed topology packet; it exports no detached host powerset, open-set lattice, quotient subset equality, selected ambient representative, or independent topology replacement.*

Proof. Project the carrier of Definition 5993.1. The ambient topology row X, admission row A, relative-open row O, restriction-exactness row R, replay row C, provenance row P, and local naming row N are visible before any subspace-open row is public.

Apply the NameCert obligations of Definition 5993.2. They force the relative-open read through the ambient $\mathsf{Topology}^{\uparrow}$ carrier, the subcarrier classifier, restriction exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$.

The topology-forward route of Definition 5993.6 identifies this as a horizontal dependency on chapter 88. Since host powersets, open-set lattices, quotient subset equality, selected ambient representatives, and independent topology replacements are absent from the carrier, no sibling consumer can export them. □

Chapter 5994

A Concrete Naming Certificate for NormalizationCandidateFrontier$^{\uparrow}$

The NormalizationCandidateFrontier$^{\uparrow}$ packet realizes the candidate-mediated boundary of chapter 9383 as finite evidence and refusal rows. It sits beside the candidate socket of chapter 3566, the bounded candidate route of chapter 4196, the MetaCIC normalization frontier of chapter 892, and the critical-path packet of chapter 765. The packet separates positive candidate evidence from requests for global strong normalization, so later audit consumers can cite a concrete frontier without turning candidate-mediated evidence into an evidence-free theorem.

Definition 5994.1 (NormalizationCandidateFrontier carrier)**.** *A* NormalizationCandidateFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, E, B, S, I, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed typed MetaCIC term window, recording the term, type, context boundary, and closedness evidence visible to the audit map.*
2. *E is the candidate-evidence row, carrying reducibility candidate, closed-candidate, or candidate-set membership data supplied by the sibling socket.*
3. *B is the bounded-candidate row, recording finite fuel, Pi adequacy, application adequacy, and candidate-mediated route data read through* BoundedNormalizationCandidate$^{\uparrow}$*.*
4. *S is the candidate-supported strong-normalization projection, downstream of E and B.*
5. *I is the no-infinite-reduction projection, downstream of the same candidate-supported route.*
6. *O is the frontier-obstruction row, recording requests for evidence-free closed-term strong normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, or completed closed consistency.*
7. *H records componentwise* hsame *transport for the closed term window, candidate evidence, bounded route, strong-normalization projection, no-infinite-reduction projection, obstruction row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a normalization-frontier request through T, E, B, S, I, O, H.*

9. *P is the* Pkg *provenance over* $\mathsf{NormalizationCandidateFrontier}^{\uparrow}$, $\mathsf{NormalizationCandidateSocket}^{\uparrow}$, $\mathsf{BoundedNormalizationCandidate}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, *chapter 9383,* BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{NormalizationCandidateFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, E, B, S, I, O, H, C, P, N$. It has no coordinate for global strong normalization, candidate-erased evidence, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, completed closed consistency, Lean verification, or bridge checking.

Theorem 5994.2 (NormalizationCandidateFrontier stability)**.** *For every accepted* $\mathsf{NormalizationCandidateFrontier}^{\uparrow}$ *carrier $F = (T, E, B, S, I, O, H, C, P, N)$, any public strong-normalization or no-infinite-reduction read is stable only along classifier transport that preserves the candidate evidence row E and bounded route row B. If a consumer keeps the closed term window T but drops E or B, the read reaches the obstruction row O and cannot export S or I from this packet.*

Proof. Project the carrier of Definition 5994.1. The closed term window is T, but the positive normalization rows are not attached directly to T.

The candidate evidence E and bounded route B are the gate. The strong-normalization projection S is downstream of those rows, and the no-infinite-reduction projection I is downstream of the same candidate-supported route.

Classifier transport through H must preserve E and B before S or I can be replayed. The replay row C therefore transports positive evidence only together with the candidate and bounded-route data that justify it.

If a consumer keeps T while dropping E or B, the carrier has no displayed route from the term window to S or I. The frontier-obstruction row O is then the only available response, and it records exactly the evidence-free global requests excluded from the packet. □

Theorem 5994.3 (NormalizationCandidateFrontier audit handoff)**.** *Every MetaCIC normalization audit consumer of an accepted* $\mathsf{NormalizationCandidateFrontier}^{\uparrow}$ *packet factors through the finite route*

$$T \longmapsto E \longmapsto B \longmapsto S \longmapsto I \longmapsto O$$

before citing a candidate-mediated normalization consequence. The route is compatible with the sibling $\mathsf{NormalizationCandidateSocket}^{\uparrow}$, $\mathsf{BoundedNormalizationCandidate}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, *and* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *packets, but it does not claim global strong normalization for every closed typed MetaCIC term.*

Proof. Start with a public audit read. The term row T supplies the closed typed term window, but Definition 5994.2 requires candidate evidence and bounded route data before any positive normalization projection can be consumed.

Read E from the candidate socket surface and B from the bounded candidate route. These rows expose the reducibility-candidate or candidate-set evidence, finite fuel, and Pi/application adequacy data used by the audit consumer.

The strong-normalization projection S and no-infinite-reduction projection I are then available as candidate-mediated consequences. Requests that erase candidate evidence, demand unrestricted subject reduction, assert global confluence, identify quotient syntax, trust host evaluation, or claim completed closed consistency are retained in O.

The structural rows H, C, P, N preserve this route under transport, replay, provenance, and local naming. Therefore the packet is a finite frontier handoff for the audit map, not a global strong-normalization theorem. □

Theorem 5994.4 (NormalizationCandidateFrontier sibling dependency)**.** *Every accepted* NormalizationCandidateF *audit read supplies evidence and refusal rows to the MetaCIC normalization route of chapter 892 and chapter 9383. The rows $E, B, S, I, O, H, C, P, N$ are consumed as candidate-evidence, bounded-route, projection, obstruction, transport, replay, provenance, and local naming data; they are not a replacement for the sibling normalization frontier and do not assert evidence-free closed-term normalization.*

Proof. Use the audit handoff of Definition 5994.3. It routes every public read through the closed term window, candidate evidence, bounded route, positive projections, and obstruction row before a normalization audit consumer may cite the packet.

The MetaCIC normalization frontier sibling consumes exactly those rows as finite evidence and refusal data. The audit map supplies the route on which they are read, while H, C, P, N preserve the same dependency under transport, replay, provenance, and local naming.

Since the packet retains O as an explicit obstruction row, the dependency cannot erase candidate evidence or promote the frontier into a global strong-normalization theorem. □

Theorem 5994.5 (NormalizationCandidateFrontier obligation closure route)**.** *Every accepted* $\mathsf{NormalizationCandidateFrontier}^{\uparrow}$ *read consumed by the* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *route of chapter 892 remains valid only while the closed term window T, candidate evidence row E, bounded route B, strong-normalization projection S, no-infinite-reduction projection I, obstruction row O, componentwise transport H, displayed replay C, provenance P, and local naming row N remain visible.*

The obstruction row is part of the dependency lattice. It records evidence-erasing or global normalization requests as refusals rather than surrounding prose.

Proof. Use Definition 5994.4. The sibling dependency theorem sends the candidate-evidence, bounded-route, projection, obstruction, transport, replay, provenance, and naming rows to the MetaCIC normalization route.

Now include the source window from Definition 5994.1. The closed term row T is the term boundary on which E and B are interpreted, so a consumer cannot keep the projections S and I while hiding T.

Finally apply Definition 5994.2. Dropping E or B forces the read into O, and retaining O prevents the consumer from treating candidate-mediated evidence as evidence-free global normalization. Thus $T, E, B, S, I, O, H, C, P, N$ form the visible dependency lattice for the $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ consumer. □

Theorem 5994.6 (NormalizationCandidateFrontier obstruction exactness)**.** *Let $F = (T, E, B, S, I, O, H, C, P, N)$ be an accepted* $\mathsf{NormalizationCandidateFrontier}^{\uparrow}$ *carrier. Any public read that exports the candidate-supported strong-normalization row S or the no-infinite-reduction row I must preserve the candidate-evidence row E, the bounded-candidate route row B, and the obstruction row O. If E or B is absent from the read, the only public route supplied by this packet is the obstruction row O, so evidence-erasing requests cannot be converted into global strong normalization.*

Proof. Project the carrier of Definition 5994.1. The rows S and I are displayed only downstream of E and B, while O records the requests that erase candidate evidence, bounded routes, or the explicit obstruction boundary.

Use stability, Definition 5994.2. It already forces any public strong-normalization or no-infinite-reduction read to preserve E and B under classifier transport. When either row is dropped, the read has no carrier coordinate from which S or I can be exported.

Now apply the audit handoff and sibling dependency results, Definition 5994.3 and Definition 5994.4. They route MetaCIC audit consumers through the candidate socket, bounded candidate packet, normalization frontier, and critical-path surface before any positive projection is public, and they keep O visible as a refusal row rather than prose outside the packet.

Finally use the obligation closure route of Definition 5994.5. Since $T, E, B, S, I, O, H, C, P, N$ are the visible dependency lattice, a read lacking E or B cannot bypass O. The obstruction row is therefore exact for evidence-erasing requests: it is the public result of the packet in those cases, and it cannot be erased into a global strong-normalization claim. □

Theorem 5994.7 (NormalizationCandidateFrontier local confluence scope)**.** *Let $F = (T, E, B, S, I, O, H, C, P, N)$ be an accepted* $\mathsf{NormalizationCandidateFrontier}^{\uparrow}$ *carrier. A local confluence consumer may read a join scope from this packet only when the closed typed window T, candidate evidence row E, bounded route row B, positive projection rows S, I, and obstruction row O remain visible through H, C, P, N.*

The licensed join scope is therefore candidate-mediated frontier evidence for a closed typed window. It is not global confluence, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, or completed consistency.

Proof. Project the carrier of Definition 5994.1. The rows T, E, B, S, I, O are the only displayed normalization and obstruction rows, while H, C, P, N transport, replay, source, and name that same finite route.

Apply stability and audit handoff, Definition 5994.2 and Definition 5994.3. They keep candidate evidence and bounded routing visible before S or I can be exported to an audit or confluence-facing consumer.

Use sibling dependency and obligation closure from Definition 5994.4 and Definition 5994.5. These force the closed typed window and frontier siblings to remain part of the same read instead of being replaced by a detached join theorem.

Finally apply obstruction exactness, Definition 5994.6. If E, B, or O is erased, the packet supplies only the obstruction route, so the local join scope cannot become global confluence, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, or completed consistency. □

Theorem 5994.8 (NormalizationCandidateFrontier candidate-mediated confluence)**.** *Let $F = (T, E, B, S, I, O, H, C, P, N)$ be an accepted* $\mathsf{NormalizationCandidateFrontier}^{\uparrow}$ *carrier. A local confluence consumer may compose the rows $T, E, B, S, I, O, H, C, P, N$ only while preserving the candidate evidence E, bounded route B, and obstruction row O as visible coordinates of the same packet.*

The composed read is candidate-mediated frontier evidence for the closed typed window T. It cannot promote the packet to global confluence, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, or completed closed consistency.

Proof. Start with stability, Definition 5994.2. It forces every positive normalization read to preserve the candidate-evidence row E and bounded route row B before S or I can be exported.

Apply the audit handoff of Definition 5994.3. The handoff routes MetaCIC consumers through T, E, B, S, I, O before any candidate-mediated consequence is public, so the composition cannot erase the candidate rows.

Use obstruction exactness, Definition 5994.6. The row O remains part of the public route and records evidence-erasing, global confluence, unrestricted subject-reduction, quotient-syntax, host-evaluator, and completed-consistency requests as refusals.

Finally use the local confluence scope of Definition 5994.7. It permits only a closed-window, candidate-mediated join scope transported and replayed by H, C, P, N. Therefore the composed read remains local frontier evidence and cannot become a global normalization or confluence theorem. □

Theorem 5994.9 (NormalizationCandidateFrontier nontrivial witness)**.** *Let $F = (T, E, B, S, I, O, H, C, P, N)$ be an accepted* NormalizationCandidateFrontier$^{\uparrow}$ *carrier. Any accepted read exposing a normalization candidate must preserve whether the exposed row came from the positive candidate-evidence route E, B, S, I or from the retained obstruction boundary O. The local classifier cannot identify these rows under* hsame *transport or* Cont *replay; bounded-route evidence and obstruction retention remain distinct carrier coordinates.*

Proof. Project the carrier of Definition 5994.1. The positive candidate route is carried by E, B, S, I, while the retained obstruction boundary is the separate row O.

Use stability and audit handoff, Definition 5994.2 and Definition 5994.3. They require candidate evidence and bounded-route rows to stay visible before a public normalization projection may be read.

Apply obstruction exactness, Definition 5994.6. A read that drops E or B reaches O instead of exporting S or I, so the obstruction row cannot be identified with the positive route.

Finally use candidate-mediated confluence, Definition 5994.8. It composes only reads that preserve E, B, O, H, C, P, N as visible coordinates of the same packet. Componentwise hsame transport and displayed Cont replay therefore carry the distinction between bounded-route evidence and obstruction retention rather than collapsing the two rows. □

Falsifiable prediction: An accepted NormalizationCandidateFrontier$^{\uparrow}$ consumer that exports closed-term strong normalization while omitting the candidate-evidence row E, bounded route row B, or obstruction row O refutes the packet.

Independence witness: normalization_candidate_socket, bounded_normalization_candidate, metacicnormalizationfrontier, metaciccriticalpath: the socket separates candidate families, the bounded candidate packet records finite fuel and adequacy data, the MetaCIC frontier records normalization boundary rows, and the critical path records dependency pressure; none is bijective with NormalizationCandidateFrontier$^{\uparrow}$ because this packet jointly carries the closed term window, candidate evidence, bounded route, positive projections, explicit obstruction, transport, replay, provenance, and local naming as one frontier carrier.

Later Lean TasteGate coverage for this packet must provide Nontrivial and FieldFaithful instances for the candidate-evidence row family, bounded-route row family, obstruction row, and frontier classifier before BEDC.Derived.NormalizationCandidateFrontierUp can serve as a checked carrier.

Closure status for NameCert$_{\text{NormalizationCandidateFrontier}^{\uparrow}}$ **.**

Constructive story: A NormalizationCandidateFrontier$^{\uparrow}$ packet is generated from a closed typed MetaCIC term window, candidate-evidence row, bounded-candidate route, candidate-supported strong-normalization projection, no-infinite-reduction projection, frontier obstruction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\text{NormalizationCandidateFrontier}^{\uparrow}}$, seed)

Scope closed: Definition 5994.1, Definition 5994.2, Definition 5994.3, and Definition 5994.4 seed the finite candidate/refusal boundary for MetaCIC normalization audit consumers.

Formal verification: FormalStatus(NameCert$_{\text{NormalizationCandidateFrontier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, global strong normalization, candidate-erased closed-term normalization, unrestricted subject reduction, global confluence, quotient syntax equality, host evaluator soundness, completed closed consistency, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate evidence preservation, bounded-route preservation, SN and no-infinite-reduction projection stability, obstruction exactness, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.NormalizationCandidateFrontierUp.

Theorem 5994.10 (NormalizationCandidateFrontier typed SN scope)**.** *For every accepted* NormalizationCandidate *carrier* $F = (T, E, B, S, I, O, H, C, P, N)$*, candidate-mediated strong-normalization scope is public only through the typed-term source* T*, candidate row* E*, residual-window and bounded-route row* B*, local join row carried by the audit handoff, normal-form seal represented by the projections* S, I*, transport* H*, replay* C*, provenance* P*, and local* NameCert *row* N*. The scope exports no global strong-normalization theorem, unrestricted subject reduction, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Project the carrier of Definition 5994.1. The typed source, candidate evidence, bounded route, normalization projections, obstruction, transport, replay, provenance, and local naming rows are exactly $T, E, B, S, I, O, H, C, P, N$.

Use the local obligation route of Definition 5994.5. It keeps candidate evidence and bounded-route data visible before any strong-normalization projection can be read, and it retains the obstruction row for evidence-erasing requests.

Apply the audit handoff of Definition 5994.3 and the sibling dependency of Definition 5994.4. They route the candidate-mediated read through the MetaCIC normalization frontier and local audit rows rather than through a host evaluator or quotient term equality.

Thus the typed SN scope is confined to the displayed finite packet. Since no carrier coordinate supplies global SN, unrestricted subject reduction, evaluator equality, quotient term equality, or kernel consistency, none of those endpoints is exported by the theorem. □

Chapter 5995

A Concrete Naming Certificate for $\mathsf{EffrosBorelSpace}^{\uparrow}$

Following Effros and standard descriptive-set-theoretic hyperspace practice, the $\mathsf{EffrosBorelSpace}^{\uparrow}$ packet records the finite hit–miss Borel surface of a hyperspace without importing a host sigma-algebra, a completed measure object, or choice-selected closed sets. It sits beside the compact-subset carrier of chapter 1660, the Vietoris routing of chapter 2375, the compact metric source of chapter 129, and the metric carrier of chapter 57.

Definition 5995.1 (Effros Borel hit–miss carrier)**.** *An* $\mathsf{EffrosBorelSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (H, A, M, V, K, D, T, C, P, N)$$

with the following displayed rows:

1. *H is the underlying* $\mathsf{Hyperspace}^{\uparrow}$ *carrier row, exposing only finite compact-subset names and Hausdorff-facing inspection data.*
2. *A is the hit-row ledger, recording the finite open-window tests whose positive intersection is visible to the packet.*
3. *M is the miss-row ledger, recording the finite closed-window tests whose avoidance is visible to the packet.*
4. *V is the* $\mathsf{VietorisTopology}^{\uparrow}$ *routing row that places the hit and miss ledgers in the same finite topological basis.*
5. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row and D is the* $\mathsf{Met}^{\uparrow}$ *distance row used before any hyperspace read is admitted.*
6. *T records componentwise* hsame *transport for hyperspace, hit, miss, Vietoris, compact-metric, metric, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a hit–miss request through H, A, M, V, K, D, T.*
8. *P is the* Pkg *provenance over* $\mathsf{EffrosBorelSpace}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{VietorisTopology}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{EffrosBorelSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host powerset of closed sets, an ambient Borel sigma-algebra, a completed measure space, a selected representative, quotient closed-set equality, or countable-choice enumeration of tests.

Lean4 (definition) `BEDC.Derived.EffrosBorelSpaceUp.EffrosBorelSpaceUp`

Theorem 5995.2 (Effros Borel NameCert obligations)**.** *For every accepted* $\mathsf{EffrosBorelSpace}^{\uparrow}$ *carrier* $E = (H, A, M, V, K, D, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EffrosBorelSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, hit-row stability, miss-row stability, hyperspace nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The hit and miss rows are admitted only through the common* $\mathsf{VietorisTopology}^{\uparrow}$ *route over the displayed* $\mathsf{Hyperspace}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*, and* $\mathsf{Met}^{\uparrow}$ *source rows.*

Proof. Project the carrier of Definition 5995.1. The only observable hyperspace data are the finite compact-subset row H, the hit ledger A, the miss ledger M, and the common Vietoris route V.

The compact and metric rows K, D fix the source on which the hit and miss tests are read. Since both ledgers pass through V, a consumer cannot separate hit stability from miss stability by appealing to an external topology.

Transport and replay are then forced through T and C, with provenance and local naming supplied by P, N. No remaining coordinate can introduce a host sigma-algebra, a completed measure object, a quotient closed-set representative, or a choice-selected enumeration. □

Theorem 5995.3 (Effros Borel hyperspace nonescape)**.** *Every Borel-facing consumer of an accepted* $\mathsf{EffrosBorelSpace}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Hyperspace}^{\uparrow}, \mathsf{VietorisTopology}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$$

before it receives a hit–miss name. The read remains inside the displayed hyperspace packet and exports no host Borel sigma-algebra, no completed measure structure, no selected closed subset, no quotient equality of closed sets, and no countable-choice schedule for tests.

Proof. Begin with a Borel-facing read. Carrier admission exposes the hyperspace row H, but no hit–miss information is public until the hit row A and miss row M have both been routed through the same Vietoris row V.

The source rows K, D keep the route tied to the compact metric and metric carriers already displayed in the packet. Thus a consumer can inspect finite hit and miss windows, but it cannot leave the packet for a host powerset or a detached measurable-space object.

Finally T, C, P, N transport, replay, source, and name the same finite route. The carrier omissions in Definition 5995.1 rule out the remaining exits, so every accepted read is a hyperspace nonescape read. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffrosBorelSpace}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EffrosBorelSpace}^{\uparrow}$ packet is generated from a Hyperspace row, finite hit rows, finite miss rows, VietorisTopology routing, CompactMetric and Metric source rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EffrosBorelSpace}^{\uparrow}}$, seed)

Scope closed: Definition 5995.1, Definition 5995.2, and Definition 5995.3 seed the hit–miss hyperspace Borel carrier over Hyperspace, VietorisTopology, CompactMetric, Metric, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{EffrosBorelSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host sigma-algebras, completed measure spaces, selected closed-set representatives, quotient closed-set equality, countable-choice test schedules, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, hit-row stability, miss-row stability, hyperspace nonescape, transport, replay, provenance, and local naming for BEDC.Derived.EffrosBorelSpaceUp.

Chapter 5996

A Concrete Naming Certificate for $\mathsf{CountingMeasure}^{\uparrow}$

Following Halmos, Feller, and Kolmogorov, the $\mathsf{CountingMeasure}^{\uparrow}$ packet records the finite counting-measure surface as BEDC NameCert data. It sits over the measurable carrier of chapter 92, the probability-space normalization discipline of chapter 184, the finite index rows of chapter 28 and chapter 36, and the point-mass boundary of chapter 5181. The packet names finite event tallies only; it does not import a host measure object, a powerset sigma algebra, countable additivity, quotient equality of subsets, or a completed scalar measure theory.

Definition 5996.1 (CountingMeasure carrier)**.** *A* $\mathsf{CountingMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (E, F, T, L, R, H, C, P, N)$$

with the following displayed rows:

1. *E is the finite event row, recording the displayed event entries whose membership is being counted.*
2. *F is the finite-support row, listing exactly the displayed points or atoms whose event-membership rows are visible to the packet.*
3. *T is the tally row, assigning to each event row the* $\mathsf{Nat}^{\uparrow}$ *count obtained by traversing the finite support.*
4. *L is the* $\mathsf{List}^{\uparrow}$ *provenance row, recording the finite traversal order and the duplicate-control evidence used by the tally.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *mass readback row, transporting the* $\mathsf{Nat}^{\uparrow}$ *tally to the displayed non-negative scalar endpoint consumed by* $\mathsf{Measure}^{\uparrow}$ *and* $\mathsf{ProbSpace}^{\uparrow}$ *readers.*
6. *H records componentwise* hsame *transport for event rows, finite support rows, tally rows, list provenance, Real mass readback, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an event request through E, F, L, T, R and then to the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{CountingMeasure}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DiracPointMass}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CountingMeasure}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host measure object, sigma-additivity, a selected ambient support, a powerset event oracle, quotient equality of subsets, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CountingMeasureUp.TasteGate.CountingMeasureTasteGate single carrier alignment`

Theorem 5996.2 (CountingMeasure NameCert obligation surface)**.** *For every accepted* $\mathsf{CountingMeasure}^{\uparrow}$ *carrier* $Q = (E, F, T, L, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CountingMeasure}^{\uparrow}}$ *surface consists exactly of the finite event row, finite support row, Nat tally row, List traversal provenance, Real mass readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. Every* $\mathsf{Measure}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*,* $\mathsf{Distribution}^{\uparrow}$*, or* $\mathsf{DiracPointMass}^{\uparrow}$ *consumer that reads a counting-mass value must expose those rows before it treats the value as a measure-facing endpoint.*

Proof. Project the accepted carrier of Definition 5996.1. The rows E and F supply the only event and finite-support data, so a consumer can inspect membership only through the displayed finite event packet.

The tally is then forced through L and T. The $\mathsf{List}^{\uparrow}$ row records the finite traversal and duplicate-control evidence, while the $\mathsf{Nat}^{\uparrow}$ row records the resulting count; no outside cardinality oracle or selected support is part of the packet.

The scalar mass row R is downstream of that tally. It transports the finite natural count into the displayed $\mathsf{Real}^{\uparrow}$ endpoint used by measure-facing readers, and the route is preserved only by the componentwise hsame transport and displayed Cont replay in H and C.

Finally P and N source and name the same finite packet. Since the carrier contains no host measure object, sigma-additivity row, powerset event oracle, quotient equality, countable choice, or ambient Real-completeness coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 5996.3 (CountingMeasure finite disjoint-union additivity)**.** *Let an accepted* $\mathsf{CountingMeasure}^{\uparrow}$ *packet display two finite event rows* E_0, E_1 *over the same finite support row* F*, together with a displayed disjointness row saying that no listed support point is counted by both events. Then the tally row for the displayed union event is classified with the* $\mathsf{Nat}^{\uparrow}$ *sum of the two tally rows, and the* $\mathsf{Real}^{\uparrow}$ *mass readback follows the same finite Nat-to-Real route.*

The statement is internal to the displayed carrier rows: it uses the finite support, event rows, tally rows, $\mathsf{List}^{\uparrow}$ *traversal provenance,* $\mathsf{Nat}^{\uparrow}$ *addition ledger,* $\mathsf{Real}^{\uparrow}$ *mass readback, componentwise transport, replay, provenance, and local naming. It does not assert countable additivity, a powerset sigma algebra, quotient equality of subsets, a host measure object, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier through Definition 5996.1. The two event rows and their union are read over the same finite support row F, so the traversal is the single $\mathsf{List}^{\uparrow}$ route already recorded by L.

Traverse the support once. At each listed point, the displayed disjointness row splits membership into the E_0 side, the E_1 side, or neither side; the mixed counted-by-both case is refused by that row.

Accumulate the two tallies through the $\mathsf{Nat}^{\uparrow}$ addition ledger. Because every counted point contributes to exactly one of the two displayed event rows, the union tally is the finite sum of the two component tallies.

Transport the result through the mass readback row R and the structural rows H, C, P, N. This gives the same finite Nat-to-Real route used by the NameCert obligation surface, without importing countable additivity or any ambient host measure structure. □

Closure status for $\mathsf{NameCert}_{\mathsf{CountingMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{CountingMeasure}^{\uparrow}$ packet is generated from finite event rows, finite support rows, Nat tally rows, List traversal provenance, RealUp mass readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CountingMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5996.1 and Definition 5996.2 seed the finite counting-measure packet over MeasureUp, ProbSpaceUp, NatUp, ListUp, RealUp, and DiracPointMassUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CountingMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim sigma-additivity, a host measure object, powerset sigma-algebra generation, quotient equality of subsets, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite event support, Nat tally exactness, List traversal provenance, Real mass readback, transport, replay, provenance, and local naming for BEDC.Derived.CountingMeasureUp.CountingMe

Chapter 5997

A Concrete Naming Certificate for $\mathsf{RationalOpenIntervalBasis}^{\uparrow}$

Following Bishop and Bridges on rational interval approximations and Bourbaki on bases for ordered topological spaces, the $\mathsf{RationalOpenIntervalBasis}^{\uparrow}$ packet records the finite BEDC carrier for rational open balls on the real line. It sits between the rational arithmetic of chapter 37, the dyadic tolerance rows of chapter 291, the finite-window naming surface of chapter 126, the regular-rational handoff of chapter 301, the real seal of chapter 38, the second-countability boundary of chapter 1901, and the dyadic interval comparison packet of chapter 1916. The chapter names only finite rational centers, positive radii, membership rows, finite observation windows, regular-sequence handoff, terminal real seals, transport, replay, provenance, and local naming.

Definition 5997.1 (Rational open interval basis carrier)**.** *A* $\mathsf{RationalOpenIntervalBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (Q, D, M, S, G, E, H, C, P, N)$$

whose rows have the following displayed roles.

1. *Q is the rational-center row, carrying the* $\mathsf{Rat}^{\uparrow}$ *center and the rational arithmetic needed to compare endpoints.*
2. *D is the positive radius row, displayed either as a positive rational radius or through a positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement.*
3. *M is the interval-membership row, exposing exactly the two strict rational inequalities that certify an inspected point lies between the displayed endpoints.*
4. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the coordinates read before the interval predicate is evaluated.*
5. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, sending the inspected rational-window evidence into a regular rational sequence name.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after Q, D, M, S, G have all remained visible.*
7. *H is the componentwise* hsame *transport for the displayed rows.*
8. *C is the displayed* Cont *replay route for rational centers, radii, membership checks, finite windows, regular-sequence handoff, and real seals.*

9. *P is the* Pkg *provenance over* $\mathsf{RationalOpenIntervalBasis}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SecondCountable}^{\uparrow}$, $\mathsf{DyadicIntervalBasis}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalOpenIntervalBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, D, M, S, G, E, H, C, P, N$. It has no coordinate for host topology, arbitrary open sets, quotient equality of reals, selected representatives, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RationalOpenIntervalBasisUp.RationalOpenIntervalBasisTasteGate single carrier alignment`

Theorem 5997.2 (Rational open interval basis NameCert obligations)**.** *For every accepted* RationalOpenIntervalBas *carrier $I = (Q, D, M, S, G, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalOpenIntervalBasis}^{\uparrow}}$ *surface consists exactly of the following five obligation rows.*

1. *carrier admission for the displayed rational center Q and positive radius D;*
2. *interval-membership exposure through M, with membership read only by the strict endpoint inequalities determined by Q, D;*
3. *finite-window exposure through S, requiring every inspected real name to pass through a displayed* $\mathsf{StreamName}^{\uparrow}$ *window before M is consulted;*
4. *regular-to-real handoff through G, E, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row before the terminal* $\mathsf{Real}^{\uparrow}$ *seal;*
5. *structural closure through H, C, P, N, with provenance over the rational, dyadic, stream, regular-sequence, real, second-countable, and dyadic-interval sibling rows.*

No obligation row may be replaced by a host topology, an arbitrary open set lattice, quotient equality of reals, selected representatives, countable choice, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.RationalOpenIntervalBasisUp.RationalOpenIntervalBasisCarrier namecert obligations`

Proof. Project the carrier of Definition 5997.1. The rows Q and D are the only rows carrying the center and radius data, and M is the only row assigned to interval membership.

The finite observation discipline is supplied by S. Any point-facing membership read must first expose its $\mathsf{StreamName}^{\uparrow}$ window, after which G and E provide the regular-sequence handoff and terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally, H, C, P, N transport, replay, source, and name exactly those rows. Since the carrier contains no coordinate for host topology, arbitrary opens, quotient real equality, selected representatives, countable choice, or ambient completeness, the five obligations exhaust the local naming surface. □

Theorem 5997.3 (Rational open interval basis finite-window nonescape)**.** *For every accepted* $\mathsf{RationalOpenIntervalBasis}^{\uparrow}$ *carrier $I = (Q, D, M, S, G, E, H, C, P, N)$, every basis-membership read factors through the finite route*

$$\mathsf{Rat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

before any second-countability or dyadic-interval consumer can cite it. The read exports no host topology, arbitrary open set, quotient equality of reals, selected representative, countable choice, or ambient real-completeness endpoint.

Proof. Use Definition 5997.2. The membership row M cannot be read until the center row Q, radius row D, and finite stream window S have been displayed.

The completion-facing part of the route is then G, E. These rows place the regular rational handoff before the terminal real seal, so downstream references by $\mathsf{SecondCountable}^{\uparrow}$ or $\mathsf{DyadicIntervalBasis}^{\uparrow}$ receive only the finite basis packet.

The structural rows H, C, P, N add transport, replay, provenance, and naming, but no host topology or quotient endpoint. Thus the finite-window route is the whole export surface. □

Falsifiable prediction: Every accepted $\mathsf{RationalOpenIntervalBasis}^{\uparrow}$ membership read exposes a rational center row, a positive rational or dyadic radius row, the strict interval-membership row, a finite StreamName window, a RegSeqRat handoff, a RealUp seal, componentwise transport, continuation replay, provenance, and local naming.

Independence witness: rat, dyadicratcore, streamname, regseqrat, real, secondcountable, dyadicintervalbasis: $\mathsf{RationalOpenIntervalBasis}^{\uparrow}$ is not identical to any listed sibling because it binds rational centers and positive-radius membership before the finite-window handoff to regular rational names and the terminal RealUp seal.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalOpenIntervalBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalOpenIntervalBasis}^{\uparrow}$ packet is generated from rational center rows, positive rational or dyadic radius rows, strict interval-membership rows, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalOpenIntervalBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5997.1, Definition 5997.2, and Definition 5997.3 seed the finite rational-center, positive-radius, membership, window, handoff, seal, transport, replay, provenance, and local naming surface over $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SecondCountable}^{\uparrow}$, and $\mathsf{DyadicIntervalBasis}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalOpenIntervalBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host topology, arbitrary open set lattices, quotient equality of reals, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational-center and positive-radius exactness, strict interval-membership exposure, finite-window membership exactness, finite-window handoff, $\mathsf{RegSeqRat}^{\uparrow}$-to-$\mathsf{Real}^{\uparrow}$ sealing, terminal seal nonescape, transport, replay, provenance, and local naming for the same finite packet and for BEDC.Derived.RationalOpenIntervalBasisUp.

Chapter 5998

A Concrete Naming Certificate for $\mathsf{FreudenthalEnd}^{\uparrow}$

Following Freudenthal and the classical theory of ends of locally compact spaces, the $\mathsf{FreudenthalEnd}^{\uparrow}$ packet records escaping components of a displayed locally compact or proper metric source as finite NameCert data. It reads the compact-neighbourhood surface of chapter 1726, the closed-ball compactness route of **??**, the compact metric witness of chapter 129, and the metric carrier of chapter 57. The packet names the tail-equivalence boundary of escaping rays without importing a host compactification, an ideal point selector, open-cover compactness, quotient end space, or choice-selected ray representative.

Definition 5998.1 (FreudenthalEnd carrier)**.** *A* $\mathsf{FreudenthalEnd}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, E, C_0, C_1, T, R, H, Q, P, N)$$

with the following displayed rows:

1. *X is the source metric or locally compact row, including the* $\mathsf{Met}^{\uparrow}$, $\mathsf{LocallyCompact}^{\uparrow}$, *and optional* $\mathsf{ProperMetric}^{\uparrow}$ *support used by the packet.*
2. *E is the exhaustion row by compact metric subsets. Each inspected stage exposes a compact witness through* $\mathsf{CompactMetric}^{\uparrow}$ *and, in the proper metric case, through the displayed closed-ball route of* $\mathsf{ProperMetric}^{\uparrow}$.
3. *C_0 and C_1 are component rows for complements outside compact stages. A row records only the finite component identifier, the compact stage it avoids, and the displayed adjacency data needed to replay the complement read.*
4. *T is the tail-comparison ledger. It records that the two component rows eventually enter the same complement component after passing to a later compact stage.*
5. *R is the escaping-ray ledger. It records finite ray prefixes together with the compact stages already avoided and exposes no selected infinite ray object.*
6. *H records componentwise* hsame *transport for the source, exhaustion, complement-component rows, tail ledger, ray prefixes, provenance, and local naming rows.*
7. *Q records displayed* Cont *replay from an end request through X, E, C_0, C_1, T, R, H.*
8. *P is the* Pkg *provenance over* $\mathsf{FreudenthalEnd}^{\uparrow}$, $\mathsf{LocallyCompact}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{FreudenthalEnd}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host compactification, an ideal boundary point, a quotient space of ends, open-cover compactness, a selected infinite ray, or countable-choice enumeration of components.

Lean4 ✓ `BEDC.Derived.FreudenthalEndUp.FreudenthalEndTasteGate single carrier alignment`

Theorem 5998.2 (FreudenthalEnd NameCert obligation surface)**.** *For every accepted* $\mathsf{FreudenthalEnd}^{\uparrow}$ *carrier* $F = (X, E, C_0, C_1, T, R, H, Q, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FreudenthalEnd}^{\uparrow}}$ *surface consists exactly of source admission, compact-exhaustion admission, complement-component stability, tail-equivalence readback, escaping-ray prefix replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A downstream end consumer must read the compact exhaustion E before either complement row is public, must read both C_0 and C_1 before the tail ledger T is public, and must keep the ray-prefix ledger R separate from any host-selected ideal point.*

Proof. Project the carrier of Definition 5998.1. The only source data are the displayed metric, locally compact, and proper metric rows in X, and the only compact boundary data are the finite compact stages in E.

The complement rows C_0 and C_1 can therefore be inspected only after the compact stage they avoid has been displayed. The tail ledger T compares those component rows by passing to later compact stages, so it is a finite readback of eventual component agreement rather than a quotient end object.

The ray-prefix row R supplies only finite escaping prefixes and the compact stages already avoided. Transport through H and replay through Q preserve the same source, exhaustion, component, tail, and prefix rows.

Finally P and N name precisely this displayed packet. Since no carrier coordinate stores a compactification point, quotient end space, open-cover compactness proof, selected infinite ray, or countable-choice component enumeration, the listed rows exhaust the local NameCert obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FreudenthalEnd}^{\uparrow}}$.

Constructive story: A $\mathsf{FreudenthalEnd}^{\uparrow}$ packet is generated from a locally compact or proper metric source, a compact metric exhaustion row, complement-component rows outside displayed compact stages, a tail-equivalence readback ledger, escaping-ray finite prefixes, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FreudenthalEnd}^{\uparrow}}$, seed)

Scope closed: Definition 5998.1 and Definition 5998.2 seed the Freudenthal end carrier over LocallyCompact, ProperMetric, CompactMetric, MetricSpace, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FreudenthalEnd}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a host compactification, quotient end topology, selected ideal points, selected infinite rays, countable-choice component enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-exhaustion stability, complement-component stability, tail-equivalence readback, escaping-prefix replay, transport, replay, provenance, and local naming for BEDC.Derived.FreudenthalEndUp.

Chapter 5999

A Concrete Naming Certificate for $\mathsf{FiniteWindowBaireCategory}^{\uparrow}$

Following Baire and Osgood, the $\mathsf{FiniteWindowBaireCategory}^{\uparrow}$ packet records the finite window of the Baire-category construction that a completion-facing consumer can inspect before any ambient theorem about residual sets is available. It sits over the complete-metric Baire surface of chapter 3535, the complete-metric service of chapter 128, the convergence ledger of chapter 2074, the pointwise stream metric route of chapter 4139, and the nested-ball completion neighbor chapter 5985. The packet is a finite-means dense-open route for Real and Completion consumers; it is not a countable-choice selector, arbitrary open-cover compactness theorem, quotient stream equality, host completeness assertion, or selected generic point.

Definition 5999.1 (Finite-window Baire category carrier)**.** *A* $\mathsf{FiniteWindowBaireCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, U, D, Q, S, R, E, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the complete metric source row. It exposes only the complete-metric service already named by* $\mathsf{CompleteMetric}^{\uparrow}$ *and the metric-distance rows consumed by the window.*
2. *U is the nested dense-open window. It records a finite prefix of dense-open requests, the displayed ball-refinement clauses, and the order in which those clauses are read.*
3. *D is the dyadic radius ledger. It stores the finite sequence of positive dyadic radii, their shrink comparisons, and the lower-radius bounds needed before the next dense-open request is inspected.*
4. *Q is the finite center and ball ledger. It records the named center histories, ball inclusions, and branch-local containment rows produced by the complete-metric source.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row for the center and radius observations.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the scheduled finite observations and the dyadic radius ledger.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, U, D, Q, S, R have been displayed.*
8. *T is the completion transport row. It records the consumer-facing route from the complete-metric source to the Real seal without replacing the source by a host completeness theorem.*

9. *H records componentwise* hsame *transport for complete-metric rows, dense-open windows, dyadic radius ledgers, center ledgers, stream schedules, regular readbacks, Real seals, completion transport, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a finite Baire-window request through $M, U, D, Q, S, R, E, T, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteWindowBaireCategory}^{\uparrow}$, $\mathsf{CompleteMetricBaireSurface}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{RealModulusOfConvergence}^{\uparrow}$, $\mathsf{PointwiseStreamMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowBaireCategory}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, U, D, Q, S, R, E, T, H, C, P, N$. It has no coordinate for countable choice, arbitrary open-cover compactness, quotient stream equality, host completeness, selected generic points, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 (definition) `BEDC.Derived.FiniteWindowBaireCategoryUp.FiniteWindowBaireCategoryUp`
Lean4 ✓ `BEDC.Derived.FiniteWindowBaireCategoryUp.FiniteWindowBaireCategoryTasteGate single carrier alignment`

Theorem 5999.2 (Finite-window Baire category NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWindowBaireCategory}^{\uparrow}$ *carrier*

$$W = (M, U, D, Q, S, R, E, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteWindowBaireCategory}^{\uparrow}}$ *surface consists exactly of complete-metric source exposure through M, nested dense-open finite-window exposure through U, dyadic radius-ledger exactness through D, finite center and ball routing through Q,* $\mathsf{StreamName}^{\uparrow}$ *scheduling through S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *sealing through E, completion transport through T, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5999.1. The projection displays the complete-metric source, the dense-open window, the dyadic radius ledger, the center and ball ledger, the stream schedule, the regular readback, the Real seal, and the structural transport, replay, provenance, and naming rows.

The dense-open part is finite. Row U gives only the displayed prefix of dense-open requests, while D and Q record the radius shrinkage and center-ball refinements used by that prefix. Thus a consumer cannot replace the window by a host countable intersection or an arbitrary open-cover compactness theorem.

The Real-facing part is downstream. Rows S and R schedule and repack the finite observations, and E is read only after that regular-rational route is visible. The completion transport row T preserves the same displayed source rather than adding a separate host-completeness claim.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since the carrier contains no countable-choice selector, quotient stream coordinate, host completeness field, or selected generic point, the listed rows exhaust the NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowBaireCategory}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteWindowBaireCategory}^{\uparrow}$ packet is generated from a complete metric source row, nested dense-open finite windows, a dyadic radius ledger, finite center and ball rows, StreamName schedules, RegSeqRat readback, a RealUp seal, completion transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteWindowBaireCategory}\uparrow}$, seed)

Scope closed: Definition 5999.1 and Definition 5999.2 seed the finite Baire dense-open window consumed by Real and Completion routes.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteWindowBaireCategory}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close countable choice, arbitrary open-cover compactness, quotient stream equality, host completeness, selected generic points, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-open window exposure, dyadic radius-ledger exactness, StreamName scheduling, RegSeqRat readback, Real sealing, completion transport, provenance, and local naming for BEDC.Derived.FiniteWindowBaireCategoryUp.

Chapter 6000

A Concrete Naming Certificate for $\mathsf{FiniteSubcoverRadiusLedger}^{\uparrow}$

Following Lebesgue and Heine–Cantor, the $\mathsf{FiniteSubcoverRadiusLedger}^{\uparrow}$ packet records the finite radius ledger extracted from a compact metric subcover before a uniform-modulus consumer reads it. It sits over the compact metric carrier of chapter 129, the finite-subcover criterion of chapter 3503, the compact-cover Lebesgue ledger of chapter 1302, the rational lower-bound fold of chapter 4096, and the uniform-modulus surface of chapter 369. The packet exposes the compact finite-cover lower-bound route as BEDC data without host compactness, choice-selected centers, arbitrary open-cover compactness, semantic continuity, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6000.1 (Finite subcover radius ledger carrier)**.** *A* $\mathsf{FiniteSubcoverRadiusLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, F, G, R, B, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only the metric carrier, finite-net, and total-bounded inspection rows available to compact-metric consumers.*
2. *F is the* $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$ *row. It records the finite selected subcover spine and the displayed coverage witnesses over the compact metric source.*
3. *G is the compact-cover Lebesgue ledger row. It stores the positive radius candidates attached to the displayed subcover entries and the local containment clauses they support.*
4. *R is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row, obtained by primitive recursion over the finite subcover spine and read only as a positive rational history.*
5. *B is the uniform radius bound row. It records that the folded lower bound is below each displayed local radius and therefore may be consumed by the compact-uniform route.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row reached only after K, F, G, R, B have been projected.*
7. *H records componentwise* hsame *transport for compact-metric rows, finite-subcover rows, Lebesgue-ledger rows, rational lower-bound folds, uniform-radius bounds, uniform-modulus handoffs, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a compact-cover request through $K, F, G, R, B, U, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteSubcoverRadiusLedger}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$, $\mathsf{CompactCoverLebesgueLedger}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteSubcoverRadiusLedger}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, F, G, R, B, U, H, C, P, N$. It has no coordinate for host compactness, selected centers outside the displayed subcover, arbitrary open-cover compactness, semantic continuity, external finite minima, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.FiniteSubcoverRadiusLedgerUp.TasteGate.FiniteSubcoverRadiusLedgerTasteGate`
`single carrier alignment`

Theorem 6000.2 (Finite subcover radius ledger NameCert obligations)**.** *For every accepted* $\mathsf{FiniteSubcoverRadiusLedger}^{\uparrow}$ *carrier*

$$L = (K, F, G, R, B, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteSubcoverRadiusLedger}^{\uparrow}}$ *surface consists exactly of* $\mathsf{CompactMetric}^{\uparrow}$ *source exposure through K,* $\mathsf{FiniteSubcoverCriterion}^{\uparrow}$ *coverage exposure through F, CompactCoverLebesgueLedger radius exposure through G,* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold exactness through R, uniform radius-bound routing through B,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff through U, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6000.1. The rows $K, F, G, R, B, U, H, C, P, N$ are the only displayed coordinates, so every compact-uniform consumer begins with the compact metric source and the finite subcover spine.

Rows F and G supply the coverage and local positive-radius data. The subcover is already finite as a displayed BHist spine, and the Lebesgue ledger gives radius candidates only for those displayed entries.

Row R folds those rational candidates by the $\mathsf{Rat}^{\uparrow}$ lower-bound route, and B records that the folded bound is below each local radius. The $\mathsf{UniformModulus}^{\uparrow}$ handoff U is downstream of that finite bound rather than a separate compactness theorem.

Finally H, C, P, N transport, replay, source, and name the same route. Since no coordinate stores host compactness, selected centers outside the subcover, arbitrary open-cover compactness, semantic continuity, an external finite minimum, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSubcoverRadiusLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteSubcoverRadiusLedger}^{\uparrow}$ packet is generated from a CompactMetric source row, a FiniteSubcoverCriterion coverage row, a compact-cover Lebesgue radius ledger, a RatUp lower-bound fold, a uniform radius-bound row, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteSubcoverRadiusLedger}^{\uparrow}}$, seed)

Scope closed: Definition 6000.1 and Definition 6000.2 seed the finite subcover lower-bound route consumed by compact-uniform-modulus arguments.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteSubcoverRadiusLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host compactness, selected centers outside the displayed subcover, arbitrary open-cover compactness, semantic continuity, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, CompactMetric source exposure, FiniteSubcoverCriterion coverage, compact-cover Lebesgue radius exposure, RatUp lower-bound fold exactness, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteSubcoverRadiusLedgerUp.

Chapter 6001

A Concrete Naming Certificate for BishopLocatedInverseFunction$^{\uparrow}$

Following Bishop–Bridges constructive analysis, the BishopLocatedInverseFunction$^{\uparrow}$ packet records the finite local inverse read for a located continuous real map after interval location, apartness separation, regular rational readback, dyadic tolerance accounting, and the terminal real-name seal have all been displayed. It sits beside the monotone inverse route of chapter 1929, the local analytic inverse route of chapter 2055, the continuous-map surface of chapter 130, the located apartness bridge of chapter 3564, and the L10 real-name lattice of chapter 126, chapter 301, chapter 291, and chapter 38. The chapter names a located local inverse certificate, not a host inverse function, quotient real equality, trichotomy, selected representative, ambient completeness principle, or bridge verification.

Definition 6001.1 (Bishop located inverse function carrier)**.** *A* BishopLocatedInverseFunction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, A, B, U, V, S, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* ContinuousMap$^{\uparrow}$ *row naming the displayed map and the finite continuity modulus cells used by the local read.*
2. *A is the* LocatedApartnessRealBridge$^{\uparrow}$ *row. It records the located separation data that keeps candidate preimage windows apart before any inverse request is admitted.*
3. *B is the source and target interval row, carrying the displayed source window, target window, endpoint images, and located target request.*
4. *U is the uniqueness-window row. It records the finite apartness comparison showing that two accepted source windows for the same target request cannot remain distinct under the displayed bridge data.*
5. *V is the existence-window row. It records the finite bisection or refinement schedule that locates a source window for the displayed target request.*
6. *S is the* StreamName$^{\uparrow}$ *finite-window row opened for source endpoints, target requests, function values, and retained source windows.*
7. *Q is the* RegSeqRat$^{\uparrow}$ *readback row attached to the same stream windows.*

8. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row recording dyadic radii, branch budgets, comparison slack, and endpoint-readback tolerances.*
9. *R is the terminal* Real$^{\uparrow}$ *seal row reached only after the continuous-map, located-apartness, interval, uniqueness, existence, stream, regular rational, and dyadic rows have been displayed.*
10. *H records componentwise* hsame *transport for all rows listed above, together with replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from a located inverse request through $F, A, B, U, V, S, Q, D, R, H, P, N$.*
12. *P is the* Pkg *provenance over* BishopLocatedInverseFunction$^{\uparrow}$, ContinuousMap$^{\uparrow}$, LocatedApartnessRealBridge$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{BishopLocatedInverseFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, A, B, U, V, S, Q, D, R, H, C, P, N$. It has no coordinate for a host inverse function, quotient real equality, real trichotomy, selected representative, ambient Real$^{\uparrow}$ *completeness, or an unrecorded equality of functions.*

Lean4 (definition) `BEDC.Derived.BishopLocatedInverseFunctionUp.BishopLocatedInverseFunctionUp`
Lean4 ✓ `BEDC.Derived.BishopLocatedInverseFunctionUp.BishopLocatedInverseFunctionTasteGate`
`single carrier alignment`

Theorem 6001.2 (Bishop located inverse function NameCert obligations)**.** *For every accepted* BishopLocatedInverseFunction$^{\uparrow}$ *carrier*

$$L = (F, A, B, U, V, S, Q, D, R, H, C, P, N),$$

the local NameCert$_{\text{BishopLocatedInverseFunction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the* ContinuousMap$^{\uparrow}$ *row,* LocatedApartnessRealBridge$^{\uparrow}$ *row, interval row, uniqueness-window row, existence-window row,* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback,* DyadicRatCore$^{\uparrow}$ *tolerance ledger,* Real$^{\uparrow}$ *seal, transport, replay, provenance, and local naming;*
2. *continuity exposure, requiring every inverse read to open the displayed* ContinuousMap$^{\uparrow}$ *modulus cells before endpoint-image or retained-window comparisons are consumed;*
3. *located apartness exposure, requiring the row A to be read before uniqueness of the source window is inspected;*
4. *existence-window discipline, requiring V, S, Q, D to display the refinement schedule, finite windows, regular rational readbacks, and dyadic tolerance budget before the terminal* Real$^{\uparrow}$ *seal is available;*
5. *uniqueness-window discipline, requiring U to use the same located apartness and dyadic comparison rows rather than a host equality of real values;*
6. *structural nonescape, requiring H, C, P, N to preserve only the displayed route and no host inverse function, quotient real equality, real trichotomy, selected representative, ambient Real completeness, or bridge credential.*

No Bishop located inverse-function obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6001.1. The accepted packet displays exactly the continuous-map row, located-apartness bridge row, interval row, uniqueness and existence windows, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, and structural rows.

The local inverse read begins with continuity and location. The row F supplies the finite modulus cells used for endpoint-image and retained-window comparisons, while A supplies the located apartness data that separates candidate source windows.

The existence route is finite. The row V records the refinement schedule, S exposes the relevant finite windows, Q reads those windows as regular rational data, and D records the dyadic comparison budget before the terminal seal R is inspected.

The uniqueness route uses the same displayed data. The row U can compare two source windows only through the already opened located apartness and dyadic tolerance rows, so it cannot import trichotomy or host equality of completed reals.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no carrier coordinate stores a host inverse function, quotient real equality, selected representative, ambient completeness principle, or bridge credential, the local NameCert surface is exhausted by the listed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedInverseFunction}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedInverseFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6001.1 and Definition 6001.2 seed the finite located inverse-function certificate over $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedInverseFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host inverse functions, quotient real equality, real trichotomy, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, continuity exposure, located apartness exposure, existence-window discipline, uniqueness-window discipline, structural nonescape, and local naming for BEDC.Derived.BishopLocatedInverseFun

Constructive story: A $\mathsf{BishopLocatedInverseFunction}^{\uparrow}$ packet is generated from a $\mathsf{ContinuousMap}^{\uparrow}$ row, a $\mathsf{LocatedApartnessRealBridge}^{\uparrow}$ row, interval rows, uniqueness and existence windows, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6002

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}$

Bishop–Bridges style diagonal arguments turn a displayed family of regular Cauchy rational names into a limit-facing regular read by synchronizing finite windows and tolerance ledgers before any real seal is exposed. The $\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}$ packet records that consumer route as one finite NameCert surface. It sits after the $\mathsf{StreamName}^{\uparrow}$ window interface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular-rational readback of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the regular-Cauchy diagonal sibling of chapter 1773. The packet names the L10 diagonal-limit consumer for regular rational sequences and real-name seals; it is not quotient stream equality, a host-selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6002.1 (Regular Cauchy diagonal limit carrier)**.** *A* $\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the displayed source-family row of regular Cauchy rational names whose diagonal entries may be inspected.*
2. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window family for the source row, diagonal selector reads, and limit-facing output read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback row assembled from the accepted source windows.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, slack, and comparison ledger used to align the source windows with the diagonal readback.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after S, W, R, Q have been displayed.*
6. *H records componentwise* hsame *transport for the source family, synchronized windows, regular readback, dyadic ledger, real seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each limit-facing precision request through S, W, Q, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalWindow}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, W, R, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, countable-choice schedules, host limits, trichotomy, ambient completeness, Lean verification, or bridge credentials.

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalLimitUp.RegularCauchyDiagonalLimitTasteGate single carrier alignment`

Theorem 6002.2 (Regular Cauchy diagonal limit NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}$ *carrier*

$$D = (S, W, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source family, synchronized windows, regular readback, dyadic tolerance ledger, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *window coverage, requiring every limit-facing request to read only windows listed in W and only source data displayed by S;*
3. *dyadic exactness, requiring Q to be the sole tolerance, slack, and comparison ledger used to align the diagonal readback;*
4. *RegSeqRat handoff, requiring R to be downstream of S, W, Q and upstream of the terminal real seal E;*
5. *Real seal non-escape, requiring E, H, C, P, N to expose no quotient stream equality, host-selected limit, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No Regular Cauchy diagonal-limit obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 6002.1. The displayed tuple $S, W, R, Q, E, H, C, P, N$ is the entire public surface, so carrier admission is exactly admission of those rows.

The window and dyadic clauses are read next. A limit-facing request enters through the synchronized window family W, while Q supplies the tolerance, slack, and comparison cells attached to that window. The source-family row S is inspected only through those displayed windows.

The regular readback row R is therefore downstream of S, W, Q. Once R has been displayed, the seal row E may be read as a $\mathsf{Real}^{\uparrow}$ boundary, and the structural rows H, C, P, N transport, replay, source, and name the same route.

Because the carrier has no further coordinate, the excluded analytic and choice-theoretic objects cannot be exported by the local NameCert surface. □

Theorem 6002.3 (Regular Cauchy diagonal limit RegSeqRat handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}$ *carrier first reads the finite route*

$$S, W, Q \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the L10 diagonal route hands off a $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the real seal is available, and the consumer receives no quotient stream equality, selected limit, countable-choice schedule, trichotomy row, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start from a limit-facing request. The carrier admits no direct read of the real seal, so the request must first pass through the source row S, the synchronized windows W, and the dyadic tolerance ledger Q.

These rows assemble the regular rational diagonal readback R. The readback is the only row that can feed the terminal $\mathsf{Real}^{\uparrow}$ seal E, so any consumer reaching the seal has already consumed the RegSeqRat handoff.

The rows H, C, P, N preserve this displayed route under transport, replay, provenance, and local naming. Since no excluded coordinate occurs in the carrier, the handoff exports only the finite diagonal-limit packet. □

Falsifiable prediction: Every $\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}$ Real-facing read factors through a displayed source family, synchronized StreamName windows, one DyadicRatCore tolerance ledger, one RegSeqRat diagonal readback, one terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, regular-cauchy-diagonal-extraction, regular-cauchy-diagonal-window, regular-cauchy-diagonal-seal: $\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the limit-facing source family, synchronized windows, tolerance ledger, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}$ packet is generated from a regular Cauchy source family, synchronized StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat diagonal readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6002.1, Definition 6002.2, and Definition 6002.3 seed the finite diagonal-limit route from regular Cauchy source windows through RegSeqRat readback to a terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window coverage, dyadic exactness, RegSeqRat handoff, Real seal non-escape, componentwise transport, displayed replay, and local naming for BEDC.Derived.RegularCauchyDiagonalLimitUp

Chapter 6003

Finite Cauchy Density Net NameCert Construction

Following Bishop and Bridges, finite density data for real completion is represented by explicit dyadic finite nets and moduli, not by selected representatives or quotient completions. The $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ packet sits between the dyadic arithmetic of chapter 291, the finite dyadic cell surface of chapter 5966, the finite window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. It gives L10 completion consumers a finite density witness object without asserting ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6003.1 (Finite Cauchy density-net packet)**.** *A* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (D, W, R, E, M, T, C, P, L)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite-net ledger, listing the dyadic centers, dyadic radii, and finite containment comparisons used by the density read.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that records exactly which prefixes of an inspected Cauchy name are opened before the net row is consulted.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed window and dyadic ledger.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after D, W, R have all been displayed.*
5. *M is the modulus row, recording the finite precision budget that makes the displayed dyadic net adequate for the requested readback.*
6. *T records componentwise* hsame *transport for dyadic net rows, stream windows, regular readback rows, Real seals, modulus rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a density-net request through D, W, R, E, M, T.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *L is the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyDensityNet}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, a selected representative of a completed real, countable choice over nets, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6003.2 (Finite Cauchy density-net obligation carrier)**.** *Every accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *density read must expose dyadic tolerance rows, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyDensityNet}^{\uparrow}}$ *before it can serve a density-net consumer. In carrier notation the admissible route is the displayed packet*

$$D, W, R, E, M, T, C, P, L$$

of Definition 6003.1; no consumer may replace it by quotient streams, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows in Definition 6003.1. The dyadic tolerance data are contained in D and M, the finite stream inspection is contained in W, the regular readback is R, and the terminal Real-facing row is E.

Use the finite density-net route already displayed by the carrier: the density read first opens the dyadic ledger and finite stream window, then reads back through $\mathsf{RegSeqRat}^{\uparrow}$, and only then exposes the $\mathsf{Real}^{\uparrow}$ seal. The structural rows T, C, P, L keep the same route under transport, replay, provenance, and local naming.

The sibling routes input by the hub supply the same L10 discipline for finite density and regular readback consumers, so the carrier cannot be consumed as an unrecorded density assertion. Since the packet has no row for quotient streams, selected limits, countable choice, or ambient Real completeness, the displayed rows exhaust the obligation surface. □

Theorem 6003.3 (Finite Cauchy density-net extraction)**.** *For every accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *carrier* $N = (D, W, R, E, M, T, C, P, L)$*, every density-net read extracts exactly the displayed finite dyadic net rows* D*, the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal route* E*, and the modulus row* M*, preserved by* T, C, P, L*. The extraction supplies a finite L10 density witness for Real-facing completion routes, but it does not claim* $\mathsf{Real}^{\uparrow}$ *completeness, quotient representatives, selected limits, countable choice, trichotomy, or host real equality.*

Proof. Project the carrier of Definition 6003.1. The dyadic net row D is the only row carrying centers, radii, and finite containment comparisons, while W is the only row opening inspected stream prefixes.

The readback row R is downstream of D, W and the modulus row M. Thus any density read reaches the regular rational surface through displayed finite data rather than through a detached sequence or host completion object.

The terminal row E seals only that readback route as a $\mathsf{Real}^{\uparrow}$ handoff. Rows T, C, P, L transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for quotient streams, selected representatives, countable choice, trichotomy, host real equality, or ambient Real completeness, the listed rows exhaust the extraction surface. □

Theorem 6003.4 (Finite Cauchy density-net Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the displayed carrier rows $D, W, R, E, M, T, C, P, L$*. The packet can be cited as a finite density witness by separability, completion, and compactness consumers, but it exports no completed-real theorem and no selector for representatives or limits.*

Proof. Apply Definition 6003.3. The extraction theorem identifies the dyadic net ledger, finite stream window, regular readback, Real seal, and modulus rows as the whole analytic route.

The structural rows T, C, P, L preserve that route under componentwise transport, continuation replay, provenance, and local naming. They do not add a second completion-facing row.

Therefore a Real-facing consumer receives only the displayed finite density packet. Any claim of completed Real separability, ambient completeness, quotient representatives, selected limits, or countable-choice net selection lies outside the local carrier. □

Theorem 6003.5 (Finite Cauchy density-net stream route)**.** *Every finite density-net consumer of an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet must first expose the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row of chapter 126 and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row of chapter 301 before treating the dyadic net as a* $\mathsf{Real}^{\uparrow}$*-facing density witness. Equivalently, the dyadic rows D become Real-facing only along the displayed carrier route $D, W, R, E, M, T, C, P, L$.*

Proof. Project the carrier of Definition 6003.1. The rows $D, W, R, E, M, T, C, P, L$ are the whole displayed packet, with W the finite window row and R the regular rational readback row.

Apply Definition 6003.3. It identifies the dyadic net ledger D, the $\mathsf{StreamName}^{\uparrow}$ window W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, the terminal $\mathsf{Real}^{\uparrow}$ seal E, and the modulus row M as the extracted analytic route.

Apply Definition 6003.4. A Real-facing consumer can read a seal only after the same rows have been displayed. The structural rows T, C, P, L transport, replay, source, and name that route, so the dyadic density net cannot be consumed as a Real-facing witness before W and R have been exposed. □

Theorem 6003.6 (Finite Cauchy density-net sibling route)**.** *Every completion-facing sibling consumer of an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet, including the real-uniform route of chapter 1624 and the modulus route of chapter 292, must consume the finite density-net read only after the displayed rows $D, W, R, E, M, T, C, P, L$ have all been exposed. The read may first consume the finite dyadic cell surface of chapter 5966:* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *supplies the displayed cells and endpoint incidence, while* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *supplies the density witness and Real-facing seal. In particular, the packet supplies a completion-facing dependency edge through dyadic cells, endpoint incidence, stream windows, regular rational readback, Real sealing, finite modulus, transport, replay, provenance, and local naming, not through a kernel-only density assertion.*

Proof. Start with Definition 6003.5. It forces every density-net consumer to expose the $\mathsf{StreamName}^{\uparrow}$ row W and $\mathsf{RegSeqRat}^{\uparrow}$ row R before the dyadic net can be read as Real-facing data.

Before that Real-facing export, the consumer may read the sibling $\mathsf{DyadicIntervalNet}^{\uparrow}$ surface of chapter 5966. That sibling supplies the displayed dyadic cells and endpoint incidence; the density-net packet keeps those cells tied to D and then supplies the density witness, modulus row M, and terminal seal E.

Apply Definition 6003.4. The terminal $\mathsf{Real}^{\uparrow}$ seal E is available only along the same carrier route, so a $\mathsf{RealUniformStructure}^{\uparrow}$ or $\mathsf{CauchyModulus}^{\uparrow}$ consumer cannot bypass $D, W, R, E, M, T, C, P, L$ when it asks for completion-facing density.

Finally use Definition 6003.3. The extraction theorem keeps the dyadic ledger D, modulus row M, structural transport T, replay C, provenance P, and local naming L attached to the read. Thus the sibling dependency edge is a finite displayed route into later completion consumers, not an ambient Real-completion fact or an unrecorded selector for dense representatives. □

Theorem 6003.7 (Finite Cauchy density-net finite-window comparison)**.** *Every accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *comparison exported to a* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer factors through the displayed finite net extraction,* $\mathsf{StreamName}^{\uparrow}$ *window, dyadic tolerance row, and* $\mathsf{Real}^{\uparrow}$ *seal row of* $N = (D, W, R, E, M, T, C, P, L)$*. The sibling route fixes the same* BHist *provenance, so the comparison uses one displayed window route rather than host limit selection, quotient representatives, or ambient completeness.*

Proof. First apply finite density-net extraction, Definition 6003.3. It obtains the finite dyadic net row D, the finite stream observation row W, the regular readback R, the Real seal E, and the modulus row M from the accepted carrier.

Next use the stream route of Definition 6003.5. It permits the comparison to read only the listed StreamName windows and the RegSeqRat readback attached to those windows.

Finally apply the sibling route and Real seal nonescape, Definition 6003.6 and Definition 6003.4. They keep the same BHist provenance and terminal Real seal attached to $D, W, R, E, M, T, C, P, L$, excluding host limit selection, quotient representatives, and ambient completeness. □

Theorem 6003.8 (Finite Cauchy density-net tail extraction)**.** *For every accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet* $N = (D, W, R, E, M, T, C, P, L)$*, every completion-facing tail read consumed by* $\mathsf{RegularSequenceSpace}^{\uparrow}$*,* $\mathsf{RealUniformStructure}^{\uparrow}$*, or* $\mathsf{CauchyModulus}^{\uparrow}$ *exposes the same finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the same dyadic net ledger* D*, the same finite modulus row* M*, the same terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, and the same structural rows* T, C, P, L*. The tail read is therefore a displayed finite BEDC route, not a quotient stream, not a chosen representative, and not an appeal to ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 6003.5. It forces every completion-facing read to pass through the displayed $\mathsf{StreamName}^{\uparrow}$ window W and the $\mathsf{RegSeqRat}^{\uparrow}$ row R before any tail data can be consumed.

Then apply Definition 6003.6. That theorem keeps the same displayed route attached to completion-facing readers such as $\mathsf{RealUniformStructure}^{\uparrow}$ and $\mathsf{CauchyModulus}^{\uparrow}$, so the tail read cannot bypass $D, W, R, E, M, T, C, P, L$.

Finally use Definition 6003.7. The comparison theorem factors the completion-facing read through the same finite packet data, and Definition 6003.1 lists exactly the rows $D, W, R, E, M, T, C, P, L$ with no coordinate for quotient streams, chosen representatives, or ambient completeness. Row exhaustion gives the claim. □

Theorem 6003.9 (Finite Cauchy density-net regular-sequence handoff)**.** *Every handoff from an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet* $N = (D, W, R, E, M, T, C, P, L)$ *to* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *exposes the finite dyadic net rows* D*, the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*, the finite modulus row* M*, and the structural rows* T, C, P, L *before any regular-sequence consumer reads it. The handoff is therefore finite BEDC evidence only: it does not export a quotient stream, a selected representative, a completed Real limit, countable choice, trichotomy, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with finite density-net extraction, Definition 6003.3. It displays the dyadic net ledger D, the stream window W, the regular rational readback R, the Real seal E, and the modulus row M from the accepted packet.

Use the stream route of Definition 6003.5. A regular-sequence consumer can read the handoff only after the finite $\mathsf{StreamName}^{\uparrow}$ window and the $\mathsf{RegSeqRat}^{\uparrow}$ readback have been exposed.

Now apply tail extraction, Definition 6003.8. It keeps the same rows visible for completion-facing tail reads, including the structural rows T, C, P, L.

Finally use the sibling route of Definition 6003.6. The handoff to $\mathsf{RegularSequenceSpace}^{\uparrow}$ remains a displayed route through $D, W, R, E, M, T, C, P, L$, so no quotient stream, selected representative, completed limit, choice schedule, trichotomy, host equality, or ambient completeness is introduced. □

Theorem 6003.10 (Finite Cauchy density-net diagonal tightening)**.** *For every accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet* $N = (D, W, R, E, M, T, C, P, L)$*, any two completion-facing tail reads of* N *can be tightened to a shared finite* $\mathsf{StreamName}^{\uparrow}$ *window row and a shared dyadic tolerance row before either* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or* $\mathsf{Real}^{\uparrow}$ *sealing is consumed. The tightening remains inside the displayed route* $D, W, R, E, M, T, C, P, L$ *and exports no quotient representatives, selected limits, countable choice, trichotomy, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with finite-window comparison, Definition 6003.7. It forces each completion-facing comparison to use the displayed finite net extraction, the $\mathsf{StreamName}^{\uparrow}$ window, the dyadic tolerance row, and the terminal seal route attached to the same BHist provenance.

Apply tail extraction from Definition 6003.8. Both tail reads must expose W, R, D, M, E, and the structural rows T, C, P, L before any completion-facing consumer can use them.

Now use the sibling route of Definition 6003.6. A $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer receives only this displayed density-net route, so the two reads meet at one finite stream window and one dyadic tolerance row before readback or sealing.

Since the carrier has no coordinate for quotient representatives, selected limits, countable choice, trichotomy, host equality, or ambient Real completeness, the shared window and tolerance row are obtained by row tightening inside the accepted packet rather than by an external selector. □

Theorem 6003.11 (Finite Cauchy density-net refinement)**.** *Let* $N = (D, W, R, E, M, T, C, P, L)$ *be an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet. Refining the dyadic cell surface of* N *preserves the density witness* D*, the finite modulus row* M*, the* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal route* E, T, C, P, L*. The refined packet consumes only finite dyadic cells and exports no ambient completeness, quotient representatives, selected limits, countable choice, trichotomy, or host real equality.*

Proof. Start with the sibling route of Definition 6003.6. It lets the refinement read the $\mathsf{DyadicIntervalNet}^{\uparrow}$ cell surface before any Real-facing export, while keeping the density-net rows $D, W, R, E, M, T, C, P, L$ attached to the same finite packet.

Apply the diagonal tightening theorem, Definition 6003.10. Any two refined completion-facing reads meet at one displayed $\mathsf{StreamName}^{\uparrow}$ window and one dyadic tolerance row before regular rational readback or Real sealing is consumed.

Now use tail extraction and finite-window comparison, Definition 6003.8 and Definition 6003.7. These rows preserve the modulus, stream window, RegSeqRat readback, and terminal Real seal through the same displayed carrier route.

Finally replay T, C, P, L. Componentwise transport, continuation replay, provenance, and local naming preserve the refined finite-cell route and add no coordinate for ambient completeness, quotient representatives, selected limits, countable choice, trichotomy, or host real equality. □

Theorem 6003.12 (Finite Cauchy density-net regular readback)**.** *Let* $N = (D, W, R, E, M, T, C, P, L)$ *be an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet. Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer of* N *must read the same finite* $\mathsf{StreamName}^{\uparrow}$ *window* W*, dyadic net ledger* D*, finite modulus row* M*, and readback row* R *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is available. The readback is therefore the displayed route*

through $D, W, R, E, M, T, C, P, L$ and exports no quotient representatives, selected limits, countable choice, trichotomy, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with finite density-net extraction, Definition 6003.3. It displays the dyadic net ledger D, stream window W, regular readback R, Real seal E, and modulus row M as the analytic rows of the accepted packet.

Apply the stream route and tail extraction, Definition 6003.5 and Definition 6003.8. They force every regular-facing and completion-facing read through the same W, R, D, M, E route before the terminal seal can be consumed.

Now use diagonal tightening and refinement, Definition 6003.10 and Definition 6003.11. The refined readback still meets at one displayed finite window and dyadic ledger before $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ sealing is public.

Finally replay T, C, P, L. Componentwise transport, continuation replay, provenance, and local naming preserve the same finite readback route, so no coordinate remains for quotient representatives, selected limits, countable choice, trichotomy, host equality, or ambient Real completeness. □

Definition 6003.13 (Finite Cauchy density-net cofinal window)**.** *Let $N = (D, W, R, E, M, T, C, P, L)$ be an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet. Its cofinal-window density subpacket is the displayed tuple*

$$N_{\mathrm{cof}} = (D, W, R, E, M, T, C, P, L)$$

read with the following completion-facing order: D is the finite $\mathsf{DyadicRatCore}^{\uparrow}$ *density ledger, W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window through which the tail request is opened, M is the finite precision budget attached to that window, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from D, W, M, E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after R, and T, C, P, L transport, replay, source, and locally name that same finite route. The subpacket has no coordinate for a quotient stream, a chosen limit, an ambient complete real, trichotomy, host equality, or a selector over hidden tail representatives.*

Theorem 6003.14 (Finite Cauchy density-net cofinal window)**.** *Let $N = (D, W, R, E, M, T, C, P, L)$ be an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet. Any two completion-facing tail reads of N that are later consumed by* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *refine to the displayed cofinal-window subpacket N_{cof}: they meet at one finite* $\mathsf{StreamName}^{\uparrow}$ *window W and one dyadic tolerance row controlled by D and M before either* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or terminal* $\mathsf{Real}^{\uparrow}$ *sealing is available. The refinement is internal to $D, W, R, E, M, T, C, P, L$ and exports no quotient representatives, selected limits, countable choice, trichotomy, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply finite-window comparison, Definition 6003.7. Each completion-facing comparison must pass through the displayed finite net extraction, the $\mathsf{StreamName}^{\uparrow}$ window, the dyadic tolerance row, and the terminal seal route attached to the same BHist provenance.

Use tail extraction and diagonal tightening, Definition 6003.8 and Definition 6003.10. The two tail reads therefore expose the same W, R, D, M, E rows before any regular rational readback or Real sealing is consumed, and the tightening occurs inside the accepted carrier.

Finally apply refinement and regular readback, Definition 6003.11 and Definition 6003.12. Refining the dyadic cell surface preserves $D, W, R, E, M, T, C, P, L$, while the regular readback theorem forces every $\mathsf{RegSeqRat}^{\uparrow}$-facing consumer to read that same finite route first. Hence both reads factor through N_{cof} with no external selector, quotient representative, chosen limit, trichotomy, host equality, or ambient completeness. □

Theorem 6003.15 (Finite Cauchy density-net RegSeqRat density handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet receives density evidence only*

through the cofinal-window subpacket of Definition 6003.13. In particular, the consumer may use the displayed finite dyadic ledger D, finite $\mathsf{StreamName}^{\uparrow}$ *window W, finite precision budget M,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and structural rows T, C, P, L, but it receives no quotient representatives, selected limits, countable choice, trichotomy, host equality, or ambient Real-completeness principle.*

Proof. Start with the cofinal-window theorem, Definition 6003.14. It refines any two completion-facing tail reads to one displayed $\mathsf{StreamName}^{\uparrow}$ window and one dyadic tolerance row before regular readback or Real sealing.

Apply regular readback, Definition 6003.12. A $\mathsf{RegSeqRat}^{\uparrow}$-facing consumer cannot reach R without first reading the same finite W, D, M route, and the terminal $\mathsf{Real}^{\uparrow}$ seal E remains downstream of that readback.

Use Real seal nonescape, Definition 6003.4. The $\mathsf{Real}^{\uparrow}$ consumer receives only the displayed finite density packet; the structural rows T, C, P, L transport, replay, source, and name that packet without creating a second completion coordinate.

The carrier exhaustion clause in Definition 6003.13 removes the remaining alternatives. Since N_{cof} has no coordinate for quotient representatives, selected limits, countable choice, trichotomy, host equality, or ambient Real completeness, every accepted density handoff to $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ is mediated by the displayed cofinal-window packet. □

Theorem 6003.16 (Finite Cauchy density-net regular-sequence forward link)**.** *Every accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet is consumed by the regular sequence-space route of chapter 5965 and the regular rational readback route of chapter 301 only after the displayed finite net row D, dyadic tolerance and modulus rows D, M, finite* $\mathsf{StreamName}^{\uparrow}$ *window W, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R have all been exposed inside $N = (D, W, R, E, M, T, C, P, L)$. The forward link is therefore a finite row dependency from density nets to* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$*, not a host-density theorem, quotient stream equality, selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Start with the regular-sequence handoff of Definition 6003.9. It requires the finite dyadic net, stream window, regular readback, Real seal, finite modulus, and structural rows to be visible before a $\mathsf{RegularSequenceSpace}^{\uparrow}$ consumer reads the packet.

Apply the RegSeqRat density handoff of Definition 6003.15. It keeps every $\mathsf{RegSeqRat}^{\uparrow}$-facing read inside the cofinal-window subpacket, so the readback row R is reached only through the displayed D, W, M surface.

Finally use the regular readback theorem, Definition 6003.12. It ties the same finite window and dyadic ledger to the terminal seal route E, T, C, P, L, excluding quotient streams, selected representatives, host density assertions, and ambient Real completeness from the forward dependency. □

Theorem 6003.17 (Finite Cauchy density-net regular-approximation handoff)**.** *Every* $\mathsf{RealApproximationScheme}^{\uparrow}$ *or* $\mathsf{RealApproximationEnvelope}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet must export its real-approximation handoff only after reading the displayed dyadic ledger D, finite* $\mathsf{StreamName}^{\uparrow}$ *window W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, modulus row M, componentwise* hsame *transport T, displayed* Cont *replay C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyDensityNet}^{\uparrow}}$ *row L of Definition 6003.1. The handoff is therefore a finite BEDC route into real-approximation consumers, not a quotient representative, selected limit, countable-choice schedule, host density theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project the carrier rows in Definition 6003.1. The only analytic rows available to a real-approximation consumer are the dyadic ledger D, finite stream window W, regular readback R, terminal seal E, and modulus row M, while T, C, P, L preserve the same route under transport, replay, provenance, and local naming.

Apply the RegSeqRat density handoff of Definition 6003.15. It forces every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ density read through the displayed cofinal-window subpacket before a downstream approximation surface can consume it.

Now use the Real seal nonescape theorem, Definition 6003.4. The seal row E exports only the finite route already displayed by D, W, R, M, T, C, P, L, so a $\mathsf{RealApproximationScheme}^{\uparrow}$ or $\mathsf{RealApproximationEnvelope}^{\uparrow}$ consumer cannot replace the route by a hidden completion object.

Since the carrier has no coordinate for quotient representatives, selected limits, countable choice, host density assertions, or ambient $\mathsf{Real}^{\uparrow}$ completeness, row exhaustion gives the claimed real-approximation handoff boundary. □

Falsifiable prediction: Every accepted $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ read exposes a DyadicRatCore finite-net ledger, a StreamName finite-window row, a RegSeqRat readback row, a terminal RealUp seal, a finite modulus row, componentwise transport, continuation replay, provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ is not identical to any listed sibling because it binds dyadic finite-net rows and a modulus row before the regular rational readback and terminal RealUp seal.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyDensityNet}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ packet is generated from a DyadicRatCore finite-net ledger, a StreamName finite-window row, a RegSeqRat readback row, a RealUp seal, a finite modulus row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCauchyDensityNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6003.1, Definition 6003.3, and Definition 6003.4 seed the finite dyadic density-net route from displayed Cauchy windows to the terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCauchyDensityNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, completed-real separability, compactness, quotient representatives, selected limits, countable choice, trichotomy, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic finite-net exactness, StreamName window admission, RegSeqRat readback, Real seal nonescape, finite modulus stability, replay, provenance, and local naming for BEDC.Derived.FiniteCauchyDensityNetUp.

Theorem 6003.18 (Finite Cauchy density-net Bishop Cauchy route)**.** *Every Bishop Cauchy, regular-sequence, or completion-facing consumer of an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet*

$$N = (D, W, R, E, M, T, C, P, L)$$

reads the finite density witness only through the dyadic arithmetic source D, finite $\mathsf{StreamName}^{\uparrow}$ *window W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, modulus row M, componentwise* hsame *transport T, displayed* Cont *replay C,* Pkg *provenance P, and local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyDensityNet}^{\uparrow}}$ *row L. In particular, the handoff to the Bishop Cauchy route of chapter 5965 is a finite L10 sibling dependency and not a quotient-completion argument, selected representative, host equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Start with finite density-net extraction, Definition 6003.3. It identifies $D, W, R, E, M, T, C, P, L$ as the displayed density-net route and leaves no hidden completion row.

Use the regular-sequence handoff theorem, Definition 6003.9. A regular-sequence consumer reaches the density witness only after the $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, dyadic net ledger, modulus row, and terminal $\mathsf{Real}^{\uparrow}$ seal have been displayed.

Now compare with the regular sequence-space chapter named by chapter 5965. Its Bishop Cauchy consumer can read the density-net packet only as this already displayed finite handoff, so the dependency edge is the same L10 route through $D, W, R, E, M, T, C, P, L$.

Finally apply Real seal nonescape, Definition 6003.4. Since the accepted packet has no coordinate for quotient completion, selected representatives, host equality, countable choice, or ambient Real completeness, no Bishop Cauchy consumer can bypass the finite density-net route. □

Theorem 6003.19 (Finite Cauchy density-net L10 sibling route)**.** *Every completion-facing consumer of an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet must read the dyadic density-net row through chapter 291, the finite observation window through chapter 126, the regular rational readback through chapter 301, and the terminal seal through chapter 38 before the density witness reaches any* $\mathsf{Real}^{\uparrow}$*-completion consumer.*

Equivalently, the L10 sibling dependency route is the displayed carrier path $D, W, R, E, M, T, C, P, L$ *of Definition 6003.1, not a direct assertion of density inside ambient completed reals, quotient stream equality, selected representatives, or host real equality.*

Proof. Start with Definition 6003.3. It identifies the dyadic ledger D, finite stream window W, regular rational readback R, terminal Real seal E, and modulus row M as the extracted density surface.

Next apply Definition 6003.5. The route forces the $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{RegSeqRat}^{\uparrow}$ readback to stand between the dyadic net and any Real-facing interpretation, so the sibling chapters are read in the displayed order.

Finally use Definition 6003.4. The terminal seal is available only after $D, W, R, E, M, T, C, P, L$ have been exposed, and the structural rows keep transport, replay, provenance, and local naming attached to the same finite witness. Thus the completion-facing consumer receives an L10 density route through the named sibling chapters rather than an unrecorded ambient completion principle. □

Theorem 6003.20 (Finite Cauchy density-net regular-sequence consumer route)**.** *Every regular-sequence consumer of an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet reads the density witness only after the route through chapter 5965 and the finite-window extraction route of chapter 7135 have exposed the same* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and terminal* $\mathsf{Real}^{\uparrow}$ *seal. Thus the finite density-net row is a downstream L10 dependency edge for regular Cauchy tails, not an ambient density assertion inside completed reals.*

Proof. Start with Definition 6003.19. It forces every completion-facing density read to pass through the displayed dyadic ledger, stream window, regular rational readback, and terminal Real seal.

The regular-sequence-space consumer contributes the ambient L10 sequence carrier, while the regular Cauchy window extraction consumer contributes the inspected finite tail window. Both consumers therefore meet the density-net packet at the already displayed route $D, W, R, E, M, T, C, P, L$ of Definition 6003.1.

Apply Definition 6003.4. Since the packet exports no quotient representatives, selected limits, countable-choice schedule, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the dependency edge remains the finite L10 route through the named regular-sequence and window-extraction chapters. □

Theorem 6003.21 (Finite Cauchy density-net public density export)**.** *Every* $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegularSequenceSpace}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet receives the public density package exactly through the finite rows*

$$D, W, R, E, M, T, C, P, L.$$

The export is the displayed dyadic density ledger D, finite StreamName window W, RegSeqRat readback R, terminal Real seal E, finite modulus row M, componentwise hsame *transport T, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row L. The downstream sibling consumers are chapter 1624, chapter 292, chapter 5965, and chapter 38. It does not assert completed-real separability, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient representatives, selected limits, countable choice, trichotomy, or host real equality.*

Proof. First apply finite Cauchy density-net extraction, Definition 6003.3. It exposes $D, W, R, E, M, T, C, P, L$ as the finite density witness extracted from the accepted carrier.

Next use the stream route and sibling route, Definition 6003.5 and Definition 6003.6. These results place $\mathsf{RealUniformStructure}^{\uparrow}$ and $\mathsf{CauchyModulus}^{\uparrow}$ consumers downstream of the same StreamName window, RegSeqRat readback, dyadic ledger, Real seal, modulus, transport, replay, provenance, and local naming rows.

Now apply tail extraction, Definition 6003.8. It identifies the completion-facing reads used by $\mathsf{RegularSequenceSpace}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, and $\mathsf{CauchyModulus}^{\uparrow}$ with the same finite packet rows.

Finally use refinement, Definition 6003.11. Refining the dyadic cell surface preserves the displayed density route and adds no coordinate for completed-real separability, ambient completeness, quotient representatives, selected limits, countable choice, trichotomy, or host real equality. Thus the public density package exported to the listed consumers is exactly $D, W, R, E, M, T, C, P, L$. □

The $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ packet supplies the finite witness surface consumed by chapter 1809: its carrier exposes explicit finite dyadic representatives, stream windows, regular-Cauchy readback, and a terminal Real seal before separability reads density. This makes the density handoff a displayed finite BEDC route rather than a host-level countability assumption or a selected dense subset. The $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ packet supplies the finite density row consumed by chapter 1809 only after the dyadic, StreamName, RegSeqRat, and Real sibling route exposed by chapter 291, chapter 126, chapter 301, and chapter 38. Every $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ density read that serves a $\mathsf{Real}^{\uparrow}$ consumer first consumes the finite mesh rows of $\mathsf{DyadicIntervalNet}^{\uparrow}$ from chapter 5966 and the regular readback rows of $\mathsf{RegSeqRat}^{\uparrow}$ from chapter 301. The route exposes dyadic cells, endpoint incidence, finite stream windows, regular rational readback, terminal real sealing, hsame transport, Cont replay, Pkg provenance, and local NameCert data before any downstream density consumer reads the packet; it exports no ambient completeness theorem or selector for dense representatives. The $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ packet supplies the visible dyadic net rows consumed by the bounded Cauchy subsequence-modulus route of chapter 9185. A downstream extractor first reads the finite density ledger, $\mathsf{StreamName}^{\uparrow}$ windows, and $\mathsf{RegSeqRat}^{\uparrow}$ readback already exposed by chapter 301, then carries those rows to the terminal $\mathsf{Real}^{\uparrow}$ consumer of chapter 38. The handoff is a finite row dependency from density nets into subsequence-modulus extraction, not a hidden sequential compactness assertion or a choice-selected subsequence.

Theorem 6003.22 (Finite Cauchy density-net sibling dependency)**.** *Every accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *carrier consumes its density row through the concrete L10 sibling chain*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

before a completion-facing consumer may read the exported density-net data. The dyadic tolerance ledger is supplied by chapter 291, the inspected finite window by chapter 126, the regular rational readback by chapter 301, and the terminal Real seal by chapter 38. In carrier notation, the dependency route is the displayed path

$$D, W, R, E, M, T, C, P, L$$

of Definition 6003.1, where D records the dyadic cell and tolerance ledger, W records the inspected StreamName window, R records the RegSeqRat readback, and E records the terminal Real seal. The route therefore records a concrete sibling dependency edge through dyadic tolerance, finite stream windows, regular readback, and Real sealing, not a kernel-only density assertion, quotient representative, selected limit, countable-choice net, or ambient completeness theorem.

Proof. Project the carrier of Definition 6003.1. Its analytic rows are exactly the dyadic ledger D, stream window W, regular readback R, terminal seal E, and modulus row M, with T, C, P, L preserving that same packet.

Apply Definition 6003.19. It already forces every completion-facing density read through the dyadic, StreamName, RegSeqRat, and Real sibling chapters before the read is exported.

Now refine the dyadic step through chapter 291 and the finite cell surface of chapter 5966. The dyadic core supplies the tolerance arithmetic read by D, and the interval net supplies the displayed cells and incidence rows.

The finite stream and readback steps are then forced by chapter 126 and chapter 301. The $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ packet can export density only after W and R are displayed, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38 remains downstream of those rows.

Finally apply Definition 6003.4. Since the carrier has no coordinate for quotient representatives, selected limits, countable-choice nets, host equality, or ambient completeness, the only available dependency route is the displayed sibling route through $D, W, R, E, M, T, C, P, L$. □

Theorem 6003.23 (Finite Cauchy density-net regular readback scope)**.** *Let $N = (D, W, R, E, M, T, C, P, L)$ be an accepted* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *packet. Every density-net readback consumed by a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *route passes through the finite density net D, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{Real}^{\uparrow}$ *seal E,* hsame *transport T,* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}$ *row L. The scope exports no quotient representative, selected limit, countable-choice net, trichotomy, host equality, or ambient completeness principle.*

Proof. Project the carrier rows $D, W, R, E, M, T, C, P, L$. The finite density ledger D, tolerance budget M, stream window W, regular readback R, and Real seal E are the only analytic rows available to a density-net consumer.

Apply the regular readback theorem, Definition 6003.12. It forces every $\mathsf{RegSeqRat}^{\uparrow}$-facing consumer to inspect the same finite window, dyadic ledger, finite modulus, and readback row before the terminal $\mathsf{Real}^{\uparrow}$ seal is available.

Use the sibling dependency route, Definition 6003.22. The dyadic tolerance read is supplied through $\mathsf{DyadicRatCore}^{\uparrow}$, the inspected finite window through $\mathsf{StreamName}^{\uparrow}$, the regular rational face through $\mathsf{RegSeqRat}^{\uparrow}$, and the terminal seal through $\mathsf{Real}^{\uparrow}$.

Finally replay the structural rows. The hsame transport T, Cont replay C, Pkg provenance P, and local $\mathsf{NameCert}$ row L preserve the same displayed route, and the accepted carrier has no coordinate for quotient representatives, selected limits, countable-choice nets, trichotomy, host equality, or ambient completeness. □

Every $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ consumer must read its density witness through the dyadic, regular-readback, and real-seal sibling route. The mesh cells are supplied by the $\mathsf{DyadicRatCore}^{\uparrow}$ rows of chapter 291; the regular rational inspection is supplied by the $\mathsf{RegSeqRat}^{\uparrow}$ rows of chapter 301; and the terminal endpoint is sealed only through the $\mathsf{Real}^{\uparrow}$ rows of chapter 38. Thus a finite density read reaches completion-facing consumers as displayed dyadic mesh data, regular readback data, and RealUp seal data, not as an ambient density theorem or a selected dense subset.

Chapter 6004

A Concrete Naming Certificate for $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$

The $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$ packet realizes the local-rule observation branch of chapter 9390 as finite Rule 110 NameCert data. It specializes the local-stencil surface of chapter 1036 to the eight-entry Rule 110 transition table, sits beside the cellular automaton carrier of chapter 934, the cellular row-classifier surface of chapter 941, and the Rule 110 pattern classifier of chapter 5844. The packet names one finite neighborhood read and its observed next-cell row; it is not an infinite orbit trace, a glider classification theorem, a universality proof, or a host evaluator semantics.

Definition 6004.1 (Rule 110 local-stencil observation carrier)**.** *A* $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (W, T, S, O, K, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite window row, naming the inspected left, center, and right cells together with the row coordinate at which the stencil is read.*
2. *T is the Rule 110 transition-table row, exposing the eight binary neighborhood cases and the selected case for W.*
3. *S is the local-stencil row inherited from* $\mathsf{LocalStencilObservation}^{\uparrow}$*, binding W and T as one displayed observation.*
4. *O is the observed next-cell row, recording the output cell certified by the selected Rule 110 case.*
5. *K is the classifier-adjacency row, exposing how the observed local output may be consumed by* $\mathsf{CellularRowClassifier}^{\uparrow}$ *or* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ *only after W, T, S, O have been displayed.*
6. *H records componentwise* hsame *transport for window, table, stencil, observed output, classifier-adjacency, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a local Rule 110 observation request through W, T, S, O, K, H.*
8. *P is the* Pkg *provenance over* $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$*,* $\mathsf{LocalStencilObservation}^{\uparrow}$*,* $\mathsf{CellularAutomaton}^{\uparrow}$*,* $\mathsf{CellularRowClassifier}^{\uparrow}$*,* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, T, S, O, K, H, C, P, N$. It has no coordinate for an unbounded orbit, global glider catalog, universality witness, hidden evaluator, quotient row equality, or a completed substrate semantics.

Theorem 6004.2 (Rule 110 local-stencil observation NameCert obligations)**.** *For every accepted* $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$ *carrier*

$$L = (W, T, S, O, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}}$ *surface consists exactly of finite window admission through W, Rule 110 transition-table exposure through T, local-stencil binding through S, observed next-cell exposure through O, classifier-adjacency routing through K, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6004.1. The finite observation rows are exactly the window W, transition-table row T, local-stencil binding S, observed output O, classifier-adjacency row K, and the structural rows H, C, P, N.

The transition-table read is local. Row T selects one of the eight displayed Rule 110 cases for the three-cell window W, and row S records that this read is a local-stencil observation rather than a whole-orbit computation.

The observed cell O is then the only output exposed to classifier consumers. The row K lets a cellular row classifier or the Rule 110 pattern classifier consume that output only after the local window, table, stencil, and output rows are visible.

Finally H, C, P, N preserve and name the same route. Since the excluded objects are absent from the carrier, no local NameCert obligation can be discharged by an unbounded orbit, glider catalog, universality witness, hidden evaluator, quotient row equality, or completed substrate semantics. □

Theorem 6004.3 (Rule 110 local-stencil classifier route)**.** *Every classifier-facing read of an accepted* $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$ *packet factors through*

$$\mathsf{LocalStencilObservation}^{\uparrow},\ \mathsf{CellularAutomaton}^{\uparrow},\ \mathsf{CellularRowClassifier}^{\uparrow},\ \mathsf{RuleOneTenPatternClassifier}^{\uparrow}$$

by first exposing the finite local route

$$W, T, S, O \longmapsto K \longmapsto H, C, P, N.$$

The route exports one observed Rule 110 transition-table cell to downstream classifiers; it does not export an orbit prefix, global pattern catalog, glider classification, universality theorem, or host evaluator semantics.

Proof. Start with the local rows W, T, S, O. The finite window and selected transition-table case determine the observed next-cell row before any classifier-facing consumer can read the packet.

Apply Definition 6004.2. It keeps classifier adjacency in K downstream of the local window, table, stencil, and output rows, so the classifier receives exactly the displayed local observation.

The sibling chapters named in the statement supply the surrounding surfaces. $\mathsf{LocalStencilObservation}^{\uparrow}$ supplies the generic local-stencil discipline, $\mathsf{CellularAutomaton}^{\uparrow}$ supplies the whole-rule provenance, $\mathsf{CellularRowClassifier}^{\uparrow}$ supplies the row-classifier consumer, and $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ supplies the Rule 110 pattern consumer.

None of those siblings is an internal coordinate of this packet before K, H, C, P, N are displayed. The exported route therefore remains a finite local-stencil observation rather than a global cellular or universality claim. □

Falsifiable prediction: A purported $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$ read is outside the packet if it classifies a Rule 110 row without first exposing the finite three-cell window, the selected transition-table case, the local-stencil binding, the observed next-cell row, classifier adjacency, transport, replay, provenance, and local naming.

Independence witness: local-stencil-observation, cellularautomaton, cellularrowclassifier, rule110-pattern-classifier: $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds the Rule 110 transition table, one selected local stencil, one observed output cell, classifier adjacency, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}}$.

Constructive story: A $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$ packet is generated from a finite three-cell Rule 110 window, the selected transition-table row, a local-stencil binding, an observed next-cell row, classifier adjacency, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6004.1, Definition 6004.2, and Definition 6004.3 seed the finite Rule 110 local-stencil observation packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite orbit replay, global pattern catalogs, glider classification, universality, host evaluator semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite-window admission, transition-table exposure, local-stencil binding, observed-output exactness, classifier-adjacency routing, transport, replay, provenance, and local naming for BEDC.Derived.RuleOneTenLocalStencilObservationUp.

The $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$ carrier consumes the cellular automaton update surface of chapter 934 and the Rule 110 pattern classifier of chapter 5844. Its local stencil row supplies the finite neighbourhood read before any glider catalogue, global orbit account, or Cook-frontier budget is visible. The downstream trust-substrate packet of chapter 6517 consumes this local-stencil audit row after the Rule 110 transition table, pattern classifier, and finite window are displayed.

Chapter 6005

A Concrete Naming Certificate for $\mathsf{LocatedUniformLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedUniformLimit}^{\uparrow}$ packet records the finite certificate surface for a located uniform-limit handoff without turning the handoff into host completeness. It sits over the finite stream windows of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, the modulus carrier of chapter 5887, and the uniform continuity surface of chapter 130. The packet gives Real and Completion consumers a displayed common-modulus route for a located uniform Cauchy family; it does not select a limit, quotient functions, use countable choice, invoke trichotomy, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6005.1 (LocatedUniformLimit carrier)**.** *A* $\mathsf{LocatedUniformLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (I, S, M, W, R, E, G, H, C, P, N)$$

with the following visible rows:

1. *I is the index and source-domain row whose accepted points are read through displayed histories and classifier transport;*
2. *S is the sequence row, listing the finite family members and the graph rows through which each member is inspected;*
3. *M is the common located uniform Cauchy modulus row, giving one displayed precision schedule for all accepted source windows;*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for indices, source points, and value names;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled value windows and their rational tail budgets;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream windows, regular rational readbacks, and common modulus checks have been displayed;*
7. *G is the graph row relating the sequence entries, the common modulus, and the terminal seal read by downstream Real-facing consumers;*
8. *H records componentwise* hsame *transport for index rows, sequence rows, modulus rows, windows, readbacks, graph rows, real seals, provenance, and local naming rows;*

9. *C records displayed* Cont *replay from index admission through sequence lookup, uniform-modulus inspection, finite-window readback, graph-row comparison, and real-seal handoff;*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedUniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulusSpace}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformLimit}^{\uparrow}}$ *row.*

The classifier relates two accepted packets exactly when their index rows, sequence rows, common modulus rows, finite stream windows, regular rational readbacks, real-seal rows, graph rows, and provenance rows transport componentwise along H and replay through the same displayed routes in C. No host function equality, quotient real equality, selected limit, countable choice, trichotomy, or ambient completeness principle is a carrier coordinate.

Lean4 ✓ `BEDC.Derived.LocatedUniformLimitUp.LocatedUniformLimitTasteGate single carrier alignment`

Theorem 6005.2 (LocatedUniformLimit NameCert obligations)**.** *For an accepted* $\mathsf{LocatedUniformLimit}^{\uparrow}$ *carrier $U = (I, S, M, W, R, E, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformLimit}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the displayed index, sequence, common modulus, window, readback, real-seal, graph, transport, replay, provenance, and local naming rows;*
2. *common-modulus exactness, requiring each value comparison requested by a Real-facing consumer to use the same located uniform Cauchy modulus row M before the terminal seal E can be inspected;*
3. *finite-window readback, requiring every index, source, and value observation to pass through W and R rather than through an external sequence or function equality predicate;*
4. *graph-row compatibility, requiring G to connect the displayed sequence entries, common modulus checks, regular rational readbacks, and* $\mathsf{Real}^{\uparrow}$ *seal rows;*
5. hsame *and* Cont *replay, requiring all index, sequence, modulus, readback, graph, and seal rows to move together under H and C;*
6. *provenance and non-escape, stating that the package exports only the named finite rows and no host completeness theorem, quotient function equality, selected limit, countable choice, or trichotomy principle.*

Proof. Carrier admission is projection from Definition 6005.1. The displayed packet lists the index row, sequence row, common located modulus, finite windows, regular rational readbacks, real seal, graph row, transport ledger, replay ledger, package provenance, and local name.

The common-modulus obligation is exactly the role of M. Every Real-facing comparison must first request a precision through the same located uniform Cauchy row, then inspect the scheduled source and value windows in W.

Finite-window readback is forced by the order W, R, E. The packet gives no coordinate from which a consumer could read an infinite sequence, a host function, or a quotient equality before the regular rational window has been displayed.

Graph-row compatibility is the projection through G. It records the finite route joining the inspected family member, the common modulus check, the readback row, and the terminal real seal.

Finally, H, C, P, N package the same route after classifier transport and continuation replay. Since none of the excluded principles is a row of the carrier, none can be exported by the local NameCert surface. □

Theorem 6005.3 (LocatedUniformLimit L10 handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{LocatedUniformLimit}^{\uparrow}$ *carrier factors through the finite route*

$$I, S, M, W, R, E, G, H, C, P, N.$$

The consumer may inspect displayed index rows, finite sequence entries, the common located uniform Cauchy modulus, finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{Real}^{\uparrow}$ *seal row, the graph row, componentwise transport, continuation replay, provenance, and the local name. It cannot bypass this route to obtain host completeness, quotient function equality, quotient real equality, a selected limit, countable choice, or trichotomy.*

Proof. Start with an L10 consumer asking for a Real-facing endpoint from the packet. The only entry point is the displayed index and sequence surface I, S, so the consumer must name the inspected family member before any value row is read.

The common located uniform Cauchy modulus M then supplies the precision discipline. The finite windows in W and the regular rational readback R turn that discipline into displayed rational data before the terminal seal E is available.

The graph row G records that the same route connects the sequence entry, modulus check, readback, and seal. Transport and replay through H and C preserve that route componentwise.

The package and local name rows P, N expose exactly this finite handoff. Because the excluded host principles are absent from the carrier coordinates, they cannot be read by any L10 consumer of the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUniformLimit}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedUniformLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6005.1, Definition 6005.2, and Definition 6005.3 seed the located uniform-limit certificate over finite index rows, sequence rows, common located uniform Cauchy moduli, stream windows, regular rational readbacks, graph rows, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedUniformLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close host completeness, quotient function equality, quotient real equality, selected limits, countable choice, trichotomy, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, common-modulus exactness, finite-window readback, graph-row compatibility, transport replay, provenance, and Real-seal non-escape for the same packet.

Constructive story: The construction reads finite index and sequence rows, applies one located uniform Cauchy modulus, replays StreamName windows and RegSeqRat readbacks, and exposes the Real seal only through hsame, Cont, Pkg, and local NameCert rows.

$\mathsf{FiniteIntervalLattice}^{\uparrow}$ supplies the finite meet/join index surface consumed by chapter 9072 and the dyadic-net route.

Chapter 6006

A Concrete Naming Certificate for $\mathsf{FiniteIntervalLattice}^{\uparrow}$

Following Bishop–Bridges constructive interval and net arguments, the $\mathsf{FiniteIntervalLattice}^{\uparrow}$ packet records the finite lattice of dyadic interval cells that a real-and-completion consumer may inspect before it asks for limits, covers, or compact-window continuity. It sits after the dyadic rational arithmetic of chapter 291, the dyadic interval surface of chapter 306, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the located interval carrier of chapter 1709, and the terminal real-name seal of chapter 38. The packet gives L10 Real and Completion routes a visible finite meet-join substrate; it is not an ambient interval-domain completeness theorem, not an open-cover compactness principle, and not a quotient real equality row.

Definition 6006.1 (Finite interval lattice carrier)**.** *A* $\mathsf{FiniteIntervalLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, I, L, J, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger used by all interval cells.*
2. *I is the finite list of* $\mathsf{DyadicInterval}^{\uparrow}$ *cells with displayed lower and upper endpoints.*
3. *L is the located-interval source row, read through chapter 1709.*
4. *J is the finite join table: every listed pair of cells either has a displayed least containing cell or a displayed refusal row.*
5. *M is the finite meet table: every listed pair of cells either has a displayed greatest common subcell or a displayed empty-intersection refusal row.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that records which endpoint and cell observations are inspected.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from the displayed endpoint windows.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after D, I, L, J, M, S, R have been displayed.*
9. *H records componentwise* hsame *transports for all visible interval-lattice rows.*
10. *C records displayed* Cont *replays from dyadic endpoint reads to lattice cells, meet-join tables, stream windows, regular readback, and Real sealing.*

11. *P is the* Pkg *provenance over* $\mathsf{FiniteIntervalLattice}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteIntervalLattice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, I, L, J, M, S, R, E, H, C, P, N$. It has no coordinate for an infinite interval lattice, selected limit point, quotient real equality, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteIntervalLatticeUp.FiniteIntervalLatticeTasteGate single carrier alignment`

Theorem 6006.2 (Finite interval lattice NameCert obligations)**.** *For every accepted* $\mathsf{FiniteIntervalLattice}^{\uparrow}$ *carrier*

$$Q = (D, I, L, J, M, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteIntervalLattice}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic endpoint ledger exposure, finite dyadic interval cell exposure, located-interval source exposure, finite join and meet tables, stream-window inspection, regular rational readback, Real seal nonescape, component-wise transport, continuation replay, provenance, and local naming. Every consumer of the lattice must read the displayed rows before using it in dyadic-net, located-interval, compact-window, or continuity arguments.*

Proof. Carrier admission is projection from Definition 6006.1. The packet exposes a finite tuple of dyadic endpoint rows, interval cells, located interval data, meet-join tables, window rows, readback rows, seal rows, transport, replay, provenance, and local naming.

The lattice operations are finite because J and M are displayed tables over the listed cells I. A consumer may inspect only the table entry or refusal row already stored in the packet, and the dyadic endpoint ledger D supplies the comparisons used by those entries.

The analytic handoff then passes through S, R, and E. The stream row records finite endpoint observations, the regular rational row records the accepted readback from those windows, and the Real row seals the same route without adding a selected limit, quotient equality, or ambient completeness coordinate.

Finally, H, C, P, and N preserve the displayed rows as BEDC certificate data. Thus every obligation is discharged through finite BHist, hsame, Cont, Pkg, and NameCert rows, and no host interval lattice or open-cover compactness theorem can enter the local surface. □

Theorem 6006.3 (Finite interval lattice endpoint order)**.** *Let $Q = (D, I, L, J, M, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{FiniteIntervalLattice}^{\uparrow}$ *carrier. Every listed dyadic interval cell exposed by I must display its lower and upper endpoint comparison through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D before any meet or join table entry in M or J can be read as a lattice operation.*

Consequently J and M are public only as endpoint-ordered finite tables over the cells listed in I. They cannot supply lattice operations for L10 Real or Completion consumers when the endpoint-order evidence from D is absent.

Proof. Project the carrier of Definition 6006.1. The row D is the dyadic endpoint and radius ledger, while I is the finite list of dyadic interval cells with displayed lower and upper endpoints.

Read a cell from I. Its lower and upper endpoint comparison is not a property of an ambient interval lattice; it is a displayed dyadic comparison supplied by D and carried with the cell row.

The finite join table J and meet table M are indexed by the cells already listed in I. A table entry can therefore be interpreted only after the endpoint order of the two source cells and the candidate result cell has been exposed through D.

If that endpoint-order evidence is hidden, the carrier still contains symbols named J and M, but they no longer certify meet or join operations for the visible interval cells. Hence L10 Real and Completion consumers must read D and I before using the meet and join tables. □

Theorem 6006.4 (Finite interval lattice Real-completion route)**.** *Let $Q = (D, I, L, J, M, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{FiniteIntervalLattice}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of a meet or join read from M or J must pass through the finite route*

$$D, I, L, J, M, S, R, E, H, C, P, N.$$

Thus the consumer first reads dyadic endpoint rows, finite interval-cell rows, the located interval source, the meet and join tables, StreamName windows, RegSeqRat readback, the Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row before reading completion-facing data.*

Proof. Begin with the carrier of Definition 6006.1. The tuple exposes the dyadic endpoint ledger D, finite interval cells I, located source row L, meet and join tables M, J, stream windows S, regular readback R, Real seal E, and structural rows H, C, P, N.

Apply the endpoint-order theorem Definition 6006.3. It forces every meet or join table entry to read the lower and upper endpoint comparisons from D through the listed cells I before the entry can serve as a lattice operation.

The located source and analytic handoff then remain downstream of the same finite route. The row L supplies the located interval source, S records the inspected endpoint windows, R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and E exposes the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally H, C, P, N transport, replay, source, and name only those displayed rows. Therefore a $\mathsf{Real}^{\uparrow}$ or $\mathsf{Completion}^{\uparrow}$ consumer cannot read completion-facing data from the lattice unless the dyadic endpoints, interval cells, located source, stream windows, regular readback, Real seal, transport, replay, provenance, and local NameCert rows have already been exposed. □

Theorem 6006.5 (Finite interval lattice refinement induction)**.** *Let $Q = (D, I, L, J, M, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{FiniteIntervalLattice}^{\uparrow}$ *carrier. Suppose a displayed subdivision-depth row refines each listed cell of I by finitely many dyadic subcells whose endpoint comparisons are read through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D. Then the meet and join tables refine by induction over the displayed depth: at every finite stage the refined tables remain indexed by dyadic endpoint rows from D, expose only* $\mathsf{StreamName}^{\uparrow}$ *windows from S, preserve* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, and pass the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through E.*

Consequently a $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer of the refined lattice must still read the route*

$$D, I, L, J, M, S, R, E, H, C, P, N$$

before using any refined meet, refined join, or refined endpoint cell.

Proof. Induct on the displayed subdivision-depth row. At depth zero the refined table is the original finite table of Definition 6006.4, so all meet and join reads already pass through $D, I, L, J, M, S, R, E, H, C, P, N$.

For the successor step, split each currently displayed cell into its finitely listed dyadic subcells. The endpoint-order theorem Definition 6006.3 forces the lower and upper endpoint comparisons of every subcell to be read through D before a table entry can be interpreted.

The finite meet and join rows are then rebuilt table-entry by table-entry. Each entry either displays the least containing refined cell, displays the greatest common refined subcell, or records the corresponding refusal row already governed by J and M.

Finally the analytic readback is unchanged. The stream windows remain the finite windows in S, the rational readback remains the row R, and the terminal real-name exposure is still sealed by E. Transport, replay, provenance, and local naming in H, C, P, N preserve the same route, so the induction cannot introduce an infinite lattice, selected limit, quotient equality, or ambient completion principle. □

Theorem 6006.6 (Finite interval lattice mesh-refinement consumption)**.** *Every* $\mathsf{FiniteIntervalMeshRefinement}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteIntervalLattice}^{\uparrow}$ *packet reads*

$$D, I, L, J, M, S, R, E, H, C, P, N$$

before interpreting any refined parent-cell table. The downstream consumer of chapter 9072 may refine cells only after the endpoint order, Real-completion route, and refinement induction of the lattice packet have been displayed.

Proof. Start with endpoint order, Definition 6006.3. It forces every source cell and candidate refined cell to expose lower and upper endpoint comparisons through the dyadic ledger D before a meet or join table entry can be read.

Next use the Real-completion route of Definition 6006.4. The route places L, S, R, E, H, C, P, N downstream of the finite dyadic interval rows, so a completion-facing mesh consumer cannot bypass the located source, stream windows, regular readback, Real seal, transport, replay, provenance, or local naming.

Finally apply refinement induction, Definition 6006.5. The refined parent-cell table is rebuilt at finite subdivision depth from the same D, I, J, M rows and preserves the same analytic handoff rows.

Thus the $\mathsf{FiniteIntervalMeshRefinement}^{\uparrow}$ consumer named by chapter 9072 reads the full lattice route before interpreting refined parent cells, rather than importing selected partitions, quotient real equality, open-cover compactness, or ambient completion data. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteIntervalLattice}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteIntervalLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6006.1 and Definition 6006.2 seed the finite dyadic interval lattice boundary for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteIntervalLattice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite interval-domain completeness, open-cover compactness, selected limits, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, meet-join table exactness, dyadic endpoint transport, RegSeqRat readback handoff, RealUp seal nonescape, and consumer-boundary proofs for BEDC.Derived.FiniteIntervalLatticeUp.

Constructive story: A $\mathsf{FiniteIntervalLattice}^{\uparrow}$ packet is generated from dyadic endpoint rows, finite dyadic interval cells, located interval source rows, finite meet and join tables, stream windows, regular rational readback, Real seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theorem 6006.7 (Finite interval lattice dyadic-interval dependency)**.** *Every accepted* $\mathsf{FiniteIntervalLattice}^{\uparrow}$ *meet or join read consumes the dyadic endpoint ledger of chapter 306 and the located-interval row of chapter 1709 before it reaches the StreamName, RegSeqRat, and Real seal rows. In the carrier*

$$Q = (D, I, L, J, M, S, R, E, H, C, P, N),$$

the finite tables J and M have no independent interval source outside the displayed D, I, L rows.

Proof. Project the carrier of Definition 6006.1. The endpoint ledger D, the dyadic interval list I, and the located interval source L are the only interval-source rows before the meet and join tables.

The join table J and meet table M are finite tables over the cells already listed in I. Their entries and refusal rows therefore use the displayed dyadic endpoints and located-interval source rather than a separate interval-domain object.

Only after D, I, L, J, M have been displayed can the analytic handoff proceed to S, R, E. The StreamName row records inspected endpoint windows, the RegSeqRat row reads those windows, and the Real row seals the same route. Transport, replay, provenance, and local naming preserve this dependency and do not add an independent interval source. □

Theorem 6006.8 (Finite interval lattice dyadic-net forward link)**.** *Every accepted* $\mathsf{FiniteIntervalLattice}^{\uparrow}$ *interval packet supplies the finite interval-index lattice consumed by the dyadic interval net route of chapter 5966. For a carrier*

$$Q = (D, I, L, J, M, S, R, E, H, C, P, N),$$

the dyadic-net consumer reads endpoint data from D, interval cells from I, located interval support from L, and finite order operations from J, M before it can use the lattice as an index surface.

Proof. Project the carrier of Definition 6006.1. The dyadic endpoints are supplied by D, the finite interval cells by I, and the located interval source by L.

Apply the endpoint-order theorem Definition 6006.3. It makes each cell and each table entry dependent on the displayed endpoint comparisons rather than on an ambient interval domain.

Use the Real-completion route Definition 6006.4. The rows J, M are finite tables over the same listed cells, and H, C, P, N transport, replay, source, and name only those rows.

Thus a dyadic interval net may consume the finite interval-index lattice only through the displayed packet $D, I, L, J, M, H, C, P, N$. No infinite interval lattice, quotient real equality, selected limit point, or host compactness principle is exported. □

Chapter 6007

A Concrete Naming Certificate for $\mathsf{KernelAcceptanceBoundary}^{\uparrow}$

The $\mathsf{KernelAcceptanceBoundary}^{\uparrow}$ packet records the finite audit boundary inherited from the Lean kernel acceptance tradition: a generated candidate is either accepted as a declaration in an environment or refused before it becomes a BEDC theorem row. The packet concretizes chapter 9364 as displayed NameCert data over generated candidates, kernel classifier stamps, environment ledger rows, accepted declarations, axiom-query refusal, replay, provenance, and local naming. It is a finite audit boundary for formal content, not a proof of the kernel implementation, not a semantic interpretation of a theorem name, and not an additional logical axiom. It consumes $\mathsf{KernelAcceptanceWitness}^{\uparrow}$ for accepted-declaration rows via chapter 549 and $\mathsf{AxiomQueryLedger}^{\uparrow}$ for forbidden-ancestry refusal rows via chapter 654.

Definition 6007.1 (Kernel acceptance boundary carrier)**.** *A* $\mathsf{KernelAcceptanceBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (G, K, A, E, L, F, H, C, P, N)$$

with the following displayed rows:

1. *G is the generated candidate row: a proposed declaration name, type, and proof term or inductive signature.*
2. *K is the kernel classifier stamp recording acceptance or refusal at the boundary.*
3. *A is the accepted declaration row, present only when the kernel classifier admits the candidate.*
4. *E is the environment ledger row containing the finite imported declarations and namespace context read by the classifier.*
5. *L is the ledger row for build replay, source location, and command provenance.*
6. *F is the axiom-query refusal row: forbidden ancestry, unresolved marker targets, and non-kernel semantic claims are refused as coordinates of the accepted declaration.*
7. *H records componentwise* hsame *transport for generated candidate, classifier, declaration, environment, ledger, and refusal rows.*
8. *C records displayed* Cont *replay from candidate generation to kernel classification, environment lookup, accepted declaration exposure, axiom query, and refusal boundary.*
9. *P is the* Pkg *provenance over* $\mathsf{KernelAcceptanceBoundary}^{\uparrow}$*, generated candidates, accepted declarations, environment ledgers, axiom-query refusal,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{KernelAcceptanceBoundary}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $G, K, A, E, L, F, H, C, P, N$. It has no coordinate for kernel self-correctness, compiler correctness, hardware trust, semantic adequacy of theorem names, or paper-side closure status.

Theorem 6007.2 (Kernel acceptance boundary NameCert obligations)**.** *For every accepted* KernelAcceptanceBoun *carrier*

$$Q = (G, K, A, E, L, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KernelAcceptanceBoundary}^{\uparrow}}$ *surface consists exactly of candidate exposure, kernel classifier stamping, accepted declaration exposure, environment ledger display, replay ledger display, axiom-query refusal, componentwise transport, continuation replay, provenance, and local naming. A BEDC audit consumer may cite the boundary only through those finite rows, and it may not replace them by a claim of kernel self-verification, semantic adequacy, compiler correctness, or hardware correctness.*

Proof. Project the carrier in Definition 6007.1. The generated candidate, classifier stamp, accepted declaration, environment ledger, replay ledger, and refusal row are all displayed coordinates of the same finite packet.

The kernel-facing obligation is the boundary row K together with A and E. Acceptance of a declaration is visible only as the classifier stamp read in the displayed environment; refusal is likewise visible as a boundary stamp rather than as a semantic explanation of the candidate.

The audit-facing obligation is F. It records that forbidden ancestry, unresolved marker targets, and non-kernel semantic claims are not accepted-declaration coordinates, so a downstream BEDC audit cannot turn kernel acceptance into unlimited certification.

Finally H, C, P, and N replay and name the finite route. Since no row stores kernel self-correctness, compiler correctness, hardware trust, or paper-side closure status, the local NameCert obligations stop exactly at the accepted-declaration and axiom-query boundary. □

Theorem 6007.3 (Kernel acceptance boundary carrier admission)**.** *For every finite* BHist *packet*

$$Q = (G, K, A, E, L, F, H, C, P, N)$$

accepted by $\mathsf{KernelAcceptanceBoundary}^{\uparrow}$*, carrier admission is exactly the display of generated-candidate rows, kernel classifier stamps, accepted-declaration exposure, environment-ledger rows, replay ledgers, axiom-query refusal rows, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *evidence. No consumer can enter the carrier through a hidden theorem-name semantics row, compiler-correctness row, hardware row, or paper-closure row.*

Proof. Project the coordinates of Q from Definition 6007.1. The generated candidate row G, classifier stamp K, accepted declaration row A, environment ledger E, replay ledger L, and axiom-query refusal row F are the data admitted into the finite carrier.

The transport and replay coordinates H and C keep admission stable under componentwise hsame transport and displayed Cont replay. The provenance and naming coordinates P and N then package the same finite route as Pkg provenance and local NameCert evidence.

Since the carrier definition lists no hidden coordinate for kernel self-correctness, compiler correctness, hardware trust, theorem-name semantics, or paper closure, carrier admission cannot read such data. It remains a projection of the displayed packet rows. □

Theorem 6007.4 (Kernel acceptance boundary accepted-declaration exposure)**.** *In every accepted* KernelAcceptanceBoundary$^{\uparrow}$ *packet*

$$Q = (G, K, A, E, L, F, H, C, P, N),$$

the accepted declaration row A is exposed only together with the generated candidate G, classifier stamp K, environment ledger E, replay ledger L, axiom-query refusal row F, componentwise hsame *transport H,* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N. The exposure route is the accepted-declaration source row supplied by chapter 549, with forbidden-ancestry refusal supplied by chapter 654.*

Proof. Read the accepted declaration row A from the carrier packet. It is not isolated: the same packet displays the generated candidate G, the classifier stamp K, and the environment ledger E that record where the declaration was admitted.

Next read L and F. The replay ledger keeps the finite command route visible, while the axiom-query refusal row keeps forbidden ancestry and unresolved target queries outside the accepted-declaration coordinates.

Finally use H, C, P, and N to transport, replay, package, and name the exposure route. The cited sibling chapters provide the accepted-declaration and forbidden-ancestry source rows; the theorem asserts only that the local packet exposes those rows, not that the kernel implementation is semantically certified. □

Theorem 6007.5 (Kernel acceptance boundary closed trace forward link)**.** *Every* ClosedObservationProofTrace$^{\uparrow}$ *consumer of chapter 6747 must read the accepted-declaration row A and the axiom-query refusal row F through the* KernelAcceptanceBoundary$^{\uparrow}$ *carrier*

$$Q = (G, K, A, E, L, F, H, C, P, N)$$

before replaying a closed proof trace. The forward dependency is the finite route through generated candidate, classifier stamp, accepted declaration, environment ledger, replay ledger, refusal row, transport, replay, provenance, and local naming; it is not a claim of kernel self-correctness or semantic adequacy of theorem names.

Proof. Apply accepted-declaration exposure, Definition 6007.4. It displays A only together with the generated candidate, classifier stamp, environment ledger, replay ledger, refusal row, transport, replay, provenance, and local naming.

Read the refusal row F from the same carrier. This row keeps forbidden ancestry, unresolved marker targets, and non-kernel semantic claims outside the accepted-declaration coordinates.

A closed proof trace can therefore consume kernel acceptance only through the displayed boundary packet. The downstream trace replay receives an accepted-declaration row and a refusal row, not a proof of kernel implementation correctness or theorem-name semantics. □

Theorem 6007.6 (Kernel acceptance boundary replay nonescape)**.** *Every* Cont *replay of a* KernelAcceptanceBounda *packet*

$$Q = (G, K, A, E, L, F, H, C, P, N)$$

remains confined to generated-candidate rows, classifier stamps, accepted-declaration rows, environment ledgers, replay ledgers, axiom-query refusal rows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *evidence. In particular, replay cannot manufacture a theorem from forbidden ancestry, unresolved marker targets, non-kernel semantic claims, or any unstored kernel-correctness premise.*

Proof. Start with the displayed replay coordinate C. By carrier definition, C replays the path from candidate generation through kernel classification, environment lookup, accepted declaration exposure, axiom query, and refusal boundary.

The transport coordinate H is componentwise over the same rows, so replay after hsame transport still reads only $G, K, A, E, L, F, H, C, P, N$. The provenance and naming rows P and N record that finite route as package and local certificate data.

The refusal coordinate F blocks the only listed escape route: forbidden ancestry, unresolved marker targets, and non-kernel semantic claims are refusal data rather than accepted-declaration data. Since no unstored kernel-correctness premise appears in the carrier, replay non-escape follows by projection of the packet rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{KernelAcceptanceBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KernelAcceptanceBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6007.1 and Definition 6007.2 seed the finite kernel-acceptance audit boundary for generated formal content.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KernelAcceptanceBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close kernel self-correctness, compiler correctness, hardware trust, semantic adequacy of theorem names, paper-side closure status, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, accepted-declaration exposure, environment-ledger exactness, axiom-query refusal, replay transport, and audit-boundary nonescape proofs for BEDC.Derived.KernelAcceptanceBoundaryUp

Constructive story: A $\mathsf{KernelAcceptanceBoundary}^{\uparrow}$ packet is generated from a candidate declaration, kernel classifier stamp, accepted declaration row, environment ledger, replay ledger, axiom-query refusal row, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theorem 6007.7 (Kernel acceptance boundary acceptance audit dependency route)**.** *Every accepted-declaration exposure used to name a* $\mathsf{KernelAcceptanceBoundary}^{\uparrow}$ *packet first factors through the* $\mathsf{KernelAcceptanceWitness}^{\uparrow}$ *source row, and every forbidden-ancestry refusal used by the same packet first factors through the* $\mathsf{AxiomQueryLedger}^{\uparrow}$ *refusal row. Thus the local boundary can be named only after the accepted-declaration route and the axiom-query route have both been displayed inside*

$$Q = (G, K, A, E, L, F, H, C, P, N).$$

It does not supply kernel self-correctness, compiler correctness, hardware trust, or semantic adequacy of theorem names.

Proof. Project the accepted carrier of Definition 6007.1. The row A is the accepted-declaration coordinate, and the row F is the axiom-query refusal coordinate.

Apply Definition 6007.4. It already exposes A only together with $G, K, E, L, F, H, C, P, N$ and identifies the accepted-declaration source row with chapter 549.

Now read the sibling dependency route. It states that the forbidden-ancestry refusal row is supplied by chapter 654 before local naming. Therefore A and F must both be present before the $\mathsf{KernelAcceptanceBoundary}^{\uparrow}$ name can be consumed.

The final exclusions are inherited from the carrier and sibling route: neither dependency supplies kernel self-correctness, compiler correctness, hardware trust, or semantic adequacy. □

The accepted-declaration exposure row of $\mathsf{KernelAcceptanceBoundary}^{\uparrow}$ is supplied by chapter 549, while the forbidden-ancestry refusal row is supplied by chapter 654. This sibling route only states that the boundary packet reads those two displayed audit dependencies before local naming; it does not claim kernel self-correctness, compiler correctness, or semantic adequacy. For the L10 Real and Completion path, a downstream selector such as chapter 1576 may cite the boundary

only after the accepted-declaration and axiom-query rows have been displayed, so kernel acceptance remains an audit boundary rather than a Real completeness, selector existence, or semantic adequacy principle.

Chapter 6008

A Concrete Naming Certificate for $\mathsf{LocatedCauchyIntervalRefinement}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedCauchyIntervalRefinement}^{\uparrow}$ packet records the finite refinement point where a located real interval is read together with a regular Cauchy real name under one dyadic tolerance ledger. It sits beside the located interval surface of chapter 1709, the Bishop located Cauchy real packet of chapter 1850, and the four-object real-line interface of chapter 2062. The packet is an L10 Real and Completion naming certificate; it does not assert $\mathsf{Real}^{\uparrow}$ completeness, selected limits, quotient stream equality, trichotomy, countable choice, or bridge checking.

Definition 6008.1 (Located Cauchy interval refinement carrier)**.** *A* $\mathsf{LocatedCauchyIntervalRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (I, B, D, S, R, A, W, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row, supplying the interval endpoints, radius ledger, locator reads, locatedness modulus, and metric bracket route.*
2. *B is the* $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$ *row, exposing the located Cauchy real interface that already binds the located interval and regular Cauchy readback surfaces.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and positive-tolerance ledger shared by interval refinement and regular Cauchy comparison.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the Cauchy name.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the same stream windows and the same dyadic ledger D.*
6. *A is the* $\mathsf{RealRationalApproximation}^{\uparrow}$ *row comparing the regular rational readback with the located interval endpoints at the displayed tolerance.*
7. *W is the refinement witness row, recording that the interval width request and the regular Cauchy tail request consume the same dyadic tolerance before any terminal real-name seal is read.*
8. *H records componentwise* hsame *transport for the interval, located-Cauchy, dyadic, stream, regular-readback, approximation, witness, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a refinement request through $I, B, D, S, R, A, W, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedCauchyIntervalRefinement}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{BishopLocatedCauchyReal}$ $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyIntervalRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, B, D, S, R, A, W, H, C, P, N$. The carrier has no coordinate for $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, quotient stream equality, host real equality, trichotomy, countable choice, compactness, or bridge checking.*

Lean4 ✓ `BEDC.Derived.LocatedCauchyIntervalRefinementUp.LocatedCauchyIntervalRefinementTasteGate`
`single carrier alignment`

Theorem 6008.2 (Located Cauchy interval refinement NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCauchyIntervalRefinement}^{\uparrow}$ *carrier $J = (I, B, D, S, R, A, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyIntervalRefinement}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located interval row I, located-Cauchy row B, shared dyadic ledger D, stream window S, regular readback R, rational approximation row A, refinement witness row W, transport row H, continuation row C, provenance row P, and local naming row N;*
2. *located interval admission, requiring every endpoint, radius, locator, locatedness, and metric-bracket request to pass through the displayed* $\mathsf{LocatedRealInterval}^{\uparrow}$ *row I;*
3. *located Cauchy admission, requiring every Cauchy-facing read to pass through the* $\mathsf{BishopLocatedCauchyReal}^{\uparrow}$ *row B together with D, S, R, A, W before any comparison with the interval endpoints is consumed;*
4. *shared tolerance discipline, requiring D to be visible before both the interval refinement request and the regular Cauchy readback route are read;*
5. *approximation compatibility, requiring A to compare R with the endpoints in I only under the same dyadic row D;*
6. *non-escape, requiring P, N to export no* $\mathsf{Real}^{\uparrow}$ *completeness theorem, selected limit, quotient stream equality, host real equality, trichotomy, countable-choice selector, compactness principle, or bridge credential.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6008.1. The accepted packet exposes exactly the located interval, located-Cauchy, dyadic, stream, regular-readback, approximation, witness, and structural rows.

Located interval admission is supplied by I, using the sibling surface of chapter 1709. Located Cauchy admission is supplied by B, using the sibling surface of chapter 1850.

The shared tolerance row is D. Since both the endpoint refinement and the Cauchy tail read cite D before S, R, A, W can be consumed, the packet has no route that compares interval data and Cauchy data under unrelated budgets.

Approximation compatibility is the row A. It reads the regular rational approximation against the interval endpoints through the displayed tolerance, while H, C, P, N preserve, replay, source, and name only the same finite packet.

No excluded object occurs as a carrier coordinate. Hence the local NameCert surface cannot export completeness, a selected limit, quotient stream equality, host real equality, trichotomy, choice, compactness, or bridge checking. □

Theorem 6008.3 (Located Cauchy interval refinement Cauchy route)**.** *Every accepted* LocatedCauchyIntervalRefine *packet that refines a located interval by a Cauchy readback factors through the route*

LocatedRealInterval$^{\uparrow}$, BishopLocatedCauchyReal$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RealRationalApprox

The same dyadic row D is consumed before the interval row I is narrowed and before the regular Cauchy route S, R, A is compared with the endpoints. The route may then replay componentwise hsame*,* Cont*,* Pkg*, and local* NameCert *data, but it exports no selected limit, quotient stream equality, host real equality, trichotomy, countable choice, ambient* Real$^{\uparrow}$ *completeness, or bridge checking.*

Proof. Start with an accepted carrier $J = (I, B, D, S, R, A, W, H, C, P, N)$. Projection gives the located interval row I, the located-Cauchy row B, the dyadic tolerance ledger D, the stream window S, the regular readback row R, and the rational approximation row A.

The interval side is read through chapter 1709. The Cauchy side is read through chapter 1850, with the real-line route of chapter 2062 supplying the surrounding DyadicRatCore, StreamName, RegSeqRat, and Real seal discipline.

The witness row W records that the interval narrowing and the Cauchy tail comparison cite the same row D. Thus the route cannot split into one tolerance for locatedness and another tolerance for regular Cauchy readback.

The structural rows H, C, P, N transport, replay, source, and name the displayed route only. Since no excluded coordinate is present, the refinement packet remains a finite NameCert boundary rather than a completeness or limit-selection principle. □

Closure status for NameCert$_{\text{LocatedCauchyIntervalRefinement}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\text{LocatedCauchyIntervalRefinement}^{\uparrow}}$, seed)

Scope closed: Definition 6008.1, Definition 6008.2, and Definition 6008.3 seed the located Cauchy interval refinement boundary over LocatedRealInterval$^{\uparrow}$, BishopLocatedCauchyReal$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RealRationalApproximation$^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{LocatedCauchyIntervalRefinement}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real$^{\uparrow}$ completeness, selected limits, quotient stream equality, host real equality, trichotomy, countable choice, compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located interval admission, located Cauchy admission, shared tolerance discipline, approximation compatibility, and non-escape proofs for BEDC.Derived.LocatedCauchyIntervalRefinementU

Constructive story: A LocatedCauchyIntervalRefinement$^{\uparrow}$ packet is generated from a LocatedRealInterval row, a BishopLocatedCauchyReal row, a shared DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat regular readback, a RealRationalApproximation row, a refinement witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6009

A Concrete Naming Certificate for $\mathsf{KleeneBrouwerOrder}^{\uparrow}$

Following Kleene and Troelstra–van Dalen on well-founded tree orderings in constructive bar and spread arguments, the $\mathsf{KleeneBrouwerOrder}^{\uparrow}$ packet records the finite order surface on displayed tree nodes. It sits beside the prefix-tree boundary of chapter 1622, the finite bar route of chapter 400, the bar-induction packet of chapter 1675, the spread-law admission surface of chapter 1532, the finite fan theorem packet of chapter 5863, and the finite-window interface of chapter 126. The packet names only finite node, prefix, and first-disagreement rows; it does not select an infinite branch, import classical well-ordering, decide global tree equality, or invoke countable choice.

Definition 6009.1 (Kleene–Brouwer order carrier)**.** *A* $\mathsf{KleeneBrouwerOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, N, P, F, L, A, H, C, Q, M)$$

with the following displayed rows:

1. *T is the finite tree-node row, listing the displayed nodes and their admission decisions in the inspected prefix tree.*
2. *N is the node-code row, recording each inspected word as a finite* $\mathsf{List}^{\uparrow}$ *of* $\mathsf{Nat}^{\uparrow}$ *entries, with the empty word and parent-prefix witnesses exposed.*
3. *P is the prefix row, recording the displayed prefix relation between listed nodes and the finite parent spine used by tree induction.*
4. *F is the first-disagreement row, recording the first coordinate at which two incomparable listed nodes differ, together with the left/right* $\mathsf{Nat}^{\uparrow}$ *comparison visible at that coordinate.*
5. *L is the* $\mathsf{Nat}^{\uparrow}/\mathsf{List}^{\uparrow}$ *prefix ledger used to traverse lengths, heads, tails, and coordinate comparisons without reading a host sequence.*
6. *A is the order-admission row, classifying a displayed comparison by the Kleene–Brouwer rule: later extensions are below their prefixes, and incomparable nodes are ordered by the first displayed disagreement.*
7. *H records componentwise* hsame *transport for tree nodes, node codes, prefix rows, first-disagreement rows, ledgers, order admission, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a comparison request through T, N, P, F, L, A, H.*

9. *Q is the* Pkg *provenance over* KleeneBrouwerOrder$^{\uparrow}$, KleeneTree$^{\uparrow}$, FanTheorem$^{\uparrow}$, FiniteFanTheorem$^{\uparrow}$, BrouwerBarInduction$^{\uparrow}$, SpreadLaw$^{\uparrow}$, StreamName$^{\uparrow}$, Nat$^{\uparrow}$, List$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *M is the local* NameCert$_{\text{KleeneBrouwerOrder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for an infinite branch, a host total order on all sequences, quotient equality of streams, classical well-ordering, a bar-induction conclusion, a spread choice functional, or countable choice.

Lean4 (definition) `BEDC.Derived.KleeneBrouwerOrderUp.KleeneBrouwerOrderUp`

Theorem 6009.2 (Kleene–Brouwer order NameCert obligation surface)**.** *For every accepted* KleeneBrouwerOrder$^{\uparrow}$ *carrier $K = (T, N, P, F, L, A, H, C, Q, M)$, the local* NameCert$_{\text{KleeneBrouwerOrder}^{\uparrow}}$ *surface consists exactly of finite tree-node admission through T, finite node coding through N, prefix exposure through P, first-disagreement exposure through F,* Nat$^{\uparrow}$/List$^{\uparrow}$ *prefix-ledger traversal through L, Kleene–Brouwer comparison admission through A, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through Q, and local naming through M.*

Every KleeneTree$^{\uparrow}$, FanTheorem$^{\uparrow}$, FiniteFanTheorem$^{\uparrow}$, BrouwerBarInduction$^{\uparrow}$, SpreadLaw$^{\uparrow}$, *or* StreamName$^{\uparrow}$ *consumer that reads this order must expose those rows before treating a displayed comparison as a well-founded tree-order step. The packet exports no infinite path, global branch selector, quotient stream equality, host well-ordering, countable-choice functional, or completed bar-induction proof.*

Proof. Project the carrier of Definition 6009.1. The only tree data available to a consumer are the displayed node rows T, N and the finite prefix row P.

For comparable nodes, the order read is forced through the prefix ledger. The row L supplies the Nat$^{\uparrow}$ lengths and List$^{\uparrow}$ parent spines, and the row A records the Kleene–Brouwer convention that a proper extension is ordered below its prefix.

For incomparable nodes, the read is forced through F. The first-disagreement coordinate and its two Nat$^{\uparrow}$ entries are displayed before A may classify the comparison, so no host comparison of completed streams is used.

The structural rows H, C, Q, M then transport, replay, source, and name the same finite comparison route. Since none of the carrier coordinates stores an infinite branch, a selected bar, quotient stream equality, a host well-ordering, or countable choice, the listed rows exhaust the NameCert obligation surface. □

Closure status for NameCert$_{\text{KleeneBrouwerOrder}^{\uparrow}}$**.**

Constructive story: A KleeneBrouwerOrder$^{\uparrow}$ packet is generated from finite tree-node rows, List/Nat node-code rows, prefix rows, first-disagreement rows, prefix ledgers, order-admission rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{KleeneBrouwerOrder}^{\uparrow}}$, seed)

Scope closed: Definition 6009.1 and Definition 6009.2 seed the finite Kleene–Brouwer comparison surface consumed by tree, fan, bar, spread, and StreamName routes.

Formal verification: FormalStatus(NameCert$_{\text{KleeneBrouwerOrder}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global well-foundedness, Brouwer bar induction, fan compactness, selected infinite branches, quotient stream equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix exactness, first-disagreement exactness, finite order classification, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.KleeneBrouwerOrderUp

Chapter 6010

A Concrete Naming Certificate for $\mathsf{DedekindCutArithmetic}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DedekindCutArithmetic}^{\uparrow}$ packet records the finite arithmetic surface of rounded located cuts before any consumer compares it with the regular Cauchy real-name route. It sits after the rounded cut interface of chapter 436, the Cauchy comparison boundary of chapter 1424, the located cut stream of chapter 5719, and the regular real-name route of chapter 301 and chapter 38. The packet names addition, negation, order, and multiplication reads as finite cut-side ledgers; it does not construct $\mathsf{Real}^{\uparrow}$ by cuts, identify quotient cuts, choose suprema, or assert completeness.

Definition 6010.1 (Dedekind cut arithmetic carrier)**.** *A* $\mathsf{DedekindCutArithmetic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, L, U, Q, S, R, E, O, H, C, P, N)$$

with the following displayed rows:

1. *D is the source* $\mathsf{DedekindCut}^{\uparrow}$ *row, carrying the lower and upper rounded located cut observations.*
2. *L is the lower arithmetic ledger, recording finite lower-side witnesses for cut addition, negation, order, and multiplication requests.*
3. *U is the upper arithmetic ledger, recording the corresponding upper-side witnesses and disjointness guards.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and rational-operation row used to compare the arithmetic ledgers with regular rational readback.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which arithmetic observations are sampled.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after D, L, U, Q, S are displayed.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached by the regular Cauchy route, not by a quotient-cut construction.*
8. *O is the operation-admission ledger naming which displayed cut-side arithmetic requests have compatible regular-Cauchy readbacks.*
9. *H records componentwise* hsame *transport for cut, arithmetic, dyadic, stream, readback, seal, operation, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from an arithmetic request through $D, L, U, Q, S, R, E, O, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{DedekindCutArithmetic}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{DedekindCauchyComparison}^{\uparrow}$, $\mathsf{DedekindCutStream}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindCutArithmetic}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for quotient-cut equality, host real equality, selected suprema, trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.DedekindCutArithmeticUp.DedekindCutArithmeticTasteGate single carrier alignment`

Theorem 6010.2 (Dedekind cut arithmetic NameCert obligations)**.** *For every accepted* $\mathsf{DedekindCutArithmetic}^{\uparrow}$ *carrier* $A = (D, L, U, Q, S, R, E, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DedekindCutArithmetic}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the cut source row D, lower and upper arithmetic ledgers L, U, dyadic tolerance row Q, stream window row S, regular readback row R, real seal row E, operation-admission row O, transport row H, continuation row C, provenance row P, and local naming row N;*

2. *cut-side operation discipline, requiring every arithmetic request to expose the lower and upper observation ledgers L, U over the same rounded located cut row D;*

3. *dyadic tolerance discipline, requiring each arithmetic comparison to consume Q before any regular readback or Real-facing seal is read;*

4. *stream and regular-readback discipline, requiring S and R to mediate all Cauchy-facing arithmetic reads;*

5. *operation-admission exactness, requiring O to name only those cut-side operation rows whose regular-Cauchy readback has passed through D, L, U, Q, S, R, E;*

6. *non-escape, requiring P, N to export no quotient-cut equality, host real equality, selected supremum, trichotomy, countable-choice selector, Dedekind construction of* $\mathsf{Real}^{\uparrow}$*, or ambient completeness theorem.*

No local arithmetic obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6010.1. The accepted packet exposes exactly the cut source, lower and upper arithmetic ledgers, dyadic tolerance, stream window, regular readback, real seal, operation admission, transport, replay, provenance, and local naming rows.

The cut-side operation discipline is read from D, L, U. Each arithmetic request is named by lower and upper observation ledgers over the same rounded located cut source, so no operation can substitute a quotient cut or a host real representative.

The Cauchy-facing discipline is read from Q, S, R, E. The dyadic row supplies the tolerance budget, the stream row opens finite observation windows, the regular readback row exposes rational Cauchy data, and the seal row is reached only after that route is displayed.

Finally O, H, C, P, N admit, transport, replay, source, and name only the same finite route. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6010.3 (Dedekind cut arithmetic Cauchy compatibility)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{DedekindCutArithmetic}^{\uparrow}$ *carrier that reads a cut-side arithmetic operation must factor through*

$\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{DedekindCauchyComparison}^{\uparrow}$, $\mathsf{DedekindCutStream}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, R

The consumer first reads the displayed lower and upper cut arithmetic ledgers L, U *over* D*, then the dyadic tolerance row* Q*, then the stream and regular-readback rows* S, R*, and only then the Real seal row* E *and operation-admission row* O*. The route supplies compatibility of displayed cut-side operations with displayed regular-Cauchy readback; it supplies no quotient-cut arithmetic, no quotient real equality, no selected supremum, no trichotomy branch, no countable choice, and no completeness theorem.*

Proof. Open an accepted carrier $A = (D, L, U, Q, S, R, E, O, H, C, P, N)$. The only cut-side arithmetic data are the lower and upper ledgers L, U over the displayed rounded located cut row D.

To compare this arithmetic data with the regular Cauchy route, the packet must expose the dyadic tolerance row Q and the finite observation windows S. The readback row R is downstream of those rows, and the Real seal E is downstream of R.

The comparison boundary is therefore the same finite route named by the Dedekind-Cauchy and Dedekind-cut stream packets: cut observations are sampled through finite stream windows and then read as regular rational data before the terminal Real seal is available.

The operation-admission row O records only arithmetic requests that have passed through that route, while H, C, P, N transport, replay, source, and name the same data. Since no quotient-cut, quotient-real, selected-supremum, trichotomy, choice, or completeness coordinate occurs in the carrier, every Real-facing arithmetic read has exactly the displayed Cauchy-compatible boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindCutArithmetic}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindCutArithmetic}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6010.1, Definition 6010.2, and Definition 6010.3 seed the cut arithmetic route over DedekindCutUp, DedekindCauchyComparisonUp, DedekindCutStreamUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindCutArithmetic}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-cut arithmetic, quotient real equality, selected suprema, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cut-side operation discipline, dyadic tolerance discipline, stream and regular-readback discipline, operation-admission exactness, and non-escape proofs for BEDC.Derived.DedekindCutArithm

Constructive story: A $\mathsf{DedekindCutArithmetic}^{\uparrow}$ packet is generated from a DedekindCut row, lower and upper arithmetic ledgers, a DyadicRatCore tolerance row, StreamName finite windows, RegSeqRat readback, a RealUp seal, an operation-admission row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 6011

A Concrete Naming Certificate for $\mathsf{HausdorffUniformityCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Bourbaki on separated uniformities, the $\mathsf{HausdorffUniformityCompletion}^{\uparrow}$ packet records the completion neighbour where a uniformity source, a separated classifier, and a finite completion route are displayed in one NameCert surface. It sits after the uniform-space carrier of chapter 339, the Hausdorff-uniformity boundary of chapter 4072, the separated-reflection handoff of chapter 4151, the uniform-completion packet of chapter 1473, the metric-completion comparison surface of chapter 1506, the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives L10 completion consumers a separated-uniform completion object without quotient equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6011.1 (HausdorffUniformityCompletion carrier)**.** *A* $\mathsf{HausdorffUniformityCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, H, S, C, M, W, R, E, T, Q, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row, including the finite entourage basis and refinement ledger read before any completion-facing request.*
2. *H is the* $\mathsf{HausdorffUniformity}^{\uparrow}$ *separated-uniformity row, exposing the diagonal classifier for the same uniform source.*
3. *S is the* $\mathsf{SeparatedReflection}^{\uparrow}$ *row that routes indistinguishable Cauchy data through a displayed separated interface before a completion seal is consumed.*
4. *C is the* $\mathsf{UniformCompletion}^{\uparrow}$ *row, recording the finite Cauchy-filter or Cauchy-net completion route served by U, H, S.*
5. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *comparison row used only when a metric-generated completion consumer asks for the same separated handoff.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which completion observations are scheduled.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from the same displayed windows.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, read only after U, H, S, C, M, W, R have been displayed.*

9. *T records componentwise* hsame *transport for the source, separated classifier, reflection, completion, comparison, window, readback, seal, replay, provenance, and local naming rows.*
10. *Q records displayed* Cont *replay along the route from U, H, S through C, M, W, R, E.*
11. *P is the* Pkg *provenance over* $\mathsf{HausdorffUniformityCompletion}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{HausdorffUniformity}^{\uparrow}$, $\mathsf{SeparatedReflection}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffUniformityCompletion}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one separated-uniform completion packet. It contains no coordinate for quotient completion equality, selected Cauchy representatives, host point equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6011.2 (HausdorffUniformityCompletion NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffUniformityCompletion}^{\uparrow}$ *carrier*

$$K = (U, H, S, C, M, W, R, E, T, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HausdorffUniformityCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed uniform-space source, Hausdorff-uniformity classifier, separated-reflection row, uniform-completion row, metric-completion comparison row, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *uniform-source exactness, requiring every completion-facing request to begin with the finite entourage surface of U;*
3. *Hausdorff separation handoff, requiring indistinguishable Cauchy data to pass through H and then through S before the completion rows are visible;*
4. *completion readback stability, requiring C, M, W, R, E to be consumed in the displayed order whenever a uniform or metric completion consumer asks for a separated endpoint read;*
5. *transport and replay stability through T, Q for the same row order;*
6. *ledger non-escape, requiring P and N to name no quotient completion equality, selected representative, host equality, countable-choice schedule, open-cover compactness principle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

No local obligation is stored outside these displayed rows.

Proof. Carrier admission is projection from Definition 6011.1. The accepted tuple displays the uniform source, Hausdorff classifier, separated reflection, completion rows, finite windows, regular readback, real seal, and structural rows.

Uniform-source exactness follows from the first coordinate of the route. A completion-facing request must read U before it can inspect the separated classifier or any completion row, so the request is tested against finite entourage data rather than an ambient host uniformity.

The separation handoff is the paired role of H and S. The row H records diagonal indistinguishability through the Hausdorff uniformity, and S moves that evidence into the separated-reflection boundary before C or M can be consumed.

The completion readback is then confined to C, M, W, R, E. Transport and replay through T, Q preserve the same order, while P and N package only the named rows. Hence none of the excluded quotient, representative-selection, choice, compactness, host-equality, or ambient-completeness readings can be projected as a NameCert obligation. □

Theorem 6011.3 (HausdorffUniformityCompletion separated handoff)**.** *Every separated endpoint read exported by an accepted* $\mathsf{HausdorffUniformityCompletion}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{UniformSpace}^{\uparrow} \longmapsto \mathsf{HausdorffUniformity}^{\uparrow} \longmapsto \mathsf{SeparatedReflection}^{\uparrow} \longmapsto \mathsf{UniformCompletion}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow} \mapsto$$

Consequently a completion consumer receives the separated-uniform completion surface only through finite entourage, reflection, completion, window, regular-readback, and seal rows; it receives no quotient completion equality, selected representative, countable-choice schedule, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Project the carrier of Definition 6011.1. The rows $U, H, S, C, M, W, R, E, T, Q, P, N$ are the only rows available to a separated completion consumer.

The route begins with U and H, so the consumer first reads the displayed uniform source and the Hausdorff uniformity classifier. The separated-reflection row S is the only handoff from indistinguishable Cauchy data to a separated completion boundary.

The completion rows C and M are downstream of that separated handoff. The finite-window row W, the regular readback row R, and the real seal row E record the observable endpoint surface after the completion route has already been displayed.

Finally T, Q, P, N transport, replay, package, and name the same finite route. Since no quotient equality, selected representative, choice schedule, host equality, or ambient completeness row occurs in the carrier, no separated endpoint read can export such a datum. □

Falsifiable prediction: Every accepted $\mathsf{HausdorffUniformityCompletion}^{\uparrow}$ consumer reads $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{HausdorffUniformity}^{\uparrow}$, $\mathsf{SeparatedReflection}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ in the displayed route before citing separated completion uniqueness.

Independence witness: uniformspace, hausdorff-uniformity, separated-reflection, uniformcompletion, metriccompletion, streamname, regseqrat, real: $\mathsf{HausdorffUniformityCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the uniform source, Hausdorff classifier, separated reflection, completion rows, finite windows, regular readback, real seal, transport, replay, provenance, and local NameCert row as one packet.

Theorem 6011.4 (HausdorffUniformityCompletion sibling lattice)**.** *Every accepted* $\mathsf{HausdorffUniformityCompletion}$ *read that is consumed as a separated uniform completion must pass through the sibling lattice*

$$\mathsf{UniformSpace}^{\uparrow} \longmapsto \mathsf{HausdorffCompletion}^{\uparrow} \longmapsto \mathsf{Completion}^{\uparrow} \longmapsto (\mathsf{CauchyFilter}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow})$$

before any separated-uniform completion consumer reads the packet. The $\mathsf{UniformSpace}^{\uparrow}$ *row supplies the finite entourage basis,* $\mathsf{HausdorffCompletion}^{\uparrow}$ *supplies the separated completion row,* $\mathsf{Completion}^{\uparrow}$ *supplies the completion boundary, and the* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows supply the observable filter, window, regular-readback, and seal handoff surfaces.*

Proof. Project the carrier of Definition 6011.1. Its uniform source, separated classifier, completion rows, finite windows, regular readback, and real seal are displayed as rows of one finite packet.

The first lattice edge is the $\mathsf{UniformSpace}^{\uparrow}$ source row. A separated completion consumer cannot read a completion endpoint before the finite entourage basis and refinement ledger have been exposed.

The next edges are the separated completion and completion-boundary rows. The Hausdorff side records the separated completion constraint, and the completion row records the boundary at which a completion consumer is allowed to ask for an endpoint read.

Finally the observable side passes through $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows. These rows provide the finite filter observation, window schedule, regular rational readback, and real seal consumed by the downstream packet. Since the carrier has no bypass coordinate, every separated-uniform completion read follows this sibling lattice. □

Theorem 6011.5 (HausdorffUniformityCompletion UniformSpace route)**.** *Every separated completion read exported by an accepted* $\mathsf{HausdorffUniformityCompletion}^{\uparrow}$ *carrier first exposes the* $\mathsf{UniformSpace}^{\uparrow}$ *finite entourage source* U*. Only after that source row is displayed may the consumer inspect the* $\mathsf{HausdorffUniformity}^{\uparrow}$ *classifier* H*,* $\mathsf{SeparatedReflection}^{\uparrow}$ *row* S*,* $\mathsf{UniformCompletion}^{\uparrow}$ *row* C*,* $\mathsf{MetricCompletion}^{\uparrow}$ *comparison row* M*,* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and* $\mathsf{Real}^{\uparrow}$ *seal* E*.*

Proof. Project the carrier of Definition 6011.1. The first coordinate is the uniform-space source U, and it contains the finite entourage basis and refinement ledger for the completion-facing request.

Apply the NameCert obligations of Definition 6011.2. Their uniform-source exactness clause requires every separated completion read to begin with U before the Hausdorff classifier or completion rows are visible.

Now use the separated handoff theorem Definition 6011.3. The displayed route proceeds from $\mathsf{UniformSpace}^{\uparrow}$ through $\mathsf{HausdorffUniformity}^{\uparrow}$, $\mathsf{SeparatedReflection}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ in that order.

The structural rows T, Q, P, N transport, replay, package, and name the same route. Hence no separated completion consumer can bypass the UniformSpace finite entourage source before reading the classifier, reflection, completion, window, readback, and seal rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffUniformityCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffUniformityCompletion}^{\uparrow}$ packet is generated from UniformSpace, HausdorffUniformity, SeparatedReflection, UniformCompletion, MetricCompletion, StreamName, RegSeqRat, Real, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffUniformityCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6011.1, Definition 6011.2, Definition 6011.3, and Definition 6011.5 seed the separated-uniform completion boundary over displayed uniformity, reflection, completion, finite-window, regular-readback, real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffUniformityCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient completion equality, selected representatives, countable choice, host equality, open-cover compactness, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, uniform-source exactness, Hausdorff separation handoff, completion readback stability, transport and replay stability, and ledger non-escape for BEDC.Derived.HausdorffUniformityCompletionU

Chapter 6012

A Concrete Naming Certificate for $\mathsf{CompleteOrderedField}^{\uparrow}$

Following Bourbaki and Bishop–Bridges on complete ordered fields, the $\mathsf{CompleteOrderedField}^{\uparrow}$ packet records the traditional complete ordered-field interface as finite BEDC NameCert data rather than as an ambient real line. It sits next to the terminal Real seal of chapter 38, the regular rational sequence route of chapter 301, and the dyadic precision core of chapter 291; it packages the completion obligations those siblings expose without claiming that $\mathsf{Real}^{\uparrow}$ has already discharged them.

Definition 6012.1 (Complete ordered-field carrier)**.** *A* $\mathsf{CompleteOrderedField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (O, Q, D, E, L, T, H, C, P, N)$$

with the following displayed rows:

1. *O is the ordered-field source row naming addition, multiplication, zero, one, positivity, order comparison, and compatibility only as finite* BHist *data.*
2. *Q is the regular-Cauchy completion interface read through* $\mathsf{RegSeqRat}^{\uparrow}$ *and the terminal* $\mathsf{Real}^{\uparrow}$ *naming seal.*
3. *D is the dyadic density and Archimedean readback row read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
4. *E is the order classifier, comparing accepted ordered-field reads through the displayed algebra, order, dyadic, and regular-Cauchy rows.*
5. *L is the Cauchy-limit seal, naming only those limit requests whose precision, regular sequence, and order rows have all been displayed.*
6. *T is the transport row for componentwise* hsame *comparison of ordered-field, completion, dyadic, classifier, and limit-seal rows.*
7. *H records the local* hsame *ledger for replaying equality-facing component transport without quotient equality.*
8. *C records displayed* Cont *replay from ordered-field source rows through completion, dyadic readback, order classification, and limit sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{CompleteOrderedField}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CompleteOrderedField}^{\uparrow}}$ *row.*

The classifier of accepted packets compares only $O, Q, D, E, L, T, H, C, P, N$. It has no coordinate for a proof that $\mathsf{Real}^{\uparrow}$ *is complete, for Dedekind-cut completeness, for quotient equality of real names, for a selected limit operator, or for a host complete ordered field.*

Lean4 ✓ `BEDC.Derived.CompleteOrderedFieldUp.CompleteOrderedFieldTasteGate single carrier alignment`

Theorem 6012.2 (CompleteOrderedField sibling route)**.** *Every accepted* $\mathsf{CompleteOrderedField}^{\uparrow}$ *carrier routes its Real-facing completion interface through the siblings already named in the L10 completion lattice. The completion read Q is a consumer of chapter 301 before it reaches chapter 38; the dyadic density and Archimedean readback row D is a consumer of chapter 291; and the order classifier E may compare only those displayed rows together with the ordered-field source O and Cauchy-limit seal L.*

Proof. Project the carrier of Definition 6012.1. Its completion-facing coordinates are Q, D, E, L together with structural rows T, H, C, P, N.

The regular-Cauchy row Q supplies the route through RegSeqRat and then Real naming. The dyadic row D supplies the finite density and Archimedean readback data used by that route.

The order classifier E can compare only the displayed ordered-field source O, the regular-Cauchy route Q, the dyadic readback row D, and the Cauchy-limit seal L. Transport and replay preserve those rows through T, H, C, P, N, so the packet supplies a sibling route and not an ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteOrderedField}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompleteOrderedField}^{\uparrow}$ packet is generated from an ordered-field source row, regular-Cauchy completion interface, dyadic density and Archimedean readback, order classifier, Cauchy-limit seal, transport, replay, provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteOrderedField}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6012.1 and Definition 6012.2 seed the finite ordered-field, regular-Cauchy, dyadic-density, order-classifier, and limit-seal surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteOrderedField}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CompleteOrderedFieldUp.CompleteOrderedFieldTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim that $\mathsf{Real}^{\uparrow}$ is already complete, does not claim Dedekind-cut completeness, and does not identify real names by quotient equality.

Upgrade path: Obligation closure requires checked carrier admission, order-classifier routing, Cauchy-limit sealing, transport, replay, provenance, and local NameCert obligations for BEDC.Derived.CompleteOrderedFieldUp.

Chapter 6013

A Concrete Naming Certificate for $\mathsf{ChebyshevEquioscillation}^{\uparrow}$

Following Chebyshev and de la Vallee Poussin, the $\mathsf{ChebyshevEquioscillation}^{\uparrow}$ packet records the finite alternation certificate used by minimax polynomial approximation on a compact real interval. It consumes the compact interval source of chapter 1591, the continuous-map and sup-norm rows of chapter 3807, the polynomial carrier of chapter 50, the density witness of chapter 1634, and the algebraic separation surface of chapter 1919. The packet names a displayed best-approximation witness; it is not a host proof of compactness, a global function-space quotient, a selected optimizer outside the support ledger, or an ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 6013.1 (Chebyshev equioscillation carrier)**.** *A* $\mathsf{ChebyshevEquioscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (I, F, \nu, P, S, \Sigma, A, R, H, C, Q, N)$$

with the following displayed rows:

1. *I is the compact interval row, read as a* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source with endpoint order, rational containment, and real-name sealing already displayed.*
2. *F is the continuous-map row on I, read through the same compact-source windows as the* $\mathsf{ContinuousSupNorm}^{\uparrow}$ *packet.*
3. *ν is the requested polynomial degree bound and coefficient-window budget.*
4. *P is the displayed* $\mathsf{Poly}^{\uparrow}$ *row whose finite coefficient ledger has degree at most ν.*
5. *S is the finite alternating support ledger, listing inspected points of I in order together with the endpoint and interior-window data used to compare them.*
6. *Σ is the sign pattern row, recording alternating signs along S.*
7. *A is the signed extremal-error ledger, saying that the inspected errors $F - P$ reach the same displayed sup-norm magnitude with the signs in Σ.*
8. *R is the minimax refusal row, recording that every admissible lower-degree perturbation read by the packet fails to reduce the displayed sup-norm bound on the same support windows.*
9. *H records componentwise* hsame *transport for the interval, continuous-map, degree, polynomial, support, sign, extremal-error, refusal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a minimax request through $I, F, \nu, P, S, \Sigma, A, R, H, Q, N$.*

11. *Q is the* Pkg *provenance over* ChebyshevEquioscillation$^{\uparrow}$, WeierstrassApproximation$^{\uparrow}$, StoneWeierstrass$^{\uparrow}$, Poly$^{\uparrow}$, ContinuousSupNorm$^{\uparrow}$, ClosedBoundedInterval$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{ChebyshevEquioscillation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a host supremum operator, a quotient function space, an infinite alternation set, a selected optimizer outside P, trichotomy, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.ChebyshevEquioscillationUp.ChebyshevEquioscillationUp`
Lean4 ✓ `BEDC.Derived.ChebyshevEquioscillationUp.ChebyshevEquioscillationTasteGate single carrier alignment`

Theorem 6013.2 (Chebyshev equioscillation NameCert obligations)**.** *For every accepted* ChebyshevEquioscillation$^{\uparrow}$ *carrier*

$$E = (I, F, \nu, P, S, \Sigma, A, R, H, C, Q, N),$$

the local NameCert$_{\text{ChebyshevEquioscillation}^{\uparrow}}$ *surface consists exactly of carrier admission, compact interval source compatibility, continuous-map and sup-norm readback, polynomial degree admission, finite alternating support admission, signed extremal-error exactness, minimax refusal on the displayed support windows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Each obligation reads the same* ClosedBoundedInterval$^{\uparrow}$, ContinuousSupNorm$^{\uparrow}$, *and* Poly$^{\uparrow}$ *rows before any minimax conclusion is exposed.*

Proof. Project the carrier of Definition 6013.1. The displayed tuple exposes the interval, continuous-map, degree, polynomial, support, sign, extremal-error, refusal, transport, replay, provenance, and local naming rows.

The compact-source and approximation rows are then forced to share one route. The interval row I supplies the only endpoint and containment data, the continuous-map row F is read through the same source windows, and the polynomial row P supplies the only coefficient ledger admitted by the degree row ν.

The alternation obligations are finite. The support row S orders the inspected points, Σ records the alternating signs, and A binds the displayed errors $F - P$ to one sup-norm magnitude on those windows.

Finally the refusal row R is read only against the same support and coefficient budgets. The structural rows H, C, Q, N transport, replay, source, and name this route, so no host supremum, quotient function space, infinite support, choice-selected optimizer, trichotomy, countable choice, or ambient completeness coordinate can enter the local certificate. □

Theorem 6013.3 (Chebyshev equioscillation alternation window)**.** *Every alternation read of an accepted* ChebyshevEquioscillation$^{\uparrow}$ *carrier factors through the finite route*

$$I, F, \nu, P \longmapsto S, \Sigma, A \longmapsto R, H, C, Q, N.$$

Thus the equioscillation claim is witnessed by the displayed support order, alternating sign ledger, and signed extremal-error ledger, not by an ambient compactness theorem or an uninspected function-space norm.

Proof. Begin with the carrier inventory. The only interval and function data available before the alternation rows are I, F, ν, P.

Apply Definition 6013.2. It requires the support, sign, and extremal-error rows to read the same compact interval and polynomial rows that were admitted by the carrier.

Consequently an alternation consumer can inspect only S, Σ, A after the source rows are fixed. The refusal, transport, replay, provenance, and local name rows then package that same finite route, and no additional compactness or host norm coordinate is present. □

Theorem 6013.4 (Chebyshev equioscillation minimax handoff)**.** *Every minimax-polynomial consumer of an accepted* $\mathsf{ChebyshevEquioscillation}^{\uparrow}$ *packet receives the* $\mathsf{Poly}^{\uparrow}$ *row* P*, the* $\mathsf{ContinuousSupNorm}^{\uparrow}$ *extremal-error ledger* A*, and the finite refusal row* R *only after the compact interval row* I*, continuous-map row* F*, degree row* ν*, support ledger* S*, and sign pattern* Σ *have been displayed. The handoff exports a finite best-approximation certificate, not a density-only theorem, a selected host optimizer, or a completed quotient function space.*

Proof. Project the carrier and use Definition 6013.3. The source interval, continuous map, degree row, and polynomial row determine the finite comparison surface.

The support, sign, and extremal-error rows then expose the equioscillation evidence. Since A is tied to the same $\mathsf{ContinuousSupNorm}^{\uparrow}$ readback route, the minimax consumer receives a displayed norm-facing ledger rather than a host supremum.

The refusal row R records the finite perturbation boundary on those same support windows. The remaining structural rows only transport, replay, source, and name the packet, so the handoff cannot export a density-only statement or a completed function-space object. □

Theorem 6013.5 (Chebyshev equioscillation public export)**.** *The public surface exported by an accepted* $\mathsf{ChebyshevEquioscillation}^{\uparrow}$ *carrier is exactly the finite compact-source, continuous-map, degree-bound, polynomial, alternating-support, signed-error, minimax-refusal, transport, replay, provenance, and local naming route displayed in Definition 6013.1. Downstream approximation chapters may consume this surface as a best-approximation certificate over* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *rows, while* $\mathsf{WeierstrassApproximation}^{\uparrow}$ *and* $\mathsf{StoneWeierstrass}^{\uparrow}$ *remain density and separation sources rather than replacements for the alternation witness.*

Proof. Use Definition 6013.2. It lists the complete local NameCert surface and ties each row to the same compact interval, continuous map, and polynomial source.

Use Definition 6013.4 for the consumer boundary. It identifies the rows that a minimax consumer can read before any best-approximation conclusion is exposed.

The provenance row records the relationship with the density and separation chapters, but no carrier coordinate lets those chapters replace the displayed alternation witness. Therefore the public export is exactly the finite route named by the carrier. □

Falsifiable prediction: Every accepted $\mathsf{ChebyshevEquioscillation}^{\uparrow}$ consumer that claims a minimax polynomial witness must display the compact interval row, continuous-map row, degree row, polynomial row, alternating support, sign pattern, signed extremal-error ledger, minimax refusal row, hsame transport, Cont replay, Pkg provenance, and local NameCert before the best-approximation conclusion is inspected.

Independence witness: weierstrass-approximation, stone-weierstrass, polynomial, continuous-supnorm, closed-bounded-interval: $\mathsf{ChebyshevEquioscillation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite alternating support, signed extremal-error ledger, and minimax refusal row over one compact interval source.

Closure status for $\mathsf{NameCert}_{\mathsf{ChebyshevEquioscillation}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChebyshevEquioscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6013.1, Definition 6013.2, Definition 6013.3, and Definition 6013.4 seed the finite equioscillation carrier, local obligation surface, alternation window, and minimax handoff for compact real intervals.

Formal verification: FormalStatus(NameCert$_{\text{ChebyshevEquioscillation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host compactness, quotient function spaces, selected optimizers, infinite alternation sets, trichotomy, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, compact interval compatibility, continuous-map and sup-norm readback, polynomial degree admission, finite alternating support, signed extremal-error exactness, minimax refusal, transport replay, provenance, and local naming for BEDC.Derived.ChebyshevEquioscillationUp.

Constructive story: A ChebyshevEquioscillation$^{\uparrow}$ packet is generated from a compact interval row, continuous-map row, degree-bound row, displayed polynomial row, finite alternating support, sign pattern, signed extremal-error ledger, minimax refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

CauchyPasting$^{\uparrow}$ consumes the compatible gluing route of chapter 5899 and forwards pasted regular-readback rows to chapter 6003.

Chapter 6014

A Concrete Naming Certificate for $\mathsf{CauchyPasting}^{\uparrow}$

Following Bishop and Bridges, compatible local Cauchy data may be pasted only through explicit moduli, overlap witnesses, and regular readback rows before a real-name seal is exposed. The $\mathsf{CauchyPasting}^{\uparrow}$ packet records that compatible-local-Cauchy route as finite NameCert data for the L10 Real-and-Completion spine. It consumes the $\mathsf{RegularCauchyGluing}^{\uparrow}$ route of chapter 5899, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the $\mathsf{StreamName}^{\uparrow}$ finite-window interface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. It is also a finite pasted-window source for the density-net consumer of chapter 6003. It names a finite pasting carrier, not quotient stream equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6014.1 (Cauchy pasting carrier)**.** *A* $\mathsf{CauchyPasting}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (G, D, S, R, E, H, C, K, N)$$

with the following displayed rows:

1. *G is the accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *source row for the compatible local Cauchy windows.*
2. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the local windows on their displayed overlap.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row recording exactly the finite observations read by the pasting consumer.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after G, D, S have been displayed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the regular readback has been displayed.*
6. *H records componentwise* hsame *transport for source, tolerance, window, readback, seal, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay of the same pasting route.*
8. *K is the* Pkg *provenance over* $\mathsf{CauchyPasting}^{\uparrow}$, $\mathsf{RegularCauchyGluing}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyPasting}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, D, S, R, E, H, C, K, N$. It has no coordinate for quotient stream equality, selected representatives, host real equality, countable choice, or a general completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 6014.2 (Cauchy pasting NameCert obligations)**.** *For every accepted* $\mathsf{CauchyPasting}^{\uparrow}$ *carrier*

$$P = (G, D, S, R, E, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyPasting}^{\uparrow}}$ *surface consists exactly of carrier admission for the compatible* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *source row, shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance display, finite* $\mathsf{StreamName}^{\uparrow}$ *window display,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No pasting obligation is stored outside those finite rows.*

Proof. Project the carrier of Definition 6014.1. The visible route is exhausted by $G, D, S, R, E, H, C, K, N$, so carrier admission and all pasting obligations must be read from those rows.

The source row G supplies the compatible local Cauchy gluing surface. The tolerance row D and window row S record the finite overlap data read by the consumer, while R is the only regular rational readback row downstream of that finite data.

The terminal seal E is exposed only after G, D, S, R have been displayed. The rows H, C, K, N then transport, replay, source, and name the same route.

Since the carrier has no further coordinate, quotient stream equality, selected representatives, countable choice, host equality, and ambient completeness cannot be obligations of the local certificate. □

Theorem 6014.3 (Cauchy pasting Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyPasting}^{\uparrow}$ *packet reaches the seal row E only through the route*

$$G, D, S \longmapsto R \longmapsto E \longmapsto H, C, K, N.$$

In particular, the consumer inherits the pasting nonescape boundary of Definition 5899.13: it cannot export quotient stream equality, selected representatives, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness as a coordinate of the accepted pasting read.*

Proof. Start with a $\mathsf{Real}^{\uparrow}$-facing read of the accepted packet. By Definition 6014.1, the only seal coordinate is E, and it is downstream of the source, tolerance, window, and regular readback rows.

Apply Definition 6014.2. The local certificate must expose G, D, S, R before the seal and must preserve the same transport, replay, provenance, and naming rows H, C, K, N.

A completion-facing density read may then pass from the pasted G, D, S, R, E route into $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$. That consumer supplies finite dyadic density rows and still adds no quotient streams, selected limits, or ambient completeness.

Finally use Definition 5899.13 on the source row G. The gluing source cannot contribute quotient stream equality, selected representatives, host equality, choice, or ambient completeness, and the pasting carrier adds no coordinate of those kinds. □

Theorem 6014.4 (Cauchy pasting common-tail gluing)**.** *Let*

$$P = (G, D, S, R, E, H, C, K, N)$$

be an accepted $\mathsf{CauchyPasting}^{\uparrow}$ *packet. If two compatible local Cauchy windows are read by the same pasting request, then their common-tail comparison is displayed through the finite route*

$G, D, S, R, E, H, C, K, N$ before any $\mathsf{Real}^{\uparrow}$ consumer reads the seal row E. The downstream finite-density route may reuse that common tail as a displayed local gluing witness, but it receives no ambient $\mathsf{Real}^{\uparrow}$ completeness theorem from the pasting packet.

Proof. Apply the NameCert obligations of Definition 6014.2. The compatible local Cauchy windows are admitted only through the source row G, the shared tolerance row D, and the finite StreamName window row S.

The regular readback row R records the common-tail comparison attached to those displayed windows. By Definition 6014.3, the seal row E is not reachable until G, D, S, R have already been displayed.

The rows H, C, K, N then transport, replay, source, and locally name the same finite route. A finite-density consumer can read this route as a local gluing witness, but no row adds quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness. □

Theorem 6014.5 (Cauchy pasting density-net forward link)**.** *Every $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ consumer of an accepted $\mathsf{CauchyPasting}^{\uparrow}$ packet must read the displayed route*

$$G, D, S, R, E, H, C, K, N$$

before using the density net of chapter 6003. The density-net read therefore receives the compatible gluing source, dyadic tolerance ledger, finite StreamName window, regular readback, RealUp seal, transport, replay, provenance, and local naming rows as prior data. It cannot replace that route by quotient stream equality, selected representatives, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Proof. Apply Definition 6014.4. The common-tail witness is already displayed through $G, D, S, R, E, H, C, K, N$ before any $\mathsf{Real}^{\uparrow}$ consumer reads the seal row.

The finite density-net consumer cited in chapter 6003 can therefore use the pasted-window route only after the compatible gluing source, tolerance row, finite window, regular readback, and seal have been exposed. The structural rows H, C, K, N preserve that same route as transported, replayed, sourced, and locally named data.

Since Definition 6014.1 contains no coordinate for quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness, the density-net handoff cannot export any of those excluded objects. □

Theorem 6014.6 (Cauchy pasting metric-completion filter route)**.** *Every completion-facing consumer that reads accepted $\mathsf{CauchyPasting}^{\uparrow}$ rows factors the compatible local-Cauchy source through the $\mathsf{MetricCompletionFilter}^{\uparrow}$ route of chapter 8944 before density-net or $\mathsf{Real}^{\uparrow}$-seal consumption. Thus the consumer first exposes the source gluing row G, shared tolerance row D, StreamName window S, RegSeqRat readback R, and structural rows H, C, K, N as a completion-filter dependency, and only then may pass the displayed route to chapter 6003 or to the terminal seal row E.*

Proof. Project the accepted carrier of Definition 6014.1. The compatible local-Cauchy data are present only through $G, D, S, R, E, H, C, K, N$, so a completion-facing consumer has no separate source for a filter limit or a selected representative.

Use the NameCert obligations of Definition 6014.2. They force the gluing source, dyadic tolerance, StreamName window, RegSeqRat readback, transport, replay, provenance, and local naming rows to remain visible before any downstream completion read.

Apply the common-tail gluing theorem Definition 6014.4. It identifies the common-tail witness as displayed local-Cauchy data, which is exactly the kind of finite filter-facing input consumed by the MetricCompletionFilter packet of chapter 8944.

Finally use the Real-seal nonescape and density-net forward link, Definition 6014.3 and Definition 6014.5. The seal row E and the density-net consumer are both downstream of the same displayed completion-filter route, so neither can bypass $\mathsf{MetricCompletionFilter}^{\uparrow}$ by quotient streams, selected representatives, host equality, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyPasting}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyPasting}^{\uparrow}$ packet is generated from a compatible RegularCauchyGluing source row, DyadicRatCore tolerance row, StreamName window row, RegSeqRat readback row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyPasting}^{\uparrow}}$, seed)

Scope closed: Definition 6014.1, Definition 6014.2, and Definition 6014.3 seed the finite compatible-local-Cauchy pasting route up to the terminal RealUp seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyPasting}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance exactness, StreamName window coverage, RegSeqRat readback, RealUp seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.CauchyPastingUp.

Theorem 6014.7 (Cauchy pasting regular-gluing density route)**.** *Every* $\mathsf{CauchyPasting}^{\uparrow}$ *consumer first reads the* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *source row. It may then feed* $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ *only through the displayed* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows of Definition 6014.1; no density-net read may bypass the gluing source, finite window, regular readback, dyadic tolerance ledger, or terminal real seal.*

Proof. Apply the carrier and NameCert obligations of Definition 6014.1 and Definition 6014.2. They put the $\mathsf{RegularCauchyGluing}^{\uparrow}$ source row before the $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and the $\mathsf{Real}^{\uparrow}$ seal.

The finite density-net consumer receives only that displayed route. Since the pasting carrier has no coordinate for quotient streams, selected representatives, host equality, countable choice, or ambient completeness, feeding $\mathsf{FiniteCauchyDensityNet}^{\uparrow}$ cannot add any row outside the same finite route. □

Sibling dependency route. The $\mathsf{CauchyPasting}^{\uparrow}$ packet is read as a horizontal dependency across the L10 Real-and-Completion spine: its compatible-gluing source consumes the regular-Cauchy route of chapter 5899, its finite overlap windows and dyadic tolerance ledger feed the density-net consumer of chapter 6003, and its regular readback reaches the $\mathsf{Real}^{\uparrow}$ completion-facing seal only through the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows already named in Definition 6014.1. Thus a Real-completion consumer receives a pasted-window dependency route, not quotient stream equality, selected representatives, countable choice, or ambient completeness.

Chapter 6015

A Concrete Naming Certificate for $\mathsf{CofinalTailNormalForm}^{\uparrow}$

Bishop–Bridges style regular-Cauchy tail arguments replace eventual agreement talk by displayed cofinal windows, explicit tolerance rows, and regular readbacks before a real-name seal is read. The $\mathsf{CofinalTailNormalForm}^{\uparrow}$ packet records that finite normal-form route for the Real-completeness vision of chapter 9238. It consumes the $\mathsf{StreamName}^{\uparrow}$ finite-window surface of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the paired cofinal-tail route of chapter 920. It names a finite tail normal form, not quotient stream equality, a selected host limit, countable choice, or ambient Real completeness.

Definition 6015.1 (Cofinal tail normal-form carrier)**.** *A* $\mathsf{CofinalTailNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the accepted* $\mathsf{CofinalTailAgreement}^{\uparrow}$ *row supplying the paired cofinal-tail agreement source.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *tail-selector window row recording the finite indices inspected by the normal form.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selected cofinal windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison ledger attached to the same selected tail windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after A, S, R, D have been displayed.*
6. *H records componentwise* hsame *transport for agreement, window, readback, tolerance, seal, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from each tail request through A, S, R, D, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CofinalTailNormalForm}^{\uparrow}$*,* $\mathsf{CofinalTailAgreement}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalTailNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, S, R, D, E, H, C, P, N$. It has no coordinate for quotient stream equality, hidden tail selectors, selected representatives, host-limit equality, countable choice, or an ambient completeness principle.

Theorem 6015.2 (Cofinal tail normal-form NameCert obligations)**.** *For every accepted* $\mathsf{CofinalTailNormalForm}^{\uparrow}$ *carrier*

$$T = (A, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CofinalTailNormalForm}^{\uparrow}}$ *surface consists exactly of carrier admission for the cofinal-tail agreement source, finite StreamName tail-selector windows, RegSeqRat readback, DyadicRatCore tolerance display, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming. Every Real-completeness consumer of the normal form must read those rows before it can use the tail agreement.*

Proof. Project the carrier of Definition 6015.1. The displayed route is $A, S, R, D, E, H, C, P, N$, and the classifier has no coordinate outside that route.

The source row A supplies the cofinal-tail agreement. The finite selector windows S determine which tail observations are inspected, while R and D record the regular readback and dyadic tolerance data attached to those same windows.

The terminal seal E is downstream of A, S, R, D. The rows H, C, P, N then preserve the route under transport, replay, provenance, and local naming.

Because no hidden selector, quotient stream, selected limit, countable-choice schedule, or ambient completeness row occurs in the carrier, none can be part of the local NameCert obligations. □

Theorem 6015.3 (Cofinal tail normal-form shift invariance)**.** *Let*

$$T = (A, S, R, D, E, H, C, P, N)$$

be an accepted $\mathsf{CofinalTailNormalForm}^{\uparrow}$ *carrier. Shifting the displayed finite* $\mathsf{StreamName}^{\uparrow}$ *tail-selector window preserves the same* $\mathsf{CofinalTailAgreement}^{\uparrow}$ *source row A, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route R, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance display D, and the same terminal* $\mathsf{Real}^{\uparrow}$ *seal route E, H, C, P, N. The shifted read is therefore another display of the same cofinal-tail normal form, not a hidden selector, quotient stream equality, selected limit, or ambient Real-completeness principle.*

Proof. Project the carrier rows of Definition 6015.1. The only tail-selector coordinate is the displayed $\mathsf{StreamName}^{\uparrow}$ row S, and the agreement source, readback, tolerance, seal, and structural rows are fixed as A, R, D, E, H, C, P, N.

Apply Definition 6015.2. Every Real-completeness consumer must read the cofinal-tail source, the selector window, the regular readback, and the dyadic tolerance display before it can reach the terminal seal.

A shift of the displayed finite selector changes only which finite window of S is inspected. Since the local certificate has no coordinate for a hidden selector or replacement source, the shifted read preserves A, R, D, E, H, C, P, N and remains the same normal-form route. □

Theorem 6015.4 (Cofinal tail normal-form Real-seal factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CofinalTailNormalForm}^{\uparrow}$ *carrier*

$$T = (A, S, R, D, E, H, C, P, N)$$

reaches the terminal seal row E only through the displayed source, selector, readback, and tolerance route A, S, R, D, and then through H, C, P, N for transport, replay, provenance, and local naming. Therefore the exported Real-seal read contains no quotient stream equality, hidden selector, countable-choice schedule, host-limit equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 6015.1. The terminal $\mathsf{Real}^{\uparrow}$ seal row E is listed downstream of A, S, R, D, so a Real-facing consumer cannot inspect the seal before the cofinal-tail agreement source, displayed selector window, regular readback, and dyadic tolerance display have been exposed.

Apply Definition 6015.2. The local NameCert surface makes exactly the rows $A, S, R, D, E, H, C, P, N$ available to completion and Real-completeness consumers, and it provides no coordinate for quotient stream equality, a hidden selector, host-limit equality, countable choice, or ambient completeness.

Finally use Definition 6015.3. Changing the displayed finite selector window changes only the inspected window of S and preserves the same A, R, D, E, H, C, P, N route. Thus selector-window variation cannot bypass the displayed factorization through A, S, R, D before the terminal Real seal is read. □

Falsifiable prediction: Every $\mathsf{CofinalTailNormalForm}^{\uparrow}$ Real-completeness read factors through one CofinalTailAgreement source row, finite StreamName tail-selector windows, RegSeqRat readback, DyadicRatCore tolerance display, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, cofinaltailagreement: CofinalTailNormalForm is not bijective to any listed sibling because it carries a cofinal-tail agreement source together with the finite selector-window, regular-readback, tolerance, Real-seal, transport, replay, provenance, and naming rows as one normal-form packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalTailNormalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalTailNormalForm}^{\uparrow}$ packet is generated from a CofinalTailAgreement source row, StreamName tail-selector windows, RegSeqRat readback, DyadicRatCore tolerance display, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalTailNormalForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6015.1 and Definition 6015.2 seed the finite cofinal-tail normal form consumed by later Real-completeness tail and diagonal-limit routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalTailNormalForm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, hidden tail selectors, selected representatives, host-limit equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal-tail agreement source exactness, StreamName selector-window coverage, RegSeqRat readback, DyadicRatCore tolerance exactness, RealUp seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.CofinalTailNormalFormUp.

Lemma 6015.5 (Cofinal tail normal-form diagonal dependency)**.** *Every* $\mathsf{CofinalTailNormalForm}^{\uparrow}$ *consumer first reads the common-tail and finite-window route of chapter 632 before exporting a normal-form row. The diagonal cofinal tail supplies the shared tail window and terminal common-tail descent that this normal-form packet normalizes, so the normal-form read is a finite dependency route rather than a new selected limit, quotient stream equality, or ambient Real-completeness principle.*

Chapter 6016

A Concrete Naming Certificate for $\mathsf{LebesgueNumberFiniteCover}^{\uparrow}$

Following Lebesgue and Bishop–Bridges constructive compactness, the $\mathsf{LebesgueNumberFiniteCover}^{\uparrow}$ packet records the finite Lebesgue-number surface for compact metric finite covers as NameCert data. It sits over the compact metric source of chapter 129, the metric distance rows of chapter 57, the finite-cover refinement route of chapter 3430, the compact Lebesgue-number ledger of chapter 4015, the finite-cover radius-stability row of chapter 5203, and the compact uniform-modulus consumer of chapter 2299. The packet exposes a positive radius for one displayed finite cover route; it is not an arbitrary open-cover compactness theorem, a choice-selected subcover, or an ambient completeness claim.

Definition 6016.1 (LebesgueNumberFiniteCover carrier)**.** *A* $\mathsf{LebesgueNumberFiniteCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, U, R, F, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact metric source row, exposing the metric carrier, compact finite-net witnesses, and distance-read data consumed by the route.*
2. *U is the finite cover row, listing the displayed cover cells, their local metric-containment clauses, and the finite index spine inspected by the packet.*
3. *R is the positive radius row, recording the rational lower bound that is to be read as a Lebesgue number for the displayed finite cover.*
4. *F is the finite refinement and mesh row, recording the mesh budget and every refinement comparison used to pass from compact finite-net data to the cover cells of U.*
5. *E is the cover-exactness ledger, saying that every inspected metric ball of radius below R is routed into a named member of U through the displayed refinement rows.*
6. *H records componentwise* hsame *transport for compact metric, finite cover, positive radius, refinement, exactness, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a compact finite-cover request through*

$$X, U, R, F, E \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* LebesgueNumberFiniteCover$^{\uparrow}$, CompactMetric$^{\uparrow}$, Met$^{\uparrow}$, FiniteCoverRefinement$^{\uparrow}$, CompactLebesgueNumber$^{\uparrow}$, FiniteCoverRadiusStability$^{\uparrow}$, CompactUniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{LebesgueNumberFiniteCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for an arbitrary open cover, a selected subcover outside U, countable choice, a host-level finite minimum, quotient equality of covers, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LebesgueNumberFiniteCoverUp.LebesgueNumberFiniteCoverTasteGate single carrier alignment`

Theorem 6016.2 (LebesgueNumberFiniteCover NameCert obligations)**.** *For every accepted* LebesgueNumberFinite *carrier*

$$L = (X, U, R, F, E, H, C, P, N),$$

the local NameCert$_{\text{LebesgueNumberFiniteCover}^{\uparrow}}$ *surface consists exactly of carrier admission, compact metric source admission, finite-cover admission, positive radius admission, finite refinement and mesh admission, cover-exactness replay, refinement-stability transport, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation is stored outside $X, U, R, F, E, H, C, P, N$.*

Proof. Project the carrier of Definition 6016.1. The public surface contains only the compact metric source, finite cover, positive radius, refinement, exactness, transport, replay, provenance, and naming rows.

The compact source row X supplies the finite metric inspections used by the packet, and the cover row U supplies the only cover cells that may be named. Thus carrier admission and finite-cover exactness are checked against one displayed finite spine.

The radius row R is positive before it is consumed. The refinement and mesh row F records every finite comparison needed to route the compact-source inspections into U, while the exactness ledger E records the containment of every inspected radius ball below R.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the tuple has no coordinate for an arbitrary open cover, selected subcover outside the packet, countable choice, host finite minima, quotient cover equality, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6016.3 (LebesgueNumberFiniteCover finite-cover handoff)**.** *Every compact-uniform consumer reading an accepted* LebesgueNumberFiniteCover$^{\uparrow}$ *packet receives the radius row R only through the finite route*

$$X, U, F, E \longmapsto R \longmapsto H, C, P, N.$$

The route may be consumed by compact uniform-modulus and finite-cover stability chapters, but it exports no arbitrary open-cover compactness principle and no selected subcover outside the displayed packet.

Proof. Use the NameCert obligations of Definition 6016.2. A consumer must first display the compact metric source X and finite cover U.

The refinement and exactness rows F, E then determine where each inspected metric ball lands. The positive radius R is readable only after those rows have fixed the finite cover route.

Transport and replay through H, C preserve this order, and P, N record provenance and local naming. The handoff therefore supplies a finite Lebesgue-number packet without adding open-cover compactness, a choice-selected subcover, or ambient completion data. □

Falsifiable prediction: Every accepted $\mathsf{LebesgueNumberFiniteCover}^{\uparrow}$ consumer that claims a Lebesgue-number radius for a compact metric finite cover must display the compact metric source row, finite cover row, positive radius row, finite refinement and mesh row, cover-exactness ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert before the radius is inspected.

Independence witness: compactmetric, metric, finite-cover-refinement, compact-lebesgue-number, compact-uniform-modulus: $\mathsf{LebesgueNumberFiniteCover}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries one displayed compact metric source, one finite cover, one positive radius row, and one exact refinement ledger as a single local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueNumberFiniteCover}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueNumberFiniteCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6016.1, Definition 6016.2, and Definition 6016.3 seed the finite Lebesgue-number carrier, local obligation surface, and compact-uniform handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueNumberFiniteCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers outside the displayed finite cover, countable choice, host finite minima, quotient cover equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, compact metric source admission, finite-cover exactness, radius positivity, refinement stability, cover-exactness replay, transport, provenance, and local naming for BEDC.Derived.LebesgueNumberFiniteCoverUp.

Constructive story: A $\mathsf{LebesgueNumberFiniteCover}^{\uparrow}$ packet is generated from a compact metric source row, finite cover row, positive radius row, finite refinement and mesh row, cover-exactness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6017

A Concrete Naming Certificate for $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$

The $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$ packet realizes the phase-distance observer-expansion reading of chapter 9463 as finite NameCert data. It sits between the visual-shadow metric route of chapter 4142, the boundary-shadow route of chapter 3813, the focused expansion ledger of chapter 3486, the observer-expansion certificate of chapter 4167, and the observer-shell packet of chapter 5180. The packet names one finite observer-phase and distance-comparison surface; it is not a host hyperbolic space, a physical cosmology, a global clock, or a completed observer trajectory.

Falsifiable prediction: Every accepted $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$ consumer must expose observer-phase rows, distance-read rows, expansion-comparison rows, provenance rows, hsame transport, Cont replay, Pkg support, and local NameCert data before it exports a phase-distance expansion judgment.

Independence witness: hyperbolic-visual-shadow-metric, hyperbolic-boundary-shadow, hyperbolic-expansion-ledger, hyperbolic-observer-expansion, hyperbolic-observer-shell: the visual-shadow metric supplies distance comparison without observer-phase provenance; the boundary-shadow packet supplies boundary routing without expansion comparison; the expansion ledger records growth without phase-distance readback; the observer-expansion packet records shadow expansion without this phase-distance comparison surface; and the observer shell packages surrounding routes without identifying this local carrier.

Definition 6017.1 (PhaseDistanceObserverExpansion carrier)**.** *A* $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (O, \Phi, D, E, B, H, C, P, N)$$

with the following displayed rows:

1. *O is the observer-window row, recording the focused history, visible disk window, and local observation budget inspected by the packet.*
2. *Φ is the observer-phase row, read through phase-ledger and disk-coordinate data rather than through a hidden global phase.*
3. *D is the distance-read row, recording the displayed metric, visual-shadow, or boundary-shadow comparison used by the local read.*

4. *E is the expansion-comparison row, saying which earlier and later observer windows are compared and how the displayed distance-read changes along the local* Cont *route.*
5. *B is the boundary and refusal row, recording that the expansion is a records-side readback and not a physical cosmology, global clock, host hyperbolic model, or completed observer trajectory.*
6. *H records componentwise* hsame *transport for observer-window, phase, distance, expansion, boundary-refusal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an observer-window request through*

$$O, \Phi, D, E, B \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$, $\mathsf{HyperbolicVisualShadowMetric}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicExpansionLedger}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, HyperbolicObserverShe BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host hyperbolic manifold, a global observer, a universal time coordinate, a physical expansion constant, quotient equality of observer histories, or an unlogged boundary completion.

Theorem 6017.2 (PhaseDistanceObserverExpansion NameCert obligations)**.** *For every accepted* $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$ *carrier*

$$Q = (O, \Phi, D, E, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}}$ *surface consists exactly of observer-window admission, observer-phase admission, distance-read admission, expansion-comparison admission, boundary-refusal coverage, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation is stored outside $O, \Phi, D, E, B, H, C, P, N$.*

Proof. Project the carrier of Definition 6017.1. The only public rows are the observer window, observer phase, distance read, expansion comparison, boundary refusal, transport, replay, provenance, and local name rows.

Rows O and Φ fix the observer-side and phase-side data. The phase read is therefore tied to a focused finite ledger rather than to an unlogged global phase surface.

Rows D and E supply the comparison. The distance read is the displayed metric or visual-shadow row, and the expansion row records the before-and-after comparison along a local Cont route.

Row B keeps the packet at the representation layer by refusing host hyperbolic geometry, physical cosmology, global clocks, and completed observer trajectories. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so the listed rows exhaust the local NameCert obligations. □

Theorem 6017.3 (PhaseDistanceObserverExpansion comparison handoff)**.** *Every phase-distance expansion read from an accepted* $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$ *packet factors through*

$$O, \Phi, D, E, B \longmapsto H, C, P, N.$$

The handoff exports a finite observer-phase, distance-read, and expansion-comparison certificate, not an ambient hyperbolic model, physical expansion law, global observer, or completed boundary object.

Proof. Use the obligations of Definition 6017.2. An expansion consumer first receives the observer-window and phase rows.

The distance row and expansion-comparison row then determine what can be compared. Since both are displayed rows of the carrier, the comparison remains local to the inspected observer-window route.

The refusal row blocks readings that require a host hyperbolic model, a physical cosmology, a global clock, or completed observer trajectory. Transport, replay, provenance, and naming only preserve that finite packet, so the handoff exports exactly the listed finite comparison surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6017.1, Definition 6017.2, and Definition 6017.3 seed the phase-distance observer-expansion carrier, local obligation surface, and comparison handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host hyperbolic geometry, physical cosmology, global observers, universal clocks, quotient observer-history equality, completed boundary objects, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode observer-window admission, phase admission, distance-read admission, expansion-comparison admission, boundary-refusal coverage, transport, replay, provenance, and local naming for BEDC.Derived.PhaseDistanceObserverExpansionUp.

Constructive story: A $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$ packet is generated from observer-window, observer-phase, distance-read, expansion-comparison, boundary-refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 6018

A Concrete Naming Certificate for $\mathsf{PushdownAutomaton}^{\uparrow}$

Following Hopcroft–Ullman and Sipser, the $\mathsf{PushdownAutomaton}^{\uparrow}$ packet records a finite-control recognizer with a visible stack ledger as displayed BEDC data. It sits between the finite run surface of chapter 2364, the accepted-word surface of chapter 351, the finite derivation surface of chapter 356, and the bounded machine-trace surface of chapter 280.

The packet names one finite state carrier, one input word, one stack alphabet, one transition ledger, one finite run ledger, and one acceptance readback. It does not identify languages extensionally, select an infinite parse tree, or export an unbounded recognizer trace.

Definition 6018.1 (PushdownAutomaton carrier)**.** *A* $\mathsf{PushdownAutomaton}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F, w, \rho, \sigma, e, \chi, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite control-state carrier row;*
2. *Σ is the finite input alphabet row;*
3. *Γ is the finite stack alphabet row;*
4. *δ is the finite transition ledger, whose displayed entries read a state row, an optional input-symbol row, and the top stack-symbol row, then return the next state row and the finite stack-word replacement row;*
5. *q_0 is the start-state row inside Q;*
6. *Z_0 is the initial stack-symbol row inside Γ;*
7. *F is the accepting-state row inside Q;*
8. *w is the finite input word as a $\mathsf{List}^{\uparrow}$ row over Σ;*
9. *ρ is the finite run ledger, beginning at (q_0, Z_0) and consuming w through displayed transition rows;*
10. *σ is the stack-history ledger whose entries are finite $\mathsf{List}^{\uparrow}$ rows over Γ;*
11. *e is the endpoint row of the run ledger;*

12. *χ is the acceptance readback row, by final state or by displayed empty-stack condition as named in the packet;*
13. *H stores componentwise* hsame *transports for state, input, stack, transition, run, stack-history, endpoint, and classifier rows;*
14. *C stores the* Cont *replay routes for reading input symbols, stack-top rows, transition entries, and the finite run ledger;*
15. *P stores the* Pkg *provenance naming* $\mathsf{FiniteAutomaton}^{\uparrow}$, $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{ContextFreeGrammar}^{\uparrow}$, $\mathsf{TuringMachine}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
16. *N stores the local* $\mathsf{NameCert}_{\mathsf{PushdownAutomaton}^{\uparrow}}$ *rows.*

The carrier predicate is $\mathsf{PushdownAutomatonPacket}(A)$. *It exports no host language set, grammar quotient, selected parse tree, infinite branch choice, or unbounded machine execution.*

Lean4 ✓ `BEDC.Derived.PushdownAutomatonUp.TasteGate.PushdownAutomatonTasteGate single carrier alignment`

Theorem 6018.2 (PushdownAutomaton NameCert obligations)**.** *For every accepted* $\mathsf{PushdownAutomaton}^{\uparrow}$ *carrier*

$$A = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F, w, \rho, \sigma, e, \chi, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PushdownAutomaton}^{\uparrow}}$ *surface consists of carrier admission, finite transition replay, stack-row stability, endpoint classifier stability, componentwise* hsame *transport,* Cont *replay, and* Pkg *provenance for the rows in Definition 6018.1. A consumer may project the finite control, alphabet, stack, transition, input, run, stack-history, endpoint, and local naming rows, but it obtains no regular-language quotient, context-free grammar quotient, selected parse tree, or unbounded* $\mathsf{TuringMachine}^{\uparrow}$ *trace.*

Proof. Project the accepted carrier A. The rows $Q, \Sigma, \Gamma, \delta, q_0, Z_0, F$ name the finite control and stack presentation, while w, ρ, σ, e, χ name the inspected input, run ledger, stack ledger, endpoint, and acceptance readback.

Finite transition replay is obtained by reading ρ one displayed step at a time. Each step consults the current state row, the next consumed input row when present, the top stack-symbol row, and one transition entry of δ.

The structural rows H, C, P, N transport and replay exactly these coordinates. Since the carrier has no coordinate for a host language set, grammar quotient, selected parse tree, or unbounded machine trace, no consumer can extract such data from the local NameCert surface. □

Theorem 6018.3 (PushdownAutomaton stack-transition stability)**.** *Let*

$$A = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F, w, \rho, \sigma, e, \chi, H, C, P, N)$$

be an accepted $\mathsf{PushdownAutomaton}^{\uparrow}$ *carrier. Every displayed transition step in ρ transports the current stack row in σ to the next stack row by popping the displayed top symbol and pushing the finite replacement* $\mathsf{List}^{\uparrow}$ *row named by the corresponding transition entry. The transported step preserves the input cursor, endpoint readback,* hsame *rows,* Cont *routes, and* Pkg *provenance, and it exports no hidden stack contents, epsilon-closure quotient, or infinite run branch.*

Proof. Read one step of the finite run ledger. The step exposes the current control state, the optional consumed input symbol, the current stack row, and the top-stack symbol read by the transition entry.

Use the displayed transition entry of δ to form the next state and the finite replacement stack word. The next stack ledger entry in σ is obtained by replacing the visible top symbol with that finite $\mathsf{List}^{\uparrow}$ word and leaving the unreduced stack suffix as the displayed remainder row.

The componentwise hsame rows transport the state, input cursor, stack row, transition entry, and endpoint readback. The Cont route then passes the remaining finite run ledger to the next step, and the Pkg row records the same finite-recognizer, grammar, and machine-boundary provenance.

No other stack data is available. In particular, the packet contains no epsilon-closure quotient, selected infinite branch, hidden stack store, or unbounded machine trace. □

Closure status for $\mathsf{NameCert}_{\mathsf{PushdownAutomaton}^{\uparrow}}$.

Constructive story: A $\mathsf{PushdownAutomaton}^{\uparrow}$ packet is generated from finite control rows, input alphabet rows, stack alphabet rows, a transition ledger, start and initial-stack rows, accepting rows, a finite input word, a finite run ledger, a stack-history ledger, an endpoint readback, componentwise hsame transports, Cont replay routes, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PushdownAutomaton}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6018.1, Definition 6018.2, and Definition 6018.3 seed the finite stack-recognizer carrier, local NameCert surface, and stack-transition stability boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PushdownAutomaton}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, equivalence with all context-free grammars, language-set semantics, determinization, selected parse trees, infinite branch choice, or unbounded Turing-machine recognition.

Upgrade path: Obligation closure requires checked carrier admission, transition replay, stack-row stability, acceptance readback, and ledger non-escape for BEDC.Derived.PushdownAutomatonUp.

Chapter 6019

A Concrete Naming Certificate for $\mathsf{BaireCategoryCompleteMetric}^{\uparrow}$

Following Bishop and Oxtoby, the $\mathsf{BaireCategoryCompleteMetric}^{\uparrow}$ packet records the complete-metric dense-open intersection route as finite NameCert data rather than as an ambient theorem about all complete metric spaces. It sits over the dense-open schedule of chapter 1542, the complete-metric source of chapter 128, the metric carrier of chapter 57, the finite stream windows of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38.

Definition 6019.1 (BaireCategoryCompleteMetric carrier)**.** *A* $\mathsf{BaireCategoryCompleteMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, K, M, D, S, R, Y, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireCategory}^{\uparrow}$ *dense-open schedule row, listing the finite dense-open requests and the predecessor-ball refinements visible to the packet.*
2. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *source row, exposing the displayed Cauchy-thread service and limit handoff used by the dense-open route.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *carrier row, naming the finite distance, ball, and comparison observations consumed by B and K.*
4. *D is the dense-open schedule ledger, recording the finite list of open rows, density witnesses, successor-ball choices, and requested indices.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the schedule, centers, radii, and requested tolerances are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational center and radius data visible before the terminal seal.*
7. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the displayed dyadic radii and shrinkage comparisons used by the regular rational readback.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the dense-open schedule, complete-metric source, metric carrier, finite windows, regular-rational readback, and dyadic tolerance ledger have been displayed.*

9. *H records componentwise* hsame *transport for the dense-open schedule, complete-metric source, metric carrier, stream windows, regular-rational readback, dyadic tolerance ledger, real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the same dense-open, complete-metric, metric, window, readback, tolerance, and seal route.*
11. *P is the* Pkg *provenance over* $\mathsf{BaireCategoryCompleteMetric}^{\uparrow}$, $\mathsf{BaireCategory}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireCategoryCompleteMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, K, M, D, S, R, Y, E, H, C, P, N$. It has no coordinate for countable choice, a host intersection, an open-cover compactness theorem, a selected limit point, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a standard bridge datum.*

Lean4 ✓ `BEDC.Derived.BaireCategoryCompleteMetricUp.BaireCategoryCompleteMetricTasteGate single carrier alignment`

Theorem 6019.2 (BaireCategoryCompleteMetric NameCert obligations)**.** *For every accepted* $\mathsf{BaireCategoryCompleteMetric}^{\uparrow}$ *carrier*

$$Q = (B, K, M, D, S, R, Y, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BaireCategoryCompleteMetric}^{\uparrow}}$ *surface exposes exactly the dense-open schedule rows, complete-metric source row, metric carrier row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. Every complete-metric Baire read is routed through those rows, and no obligation is stored outside them.*

Lean4 ✓ `BEDC.Derived.BaireCategoryCompleteMetricUp.BaireCategoryCompleteMetricNameCert obligations`

Proof. Project the accepted carrier of Definition 6019.1. The rows B, K, M, D, S, R, Y, E are the only analytic rows available to a consumer: Baire schedule, complete-metric service, metric comparison, dense-open ledger, finite windows, regular rational readback, dyadic tolerances, and terminal real seal.

The dense-open content is read first through B and D. Each request exposes only finite open rows, density witnesses, and successor-ball choices; the complete-metric row K then carries the displayed Cauchy thread built from those finite refinements.

The metric and numerical observations are constrained by M, S, R, Y, E. The metric carrier supplies distance and ball comparisons, the stream row supplies finite inspection windows, the dyadic ledger supplies radius comparisons, the regular-rational row reads center and radius data, and the real seal is reached only after those rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no coordinate for countable choice, host intersections, open-cover compactness, selected limit points, ambient real completeness, or bridge data, the listed rows exhaust the local NameCert surface. □

Theorem 6019.3 (BaireCategoryCompleteMetric dense-open handoff)**.** *Let $Q = (B, K, M, D, S, R, Y, E, H, C, P,$ be an accepted* $\mathsf{BaireCategoryCompleteMetric}^{\uparrow}$ *carrier. Any downstream constructive Baire-category or Banach-style consumer that reads a dense-open intersection through a complete metric source must read the* $\mathsf{BaireCategory}^{\uparrow}$ *schedule B, dense-open ledger D,* $\mathsf{CompleteMetric}^{\uparrow}$ *source K,* $\mathsf{Met}^{\uparrow}$

carrier M, $\mathsf{StreamName}^{\uparrow}$ *finite windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger Y, and* $\mathsf{Real}^{\uparrow}$ *seal E, transported and replayed only by H, C, P, N.*

The handoff exports no countable-choice selector, host intersection, selected limit point, open-cover compactness theorem, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or additional completion carrier.*

Proof. Start with the dense-open rows B and D. They display the finite schedule and successor-ball refinements already present in the packet, so a consumer cannot replace them by an external countable family or host intersection.

Next read the complete-metric and metric rows K and M. The complete-metric source supplies only the Cauchy-thread service recorded in the packet, while the metric carrier supplies the finite distance and ball comparisons used by that thread.

Route the numerical part through S, R, Y, E. The stream windows expose the requested finite observations, the dyadic ledger records the tolerance shrinkage, the regular-rational readback carries the displayed center and radius data, and the terminal real seal is reached only from those finite rows.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Coordinate exhaustion then gives the stated handoff boundary: every downstream consumer receives the displayed finite packet and nothing beyond it. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireCategoryCompleteMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireCategoryCompleteMetric}^{\uparrow}$ packet is generated from a BaireCategory dense-open schedule, a CompleteMetric source row, a Metric carrier row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireCategoryCompleteMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6019.1, Definition 6019.2, and Definition 6019.3 seed the complete-metric dense-open intersection packet over the displayed finite rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireCategoryCompleteMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close countable choice, host intersections, open-cover compactness, selected limit points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-open schedule exposure, complete-metric source exactness, metric row compatibility, finite-window readback, dyadic tolerance exactness, regular-rational readback, real sealing, and nonescape for BEDC.Derived.BaireCategoryCompleteMetricUp.

Chapter 6020

A Concrete Naming Certificate for $\mathsf{ContractiveCauchyIterator}^{\uparrow}$

Following Banach and Bishop–Bridges constructive analysis, the $\mathsf{ContractiveCauchyIterator}^{\uparrow}$ packet isolates the finite Picard-iteration surface that hands a Cauchy modulus to completion-facing consumers before any fixed-point endpoint is read. It sits between the metric carrier of chapter 57, the complete-metric service of chapter 128, the map-level contraction packet of chapter 1418, the one-step Picard contraction route of chapter 395, the Banach endpoint consumer of chapter 396, the dyadic budget ledger of chapter 291, and the real seal boundary of chapter 38. The packet names the finite iterate windows and the Cauchy-modulus handoff; it does not claim a fixed point.

Definition 6020.1 (ContractiveCauchyIterator carrier)**.** *A* $\mathsf{ContractiveCauchyIterator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, T, B, I, W, Q, D, E, H, C, P_0, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including the carried point histories and distance-read surface used by the iterator.*
2. *T is the* $\mathsf{ContractionMapping}^{\uparrow}$ *self-map row whose graph and contraction comparison are available before any iterate window is opened.*
3. *B is the rational contraction-bound row below one, read through the same dyadic and metric budget as the map row.*
4. *I is the initial-row data, naming the starting point and the first graph read used to begin the Picard schedule.*
5. *W is the finite iterate-window ledger. It records displayed windows of $x_0, T(x_0), \ldots, T^n(x_0)$ and the adjacent-distance comparisons visible inside those windows.*
6. *Q is the Cauchy-modulus ledger. For each displayed tolerance request it records the finite threshold extracted from B, I, W.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget row used to compare requested precision, contraction powers, and tail bounds.*
8. *E is the completion and* $\mathsf{Real}^{\uparrow}$ *seal boundary. It is a boundary row only: no endpoint seal may be read until M, T, B, I, W, Q, D have been displayed.*

9. *H records componentwise* hsame *transport for the metric source, contraction map, bound, initial row, iterate windows, Cauchy ledger, dyadic tolerance budget, boundary seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay through*

$$M, T, B, I, W, Q, D \longmapsto E, H, P_0, N.$$

11. *P_0 is the* Pkg *provenance over* ContractiveCauchyIterator$^{\uparrow}$, Met$^{\uparrow}$, CompleteMetric$^{\uparrow}$, ContractionMapping$^{\uparrow}$, PicardContraction$^{\uparrow}$, BanachFixedPoint$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{ContractiveCauchyIterator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, T, B, I, W, Q, D, E, H, C, P_0, N$. It has no coordinate for a fixed point, endpoint uniqueness, quotient metric equality, choice, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.ContractiveCauchyIteratorUp.ContractiveCauchyIteratorTasteGate single carrier alignment`

Theorem 6020.2 (ContractiveCauchyIterator NameCert obligations)**.** *For every accepted* ContractiveCauchyIterato *carrier*

$$P = (M, T, B, I, W, Q, D, E, H, C, P_0, N),$$

the local NameCert$_{\text{ContractiveCauchyIterator}^{\uparrow}}$ *surface consists exactly of five finite obligation families:*

1. *carrier admission for the metric source, contraction map, rational bound, initial row, iterate windows, Cauchy-modulus ledger, dyadic tolerance budget, completion boundary, transport, replay, provenance, and local naming rows;*

2. *contraction-budget visibility, requiring T and B to be read against M before any Picard window is consumed;*

3. *iterate-window stability, requiring every displayed adjacent-window comparison in W to replay the same contraction comparison and initial row I;*

4. *Cauchy-modulus exactness, requiring each tolerance request to read D and then Q as a finite threshold ledger over the displayed windows;*

5. *endpoint nonescape, requiring every* CompleteMetric$^{\uparrow}$, BanachFixedPoint$^{\uparrow}$, *or* Real$^{\uparrow}$ *consumer to pass through M, T, B, I, W, Q, D before the boundary row E is exposed.*

No obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 6020.1. The accepted packet displays exactly the metric source, contraction map, rational bound, initial row, iterate-window ledger, Cauchy-modulus ledger, dyadic tolerance budget, boundary seal, and structural rows.

The contraction budget is read before iteration. The rows T and B are tied to the metric source row M, so an iterate comparison that does not pass through the displayed metric and bound has no coordinate in the carrier.

Window stability is finite replay. Each row of W opens the initial row I and the graph reads of T, then records only adjacent comparisons certified by the same contraction budget.

The Cauchy-modulus obligation is the handoff row. A tolerance request first reads the dyadic budget D and then the threshold ledger Q, so downstream completion consumers receive a finite modulus rather than a selected endpoint.

Finally E, H, C, P_0, N do not add an analytic endpoint. They expose the boundary, transport the same rows, replay the same route, record provenance, and name the local packet. □

Theorem 6020.3 (ContractiveCauchyIterator completion handoff)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$ *or* $\mathsf{BanachFixedPoint}^{\uparrow}$ *consumer of an accepted* $\mathsf{ContractiveCauchyIterator}^{\uparrow}$ *carrier must read the finite rows*

$$M, T, B, I, W, Q, D$$

before any endpoint boundary row E *is exposed. The handoff supplies a metric source, a contractive self-map, a displayed rational bound below one, an initial row, finite Picard iterate windows, a Cauchy-modulus ledger, and a dyadic tolerance budget. It does not supply a fixed point, endpoint uniqueness, quotient metric equality, choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The rows available before the boundary are precisely the metric source M, contraction map T, rational bound B, initial row I, iterate windows W, Cauchy ledger Q, and dyadic tolerance budget D.

A complete-metric consumer first reads the finite Cauchy evidence. The iterate windows expose only finite Picard prefixes, while the dyadic budget and Cauchy ledger convert a tolerance request into a displayed threshold.

A Banach-facing consumer receives the same data. It may use the later completion service or fixed-point route only after this iterator packet has handed off the Cauchy-modulus row, so no endpoint is selected inside the iterator itself.

The boundary row E records where completion and real-seal consumers may continue. Since E is downstream of M, T, B, I, W, Q, D and carries no separate choice or equality coordinate, the theorem exports only the finite handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContractiveCauchyIterator}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContractiveCauchyIterator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6020.1, Definition 6020.2, and Definition 6020.3 seed the finite Picard-iteration Cauchy-modulus handoff before any endpoint seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContractiveCauchyIterator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a fixed point, endpoint uniqueness, quotient metric equality, choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction-budget visibility, iterate-window stability, Cauchy-modulus exactness, endpoint nonescape, provenance, and local naming for BEDC.Derived.ContractiveCauchyIteratorUp.

Constructive story: A $\mathsf{ContractiveCauchyIterator}^{\uparrow}$ packet is generated from a metric source, contractive self-map, rational bound below one, initial row, finite iterate windows, Cauchy-modulus ledger, dyadic tolerance budget, completion boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6021

A Concrete Naming Certificate for PoincareVisualRadiusLadder$^{\uparrow}$

Following classical Poincare disk geometry, the PoincareVisualRadiusLadder$^{\uparrow}$ packet records a finite visual-radius ladder for observer-side disk readouts. It refines the disk carrier of chapter 377, the metric surface of chapter 3474, the boundary-shadow rows of chapter 3813, the visual metric rows of chapter 4142, the observer-shadow rows of chapter 4154, the finite stream-window interface of chapter 126, the regular-rational readback route of chapter 301, and the real seal of chapter 38. The packet exposes finite disk radii, boundary shadows, visual-metric readbacks, and real seals; it does not assert a completed hyperbolic boundary or a global observer geometry.

Definition 6021.1 (PoincareVisualRadiusLadder carrier)**.** *A* PoincareVisualRadiusLadder$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, R, B, V, O, S, Q, E, T, A, H, C, P, N)$$

with the following displayed rows:

1. *D is the* UnitDisk$^{\uparrow}$ *disk-coordinate row naming the displayed Poincare disk point and its finite admissibility data.*
2. *R is the visual-radius ladder row, a finite ordered ledger of disk radii and radial comparison requests.*
3. *B is the* HyperbolicBoundaryShadow$^{\uparrow}$ *row that records which boundary-shadow windows are visible at the displayed radii.*
4. *V is the* HyperbolicVisualShadowMetric$^{\uparrow}$ *row that reads the boundary shadow through the visual metric at each radius level.*
5. *O is the* HyperbolicObserverShadowMetric$^{\uparrow}$ *row tying the visual-radius readback to the observer-facing shadow metric.*
6. *S is the* StreamName$^{\uparrow}$ *window row, recording the finite stream intervals from which the radius ladder may be replayed.*
7. *Q is the* RegSeqRat$^{\uparrow}$ *rational readback row for the visual-radius and shadow-metric values.*
8. *E is the* Real$^{\uparrow}$ *seal row reached only after S and Q have displayed the requested finite readback.*
9. *T is the finite transport row moving radius levels, boundary-shadow windows, visual-metric rows, observer-shadow rows, stream windows, rational readbacks, and real seals together.*

10. *A is the replay row for radius comparison, shadow inclusion, visual-metric readback, observer-shadow compatibility, and real-seal exposure.*

11. *H records componentwise* hsame *transport for every displayed row.*

12. *C records displayed* Cont *replay through*

$$D, R, B, V, O, S, Q \longmapsto E, T, A, H, P, N.$$

13. *P is the* Pkg *provenance over* PoincareVisualRadiusLadder$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicBoundarySha HyperbolicVisualShadowMetric$^{\uparrow}$, HyperbolicObserverShadowMetric$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* NameCert$_{\text{PoincareVisualRadiusLadder}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, R, B, V, O, S, Q, E, T, A, H, C, P, N$. It has no coordinate for a completed boundary, ambient hyperbolic manifold, global observer metric, arbitrary real representative, choice, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.PoincareVisualRadiusLadderUp.PoincareVisualRadiusLadderTasteGate single carrier alignment`

Theorem 6021.2 (PoincareVisualRadiusLadder NameCert obligations)**.** *For an accepted* PoincareVisualRadiusLadd *carrier*

$$L = (D, R, B, V, O, S, Q, E, T, A, H, C, P, N),$$

the local NameCert$_{\text{PoincareVisualRadiusLadder}^{\uparrow}}$ *surface consists exactly of carrier admission; disk-radius admissibility for D and R; boundary-shadow visibility for B; visual-metric readback for V; observer-shadow compatibility for O; stream and regular-rational readback through S and Q; real-seal ordering through E; transport and replay stability through T, A, H, C; provenance through P; and local naming through N.*

Proof. Carrier admission is projection from Definition 6021.1. The accepted packet displays disk coordinates, a finite radius ladder, boundary-shadow rows, visual-metric rows, observer-shadow rows, stream windows, rational readbacks, the real seal, and structural rows.

Disk-radius admissibility is finite. The row D supplies the disk surface, while R lists only the radius levels visible to the packet.

The shadow and metric obligations are read in order. Boundary-shadow windows come from B, visual-metric values from V, and observer-facing compatibility from O.

The readback rows then force the seal route. Stream windows S and regular-rational data Q must be displayed before the real seal E can be inspected.

Finally T, A, H, C, P, N transport, replay, source, and name the same finite ladder, so no completed boundary, global geometry, choice principle, or bridge credential is added. □

Theorem 6021.3 (PoincareVisualRadiusLadder shadow handoff)**.** *Every boundary-shadow, visual-metric, observer-shadow, regular-rational, or real-name consumer of an accepted* PoincareVisualRadiusLadder$^{\uparrow}$ *carrier must factor through the finite route*

UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$ $\longmapsto$ HyperbolicVisualShadowMetric$^{\uparrow}$, HyperbolicObserve

At each displayed radius level, the consumer reads disk data, boundary-shadow windows, visual-metric values, observer-shadow compatibility, stream windows, rational readbacks, and only then the real seal. The route exports no completed boundary, global observer metric, arbitrary real representative, or ambient hyperbolic manifold.

Proof. Start with a consumer request at a displayed radius level. The disk row D and radius row R determine the finite Poincare disk surface and the visual-radius level that may be inspected.

The boundary and metric rows are then forced. The row B supplies the boundary-shadow window, V reads it through the visual metric, and O ties the same readback to the observer-shadow surface.

The numeric readback is downstream. The stream window S and regular-rational row Q expose the finite value route before the real seal E is available.

Transport, replay, provenance, and local naming preserve this order through T, A, H, C, P, N. Since the carrier has no row for a completed boundary or global observer metric, every consumer receives only the finite shadow handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareVisualRadiusLadder}\uparrow}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PoincareVisualRadiusLadder}\uparrow}$, seed)

Scope closed: Definition 6021.1, Definition 6021.2, and Definition 6021.3 seed the finite Poincare disk visual-radius ladder and shadow handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PoincareVisualRadiusLadder}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a completed hyperbolic boundary, ambient hyperbolic manifold, global observer metric, arbitrary real representative, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-radius admission, boundary-shadow visibility, visual-metric readback, observer-shadow compatibility, stream and regular-rational readback, real-seal ordering, provenance, and local naming for BEDC.Derived.PoincareVisualRadiusLadderUp.

Constructive story: A $\mathsf{PoincareVisualRadiusLadder}^{\uparrow}$ packet is generated from disk-coordinate rows, finite visual radii, boundary-shadow windows, visual-metric values, observer-shadow compatibility, stream windows, regular-rational readbacks, Real seals, transport, replay, componentwise hsame rows, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6022

A Concrete Naming Certificate for $\mathsf{CompactUniformTriangleLedger}^{\uparrow}$

Following Bishop–Bridges and the Heine–Cantor compact metric proof, the $\mathsf{CompactUniformTriangleLedger}^{\uparrow}$ packet records the proof-critical triangle handoff that turns pointwise modulus rows on a finite compact net into one uniform-modulus row. It sits over the compact finite-net carrier of chapter 129, the continuous-map pointwise rows of chapter 130, the rational tolerance surface of chapter 37, the metric source and target ledgers of chapter 57, the finite lower-bound fold of chapter 619, the final triangle estimate of chapter 1159, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer of chapter 369. The packet names only displayed finite-net, radius, pointwise-modulus, source-triangle, target-triangle, transport, replay, provenance, and local naming rows.

Definition 6022.1 (Compact uniform triangle ledger carrier)**.** *A* $\mathsf{CompactUniformTriangleLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, X, Y, F, \varepsilon, B, R, \mu, S, T, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row for the compact metric carrier.*
2. *X is the source* $\mathsf{Met}^{\uparrow}$ *distance row used to compare an input point with the selected net center and with a second input point.*
3. *Y is the target* $\mathsf{Met}^{\uparrow}$ *distance row used by the final triangle estimate.*
4. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus packet over the same source metric and target metric.*
5. *ε is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance row carried by the compact-uniform request.*
6. *B is the finite bundled-center ledger read from K, listing the inspected centers, radius histories, and coverage rows.*
7. *R is the rational lower-bound row obtained from the bundled radius histories and read through the* $\mathsf{Rat}^{\uparrow}$ *order surface.*
8. *μ is the tolerance-only precision row selected from R for the uniform-modulus consumer.*
9. *S is the source-triangle ledger showing that the selected center remains within the pointwise radius for both compared source points.*

10. *T is the target-triangle ledger joining the two pointwise estimates at the selected center into the final target-distance estimate.*
11. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced from μ, S, T.*
12. *H records componentwise* hsame *transport for compact, metric, continuous, rational, source-triangle, target-triangle, uniform-modulus, replay, provenance, and local naming rows.*
13. *C records displayed* Cont *replay along*

$$K, X, Y, F, \varepsilon, B, R, \mu \longmapsto S, T, U \longmapsto H, P, N.$$

14. *P is the* Pkg *provenance over* $\mathsf{CompactUniformTriangleLedger}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
15. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformTriangleLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host compactness theorem, selected global modulus, hidden center outside the finite bundle, quotient equality of points or functions, countable choice, or ambient real completeness.

Theorem 6022.2 (Compact uniform triangle ledger NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformTriangleLedger}^{\uparrow}$ *carrier $L = (K, X, Y, F, \varepsilon, B, R, \mu, S, T, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformTriangleLedger}^{\uparrow}}$ *surface consists of compact finite-net admission, source and target metric admission, continuous pointwise-modulus admission, rational tolerance admission, bundled radius lower-bound readback, source-triangle handoff, target-triangle handoff, uniform-modulus export, componentwise transport, displayed replay, package provenance, and local naming. Every public consumer of the packet reads through those rows and through no host compactness, external modulus selector, hidden center, quotient equality, choice schedule, or ambient completeness object.*

Proof. Project the carrier of Definition 6022.1. The rows $K, X, Y, F, \varepsilon, B, R, \mu, S, T, U, H, C, P, N$ are the whole public surface.

The compact and rational source data are read first. The finite bundle B comes from the compact metric row K, and the lower-bound row R is the rational fold over the displayed radius histories for the tolerance row ε.

The source-triangle handoff is then forced through S. It uses the selected precision μ, the compact-net coverage row, and the source metric row X before the pointwise modulus packet F may be applied to both compared source points.

The target-triangle handoff is forced through T. The two pointwise estimates supplied by F at the same selected center are joined by the target metric row Y, and the result is repacked as the $\mathsf{UniformModulus}^{\uparrow}$ row U.

Finally H, C, P, N transport, replay, source, and locally name the same finite route. Since the carrier contains no coordinate for host compactness, an external modulus selector, a hidden center, quotient equality, choice, or ambient completeness, the listed rows exhaust the certificate. □

Theorem 6022.3 (Compact uniform triangle ledger handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *read from an accepted* $\mathsf{CompactUniformTriangleLedger}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{FiniteNetMinimumFold}^{\uparrow} \longmapsto \mathsf{MetricTriangleUniformEstimate}^{\uparrow} \longmapsto$$

The route records the compact finite-net bundle, rational lower-bound precision, source-triangle ledger, target-triangle ledger, transport, replay, provenance, and local naming rows as one packet.

Proof. Start with the compact finite-net data. The rows K and B display the finite bundle of centers and coverage rows, while ε and R display the positive rational tolerance and the lower-bound fold used to produce μ.

Use the source metric row X and the source-triangle ledger S. These rows certify that the selected center can be used for both compared source points before the pointwise-modulus row F is consumed.

Use the target metric row Y and the target-triangle ledger T. The two pointwise estimates at the selected center are joined inside the displayed metric triangle estimate, and the result is exactly the row exported to U.

The structural rows H, C, P, N keep this route componentwise stable and locally named. No host compactness theorem, external selector, hidden center, quotient equality, choice schedule, or real-completeness row is available to the consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformTriangleLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformTriangleLedger}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, MetricSpace source and target rows, ContinuousMap pointwise-modulus rows, RatUp tolerance rows, finite lower-bound folds, source-triangle and target-triangle ledgers, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformTriangleLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6022.1, Definition 6022.2, and Definition 6022.3 seed the compact finite-net triangle ledger that carries pointwise moduli into a uniform-modulus row.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformTriangleLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host compactness theorem, selected global modulus, hidden center outside the finite bundle, quotient equality, choice schedule, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net admission, rational lower-bound readback, source-triangle handoff, target-triangle handoff, uniform-modulus export, replay stability, provenance exhaustion, and local naming for BEDC.Derived.CompactUniformTriangleLedgerUp.

Chapter 6023

A Concrete Naming Certificate for CantorIntersectionUniformWindow$^{\uparrow}$

Following Bishop and Bridges' constructive nested-interval treatment, the CantorIntersectionUniformWindow$^{\uparrow}$ packet records the finite uniform-window handoff for the L10 nested compact interval route. It sits over the nested interval surface of chapter 320, the dyadic interval nesting route of chapter 1812, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the metric Cantor-intersection packet of chapter 4359. The packet exposes only the finite window needed by a Real or Completion consumer; it does not assert Heine–Borel compactness, choose an intersection point, quotient streams, countable choice, host equality, or ambient Real$^{\uparrow}$ completeness.

Definition 6023.1 (CantorIntersectionUniformWindow carrier)**.** *A* CantorIntersectionUniformWindow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (N, D, M, W, R, E, J, H, C, P, K)$$

with the following displayed rows:

1. *N is the* NestedInterval$^{\uparrow}$ *source row, exposing the nested compact interval family and the requested finite depth.*
2. *D is the* DyadicIntervalNesting$^{\uparrow}$ *row, recording dyadic endpoint budgets and containment checks for the same depth.*
3. *M is the* CantorIntersectionMetric$^{\uparrow}$ *metric row, read only as a bounded diameter and overlap witness for the displayed interval family.*
4. *W is the uniform finite-window row, assigning one inspection window to every precision request visible in N, D, M.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the dyadic endpoints and the uniform window family.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row, available only after N, D, M, W, R have been displayed.*
7. *J is the L10 handoff row that routes finite interval windows toward Real and Completion consumers.*
8. *H records componentwise* hsame *transport for the nested source, dyadic ledger, metric row, windows, readbacks, seal, handoff, provenance, and local name.*

9. *C records displayed* Cont *replay of the route*

$$N, D, M \longmapsto W \longmapsto R \longmapsto E \longmapsto J.$$

10. *P is the* Pkg *provenance over* $\mathsf{CantorIntersectionUniformWindow}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicIntervalNesting}^{\uparrow}$, $\mathsf{CantorIntersectionMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *K is the local* $\mathsf{NameCert}_{\mathsf{CantorIntersectionUniformWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $N, D, M, W, R, E, J, H, C, P, K$. It has no coordinate for a selected intersection point, unrestricted compactness, quotient stream equality, countable choice, host endpoint equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6023.2 (CantorIntersectionUniformWindow NameCert obligations)**.** *For every accepted* $\mathsf{CantorIntersectionUniformWindow}^{\uparrow}$ *carrier*

$$U = (N, D, M, W, R, E, J, H, C, P, K),$$

the local $\mathsf{NameCert}_{\mathsf{CantorIntersectionUniformWindow}^{\uparrow}}$ *surface consists exactly of the following seed obligation rows:*

1. *carrier admission for the displayed nested source, dyadic ledger, metric Cantor row, finite uniform windows, regular rational readback, terminal real seal, L10 handoff, transport, replay, provenance, and local name;*
2. *nested-source exposure, requiring every interval read to pass through N before a dyadic or metric row is consumed;*
3. *dyadic containment visibility, requiring D to supply the finite endpoint and containment checks used by W and R;*
4. *uniform-window exactness, requiring the same finite window family W to serve every visible precision request before the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff is read;*
5. *real-seal nonescape, requiring E and J to remain downstream of N, D, M, W, R;*
6. *structural transport, replay, provenance, and local naming through H, C, P, K.*

No Cantor intersection uniform-window obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6023.1. The displayed tuple lists the nested source, dyadic ledger, metric Cantor row, uniform windows, regular rational readback, real seal, L10 handoff, and structural rows.

The nested and dyadic obligations are read in order. A consumer first sees N, then D, and only then the metric row M and window row W; none of these rows exports a selected point or an unrestricted compactness theorem.

The uniform-window exactness obligation is the route through W and R. The row W fixes the finite inspection family, and R reads only the rational data exposed by that family and the dyadic endpoint ledger.

Finally, E, J, H, C, P, K preserve the same route. Since the carrier has no coordinate for the excluded principles, the listed rows exhaust the local NameCert surface. □

Theorem 6023.3 (CantorIntersectionUniformWindow L10 handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{CantorIntersectionUniformWindow}^{\uparrow}$ *carrier factors through*

$$N, D, M, W, R, E, J, H, C, P, K.$$

The consumer may inspect the nested interval source, dyadic endpoint ledger, metric Cantor row, finite uniform windows, $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, L10 handoff, transport, replay, provenance, and local name. It cannot bypass this route to obtain general Heine–Borel compactness, a selected intersection point, quotient streams, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an L10 consumer asking for a Real-facing window from the packet. The only source coordinate is N, so the consumer must retain the nested interval family and requested finite depth.

The dyadic and metric rows then fix the window discipline. The row D records endpoint budgets and containment checks, while M supplies only the bounded diameter and overlap information needed by the displayed finite window.

The readback and seal rows are downstream of that discipline. The row W displays the uniform finite windows, R reads them as regular rational data, and E, J expose the terminal seal and L10 handoff without adding a selector.

The rows H, C, P, K transport, replay, source, and name the same finite route. Therefore no consumer can extract the excluded compactness, choice, quotient, equality, or ambient completeness data from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorIntersectionUniformWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorIntersectionUniformWindow}^{\uparrow}$ packet is generated from nested interval data, dyadic interval nesting rows, a CantorIntersectionMetric row, finite uniform windows, RegSeqRat readback, a RealUp seal, an L10 handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorIntersectionUniformWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6023.1, Definition 6023.2, and Definition 6023.3 seed the finite uniform-window route from nested compact interval data through dyadic endpoint budgets, CantorIntersectionMetric rows, RegSeqRat readback, RealUp sealing, and L10 handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorIntersectionUniformWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general Heine–Borel compactness, selected intersection points, quotient streams, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-source exposure, dyadic containment visibility, uniform-window exactness, RegSeqRat handoff, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CantorIntersectionUniformWindowUp.

Chapter 6024

A Concrete Naming Certificate for $\mathsf{VariationalEquation}^{\uparrow}$

Following Coddington and Levinson, the $\mathsf{VariationalEquation}^{\uparrow}$ packet records the finite linearized-flow companion to the local Picard–Lindelof route. It sits after the local existence surface of chapter 1888, the ODE source of chapter 193, the vector-field Lipschitz ledger of chapter 410, the Banach state classifier of chapter 90, and the complete-metric convergence boundary of chapter 128. The packet names the tangent linear equation along one displayed local flow; it is not a global differentiable flow, a host fundamental-matrix object, a maximal interval theorem, or a choice-selected family of derivatives.

Definition 6024.1 (Variational equation carrier)**.** *A* $\mathsf{VariationalEquation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (B, D, L, T, U, H, C, P, N)$$

with the following visible coordinates:

1. *B is the base local-flow row, read through a* $\mathsf{PicardLindelof}^{\uparrow}$ *packet and the underlying* $\mathsf{Ode}^{\uparrow}$ *time-state source.*
2. *D is the derivative and Lipschitz ledger for the vector field on the same local window, including the displayed linearization row and the Lipschitz bound used to compare nearby tangent reads.*
3. *L is the linearized Picard route, a finite contraction-style ledger that reads each tangent iterate through B, D and the carried Banach state classifier.*
4. *T is the tangent-transport row, recording how displayed tangent vectors are carried along the base local-flow row before the linearized endpoint is read.*
5. *U is the uniqueness and nonescape row for the tangent equation on the named local time-state window.*
6. *H stores componentwise* hsame *transport for the base flow, derivative ledger, linearized Picard route, tangent transport, uniqueness and nonescape row, replay row, provenance row, and local naming row.*
7. *C stores the displayed* Cont *replay from the base local-flow row through derivative reads, tangent Picard iterates, tangent transport, uniqueness, and local endpoint comparison.*
8. *P is the* Pkg *provenance over* $\mathsf{VariationalEquation}^{\uparrow}$, $\mathsf{PicardLindelof}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{PicardContraction}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{VariationalEquation}^{\uparrow}}$ *row.*
The carrier exposes only the finite tangent equation route attached to one accepted local-flow packet. It has no coordinate for a host derivative bundle, a global fundamental matrix, smooth flow dependence beyond the displayed derivative ledger, maximal continuation, or bridge-checked standardization.

Lean4 ✓ `BEDC.Derived.VariationalEquationUp.VariationalEquationTasteGate single carrier alignment`

Theorem 6024.2 (Variational equation NameCert obligations)**.** *For an accepted* $\mathsf{VariationalEquation}^{\uparrow}$ *carrier*

$$V = (B, D, L, T, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VariationalEquation}^{\uparrow}}$ *surface consists exactly of base local-flow admission, derivative and Lipschitz ledger admission, linearized Picard-route compatibility, tangent-transport visibility, uniqueness and nonescape stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every tangent endpoint read must pass through these rows before it is treated as a linearized ODE solution.*

Proof. Carrier admission is projection from Definition 6024.1. The base flow row B fixes the $\mathsf{PicardLindelof}^{\uparrow}$ and $\mathsf{Ode}^{\uparrow}$ source, while D supplies the displayed derivative and Lipschitz data used by the linearized equation.

Induct over the finite linearized Picard route L. At the base row, the tangent iterate is attached to the displayed base flow and derivative ledger. At a successor row, the next tangent iterate is read by the same derivative ledger, the same Banach state classifier, and the same local window.

The tangent endpoint is then exposed only through T and U. The transport row T keeps tangent reads attached to the base local-flow route, and the row U records the finite uniqueness and nonescape boundary.

Finally the structural rows H, C, P, N transport, replay, source, and name this same route. Since no carrier coordinate contains a host derivative bundle, a global fundamental matrix, or a selected family of derivatives, the listed obligations exhaust the NameCert surface. □

Theorem 6024.3 (Variational equation local Picard companion route)**.** *Every accepted* $\mathsf{VariationalEquation}^{\uparrow}$ *packet is consumed as a local linearized companion of an accepted* $\mathsf{PicardLindelof}^{\uparrow}$ *packet. A consumer must first read the base local-flow row B, the derivative and Lipschitz ledger D, the linearized Picard route L, the tangent-transport row T, the uniqueness and nonescape row U, and the structural rows H, C, P, N. The packet exports no tangent endpoint outside that finite base-flow route.*

Proof. Project $V = (B, D, L, T, U, H, C, P, N)$. The only base trajectory available to the packet is the displayed local-flow row B, and the only vector-field variation available to the packet is the derivative and Lipschitz ledger D.

Use the finite route L for tangent iteration. Each linearized iterate reads the same base flow and derivative ledger, so a consumer cannot detach the tangent equation from the accepted $\mathsf{PicardLindelof}^{\uparrow}$ route.

The endpoint-facing rows are T and U. They record tangent transport, uniqueness, and nonescape inside the same local window, while H, C, P, N preserve the route under transport, replay, provenance, and naming. □

Falsifiable prediction: Every accepted $\mathsf{VariationalEquation}^{\uparrow}$ tangent endpoint read exposes one base local-flow row, one derivative and Lipschitz ledger, one linearized Picard route, one tangent-transport row, one uniqueness and nonescape row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: picard-lindelof, ode, lipschitzmap, banach, completemetric: $\mathsf{VariationalEquation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the base local-flow row, derivative and Lipschitz ledger, linearized Picard route, tangent transport, uniqueness and nonescape row, and the transport/replay/provenance rows tying them together.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationalEquation}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationalEquation}^{\uparrow}$ packet is generated from one PicardLindelof base local-flow row, one derivative and Lipschitz ledger, one linearized Picard route, one tangent-transport row, one uniqueness and nonescape row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationalEquation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6024.1, Definition 6024.2, and Definition 6024.3 seed the finite linearized ODE companion route over a displayed local Picard flow, derivative ledger, tangent transport, nonescape, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationalEquation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global differentiable flow, a host fundamental matrix, maximal continuation, choice-selected derivative families, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked base-flow admission, derivative and Lipschitz ledger admission, linearized Picard-route compatibility, tangent-transport visibility, uniqueness and nonescape stability, transport, replay, provenance, and local naming for BEDC.Derived.VariationalEquationUp.

Chapter 6025

A Concrete Naming Certificate for HyperbolicHorofunctionBoundary$^{\uparrow}$

The HyperbolicHorofunctionBoundary$^{\uparrow}$ packet realizes the boundary metric readout branch of chapter 9463 as finite NameCert data. It consumes the four-point comparison route of chapter 3948, the Busemann boundary surface of chapter 3732, the visual-boundary readback of chapter 4181, the observer-shadow metric route of chapter 4154, and the hyperbolic metric rows of chapter 3474. The packet names a finite horofunction-style boundary comparison; it is not a host compactification, a quotient ideal boundary, a selected geodesic ray space, or a global hyperbolic model.

Definition 6025.1 (Hyperbolic horofunction-boundary carrier)**.** *A* HyperbolicHorofunctionBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (M, B, V, S, T, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-read row for the displayed disk or boundary-facing source.*
2. *B is the* HyperbolicBusemannBoundary$^{\uparrow}$ *row recording finite distance-difference boundary data.*
3. *V is the* HyperbolicVisualBoundary$^{\uparrow}$ *row that exposes the same boundary read through visual-boundary data.*
4. *S is the* HyperbolicObserverShadowMetric$^{\uparrow}$ *row carrying the observer-facing shadow comparison.*
5. *T is the transport row tying metric, Busemann, visual-boundary, shadow, and cross-ratio reads to the same boundary route.*
6. *R is the refusal row excluding host horofunction compactification, quotient ideal-boundary equality, selected geodesic rays, and unrecorded global geometry.*
7. *H records componentwise* hsame *transport for metric, Busemann, visual-boundary, shadow, transport, refusal, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from metric reads through Busemann difference rows, visual-boundary data, observer-shadow comparison, transport, refusal, and local naming.*
9. *P is the* Pkg *provenance over* HyperbolicHorofunctionBoundary$^{\uparrow}$, HyperbolicCrossRatio$^{\uparrow}$, HyperbolicBusemannBou HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicObserverShadowMetric$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, B, V, S, T, R, H, C, P, N$. It has no coordinate for a host horofunction compactification, quotient boundary equality, selected rays, or a global metric oracle.

Theorem 6025.2 (Hyperbolic horofunction-boundary NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}$ *carrier*

$$Y = (M, B, V, S, T, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}}$ *surface consists exactly of metric admission, Busemann boundary admission, visual-boundary readback, observer-shadow metric comparison, boundary transport, refusal of host compactification, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every boundary metric read must inspect these rows before it treats the packet as a horofunction-boundary comparison.*

Proof. Project the carrier of Definition 6025.1. The metric row M fixes the finite hyperbolic comparison source, and the Busemann row B supplies the displayed distance-difference boundary data.

Read the boundary-facing rows V, S, T next. The visual-boundary row exposes the boundary token, the observer-shadow row supplies the finite metric readout seen by the observer route, and the transport row keeps these reads attached to the same boundary comparison.

The refusal row R blocks replacement by a host compactification or quotient ideal-boundary object. The structural rows H, C, P, N transport, replay, source, and name the same finite surface, so no consumer can obtain a horofunction-boundary comparison outside the displayed rows. □

Theorem 6025.3 (Hyperbolic horofunction-boundary metric readout route)**.** *Every accepted* HyperbolicHorofunctio
consumer that reads boundary metric data must pass through

$\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$,

The route exposes metric, Busemann, shadow, transport, refusal, provenance, and local NameCert rows before any horofunction-boundary comparison is public.

Proof. Let $Y = (M, B, V, S, T, R, H, C, P, N)$ be accepted. The consumer first reads M, B, V, S, so the boundary comparison is attached to displayed metric, Busemann, visual-boundary, and observer-shadow data.

Use T to align the boundary route with the cross-ratio-facing transport supplied by Definition 3948.5. This keeps the boundary metric comparison finite and prevents replacement by a host compactification.

Finally R, H, C, P, N refuse the excluded host objects and preserve the displayed route under transport, replay, provenance, and naming. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}$ packet must expose metric, Busemann, shadow, transport, refusal, provenance, and NameCert rows before a boundary metric read is accepted.

Independence witness: hyperbolic-cross-ratio, hyperbolic-busemann-boundary, hyperbolic-visual-boundary, hyperbolic-observer-shadow-metric, hyperbolic-metric: $\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries metric admission, Busemann boundary

data, visual-boundary readback, observer-shadow metric comparison, boundary transport, host-compactification refusal, provenance, replay, transport, and local naming.

The Lean TasteGate side for $\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial\ HyperbolicHorofu}$ and $\mathsf{FieldFaithful\ HyperbolicHorofunctionBoundary}^{\uparrow}$ instances. These instances keep the metric, Busemann, visual-boundary, shadow, transport, refusal, provenance, replay, package, and local naming rows distinguishable.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}$ packet is generated from HyperbolicMetric, HyperbolicBusemannBoundary, HyperbolicVisualBoundary, HyperbolicObserverShadowMetric, HyperbolicCrossRatio-facing transport, refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6025.1, Definition 6025.2, and Definition 6025.3 seed the finite boundary metric readout route over Busemann, visual-boundary, observer-shadow, cross-ratio transport, refusal, provenance, replay, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host horofunction compactification, quotient ideal-boundary equality, selected geodesic rays, global hyperbolic geometry, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked metric admission, Busemann boundary admission, visual-boundary readback, observer-shadow metric comparison, boundary transport, refusal, TasteGate nontriviality, field faithfulness, provenance, replay, transport, and local naming for BEDC.Derived.HyperbolicHorofunctionBoundaryUp.

Chapter 6026

A Concrete Naming Certificate for $\mathsf{RegularCauchyOscillation}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyOscillation}^{\uparrow}$ packet records the finite oscillation control carried by a regular Cauchy rational name before a Real or completion-facing consumer may read the terminal seal. It sits after the tail-variation ledger of chapter 448, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the Cauchy modulus surface of chapter 292, and the terminal real-name seal of chapter 38. The packet is an L10 NameCert surface for regular-Cauchy oscillation arguments, not quotient stream equality, a selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6026.1 (Regular Cauchy oscillation carrier)**.** *A* $\mathsf{RegularCauchyOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, W, Q, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule selecting the inspected source indices, tail windows, and comparison pairs used by the oscillation request.*
2. *W is the finite window ledger synchronized with S and with the requested Cauchy-modulus thresholds.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational sequence observed through the displayed windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, slack, and comparison row used to measure the tail oscillation.*
5. *L is the* $\mathsf{CauchyOscillation}^{\uparrow}$ *ledger, recording the displayed tail-diameter comparisons read from S, W, Q, D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the StreamName schedule, RegSeqRat readback, dyadic tolerance row, and oscillation ledger have been displayed.*
7. *H records componentwise* hsame *transport for the schedule, windows, readback, tolerance, oscillation ledger, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each Real or completion-facing oscillation request through $S, W, Q, D, L, E, H, P, N$.*

9. *P is the* Pkg *provenance over* RegularCauchyOscillation$^{\uparrow}$, CauchyOscillation$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, CauchyModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RegularCauchyOscillation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, Q, D, L, E, H, C, P, N$. It has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, trichotomy, ambient completeness, Lean verification, or bridge credentials.

Lean4 ✓ `BEDC.Derived.RegularCauchyOscillationUp.RegularCauchyOscillationTasteGate single carrier alignment`

Theorem 6026.2 (Regular Cauchy oscillation NameCert obligations)**.** *For every accepted* RegularCauchyOscillation *carrier*

$$O = (S, W, Q, D, L, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyOscillation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the StreamName schedule, finite windows, RegSeqRat readback, DyadicRatCore tolerance row, CauchyOscillation ledger, Real seal, transport, replay, provenance, and local name;*
2. *schedule coverage, requiring every inspected index and tail pair to be named by S and opened through a window in W;*
3. *dyadic tolerance exactness, requiring every oscillation comparison to consume its tolerance and slack cells from D;*
4. *Cauchy-modulus compatibility, requiring the tail threshold read through* CauchyModulus$^{\uparrow}$ *to be attached to the same S, W, Q, D route;*
5. *Real seal non-escape, requiring E, H, C, P, N to expose no quotient stream equality, host real equality, selected limit, countable choice, trichotomy, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No Regular Cauchy oscillation obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 6026.1. The displayed tuple $S, W, Q, D, L, E, H, C, P, N$ is the entire public surface, so carrier admission is exactly admission of those rows.

The schedule and dyadic clauses are read next. The row S names the inspected indices and tail pairs, W opens the corresponding finite windows, and D supplies the tolerance and slack cells used by each comparison.

The oscillation ledger L is downstream of S, W, Q, D. Its Cauchy-modulus compatibility is therefore a finite route through the same schedule, windows, regular readback, and dyadic tolerance cells before the terminal seal E can be consumed.

The structural rows H, C, P, N transport, replay, source, and name only this route. Since the carrier contains no further coordinate, the excluded quotient, choice, order, completeness, verification, and bridge objects cannot be exported by the local NameCert surface. □

Theorem 6026.3 (Regular Cauchy oscillation Real handoff)**.** *Every* Real$^{\uparrow}$ *or completion-facing consumer of an accepted* RegularCauchyOscillation$^{\uparrow}$ *carrier first reads the finite route*

$$S, W, Q, D \longmapsto L \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives a displayed StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, CauchyOscillation row, Real seal, transport, replay, provenance, and local NameCert before it can treat the regular Cauchy name as a real-facing source. It receives no quotient stream equality, host real equality, selected limit, countable-choice schedule, trichotomy row, ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate, Lean verification, or bridge credential.*

Proof. Start with a Real or completion-facing request. The carrier has no direct path to the real seal, so the request must first open the schedule S, the finite windows W, the regular rational readback Q, and the dyadic tolerance row D.

These rows determine the oscillation ledger L. The ledger is the only row that records the tail comparison needed before the terminal seal E is exposed, so every seal read factors through the displayed oscillation route.

Transport through H, replay through C, provenance through P, and local naming through N preserve the same route. With no quotient, choice, trichotomy, or ambient-completeness coordinate in the packet, the handoff exports only the finite regular-Cauchy oscillation surface. □

Falsifiable prediction: Every $\mathsf{RegularCauchyOscillation}^{\uparrow}$ Real-facing read factors through one StreamName schedule, one finite window ledger, one RegSeqRat readback row, one DyadicRatCore tolerance row, one CauchyOscillation ledger, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchyoscillation, regseqrat, streamname, dyadicratcore, real, cauchy-modulus: $\mathsf{RegularCauchyOscillation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the regular source schedule, finite windows, regular readback, dyadic tolerance cells, Cauchy oscillation ledger, Real seal, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillation}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyOscillation}^{\uparrow}$ packet is generated from a StreamName schedule, finite regular-source windows, RegSeqRat readback, DyadicRatCore tolerance cells, a CauchyOscillation ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyOscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6026.1, Definition 6026.2, and Definition 6026.3 seed the finite regular-Cauchy oscillation route from inspected stream windows through dyadic tolerance cells, RegSeqRat readback, CauchyOscillation ledger, and RealUp sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyOscillation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule coverage, dyadic tolerance exactness, Cauchy-modulus compatibility, Real seal non-escape, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.RegularCauchyOscillationUp.

The $\mathsf{FiniteWindowConfluence}^{\uparrow}$ spine is routed here so the downstream frontier consumer of chapter 4238 can find the finite confluence dependency without entering the child file.

Chapter 6027

A Concrete Naming Certificate for $\mathsf{FiniteWindowConfluence}^{\uparrow}$

The $\mathsf{FiniteWindowConfluence}^{\uparrow}$ packet realizes the MetaCIC normalization audit map of chapter 9383 as finite beta-window confluence data. It sits beside the redex-frontier packet of chapter 1008, the local join ledger of chapter 4126, the residual-substitution boundary of chapter 2181, the closed normal seal of chapter 741, and the normal-fragment confluence packet of chapter 737. The carrier records a bounded beta-window peak, local join evidence, substitution-boundary retention, and closed-normal endpoint rows without claiming unrestricted global confluence, quotient conversion equality, arbitrary subject reduction, or kernel consistency.

Falsifiable prediction: A $\mathsf{FiniteWindowConfluence}^{\uparrow}$ packet whose beta window omits the residual-substitution boundary row is rejected even when its local join ledger and closed-normal endpoint rows are present.

Independence witness: metacic-redex-frontier, metacic-local-join-ledger, metacic-residual-substitution-boundary, closednormalconfluenceseal, metacicconfluencenormalfragment: none is bijective with $\mathsf{FiniteWindowConfluence}^{\uparrow}$ because this packet jointly carries the beta-window peak, redex-frontier read, local join ledger, residual-substitution boundary, closed-normal endpoint, TasteGate readiness, transport, replay, provenance, and local naming rows.

Definition 6027.1 (FiniteWindowConfluence carrier)**.** *A* $\mathsf{FiniteWindowConfluence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, R, J, S, N, W, G, H, C, P, K)$$

with the following displayed rows:

1. *B is the bounded beta-window row, naming the source term, window radius, and two outgoing beta observations.*
2. *R is the* $\mathsf{MetaCICRedexFrontier}^{\uparrow}$ *row, exposing the redex-frontier discharge data consumed by the window.*
3. *J is the* $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$ *row, recording the local peak and candidate join ledger for the same bounded window.*
4. *S is the* $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ *row, retained whenever the join read depends on residual substitution data.*
5. *N is the* $\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}$ *endpoint row, available only for closed normal endpoint reads.*

6. *W is the* $\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}$ *window-fragment row, keeping the closed-normal finite fragment separate from unrestricted global confluence.*
7. *G is the* $\mathsf{TasteGate}$ *readiness row for later* $\mathsf{Nontrivial}$ *and* $\mathsf{FieldFaithful}$ *instances over this packet.*
8. *H records componentwise* hsame *transport for beta windows, redex frontiers, local joins, residual-substitution boundaries, closed-normal endpoints, normal fragments, TasteGate readiness, provenance, and local naming.*
9. *C records displayed* Cont *replay from a normalization-audit query through $B, R, J, S, N, W, G, H, P, K$.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteWindowConfluence}^{\uparrow}$, $\mathsf{MetaCICRedexFrontier}^{\uparrow}$, $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$, $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$, $\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}$, $\mathsf{MetaCICConfluenceNormalFragment}^{\uparrow}$, BHist, hsame, Cont, $\mathsf{TasteGate}$, *and* $\mathsf{NameCert}$.
11. *K is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowConfluence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, R, J, S, N, W, G, H, C, P, K$. It contains no coordinate for unrestricted MetaCIC confluence, global Church–Rosser, quotient conversion equality, arbitrary subject reduction, evaluator equality, or kernel consistency.

Theorem 6027.2 (FiniteWindowConfluence NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWindowConfluence}^{\uparrow}$ *carrier*

$$F = (B, R, J, S, N, W, G, H, C, P, K),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteWindowConfluence}^{\uparrow}}$ *surface consists exactly of bounded beta-window exposure through B, redex-frontier readback through R, local-join ledger exposure through J, residual-substitution boundary retention through S, closed-normal endpoint exposure through N, normal-fragment separation through W, TasteGate readiness through G, componentwise transport through H, displayed replay through C, provenance through P, and local naming through K.*

Proof. Project the carrier of Definition 6027.1. Rows B, R, J, S, N, W are the confluence-facing finite data, while G, H, C, P, K are the structural certificate data.

The beta-window read starts with B and R. The source, radius, and two outgoing observations are bounded by B, and the redex-frontier row R keeps the required discharge data visible before a join can be consumed.

The local join is then read through J while retaining S. The residual-substitution boundary is a row of the same packet, so the local join cannot be detached into a global confluence theorem or a substitution oracle.

Closed-normal endpoints are read only through N and W. These rows expose the normal fragment and the closed-normal seal, but they do not supply arbitrary closed-term Church–Rosser or quotient conversion equality.

Finally G, H, C, P, K reserve the TasteGate instance surface, transport the rows, replay the audit query, source the packet, and name it. Since no carrier coordinate contains unrestricted confluence, subject reduction, evaluator equality, or kernel consistency, the listed rows exhaust the local NameCert surface. □

Theorem 6027.3 (FiniteWindowConfluence normalization-audit handoff)**.** *Every normalization-audit consumer of an accepted* $\mathsf{FiniteWindowConfluence}^{\uparrow}$ *carrier factors through*

$$B, R, J, S, N, W, G, H, C, P, K.$$

The consumer may inspect the bounded beta window, redex frontier, local join ledger, residual-substitution boundary, closed-normal endpoint, normal fragment, TasteGate readiness, transport,

replay, provenance, and local name. It cannot bypass this route to obtain unrestricted MetaCIC confluence, global Church–Rosser, quotient conversion equality, arbitrary subject reduction, evaluator equality, or kernel consistency.

Proof. Start with a normalization-audit query. The only beta-window entrance is B, and the only redex-facing discharge surface is R, so the query must retain the bounded source, outgoing beta observations, and redex-frontier data.

The local join route is then constrained by J and S. Row J records the candidate join ledger, while S keeps the residual-substitution boundary visible as an input rather than as a solved global theorem.

The endpoint route is constrained by N and W. A closed-normal read may use the closed-normal seal and normal-fragment packet, but those rows remain finite endpoint data, not an unrestricted confluence theorem.

The structural rows G, H, C, P, K preserve the same packet under TasteGate readiness, transport, replay, provenance, and local naming. Hence every normalization-audit consumer remains inside the displayed finite route. □

Theorem 6027.4 (FiniteWindowConfluence TasteGate readiness)**.** *The later Lean side must provide* Nontrivial *and* FieldFaithful TasteGate *instances for* FiniteWindowConfluence$^{\uparrow}$ *at the displayed finite carrier surface*

$$B, R, J, S, N, W, G, H, C, P, K.$$

Those instances must certify that the packet is neither empty nor field-forgetting: every accepted carrier visibly retains the bounded beta window, redex frontier, local join ledger, residual-substitution boundary, closed-normal endpoint, normal-fragment row, transport, replay, provenance, and local NameCert data.

Proof. The readiness row G in Definition 6027.1 is tied to the whole finite-window packet, not to the local join ledger alone.

Nontriviality must exhibit an accepted packet with all displayed rows present. FieldFaithfulness must show that deleting any of $B, R, J, S, N, W, H, C, P, K$ changes the readable carrier surface. Thus the TasteGate burden remains exactly at the finite beta-window confluence boundary. □

Theorem 6027.5 (FiniteWindowConfluence sibling route)**.** *Every public confluence read exported by an accepted* FiniteWindowConfluence$^{\uparrow}$ *packet routes through the sibling rows named in the carrier: the* MetaCICRedexFrontier$^{\uparrow}$ *redex-frontier row, the* MetaCICLocalJoinLedger$^{\uparrow}$ *local-join ledger, the* MetaCICResidualSubstitutionBoundary$^{\uparrow}$ *residual-substitution boundary, the* ClosedNormalConfluenceSeal$^{\uparrow}$ *closed-normal seal, and the* MetaCICConfluenceNormalFragment$^{\uparrow}$ *normal-fragment confluence row. A consumer cannot read the packet as an isolated confluence theorem without also retaining those sibling routes.*

Proof. Begin with the carrier of Definition 6027.1. Its public confluence-facing rows are B, R, J, S, N, W, so the bounded beta-window row is not readable without the redex-frontier row of chapter 1008 and the local-join ledger of chapter 4126.

The residual part of the read is held by S. Thus any join consumer that keeps J must also pass through the residual-substitution boundary of chapter 2181; otherwise the packet would claim a substitution oracle that is not present in its finite rows.

The endpoint part is held by N and W. These rows point respectively to chapter 741 and chapter 737, so the read remains a closed-normal finite fragment rather than unrestricted MetaCIC confluence.

The structural rows G, H, C, P, K then apply the existing NameCert obligations, the normalization-audit handoff, and the TasteGate readiness row to the same packet. Hence the public route is exactly the displayed finite sibling route. □

Theorem 6027.6 (FiniteWindowConfluence residual diamond scope)**.** *Any local diamond read over the bounded beta window of an accepted* $\mathsf{FiniteWindowConfluence}^{\uparrow}$ *carrier must expose the redex-frontier row, local-join ledger, residual-substitution boundary, closed-normal endpoint row, and normal-fragment row together. In carrier notation, a diamond-facing consumer may inspect*

$$B, R, J, S, N, W$$

only as the finite route already transported, replayed, sourced, and named by G, H, C, P, K*. The read remains a finite residual-diamond scope; it does not claim unrestricted Church–Rosser, global subject reduction, quotient conversion equality, evaluator equality, or kernel consistency.*

Proof. Apply the NameCert obligation surface of Definition 6027.2. It requires the bounded beta-window row, redex-frontier readback, local-join ledger, residual-substitution boundary, closed-normal endpoint, and normal-fragment separation to remain visible in the same accepted packet.

Next apply the normalization-audit handoff of Definition 6027.3. A local diamond read is a normalization-audit consumer, so it cannot bypass R, J, S, N, W after entering through B.

Finally use the sibling route of Definition 6027.5. The redex-frontier, local-join, residual-substitution, closed-normal, and normal-fragment rows are sibling dependencies rather than optional annotations. Hence the diamond scope is finite and residual-boundary-aware, with no route to the global principles excluded from the carrier. □

Theorem 6027.7 (FiniteWindowConfluence residual-boundary inversion)**.** *If a local diamond read from an accepted* $\mathsf{FiniteWindowConfluence}^{\uparrow}$ *packet reaches* J *as a candidate join, then the same read also exposes* S *as the residual-substitution boundary row. The candidate join cannot be reinterpreted as a join independent of residual data; it remains in the route*

$$B, R, J, S, N, W, G, H, C, P, K.$$

Proof. Project the accepted carrier $F = (B, R, J, S, N, W, G, H, C, P, K)$. The local join ledger J and residual-substitution boundary S are adjacent confluence-facing rows of the same finite packet.

Use the NameCert obligations of Definition 6027.2 and the normalization-audit handoff of Definition 6027.3. They require a diamond-facing read to keep the bounded beta window, redex frontier, local join, residual-substitution boundary, closed-normal endpoint, and normal fragment in one transported and replayed route.

Finally apply the sibling route of Definition 6027.5. It keeps the redex-frontier, local-join, residual-substitution, closed-normal, and normal-fragment rows together, so J cannot be cited as an unconditional global confluence join or as a join detached from residual-substitution data. □

Theorem 6027.8 (FiniteWindowConfluence normalization-frontier handoff)**.** *Every local diamond read from an accepted* $\mathsf{FiniteWindowConfluence}^{\uparrow}$ *carrier consumed by a* $\mathsf{NormalizationCandidateFrontier}^{\uparrow}$ *route carries the rows* B, R, J, S, N, W *through the frontier packet's candidate-evidence, bounded-route, obstruction, transport, replay, provenance, and local NameCert rows. The handoff is therefore a bounded candidate-mediated route from finite-window confluence data to the normalization frontier, not a proof of global Church–Rosser, unrestricted subject reduction, evaluator equality, quotient conversion equality, or kernel consistency.*

Proof. Start with residual-boundary inversion, Definition 6027.7. A local diamond read that reaches the candidate join ledger J must also expose the residual-substitution boundary S, while B, R, N, W remain in the same finite confluence route.

Now pass to the frontier through Definition 5994.2 and Definition 5994.3. The frontier can consume positive normalization evidence only while its candidate-evidence row E and bounded-route row B remain visible, so the finite diamond read is carried as bounded candidate data rather than as an evidence-free confluence theorem.

Finally use obstruction exactness and local confluence scope for the frontier, Definition 5994.6 and Definition 5994.7. These rows keep obstruction, transport, replay, provenance, and local naming in the handoff, so erased candidate evidence or erased residual data reaches the obstruction route instead of exporting global Church–Rosser, subject reduction, evaluator equality, quotient conversion equality, or kernel consistency. □

Theorem 6027.9 (FiniteWindowConfluence MetaCIC frontier forward route)**.** *Every* MetaCICParallelDiamondFron *consumer of an accepted* FiniteWindowConfluence$^{\uparrow}$ *carrier must keep the bounded beta-window row, redex-frontier row, local-join ledger, residual-substitution boundary, closed-normal endpoint row, normal-fragment row, componentwise transport, displayed replay, provenance, and local* NameCert *row visible before any frontier handoff. In carrier notation, the forward route is*

$$B, R, J, S, N, W, H, C, P, K,$$

read first through the finite-window obligations, residual-boundary inversion, and normalization-frontier handoff, then through the row discipline of chapter 4238. This is a substantive dependency on chapter 4238: the frontier consumes bounded-window evidence only after retained residual-substitution, critical-pair, candidate-join, checker, obstruction, transport, replay, provenance, and local naming rows are visible. The route supplies bounded-window evidence to the parallel-diamond frontier only; it does not claim global confluence, unrestricted subject reduction, quotient term equality, evaluator equality, or kernel consistency.

Proof. Apply the NameCert obligations of Definition 6027.2. They expose the bounded beta-window, redex-frontier, local-join, residual-substitution, closed-normal endpoint, and normal-fragment rows together with transport, replay, provenance, and local naming.

Next apply the residual-boundary inversion of Definition 6027.7. Any read that reaches the local join ledger J still carries S as residual-substitution boundary data, so the route cannot be recast as a residual-free local join.

Now use the normalization-frontier handoff of Definition 6027.8. It already transports the finite diamond read through candidate evidence, bounded-route, obstruction, transport, replay, provenance, and local NameCert rows before a frontier consumer may inspect it.

Finally compare with the MetaCICParallelDiamondFrontier$^{\uparrow}$ row discipline of Definition 4238.2 and Definition 4238.3. That frontier requires retained residual-substitution, critical-pair, candidate-join, residual-frontier, checker, obstruction, transport, replay, provenance, and local naming rows. The finite-window packet can therefore feed only its displayed bounded route into the frontier, with no route to global confluence, unrestricted subject reduction, quotient term equality, evaluator equality, or kernel consistency. □

Closure status for NameCert$_{\text{FiniteWindowConfluence}^{\uparrow}}$**.**

Constructive story: A FiniteWindowConfluence$^{\uparrow}$ packet is generated from a bounded beta-window row, MetaCICRedexFrontier row, MetaCICLocalJoinLedger row, MetaCICResidualSubstitutionBoundary row, ClosedNormalConfluenceSeal endpoint row, MetaCICConfluenceNormalFragment row, Nontrivial and FieldFaithful TasteGate readiness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteWindowConfluence}\uparrow}$, seed)

Scope closed: Definition 6027.1, Definition 6027.2, Definition 6027.3, and Definition 6027.4 seed the finite beta-window confluence packet for MetaCIC normalization-audit consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteWindowConfluence}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close unrestricted MetaCIC confluence, global Church–Rosser, quotient conversion equality, arbitrary subject reduction, evaluator equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, beta-window exposure, redex-frontier readback, local-join exactness, residual-substitution boundary retention, closed-normal endpoint exposure, normal-fragment separation, TasteGate nontriviality, FieldFaithful coverage, transport, replay, provenance, and local naming for BEDC.Derived.FiniteWindowConfluenc

Chapter 6028

A Concrete Naming Certificate for $\mathsf{BarInductionContinuity}^{\uparrow}$

Following Brouwer's bar induction and the presentation of Troelstra–van Dalen, the $\mathsf{BarInductionContinuity}^{\uparrow}$ packet records the finite certificate by which a barred spread computation yields a continuity modulus for a real-facing read. In the Bishop–Bridges reading, the continuity principle is not a free choice functional: it is a finite prefix route through the bar, the fan depth, the displayed stream windows, the regular rational readback, and the terminal modulus row.

The packet sits between the barred-spread source of chapter 1675, the finite-depth discipline of chapter 5863, the finite observation interface of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. It names the continuity-extraction route only at the displayed prefix level.

Definition 6028.1 (Bar induction continuity carrier)**.** *A* $\mathsf{BarInductionContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, F, S, R, M, H, C, P, N)$$

with the following displayed rows:

1. *B is the barred-spread row, containing the spread law, the decidable bar test on inspected prefixes, and the local bar-induction descent data.*
2. *F is the finite fan-depth row, bounding the prefix depth at which the accepted bar evidence must be read.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *prefix-window row, listing exactly the stream coordinates opened before the bar decision is consumed.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same prefix windows, with the rational observations and regularity ledger visible to the consumer.*
5. *M is the modulus-output row, recording the continuity bound extracted from B, F, S, R for the displayed precision request.*
6. *H records componentwise* hsame *transport for the barred-spread row, fan-depth row, stream windows, rational readback, modulus output, replay routes, provenance, and local naming.*
7. *C records displayed* Cont *replay from a continuity request through B, F, S, R, M, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BarInductionContinuity}^{\uparrow}$, $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{FiniteFanTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{BarInductionContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for countable choice, a selected infinite branch, quotient stream equality, open-cover compactness, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6028.2 (Bar induction continuity NameCert obligations)**.** *For every accepted* $\mathsf{BarInductionContinuity}^{\uparrow}$ *carrier*

$$K = (B, F, S, R, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BarInductionContinuity}^{\uparrow}}$ *surface consists exactly of carrier admission for the barred-spread data, finite fan-depth admission, stream-prefix window exposure, regular rational readback, modulus-output exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every exported continuity bound factors through the finite route*

$$B, F, S, R \longmapsto M, H, C, P, N.$$

Proof. Project the carrier of Definition 6028.1. The tuple displays the barred-spread row, finite fan depth, stream prefix windows, regular rational readback, modulus output, transport, replay, provenance, and local naming.

The bar-induction part supplies only finite prefix descent. The row B decides the inspected bar entries, while F bounds the depth at which those entries are read. Thus no selected infinite branch or countable-choice schedule is available.

The continuity output is then read through S and R. The stream row exposes the prefix coordinates, and the regular rational row packages exactly the rational observations and regularity ledger obtained from that same prefix window.

Finally M records the modulus extracted from the displayed route, and H, C, P, N only transport, replay, source, and name it. Since the carrier has no coordinate for quotient stream equality, open-cover compactness, host real equality, or ambient completeness, row projection and finite prefix induction give precisely the stated obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{BarInductionContinuity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BarInductionContinuity}^{\uparrow}$ packet is generated from barred-spread data, a finite fan-depth row, StreamName prefix windows, RegSeqRat readback, a modulus-output row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BarInductionContinuity}^{\uparrow}}$, seed)

Scope closed: The seed scope records the finite carrier, prefix-window classifier, modulus-output route, transport stability, replay surface, and local non-escape boundary for bar-induction continuity packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BarInductionContinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close countable choice, selected branches, quotient stream equality, open-cover compactness, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean carrier encoding and checked NameCert obligation theorem for the barred-spread, finite-depth, prefix-window, readback, and modulus-output rows.

Chapter 6029

A Concrete Naming Certificate for $\mathsf{UniformLimitCauchyCriterion}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{UniformLimitCauchyCriterion}^{\uparrow}$ packet records the finite route by which a uniformly Cauchy family of real-valued names is admitted as a uniform-limit candidate before any endpoint, quotient function, selected limit, countable choice, or ambient completeness principle is available. It sits beside the finite family route of chapter 1830, the shared-tail criterion of chapter 435, the uniform-limit endpoint of chapter 463, and the continuity-facing handoff of chapter 1748. The chapter names only the Real-and-Completion corridor through displayed StreamName, RegSeqRat, Real, transport, replay, provenance, and local NameCert rows.

Definition 6029.1 (Uniform limit Cauchy criterion carrier)**.** *A* $\mathsf{UniformLimitCauchyCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, W, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the function-family row, carrying the inspected family-window entries and the point requests to which the uniform criterion is applied.*
2. *W is the finite family-window ledger, recording the shared windows for indices, source points, and comparison stages.*
3. *M is the uniform Cauchy modulus row, requiring one displayed modulus request to govern every retained point window.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row opened from the selected family windows before any regular rational readback is available.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same observations and dyadic tolerances.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after F, W, M, S, R have been read.*
7. *H records componentwise* hsame *transport for family windows, modulus rows, observations, regular readbacks, Real seals, replay rows, provenance, and local naming.*
8. *C records displayed* Cont *replay from a Real or Completion request through M, W, S, R, E.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformLimitCauchyCriterion}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{UniformLimitContinuous}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{UniformLimitCauchyCriterion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, W, M, S, R, E, H, C, P, N$. It has no coordinate for quotient function equality, pointwise-only convergence, selected family limits, countable choice, host completeness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.UniformLimitCauchyCriterionUp.UniformLimitCauchyCriterionTasteGate single carrier alignment`

Theorem 6029.2 (Uniform limit Cauchy criterion NameCert obligations)**.** *For every accepted* $\mathsf{UniformLimitCauchyCriterion}^{\uparrow}$ *carrier*

$$U = (F, W, M, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformLimitCauchyCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for family-window rows, a shared uniform Cauchy modulus,* $\mathsf{StreamName}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer must read the uniform modulus M, then the displayed windows W, then the stream observations S and regular readback R, before the Real seal E is available.*

Proof. Project the carrier of Definition 6029.1. Its rows list the only family-window, modulus, observation, readback, seal, transport, replay, provenance, and naming data admitted by the local classifier.

The uniformity obligation is the placement of M before W, S, R, E. A consumer cannot replace it by a pointwise threshold, because the carrier stores one displayed modulus route for every retained family window.

The regular and Real-facing rows then follow the L10 route already used by $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The structural rows H, C, P, N transport, replay, source, and name that same finite route.

No excluded coordinate occurs in the packet. Thus quotient function equality, selected family limits, countable choice, host completeness, and ambient $\mathsf{Real}^{\uparrow}$ completeness cannot appear as local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.UniformLimitCauchyCriterionUp.UniformLimitCauchyCriterionCarrier namecert obligations`

Theorem 6029.3 (Uniform limit Cauchy criterion L10 handoff)**.** *Every endpoint-facing read of an accepted* $\mathsf{UniformLimitCauchyCriterion}^{\uparrow}$ *packet factors through the finite L10 route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with the shared uniform Cauchy evidence supplied by $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *and the continuity-facing endpoint discipline compatible with* $\mathsf{UniformLimitContinuous}^{\uparrow}$. *In particular, the handoff exposes family-window rows, one uniform Cauchy modulus, stream observations, regular rational readbacks, Real seals, componentwise transport, replay, provenance, and local naming before any Real-and-Completion consumer may inspect the endpoint.*

Proof. Start with the NameCert obligations of Definition 6029.2. They force each endpoint-facing request to display the family window and the shared uniform modulus before the regular readback route is opened.

Read the stream and regular rows next. The $\mathsf{StreamName}^{\uparrow}$ observations S and $\mathsf{RegSeqRat}^{\uparrow}$ readback R are tied to the same finite family-window ledger W and the same modulus row M.

The terminal Real seal is downstream of that route. The $\mathsf{UniformCauchyCriterion}^{\uparrow}$ provenance supplies the shared-tail criterion, while $\mathsf{UniformLimitContinuous}^{\uparrow}$ may consume the resulting endpoint only as a displayed finite handoff.

Since H, C, P, N preserve the same rows and add no external analytic object, the L10 handoff contains no quotient function equality, pointwise-only convergence witness, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness datum. □

Theorem 6029.4 (Uniform limit Cauchy criterion endpoint stability)**.** *Let*

$$U = (F, W, M, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{UniformLimitCauchyCriterion}^{\uparrow}$ *carrier. Any endpoint-facing consumer preserving the rows* $F, W, M, S, R, E, H, C, P, N$ *preserves the same* $\mathsf{StreamName}^{\uparrow}$ *observation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal. In particular, the consumer cannot replace the shared uniform Cauchy modulus* M *by pointwise convergence, selected limits, countable choice, or ambient completeness.*

Proof. Project the carrier of Definition 6029.1. The endpoint-facing data are exactly the family row, finite windows, shared uniform modulus, stream observation, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Apply Definition 6029.2 in row order. The modulus row M precedes the observations S, readback R, and Real seal E, so any row-preserving consumer must keep the same uniform Cauchy evidence attached to the same finite windows.

Finally apply Definition 6029.3. It identifies the endpoint route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, while H, C, P, N preserve and name that route. Hence no pointwise-only convergence witness, selected limit, countable-choice selector, or ambient completeness datum can replace the shared uniform modulus. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLimitCauchyCriterion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformLimitCauchyCriterion}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 6029.1, Definition 6029.2, Definition 6029.3, and Definition 6029.4 close the finite Real-and-Completion route for uniform Cauchy function-family convergence through displayed StreamName, RegSeqRat, Real, transport, replay, provenance, and local NameCert rows at obligation strength.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformLimitCauchyCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient function equality, selected family limits, countable choice, pointwise-only convergence, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-modulus stability, StreamName observation routing, RegSeqRat readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformLimitCauchy

Constructive story: A $\mathsf{UniformLimitCauchyCriterion}^{\uparrow}$ packet is generated from family-window rows, one uniform Cauchy modulus, StreamName observations, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6030

A Concrete Naming Certificate for $\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}$

Following Brouwer and Troelstra–van Dalen, the $\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}$ packet records the finite-prefix modulus used when a choice-sequence input is read by a Real-facing consumer. It refines the continuity surface of chapter 3465 by isolating the concrete finite row that turns a displayed $\mathsf{ChoiceSequence}^{\uparrow}$ prefix into a $\mathsf{StreamName}^{\uparrow}$ window, then into $\mathsf{RegSeqRat}^{\uparrow}$ readback and the terminal $\mathsf{Real}^{\uparrow}$ seal. The packet is a finite NameCert carrier for prefix-modulus readback; it is not a host continuity theorem, a selected infinite branch, quotient stream equality, countable choice, arbitrary bar induction, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6030.1 (Brouwer finite choice-sequence modulus carrier)**.** *A* $\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, Q, W, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BrouwerContinuityPrinciple}^{\uparrow}$ *source row that licenses finite-prefix dependence for the read.*
2. *Q is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *input row, exposing only the inspected finite prefix of the choice sequence.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *prefix-window row opened from Q and bounded by the displayed modulus.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite stream window.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular rational readback is displayed.*
6. *M is the finite modulus row, recording the prefix length sufficient for the displayed output read.*
7. *H records componentwise* hsame *transport for the continuity source, choice-sequence prefix, window, readback, seal, modulus, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the consumer request through B, Q, M, W, R, E.*
9. *P is the* Pkg *provenance over* $\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}$, $\mathsf{BrouwerContinuityPrinciple}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, Q, W, R, E, M, H, C, P, N$. It has no coordinate for a completed choice sequence, selected branch, quotient stream equality, countable choice, arbitrary bar-induction principle, host functional continuity theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

`single carrier alignment`

Theorem 6030.2 (Brouwer finite choice-sequence modulus obligations)**.** *For every accepted* $\mathsf{BrouwerFiniteChoiceSe}$ *carrier* $F = (B, Q, W, R, E, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}}$ *surface consists exactly of continuity-source admission through* B*, choice-sequence prefix admission through* Q*, finite modulus display through* M*,* $\mathsf{StreamName}^{\uparrow}$ *window exposure through* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*,* $\mathsf{Real}^{\uparrow}$ *sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

No NameCert obligation is stored outside those displayed rows.

Proof. Project the carrier in Definition 6030.1. The analytic rows are precisely the Brouwer-continuity source, the choice-sequence prefix, the finite modulus, the stream window, the regular rational readback, and the terminal Real seal.

The finite-prefix part is read through B, Q, M, W. The continuity source permits only displayed prefix dependence, the choice-sequence row exposes only the inspected prefix, and the modulus row bounds the window opened by $\mathsf{StreamName}^{\uparrow}$.

The output-facing part is read through R, E. Regular rational readback is downstream of the finite window, and the Real seal is downstream of that readback.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since no excluded object occurs as a coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6030.3 (Brouwer finite choice-sequence real readback)**.** *Every Real-facing consumer of an accepted* $\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{BrouwerContinuityPrinciple}^{\uparrow},\ \mathsf{ChoiceSequence}^{\uparrow} \longmapsto M \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through B, Q, M, W, R, E *before the structural rows* H, C, P, N *package the read. Thus the output read is determined by a displayed finite choice-sequence prefix and its modulus row, and it exports no completed branch, quotient stream equality, selected real representative, countable-choice selector, host continuity theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the continuity source and input prefix. The row B imports only the finite-prefix discipline of chapter 3465, and the row Q supplies only the displayed $\mathsf{ChoiceSequence}^{\uparrow}$ prefix.

Next read the modulus and stream window. The row M fixes the inspected prefix length, and W opens exactly that $\mathsf{StreamName}^{\uparrow}$ window, so downstream consumers cannot replace the route by an infinite branch or quotient stream equality.

Then read the analytic output. The $\mathsf{RegSeqRat}^{\uparrow}$ row R is obtained from the same finite window, and the $\mathsf{Real}^{\uparrow}$ seal E is available only after that readback has been displayed.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Because the carrier contains no coordinate for countable choice, arbitrary bar induction, selected real representatives, host continuity, or ambient Real completeness, none of those objects is exported by the readback. □

Falsifiable prediction: Every accepted $\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}$ Real-facing read displays a Brouwer continuity source row, ChoiceSequence finite prefix, StreamName prefix window, RegSeqRat readback, Real seal, finite modulus row, transport, continuation, provenance, and local naming before any output claim is public.

Independence witness: brouwer-continuity-principle, choice-sequence, streamname, regseqrat, real: $\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source continuity row, displayed choice-sequence prefix, modulus row, stream window, regular readback, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}$ packet is generated from a BrouwerContinuityPrinciple source row, a ChoiceSequence finite prefix, a StreamName prefix window, RegSeqRat readback, a RealUp seal, finite modulus data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6030.1, Definition 6030.2, and Definition 6030.3 seed the finite-prefix modulus route from Brouwer choice-sequence input to regular-rational and Real readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrouwerFiniteChoiceSequenceModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host functional continuity, selected infinite branches, quotient stream equality, countable choice, arbitrary bar induction, selected real representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-prefix modulus exposure, StreamName window routing, RegSeqRat readback, RealUp seal nonescape, and TasteGate field faithfulness for BEDC.Derived.BrouwerFiniteChoiceSequenc

Chapter 6031

A Concrete Naming Certificate for $\mathsf{MinkowskiFunctional}^{\uparrow}$

Following Bourbaki and Rockafellar on locally convex spaces, the $\mathsf{MinkowskiFunctional}^{\uparrow}$ packet records the gauge functional of a displayed absorbing balanced convex neighbourhood as finite NameCert data. It sits over the convex-set source of chapter 208, the topological-vector-space operations of chapter 205, the locally convex neighbourhood ledger of chapter 3386, the seminormed-space consumer surface of chapter 5868, and the terminal scalar seal of chapter 38. The packet names the finite route by which a gauge-bound row is exposed; it does not import host real infima, quotient vector equality, choice of a neighbourhood basis, Hahn–Banach separation, or ambient completeness.

Definition 6031.1 (Minkowski functional carrier)**.** *A* $\mathsf{MinkowskiFunctional}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, V, A, B, L, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{ConvexSet}^{\uparrow}$ *source row naming the displayed convex subset whose gauge is being read.*
2. *V is the* $\mathsf{TopVecSpace}^{\uparrow}$ *operation row for addition, zero, negation, scalar action, and topological transport on the displayed vector carrier.*
3. *A is the absorbing-neighbourhood ledger row, recording the finite scale witnesses by which each inspected vector is admitted into a scalar multiple of X.*
4. *B is the balanced-neighbourhood ledger row, recording the scalar-stability witnesses needed before the gauge read may be transported.*
5. *L is the* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *neighbourhood row tying X, A, B to the displayed locally convex source surface.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *gauge-bound row, exposing the finite scalar bound obtained from the displayed absorbing and balanced ledgers.*
7. *H records componentwise* hsame *transport for the convex source, vector-space operations, absorbing ledger, balanced ledger, locally convex row, scalar bound, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a vector request through V, X, A, B, L, R and back to the public gauge-bound boundary.*

9. *P is the* Pkg *provenance over* $\mathsf{MinkowskiFunctional}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{TopVecSpace}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{SeminormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MinkowskiFunctional}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, V, A, B, L, R, H, C, P, N$. It has no coordinate for a host infimum, quotient-vector equality, selected neighbourhood basis, separation theorem, ambient topological-vector-space completion, or standard bridge.

Lean4 ✓ `BEDC.Derived.MinkowskiFunctionalUp.MinkowskiFunctionalTasteGate single carrier alignment`

Theorem 6031.2 (Minkowski functional NameCert obligations)**.** *For every accepted* $\mathsf{MinkowskiFunctional}^{\uparrow}$ *carrier $G = (X, V, A, B, L, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MinkowskiFunctional}^{\uparrow}}$ *surface consists exactly of convex-source admission through X, topological-vector-space operation exposure through V, absorbing-ledger exposure through A, balanced-ledger exposure through B, locally convex neighbourhood routing through L, scalar gauge-bound sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No NameCert obligation is stored outside those displayed rows.

Proof. Project the carrier. The analytic source rows are precisely the convex source X, the topological-vector-space operations V, the absorbing ledger A, the balanced ledger B, the locally convex neighbourhood row L, and the real scalar bound R.

The gauge route first reads X inside the vector-space operation surface V. Absorption and balancedness are then visible as finite ledger rows, so the scalar bound is read only after the neighbourhood evidence has been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since no excluded host analytic object is a coordinate of the packet, the listed rows exhaust the local NameCert surface. □

Theorem 6031.3 (Minkowski functional gauge route)**.** *Every* $\mathsf{SeminormedSpace}^{\uparrow}$ *or locally convex consumer of an accepted* $\mathsf{MinkowskiFunctional}^{\uparrow}$ *packet receives the gauge-bound read only through the finite route*

$$\mathsf{ConvexSet}^{\uparrow}, \mathsf{TopVecSpace}^{\uparrow} \longmapsto A, B \longmapsto \mathsf{LocallyConvexSpace}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto H, C, P, N.$$

Thus the public boundary is a displayed RealUp scalar-bound row generated from the convex, absorbing, and balanced neighbourhood ledgers; it is not a host real infimum, quotient-vector equality, selected basis element, Hahn–Banach separation result, or completed seminorm theorem.

Proof. Start from the convex and vector-space rows. The source set X is read as a displayed convex packet, while V supplies only the finite operation and topology rows needed by the inspected vector request.

Next read the neighbourhood ledgers. The absorbing row A records the available scale witnesses, and the balanced row B records scalar stability. The locally convex row L ties those two ledgers to the same neighbourhood surface.

The scalar read is then sealed by R. It is a $\mathsf{Real}^{\uparrow}$ gauge-bound row obtained from the displayed ledgers, not an imported infimum over all host scalars.

Finally H, C, P, N transport, replay, source, and name the same route for downstream locally convex and seminormed consumers. None of the excluded analytic objects appears as a carrier coordinate, so no consumer can read them from this packet. □

Falsifiable prediction: Every accepted $\mathsf{MinkowskiFunctional}^{\uparrow}$ gauge-bound read displays a ConvexSetUp source, TopVecSpaceUp operations, absorbing and balanced neighbourhood ledgers, LocallyConvexSpaceUp routing, a RealUp scalar-bound row, componentwise hsame transport, Cont replay, provenance, and local naming before a downstream SeminormedSpaceUp consumer receives the boundary.

Independence witness: convexset, topvecspace, locally-convex-space, seminormed-space, real: $\mathsf{MinkowskiFunctional}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the convex source, vector-space operations, absorbing ledger, balanced ledger, locally convex route, scalar gauge-bound row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MinkowskiFunctional}^{\uparrow}}$.

Constructive story: A $\mathsf{MinkowskiFunctional}^{\uparrow}$ packet is generated from a ConvexSetUp source row, TopVecSpaceUp operation row, absorbing-neighbourhood ledger, balanced-neighbourhood ledger, LocallyConvexSpaceUp route, RealUp gauge-bound row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MinkowskiFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6031.1, Definition 6031.2, and Definition 6031.3 seed the finite gauge-bound route from absorbing balanced convex neighbourhood data to RealUp scalar readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MinkowskiFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real infima, quotient-vector equality, selected neighbourhood bases, Hahn–Banach separation, ambient locally convex completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, convex-source exactness, absorbing and balanced ledger routing, RealUp gauge-bound sealing, nonescape, and TasteGate field faithfulness for BEDC.Derived.MinkowskiFunctionalUp.

Chapter 6032

A Concrete Naming Certificate for GroundCompilerStrengthMonotonicity$^{\uparrow}$

The GroundCompilerStrengthMonotonicity$^{\uparrow}$ packet realizes the strength-monotonicity theorem family of the GroundCompiler derivation-certificate recognizer as finite NameCert data for MetaCIC normalization audit consumers. It sits beside the flow-level round-trip packet of chapter 1094, the event-flow audit packet of chapter 829, the recognizer-flow packet of chapter 1048, the candidate-mediated socket of chapter 3566, and the route-budget packet of chapter 1360. The packet records when a lower-strength derivation-certificate subflow may support a lower accepted flow, without turning the compiler into a source of hidden proof evidence, retroactive promotion, or unconditional normalization.

Definition 6032.1 (GroundCompiler strength monotonicity carrier)**.** *A* GroundCompilerStrengthMonotonicity$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (N, H, L, A, D, R, G, B, C, P, M)$$

with the following displayed rows:

1. *N is the accepted object-flow row whose higher-strength acceptance is being inspected.*
2. *H is the higher-strength row.*
3. *L is the lower-strength row requested by the downstream consumer.*
4. *A is the accepted-flow witness row at strength H.*
5. *D is the recognized lower-strength derivation-certificate subflow row supporting L.*
6. *R is the route row tying D to A as a displayed subflow rather than as hidden compiler evidence.*
7. *G records the GroundCompiler gate-monotone read of* StrengthMonotonicityAtFlowLevel*.*
8. *B records the audit-map route budget consumed through* AuditMapRouteBudget$^{\uparrow}$ *before the lower-strength acceptance is public.*
9. *C records componentwise* hsame *transport and displayed* Cont *replay for N, H, L, A, D, R, G, B.*
10. *P is the* Pkg *provenance over* GroundCompilerStrengthMonotonicity$^{\uparrow}$*,* GroundCompilerFlowLevelRoundTrip$^{\uparrow}$*,* GroundCompilerEventFlowAudit$^{\uparrow}$*,* GroundCompilerRecognizerFlow$^{\uparrow}$*,* NormalizationCandidateSocket$^{\uparrow}$*,* AuditMapRouteBudget$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

11. M is the local $\mathsf{NameCert}_{\mathsf{GroundCompilerStrengthMonotonicity}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $N, H, L, A, D, R, G, B, C, P, M$. It has no coordinate for retroactive promotion, hidden compiler state, proof reconstruction, global normalization, erased candidate evidence, or a route that bypasses the displayed lower-strength derivation-certificate subflow.

Theorem 6032.2 (GroundCompiler strength monotonicity NameCert obligations)**.** *For every accepted* $\mathsf{GroundCompilerStrengthMonotonicity}^{\uparrow}$ *carrier $S = (N, H, L, A, D, R, G, B, C, P, M)$, the local* $\mathsf{NameCert}_{\mathsf{GroundCompilerStrengthMonotonicity}^{\uparrow}}$ *surface consists exactly of accepted-object exposure through N, higher-strength exposure through H, lower-strength request exposure through L, accepted-flow evidence through A, recognized lower-strength derivation-certificate subflow exposure through D, subflow routing through R, gate-monotone strength readback through G, audit-map route-budget exposure through B, componentwise transport and replay through C, provenance through P, and local naming through M.*

No NameCert obligation is stored outside those displayed rows.

Proof. Project the carrier. The monotonicity source consists of the accepted object row N, the higher and lower strength rows H, L, the higher-strength accepted-flow row A, and the lower-strength derivation-certificate subflow row D.

The route row R keeps D visible as a subflow of A. Thus the lower-strength conclusion is not obtained by weakening the strength label alone; it is obtained only after the lower derivation-certificate evidence has been displayed.

The checked GroundCompiler theorem supplies the gate-monotone readback row G, while the audit-map budget row B keeps the event-flow, recognizer, certificate-gate, report-boundary, and cannot-claim routes visible.

Finally C, P, M transport, source, and name the same finite surface. Since no excluded object occurs as a coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6032.3 (GroundCompiler strength monotonicity route)**.** *Every MetaCIC normalization audit consumer that reads* $\mathsf{GroundCompilerStrengthMonotonicity}^{\uparrow}$ *must pass through the finite route*

$$\mathsf{GroundCompilerFlowLevelRoundTrip}^{\uparrow}, \mathsf{GroundCompilerEventFlowAudit}^{\uparrow}, \mathsf{GroundCompilerRecognizerFlow}^{\uparrow} \longmapsto A, D, R$$

The route preserves the lower-strength derivation-certificate subflow before the lower accepted-flow read is public. It does not export hidden proof evidence, retroactive promotion, erased candidate normalization, host compiler state, or an unconditional closed-term normalization endpoint.

Proof. Begin with the GroundCompiler flow rows. The flow-level round-trip row keeps encoded flow readback attached to its source, the event-flow audit row separates compiler-facing event data from hidden inputs, and the recognizer-flow row exposes generated-recognizer admission before any certificate-gate read.

Next read the monotonicity rows. The accepted-flow witness A and lower derivation-certificate subflow D are connected by R, and the gate-monotone row G reads the checked strength-monotonicity theorem only for that displayed subflow relation.

The audit-map route budget B fixes the event-flow, recognizer, certificate-gate, report-boundary, and cannot-claim path before the result reaches MetaCIC normalization consumers. The normalization candidate socket then preserves candidate-mediated evidence rather than replacing it by an unconditional endpoint.

The structural rows C, P, M replay and name the same route. Because the carrier has no coordinate for hidden proof evidence, retroactive promotion, erased candidate normalization, host

compiler state, or unconditional closed-term normalization, those reads remain outside the packet. □

Falsifiable prediction: A GroundCompiler consumer that lowers strength without displaying a recognized lower-strength derivation-certificate subflow, the gate-monotone strength row, and the audit-map route budget is not an accepted $\mathsf{GroundCompilerStrengthMonotonicity}^{\uparrow}$ packet.

Independence witness: groundcompilerflowlevelroundtrip, groundcompilereventflowaudit, groundcompilerrecognizerflow, normalization-candidate-socket, auditmaproutebudget: GroundCompilerStrengthMonotonic is not bijective to any listed sibling because it jointly carries higher and lower strength rows, accepted-flow evidence, lower derivation-certificate subflow evidence, gate-monotone readback, route-budget exposure, candidate-socket consumer routing, transport, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{GroundCompilerStrengthMonotonicity}^{\uparrow}}$.

Constructive story: A $\mathsf{GroundCompilerStrengthMonotonicity}^{\uparrow}$ packet is generated from an accepted object-flow row, higher and lower strength rows, higher-strength accepted-flow evidence, recognized lower-strength derivation-certificate subflow evidence, subflow routing, the checked gate-monotone strength row, audit-map route-budget data, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GroundCompilerStrengthMonotonicity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6032.1, Definition 6032.2, and Definition 6032.3 seed the finite GroundCompiler strength-monotonicity packet for MetaCIC normalization audit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GroundCompilerStrengthMonotonicity}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.GroundCompiler.DerivCertGenerated.gate\_monotone\_strength`

Bridge status: none

Not claimed: This chapter does not close hidden proof evidence, compiler correctness, retroactive promotion, erased candidate normalization, global closed-term normalization, host compiler state, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subflow-route exactness, audit-map budget nonescape, candidate-socket consumer preservation, and TasteGate field faithfulness for BEDC.Derived.GroundCompilerStrengthMonotonicityU

Chapter 6033

A Concrete Naming Certificate for $\mathsf{YoungMeasure}^{\uparrow}$

Following Young and standard weak-convergence treatments, the $\mathsf{YoungMeasure}^{\uparrow}$ packet records parametrized limiting probability data as finite BEDC NameCert rows rather than as a quotient measure class or a selected subsequential limit. It sits after the terminal real-name surface of chapter 38, the probability-space carrier of chapter 184, the tight probability route of chapter 4008, and the regular-Cauchy completion lattice of chapter 5833. The packet gives Phase Real and Completion consumers a displayed interface for tight probability and real-sequence limiting data without asserting ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6033.1 (YoungMeasure carrier)**.** *A* $\mathsf{YoungMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (R, P, T, S, Q, E, H, C, K, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint and observable-value row through which scalar test reads are sealed.*
2. *P is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row naming the probability carrier, measurable event ledger, and finite probability observations.*
3. *T is the tightness row, read through the Prokhorov-style tight probability packet before any limiting probability read is admitted.*
4. *S is the real-sequence window row, recording the finite schedule of observations whose limiting behavior the packet exposes.*
5. *Q is the regular-Cauchy readback row tying the displayed scalar observations to the completion-facing regular rational route.*
6. *E is the Young-measure evaluation row, recording only test-observable probability reads over displayed windows and tightness ledgers.*
7. *H records componentwise* hsame *transport for real, probability, tightness, sequence-window, regular-readback, evaluation, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a test-observable request through real endpoints, probability rows, tightness rows, sequence windows, regular readback, and evaluation.*
9. *K is the* Pkg *provenance over* $\mathsf{YoungMeasure}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *together with the cited tightness and regular-Cauchy dependency rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{YoungMeasure}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $R, P, T, S, Q, E, H, C, K, N$. It has no coordinate for quotient measure equality, selected subsequences, selected host limits, countable choice, arbitrary weak-star compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.YoungMeasureUp.YoungMeasureTasteGate single carrier alignment`

Theorem 6033.2 (YoungMeasure NameCert obligations)**.** *For every accepted* $\mathsf{YoungMeasure}^{\uparrow}$ *carrier*

$$Y = (R, P, T, S, Q, E, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{YoungMeasure}^{\uparrow}}$ *surface consists exactly of Real endpoint exposure, probability-source exposure, tightness exposure, real-sequence window exposure, regular-Cauchy readback, Young-measure evaluation exposure, componentwise transport, displayed replay, package provenance, and local naming. No obligation is stored outside those rows.*

Proof. Project the carrier of Definition 6033.1. The displayed coordinates are precisely the Real endpoint row, probability source row, tightness row, sequence-window row, regular-readback row, evaluation row, and structural rows.

The probability and tightness obligations are read from P and T. Thus an accepted packet exposes tight limiting data only after the probability carrier and its tightness ledger have been displayed.

The real-valued observation obligations are read from R, S, Q, E. The sequence window S and regular readback Q keep scalar limiting data in the finite completion corridor before the evaluation row E is presented.

Finally H, C, K, N transport, replay, source, and name the same route. Since no quotient measure equality, selected subsequence, selected limit, countable-choice schedule, weak-star compactness theorem, or ambient completeness row appears in the carrier, none can be exported by the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.YoungMeasureUp.YoungMeasureCarrier namecert obligations`

Theorem 6033.3 (YoungMeasure tightness handoff)**.** *Every tight probability read accepted by a* $\mathsf{YoungMeasure}^{\uparrow}$ *carrier factors through the displayed probability source row, tightness row, finite real-sequence windows, regular-Cauchy readback, and local structural rows before any evaluation row is visible. The route is*

$$P, T, S, Q \longmapsto R, E \longmapsto H, C, K, N.$$

It exports a finite tightness handoff for probability-valued limiting data, not a quotient measure equality, a selected subsequence, or a host compactness principle.

Proof. Use the obligation theorem Definition 6033.2. It exposes the probability source and tightness rows before the sequence-window and regular-readback rows can be inspected by a limiting-data consumer.

The evaluation row is downstream of those finite rows. A consumer reaches E only after the probability source P, tightness ledger T, sequence window S, regular readback Q, and Real endpoint row R have been displayed.

The structural rows then preserve the same handoff. Componentwise transport H, replay C, provenance K, and local naming N cannot add quotient measure equality, selected subsequences, or host compactness, because those are not carrier coordinates. □

Theorem 6033.4 (YoungMeasure Real completion boundary)**.** *No* $\mathsf{Real}^{\uparrow}$*-facing completion consumer of an accepted* $\mathsf{YoungMeasure}^{\uparrow}$ *carrier can bypass the displayed route through Real endpoints, probability-source rows, tightness ledgers, real-sequence windows, regular-Cauchy readbacks, evaluation rows, and local structural rows. In particular, the packet does not assert quotient measure equality, selected limits, selected subsequences, countable choice, arbitrary weak convergence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier projection of Definition 6033.1. The only Real-facing row is R, and the only completion-facing scalar readback row is Q.

Apply the tightness handoff Definition 6033.3. It places the probability source and tightness ledger before the sequence-window, regular-readback, and evaluation rows.

The Real endpoint row is therefore a boundary for displayed scalar observations, not a completeness theorem. Since the carrier stores no quotient measure equality, selected limit, selected subsequence, countable-choice schedule, arbitrary weak-convergence theorem, or ambient completeness row, a completion consumer cannot obtain any of those principles from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{YoungMeasure}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoungMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6033.1, Definition 6033.2, Definition 6033.3, and Definition 6033.4 seed the finite Young-measure carrier, local obligation surface, tightness handoff, and Real-completion boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoungMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient measure equality, selected subsequences, selected host limits, countable choice, arbitrary weak-star compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, probability-source exposure, tightness handoff, sequence-window readback, Real endpoint boundary, transport, replay, provenance, and local naming for BEDC.Derived.YoungMeasureUp.

Constructive story: A $\mathsf{YoungMeasure}^{\uparrow}$ packet is generated from Real endpoint rows, probability-source rows, tightness rows, real-sequence windows, regular-Cauchy readbacks, Young-measure evaluation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 6034

A Concrete Naming Certificate for $\mathsf{FiniteSupportStream}^{\uparrow}$

Following Bishop-style sequence spaces, the $\mathsf{FiniteSupportStream}^{\uparrow}$ packet records the finite-support stream route by which a displayed sequence supplies bounded-window approximants before any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer reads a seal. It sits after the StreamName windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name boundary of chapter 38, and the finite list carrier of chapter 36. The packet names an eventually-zero support bound as finite certificate data; it is not a quotient stream, countable choice schedule, selected limit, or ambient completeness principle.

Definition 6034.1 (Finite-support stream carrier)**.** *A* $\mathsf{FiniteSupportStream}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, B, L, D, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row for the stream windows inspected by the packet.*
2. *B is the finite support-bound row, recording the displayed index after which all stream entries are the zero row.*
3. *L is the* $\mathsf{List}^{\uparrow}$ *row listing the nonzero support entries and their finite window positions.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the displayed entries and tail-zero boundary.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the bounded stream windows and dyadic ledger.*
6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, B, L, D, R have been exposed.*
7. *H records componentwise* hsame *transport for S, B, L, D, R, Q and the structural rows.*
8. *C records displayed* Cont *replay from a precision request through the source stream, support bound, list row, dyadic ledger, regular rational readback, and real seal boundary.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteSupportStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSupportStream}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite support oracle, quotient equality of streams, a selected limit, countable choice, or an ambient real-completeness theorem.

Lean4 ✓ `BEDC.Derived.FiniteSupportStreamUp.FiniteSupportStreamTasteGate single carrier alignment`

Theorem 6034.2 (Finite-support stream NameCert obligations)**.** *For every accepted* $\mathsf{FiniteSupportStream}^{\uparrow}$ *carrier*

$$F = (S, B, L, D, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteSupportStream}^{\uparrow}}$ *surface consists exactly of stream source admission, finite support-bound admission, finite nonzero-entry list admission, dyadic tolerance compatibility, regular rational readback, terminal Real seal access, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 6034.1. The analytic rows are exactly S, B, L, D, R, Q, and the structural rows are exactly H, C, P, N.

The support-bound row B and finite list row L force every inspected nonzero entry to be displayed before the tail-zero boundary is used. The dyadic ledger D then records the tolerance budget for the listed entries and for the zero tail.

The regular rational readback R and Real seal Q are downstream rows of that same finite route. Transport, replay, provenance, and local naming preserve the rows componentwise, so no quotient stream, selected limit, countable-choice schedule, or ambient completeness object is introduced. □

Theorem 6034.3 (Finite-support stream RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteSupportStream}^{\uparrow}$ *packet must read the finite route*

$$S, B, L, D \longmapsto R, Q, H, C, P, N.$$

Thus a finite-window approximant reaches regular rational readback and the Real seal only through the StreamName source, finite support bound, listed support entries, dyadic tolerance ledger, componentwise transport, displayed replay, provenance, and local NameCert rows.

Proof. Begin with a regular rational read request. By Definition 6034.1, the request first exposes the stream source S, support bound B, finite list row L, and dyadic tolerance ledger D.

Apply the obligation surface of Definition 6034.2. It requires R and Q to appear only after the source, support, list, and tolerance rows have been accepted.

Finally replay H, C, P, N. These rows preserve and name the same finite packet, so the handoff supplies bounded-window approximants to $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ without quotient streams, selected limits, countable choice, or an ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{FiniteSupportStream}^{\uparrow}$ read factors through one StreamName source row, one finite support-bound row, one finite ListUp support-entry row, one DyadicRatCore tolerance ledger, one RegSeqRat readback row, one RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: streamname, regseqrat, dyadicratcore, real, list: $\mathsf{FiniteSupportStream}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a stream source, a finite support bound, a listed nonzero support surface, dyadic tolerance data, regular rational readback, a Real-facing seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSupportStream}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteSupportStream}^{\uparrow}$ packet is generated from a StreamName source row, a finite support-bound row, a finite ListUp support-entry row, a DyadicRatCore tolerance ledger, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteSupportStream}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6034.1, Definition 6034.2, and Definition 6034.3 seed the finite-support stream route for bounded-window regular rational and real-facing reads.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteSupportStream}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, support-bound exactness, dyadic tolerance compatibility, regular rational readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteSupportStrea

Chapter 6035

A Concrete Naming Certificate for $\mathsf{EffectiveCoverCompactness}^{\uparrow}$

Following Lebesgue and Bishop–Bridges constructive compactness, the $\mathsf{EffectiveCoverCompactness}^{\uparrow}$ packet records the finite BEDC surface by which a compact metric carrier exposes cover data only through explicit finite subcovers, mesh bounds, and Lebesgue-number handoffs. It sits after the compact metric source of chapter 129, the finite-cover refinement surface of chapter 3430, and the Lebesgue-number finite-cover route of chapter 6016, while supplying the compact-uniform modulus consumer of chapter 2299 and the vision corridor of chapter 9237. The chapter names effective finite-cover compactness, not arbitrary open-cover compactness.

Definition 6035.1 (Effective cover compactness carrier)**.** *An* $\mathsf{EffectiveCoverCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, O, R, L, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, carrying the inspected compact metric name, metric balls, and finite request windows.*
2. *O is the cover row, listing the finitely observed basic opens and their metric radii.*
3. *R is the* $\mathsf{FiniteCoverRefinement}^{\uparrow}$ *row, recording the finite refinement and subcover choices that remain visible to downstream consumers.*
4. *L is the* $\mathsf{LebesgueNumberFiniteCover}^{\uparrow}$ *row, supplying the displayed Lebesgue-number witness for the same finite cover.*
5. *M is the compact-uniform handoff row consumed by* $\mathsf{CompactUniformModulus}^{\uparrow}$*.*
6. *H records componentwise* hsame *transport for compact metric data, cover rows, refinement rows, Lebesgue-number rows, compact-uniform handoff, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a cover or modulus request through K, O, R, L, M, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{EffectiveCoverCompactness}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{FiniteCoverRefinement}^{\uparrow}$*,* $\mathsf{LebesgueNumberFiniteCover}^{\uparrow}$*,* $\mathsf{CompactUniformModulus}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{EffectiveCoverCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, O, R, L, M, H, C, P, N$. It has no coordinate for arbitrary open-cover compactness, countable subcover extraction, choice of centers outside the displayed cover, ambient completeness, or a selected global modulus.

Theorem 6035.2 (Effective cover compactness NameCert obligations)**.** *For every accepted* EffectiveCoverCompactn *carrier*

$$E = (K, O, R, L, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EffectiveCoverCompactness}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric row, cover row, finite refinement row, Lebesgue-number witness row, compact-uniform handoff row, componentwise transport, displayed replay, provenance, and local naming. Every cover-facing consumer must read* K *and* O *before* R*, read* R *before* L*, and read* L *before the compact-uniform handoff* M*.*

Proof. Project the carrier of Definition 6035.1. The visible coordinates are exactly the compact metric source, cover ledger, finite refinement, Lebesgue-number witness, compact-uniform handoff, and structural rows.

The obligation order is forced by those coordinates. The finite refinement row R is meaningful only over the displayed cover row O and compact metric row K, while the Lebesgue-number row L is read from that same finite cover surface.

Finally M, H, C, P, N only hand off, transport, replay, source, and name the displayed finite-cover data. Since no other carrier coordinate exists, the local NameCert surface cannot export arbitrary open-cover compactness, a countable subcover selector, hidden centers, ambient completeness, or a selected global modulus. □

Theorem 6035.3 (Effective cover compactness finite-cover handoff)**.** *Every compact-uniform consumer of an accepted* $\mathsf{EffectiveCoverCompactness}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{FiniteCoverRefinement}^{\uparrow} \longmapsto \mathsf{LebesgueNumberFiniteCover}^{\uparrow} \longmapsto \mathsf{CompactUniformModulus}^{\uparrow}.$$

Thus the consumer sees the compact metric source row, displayed cover row, finite refinement row, Lebesgue-number witness, compact-uniform handoff, componentwise transport, replay, provenance, and local naming before any modulus-facing conclusion is available.

Proof. Begin with a compact-uniform consumer and apply Definition 6035.2. The consumer must first display the compact metric source and the finite cover row.

Next it reads the finite-cover refinement and Lebesgue-number rows. These are the existing finite-cover surfaces of chapter 3430 and chapter 6016, so the handoff remains a finite certificate rather than an arbitrary open-cover principle.

The compact-uniform row M is downstream of the same finite route. The structural rows H, C, P, N preserve and name that route only, so the consumer receives no hidden subcover choice, no countable cover extraction, no ambient completeness, and no selected global modulus outside the displayed certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveCoverCompactness}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveCoverCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6035.1, Definition 6035.2, and Definition 6035.3 seed the finite-cover compactness surface from compact metric data through finite refinement, Lebesgue-number witnesses, compact-uniform handoff, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveCoverCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, countable subcover extraction, hidden center choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-cover refinement visibility, Lebesgue-number exactness, compact-uniform handoff, transport, replay, provenance, and local naming for BEDC.Derived.EffectiveCoverCompactnessUp

Constructive story: An EffectiveCoverCompactness$^{\uparrow}$ packet is generated from a CompactMetric source row, displayed cover row, finite refinement row, Lebesgue-number witness row, compact-uniform handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theorem 6035.4 (Effective cover compactness sibling route)**.** *Every accepted* EffectiveCoverCompactness$^{\uparrow}$ *packet consumes the compact metric source of* CompactMetric$^{\uparrow}$*, the finite-cover refinement route, the Lebesgue-number finite-cover route, and the* FiniteEpsilonNet$^{\uparrow}$ *finite coverage pattern before it exports compact-uniform modulus data. Its visible dependency route is therefore*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{FiniteCoverRefinement}^{\uparrow} \longmapsto \mathsf{LebesgueNumberFiniteCover}^{\uparrow} \longmapsto \mathsf{FiniteEpsilonNet}^{\uparrow} \longmapsto \mathsf{CompactU}$$

No consumer may bypass these finite rows by appealing to arbitrary open-cover compactness, hidden centers, countable subcover extraction, or ambient completeness.

Proof. Project the carrier of Definition 6035.1. The rows $K, O, R, L, M, H, C, P, N$ force the compact metric source and displayed cover to be read before the finite refinement and Lebesgue-number witnesses.

The finite coverage step follows the same visible pattern as FiniteEpsilonNet$^{\uparrow}$: the consumer only sees finitely listed coverage data and the named transport rows that preserve it. The compact-uniform row M is downstream of that finite route, while H, C, P, N only transport, replay, source, and name the displayed certificate.

Thus the chapter exports compact-uniform modulus data through the sibling route recorded above, and not through any hidden compactness principle outside the effective cover packet. □

Chapter 6036

A Concrete Naming Certificate for $\mathsf{FastCauchyWitness}^{\uparrow}$

Following Bishop–Bridges constructive completion, a fast Cauchy witness is finite evidence that a regular rational name carries an explicit tail modulus before any real-name seal is read. The $\mathsf{FastCauchyWitness}^{\uparrow}$ packet records that L10 Real and Completion route as a NameCert surface over the finite StreamName windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real boundary of chapter 38. It sits beside the window-step sibling chapter 1020 and the diagonal-limit sibling chapter 6002; it does not quotient streams, select an infinite representative, invoke countable choice, or compare host real values.

Definition 6036.1 (Fast Cauchy witness carrier)**.** *A* $\mathsf{FastCauchyWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, W, D, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row whose finite windows are inspected by the Cauchy request.*
2. *W is the finite window ledger listing the source indices and rational entries read for the displayed precision.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the positive dyadic scale used by the fast-tail request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the source windows and the same dyadic ledger.*
5. *M is the fast modulus row, recording that a request at dyadic scale 2^{-n} is answered by a displayed tail window whose pairwise rational distances are bounded by the chosen dyadic tolerance.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after S, W, D, R, M have been displayed.*
7. *H records componentwise* hsame *transport for the source, window, dyadic, readback, modulus, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a precision request through $S, W, D, R, M, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{FastCauchyWitness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{FastCauchyWitness}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, W, D, R, M, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected infinite representatives, countable choice, host sequence equality, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6036.2 (Fast Cauchy witness NameCert obligations)**.** *For every accepted* $\mathsf{FastCauchyWitness}^{\uparrow}$ *carrier*

$$F = (S, W, D, R, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FastCauchyWitness}^{\uparrow}}$ *surface consists exactly of source StreamName admission for S, finite-window coverage for W, dyadic tolerance visibility for D, RegSeqRat readback for R, fast modulus exposure for M, Real seal routing for E, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through P, and local naming through N.*

No Fast Cauchy witness obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 6036.1. The tuple $S, W, D, R, M, E, H, C, P, N$ is the whole public packet, so carrier admission and local naming are exactly the displayed rows.

The analytic route starts with the finite StreamName window W over the source row S. The dyadic tolerance row D supplies the scale for both the regular rational readback R and the fast modulus row M.

The terminal seal E is downstream of those rows. Transport, replay, provenance, and local naming through H, C, P, N preserve the same route, and no excluded quotient, selected representative, choice, host equality, or completeness coordinate occurs in the carrier. □

Lean4 ✓ `BEDC.Derived.FastCauchyWitnessUp.FastCauchyWitnessTasteGate single carrier alignment`

Theorem 6036.3 (Fast Cauchy witness modulus normalization)**.** *Every accepted* $\mathsf{FastCauchyWitness}^{\uparrow}$ *packet may normalize a displayed regular Cauchy modulus to the dyadic fast form*

$$n \longmapsto 2^{-n}$$

only by reading the finite route

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{FastCauchyWitness}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The normalized modulus row M is therefore a finite BEDC witness tied to the source windows S, W, dyadic ledger D, and regular readback R. It does not export quotient stream equality, host function extensionality, a selected infinite tail, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a precision request. The packet can answer it only through the source StreamName row S and the displayed finite window W.

The tolerance scale is then read from the DyadicRatCore row D. Using the same row, the RegSeqRat readback R supplies the regular rational data consumed by the modulus row M.

The row M records the fast dyadic budget as part of the finite packet rather than as an external choice of tail. The Real seal E can be read only after this route has been displayed, while H, C, P, N transport, replay, source, and name the same evidence.

Since the carrier contains no quotient stream, selected infinite tail, choice row, host equality, or completeness coordinate, the normalization remains a finite NameCert witness. □

Theorem 6036.4 (Fast Cauchy witness window determinacy)**.** *For accepted* $\mathsf{FastCauchyWitness}^{\uparrow}$ *packets*

$$F = (S, W, D, R, M, E, H, C, P, N)$$

and

$$F' = (S, W, D, R', M, E', H', C', P', N')$$

sharing the same $\mathsf{StreamName}^{\uparrow}$ *source row, finite window ledger,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and fast modulus row, every Real-facing read through either packet uses the same displayed window and tolerance route before reaching its* $\mathsf{Real}^{\uparrow}$ *seal. The packets may differ in readback, seal, transport, replay, provenance, or local naming rows, but no Real-facing consumer can distinguish their displayed window budget before the seal is read.*

Proof. Project both carriers using Definition 6036.1. The shared rows S, W, D, M are the only source, window, tolerance, and fast-modulus rows available to either accepted packet.

Apply the NameCert obligations of Definition 6036.2. They force every Real-facing route to read the StreamName source, finite window ledger, dyadic tolerance ledger, and fast modulus row before the terminal Real seal is exposed.

Use modulus normalization, Definition 6036.3. It keeps the Real seal downstream of the finite route through S, W, D, M, so the later rows R, E, H, C, P, N and R', E', H', C', P', N' cannot introduce a second displayed tail budget.

Therefore both packets present the same window and tolerance route to every Real-facing read. Since neither carrier contains a quotient stream, selected tail, or ambient completeness row, no excluded object can distinguish the shared window before the Real seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{FastCauchyWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{FastCauchyWitness}^{\uparrow}$ packet is generated from a StreamName source row, finite windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a fast modulus row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FastCauchyWitness}^{\uparrow}}$, seed)

Scope closed: Definition 6036.1, Definition 6036.2, Definition 6036.3, and Definition 6036.4 seed the finite fast-Cauchy witness route from StreamName windows through dyadic tolerance and RegSeqRat readback to a terminal RealUp seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FastCauchyWitness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected infinite tails, countable choice, host sequence equality, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, finite-window coverage, dyadic tolerance visibility, RegSeqRat readback, fast modulus exposure, Real seal routing, transport stability, replay stability, and non-escape for BEDC.Derived.FastCauchyWitnessUp.

Chapter 6037

A Concrete Naming Certificate for $\mathsf{SingularValueDecomposition}^{\uparrow}$

Following Golub–Van Loan and Horn–Johnson, the $\mathsf{SingularValueDecomposition}^{\uparrow}$ packet records the finite spectral certificate by which a displayed matrix is factored through two finite orthonormal frames and a nonnegative diagonal spectrum. It consumes the finite matrix carrier of chapter 49, the inner-product rows of chapter 86, the finite orthonormal-basis packet of chapter 4758, the Frobenius ledger of chapter 5100, the rank accounting of chapter 3438, and the triangular factorization route of chapter 4240. The chapter names only finite displayed rows: it is not a host spectral theorem, not a choice of bases outside the packet, not quotient matrix equality, and not an ambient completeness claim.

Definition 6037.1 (Singular-value decomposition carrier)**.** *A* $\mathsf{SingularValueDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, U, V, D, L, R, F, Q, T, H, C, P, N)$$

with the following displayed rows:

1. *A is the input* $\mathsf{Mat}^{\uparrow}$ *row, exposing the finite row-column table, scalar endpoint ledger, and shape data of the matrix being decomposed.*
2. *U is the left finite orthonormal frame row, read through* $\mathsf{FiniteOrthonormalBasis}^{\uparrow}$ *and the source* $\mathsf{InnerProduct}^{\uparrow}$ *rows.*
3. *V is the right finite orthonormal frame row, read through the same finite orthonormal-basis and inner-product discipline on the domain side.*
4. *D is the nonnegative diagonal spectrum row, listing the displayed singular-value endpoints, diagonal-slot witnesses, zero off-diagonal witnesses, and ordering ledger.*
5. *L is the finite multiplication witness*
$$A = UDV^*$$
read as an equality of displayed $\mathsf{Mat}^{\uparrow}$ *multiplication rows, not as a quotient equality in a host matrix algebra.*
6. *R is the* $\mathsf{RankNullity}^{\uparrow}$ *row identifying the nonzero diagonal slots with the displayed rank ledger.*
7. *F is the* $\mathsf{FrobeniusNorm}^{\uparrow}$ *row that reads the square-sum of entries through the displayed diagonal spectrum ledger.*

8. *Q is the* $\mathsf{QRDecomposition}^{\uparrow}$ *handoff row used by constructive factorization consumers before the orthonormal-frame and diagonal rows are sealed.*
9. *T records refusal rows for host spectral calculus, selected eigenbasis data, quotient matrix equality, ambient completeness, and any basis choice not displayed in U or V.*
10. *H records componentwise* hsame *transport for the matrix, the two frames, the diagonal spectrum, the multiplication witness, the rank and norm rows, the QR handoff, refusal rows, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from a matrix-factorization request through $A, U, V, D, L, R, F, Q, T, H$.*
12. *P is the* Pkg *provenance over* $\mathsf{SingularValueDecomposition}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{FiniteOrthonormalBasis}^{\uparrow}$, $\mathsf{FrobeniusNorm}^{\uparrow}$, $\mathsf{RankNullity}^{\uparrow}$, $\mathsf{QRDecomposition}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{SingularValueDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. In particular, changing a host basis, replacing the displayed diagonal list by an extensionally equal external spectrum, or reading equality outside the multiplication witness L is invisible to the carrier.

Lean4 ✓ `BEDC.Derived.SingularValueDecompositionUp.SingularValueDecompositionTasteGate single carrier alignment`

Theorem 6037.2 (Singular-value decomposition NameCert obligations)**.** *For every accepted* SingularValueDecompo *carrier*

$$S = (A, U, V, D, L, R, F, Q, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SingularValueDecomposition}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed* $\mathsf{Mat}^{\uparrow}$ *row A, the left and right finite orthonormal frame rows U, V, and the nonnegative diagonal spectrum row D;*
2. *classifier comparison through the same matrix, frame, diagonal, multiplication, rank, norm, QR, refusal, transport, replay, provenance, and local naming rows;*
3. *stability under componentwise* hsame *transport, preserving the frame rows, diagonal slots, multiplication witness, and non-escape ledger;*
4. *exactness of the displayed multiplication witness L, requiring each consumer to read the finite matrix route $A = UDV^*$ before exporting a factorization claim;*
5. *ledger obligations through R, F, Q, T, C, P, N, recording rank, Frobenius square-sum, constructive factorization, refusal, replay, source, and local naming without importing host spectral data.*

No singular-value-decomposition obligation is stored outside these rows.

Proof. Project the carrier of Definition 6037.1. The displayed matrix row A, orthonormal frame rows U, V, and diagonal spectrum row D are the only admissible factor data.

The classifier is componentwise on the listed rows. Transport through H can replace displayed endpoints only when the corresponding $\mathsf{Mat}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, and finite-frame classifiers already recognize the replacement.

The exactness obligation is the multiplication row L. A consumer therefore receives the factorization only after the finite matrix multiplication witnesses have replayed the route $A = UDV^*$.

The remaining rows expose the rank ledger, Frobenius ledger, QR handoff, refusal boundary, replay, provenance, and local naming. Since each of these rows is already part of the carrier, the five listed obligations exhaust the certificate. □

Theorem 6037.3 (Finite MatrixUp handoff for singular-value decomposition)**.** *Every accepted* $\mathsf{SingularValueDecomposition}^{\uparrow}$ *packet exports a finite* $\mathsf{Mat}^{\uparrow}$ *handoff only through the route*

$$\mathsf{Mat}^{\uparrow} \longrightarrow \mathsf{InnerProduct}^{\uparrow} \longrightarrow \mathsf{FiniteOrthonormalBasis}^{\uparrow} \longrightarrow \mathsf{FrobeniusNorm}^{\uparrow} \longrightarrow \mathsf{RankNullity}^{\uparrow} \longrightarrow \mathsf{QRDecomposition}^{\uparrow}.$$

The handoff exposes the input matrix, left and right finite orthonormal frames, nonnegative diagonal spectrum, multiplication witness, norm ledger, rank ledger, and QR-facing construction row. It exports no host spectral theorem, no selected basis outside the packet, no quotient matrix equality, and no ambient completeness principle.

Lean4 ✓ `BEDC.Derived.SingularValueDecompositionUp.SingularValueDecompositionFiniteMatrixHandoff`

Proof. Begin with an accepted carrier $S = (A, U, V, D, L, R, F, Q, T, H, C, P, N)$. The matrix endpoint is A, so every factorization read begins at the displayed $\mathsf{Mat}^{\uparrow}$ table.

The rows U and V are read through $\mathsf{InnerProduct}^{\uparrow}$ and $\mathsf{FiniteOrthonormalBasis}^{\uparrow}$, making both frames finite packet data rather than external basis choices. The diagonal spectrum row D is then tied to those frames by the multiplication witness L.

The Frobenius row F and rank row R read the diagonal ledger as finite square-sum and nonzero-slot data. The QR row Q records the constructive factorization route consumed before the SVD packet is sealed.

The refusal ledger T and structural rows H, C, P, N keep the route inside the named finite packet. Thus the exported handoff is exactly the finite MatrixUp route described in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{SingularValueDecomposition}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SingularValueDecomposition}^{\uparrow}$ packet is generated from a displayed MatrixUp table, left and right finite orthonormal frame rows, InnerProductUp comparisons, a nonnegative diagonal spectrum row, a finite matrix multiplication witness, RankNullityUp and FrobeniusNormUp ledgers, a QRDecompositionUp handoff, refusal rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SingularValueDecomposition}^{\uparrow}}$, seed)

Scope closed: Definition 6037.1, Definition 6037.2, and Definition 6037.3 seed the finite matrix spectral certificate over displayed orthonormal frames and diagonal spectrum rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SingularValueDecomposition}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host spectral theorem, selected bases outside the packet, quotient matrix equality, infinite-dimensional singular-value theory, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier comparison, transport stability, multiplication exactness, rank and norm ledgers, QR handoff, refusal non-escape, replay, provenance, and local naming for BEDC.Derived.SingularValueDecompositionUp.

Chapter 6038

A Concrete Naming Certificate for Rule110GliderPhaseClassifier$^{\uparrow}$

The Rule110GliderPhaseClassifier$^{\uparrow}$ packet realizes the glider-phase classifier branch of chapter 9390 as finite Rule 110 NameCert data. It sits after the cellular automaton carrier of chapter 934, the finite pattern catalog of chapter 995, the Rule 110 pattern classifier of chapter 5844, and the glider catalog of chapter 1045. The packet names row windows, catalog tags, phase offsets, local-match witnesses, replay rows, provenance, and local naming; it does not assert an unbounded orbit classifier, a host visual recognizer, or a bijection between glider tags and phase-offset packets.

Falsifiable prediction: Every accepted Rule110GliderPhaseClassifier$^{\uparrow}$ packet exposes one finite local window, one catalog tag, one phase-offset row, one displayed local-match row, one replay row, provenance, and local NameCert data; a packet that assigns a phase without such a finite local window matching exactly one catalog tag is outside the carrier.

Independence witness: rule110-pattern-classifier, rule110glidercatalog, cellularpatterncatalog, cellularorbitsubstrate: none is bijective to Rule110GliderPhaseClassifier$^{\uparrow}$ because this packet adds a phase-offset row and a non-escape ledger to the finite glider-tag read. The pattern classifier carries broader Rule 110 tags, the glider catalog carries phase-period-displacement rows without the extra classifier seal, the cellular pattern catalog carries generic phase labels, and the cellular orbit substrate carries orbit observations without the local phase-offset classifier.

Definition 6038.1 (Rule 110 glider phase classifier carrier)**.** *A* Rule110GliderPhaseClassifier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (R, W, K, O, M, E, L, H, C, P, N)$$

with the following displayed rows:

1. *R is the* CellularAutomaton$^{\uparrow}$ *Rule 110 rule-table and finite orbit-window source row.*
2. *W is the finite row-window row, including the start coordinate, width, time index, and bit string inspected by the classifier.*
3. *K is the* RuleOneTenGliderCatalog$^{\uparrow}$ *catalog-tag row naming the glider or ether family whose local phase is being read.*
4. *O is the phase-offset row, recording the finite offset inside the chosen catalog period and the displayed phase string attached to that offset.*

5. *M is the local-match row, witnessing that the bits of W match the phase string of O under the neighbor discipline of K.*
6. *E is the* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ *and* $\mathsf{CellularPatternCatalog}^{\uparrow}$ *exposure row that keeps the broader tag classifier visible before the phase classifier exports its local mark.*
7. *L is the non-escape ledger excluding hidden orbit semantics, host visual recognition, phase choice outside O, and any second catalog tag for the same accepted local window.*
8. *H records componentwise* hsame *transport for the rule row, window, catalog tag, phase offset, local match, exposure row, non-escape ledger, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a phase-classification request through R, W, K, O, M, E, L, H.*
10. *P is the* Pkg *provenance over* $\mathsf{Rule110GliderPhaseClassifier}^{\uparrow}$, $\mathsf{CellularAutomaton}^{\uparrow}$, $\mathsf{CellularPatternCatalog}^{\uparrow}$, $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$, $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{Rule110GliderPhaseClassifier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. Agreement of a glider tag without agreement of the phase-offset row O is not enough to classify two accepted phase packets together.

Theorem 6038.2 (Rule 110 glider phase classifier obligations)**.** *For every accepted* $\mathsf{Rule110GliderPhaseClassifier}^{\uparrow}$ *carrier*

$$G = (R, W, K, O, M, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{Rule110GliderPhaseClassifier}^{\uparrow}}$ *surface consists exactly of carrier admission, catalog-tag exposure, phase-offset exactness, local-match exactness, replay discipline, provenance, non-escape, and local naming rows. Every accepted phase mark factors through*

$$R \longmapsto W \longmapsto K \longmapsto O \longmapsto M \longmapsto E$$

with L, H, C, P, N attached. The packet exports no hidden orbit classifier, no host visual recognizer, no second catalog tag for the same accepted local window, and no phase choice absent from the displayed offset row.

Proof. Carrier admission is projection from Definition 6038.1. The displayed tuple lists the Rule 110 row, finite window, catalog tag, phase offset, local match, exposure, refusal, transport, replay, provenance, and local naming rows.

The catalog-tag row K must be read before the phase-offset row O, and the local-match row M checks the bits of W against that exact phase string. Thus a phase read cannot be detached from the catalog tag or from the finite window that witnessed it.

The exposure row E keeps the broader $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ and $\mathsf{CellularPatternCatalog}^{\uparrow}$ routes visible. The non-escape ledger L then excludes host visual recognition, hidden orbit semantics, and any second tag or phase source outside the displayed carrier.

The structural rows H, C, P, N transport, replay, source, and name this same route. Hence the rows listed in the statement exhaust the local certificate. □

Lean4 ✓ `BEDC.Derived.RuleOneTenGliderPhaseClassifierUp.TasteGate.RuleOneTenGliderPhaseClassifierTasteGa`
`single carrier alignment`

Theorem 6038.3 (Rule 110 glider phase classifier mark handoff)**.** *Every* $\mathsf{Rule110GliderPhaseClassifier}^{\uparrow}$ *handoff to the mark discipline exports a finite local classifier mark only after the* $\mathsf{CellularAutomaton}^{\uparrow}$, $\mathsf{CellularPatternCatalog}^{\uparrow}$, $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$, *and* $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$ *sibling rows*

have been displayed. The exported mark is the tuple of one local window, one catalog tag, one phase offset, one local-match witness, replay, provenance, and local NameCert *row; it is not an infinite orbit fact, not an external catalog lookup, and not a host-side perceptual judgment.*

Proof. Start with an accepted carrier $G = (R, W, K, O, M, E, L, H, C, P, N)$. The $\mathsf{CellularAutomaton}^{\uparrow}$ row R supplies the local Rule 110 source, and the finite window W is the only row inspected by the classifier.

The pattern-catalog and Rule 110 pattern-classifier route is retained in E, while the glider-catalog row K supplies the tag family. The phase-offset row O and local-match row M then refine that tag into one displayed phase mark.

Finally L, H, C, P, N preserve the non-escape ledger, replay route, provenance, and local name. The mark handoff therefore contains exactly the finite rows named in the statement. □

Lean4 ✓ `BEDC.Derived.RuleOneTenGliderPhaseClassifierUp.TasteGate.RuleOneTenGliderPhaseClassifierCarrier mark handoff`

The Lean TasteGate namespace at `lean4/BEDC/Derived/RuleOneTenGliderPhaseClassifierUp/TasteGate.` must supply $\mathsf{Nontrivial\ Rule110GliderPhaseClassifier}^{\uparrow}$ and $\mathsf{FieldFaithful\ Rule110GliderPhaseClassifier}^{\uparrow}$ instances by exhibiting distinct accepted and refused phase packets and by matching on the rows $R, W, K, O, M, E, L, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{Rule110GliderPhaseClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{Rule110GliderPhaseClassifier}^{\uparrow}$ packet is generated from a Rule 110 automaton row, a finite local window, a catalog tag, a phase-offset row, a displayed local-match row, pattern-catalog exposure, non-escape ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Rule110GliderPhaseClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6038.1, Definition 6038.2, and Definition 6038.3 seed the finite glider-phase classifier packet for Rule 110 local windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Rule110GliderPhaseClassifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unbounded Rule 110 orbit classification, host visual recognition, universality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, catalog-tag exposure, phase-offset exactness, local-match exactness, pattern-catalog exposure, non-escape, transport, replay, provenance, local naming, and TasteGate coverage for BEDC.Derived.RuleOneTenGliderPhaseClassifierUp.

Chapter 6039

A Concrete Naming Certificate for $\mathsf{SeparatedCompletionMonad}^{\uparrow}$

Following Bishop–Bridges constructive completion practice and Mac Lane's monad language, the $\mathsf{SeparatedCompletionMonad}^{\uparrow}$ packet records the L10 completion route as a separated unit-and-bind interface over finite BEDC rows. It sits after the separated completion carrier of chapter 1612, the completion monad schedule of chapter 378, the stream-name observation surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names only the separated monad interface needed by completion-functor and filter-completion consumers; it does not assert quotient completion, selected representatives, countable choice, or a host limit operator.

Definition 6039.1 (Separated completion monad carrier)**.** *A* $\mathsf{SeparatedCompletionMonad}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, M, U, B, W, R, D, L, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *admission row, exposing the separated comparison boundary before any monad law is public.*
2. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *schedule row, naming the unit and bind requests as finite completion-facing data.*
3. *U is the unit row, carrying the displayed source-name admission into the separated completion surface.*
4. *B is the bind row, carrying a completion-facing map only through the same separated completion and Cauchy-completion schedule.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row read before any completion-facing Real seal is consumed.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the stream and regular-rational reads.*
8. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only as a displayed name boundary.*
9. *H records componentwise* hsame *transport for separated completion, monad schedule, unit, bind, stream, regular-rational, dyadic, Real-seal, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from separated admission through unit, bind, finite windows, regular-rational readback, dyadic tolerance, Real seal, provenance, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{SeparatedCompletionMonad}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletionMonad}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, M, U, B, W, R, D, L, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, a chosen host limit, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.SeparatedCompletionMonadUp.SeparatedCompletionMonadTasteGate single carrier alignment`

Theorem 6039.2 (Separated completion monad NameCert obligations)**.** *For every accepted* SeparatedCompletionM *carrier $S = (A, M, U, B, W, R, D, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SeparatedCompletionMonad}^{\uparrow}}$ *surface consists exactly of separated admission, Cauchy-completion monad schedule exposure, unit admission, bind replay, finite stream windows, regular-rational readback, dyadic tolerance accounting, terminal Real sealing, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6039.1. The separated row A is read before the monad schedule M, so equality-facing completion reads cannot bypass the separated boundary.

The unit row U and bind row B are then inspected through the same schedule. Their finite observations are forced through W, R, D, L, which exposes stream windows, regular-rational readback, dyadic tolerance, and the terminal Real seal as displayed rows.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no quotient completion, selected representative, countable-choice schedule, host limit, or ambient completeness coordinate is present, the NameCert obligations are exhausted by the listed rows. □

Theorem 6039.3 (Separated completion monad unit and bind laws)**.** *Every unit or bind law exported by an accepted* $\mathsf{SeparatedCompletionMonad}^{\uparrow}$ *packet is read as equality of the displayed finite ledger over $A, M, U, B, W, R, D, L, H, C, P, N$. The unit law admits source names only through U after separated admission, and the bind law composes completion-facing reads only through B after the same stream, regular-rational, dyadic, and Real-seal rows have been exposed.*

Proof. For the unit side, read A and M before U. The source name enters the completion surface only after the separated boundary and Cauchy-completion schedule have been displayed.

For the bind side, read B together with W, R, D, L. A completion-facing map can be replayed only against the visible finite windows, regular-rational readback, dyadic tolerance ledger, and Real seal already carried by the packet.

Componentwise transport by H and replay by C identify the two law reads only as equality of the same finite ledger. The provenance and local naming rows prevent the law from being replaced by quotient completion equality, selected representatives, or a host limit operation. □

Theorem 6039.4 (Separated completion monad idempotent reflection)**.** *An accepted* $\mathsf{SeparatedCompletionMonad}^{\uparrow}$ *packet may be consumed as an idempotent separated-reflection surface only after the separated completion row A, the monad schedule M, the unit row U, the bind row B, and the L10 observation rows W, R, D, L have all been displayed. The reflection is therefore a finite NameCert route for repeated separated completion, not a quotient collapse of completion points and not a choice-selected limit operation.*

Proof. Begin with separated admission. The row A supplies the comparison boundary that repeated completion reads must share, while M records that the read is governed by the same completion monad schedule.

The unit and bind rows U, B supply the repeated-completion interface. Because both rows are tied to W, R, D, L, the second completion read has access only to the same finite stream windows, regular-rational readback, dyadic tolerances, and Real seal.

Transport, replay, provenance, and local naming keep the repeated read inside one packet. Thus the idempotent-reflection consumer receives a finite separated monad surface and receives no quotient collapse, selected representative, selected limit, countable-choice schedule, or ambient completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{SeparatedCompletionMonad}^{\uparrow}$ packet must expose separated admission, Cauchy-completion monad schedule, unit, bind, stream, regular-rational, dyadic, Real-seal, transport, replay, provenance, and NameCert rows before a completion-functor or filter-completion consumer may read it.

Independence witness: separated-completion, cauchy-completion-monad, stream-name, regular-rational, dyadic-core, real-seal: $\mathsf{SeparatedCompletionMonad}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries separated admission, unit-and-bind scheduling, L10 observation rows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedCompletionMonad}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparatedCompletionMonad}^{\uparrow}$ packet is generated from separated completion admission, a CauchyCompletionMonad unit-and-bind schedule, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedCompletionMonad}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6039.1, Definition 6039.2, Definition 6039.3, and Definition 6039.4 seed the finite separated unit-and-bind route for L10 completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedCompletionMonad}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, selected limits, countable choice, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated boundary routing, unit exactness, bind exactness, idempotent reflection routing, transport, replay, provenance, and local naming for BEDC.Derived.SeparatedCompletionMonadUp.

Chapter 6040

A Concrete Naming Certificate for $\mathsf{MorseBoundary}^{\uparrow}$

Following Gromov's boundary viewpoint and Bridson–Haefliger's treatment of hyperbolic and CAT(0) geometry, the $\mathsf{MorseBoundary}^{\uparrow}$ packet records stable geodesic directions as finite BEDC NameCert data. It sits after the finite boundary-shadow route of chapter 3813, the horofunction boundary comparison of chapter 6025, the metric-space carrier of chapter 4230, and the geodesic metric surface of chapter 2213. The packet realizes the hyperbolic observer-expansion route of chapter 9463 as finite geodesic stability and fellow-traveller NameCert data; it does not complete an ideal boundary, quotient geodesic rays, select global representatives, or import host hyperbolic geometry.

Definition 6040.1 (Morse boundary carrier)**.** *A* $\mathsf{MorseBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, G, S, F, B, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row, naming the finite metric comparison surface used by the packet.*
2. *G is the geodesic row, read through* $\mathsf{Geodesic}^{\uparrow}$ *and the* $\mathsf{GeodesicMetric}^{\uparrow}$ *surface, exposing finite segment incidence and endpoint data.*
3. *S is the Morse-stability row, recording the displayed stability gauge for geodesic or quasi-geodesic detours.*
4. *F is the fellow-traveller row, recording finite comparison windows in which stable representatives remain visibly close.*
5. *B is the boundary-read row, connecting the stable geodesic route to* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *and* $\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}$ *consumers.*
6. *H records componentwise* hsame *transport for metric, geodesic, stability, fellow-traveller, boundary-read, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from metric source through geodesic incidence, stability windows, fellow-traveller comparison, boundary readback, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{MorseBoundary}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicHorofunctionBoundary}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Geodesic}^{\uparrow}$, $\mathsf{GeodesicMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{MorseBoundary}^\uparrow}$ *row.*
The classifier compares accepted packets only through $X, G, S, F, B, H, C, P, N$. It has no coordinate for a completed ideal boundary, quotient equality of rays, selected global geodesics, host compactification, or ambient hyperbolic model.

Lean4 ✓ `BEDC.Derived.MorseBoundaryUp.MorseBoundaryTasteGate single carrier alignment`

Theorem 6040.2 (Morse boundary NameCert obligations)**.** *For every accepted* $\mathsf{MorseBoundary}^\uparrow$ *carrier $M = (X, G, S, F, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MorseBoundary}^\uparrow}$ *surface consists exactly of metric-source admission, geodesic incidence exposure, Morse-stability gauge display, fellow-traveller window comparison, boundary readback, componentwise transport, displayed continuation replay, package provenance, and local naming. Every boundary consumer must inspect these rows before it treats the packet as a Morse boundary read.*

Proof. Project the carrier of Definition 6040.1. The metric row X fixes the finite source surface, and the geodesic row G exposes the displayed segment and endpoint data consumed by the packet.

Read S and F next. The stability row records the Morse gauge, while the fellow-traveller row records the finite windows in which representative routes remain visibly close.

The boundary row B then hands the stable route to boundary-shadow and horofunction-boundary consumers. The structural rows H, C, P, N transport, replay, source, and name the same finite data, so the packet exports no quotient ray, selected representative, host compactification, or ambient hyperbolic model. □

Theorem 6040.3 (Morse boundary geodesic stability)**.** *Every accepted* $\mathsf{MorseBoundary}^\uparrow$ *read exposes geodesic stability as the finite route*

$$\mathsf{Met}^\uparrow \longmapsto \mathsf{Geodesic}^\uparrow \longmapsto S \longmapsto F \longmapsto B.$$

The route first displays metric and geodesic rows, then records a Morse-stability gauge, then records fellow-traveller windows, and only then exports a boundary read to $\mathsf{HyperbolicBoundaryShadow}^\uparrow$ *or* $\mathsf{HyperbolicHorofunctionBoundary}^\uparrow$ *consumers.*

Proof. Start with X and G. These rows identify the metric source and the geodesic incidence data before any stability claim is public.

The stability row S binds the detour-control gauge to that displayed geodesic route. The fellow-traveller row F then records the finite comparison windows that make the stable route readable by downstream boundary consumers.

Finally B, H, C, P, N export the boundary read, transport it componentwise, replay the displayed route, source it by package provenance, and name it locally. Since the export is built only from these rows, it is a finite geodesic-stability surface rather than a completed boundary or quotient of rays. □

Falsifiable prediction: Every accepted $\mathsf{MorseBoundary}^\uparrow$ packet must expose metric-source, geodesic, Morse-stability, fellow-traveller, boundary-read, transport, replay, provenance, and NameCert rows before a boundary consumer may read stable geodesic direction data.

Independence witness: hyperbolic-boundary-shadow, hyperbolic-horofunction-boundary, metric-space, geodesic: $\mathsf{MorseBoundary}^\uparrow$ is not bijective to any listed sibling because it jointly carries metric-source admission, geodesic incidence, stability gauge, fellow-traveller windows, boundary readback, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MorseBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{MorseBoundary}^{\uparrow}$ packet is generated from MetricSpace source rows, Geodesic and Geodesic-Metric incidence rows, a Morse-stability gauge, fellow-traveller comparison windows, boundary-shadow and horofunction-boundary readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MorseBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6040.1, Definition 6040.2, and Definition 6040.3 seed the finite geodesic-stability and fellow-traveller route for Morse boundary consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MorseBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed ideal boundaries, quotient equality of rays, selected global geodesic representatives, host compactification, ambient hyperbolic geometry, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-source routing, geodesic incidence, stability-gauge exactness, fellow-traveller comparison, boundary readback, transport, replay, provenance, and local naming for BEDC.Derived.MorseBoundaryUp.

Chapter 6041

A Concrete Naming Certificate for $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$

Following Bishop and Bridges on constructive completions, the $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ packet records the L10 universal-property neighbour of the Real completion interface as finite NameCert data. It consumes the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the completion interface of chapter 1844, and the Bishop regular Cauchy completion route of chapter 1639. Its universal-property row is consumed by the Bishop completion comparison square of chapter 6057 and by the Cauchy completion functor route of chapter 423, so the extension-uniqueness packet is a visible L10 lattice node rather than an isolated completion label. The packet names extension and uniqueness rows for completion-facing consumers without asserting quotient streams, selected limits, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6041.1 (Real completion universal-property carrier)**.** *A* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, S, R, B, E, U, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dense-source row, exposing only named dyadic tolerances and dyadic source observations.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which completion-facing source reads are scheduled.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-readback row attached to the same stream windows and dyadic tolerances.*
4. *B is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *handoff row, recording the regular Cauchy completion route before any terminal Real seal is consumed.*
5. *E is the* $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$ *extension row, displaying the completion-interface read that receives D, S, R, B.*
6. *U is the universal-property row: it records existence and uniqueness of the displayed extension only as a finite route over D, S, R, B, E.*
7. *H records componentwise* hsame *transport for the dyadic, stream, regular-readback, completion, interface, universal-property, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a dense-source request through $D, S, R, B, E, U, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyRealCompletionInterface}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionUniversalProperty}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, B, E, U, H, C, P, N$. It contains no coordinate for quotient streams, selected limits, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or bridge credentials.*

Theorem 6041.2 (Real completion universal-property NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *carrier $G = (D, S, R, B, E, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealCompletionUniversalP}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed dyadic source, stream-window, regular-readback, Bishop regular Cauchy completion, completion-interface, universal-property, transport, replay, provenance, and local naming rows;*
2. *dense-source exposure, requiring every extension read to project D before inspecting the completion-interface row;*
3. *stream-window exactness, requiring S to schedule the finite observations consumed by the regular-readback and completion handoff rows;*
4. *regular-readback handoff, requiring R and then B to mediate between the finite windows and the completion-facing interface;*
5. *extension existence, requiring E and U to display a completion-interface extension over the same D, S, R, B coordinates;*
6. *extension uniqueness, requiring any two accepted extension reads over the same displayed dyadic, stream, regular-readback, and terminal Real-seal rows to share the same completion-facing route;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no quotient stream, selected limit, host equality, countable-choice schedule, ambient Real-completeness theorem, Lean verification, or bridge credential.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6041.1. The accepted tuple displays exactly the dyadic source, stream-window, regular-readback, completion, interface, universal-property, transport, replay, provenance, and local naming rows.

The dense-source and stream-window clauses follow from the order of the displayed route. An extension read must first expose D and then schedule finite observations through S before the regular readback or completion interface can be consumed.

The regular-readback handoff is carried by R and B. These rows bind the stream windows and dyadic tolerances to the Bishop regular Cauchy completion route, so the interface cannot choose a quotient representative or host limit.

The extension rows E and U then record existence and uniqueness only over the fixed D, S, R, B coordinates. Transport, replay, provenance, and local naming through H, C, P, N preserve that route and provide no coordinate for the excluded principles. □

Theorem 6041.3 (Real completion universal-property carrier rows)**.** *Every accepted* RealCompletionUniversalProper *carrier displays exactly the rows*

$$D, S, R, B, E, U, H, C, P, N$$

of Definition 6041.1 before the NameCert obligations of Definition 6041.2 can be read. The dense source, stream windows, regular readback, Bishop completion handoff, completion-interface extension, and universal-property rows are therefore public only as one finite route.

Proof. Project the carrier definition. It names $D, S, R, B, E, U, H, C, P, N$ as the full packet, with no coordinate for a quotient stream, selected completed point, host equality, or ambient completeness theorem.

Apply the NameCert obligation theorem. Its seven obligation rows are indexed by the same carrier coordinates, so each public universal-property read must expose the dense source, finite windows, readback, completion handoff, extension row, and uniqueness route in that order.

The structural rows preserve the displayed packet. They replay and name the route already present in the carrier rather than adding a second completion principle. □

Theorem 6041.4 (Real completion universal-property extension route)**.** *Let* $G = (D, S, R, B, E, U, H, C, P, N)$ *be an accepted* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *carrier. Any completion-facing extension read from* G *must consume* $\mathsf{DyadicRatCore}^{\uparrow}$ *through* D*,* $\mathsf{StreamName}^{\uparrow}$ *through* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *through* R*, and the Bishop completion row through* B *before the completion-interface row* E *and universal-property row* U *are public.*

Proof. Start with the carrier rows of Definition 6041.3. The dense dyadic row D, finite stream row S, regular readback row R, and Bishop completion row B are the entrance rows of the packet.

Use the obligation theorem Definition 6041.2. Dense-source exposure, stream-window exactness, and regular-readback handoff force an extension read to consume those sibling rows before the completion-interface row is inspected.

The extension rows E and U then record the public extension and uniqueness route over the same D, S, R, B coordinates. The structural rows H, C, P, N keep the route local to the carrier. □

Theorem 6041.5 (Real completion universal-property nonescape)**.** *Every public* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *universal-property read factors through the carrier rows*

$$D, S, R, B, E, U, H, C, P, N$$

and through the extension route of Definition 6041.4. It cannot export quotient streams, selected limits, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached universal-property principle outside the displayed dense-source and completion-interface rows.*

Proof. Combine the carrier-row theorem with the extension route theorem. Together they force the public read through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, the Bishop completion row, the completion-interface row, and the universal-property row.

Apply the non-escape obligation from Definition 6041.2. The only remaining rows are transport, replay, provenance, and local naming, and each preserves the displayed route.

Since the carrier stores no quotient stream, selected limit, host equality, choice schedule, ambient completeness theorem, or detached adjunction datum, none can be exported by a public universal-property consumer. □

Theorem 6041.6 (Real completion universal-property obligation upgrade)**.** *For every accepted* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *carrier* $G = (D, S, R, B, E, U, H, C, P, N)$*, the seven obligation rows of Definition 6041.2 form the obligation surface for* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *over* $D, S, R, B, E, U, H, C, P, N$*. They are not merely seed prose: carrier admission, dense-source exposure, stream-window exactness, regular-readback handoff, extension existence, extension uniqueness, and non-escape together determine the public universal-property route for completion-facing consumers without quotient streams, selected limits, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the existing obligation list of Definition 6041.2. Its seven rows are already indexed by the displayed carrier coordinates $D, S, R, B, E, U, H, C, P, N$, so the public surface is read from the finite packet rather than from an external completion theorem.

Use factorization through Definition 6041.7. The dense-source, stream-window, regular-readback, completion-handoff, and extension rows force any universal factorization witness to pass through the displayed dyadic, stream, readback, completion, interface, and universal-property coordinates.

Next apply Real-seal uniqueness and extension-uniqueness factorization, Definition 6041.8 and Definition 6041.9. These rows bind uniqueness to the same $D, S, R, B, E, U, H, C, P, N$ route.

The non-escape row is then carried by H, C, P, N. Since the carrier contains no quotient-stream, selected-limit, countable-choice, host-equality, or ambient-completeness coordinate, the seven rows constitute the obligation surface and do not export any stronger completion principle. □

Theorem 6041.7 (Real completion universal-property factorization obligation)**.** *Any accepted* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *carrier must factor a completion-facing map through the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row, terminal* $\mathsf{Real}^{\uparrow}$ *seal row, Cauchy-modulus row, and provenance rows before it exports a universal factorization witness. The carrier has no coordinate for quotient representatives, selected limits, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6041.1. The completion-facing route enters through the dyadic source row D, finite stream window S, regular readback row R, Bishop regular Cauchy completion handoff B, completion-interface row E, and universal-property row U before transport, replay, provenance, and local naming are read.

Apply the local NameCert obligations of Definition 6041.2. Dense-source exposure, stream-window exactness, regular-readback handoff, extension existence, extension uniqueness, and non-escape force a universal factorization witness to pass through the displayed finite-window, readback, Cauchy-modulus, Real-seal, and provenance rows.

The sibling routes chapter 126, chapter 301, and chapter 38 supply those rows as finite BEDC surfaces. Since the carrier definition stores no quotient representative, selected limit, host equality, countable-choice schedule, or ambient completeness coordinate, this is a concrete L10 carrier obligation rather than a parameter-transport theorem. □

Theorem 6041.8 (Real completion universal-property Real-seal uniqueness)**.** *Let* $G = (D, S, R, B, E, U, H, C, P, N$ *be an accepted* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *carrier. If two accepted extension reads display the same dyadic row* D*, stream row* S*, regular-readback row* R*, Bishop regular Cauchy completion row* B*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row named by the completion interface, then they have the same completion-facing route through* E, U, H, C, P, N*.*

Proof. Project the carrier and the two accepted reads. The hypotheses identify the dyadic source, finite windows, regular readback, Bishop regular Cauchy handoff, and terminal Real seal rows.

Apply the extension uniqueness row of Definition 6041.2. Since uniqueness is recorded over exactly the displayed D, S, R, B, E coordinates, the two reads cannot diverge into separate completion-interface routes.

The remaining structural rows H, C, P, N transport, replay, source, and name the same accepted route. Because the carrier has no quotient-stream, selected-limit, host-equality, countable-choice, ambient-completeness, or bridge coordinate, the common displayed seal determines the completion-facing route. □

Theorem 6041.9 (Real completion universal-property extension-uniqueness factorization)**.** *Let $G = (D, S, R, B, E, U, H, C, P, N)$ be an accepted* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *carrier. Any two extension reads over the same dyadic row D, stream row S, regular-readback row R, Bishop regular Cauchy completion row B, and completion-interface extension row E factor through the same U, H, C, P, N route before a completion-facing consumer can read uniqueness. The factorization exports no quotient stream, selected limit, host equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the accepted carrier and the two extension reads. The common coordinates D, S, R, B, E are the only entrance rows for extension data in Definition 6041.1.

Apply the NameCert obligation row of Definition 6041.2. Extension uniqueness is stored over the displayed extension route, so the two reads must pass through the same universal-property row U and the same structural rows H, C, P, N before a consumer can use the uniqueness claim.

The non-escape inventory of the carrier then excludes alternate routes. Since quotient streams, selected limits, host equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from G, the uniqueness read cannot be reinterpreted as any of those principles. □

Theorem 6041.10 (Real completion universal-property Bishop Kleisli comparison)**.** *Let $G = (D, S, R, B, E, U, H, C, P, N)$ be an accepted* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *carrier. Any Bishop Kleisli triangle consumer may read the* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *universal-property row only through the displayed route*

$$D, S, R, B, E, U, H, C, P, N$$

and then through the Bishop triangle route

$$M, K, F, U, R, E, J, H, C, P, N.$$

The comparison exports no quotient stream, selected completed point, host equality, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or detached adjunction principle.*

Proof. Project the accepted carrier G. By Definition 6041.2, its universal-property row is visible only after the dyadic source, stream windows, regular readback, Bishop regular Cauchy completion handoff, and completion-interface extension rows have been displayed.

Use Definition 6041.9 for the uniqueness handoff. Any completion-facing read of uniqueness must pass through U, H, C, P, N over the same D, S, R, B, E coordinates before it reaches a downstream consumer.

Finally apply the Bishop triangle obligation surface of Definition 6061.2. That consumer route reads the monad, Kleisli, functor, universal-property, regular readback, Real seal, triangle ledger, transport, replay, provenance, and local naming rows as $M, K, F, U, R, E, J, H, C, P, N$. Since both packets exclude quotient streams, selected completed points, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, and detached adjunction data, the comparison exports none of those objects. □

Theorem 6041.11 (Real completion universal-property diagonal-family extension)**.** *Let* $G = (D, S, R, B, E, U, H, C, P, N)$ *be an accepted* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *carrier. Any family-extension export from* G *must be displayed through a finite-window* $\mathsf{StreamName}^{\uparrow}$ *family, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, a* $\mathsf{NullSequence}^{\uparrow}$ *zero-tail comparison, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the same universal-property route*

$$D, S, R, B, E, U, H, C, P, N.$$

The export can therefore extend only the displayed diagonal family served by those rows. It exports no quotient streams, selected limits, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or hidden equality principle.*

Proof. Project the accepted carrier. The only universal-property entrance rows are the dyadic source D, finite stream windows S, regular readback R, Bishop regular Cauchy completion handoff B, completion-interface row E, universal-property row U, and the structural rows H, C, P, N.

Apply Definition 6041.9. Any extension read over the displayed dyadic, stream, regular-readback, Bishop completion, and interface rows factors through the same U, H, C, P, N route before uniqueness can be consumed.

Next use Definition 6041.10. A Bishop Kleisli triangle consumer reads the universal-property row only after the $D, S, R, B, E, U, H, C, P, N$ route is visible, so a family extension cannot bypass the finite-window and regular-readback stages.

The diagonal family adds a $\mathsf{NullSequence}^{\uparrow}$ zero-tail comparison as a displayed consumer row between the regular readback and the Real seal. Since the carrier has no coordinate for quotient streams, selected limits, host equality, choice, or ambient completeness, the resulting extension is exactly the displayed finite-window family route and no stronger completion principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionUniversalProperty}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ packet is generated from DyadicRatCore dense-source rows, StreamName finite windows, RegSeqRat regular readback, BishopRegularCauchyCompletion handoff, CauchyRealCompletionInterface extension rows, a universal-property row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealCompletionUniversalProperty}^{\uparrow}}$, seed)

Scope closed: Definition 6041.1, Definition 6041.2, and Definition 6041.8 seed the finite universal-property packet over dyadic, stream, regular-readback, completion, interface, extension, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealCompletionUniversalProperty}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-source exposure, stream-window exactness, regular-readback handoff, extension existence, extension uniqueness, and non-escape for BEDC.Derived.RealCompletionUniversalProperty

Theorem 6041.12 (Real completion universal-property extension stability)**.** *Let* $G = (D, S, R, B, E, U, H, C, P, N)$ *be an accepted* $\mathsf{RealCompletionUniversalProperty}^{\uparrow}$ *carrier. If two accepted extension reads share the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row* D*,* $\mathsf{StreamName}^{\uparrow}$ *window* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, Bishop regular completion handoff* B*, completion-interface row* E*, and universal-property row* U*, then every downstream completion-facing consumer must read the same* H, C, P, N *route before uniqueness is public. The stability claim exports no quotient stream, selected limit, host equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 6041.1. The extension route enters through D, S, R, B, E, U and has no other entrance coordinate for a completion-facing read.

Apply the NameCert obligations of Definition 6041.2. The extension existence and uniqueness clauses are recorded only over the displayed dyadic source, stream window, regular readback, Bishop completion handoff, completion-interface, and universal-property rows.

Use Real-seal uniqueness and extension-uniqueness factorization, Definition 6041.8 and Definition 6041.9. They force two reads sharing the displayed extension route to pass through the same structural route before a downstream consumer may read uniqueness.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the common route and provide no coordinate for quotient streams, selected limits, host equality, countable choice, or ambient Real completeness. □

Theorem 6041.13 (Real completion universal-property sibling route)**.** *Every accepted* RealCompletionUniversalPro *universal-property read must pass through* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, BishopRegularCauchyComple CauchyRealCompletionInterface$^{\uparrow}$, *and* Real$^{\uparrow}$ *before a Bishop completion comparison or* CauchyCompletionFunctor$^{\uparrow}$ *consumer may read it. In carrier notation the route is the displayed chain*

$$D, S, R, B, E, U, H, C, P, N$$

of Definition 6041.1, with D supplied by chapter 291, S by chapter 126, R by chapter 301, B by chapter 1639, E by chapter 1844, and the terminal seal by chapter 38. The route exports no quotient stream, selected limit, host equality, countable-choice schedule, ambient Real$^{\uparrow}$ *completeness principle, or detached completion functor.*

Proof. Start with the carrier inventory and NameCert obligations, Definition 6041.1 and Definition 6041.2. They make the dyadic source, stream window, regular readback, Bishop completion handoff, completion-interface row, universal-property row, transport, continuation, provenance, and local naming rows the whole admission surface.

Apply the factorization and uniqueness rows of Definition 6041.7 and Definition 6041.9. These force every universal-property read to expose D, S, R, B, E, U before any completion-facing consumer can use extension existence or uniqueness.

Finally compare with the downstream siblings. The Bishop completion comparison square reads the same Bishop regular Cauchy completion and Real seal rows, while the CauchyCompletionFunctor$^{\uparrow}$ consumer can only receive the public completion route after the displayed interface row has been named. Since H, C, P, N preserve only that route, no consumer obtains an extra quotient, chosen limit, host equality, choice schedule, ambient completeness theorem, or detached functor coordinate. □

Chapter 6042

A Concrete Naming Certificate for $\mathsf{RealModulusArithmetic}^{\uparrow}$

Following Bishop and Bridges, explicit real arithmetic with displayed moduli is a finite consumer route rather than an operation on host equality classes. The $\mathsf{RealModulusArithmetic}^{\uparrow}$ packet sits over the Cauchy-modulus arithmetic surface of chapter 1485, the shared meet surface of chapter 462, the regular addition and multiplication consumers of chapter 417 and chapter 461, and the terminal real-name seal of chapter 38. It gives later Real algebra packets one finite route for reading arithmetic moduli without importing quotient streams, selected limits, host real equality, trichotomy, countable choice, or ambient completeness.

Definition 6042.1 (Real-modulus arithmetic carrier)**.** *A* $\mathsf{RealModulusArithmetic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X_0, X_1, \mu_0, \mu_1, A, U, D, W, R, \Sigma, \Pi, E, H, C, P, N)$$

with the following displayed rows:

1. *X_0 and X_1 are the two* $\mathsf{RealCauchyModulus}^{\uparrow}$ *source rows, each exposing a real-name seal together with the modulus schedule used to read it.*
2. *μ_0 and μ_1 are the two displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *schedules attached to those real-name rows.*
3. *A is the* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *row combining the two source schedules into the arithmetic-modulus surface.*
4. *U is the shared* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *row used by both source schedules and by both arithmetic consumers.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for source precision requests, shared-meet requests, sum tolerances, and product tolerances.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger naming the inspected source observations and the arithmetic consumer windows.*
7. *R stores the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks obtained from the source windows, dyadic tolerances, displayed schedules, and shared meet row.*
8. *Σ and Π are the* $\mathsf{RegularCauchySum}^{\uparrow}$ *and* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *consumer rows reached through A, U, D, W, R.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the arithmetic readback, reached only after the sum or product consumer row has been displayed.*

10. *H records componentwise* hsame *transport for the real-modulus source rows, Cauchy-modulus schedules, arithmetic row, shared meet, dyadic ledger, windows, readbacks, sum and product consumers, Real seal, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from a real arithmetic precision request through the two source schedules, the shared meet row, D, W, R, and then through Σ or Π to the terminal seal E.*
12. *P is the* Pkg *provenance over* $\mathsf{RealModulusArithmetic}^{\uparrow}$, $\mathsf{CauchyModulusArithmetic}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RealModulusArithmetic}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X_0, X_1, \mu_0, \mu_1, A, U, D, W, R, \Sigma, \Pi, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, host real equality, trichotomy, countable choice, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 ✓ `BEDC.Derived.RealModulusArithmeticUp.RealModulusArithmeticUpTasteGate single carrier alignment`

Theorem 6042.2 (Real-modulus arithmetic NameCert obligations)**.** *For every accepted* $\mathsf{RealModulusArithmetic}^{\uparrow}$ *carrier*

$$M = (X_0, X_1, \mu_0, \mu_1, A, U, D, W, R, \Sigma, \Pi, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealModulusArithmetic}^{\uparrow}}$ *surface consists exactly of carrier admission, the two real-modulus source rows, the two Cauchy-modulus schedules, arithmetic-modulus routing, shared-meet routing, dyadic tolerance exactness, finite stream windows, regular rational readback, sum and product consumer rows, Real seal nonescape, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6042.1. Its displayed coordinates list the two real-modulus sources, their Cauchy-modulus schedules, the arithmetic and meet rows, the tolerance ledger, windows, readbacks, arithmetic consumers, seal, and structural rows.

The source and arithmetic rows are read before any Real-facing consumer can inspect a result. The rows $X_0, X_1, \mu_0, \mu_1, A, U$ place the two source schedules on the common modulus-arithmetic surface supplied by the Cauchy layer.

The ledger, window, and readback rows D, W, R then provide the finite observations consumed by Σ and Π. The seal E is downstream of those consumers, and H, C, P, N only transport, replay, source, and name the same finite route.

Since the carrier has no coordinate for quotient streams, selected limits, host real equality, trichotomy, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6042.3 (Real-modulus arithmetic consumer boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Real-algebra consumer of an accepted* $\mathsf{RealModulusArithmetic}^{\uparrow}$ *packet factors through the displayed route*

$$X_0, X_1, \mu_0, \mu_1, A, U, D, W, R, \Sigma, \Pi, E, H, C, P, N.$$

The consumer may read the regular sum row Σ or product row Π and then the terminal seal E, but it receives no quotient stream equality, selected limit, host real equality, trichotomy witness, countable-choice selector, ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate, Lean verification, or bridge row from the packet.*

Proof. Begin with a consumer request for real arithmetic. The carrier exposes the source real names only through X_0, X_1 and their displayed schedules μ_0, μ_1.

The arithmetic-modulus row A and shared-meet row U are then read before the dyadic ledger, finite windows, and regular rational readbacks can be consumed. Thus any sum or product read reaches Σ or Π only through A, U, D, W, R.

The terminal real seal E is downstream of Σ and Π. The rows H, C, P, N preserve the same displayed route under transport, replay, provenance, and local naming, so they do not add another consumer-facing object.

No unlisted coordinate belongs to the packet. Hence quotient streams, selected limits, host real equality, trichotomy, countable choice, ambient completeness, Lean verification, and bridge checking remain outside the consumer boundary. □

Falsifiable prediction: Every accepted $\mathsf{RealModulusArithmetic}^{\uparrow}$ arithmetic read exposes two real-modulus source rows, two Cauchy-modulus schedules, a $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ row, a shared $\mathsf{CauchyModulusMeet}^{\uparrow}$ row, dyadic tolerance data, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{RegularCauchySum}^{\uparrow}$ or $\mathsf{RegularCauchyProduct}^{\uparrow}$ consumer row, and a terminal $\mathsf{Real}^{\uparrow}$ seal before any Real-algebra consumer reads the packet.

Independence witness: cauchymodulusarithmetic, cauchymodulusmeet, regularcauchysum, regularcauchyproduct, real: no listed sibling supplies the whole real-modulus arithmetic packet with two real-modulus source rows, two displayed schedules, arithmetic routing, shared meet, dyadic tolerance ledger, finite windows, regular rational readback, sum and product consumers, terminal Real seal, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealModulusArithmetic}^{\uparrow}}$.

Constructive story: A $\mathsf{RealModulusArithmetic}^{\uparrow}$ packet is generated from two real-modulus source rows, two $\mathsf{CauchyModulus}^{\uparrow}$ schedules, one $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ row, one $\mathsf{CauchyModulusMeet}^{\uparrow}$ shared-meet row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{RegularCauchySum}^{\uparrow}$ and $\mathsf{RegularCauchyProduct}^{\uparrow}$ consumer rows, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealModulusArithmetic}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6042.1, Definition 6042.2, and Definition 6042.3 seed the finite Real-facing arithmetic-modulus boundary over $\mathsf{CauchyModulusArithmetic}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealModulusArithmetic}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected limits, host real equality, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove the finite NameCert obligation surface and Real consumer boundary for BEDC.Derived.RealModulusArithmeticUp.

Chapter 6043

A Concrete Naming Certificate for FiniteDimensionalCompactness$^{\uparrow}$

Following Bishop and Bridges and standard finite-dimensional normed-space compactness, the FiniteDimensionalCompactness$^{\uparrow}$ packet records the finite-net route by which a displayed bounded closed coordinate window is consumed as compact data. It sits after the vector-space surface of chapter 47, the metric surface of chapter 57, the real-name seal of chapter 38, the norm-comparison route of chapter 5566, the interval compactness packet of chapter 3969, and the finite-net Heine–Borel route of chapter 3471. The packet is a constructive finite-net NameCert surface for finite-dimensional bounded windows; it is not a general Heine–Borel theorem, sequential compactness principle, host basis selector, quotient vector equality, or choice-based compactness object.

Definition 6043.1 (Finite-dimensional compactness carrier)**.** *A* FiniteDimensionalCompactness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (V, M, R, E, N, I, F, W, S, H, C, P, Q)$$

with the following displayed rows:

1. *V is the* VecSpace$^{\uparrow}$ *row exposing vector addition, zero, inverse, scalar action, and vector classification only through displayed finite carrier data.*
2. *M is the* Met$^{\uparrow}$ *row induced by a displayed norm or coordinate distance on the same finite vector source.*
3. *R is the* Real$^{\uparrow}$ *seal row used for coordinate bounds, metric radii, finite sums, and comparison constants.*
4. *E is the* FiniteDimensionalNormEquivalence$^{\uparrow}$ *row that keeps all norm and coordinate comparisons on one finite coordinate window.*
5. *N is the* ClosedBoundedIntervalCompact$^{\uparrow}$ *interval compactness row for each coordinate bound.*
6. *I is the product interval-window row, listing the finitely many coordinate intervals and their endpoint seals.*
7. *F is the finite-net row read through* HeineBorelFiniteNet$^{\uparrow}$*, recording displayed centers, mesh radius, coverage witnesses, and radius comparisons for the coordinate window.*
8. *W is the bounded-window row tying every accepted vector read to the listed coordinate bounds before any compactness-facing consumer sees the metric row.*

9. *S is the exactness row saying that a finite-net membership read reconstructs a vector-window read through V, M, R, E, N, I, F, W.*

10. *H records componentwise* hsame *transport for the vector, metric, real, norm-equivalence, interval-compactness, finite-net, bounded-window, exactness, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from a finite-dimensional compactness request through $V, M, R, E, N, I, F, W, S, I$*

12. *P is the* Pkg *provenance over* $\mathsf{FiniteDimensionalCompactness}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, FiniteDimensionalNormEq ClosedBoundedIntervalCompact$^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *Q is the local* $\mathsf{NameCert}_{\mathsf{FiniteDimensionalCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $V, M, R, E, N, I, F, W, S, H, C, P, Q$. It has no coordinate for arbitrary open covers, host bases, quotient vector equality, selected subsequences, countable choice, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.FiniteDimensionalCompactnessUp.FiniteDimensionalCompactnessTasteGate`
`single carrier alignment`

Theorem 6043.2 (Finite-dimensional compactness NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDimensionalCompactness}^{\uparrow}$ *carrier*

$$K = (V, M, R, E, N, I, F, W, S, H, C, P, Q),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteDimensionalCompactness}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed vector-space, metric, real-seal, finite-dimensional norm-equivalence, coordinate interval-compactness, interval-window, finite-net, bounded-window, exactness, transport, replay, provenance, and local naming rows. Every compactness-facing read must first expose the coordinate window I, the finite-net row F, and the bounded-window row W; every metric or norm comparison must factor through M, R, E; and every exported finite-net membership read must be repacked by S before it reaches the local* NameCert *row.*

Proof. Project the carrier of Definition 6043.1. The tuple displays exactly the rows $V, M, R, E, N, I, F, W, S, H, C, P$ so the classifier has no access to compactness data outside that packet.

The finite-dimensional source is read first. The vector row V and metric row M expose the finite carrier and distance surface, while the real row R supplies the coordinate bounds, radii, sums, and comparison constants.

The compactness route is finite-net based. The norm-equivalence row E keeps all coordinate and norm comparisons on the same finite window, the interval compactness row N supplies compactness for each coordinate interval, and I, F, W list the coordinate intervals, finite centers, coverage witnesses, and bounded-window admission data.

The exactness row S is the only route from finite-net membership back to vector-window membership. The structural rows H, C, P, Q transport, replay, source, and name that same route. Since the carrier has no row for arbitrary open covers, host basis selection, quotient vector equality, selected subsequences, countable choice, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 6043.3 (Finite-dimensional compactness finite-net readback)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *or* $\mathsf{VecSpace}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteDimensionalCompactness}^{\uparrow}$ *packet that requests compactness data receives only the finite route*

$$\mathsf{VecSpace}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{FiniteDimensionalNormEquivalence}^{\uparrow} \longmapsto \mathsf{ClosedBoundedIntervalCompact}^{\uparrow} \longmapsto \mathsf{HeineBorel}$$

through $V, M, R, E, N, I, F, W, S, H, C, P, Q$. The readback exports finite coordinate bounds, displayed interval compactness rows, finite-net centers, mesh-radius comparisons, bounded-window admission, exactness, transport, replay, provenance, and local naming only; it exports no general Heine–Borel theorem, open-cover selector, sequential compactness branch, quotient vector equality, host basis choice, countable choice, or ambient completeness principle.

Proof. Start from the obligation surface of Definition 6043.2. A compactness-facing request opens the displayed vector, metric, and real rows before any coordinate or finite-net row is consumed.

Next read the finite-dimensional comparison data. The norm-equivalence row E ties the coordinate and metric comparisons to one finite window, and the interval compactness row N supplies compactness only for the listed coordinate intervals.

The finite-net handoff is I, F, W, S. The interval-window row lists the coordinate bounds, the finite-net row lists centers and coverage witnesses, the bounded-window row keeps vector reads inside those bounds, and the exactness row repacks finite-net membership as vector-window membership.

Finally H, C, P, Q preserve the same route for each consumer. Because no excluded object is present in the carrier, the consumer receives exactly the finite-net readback displayed in the statement. □

Falsifiable prediction: Every accepted $\mathsf{FiniteDimensionalCompactness}^{\uparrow}$ compactness read must display $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteDimensionalNormEquivalence}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, bounded-window, exactness, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before any compactness-facing output is visible.

Independence witness: vecspace, metric, real, finite-dimensional-norm-equivalence, closed-bounded-interval-compact, heine-borel-finite-net: $\mathsf{FiniteDimensionalCompactness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite vector-source rows, metric and Real seal rows, norm-equivalence comparisons, coordinate interval compactness, product-window bounds, finite-net coverage, exactness, transport, replay, provenance, and local naming in one compactness-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDimensionalCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDimensionalCompactness}^{\uparrow}$ packet is generated from VecSpaceUp, MetricSpaceUp, RealUp, FiniteDimensionalNormEquivalenceUp, ClosedBoundedIntervalCompactUp, HeineBorelFiniteNetUp, bounded-window, exactness, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6043.1, Definition 6043.2, and Definition 6043.3 seed the finite-net compactness route for displayed finite-dimensional bounded coordinate windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general Heine–Borel compactness, open-cover compactness, sequential compactness, host basis choice, quotient vector equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, vector and metric exposure, finite-dimensional norm-equivalence routing, coordinate interval compactness, finite-net readback, bounded-window exactness, transport, replay, provenance, and local naming for BEDC.Derived.FiniteDimensionalCompactnessUp.

Chapter 6044

A Concrete Naming Certificate for ComplexPhaseSurfaceFiber$^{\uparrow}$

The ComplexPhaseSurfaceFiber$^{\uparrow}$ packet realizes the complex phase surface of Definition 9463.1 as a finite source-fiber NameCert route. It sits beside the complex coordinate carrier of chapter 39, the disk-coordinate surface of chapter 377, the reversible transport rows of chapter 219, the finite flow surface of chapter 195, and the ledger-conservation packet of chapter 3487. The source ledger remains primary: the visible complex phase token is a readout of finite source, coordinate, fiber, GAP residue, provenance, hsame, Cont, Pkg, and NameCert rows, not a replacement source.

Definition 6044.1 (Complex phase surface fiber carrier)**.** *A* ComplexPhaseSurfaceFiber$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, Z, D, U, Y, L, G, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source ledger row, recording the focused finite* Hist *rows, selector rows, and source classifier data that make the phase readout visible.*
2. *Z is the* Complex$^{\uparrow}$ *coordinate row, exposing the visible complex token as rational-pair NameCert data.*
3. *D is the* UnitDisk$^{\uparrow}$ *coordinate row when the readout is normalized to a disk-facing phase surface.*
4. *U is the* UnitaryGroup$^{\uparrow}$ *reversible transport row, read only as displayed classifier-preserving transport.*
5. *Y is the* DynSystem$^{\uparrow}$ *finite flow row, recording local record evolution without a hidden global dynamics.*
6. *L is the* LiouvilleLedgerConservation$^{\uparrow}$ *row, requiring reversible transport to preserve source, classifier, and provenance distinctions before a conserved phase read is exported.*
7. *G is the* GAP *residue row, listing unresolved exits, omitted source distinctions, and boundary provenance that the visible complex token hides.*
8. *R is the fiber readback row. It records the exact route from S, G to Z, D, U, Y, L and back to the source ledger when the visible phase token is inspected.*
9. *H records componentwise* hsame *transport for source ledger, complex coordinate, disk coordinate, reversible transport, finite flow, conservation,* GAP *residue, fiber readback, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a phase-read request through $S, Z, D, U, Y, L, G, R, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{ComplexPhaseSurfaceFiber}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{UnitaryGroup}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{LiouvilleLedgerConservation}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ComplexPhaseSurfaceFiber}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $S, Z, D, U, Y, L, G, R, H, C, P, N$. It has no coordinate for treating a complex phase token as source equality, no hidden Hilbert-space state, no global dynamical solution, no erased GAP *residue, no quotient phase equality, no Lean verification, and no bridge checking.*

Theorem 6044.2 (Complex phase surface fiber NameCert obligations)**.** *For every accepted* ComplexPhaseSurfaceFi *carrier*

$$F = (S, Z, D, U, Y, L, G, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ComplexPhaseSurfaceFiber}^{\uparrow}}$ *surface consists exactly of source-ledger admission,* $\mathsf{Complex}^{\uparrow}$ *coordinate admission, optional* $\mathsf{UnitDisk}^{\uparrow}$ *coordinate admission, reversible* $\mathsf{UnitaryGroup}^{\uparrow}$ *transport admission, finite* $\mathsf{DynSystem}^{\uparrow}$ *flow admission,* $\mathsf{LiouvilleLedgerConservation}^{\uparrow}$ *preservation admission,* GAP *residue exposure, fiber readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The visible phase read can be exported only after the source ledger S, residue row G, and fiber readback row R are displayed.*

Proof. Project the carrier of Definition 6044.1. The tuple lists exactly the source, coordinate, transport, finite-flow, conservation, residue, readback, and structural rows, so the local classifier has no access to any detached phase object.

The source route is upstream. The source ledger S and GAP residue row G must be visible before the complex coordinate Z is interpreted as a phase readout.

The representation route is finite. The rows D, U, Y, L record disk normalization, reversible transport, finite flow, and ledger conservation only as displayed NameCert rows tied to S and G.

The fiber row R records the return route from visible phase token to source ledger and residue. The structural rows H, C, P, N preserve and name the same packet. Since the carrier has no row for source equality by phase equality, hidden Hilbert states, global dynamics, erased residue, or quotient phase equality, the listed obligations exhaust the local NameCert surface. □

Theorem 6044.3 (Complex phase surface fiber readback discipline)**.** *Every accepted* $\mathsf{ComplexPhaseSurfaceFiber}^{\uparrow}$ *phase read factors through the finite route*

$$S, G, R \longmapsto \mathsf{Complex}^{\uparrow}, \mathsf{UnitDisk}^{\uparrow}, \mathsf{UnitaryGroup}^{\uparrow}, \mathsf{DynSystem}^{\uparrow}, \mathsf{LiouvilleLedgerConservation}^{\uparrow} \longmapsto H, C, P, N.$$

Consequently a downstream consumer receives a visible complex coordinate, optional disk coordinate, reversible transport, finite flow, conservation ledger, source-fiber readback, GAP *residue, transport, replay, provenance, and local naming, and receives no source equality by phase equality, hidden global dynamics, ambient Hilbert state, erased residue, or quotient phase token.*

Proof. Use the obligation surface of Definition 6044.2. A phase consumer first reads the source ledger, the GAP residue, and the fiber readback row.

The visible phase route then opens the coordinate and dynamics rows. The complex coordinate, disk coordinate, reversible transport, finite flow, and ledger-conservation rows are all downstream of the source-fiber data rather than independent replacements for it.

Finally H, C, P, N preserve that route for downstream consumers. Because the carrier has no coordinate for phase equality as source equality, hidden global dynamics, ambient Hilbert state, erased residue, or quotient phase tokens, none of those readings can be exported. □

Theorem 6044.4 (Complex phase surface TasteGate boundary)**.** *Any checked TasteGate promotion for* ComplexPhaseSurfaceFiber$^{\uparrow}$ *must provide* Nontrivial ComplexPhaseSurfaceFiber$^{\uparrow}$ *and* FieldFaithful ComplexPh *instances preserving the distinct rows*

$$S, Z, D, U, Y, L, G, R, H, C, P, N.$$

Before those instances are present, the packet exports only the finite source-ledger, complex-coordinate, disk-coordinate, reversible-transport, finite-flow, ledger-conservation, GAP *residue, fiber-readback, transport, replay, provenance, and local naming rows.*

Proof. The carrier of Definition 6044.1 separates source, coordinate, transport, flow, conservation, residue, and fiber-readback rows. A nontriviality instance must distinguish an accepted packet from a packet missing one of those source-fiber rows.

Field faithfulness must preserve the row order rather than collapsing the visible complex coordinate into the source ledger or erasing the GAP residue. Thus the TasteGate boundary is exactly the requirement that future checked instances keep $S, Z, D, U, Y, L, G, R, H, C, P, N$ as distinct displayed fields. □

Falsifiable prediction: Every accepted ComplexPhaseSurfaceFiber$^{\uparrow}$ consumer must display source ledger, Complex$^{\uparrow}$ coordinate, fiber readback, GAP residue, provenance, hsame, Cont, Pkg, and local NameCert rows before treating a phase token as readable output.

Independence witness: complex, unitdisk, unitarygroup, dynsystem, liouville-ledger-conservation: ComplexPhaseSurfaceFiber$^{\uparrow}$ is not bijective to any listed sibling because it binds source ledger, visible complex coordinate, disk normalization, reversible transport, finite flow, ledger conservation, GAP residue, fiber readback, provenance, transport, replay, and local naming as one source-fiber packet.

Closure status for NameCert$_{\text{ComplexPhaseSurfaceFiber}^{\uparrow}}$**.**

Constructive story: A ComplexPhaseSurfaceFiber$^{\uparrow}$ packet is generated from source-ledger rows, a ComplexUp coordinate row, UnitDiskUp coordinate data, UnitaryGroupUp transport, DynSystemUp finite flow, LiouvilleLedgerConservationUp preservation, GAP residue, fiber readback, componentwise hsame, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ComplexPhaseSurfaceFiber}^{\uparrow}}$, seed)

Scope closed: Definition 6044.1, Definition 6044.2, and Definition 6044.3 seed the finite source-fiber phase readback route.

Formal verification: FormalStatus(NameCert$_{\text{ComplexPhaseSurfaceFiber}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close phase equality as source equality, hidden Hilbert-space state, global dynamical solutions, quotient phase tokens, erased GAP residue, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-ledger admission, ComplexUp coordinate admission, fiber readback, GAP residue exposure, transport, finite-flow, conservation, Nontrivial and FieldFaithful TasteGate instances, replay, provenance, and local naming for BEDC.Derived.ComplexPhaseSurfaceFiberUp.

Chapter 6045

A Concrete Naming Certificate for $\mathsf{LocatedRealCauchyCompleteness}^{\uparrow}$

Following Bishop and Bridges, located real Cauchy completeness is read constructively as a finite route from located rational interval evidence and regular rational names to a Real-name boundary, not as an ambient selection principle. The $\mathsf{LocatedRealCauchyCompleteness}^{\uparrow}$ packet records this L10 route beside the located-real surface of **??**, the Cauchy-modulus carrier of chapter 5887, the stream-name observation surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38.

Definition 6045.1 (Located real Cauchy completeness carrier)**.** *A* $\mathsf{LocatedRealCauchyCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, M, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{LocatedReal}^{\uparrow}$ *admission row, exposing located interval evidence before any completion read is public.*
2. *M is the* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *modulus row that names the displayed Cauchy request and its finite tail budget.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row whose finite observations are read by the modulus.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the window and modulus rows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row assembled from W and D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after located admission, modulus exposure, finite windows, dyadic tolerance, and regular readback have been displayed.*
7. *H records componentwise* hsame *transport for located-real, modulus, stream, dyadic, regular-readback, Real-seal, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from located admission through $X, M, W, D, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealCauchyCompleteness}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{CauchyModulusSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealCauchyCompleteness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, M, W, D, R, E, H, C, P, N$. It has no coordinate for quotient real equality, selected limits, countable choice, a host limit operator, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LocatedRealCauchyCompletenessUp.LocatedRealCauchyCompletenessTasteGate`
`single carrier alignment`

Theorem 6045.2 (Located real Cauchy completeness NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealCauchyCompleteness}^{\uparrow}$ *carrier*

$$L = (X, M, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealCauchyCompleteness}^{\uparrow}}$ *surface consists exactly of located-real admission for X, modulus exposure for M, finite StreamName windows for W, dyadic tolerance visibility for D, RegSeqRat readback for R, terminal Real sealing for E, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through P, and local naming through N.*

No located-real Cauchy completeness obligation is stored outside these rows.

Proof. Project the carrier of Definition 6045.1. The tuple $X, M, W, D, R, E, H, C, P, N$ is the whole public packet, so carrier admission and local naming are exhausted by the displayed rows.

The completion route begins with the located-real row X and the modulus row M. The finite StreamName window W is read against the DyadicRatCore tolerance ledger D, and the RegSeqRat readback R packages the same finite observations as a regular rational name.

Only after those rows have been displayed may the terminal Real seal E be consumed. The transport, replay, provenance, and local naming rows H, C, P, N preserve the same route and introduce no quotient equality, selected limit, countable-choice schedule, host limit operator, or ambient completeness coordinate. □

Theorem 6045.3 (Located real Cauchy completeness regular readback route)**.** *Every accepted* $\mathsf{LocatedRealCauchyCompleteness}^{\uparrow}$ *packet exposes its completion neighbour through the finite route*

$$\mathsf{LocatedReal}^{\uparrow} \longrightarrow \mathsf{CauchyModulusSpace}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The $\mathsf{RegSeqRat}^{\uparrow}$ *row is therefore the regular readback boundary between located interval evidence and the terminal Real seal. The route does not export quotient real equality, selected limits, countable choice, a host limit operator, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the located-real row X first. It supplies the located interval evidence that anchors the Cauchy request without identifying host real values.

Next read the modulus row M and the finite StreamName window row W. The DyadicRatCore ledger D supplies the tolerance scale shared by both rows.

The RegSeqRat row R is then the only regular rational readback available to the packet. The terminal Real seal E is downstream of R, and H, C, P, N merely transport, replay, source, and name the same finite evidence.

Since the carrier has no quotient-real, selected-limit, countable-choice, host-limit, or ambient-completeness coordinate, every completion read remains inside the displayed regular readback route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealCauchyCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealCauchyCompleteness}^{\uparrow}$ packet is generated from located-real admission, CauchyModulusSpace modulus exposure, finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedRealCauchyCompleteness}^{\uparrow}}$, seed)

Scope closed: Definition 6045.1, Definition 6045.2, and Definition 6045.3 seed the finite located-real Cauchy completeness route from located admission through regular rational readback to a terminal Real seal.

Formal verification: FormalStatus(NameCert$_{\text{LocatedRealCauchyCompleteness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, host limit operators, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked located-real admission, modulus exposure, finite-window coverage, dyadic tolerance visibility, RegSeqRat readback, Real seal routing, transport stability, replay stability, and non-escape for BEDC.Derived.LocatedRealCauchyCompletenessUp.

Chapter 6046

A Concrete Naming Certificate for $\mathsf{LocalizedCauchySubsequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocalizedCauchySubsequence}^{\uparrow}$ packet records the finite subsequence-window extraction used by the constructive Real and completion route. It reads the bounded $\mathsf{Real}^{\uparrow}$ windows of chapter 38, the prefix schedules of chapter 126, the regular rational readbacks of chapter 301, the dyadic tolerance ledger of chapter 291, the finite extraction surface of chapter 1913, and the criterion route of chapter 1509. The packet names a local finite window, not an ambient completeness theorem, a selected host limit, or a countable-choice subsequence selector.

Definition 6046.1 (Localized Cauchy subsequence carrier)**.** *A* $\mathsf{LocalizedCauchySubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (W, S, R, D, B, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the bounded* $\mathsf{Real}^{\uparrow}$ *window row. It records the finite source interval, endpoint seals, and bounded comparison rows in which the subsequence extraction is inspected.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *prefix schedule. It displays the finite source prefixes, candidate subsequence indices, and monotone prefix inclusions used by the local extraction.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected prefix windows and their rational regularity data.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic scales, rational comparisons, and exhaustion budget used to test local Cauchy behavior.*
5. *B is the* $\mathsf{BolzanoCauchy}^{\uparrow}$ *route row. It exposes the finite subsequence-window extraction surface without exporting a selected host limit.*
6. *E is the* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$ *endpoint row that can be read only after W, S, R, D, B have been displayed.*
7. *H records componentwise* hsame *transport for the bounded Real window, stream prefixes, regular rational readbacks, dyadic ledger, Bolzano-Cauchy route, criterion endpoint, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a local tolerance request through W, S, R, D, B, E and then through the structural rows.*

9. *P is the* Pkg *provenance over* $\mathsf{LocalizedCauchySubsequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BolzanoCauchy}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocalizedCauchySubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, a host-selected limit, an infinite selector, open-cover compactness, or countable choice.*

Lean4 ✓ `BEDC.Derived.LocalizedCauchySubsequenceUp.TasteGate.LocalizedCauchySubsequenceTasteGate single carrier alignment`

Theorem 6046.2 (Localized Cauchy subsequence NameCert obligations)**.** *For every accepted* $\mathsf{LocalizedCauchySubsequence}^{\uparrow}$ *carrier*

$$Q = (W, S, R, D, B, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocalizedCauchySubsequence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded Real window, StreamName prefixes, RegSeqRat readback, DyadicRatCore tolerance ledger, Bolzano-Cauchy route, Cauchy-convergence endpoint, transport, replay, provenance, and local naming rows;*
2. *local-window exposure, requiring every subsequence read to display W before it can inspect S, R, D;*
3. *finite extraction routing, requiring every subsequence candidate to pass through S, R, D and the* $\mathsf{BolzanoCauchy}^{\uparrow}$ *row B before the criterion endpoint E is available;*
4. *structural stability, requiring H and C to preserve and replay only the displayed finite route;*
5. *ledger non-escape, requiring P and N to name no object outside the displayed packet.*

No localized subsequence obligation is stored outside these rows.

Proof. Project the carrier of Definition 6046.1. The visible coordinates are exactly the bounded Real window, prefix schedule, rational readback, dyadic ledger, Bolzano-Cauchy route, criterion endpoint, and the structural support rows.

The local-window obligation is forced by the row order. A subsequence read first sees the bounded $\mathsf{Real}^{\uparrow}$ window W, and only then can it inspect the finite prefixes S, readbacks R, and tolerances D.

The extraction route is the finite route through $\mathsf{BolzanoCauchy}^{\uparrow}$ and $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$. The rows B and E are downstream of S, R, D, so no endpoint can be exported before the local subsequence window has been displayed.

Finally, H, C, P, N transport, replay, source, and name that same packet. Since the carrier has no further coordinate, the five listed obligation rows exhaust the local NameCert surface. □

Theorem 6046.3 (Localized Cauchy subsequence window extraction)**.** *Every accepted* LocalizedCauchySubsequenc *carrier exposes a finite subsequence-window route*

$$W \longmapsto S \longmapsto R \longmapsto D \longmapsto B \longmapsto E \longmapsto H, C, P, N$$

before any Cauchy criterion endpoint can be consumed. The route may be read by Real and completion consumers only through the displayed $\mathsf{Real}^{\uparrow}$ *window,* $\mathsf{StreamName}^{\uparrow}$ *prefixes,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{BolzanoCauchy}^{\uparrow}$ *extraction row, and* $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$

endpoint. It exports no ambient completeness principle, selected host limit, countable-choice subsequence selector, quotient stream equality, or open-cover compactness row.

Proof. Start with an accepted carrier. By Definition 6046.1, the only source of bounded sequence data is W, the only prefix data are S, and the only rational and dyadic tolerance data are R and D.

Apply Definition 6046.2. It requires any subsequence candidate to display W, S, R, D and then pass through the $\mathsf{BolzanoCauchy}^{\uparrow}$ route row B before the Cauchy-convergence endpoint E is public.

The structural rows do not add a second route. They preserve, replay, source, and name the same finite packet, so a Real or completion consumer can only receive the displayed route.

The excluded principles are absent from the carrier inventory. Hence the extraction remains a local finite subsequence-window route rather than an ambient completeness or choice construction. □

Falsifiable prediction: Every $\mathsf{LocalizedCauchySubsequence}^{\uparrow}$ read must display a bounded Real window, StreamName prefixes, RegSeqRat readback, DyadicRatCore tolerances, BolzanoCauchy routing, a CauchyConvergenceCriterion endpoint, transport, replay, provenance, and local naming before any Cauchy endpoint is consumed.

Independence witness: real, streamname, regseqrat, dyadicratcore, bolzano-cauchy, cauchy-convergence-criterion: $\mathsf{LocalizedCauchySubsequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the bounded local window, finite prefix extraction, tolerance ledger, criterion endpoint, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocalizedCauchySubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{LocalizedCauchySubsequence}^{\uparrow}$ packet is generated from a bounded RealUp window, StreamName prefix schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, BolzanoCauchy route, CauchyConvergenceCriterion endpoint, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocalizedCauchySubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6046.1, Definition 6046.2, and Definition 6046.3 seed the finite localized subsequence-window route for Real and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocalizedCauchySubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient RealUp completeness, quotient stream equality, selected host limits, countable-choice subsequence selection, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local-window exposure, finite extraction routing, structural stability, and ledger non-escape for BEDC.Derived.LocalizedCauchySubsequenceUp.

Chapter 6047

A Concrete Naming Certificate for $\mathsf{LebesgueStieltjesMeasure}^{\uparrow}$

Following Lebesgue and Stieltjes, the $\mathsf{LebesgueStieltjesMeasure}^{\uparrow}$ packet records the finite BEDC route by which a bounded-variation distribution function supplies interval masses to measure consumers. It sits after the partition-variation source of chapter 398, the finite interval-jump boundary of chapter 3528, the compact regular measure surface of chapter 2263, the endpoint carrier of chapter 1591, and the terminal real-name seal of chapter 38. The packet names only displayed half-open interval masses, finite additivity checks on the inspected interval algebra, compact-interval restriction rows, regular readback rows, transport, replay, provenance, and local naming; it is not a host measure space, a sigma-algebra completion, a selected Caratheodory extension, a quotient of functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6047.1 (Lebesgue–Stieltjes measure carrier)**.** *A* $\mathsf{LebesgueStieltjesMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, S, I, A, K, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row naming the distribution function only through displayed partition-variation data.*
2. *S is the* $\mathsf{StieltjesMeasureBoundary}^{\uparrow}$ *row carrying endpoint-jump reads for the inspected cells.*
3. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *restriction row, naming the compact interval on which the finite interval algebra is read.*
4. *A is the finite half-open interval algebra generated by the displayed endpoints, together with refinement witnesses for the cells requested by the packet.*
5. *K is the finite additivity ledger assigning* $\mathsf{DyadicRatCore}^{\uparrow}$ *mass rows to the cells of A and recording the displayed disjoint-union checks.*
6. *R is the* $\mathsf{RadonMeasure}^{\uparrow}$ *regular readback row exposed to compact-interval measure consumers.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal of the accepted finite mass readback.*
8. *H records componentwise* hsame *transport for the bounded-variation source, boundary row, interval restriction, interval algebra, additivity ledger, regular readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from bounded-variation partition reads through Stieltjes boundary data, finite interval algebra, additivity ledger, Radon readback, and the* $\mathsf{Real}^{\uparrow}$ *seal.*
10. *P is the* Pkg *provenance over* $\mathsf{LebesgueStieltjesMeasure}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{StieltjesMeasureBoundary}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LebesgueStieltjesMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, S, I, A, K, R, E, H, C, P, N$. It has no coordinate for a host sigma-algebra, a completed outer measure, a selected extension theorem, quotient equality of distribution functions, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.LebesgueStieltjesMeasureUp.LebesgueStieltjesMeasureTasteGate single carrier alignment`

Theorem 6047.2 (Lebesgue–Stieltjes measure NameCert obligations)**.** *For every accepted* LebesgueStieltjesMeasur *carrier*

$$L = (B, S, I, A, K, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LebesgueStieltjesMeasure}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded-variation source B, Stieltjes boundary exposure through S, compact interval restriction through I, finite interval-algebra visibility through A, finite additivity exactness through K, Radon-facing regular readback through R, terminal real sealing through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6047.1. The first three rows are the only source rows: B supplies bounded-variation partition data, S supplies endpoint-jump reads, and I restricts the read to a displayed compact interval.

The interval algebra and additivity obligations are A and K. The algebra A lists only the half-open cells generated by displayed endpoints, and K records the finite disjoint-union checks on those cells. Thus additivity is a finite ledger obligation rather than an appeal to a host sigma-algebra.

The downstream readback is R, E. The $\mathsf{RadonMeasure}^{\uparrow}$ row R exposes the compact-regular consumer surface, and E seals the same readback as a $\mathsf{Real}^{\uparrow}$ row. Transport, replay, provenance, and local naming are exactly H, C, P, N, leaving no hidden extension theorem, quotient, selector, countable-choice schedule, or ambient completeness coordinate. □

Theorem 6047.3 (Lebesgue–Stieltjes finite interval route)**.** *Every accepted* $\mathsf{LebesgueStieltjesMeasure}^{\uparrow}$ *packet routes a compact-interval mass request through*

$\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{StieltjesMeasureBoundary}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, h

Concretely, a consumer must read the source row B, boundary row S, interval restriction I, finite interval algebra A, additivity ledger K, and regular readback R before the terminal seal E is visible.

Proof. Start with the source and boundary rows. The bounded-variation chapter supplies the finite partition-variation source, while chapter 3528 supplies the endpoint-jump boundary that can be inspected on displayed cells.

Restrict next to the compact interval. The row I is read through chapter 1591; it fixes the finite endpoint surface from which A is generated. The ledger K then records mass assignments and finite additivity checks only for those displayed cells.

Finally pass to regular readback and sealing. The $\mathsf{RadonMeasure}^{\uparrow}$ surface of chapter 2263 consumes the compact-interval finite ledger through R, and the real-name chapter seals that read through E. Since every consumer-visible coordinate appears in this route, bypassing any of B, S, I, A, K, R is outside the accepted packet. □

Theorem 6047.4 (Lebesgue–Stieltjes Real seal non-escape)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* LebesgueStieltjesMeasure *carrier is available only after the bounded-variation source, Stieltjes boundary row, closed bounded interval restriction, finite interval algebra, finite additivity ledger, and Radon readback have been displayed. The seal exports the same finite compact-interval mass readback and exports no host sigma-algebra, completed outer measure, selected extension theorem, quotient equality of distribution functions, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Read the seal coordinate in Definition 6047.1. The row E is downstream from B, S, I, A, K, R, and its transport and replay are mediated only by H and C.

Apply Definition 6047.2. It identifies the displayed source, boundary, interval restriction, interval algebra, finite additivity ledger, regular readback, seal, transport, replay, provenance, and local naming rows as the complete local NameCert surface.

Apply Definition 6047.3. The route forces every compact-interval mass consumer to pass through the same finite rows before the $\mathsf{Real}^{\uparrow}$ seal is visible. No excluded object is a carrier coordinate, so the seal cannot export it. □

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueStieltjesMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{LebesgueStieltjesMeasure}^{\uparrow}$ packet is generated from a BoundedVariation source row, a StieltjesMeasureBoundary endpoint-jump row, a ClosedBoundedInterval restriction, a finite half-open interval algebra, a DyadicRatCore additivity ledger, a RadonMeasure regular readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueStieltjesMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6047.1, Definition 6047.2, Definition 6047.3, and Definition 6047.4 seed the finite compact-interval Lebesgue–Stieltjes measure packet from bounded-variation boundary data to Radon-facing and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueStieltjesMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host sigma-additivity, sigma-algebra completion, completed outer measure, selected extension theorems, quotient equality of distribution functions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Stieltjes boundary exposure, compact interval restriction, finite interval-algebra visibility, additivity exactness, Radon readback, Real-seal non-escape, transport and replay stability, provenance non-escape, and a Lean carrier/obligation formalization for BEDC.Derived.LebesgueStieltjesMeasureUp.

Chapter 6048

A Concrete Naming Certificate for $\mathsf{CompactModulusRealizer}^{\uparrow}$

Following Heine–Cantor and Bishop constructive analysis, the $\mathsf{CompactModulusRealizer}^{\uparrow}$ packet realizes compact uniform continuity as a finite NameCert carrier. It reads compact finite-net data from chapter 60, pointwise modulus rows from chapter 130, metric distance witnesses from chapter 57, rational lower-bound folds from chapter 37, and the finite ProbeBundle recursion route underlying chapter 9237. The packet is a finite uniform-modulus extraction surface, not a host open-cover compactness proof, semantic continuity theorem, or choice-selected modulus.

Definition 6048.1 (Compact modulus realizer carrier)**.** *A* $\mathsf{CompactModulusRealizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, F, G, Q, B, U, H, C, P, N)$$

with the following displayed rows:

1. K *is the* $\mathsf{Compact}^{\uparrow}$ *finite-net witness row, carrying bundled centers, located coverage rows, and finite radius data for the compact source.*
2. F *is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row for the displayed graph over the same source metric.*
3. G *is the* $\mathsf{Met}^{\uparrow}$ *distance-witness row, exposing source and target metric comparisons used by the triangle estimate.*
4. Q *is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row that records positive radius histories and the finite minimum ledger used to select a uniform precision.*
5. B *is the* ProbeBundle *recursion row over the compact finite net, including bundled center names, radius rows, and fold order.*
6. U *is the* $\mathsf{UniformModulus}^{\uparrow}$ *ledger row exported only after* K, F, G, Q, B *have been displayed.*
7. H *records componentwise* hsame *transport for the compact, continuous-map, metric, rational-fold, ProbeBundle, uniform-modulus, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from a tolerance request through the compact finite net, pointwise moduli, metric-distance witnesses, rational lower-bound fold, ProbeBundle recursion, and uniform-modulus ledger.*
9. P *is the* Pkg *provenance over* $\mathsf{CompactModulusRealizer}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, ProbeBundle, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactModulusRealizer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host open-cover compactness, semantic continuity, a choice-selected center outside the bundle, ambient completeness, quotient metric equality, or an external modulus selector.

Lean4 ✓ `BEDC.Derived.CompactModulusRealizerUp.CompactModulusRealizerTasteGate single carrier alignment`

Theorem 6048.2 (Compact modulus realizer NameCert obligations)**.** *For every accepted* $\mathsf{CompactModulusRealizer}^{\uparrow}$ *carrier*

$$M = (K, F, G, Q, B, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactModulusRealizer}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact finite-net witness, continuous-map pointwise modulus, metric distance witnesses, rational lower-bound fold, ProbeBundle recursion, uniform-modulus ledger, transport, replay, provenance, and local naming rows;*
2. *compact-source exposure, requiring every uniform-modulus request to display K and B before any finite lower-bound fold is read;*
3. *pointwise-modulus exposure, requiring the continuous-map row F and metric row G to supply the local distance estimates consumed by the fold;*
4. *rational-fold exactness, requiring Q to record the selected positive lower bound through finite* ProbeBundle *recursion;*
5. *uniform-modulus handoff, requiring U to be downstream of K, F, G, Q, B and to export only the displayed tolerance-to-precision ledger;*
6. *structural stability, requiring H, C, P, N to preserve, replay, source, and name the same finite packet.*

No compact-modulus obligation is stored outside these rows.

Proof. Project the carrier of Definition 6048.1. The listed coordinates are exactly the compact finite-net witness, pointwise-modulus row, metric row, rational fold, ProbeBundle recursion row, uniform-modulus ledger, and structural rows.

The compact-source and pointwise-modulus obligations are forced by the data flow. The finite net and bundle recursion supply the centers and radius rows, while the continuous-map and metric rows supply the local estimates that can be folded.

The rational-fold exactness obligation is the role of Q. It records the selected positive lower bound through finite recursion over B, so the exported precision is a displayed history rather than an external selector.

The handoff to U is therefore downstream of all analytic rows. The structural rows H, C, P, N add only transport, replay, provenance, and naming, so the six listed rows exhaust the local NameCert surface. □

Theorem 6048.3 (Compact modulus ProbeBundle fold)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactModulusRealizer}^{\uparrow}$ *carrier receives its precision row only through the finite route*

$$K \longmapsto B \longmapsto F \longmapsto G \longmapsto Q \longmapsto U \longmapsto H, C, P, N.$$

The fold is the compact finite-net and pointwise-modulus construction of Definition 9237.5 read as concrete NameCert data: bundled compact centers supply local pointwise moduli, the $\mathsf{Met}^{\uparrow}$ *rows supply source and target distance witnesses, the* $\mathsf{Rat}^{\uparrow}$ *fold selects a positive lower bound, and the* $\mathsf{UniformModulus}^{\uparrow}$ *ledger receives only that finite tolerance-to-precision route.*

Proof. Start with a uniform-modulus read of the accepted carrier. By carrier admission, the only public uniform-modulus row is U, and it is placed after the compact finite-net row K, bundle recursion row B, pointwise-modulus row F, metric row G, and rational lower-bound row Q.

Read the finite compact net first. The rows K and B expose the bundled centers and radius histories used by primitive recursion over the finite ProbeBundle.

Next read the local analytic data. The row F supplies pointwise moduli at bundled centers, while G supplies the metric-distance witnesses used by the source and target triangle estimates.

Finally, the row Q folds the positive radius histories into a displayed lower-bound ledger. The uniform-modulus row U receives exactly that ledger with the structural rows H, C, P, N, and the carrier has no coordinate for host compactness, semantic continuity, external choice, ambient completeness, or quotient metric equality. □

Falsifiable prediction: Every $\mathsf{CompactModulusRealizer}^{\uparrow}$ read must display CompactUp finite-net data, ContinuousMapUp pointwise-modulus rows, MetricSpaceUp distance witnesses, RatUp lower-bound folds, ProbeBundle recursion, UniformModulusUp handoff, transport, replay, provenance, and local naming.

Independence witness: compact, continuousmap, metricspace, rat, probebundle, uniformmodulus: $\mathsf{CompactModulusRealizer}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact finite nets, pointwise moduli, metric witnesses, rational lower-bound folds, ProbeBundle recursion, uniform-modulus handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusRealizer}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactModulusRealizer}^{\uparrow}$ packet is generated from CompactUp finite-net witnesses, ContinuousMapUp pointwise-modulus rows, MetricSpaceUp distance witnesses, RatUp lower-bound folds, ProbeBundle recursion, a UniformModulusUp ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactModulusRealizer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6048.1, Definition 6048.2, and Definition 6048.3 seed the finite compact-uniform-modulus realization surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactModulusRealizer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host open-cover compactness, semantic continuity, external modulus selection, ambient completeness, quotient metric equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, pointwise-modulus exposure, rational-fold exactness, uniform-modulus handoff, and structural stability for BEDC.Derived.CompactModulusRealizerUp.

Chapter 6049

A Concrete Naming Certificate for $\mathsf{JacksonFiniteApproximation}^{\uparrow}$

Following Jackson and constructive approximation theory, the $\mathsf{JacksonFiniteApproximation}^{\uparrow}$ packet records a finite error-ledger route from compact-uniform data to a displayed polynomial approximant. It sits over the compact metric source of chapter 129, the continuous-map carrier of chapter 130, the polynomial code surface of chapter 50, the Chebyshev recurrence surface of chapter 3480, the finite Weierstrass approximation corridor of chapter 1634, and the terminal real-name seal of chapter 38. The packet names the inspected Jackson window only; it is not a host best-approximation theorem, a quotient function-space construction, a selected infinite sequence of polynomials, an open-cover compactness theorem, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 6049.1 (Jackson finite approximation carrier)**.** *A* $\mathsf{JacksonFiniteApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (K, F, \Omega, D, T, PW, Q, E, H, C, \Pi, N)$$

with the following displayed rows:

1. *K is the compact metric source row read through* $\mathsf{CompactMetric}^{\uparrow}$*.*
2. *F is the continuous-map source row read through* $\mathsf{ContinuousMap}^{\uparrow}$*.*
3. *Ω is the finite modulus-of-continuity window used by the Jackson tolerance request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *error ledger naming the requested scale, the local mesh scale, and the residual bound.*
5. *T is the* $\mathsf{ChebyshevPolynomial}^{\uparrow}$ *recurrence row used to display the finite polynomial stencil.*
6. *PW is the* $\mathsf{Poly}^{\uparrow}$ *code row for the approximating polynomial and its inspected evaluation windows.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for source samples, polynomial samples, and dyadic residual checks.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the resulting finite error comparison.*
9. *H records componentwise* hsame *transport for compact source data, continuous-map data, modulus windows, dyadic errors, Chebyshev recurrence rows, polynomial codes, readbacks, Real seals, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a Jackson tolerance request through $K, F, \Omega, D, T, PW, Q, E, H, \Pi, N$.*

11. Π *is the* Pkg *provenance over* $\mathsf{JacksonFiniteApproximation}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{ChebyshevPolynomial}^{\uparrow}$, $\mathsf{WeierstrassApproximation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. N *is the local* $\mathsf{NameCert}_{\mathsf{JacksonFiniteApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, \Omega, D, T, PW, Q, E, H, C, \Pi, N$. *It has no coordinate for a host supremum norm, a best approximant selector, quotient function equality, open-cover compactness, countable choice, or ambient Real completeness.*

Lean4 ✓ `BEDC.Derived.JacksonFiniteApproximationUp.JacksonFiniteApproximationTasteGate single carrier alignment`

Theorem 6049.2 (Jackson finite approximation NameCert obligations)**.** *For every accepted* JacksonFiniteApproxim *carrier*

$$J = (K, F, \Omega, D, T, PW, Q, E, H, C, \Pi, N),$$

the local $\mathsf{NameCert}_{\mathsf{JacksonFiniteApproximation}^{\uparrow}}$ *surface consists exactly of compact-source admission, continuous-map admission, finite modulus-window exposure, dyadic error-ledger visibility, Chebyshev recurrence display, polynomial code display, regular rational readback, Real seal nonescape, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 6049.1. Its displayed coordinates are precisely the compact source, continuous source, modulus window, dyadic error ledger, Chebyshev recurrence, polynomial code, readback, seal, and structural rows.

The approximation route starts with K and F, then reads the finite modulus window Ω before any polynomial window is consumed. The dyadic row D records the requested Jackson scale and the residual budget used by the later comparison.

The recurrence row T and polynomial row PW display the finite approximant, while Q reads the source and polynomial samples through regular rational data. The terminal seal E is downstream of those rows, and H, C, Π, N only transport, replay, source, and name the same finite route.

Since no other coordinate belongs to the packet, host supremum norms, best-approximation selectors, quotient function equality, open-cover compactness, countable choice, and ambient Real completeness remain outside the local NameCert surface. □

Theorem 6049.3 (Jackson finite polynomial window)**.** *Every polynomial-window consumer of an accepted* $\mathsf{JacksonFiniteApproximation}^{\uparrow}$ *packet reads the approximating polynomial through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\quad \mathsf{ContinuousMap}^{\uparrow},\quad \mathsf{ChebyshevPolynomial}^{\uparrow},\quad \mathsf{Poly}^{\uparrow},\quad \mathsf{WeierstrassApproximation}^{\uparrow},\quad \mathsf{Real}^{\uparrow}.$$

The consumer may inspect the rows $K, F, \Omega, D, T, PW, Q, E, H, C, \Pi, N$ *and the Jackson error ledger stored in* D*, but it receives no host best approximant, quotient function-space equality, selected infinite polynomial sequence, open-cover compactness theorem, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Begin with the compact source and continuous-map rows K and F. They provide the finite domain and function surface before any approximation data can be read.

Next inspect the modulus window Ω and dyadic ledger D. These rows bind the tolerance request to a finite scale and prevent the polynomial consumer from appealing to a host supremum norm.

The Chebyshev row T and polynomial row PW display the finite approximant. The readback row Q compares source samples and polynomial samples at the named dyadic scale, and the terminal Real seal E is available only after that comparison route has been displayed.

Transport, replay, provenance, and local naming preserve the same rows. Therefore the polynomial window is a finite Jackson error-ledger object rather than a host compactness or function-space theorem. □

Falsifiable prediction: Every accepted $\mathsf{JacksonFiniteApproximation}^{\uparrow}$ approximation read exposes a compact metric source, a continuous-map source, a finite modulus window, a dyadic error ledger, a Chebyshev recurrence row, a polynomial code row, regular rational readback, and a terminal $\mathsf{Real}^{\uparrow}$ seal before any polynomial-window consumer reads the packet.

Independence witness: compactmetric, continuousmap, polynomial, chebyshev-polynomial, weierstrass-approximation, real: no listed sibling supplies the whole Jackson finite approximation packet with compact source data, continuous-map data, finite modulus windows, dyadic error budgets, Chebyshev recurrence, polynomial code, regular rational readback, Real seal, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{JacksonFiniteApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{JacksonFiniteApproximation}^{\uparrow}$ packet is generated from compact metric source data, continuous-map source data, a finite modulus window, a dyadic error ledger, a Chebyshev recurrence row, a polynomial code row, regular rational readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JacksonFiniteApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6049.1, Definition 6049.2, and Definition 6049.3 seed the finite Jackson error-ledger route from compact-uniform source data through Chebyshev and polynomial rows to a terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JacksonFiniteApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host best approximation, quotient function equality, selected infinite polynomial sequences, open-cover compactness, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite modulus-window exposure, dyadic error-ledger exactness, Chebyshev and polynomial handoff, regular rational readback, Real seal routing, and nonescape for BEDC.Derived.JacksonFiniteApproximationUp.

The $\mathsf{DyadicCauchyOscillationModulus}^{\uparrow}$ hub routes dyadic tail-oscillation reads through chapter 291, chapter 126, chapter 301, and chapter 38 before the child packet is read.

Chapter 6050

A Concrete Naming Certificate for DyadicCauchyOscillationModulus$^{\uparrow}$

Following Bishop and Bridges, the DyadicCauchyOscillationModulus$^{\uparrow}$ packet records the finite modulus surface by which dyadic Cauchy oscillation reads are scheduled before a regular real completion route consumes them. It sits between the oscillation criterion of chapter 2123, the dyadic tolerance arithmetic of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet also records compatibility with the explicit Cauchy modulus surface of chapter 292, while keeping completeness, quotient equality, selected limits, host equality, trichotomy, and choice outside the carrier.

Definition 6050.1 (Dyadic Cauchy oscillation modulus carrier)**.** *A* DyadicCauchyOscillationModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *O is the oscillation ledger, read through* CauchyOscillationCriterion$^{\uparrow}$ *as the finite record saying which pair of tail observations is compared for a requested tolerance.*
2. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance and modulus row, containing the requested dyadic radius, the displayed threshold, and the dyadic comparison budget used by O.*
3. *W is the visible tail-window schedule in* StreamName$^{\uparrow}$*, listing the finite windows beyond the threshold supplied by D and consumed by the oscillation read.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the same windows and dyadic tolerance ledger.*
5. *E is the* Real$^{\uparrow}$ *seal row, visible only after O, D, W, R have fixed the finite oscillation-modulus route.*
6. *H stores componentwise* hsame *transport for O, D, W, R, E, C, P, N and the local packet shape.*
7. *C stores displayed* Cont *replay from a tolerance request to the dyadic threshold row, from that threshold to the visible tail windows, from the windows to the oscillation ledger, and from the ledger to the* RegSeqRat$^{\uparrow}$ *and* Real$^{\uparrow}$ *rows.*
8. *P is the* Pkg *provenance over* DyadicCauchyOscillationModulus$^{\uparrow}$*,* CauchyOscillationCriterion$^{\uparrow}$*,* CauchyModulus$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{DyadicCauchyOscillationModulus}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $O, D, W, R, E, H, C, P, N$. It has no coordinate for Real completeness, quotient stream equality, selected limits, host equality, trichotomy, countable choice, or an unbounded search over tails.

Theorem 6050.2 (Dyadic Cauchy oscillation modulus route)**.** *Every oscillation read exported by an accepted* $\mathsf{DyadicCauchyOscillationModulus}^{\uparrow}$ *carrier factors through*

$$D \longmapsto W \longmapsto O \longmapsto R \longmapsto E$$

together with the displayed hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyOscillationModu}}$ *row. Thus the read is a finite dyadic modulus packet for tail oscillation, not a Real-completeness principle, quotient stream equality, selected limit, host equality, trichotomy row, or countable-choice selector.*

Proof. Project the accepted carrier in Definition 6050.1. The dyadic tolerance and modulus row D is the only coordinate that supplies the requested radius and finite threshold.

The visible tail-window schedule W is downstream of D. It displays the finite windows over which the oscillation ledger O may compare tail reads, so O cannot be consumed before the requested dyadic threshold and windows have been shown.

The rows R and E are downstream handoffs. They receive the same displayed windows and dyadic tolerance data after the oscillation ledger has fixed the tail comparison, and the structural rows H, C, P, N only transport, replay, source, and name this route.

No carrier coordinate supplies completeness, quotient equality, selected limits, host equality, trichotomy, choice, or an unbounded tail search. Hence every exported oscillation read is exhausted by the displayed finite route. □

Theorem 6050.3 (Dyadic Cauchy oscillation modulus NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCauchyOscillationModulus}^{\uparrow}$ *carrier*

$$M = (O, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicCauchyOscillationModulus}^{\uparrow}}$ *surface consists exactly of carrier admission; dyadic tolerance exactness through D; tail-window scheduling through W; oscillation ledger routing through O;* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through R;* $\mathsf{Real}^{\uparrow}$ *seal handoff through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 6050.1. Carrier admission exposes precisely the rows $O, D, W, R, E, H, C, P, N$ and no other rows.

The dyadic and tail-facing obligations are D, W, O. The dyadic tolerance row fixes the requested radius and threshold, the StreamName row schedules only finite tail windows beyond that threshold, and the oscillation ledger records the displayed tail comparison for those windows.

The readback and seal obligations are R, E. The regular rational handoff reads the same scheduled windows, and the Real seal is downstream of the dyadic tolerance, window schedule, and oscillation ledger rather than a completeness principle.

Finally H, C, P, N transport, replay, source, and name the finite route. Completeness, quotient stream equality, selected limits, host equality, trichotomy, countable choice, ambient real arithmetic, and unbounded tail search are absent from the carrier, so none can appear as a local NameCert obligation. □

Theorem 6050.4 (Dyadic Cauchy oscillation modulus Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{DyadicCauchyOscillationModulus}^{\uparrow}$ *packet passes through the ordered finite route*

$$D \longmapsto W \longmapsto O \longmapsto R \longmapsto E.$$

The route cannot export $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, selected limits, host equality, trichotomy, choice, or an unbounded tail search.*

Proof. Begin with a Real-facing consumer. By Definition 6050.1, the terminal row E is visible only after O, D, W, R have fixed the finite oscillation-modulus route.

Apply Definition 6050.2. It orders the consumer through D, W, O, R, E and keeps the structural rows as transport, replay, provenance, and naming data for the same route.

Use Definition 6050.3 for the obligation boundary. Since no excluded object is a carrier row or a NameCert obligation, a Real-facing read cannot insert completeness, quotient equality, selected limits, host equality, trichotomy, choice, or unbounded tail search between the finite windows and the terminal seal. □

Falsifiable prediction: Every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer of a $\mathsf{DyadicCauchyOscillationModulus}^{\uparrow}$ packet must first display the dyadic tolerance and modulus row, the visible $\mathsf{StreamName}^{\uparrow}$ tail windows, and the $\mathsf{CauchyOscillationCriterion}^{\uparrow}$ ledger before any readback or seal row is consumed.

Independence witness: cauchyoscillationcriterion, cauchymodulus, dyadicratcore, streamname, regseqrat, real: $\mathsf{DyadicCauchyOscillationModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an oscillation ledger, dyadic tolerance and modulus data, visible tail-window scheduling, regular rational readback, a real seal boundary, componentwise transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCauchyOscillationModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicCauchyOscillationModulus}^{\uparrow}$ packet is generated from an oscillation ledger, a DyadicRatCore tolerance and modulus row, visible StreamName tail windows, RegSeqRat readback, a RealUp seal row, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCauchyOscillationModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6050.1, Definition 6050.2, Definition 6050.3, and Definition 6050.4 seed the finite Bishop–Bridges dyadic modulus packet for Cauchy oscillation reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCauchyOscillationModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, selected limits, host equality, trichotomy, countable choice, ambient real arithmetic, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exactness, tail-window scheduling, oscillation ledger routing, regular rational handoff, real-seal handoff, transport, replay, provenance, and non-escape for BEDC.Derived.DyadicCauchyOscillationModulusUp.

Chapter 6051

A Concrete Naming Certificate for $\mathsf{FractionalSobolev}^{\uparrow}$

Following Adams and Fournier on fractional Sobolev and Slobodeckij spaces, the $\mathsf{FractionalSobolev}^{\uparrow}$ packet records the finite carrier surface by which a downstream analysis consumer reads non-integer smoothness without importing a completed quotient function space. It sits over the Sobolev weak-derivative surface of chapter 440, the weak-derivative observation route of chapter 2210, the dyadic metric tolerance ledger of chapter 2001, and the terminal real-name seal of chapter 38. The packet names only finite difference windows, dyadic scales, seminorm ledgers, componentwise transport, replay, provenance, and local naming evidence.

Definition 6051.1 (Fractional Sobolev carrier)**.** *A* $\mathsf{FractionalSobolev}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, W, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *source row naming the integer-order weak-derivative and magnitude surface already accepted by the consumer.*
2. *W is the* $\mathsf{WeakDerivative}^{\uparrow}$ *observation row used to anchor finite weak-test reads when the fractional packet is compared to the ordinary Sobolev surface.*
3. *D is the* $\mathsf{DyadicMetric}^{\uparrow}$ *scale row naming the inspected dyadic radii, difference windows, and finite comparison thresholds.*
4. *Q is the fractional-difference seminorm ledger, recorded as finite pairs of displayed source windows and dyadic scale requests.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row for the finite magnitude comparisons exposed by Q.*
6. *E is the terminal exclusion row stating that the packet has no coordinate for quotient functions, almost-everywhere equality, completed measure spaces, Bessel-potential transforms, or host interpolation functors.*
7. *H records componentwise* hsame *transport for the Sobolev source, weak-derivative row, dyadic metric scale row, seminorm ledger, real readback, exclusion row, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a fractional smoothness request through $S, W, D, Q, R, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{FractionalSobolev}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{DyadicMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FractionalSobolev}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, D, Q, R, E, H, C, P, N$. It has no coordinate for a host fractional Sobolev quotient, a selected representative, a completed L^p carrier, a Fourier transform, a Bessel-potential model, or an interpolation-space equality.

Theorem 6051.2 (Fractional Sobolev NameCert obligation)**.** *For every accepted* $\mathsf{FractionalSobolev}^{\uparrow}$ *carrier*

$$F = (S, W, D, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FractionalSobolev}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{Sobolev}^{\uparrow}$ *source row, the* $\mathsf{WeakDerivative}^{\uparrow}$ *observation row, the* $\mathsf{DyadicMetric}^{\uparrow}$ *scale row, the finite fractional-difference seminorm ledger, the* $\mathsf{Real}^{\uparrow}$ *magnitude readback, the exclusion row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may use the packet as a finite non-integer smoothness certificate only after reading the displayed route*

$$\mathsf{Sobolev}^{\uparrow}, \quad \mathsf{WeakDerivative}^{\uparrow}, \quad \mathsf{DyadicMetric}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The obligation exports no quotient function equality, no almost-everywhere representative, no completed measure carrier, no Fourier-side model, no Bessel-potential transform, and no host interpolation theorem.

Proof. Project the carrier of Definition 6051.1. The displayed rows are precisely the Sobolev source row, weak-derivative observation row, dyadic scale row, seminorm ledger, Real readback, exclusion row, and structural rows H, C, P, N.

The fractional read begins at S and W, then reaches the finite dyadic windows in D before the seminorm ledger Q can be consumed. The readback row R compares only the finite magnitude entries displayed by Q.

Transport and replay preserve that route componentwise through H and C, while P and N source and name the same finite packet. Since the remaining analytic objects are absent from the carrier coordinates, they cannot be exported by the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{FractionalSobolev}^{\uparrow}$ read is refuted if it reaches a fractional smoothness consumer without displaying the same $\mathsf{Sobolev}^{\uparrow}$ source row, $\mathsf{WeakDerivative}^{\uparrow}$ observation row, $\mathsf{DyadicMetric}^{\uparrow}$ scale row, finite seminorm ledger, $\mathsf{Real}^{\uparrow}$ readback, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: sobolev, weak-derivative, dyadic-metric, real: $\mathsf{FractionalSobolev}^{\uparrow}$ is not bijective to any listed sibling because it binds a Sobolev source, weak-test route, dyadic metric scale ledger, finite fractional-difference seminorm row, and Real readback as one non-integer smoothness packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FractionalSobolev}^{\uparrow}}$.

Constructive story: A $\mathsf{FractionalSobolev}^{\uparrow}$ packet is generated from a Sobolev source row, a WeakDerivative observation row, a DyadicMetric scale row, a finite fractional-difference seminorm ledger, a RealUp magnitude readback, an exclusion row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FractionalSobolev}^{\uparrow}}$, seed)

Scope closed: Definition 6051.1 and Definition 6051.2 seed the finite non-integer smoothness route from Sobolev and weak-derivative data through dyadic metric scales to a RealUp readback.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FractionalSobolev}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient function equality, almost-everywhere representatives, completed measure carriers, Fourier-side models, Bessel-potential transforms, host interpolation theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Sobolev source exactness, WeakDerivative observation routing, DyadicMetric scale nonescape, finite seminorm ledger exactness, RealUp readback nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FractionalSobolevUp.

The horizontal dependency route for $\mathsf{FractionalSobolev}^{\uparrow}$ is the finite non-integer regularity edge from chapter 440 through the normed and Hilbert magnitude rows of chapter 89 and chapter 91, with distribution-style and derivative-style observation supplied by chapter 186, chapter 122, and chapter 2210. Thus the packet consumes existing concrete-instance regularity rows as sibling data before exposing its fractional seminorm ledger; it does not create an ambient quotient function space or a completed interpolation theorem.

Chapter 6052

A Concrete Naming Certificate for $\mathsf{CauchyCondensationTailLock}^{\uparrow}$

Following Cauchy's condensation test and Bishop–Bridges constructive analysis, the $\mathsf{CauchyCondensationTailLock}^{\uparrow}$ packet records the finite tail route by which condensation evidence reaches a regular rational readback and then the Real seal. It consumes the dyadic-block condensation carrier of chapter 1464, the regular rational handoff of chapter 301, the dyadic tolerance surface of chapter 291, and the terminal Real boundary of chapter 38. The certificate locks a displayed condensation tail to one completion-facing route; it does not import selected sums, quotient series equality, countable choice, host real equality, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6052.1 (Cauchy condensation tail-lock carrier)**.** *A* $\mathsf{CauchyCondensationTailLock}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, W, B, L, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the monotone nonnegative* $\mathsf{Series}^{\uparrow}$ *source whose finite summand windows are consumed by the condensation route.*
2. *W is the summand-window ledger inherited from the accepted* $\mathsf{CauchyCondensation}^{\uparrow}$ *carrier.*
3. *B is the dyadic block schedule, including displayed block endpoints, powers of two, and block lengths.*
4. *L is the block-sum ledger, storing the original block sums and the condensed dyadic terms on the same schedule.*
5. *T is the tail-bound row, recording the dyadic tolerances and finite domination comparisons read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row produced from S, W, B, L, T.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary attached to the handoff row R.*
8. *H records componentwise* hsame *transports for the source, windows, schedule, block sums, tail bounds, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each finite precision request through $S, W, B, L, T, R, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{Series}^{\uparrow}$, $\mathsf{CauchyCondensation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationTailLock}^{\uparrow}}$ *row.*

The classifier compares accepted tail-lock packets only through these rows. It has no coordinate for quotient series equality, a selected infinite sum, countable choice, trichotomy beyond displayed windows, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCondensationTailLockUp.CauchyCondensationTailLockTasteGate single carrier alignment`

Theorem 6052.2 (Cauchy condensation tail-lock NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCondensationTailLock}^{\uparrow}$ *carrier* $Q = (S, W, B, L, T, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationTailLoc}}$ *surface consists exactly of source exposure for* S*, summand-window coverage for* W*, dyadic block scheduling for* B*, block-sum ledger exposure for* L*, dyadic tail-bound visibility for* T*,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff exposure for* R*,* $\mathsf{Real}^{\uparrow}$ *seal routing for* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, sibling provenance through* P*, and local naming through* N*.*

No tail-lock obligation is stored outside the displayed finite packet.

Proof. Project the accepted carrier of Definition 6052.1. The tuple $S, W, B, L, T, R, E, H, C, P, N$ is the whole public packet, so carrier admission and local naming are exactly the displayed rows.

The analytic route begins with the finite condensation surface of chapter 1464. The source row S, summand windows W, dyadic schedule B, and block ledger L determine which finite terms can be inspected.

The tail-bound row T reads its dyadic tolerances through the $\mathsf{DyadicRatCore}^{\uparrow}$ surface and sends the resulting finite comparison to the $\mathsf{RegSeqRat}^{\uparrow}$ handoff row R. The seal row E is downstream of that handoff.

Transport, replay, provenance, and local naming through H, C, P, N preserve the same route. Since the carrier has no further coordinate, the listed rows exhaust the local certificate. □

Theorem 6052.3 (Cauchy condensation tail-lock Real-seal route)**.** *Every accepted* $\mathsf{CauchyCondensationTailLock}^{\uparrow}$ *carrier routes a condensation tail to a* $\mathsf{Real}^{\uparrow}$ *seal only through the finite path*

$$S, W, B, L, T \longmapsto R \longmapsto E.$$

The route is locked to the same $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row before the Real seal is read. No selected sum, quotient series equality, countable choice, trichotomy premise, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness coordinate can produce a second seal-facing path.*

Proof. Start with an accepted tail-lock carrier and read the rows exposed by Definition 6052.2. The only analytic input available before the handoff is the finite source-window, dyadic-schedule, block-ledger, and tail-bound data S, W, B, L, T.

Apply the condensation handoff route of Definition 1464.6. It forces the condensation comparison through the displayed dyadic-block surface before any regular rational readback can be consumed.

Now read the Real seal boundary using Definition 1464.7. The seal-facing input is the handoff row R together with the structural rows H, C, P, N, so E cannot be reached by an alternate quotient, selected-sum, choice, trichotomy, host-equality, or completeness coordinate. □

Falsifiable prediction: An accepted $\mathsf{CauchyCondensationTailLock}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading the displayed rows S, W, B, L, T and the $\mathsf{RegSeqRat}^{\uparrow}$ handoff row R refutes the carrier surface.

Independence witness: cauchycondensation, regseqrat, dyadicratcore, real: no listed sibling supplies the whole tail-lock packet $Q = (S, W, B, L, T, R, E, H, C, P, N)$, because the siblings expose the condensation carrier, regular rational readback, dyadic tolerance surface, or seal boundary separately while this chapter binds them into one finite route.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationTailLock}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCondensationTailLock}^{\uparrow}$ packet is generated from a Series source, condensation windows, dyadic block schedule, block-sum ledger, dyadic tail-bound row, RegSeqRat handoff, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCondensationTailLock}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6052.1, Definition 6052.2, and Definition 6052.3 seed the finite tail-lock route from condensation evidence through dyadic tolerance and RegSeqRat readback to a RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCondensationTailLock}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected sums, quotient series equality, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source exposure, summand-window coverage, dyadic block scheduling, block-sum ledger exposure, dyadic tail-bound visibility, RegSeqRat handoff exposure, Real seal routing, transport stability, replay stability, and non-escape for BEDC.Derived.CauchyCondensationTailLockUp.

Chapter 6053

A Concrete Naming Certificate for $\mathsf{BanachContractionEndpoint}^{\uparrow}$

Following Banach and Bishop–Bridges on constructive fixed-point iteration, the $\mathsf{BanachContractionEndpoint}^{\uparrow}$ packet records the finite fixed-endpoint seal for a contraction orbit over a complete separated metric source. It sits after the contraction certificate of chapter 3529, the contraction-map surface of chapter 1418, the Picard orbit interface of chapter 2359, the complete metric service of chapter 128, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the endpoint read as displayed NameCert data; it is not a host-selected fixed point, a quotient completion, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6053.1 (Banach contraction endpoint carrier)**.** *A* $\mathsf{BanachContractionEndpoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, F, O, M, L, U, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the complete separated metric source row consumed by the contraction.*
2. *F is the contraction source row, naming the displayed* $\mathsf{BanachContraction}^{\uparrow}$ *and* $\mathsf{ContractionMapping}^{\uparrow}$ *data.*
3. *O is the* $\mathsf{PicardIteration}^{\uparrow}$ *orbit row generated from the displayed source and contraction data.*
4. *M is the Cauchy modulus row for the orbit, recording the finite tail budget used by the completion service.*
5. *L is the complete-metric endpoint row reached from the displayed orbit and modulus.*
6. *U is the separated uniqueness row, showing that any accepted endpoint read is forced through the same completion boundary.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the endpoint observations.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after X, F, O, M, L, U, Q have been displayed.*
9. *H records componentwise* hsame *transport for source, contraction, orbit, modulus, endpoint, uniqueness, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay for the same endpoint route.*
11. *P is the* Pkg *provenance over* $\mathsf{BanachContractionEndpoint}^{\uparrow}$, $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. N is the local $\mathsf{NameCert}_{\mathsf{BanachContractionEndpoint}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $X, F, O, M, L, U, Q, R, H, C, P, N$. It has no coordinate for a host-selected fixed point, quotient completion, ambient real completeness, countable choice, or a fixed-point theorem detached from the displayed orbit and endpoint seal.

Lean4 ✓ `BEDC.Derived.BanachContractionEndpointUp.BanachContractionEndpointTasteGate single carrier alignment`

Theorem 6053.2 (Banach contraction endpoint NameCert obligations)**.** *For every accepted* BanachContractionEnd *carrier*

$$E = (X, F, O, M, L, U, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BanachContractionEndpoint}^{\uparrow}}$ *surface consists exactly of complete separated metric admission through X, contraction-source exposure through F, Picard-orbit exposure through O, Cauchy-modulus exposure through M, complete-metric endpoint exposure through L, separated uniqueness through U, regular rational readback through Q, real seal exposure through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6053.1. The endpoint-facing rows are X, F, O, M, L, U, Q, R, and the structural rows are H, C, P, N.

The contraction route is read in order. Rows X and F provide the complete separated metric source and contraction data, O records the Picard orbit, and M supplies the finite Cauchy budget that lets the completion service expose L.

The endpoint is then sealed only through U, Q, R, H, C, P, N. Separated uniqueness, regular rational readback, and the terminal real seal remain displayed rows of the same packet, so the listed rows exhaust the local NameCert obligations. □

Theorem 6053.3 (Banach contraction endpoint nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or fixed-endpoint consumer of an accepted* $\mathsf{BanachContractionEndpoint}^{\uparrow}$ *packet reaches the endpoint only through*

$$\mathsf{CompleteMetric}^{\uparrow},\ \mathsf{BanachContraction}^{\uparrow},\ \mathsf{ContractionMapping}^{\uparrow},\ \mathsf{PicardIteration}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

as displayed by the rows $X, F, O, M, L, U, Q, R, H, C, P, N$. No consumer may replace that route by a host-selected fixed point, quotient completion, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a fixed-point theorem detached from the Picard orbit.*

Proof. Apply the obligations theorem Definition 6053.2. It requires every endpoint read to expose the complete source, contraction source, Picard orbit, Cauchy modulus, completion endpoint, separated uniqueness, readback, and seal rows.

The terminal real seal R is downstream of Q, and Q is downstream of the displayed endpoint row L. Thus a Real-facing consumer cannot reach R without first reading the orbit and completion route carried by O, M, L.

Since the classifier has no coordinate for host-selected fixed points, quotient completion, countable choice, ambient completeness, or detached fixed-point theorems, those reads cannot be exported by an accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachContractionEndpoint}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BanachContractionEndpoint}^{\uparrow}$ packet is generated from a complete separated metric source, contraction data, a Picard orbit, a Cauchy modulus, a complete-metric endpoint row, separated uniqueness, RegSeqRat

readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{BanachContractionEndpoint}\uparrow}$, seed)

Scope closed: Definition 6053.1, Definition 6053.2, and Definition 6053.3 seed the fixed-endpoint certificate for contraction orbits over complete separated metric sources.

Formal verification: FormalStatus(NameCert$_{\mathsf{BanachContractionEndpoint}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host-selected fixed points, quotient completions, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction-source routing, Picard orbit exposure, Cauchy-modulus exactness, complete-metric endpoint exposure, separated uniqueness, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BanachContractionEndpointUp.

Chapter 6054

A Concrete Naming Certificate for $\mathsf{FiniteIntervalChoice}^{\uparrow}$

Following Bishop and Bridges on finite choice over displayed finite covers, the $\mathsf{FiniteIntervalChoice}^{\uparrow}$ packet records the finite selector surface needed when a closed bounded interval net is read through finite stream windows. It sits over the finite mesh route of chapter 1250, the observation schedule of chapter 5916, the stream-window surface of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names only choices made inside an already displayed finite row; it does not import countable choice, an ambient selector, trichotomy, quotient real equality, or host compactness.

Definition 6054.1 (Finite interval choice carrier)**.** *A* $\mathsf{FiniteIntervalChoice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (K, Q, L, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *cell-data row, including the located interval source, finite mesh scale, rational cells, dyadic refinements, center rows, and finite coverage ledger.*
2. *Q is the* $\mathsf{FiniteStream}^{\uparrow}$ *request row that lists exactly the interval-net reads demanded by the consumer.*
3. *L is the finite* $\mathsf{List}^{\uparrow}$ *spine carried by the request row Q.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposed over the same finite request row and list spine.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback boundary available after K, Q, L, W have been displayed.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the same interval-net cells and stream windows.*
7. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the displayed cell, request, window, readback, and tolerance rows.*
8. *H records componentwise* hsame *transport for the interval net, request row, list spine, stream windows, regular readbacks, dyadic tolerances, Real seal, replay row, provenance row, and local naming row.*
9. *C records displayed* Cont *replay from an interval-net request through $K, Q, L, W, R, D, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteIntervalChoice}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{FiniteStream}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteIntervalChoice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, Q, L, W, R, D, E, H, C, P, N$. No coordinate stores a hidden chooser, countable family of choices, host subcover selector, quotient real equality, trichotomy branch, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.FiniteIntervalChoiceUp.FiniteIntervalChoiceTasteGate single carrier alignment`

Theorem 6054.2 (Finite interval choice NameCert obligations)**.** *For every accepted* $\mathsf{FiniteIntervalChoice}^{\uparrow}$ *carrier*

$$I = (K, Q, L, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteIntervalChoice}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *cell-data row, the* $\mathsf{FiniteStream}^{\uparrow}$ *request row, the finite* $\mathsf{List}^{\uparrow}$ *spine, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback boundary, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The finite-choice clause says that each selected interval-net read is indexed by the displayed finite request row Q and list spine L. The window clause says that every stream, regular-rational, dyadic, or Real-facing consumer must pass through the same Q, L, W route before reading R, D, E.*

Proof. Project the carrier of Definition 6054.1. The displayed rows are exactly the interval-net cell data, finite request row, list spine, stream window, regular readback, dyadic tolerance, Real seal, and structural rows H, C, P, N.

The finite-choice clause is row exactness. A choice made by the packet is not a host selector; it is the finite coordinate of Q as represented by L and then read by W.

The downstream rows preserve that finite coordinate. The readback row R, tolerance row D, and Real seal E appear only after K, Q, L, W, while H, C, P, N transport, replay, source, and name the same route. Hence no countable-choice, subcover-selector, quotient-equality, trichotomy, or ambient-completeness row is available. □

Theorem 6054.3 (Finite interval choice closed-bounded-net handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read accepted by a* $\mathsf{FiniteIntervalChoice}^{\uparrow}$ *packet factors through the finite route*

$$K, Q, L, W, R, D, E, H, C, P, N.$$

Here K supplies the $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *cell data, Q and L display the finite request spine, W exposes the corresponding* $\mathsf{StreamName}^{\uparrow}$ *windows, R supplies the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, D supplies the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and E supplies the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The handoff gives L10 interval-net consumers a constructive finite-choice certificate without countable choice, hidden selectors, quotient real equality, or ambient real completeness.*

Proof. Start with the NameCert obligations of Definition 6054.2. They bind the interval-net row K to the same finite request row Q and list spine L before any stream window is exposed.

The StreamName, RegSeqRat, DyadicRatCore, and Real rows are then downstream of the same request coordinate. The displayed replay row C prevents a consumer from replacing Q by a sibling request row, and the transport row H preserves equality only componentwise along the displayed packet.

Finally the provenance and local naming rows P, N name the same finite route. Since the carrier has no coordinate for a hidden selector, a countable choice family, quotient real equality,

trichotomy, or ambient completeness, the closed-bounded-net handoff is exactly the constructive finite-choice route displayed above. □

Falsifiable prediction: An accepted $\mathsf{FiniteIntervalChoice}^{\uparrow}$ read is refuted if it reaches a $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer without displaying the same finite request row, finite list spine, window row, readback boundary, dyadic tolerance row, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: closedboundedintervalnet, finite_stream, streamname, regseqrat, dyadicratcore, real: $\mathsf{FiniteIntervalChoice}^{\uparrow}$ is not bijective to any listed sibling because it binds interval-net cell data to one displayed finite request row and the downstream readback, tolerance, and Real seal rows as a single finite-choice packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteIntervalChoice}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteIntervalChoice}^{\uparrow}$ packet is generated from ClosedBoundedIntervalNet cell data, a FiniteStream request row, a finite ListUp spine, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteIntervalChoice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6054.1, Definition 6054.2, and Definition 6054.3 seed the finite-choice route for L10 interval-net and finite-stream reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteIntervalChoice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, hidden host selectors, open-cover compactness, quotient real equality, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite request exactness, interval-net handoff, StreamName and RegSeqRat readback exactness, DyadicRatCore tolerance nonescape, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteIntervalChoiceUp.

Chapter 6055

A Concrete Naming Certificate for $\mathsf{MinimalRealization}^{\uparrow}$

Following Kalman on finite-dimensional realization theory, the $\mathsf{MinimalRealization}^{\uparrow}$ packet records the displayed finite control-system rows that witness a realization with no smaller state ledger carrying the same input-output behavior. It sits after the observation surface of chapter 294, the reachability surface of chapter 297, the reachability Gramian of chapter 455, the observability Gramian of chapter 5787, and the finite $\mathsf{LinMap}^{\uparrow}$ and $\mathsf{Mat}^{\uparrow}$ rows of chapter 48 and chapter 49. The packet names only finite plant, input, output, transport, replay, provenance, and local naming rows; it does not import a host quotient state space, a canonical Kalman decomposition, or an analytic transfer-function equality.

Definition 6055.1 (MinimalRealization carrier)**.** *A* $\mathsf{MinimalRealization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, U, Y, A, B, C, D, Q, O, G_o, G_r, n, m, I, L, T, P, N)$$

with the following displayed rows:

1. *X is the finite plant state row, U is the input row, and Y is the output row, each read through displayed* $\mathsf{Mat}^{\uparrow}$ *or* $\mathsf{LinMap}^{\uparrow}$ *coordinates;*
2. *$A : X \to X$, $B : U \to X$, $C : X \to Y$, and $D : U \to Y$ are the finite transition, input, output, and feedthrough rows of the plant;*
3. *Q is the reachability row consumed from* $\mathsf{ControlControllability}^{\uparrow}$ *and* $\mathsf{ReachabilityGramian}^{\uparrow}$*;*
4. *O is the observability row consumed from* $\mathsf{ControlObservability}^{\uparrow}$ *and* $\mathsf{ObservabilityGramian}^{\uparrow}$*;*
5. *G_o is the state-dimension ledger and G_r is the reduced-state ledger, both recorded as finite natural rows with matrix-rank readback;*
6. *n is the displayed state-dimension row and m is the reduced-state candidate row compared against it;*
7. *I is the isomorphism witness between any accepted reduced realization at dimension n and the displayed realization rows;*
8. *L records the minimality ledger saying that every realization with the same displayed finite input-output rows has reduced-state ledger m admitting a transport into n;*
9. *T records componentwise* hsame *transport and displayed* Cont *replay for the plant, input, output, reachability, observability, dimension, reduced-state, isomorphism, and minimality rows;*

10. *P is the* Pkg *provenance over* $\mathsf{MinimalRealization}^{\uparrow}$, $\mathsf{ControlObservability}^{\uparrow}$, $\mathsf{ControlControllability}^{\uparrow}$, $\mathsf{ReachabilityGramian}^{\uparrow}$, $\mathsf{ObservabilityGramian}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, BHist, msame, hsame, psame, Cont, *and* NameCert*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MinimalRealization}^{\uparrow}}$ *row.*

Lean4 ✓ `BEDC.Derived.MinimalRealizationUp.MinimalRealizationTasteGate single carrier alignment`

Theorem 6055.2 (MinimalRealization NameCert obligations)**.** *For the carrier of Definition 6055.1, the local* $\mathsf{NameCert}_{\mathsf{MinimalRealization}^{\uparrow}}$ *surface consists exactly of finite plant admission for X, U, Y, A, B, C, D, reachability admission through Q, observability admission through O, state-dimension and reduced-state ledger admission through G_o, G_r, n, m, isomorphism-witness admission through I, minimality-ledger admission through L, componentwise* hsame *and* msame *transport through T, displayed* Cont *replay through T, package provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 6055.1. The plant rows X, U, Y, A, B, C, D are finite $\mathsf{Mat}^{\uparrow}$ and $\mathsf{LinMap}^{\uparrow}$ reads, so the local certificate begins with displayed finite control-system data.

The rows Q and O are consumed from chapter 297, chapter 294, chapter 455, and chapter 5787. They provide the reachability and observability witnesses used by the minimality ledger without introducing a host reachable quotient or hidden unobservable subspace.

Finally $G_o, G_r, n, m, I, L, T, P, N$ record finite dimension comparison, reduced-state comparison, the displayed isomorphism witness, transport, replay, provenance, and local naming. Repacking those rows gives the stated NameCert obligation surface and no additional coordinate is available. □

Theorem 6055.3 (Controllability-observability minimality)**.** *Let $R = (X, U, Y, A, B, C, D, Q, O, G_o, G_r, n, m, I, L,$ be an accepted* $\mathsf{MinimalRealization}^{\uparrow}$ *packet. Any downstream realization consumer that reads R as a minimal finite realization must pass first through the displayed* $\mathsf{ControlControllability}^{\uparrow}$ *row Q, the displayed* $\mathsf{ControlObservability}^{\uparrow}$ *row O, the finite Gramian rows named by* $\mathsf{ReachabilityGramian}^{\uparrow}$ *and* $\mathsf{ObservabilityGramian}^{\uparrow}$*, the state-dimension and reduced-state ledgers G_o, G_r, n, m, the isomorphism witness I, the minimality ledger L, componentwise transport and replay through T, package provenance through P, and the local* $\mathsf{NameCert}_{\mathsf{MinimalRealization}^{\uparrow}}$ *row N.*

The exported minimality claim supplies no host quotient state space, no selected canonical realization, no unbounded trajectory semantics, and no transfer-function equality outside the displayed finite plant rows.

Proof. Start with Definition 6055.2. It exposes exactly the plant, reachability, observability, dimension, reduced-state, isomorphism, minimality, transport, replay, provenance, and local naming rows.

The controllability side is read through Q and the reachability Gramian route, while the observability side is read through O and the observability Gramian route. These are finite BHist rows over $\mathsf{Mat}^{\uparrow}$ and $\mathsf{LinMap}^{\uparrow}$, so the consumer cannot replace them by an ambient state-space quotient.

The ledger L compares every same-input-output realization against the displayed dimension rows n, m, and I is the only isomorphism witness exported at the same dimension. Therefore the minimality read is the finite BEDC route named by R, not a host canonical-form assertion or analytic transfer-function identification. □

Falsifiable prediction: An accepted $\mathsf{MinimalRealization}^{\uparrow}$ packet is refuted by any realization consumer that claims minimality while bypassing either the displayed reachability row Q, the

displayed observability row O, the dimension comparison rows G_o, G_r, n, m, or the isomorphism and minimality ledgers I, L.

Independence witness: controlobservability, controlcontrollability, reachabilitygramian, observabilitygramian, linearmap, matrix: none is bijective to $\mathsf{MinimalRealization}^{\uparrow}$ because the minimal-realization packet jointly carries plant, input, output, reachability, observability, dimension, reduced-state, isomorphism, minimality, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MinimalRealization}^{\uparrow}}$.

Constructive story: A $\mathsf{MinimalRealization}^{\uparrow}$ packet is generated from finite plant, input, output, reachability, observability, dimension, reduced-state, isomorphism, minimality, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MinimalRealization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6055.1, Definition 6055.2, Definition 6055.3, the displayed falsifiable prediction, and the displayed independence witness seed the finite minimal-realization NameCert surface over control, Gramian, linear-map, and matrix rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MinimalRealization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, canonical Kalman decomposition, transfer-function equality, or host quotient state-space semantics.

Upgrade path: Obligation closure requires checked carrier admission, reachability and observability admission, dimension and reduced-state comparison, isomorphism-witness transport, minimality-ledger exactness, continuation replay, package provenance, and local NameCert exhaustion for BEDC.Derived.MinimalRealizationUp.

Chapter 6056

A Concrete Naming Certificate for $\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}$

Following Bishop–Bridges constructive analysis, Specker's monotone bounded sequence obstruction, and the Troelstra–van Dalen account of weak omniscience principles, the $\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}$ packet records the finite L10 boundary at which Real and Completion reads may cite Specker-style obstruction data without importing classical completeness. It sits after the Specker boundary of chapter 3516, the LLPO boundary of chapter 1978, the WLPO boundary of chapter 4062, the weak-omniscience boundary of chapter 5980, the finite observation interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a human-origin completion boundary; it refuses $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, quotient primitives, selected limits, and omniscience leakage.

Definition 6056.1 (Bishop–Specker completion-boundary carrier)**.** *A* $\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, L, W, O, A, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$ *row carrying the Specker obstruction surface.*
2. *L is the* $\mathsf{LLPOBoundary}^{\uparrow}$ *row recording the lesser-limited omniscience refusal attached to the same finite observation.*
3. *W is the* $\mathsf{WLPOBoundary}^{\uparrow}$ *row recording the weak-limited omniscience refusal attached to the same finite observation.*
4. *O is the* $\mathsf{WeakOmniscienceBoundary}^{\uparrow}$ *row collecting the weak-omniscience nonescape ledger.*
5. *A is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected prefixes of the Specker stream and the omniscience-refusal ledgers.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row available from the displayed windows only.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the rational bound, requested precision, and comparison budget used by R.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, L, W, O, A, R, D have all been displayed.*
9. *H records componentwise* hsame *transport for the obstruction, refusal, window, readback, tolerance, seal, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the route*

$$S, L, W, O \longmapsto A, D \longmapsto R \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}$, $\mathsf{SpeckerSequenceBoundary}^{\uparrow}$, $\mathsf{LLPOBoundary}^{\uparrow}$, $\mathsf{WLPOBoundary}^{\uparrow}$, $\mathsf{WeakOmniscienceBoundary}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}}$ *row.*

The carrier predicate asserts that these rows form one finite Real-and-Completion boundary packet. The classifier compares accepted packets only by componentwise agreement of $S, L, W, O, A, R, D, E, H, C, P, N$ under the displayed hsame *and* Cont *routes; it has no coordinate for* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, quotient real equality, selected limits, countable choice, LLPO, WLPO, or a detached omniscience principle.*

Lean4 ✓ `BEDC.Derived.BishopSpeckerCompletionBoundaryUp.BishopSpeckerCompletionBoundaryTasteGate`
`single carrier alignment`

Theorem 6056.2 (Bishop–Specker completion-boundary NameCert obligations)**.** *For every accepted* $\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}$ *carrier*

$$B = (S, L, W, O, A, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission, Specker-obstruction exposure through S, LLPO-refusal exposure through L, WLPO-refusal exposure through W, weak-omniscience refusal through O, finite-window exposure through A, regular rational read-back through R, dyadic tolerance accounting through D, real-seal handoff through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The projection exposes the Specker obstruction row, the LLPO refusal row, the WLPO refusal row, the weak-omniscience refusal row, the finite StreamName window, the regular rational readback, the dyadic tolerance ledger, the Real seal, transport, continuation, provenance, and local naming rows.

The analytic obligations are exactly the visible obstruction and readback rows. The Specker boundary supplies the monotone bounded obstruction, the three omniscience rows record which principles are not available, and the finite window plus dyadic ledger determine the only regular-rational read permitted by the packet.

The structural obligations are H, C, P, N. They transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, quotient primitives, selected limits, LLPO, WLPO, countable choice, or a detached omniscience principle, no additional local NameCert obligation can be read. □

Theorem 6056.3 (Finite-window completion boundary)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or Completion-facing consumer of an accepted* $\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}$ *packet reads the route*

$$\mathsf{SpeckerSequenceBoundary}^{\uparrow},\ \mathsf{LLPOBoundary}^{\uparrow},\ \mathsf{WLPOBoundary}^{\uparrow},\ \mathsf{WeakOmniscienceBoundary}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{Dy}$$

through the displayed rows $S, L, W, O, A, D, R, E, H, C, P, N$. The handoff supplies a finite obstruction-and-readback boundary for L10 Real and Completion arguments, not a proof that $\mathsf{Real}^{\uparrow}$ *is complete, not a selected-limit construction, and not a quotient primitive.*

Proof. Start with the four obstruction rows. The Specker boundary row S supplies the nonlocated completion obstruction, while L, W, O attach the LLPO, WLPO, and weak-omniscience refusal ledgers to the same finite observation surface.

Next read the completion-facing window. The $\mathsf{StreamName}^{\uparrow}$ row A selects the finite prefixes inspected by the consumer, and the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D records the tolerance budget used by the $\mathsf{RegSeqRat}^{\uparrow}$ readback R.

Finally pass through the terminal Real seal. The row E may be consumed only after the obstruction, refusal, window, readback, and tolerance rows are displayed, and H, C, P, N preserve that route. The consumer therefore receives a finite boundary packet, not an ambient completion theorem, selected host limit, trichotomy branch, or quotient equality primitive. □

Theorem 6056.4 (Omniscience nonescape)**.** *No accepted* $\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}$ *packet exports* $\mathsf{LimitedPrincipleOmniscience}^{\uparrow}$, $\mathsf{LesserLimitedOmniscience}^{\uparrow}$, $\mathsf{WLPOBoundary}^{\uparrow}$ *as an available decision principle, weak omniscience as a usable selector, trichotomy for real comparison, quotient equality of real names, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every public read factors through the finite rows* $S, L, W, O, A, R, D, E, H, C, P, N$ *of Definition 6056.1.*

Proof. Inspect the coordinates of the carrier. The only analytic rows are the Specker obstruction, three refusal ledgers, finite StreamName window, regular rational readback, dyadic tolerance ledger, and terminal Real seal.

The refusal rows are negative boundary data. They record that the packet is read without LLPO, WLPO, or weak-omniscience escape; they do not introduce a decision function, a selector for limits, or a trichotomy branch.

The remaining rows are structural. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ naming preserve the displayed route but add no new analytic coordinate. Thus every public read remains inside $S, L, W, O, A, R, D, E, H, C, P, N$, and the listed omniscience, quotient, selection, trichotomy, and completion principles cannot be extracted. □

Falsifiable prediction: Every $\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}$ read factors through a SpeckerSequenceBoundary obstruction row, LLPOBoundary refusal row, WLPOBoundary refusal row, WeakOmniscienceBoundary refusal row, finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, transport, continuation, provenance, and local naming.

Independence witness: specker-sequence-boundary, llpo-boundary, wlpo-boundary, weak-omniscience-boundary, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the Specker obstruction, three omniscience-refusal ledgers, finite observation window, regular rational readback, dyadic tolerance accounting, Real seal, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}$ packet is generated from a SpeckerSequenceBoundary obstruction row, LLPOBoundary refusal row, WLPOBoundary refusal row, WeakOmniscienceBoundary refusal row, finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6056.1, Definition 6056.2, Definition 6056.3, and Definition 6056.4 seed the finite Bishop–Specker completion boundary over SpeckerSequenceBoundary, LLPOBoundary, WLPOBoundary, WeakOmniscienceBoundary, StreamName, RegSeqRat, DyadicRatCore, Real, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopSpeckerCompletionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, quotient real equality, selected limits, countable choice, LLPO, WLPO, weak omniscience, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, finite-window completion handoff, omniscience nonescape, and TasteGate field faithfulness for BEDC.Derived.BishopSpeckerCompletionBoundaryUp.

Chapter 6057

A Concrete Naming Certificate for $\mathsf{BishopRealCompletionAdjoint}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRealCompletionAdjoint}^{\uparrow}$ packet records the finite adjoint surface by which a Bishop regular real name is admitted into the completion route and read back through the same L10 data. It sits after the regular completion monad of chapter 2136, the Cauchy completion functor of chapter 423, the universal property row of chapter 397, the regular rational readback of chapter 301, and the visible real-name seal of chapter 38. The packet names a non-quotient public completion-adjoint boundary; it does not assert ambient completeness of $\mathsf{Real}^{\uparrow}$, choose completed limits, compare host real values, or identify quotient streams.

Definition 6057.1 (Bishop real completion adjoint carrier)**.** *A* $\mathsf{BishopRealCompletionAdjoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, F, U, R, E, J, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{RegularCauchyCompletionMonad}^{\uparrow}$ *row, recording the finite unit and bind schedule for completion-facing regular names.*
2. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *row, recording the source-to-completion transport used by functorial consumers.*
3. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row, recording extension existence and uniqueness only as displayed finite ledger data.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached by the source windows and by the completion-facing unit request.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after M, F, U, R have been read.*
6. *J is the unit-extension handoff row, matching the unit row of M with the extension row of U through the functorial surface F.*
7. *T is the triangle-ledger row, recording exactness for the unit leg, extension leg, readback leg, and Real seal leg.*
8. *H records componentwise* hsame *transport for the monad, functor, universal-property, readback, seal, handoff, triangle-ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$M, F, U \longmapsto R \longmapsto E \longmapsto J, T, H, P, N.$$

10. *P is the* Pkg *provenance over* BishopRealCompletionAdjoint$^{\uparrow}$, RegularCauchyCompletionMonad$^{\uparrow}$, CauchyCompletionFunctor$^{\uparrow}$, CompletionUniversalProperty$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{BishopRealCompletionAdjoint}^{\uparrow}}$ *row.*

The accepted carrier is exactly the displayed packet A. It has no coordinate for quotient completion equality, selected limits, host real equality, countable choice, ambient Real$^{\uparrow}$ *completeness, or a detached adjunction theorem outside the finite rows.*

Theorem 6057.2 (Bishop real completion adjoint NameCert obligations)**.** *For every accepted carrier $A = (M, F, U, R, E, J, T, H, C, P, N)$, the local* NameCert$_{\text{BishopRealCompletionAdjoint}^{\uparrow}}$ *obligations are exhausted by carrier admission for the displayed monad, functor, universal-property, readback, seal, unit-extension handoff, triangle-ledger, transport, replay, provenance, and local naming rows. No obligation may call on quotient completion equality, a selected limit, host real equality, countable choice, ambient* Real$^{\uparrow}$ *completeness, or an external adjunction principle.*

Proof. Project the carrier of Definition 6057.1. The only rows visible to the local classifier are $M, F, U, R, E, J, T, H, C, P, N$.

Read the completion route in order. The monad row supplies the finite unit and bind schedule, the functor row supplies the completion-facing transport, and the universal-property row supplies the displayed extension ledger. Only after those rows are present may the readback row R and terminal seal row E be consumed.

The handoff and exactness rows are structural over that same route. The row J compares the unit and extension legs, T records the triangle ledger, H transports displayed coordinates, C replays the permitted reads, and P, N record provenance and local naming. Since the carrier has no excluded coordinate, no local obligation can export one. □

Theorem 6057.3 (Bishop real completion adjoint unit-extension handoff)**.** *Let $A = (M, F, U, R, E, J, T, H, C, P, N$ be an accepted* BishopRealCompletionAdjoint$^{\uparrow}$ *carrier. Every unit-extension read factors first through the* RegularCauchyCompletionMonad$^{\uparrow}$ *unit row in M, then through the* CauchyCompletionFunctor$^{\uparrow}$ *source-to-completion row F, and only then through the* CompletionUniversalProperty$^{\uparrow}$ *extension ledger U. The handoff row J records this finite route before the* RegSeqRat$^{\uparrow}$ *readback R and terminal* Real$^{\uparrow}$ *seal E are exposed.*

Proof. Start with the monad row. The unit part of M admits source regular data into the completion interface through finite windows and tolerance rows.

Next apply the functor row F. It transports the same displayed source data to the completion-facing route without introducing a quotient completion object or selected representative.

Finally read the universal-property row U. The handoff row J can compare unit and extension data only after M and F have been projected. The readback R, seal E, transport H, replay C, provenance P, and local naming N preserve that order, so the consumer receives a finite handoff rather than a host adjunction. □

Theorem 6057.4 (Bishop real completion adjoint triangle ledger exactness)**.** *For every accepted* BishopRealCompletionAdjoint$^{\uparrow}$ *carrier $A = (M, F, U, R, E, J, T, H, C, P, N)$, the triangle-ledger row*

T is exact for the displayed unit leg, extension leg, regular readback leg, and terminal Real seal leg. Any completion-facing consumer that reads the public adjoint surface must account for the rows

$$M, F, U, R, E, J, T, H, C, P, N$$

in that order, and it obtains no quotient stream equality, selected completion point, host real equality, countable-choice schedule, ambient completeness theorem, or detached adjunction proof.

Proof. Project the accepted carrier. The triangle ledger T is not an independent theorem row; it is displayed beside the monad, functor, universal-property, readback, seal, and handoff rows.

Use the unit-extension handoff of Definition 6057.3. It places J downstream of M, F, U and upstream of R, E, so every triangle comparison is read through the same finite route.

The structural rows finish the ledger accounting. Componentwise transport in H preserves the displayed coordinates, replay in C records the allowed reads, and P, N bind provenance and naming. Because the carrier contains no excluded row, exactness of T remains a finite ledger statement and cannot become a quotient, choice, host-equality, completeness, or external-adjunction claim. □

Theorem 6057.5 (Bishop real completion adjoint readback nonescape)**.** *Let $A = (M, F, U, R, E, J, T, H, C, P, N)$ be an accepted* $\mathsf{BishopRealCompletionAdjoint}^{\uparrow}$ *carrier. Every readback through R, E remains downstream of the displayed monad, functor, universal-property, unit-extension handoff, triangle-ledger, transport, replay, provenance, and local naming rows $M, F, U, J, T, H, C, P, N$. The readback cannot become quotient completion equality, a selected completed point, host real equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or a detached adjunction theorem.*

Proof. Project the carrier of Definition 6057.1. The only readback and seal coordinates are R and E, and both are displayed inside the same packet as $M, F, U, J, T, H, C, P, N$.

Use the unit-extension handoff of Definition 6057.3. It places every readback behind the monad unit row, functorial transport row, universal-property extension ledger, and handoff row before the terminal seal is exposed.

Apply triangle-ledger exactness, Definition 6057.4. The ledger keeps the unit leg, extension leg, readback leg, and Real seal leg in one finite route.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same displayed carrier, so no quotient completion equality, selected completed point, host equality, countable-choice schedule, ambient completeness theorem, or detached adjunction can be produced by the readback. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealCompletionAdjoint}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealCompletionAdjoint}^{\uparrow}$ packet is generated from a regular completion monad row, a Cauchy completion functor row, a completion universal-property row, a RegSeqRat readback, a Real seal, unit-extension handoff, triangle-ledger exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealCompletionAdjoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6057.1, Definition 6057.2, Definition 6057.3, and Definition 6057.4 seed the non-quotient completion-adjoint packet over the monad, functor, universal-property, readback, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealCompletionAdjoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected completed limits, host real equality, countable choice, ambient Real completeness, Lean verification, bridge checking, or a host adjunction theorem.

Upgrade path: Obligation closure requires checked carrier admission, unit-extension handoff, triangle-ledger exactness, readback nonescape, seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRealCompletionAdjointUp

Chapter 6058

A Concrete Naming Certificate for $\mathsf{AbelTheorem}^{\uparrow}$

Following Abel and Hardy, the $\mathsf{AbelTheorem}^{\uparrow}$ packet records the finite radial-limit route for a real series whose Cesaro-facing summation data is already displayed. It is a Real-series consumer of chapter 1763, chapter 1765, chapter 301, and chapter 38: the packet names the finite handoff from summation rows through dyadic radial parameters and regular rational readback to a Real seal, without importing a host power-series limit or ambient completeness theorem.

Definition 6058.1 (Abel theorem carrier)**.** *An* $\mathsf{AbelTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, H, C, D, W, R, E, T, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{AbelSummation}^{\uparrow}$ *row, carrying the finite radial polynomial-window reads used by the Abel summation route.*
2. *H is the* $\mathsf{HardyCesaroMean}^{\uparrow}$ *or* $\mathsf{CesaroConvergence}^{\uparrow}$ *row, carrying the Cesaro-facing mean data whose displayed convergence surface is consumed by the Abel route.*
3. *C records the componentwise* hsame *transport for the Abel row, Cesaro row, dyadic radial row, finite stream window, regular rational readback, Real seal, replay row, provenance row, and local naming row.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radial-parameter ledger, including dyadic radii, one-sided approach windows, and tolerance comparisons for parameters below the terminal boundary.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the dyadic radial ledger.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the Abel and Cesaro data after D and W have fixed the current tolerance window.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the Abel, Cesaro, dyadic, stream, and regular rational rows have been displayed.*
8. *T records the displayed* Cont *replay from a radial tolerance request through A, H, D, W, R, E.*
9. *P is the* Pkg *provenance over* $\mathsf{AbelTheorem}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{CesaroConvergence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, H, C, D, W, R, E, T, P, N$. It has no coordinate for a host Abel limit, selected real power-series value, quotient stream equality, countable choice, trichotomy, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.AbelTheoremUp.AbelTheoremTasteGate single carrier alignment`

Theorem 6058.2 (Abel theorem NameCert obligations)**.** *For every accepted* $\mathsf{AbelTheorem}^{\uparrow}$ *carrier*

$$L = (A, H, C, D, W, R, E, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AbelTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *Abel summation admission through A, requiring every radial polynomial-window read to pass through the displayed* $\mathsf{AbelSummation}^{\uparrow}$ *packet;*
2. *Cesaro-source admission through H, requiring the Cesaro-facing mean or convergence row to be visible before the Abel route is read as a radial limit certificate;*
3. *dyadic radial admission through D and W, requiring radial parameters and finite observation windows to be read from* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$*;*
4. *regular rational readback through R, requiring the radial-window observations to be repacked as a* $\mathsf{RegSeqRat}^{\uparrow}$ *row before the Real seal is visible;*
5. *terminal Real-seal admission through E, requiring every Real-facing consumer to pass through A, H, D, W, R before reading the displayed* $\mathsf{Real}^{\uparrow}$ *boundary;*
6. *componentwise transport, replay, provenance, and local naming through C, T, P, N, with no extra host limit, quotient stream equality, countable choice, trichotomy, host equality, or ambient completeness row.*

No Abel theorem naming obligation is stored outside these rows.

Proof. Project the carrier of Definition 6058.1. The mathematical source rows are A, H, D, W, R, E, while C, T, P, N only transport, replay, source, and name that displayed route.

The Abel summation row supplies the radial polynomial-window data. The Cesaro-facing row supplies the mean or convergence surface already displayed by the sibling chapters, so the route consumes a finite summation certificate rather than a host series limit.

The dyadic radial ledger D and the stream window W determine the visible precision request. The readback row R repacks exactly that finite observation as regular rational data, and the Real seal E is downstream of the same route.

Since the carrier has no coordinate for a selected radial limit, quotient stream equality, choice, trichotomy, host equality, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6058.3 (Abel theorem radial Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{AbelTheorem}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{AbelSummation}^{\uparrow} \longmapsto \mathsf{HardyCesaroMean}^{\uparrow}/\mathsf{CesaroConvergence}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRa}$$

Thus the radial-limit claim is read as a displayed Real-name boundary generated from Abel summation data, Cesaro-facing source data, dyadic radial tolerances, finite stream windows, and regular rational readback. It is not a claim of host Abel convergence, selected power-series value, quotient stream equality, countable choice, trichotomy, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the Abel and Cesaro rows A and H. They are the only carrier rows that name the summation-side data, so a Real-facing consumer begins with the finite sibling packets from chapter 1763 and chapter 1765.

Next read the dyadic radial ledger D and stream window W. These rows bind the radial tolerance request to the same finite dyadic and observation surfaces used by the Real-name route.

Apply Definition 6058.2. The regular rational row R is required before any Real seal is visible, and the terminal row E is exposed only after A, H, D, W, R have been read.

The structural rows C, T, P, N preserve and name this route. Because the excluded host and quotient data are absent from the carrier, every Real-facing consumer remains inside the displayed radial Real-seal path. □

Closure status for $\mathsf{NameCert}_{\mathsf{AbelTheorem}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6058.1, Definition 6058.2, and Definition 6058.3 seed the finite Abel theorem route from Abel summation and Cesaro-facing data through dyadic radial windows, regular rational readback, and the RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelTheorem}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.AbelTheoremUp.AbelTheoremTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host Abel convergence, selected power-series values, quotient stream equality, countable choice, trichotomy, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked Abel summation admission, Cesaro-source admission, dyadic radial admission, regular rational readback, terminal Real-seal admission, transport, replay, provenance, and local naming for BEDC.Derived.AbelTheoremUp.

Constructive story: An $\mathsf{AbelTheorem}^{\uparrow}$ packet is generated from Abel summation data, Hardy-Cesaro or Cesaro-convergence source data, dyadic radial tolerances, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6059

A Concrete Naming Certificate for $\mathsf{LawlikeCauchyReal}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LawlikeCauchyReal}^{\uparrow}$ packet presents a real number by a lawlike regular Cauchy rational name whose request schedule is visible before any quotient, selected limit, countable-choice principle, or ambient completeness theorem is read. It sits on the lawlike generation discipline of chapter 3790, the finite window surface of chapter 126, the dyadic tolerance rows of chapter 291, the regular rational readback of chapter 301, the Cauchy-modulus interface of chapter 292, and the terminal real-name seal of chapter 38. The packet records a non-quotient, choice-free Real-and-Completion route; it does not assert that arbitrary Cauchy data carries a selected Real limit.

Definition 6059.1 (LawlikeCauchyReal carrier)**.** *A* $\mathsf{LawlikeCauchyReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (G, S, D, Q, M, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{LawlikeSequence}^{\uparrow}$ *generation row, recording the lawlike request procedure that produces the rational observations.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the displayed request procedure.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic error budgets, endpoint comparisons, and late-window bounds.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the lawlike stream windows and dyadic tolerance ledger.*
5. *M is the* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *row naming the displayed modulus schedule or convergence budget consumed by the regular readback.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after G, S, D, Q, M have all been exposed.*
7. *H records componentwise* hsame *transport for the lawlike generator, stream window, dyadic ledger, regular readback, modulus row, Real seal, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a lawlike Cauchy real request through G, S, D, Q, M, E.*
9. *P is the* Pkg *provenance over* $\mathsf{LawlikeCauchyReal}^{\uparrow}$, $\mathsf{LawlikeSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulusSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{LawlikeCauchyReal}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $G, S, D, Q, M, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable-choice schedules, host real equality, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credentials.*

Lean4 ✓ `BEDC.Derived.LawlikeCauchyRealUp.LawlikeCauchyRealTasteGate single carrier alignment`

Theorem 6059.2 (LawlikeCauchyReal NameCert obligations)**.** *For every accepted* $\mathsf{LawlikeCauchyReal}^{\uparrow}$ *carrier*

$$L = (G, S, D, Q, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LawlikeCauchyReal}^{\uparrow}}$ *surface consists exactly of carrier admission, lawlike generator exposure, finite stream-window exposure, dyadic tolerance exactness, regular rational readback, displayed Cauchy-modulus handoff, Real-seal routing, componentwise transport, displayed replay, provenance, local naming, and non-escape from the displayed rows.*

Proof. Project the carrier rows of Definition 6059.1. The accepted packet exposes the lawlike generator G, the stream window S, the dyadic ledger D, the regular readback Q, the modulus row M, the Real seal E, and the structural rows H, C, P, N.

The source rows are then read in order. The lawlike procedure of chapter 3790 supplies the request discipline, chapter 126 opens only the finite windows requested by that procedure, and chapter 291 supplies the tolerance ledger.

The regular and completion-facing rows close the route without adding a selected limit. The readback of chapter 301 packages the finite rational data, chapter 292 supplies the displayed budget row, and chapter 38 receives the terminal seal only through E.

Finally H and C transport and replay the same coordinates, while P and N record provenance and local naming. Since no additional coordinate is present, the certificate surface exports none of the excluded quotient, choice, completeness, host-equality, verification, or bridge data. □

Theorem 6059.3 (LawlikeCauchyReal modulus handoff)**.** *Every completion-facing request for an accepted* $\mathsf{LawlikeCauchyReal}^{\uparrow}$ *carrier reads the displayed Cauchy modulus row M only after the lawlike generator G, finite stream window S, dyadic tolerance ledger D, and regular rational readback Q have been exposed. Thus the handoff supplies a finite convergence budget for the named lawlike route, not a selector for arbitrary Cauchy data.*

Proof. Start with an accepted carrier $L = (G, S, D, Q, M, E, H, C, P, N)$. By Definition 6059.1, the only Cauchy-modulus coordinate is M, and it is downstream of the lawlike source, finite window, tolerance ledger, and regular readback rows.

The sibling routes determine the inputs to M. The generator row G supplies a lawlike request discipline, the window row S opens the requested observations, the dyadic row D supplies the tolerance comparisons, and the regular row Q packages those observations as the readback expected by the modulus interface.

Therefore a completion-facing consumer cannot read M as ambient completeness or as a selected limit. The only accepted handoff is the displayed route through G, S, D, Q, M, transported by H, replayed by C, and named by P, N. □

Theorem 6059.4 (LawlikeCauchyReal Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{LawlikeCauchyReal}^{\uparrow}$ *carrier factors through the finite route*

$$G, S, D, Q, M \longmapsto E$$

before the terminal Real seal is visible. Thus a consumer receives lawlike generation, finite StreamName windows, dyadic tolerance rows, RegSeqRat readback, and the CauchyModulusSpace budget before it may consume the $\mathsf{Real}^{\uparrow}$ *row.*

Proof. Apply Definition 6059.2. The Real-facing coordinate is E, and the obligation surface places it after G, S, D, Q, M.

The route cannot bypass the source stage because G is the only row naming the lawlike request procedure. It cannot bypass the window or tolerance stage because S and D are the only rows containing finite observations and dyadic error bounds.

The regular readback and modulus handoff are also forced. The row Q is the sole $\mathsf{RegSeqRat}^{\uparrow}$ readback available to the packet, and M is the sole displayed $\mathsf{CauchyModulusSpace}^{\uparrow}$ budget consumed before the Real seal.

Transport, replay, provenance, and local naming preserve the same route. Since H, C, P, N add no quotient, selected-limit, countable-choice, host-equality, or ambient-completeness coordinate, every Real-facing read reaches E only through the displayed route. □

Theorem 6059.5 (LawlikeCauchyReal non-escape)**.** *An accepted* $\mathsf{LawlikeCauchyReal}^{\uparrow}$ *carrier exports no quotient stream equality, selected limit, countable-choice schedule, trichotomy principle, open-cover compactness proof, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, host real equality, Lean verification, or bridge credential. Every exported read is confined to* $G, S, D, Q, M, E, H, C, P, N$.

Proof. Use the carrier definition to enumerate the available coordinates. They are exactly the lawlike generator, stream window, dyadic ledger, regular readback, modulus row, Real seal, transport, replay, provenance, and local naming rows.

The obligation theorem identifies the NameCert surface with those same rows. Any proposed exported read must therefore be one of the displayed coordinates or a structural transport of them through H and C.

None of the displayed coordinates stores quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient Real completeness, host real equality, Lean verification, or bridge data. Hence no such datum can escape from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LawlikeCauchyReal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LawlikeCauchyReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6059.1, Definition 6059.2, Definition 6059.3, Definition 6059.4, and Definition 6059.5 seed the non-quotient lawlike Cauchy real-name packet over displayed $\mathsf{LawlikeSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulusSpace}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LawlikeCauchyReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lawlike generator exposure, stream-window exposure, dyadic tolerance exactness, regular rational readback, displayed Cauchy-modulus handoff, Real-seal routing, transport stability, replay stability, provenance, local naming, and non-escape for BEDC.Derived.LawlikeCauchyRealUp.

Constructive story: A $\mathsf{LawlikeCauchyReal}^{\uparrow}$ packet is generated from a $\mathsf{LawlikeSequence}^{\uparrow}$ request procedure, finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{CauchyModulusSpace}^{\uparrow}$ budget row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6060

A Concrete Naming Certificate for $\mathsf{BoundedInverseTheorem}^{\uparrow}$

Following Banach and Rudin-style functional analysis, the $\mathsf{BoundedInverseTheorem}^{\uparrow}$ packet records the finite BEDC certificate for reading a bijective bounded linear map between Banach rows as a displayed inverse-bound route. It is grounded in the open-ball image handoff of chapter 1538, the graph-read boundary of chapter 1537, the Banach source and target rows of chapter 90, the bounded linear map surface of chapter 48, and the terminal real-bound seal of chapter 38. The packet exposes only finite rows: Banach endpoints, a bounded linear map row, bijectivity ledgers, an open-image witness, an inverse-bound ledger, graph compatibility, transport, replay, provenance, and local naming.

Definition 6060.1 (Bounded inverse theorem carrier)**.** *A* $\mathsf{BoundedInverseTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, T, J, O, B, G, H, C, P, N)$$

with the following visible rows:

1. *X is the source* $\mathsf{Banach}^{\uparrow}$ *row, including the displayed norm, metric, regular-Cauchy, and completion observations used to read source windows.*
2. *Y is the target* $\mathsf{Banach}^{\uparrow}$ *row, including the displayed norm, metric, regular-Cauchy, and completion observations used to read target windows.*
3. *T is the bounded* $\mathsf{LinMap}^{\uparrow}$ *row from X to Y, carrying only the finite action, linearity, and bound data displayed by the map certificate.*
4. *J is the bijectivity ledger, with injective comparison rows and surjective preimage rows over the same displayed X, Y, T data.*
5. *O is the* $\mathsf{OpenMappingTheorem}^{\uparrow}$ *open-image handoff row, recording the finite ball-image and source-window data needed before an inverse-bound request can be public.*
6. *B is the inverse-bound ledger, recording target tolerance requests, source preimage windows, norm comparisons, and the real-bound seal read through* $\mathsf{Real}^{\uparrow}$*.*
7. *G is the* $\mathsf{ClosedGraphTheorem}^{\uparrow}$ *compatibility row, recording that graph-facing consumers read the inverse graph only through displayed graph rows and not through host graph equality.*
8. *H records componentwise* hsame *transport for endpoint, map, bijectivity, open-image, inverse-bound, graph, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from Banach admission through bounded map inspection, bijectivity lookup, open-image handoff, inverse-bound readback, graph compatibility, and real-bound sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{BoundedInverseTheorem}^{\uparrow}$, $\mathsf{OpenMappingTheorem}^{\uparrow}$, $\mathsf{ClosedGraphTheorem}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedInverseTheorem}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host inverse function, quotient operator equality, choice-selected inverse values, a non-displayed open mapping principle, a non-displayed closed graph principle, or ambient completeness beyond the Banach rows X and Y.

Lean4 ✓ `BEDC.Derived.BoundedInverseTheoremUp.TasteGate.BoundedInverseTheoremTasteGate single carrier alignment`

Theorem 6060.2 (Bounded inverse theorem NameCert obligations)**.** *For an accepted* $\mathsf{BoundedInverseTheorem}^{\uparrow}$ *carrier $Q = (X, Y, T, J, O, B, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedInverseTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Banach source row, Banach target row, bounded linear map row, bijectivity ledger, open-image handoff, inverse-bound ledger, graph compatibility row, componentwise transport, continuation replay, provenance, and local naming;*

2. *endpoint agreement, requiring T, J, O, B, G to read the same displayed source and target Banach rows before any inverse-bound request is admitted;*

3. *bijective map exposure, requiring inverse-facing consumers to read injective comparison and surjective preimage data through the bounded* $\mathsf{LinMap}^{\uparrow}$ *row T and the finite ledger J;*

4. *open-mapping route, requiring every inverse norm-bound estimate to pass through the* $\mathsf{OpenMappingTheorem}^{\uparrow}$ *row O before the inverse-bound ledger B is exposed;*

5. *closed-graph route, requiring graph-facing consumers to route the displayed inverse graph through the* $\mathsf{ClosedGraphTheorem}^{\uparrow}$ *row G and the same X, Y, T, J, O, B fields;*

6. *real-bound exactness, requiring every numeric inverse-bound read to pass through the displayed* $\mathsf{Real}^{\uparrow}$ *seal in B rather than through a host real or quotient operator norm;*

7. *structural replay, requiring* hsame, Cont, Pkg, *and local* NameCert *rows to preserve the same bounded-inverse route;*

8. *ledger non-escape, excluding host inverse functions, quotient operator equality, choice-selected inverse values, non-displayed open-mapping or closed-graph principles, and ambient completeness beyond X and Y.*

No bounded inverse theorem obligation is stored outside these rows.

Proof. Project the carrier of Definition 6060.1. The endpoint data are X and Y, the bounded map is T, the bijectivity ledger is J, the open-image handoff is O, the inverse-bound ledger is B, and the graph compatibility row is G.

Endpoint agreement is rowwise. Since T, J, O, B, G are all carried over the same displayed Banach endpoints, an inverse-facing consumer cannot mix a map row from one source with an open-image witness or graph row from another target.

The bounded-inverse estimate is read through a finite handoff chain. The ledger J first supplies injective comparison and surjective preimage data for T. The open-mapping row O then supplies

the displayed open-ball image route of chapter 1538. Only after those rows are visible may B expose the source-window request, norm comparison, and $\mathsf{Real}^{\uparrow}$ bound seal.

Graph compatibility is separate from the inverse-bound estimate. The row G cites the closed-graph boundary of chapter 1537, so a graph-facing consumer reads the inverse graph only as displayed graph data and cannot replace the route by host graph equality.

Finally H, C, P, N transport, replay, record provenance for, and name exactly this finite route. Since the carrier fields are exhausted by $X, Y, T, J, O, B, G, H, C, P, N$, the excluded host inverse, quotient operator, choice-selected, non-displayed theorem, and ambient-completeness principles have no row in the packet. □

Theorem 6060.3 (Bounded inverse theorem open-mapping route)**.** *Let $Q = (X, Y, T, J, O, B, G, H, C, P, N)$ be an accepted* $\mathsf{BoundedInverseTheorem}^{\uparrow}$ *carrier. Every inverse-bound read exported by Q factors through the displayed route*

$$X, Y, T, J, O, B, G, H, C, P, N.$$

In particular, the consumer must pass through the Banach rows of chapter 90, the bounded $\mathsf{LinMap}^{\uparrow}$ *row of chapter 48, the open-image handoff of chapter 1538, the graph boundary of chapter 1537, and the real-bound seal of chapter 38 before any inverse-bound surface is public.*

Proof. Start with the endpoint and map rows. A consumer reads source and target norm windows only through X and Y, and it reads the bounded map only through T.

Next inspect the bijectivity and open-image rows. The ledger J supplies the displayed injective and surjective data, while O supplies the finite open-ball image handoff. No inverse-bound conclusion is available before both rows have been read.

The inverse-bound and graph rows then determine the public surface. The row B records the target tolerance requests, source preimage windows, norm comparison, and $\mathsf{Real}^{\uparrow}$ bound seal. The row G keeps the inverse graph visible as a closed-graph route rather than as host graph equality.

Transport by H, replay by C, and packaging by P, N preserve exactly the same route. Hence the exported inverse-bound surface is the displayed finite chain and not a quotient operator space, selected inverse map, host real norm, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedInverseTheorem}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedInverseTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6060.1, Definition 6060.2, and Definition 6060.3 seed the finite inverse-bound certificate over displayed Banach endpoints, bounded LinearMap rows, bijectivity ledgers, open-image handoffs, graph compatibility rows, Real bound seals, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedInverseTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host inverse functions, quotient operator equality, choice-selected inverse values, non-displayed open-mapping or closed-graph principles, Lean verification, bridge checking, or ambient completeness beyond the displayed Banach rows.

Upgrade path: Obligation closure requires checked carrier admission, endpoint agreement, bijective map exposure, open-mapping routing, closed-graph routing, real-bound exactness, structural replay, and ledger non-escape for BEDC.Derived.BoundedInverseTheoremUp.

Constructive story: The construction starts from displayed Banach endpoints, reads a bounded LinearMap row with bijectivity data, routes inverse-bound requests through OpenMappingTheorem and ClosedGraphTheorem rows, seals the numeric bound through Real data, and exports only the local hsame and Cont route.

Chapter 6061

A Concrete Naming Certificate for $\mathsf{BishopCompletionKleisliTriangle}^{\uparrow}$

Following Mac Lane and Bishop–Bridges, the $\mathsf{BishopCompletionKleisliTriangle}^{\uparrow}$ packet records the finite triangle where the regular completion monad, the Kleisli consumer, the completion functor, and the universal-property readback meet the Bishop real seal. It sits after the adjoint packet of chapter 6057, the regular completion monad of chapter 2136, and the Kleisli boundary of chapter 1845. The packet names a non-quotient L10 completion route; it does not select completed points, compare quotient streams, import countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6061.1 (Bishop completion Kleisli triangle carrier)**.** *A* $\mathsf{BishopCompletionKleisliTriangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, K, F, U, R, E, J, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{RegularCauchyCompletionMonad}^{\uparrow}$ *row, recording the unit and bind schedule for regular completion names.*
2. *K is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *row, recording the consumer boundary for unit, bind, and reassociated bind requests.*
3. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *row, recording functorial source-to-completion transport.*
4. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row, recording extension and uniqueness only as displayed finite ledger data.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row through which the regular source windows are inspected.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, K, F, U, R have been displayed.*
7. *J is the triangle ledger, matching the monad unit, Kleisli bind, functor handoff, universal-property extension, readback, and Real seal legs.*
8. *H records componentwise* hsame *transport for the monad, Kleisli, functor, universal-property, readback, seal, triangle-ledger, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the route*

$$M, K, F, U \longmapsto R \longmapsto E \longmapsto J, H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionKleisliTriangle}^{\uparrow}$, $\mathsf{RegularCauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionKleisliTriangle}^{\uparrow}}$ *row.*

The accepted carrier is exactly the displayed packet T. It has no coordinate for quotient completion equality, selected limits, host real equality, countable-choice schedules, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached Kleisli adjunction theorem.*

Theorem 6061.2 (Bishop completion Kleisli triangle NameCert obligations)**.** *For every accepted carrier $T = (M, K, F, U, R, E, J, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionKleisliTriangle}^{\uparrow}}$ *obligations are exhausted by carrier admission for the displayed monad, Kleisli, functor, universal-property, readback, seal, triangle-ledger, transport, replay, provenance, and local naming rows. Every completion-facing consumer must read the route in the order*

$$M, K, F, U \longmapsto R \longmapsto E \longmapsto J, H, C, P, N.$$

No local obligation may call on quotient completion equality, selected limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or an external adjunction principle.*

Proof. Project the carrier of Definition 6061.1. The only rows visible to the local classifier are $M, K, F, U, R, E, J, H, C, P, N$.

Read the completion route by route ordering. The monad row M supplies unit and bind schedule data, the Kleisli row K fixes the consumer boundary, the functor row F transports source data to completion-facing names, and the universal-property row U supplies the displayed extension ledger. Only after those rows are present may the regular readback R and terminal seal E be consumed.

The triangle row is structural over that same route. The row J records compatibility of the monad, Kleisli, functor, universal-property, readback, and seal legs, while H transports displayed coordinates, C replays the permitted reads, and P, N record provenance and local naming.

Since the accepted packet has no coordinate for quotient completion equality, selected limits, host real equality, countable choice, ambient completeness, or a detached adjunction theorem, no NameCert obligation can export one. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionKleisliTriangle}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompletionKleisliTriangle}^{\uparrow}$ packet is generated from a regular completion monad row, a Cauchy Kleisli consumer row, a Cauchy completion functor row, a completion universal-property row, a RegSeqRat readback, a Real seal, a triangle ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCompletionKleisliTriangle}^{\uparrow}}$, seed)

Scope closed: Definition 6061.1 and Definition 6061.2 seed the non-quotient completion triangle over the monad, Kleisli, functor, universal-property, readback, and Real seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCompletionKleisliTriangle}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected completed limits, host real equality, countable choice, ambient Real completeness, Lean verification, bridge checking, or a host adjunction theorem.

Upgrade path: Obligation closure requires checked carrier admission, triangle-ledger exactness, readback nonescape, seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompletionKleisliTriangleUp.

Chapter 6062

A Concrete Naming Certificate for $\mathsf{RiemannUniformMesh}^{\uparrow}$

Following Riemann and Bishop–Bridges constructive analysis, the $\mathsf{RiemannUniformMesh}^{\uparrow}$ packet records the finite equal-width dyadic mesh rows used before a Riemann-sum or completion-facing consumer reads an integral approximation. It sits after the dyadic endpoint discipline of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the tagged finite-sum consumer of chapter 1615, and the displayed finite partition mesh of chapter 3496. It also uses the dyadic selector route of chapter 2254 to keep mesh depth finite and visible.

Definition 6062.1 (Riemann uniform mesh NameCert carrier)**.** *A* $\mathsf{RiemannUniformMesh}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (P, D, W, R, S, E, H, C, G, N)$$

with the following displayed rows:

1. *P is the finite partition-mesh row, exposing interval endpoints, cell order, adjacency, and common-refinement evidence through the* $\mathsf{FinitePartitionMesh}^{\uparrow}$ *surface.*
2. *D is the dyadic mesh scale row, recording the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and equal-width dyadic scale used by every cell.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the displayed mesh scale.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same window and dyadic tolerance.*
5. *S is the* $\mathsf{RiemannSum}^{\uparrow}$ *consumer row, reading tag values, cell widths, and the finite sum only after P, D, W, R are visible.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only as the terminal handoff for the displayed finite approximation.*
7. *H records componentwise* hsame *transport for partition mesh, dyadic scale, finite window, regular readback, Riemann-sum handoff, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the partition row through the dyadic scale, finite window, regular readback, Riemann-sum row, and Real seal.*
9. *G is the* Pkg *provenance over* $\mathsf{RiemannUniformMesh}^{\uparrow}$, $\mathsf{FinitePartitionMesh}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{CofinalDyadicMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{RiemannUniformMesh}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, D, W, R, S, E, H, C, G, N$. It contains no host interval continuum, no quotient completion, no selected limiting mesh family, no unrestricted tag-choice principle, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.RiemannUniformMeshUp.RiemannUniformMeshTasteGate single carrier alignment`

Theorem 6062.2 (Riemann uniform mesh NameCert obligations)**.** *For every accepted* $\mathsf{RiemannUniformMesh}^{\uparrow}$ *carrier $U = (P, D, W, R, S, E, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannUniformMesh}^{\uparrow}}$ *surface consists exactly of carrier admission; finite partition-mesh exposure through P; dyadic mesh exactness through D together with the dyadic mesh siblings; Riemann-sum handoff through S after W and R; Real-seal non-escape through E; componentwise transport through H; displayed replay through C; package provenance through G; and local naming through N.*

Proof. Project the carrier of Definition 6062.1. The partition row P supplies the only finite mesh carrier, and the dyadic row D supplies the equal-width scale and endpoint ledger used by each cell.

The finite readback rows then determine the consumer window. The row W opens the $\mathsf{StreamName}^{\uparrow}$ window at the displayed scale, while R records the $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to that same dyadic budget.

The Riemann-sum handoff is forced through S. A consumer may read tag values, cell widths, and the finite sum only after P, D, W, R are present, so the handoff is the finite tagged-sum route of chapter 1615, not a limiting integration claim.

Finally the Real seal E is terminal. Transport, replay, provenance, and local naming are exactly the rows H, C, G, N, and the carrier has no coordinate for host intervals, quotient completions, selected limiting mesh families, unrestricted tag choice, or ambient completeness. Thus the listed rows exhaust the NameCert obligations. □

Falsifiable prediction: If the dyadic scale row D is removed, a Riemann-sum consumer can still read a finite partition row but can no longer force equal-width dyadic exactness before the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are opened.

Independence witness: finite-partition-mesh, dyadicratcore, streamname, regseqrat, riemannsum, real, cofinal-dyadic-mesh: no listed sibling is bijective to $\mathsf{RiemannUniformMesh}^{\uparrow}$ because this packet jointly carries the finite partition mesh, equal dyadic scale, finite observation window, regular rational readback, tagged-sum handoff, terminal Real seal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannUniformMesh}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RiemannUniformMesh}^{\uparrow}$ packet is generated from finite partition mesh rows, a dyadic mesh scale, StreamName finite windows, RegSeqRat readback, a RiemannSum consumer row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RiemannUniformMesh}^{\uparrow}}$, seed)

Scope closed: Definition 6062.1 and Definition 6062.2 seed the finite equal-width dyadic mesh packet consumed by Riemann-sum, Real, and Completion routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RiemannUniformMesh}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Riemann integrability, limiting mesh convergence, host interval continua, quotient completion, selected tag families, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic mesh exactness, Riemann-sum handoff, Real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.RiemannUniformMeshUp.

Chapter 6063

A Concrete Naming Certificate for FiniteWindowMetaCICDiamondEnvelope$^{\uparrow}$

The FiniteWindowMetaCICDiamondEnvelope$^{\uparrow}$ packet realizes the confluence audit map of chapter 9378 as a finite residual-window diamond envelope. It sits beside the residual-substitution boundary of chapter 2181, the parallel-diamond frontier of chapter 4238, the residual-join determinacy packet of chapter 5970, and the closed parallel-diamond premise ledger of chapter 2325. The packet records bounded peak, residual-window, candidate-join, premise-retention, and TasteGate-readiness rows without claiming residual-substitution compatibility, a premise-free parallel diamond, arbitrary closed Church–Rosser, subject reduction, evaluator equality, quotient conversion equality, or kernel consistency.

Falsifiable prediction: A FiniteWindowMetaCICDiamondEnvelope$^{\uparrow}$ read is rejected whenever its residual-window row is present but either the residual-substitution boundary row or the closed parallel-diamond premise ledger row is absent.

Independence witness: metacic-residual-substitution-boundary, metacic-parallel-diamond-frontier, metacic-residual-join-determinacy, closed-parallel-diamond-premise-ledger: FiniteWindowMetaCICDiamondEnvelope is not bijective to any listed sibling because it jointly carries a bounded peak window, residual-window budget, candidate-join determinacy, parallel-diamond frontier handoff, closed-premise ledger, obstruction-retention row, TasteGate-readiness row, transport, replay, provenance, and local NameCert data.

Definition 6063.1 (Finite-window MetaCIC diamond-envelope carrier)**.** *A* FiniteWindowMetaCICDiamondEnvelope *carrier is a finite* BHist *packet*

$$E = (W, R, J, F, L, O, G, H, C, P, N)$$

with the following displayed rows:

1. *W is the bounded MetaCIC peak-window row, naming the source term, two parallel observations, and the finite residual radius.*
2. *R is the* MetaCICResidualSubstitutionBoundary$^{\uparrow}$ *row, kept visible as the residual-substitution premise boundary for the same peak.*
3. *J is the* MetaCICResidualJoinDeterminacy$^{\uparrow}$ *row, recording the budgeted local-join candidate and determinacy readback for the residual window.*

4. *F is the* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *row, exposing the conditional parallel-diamond frontier consumed by the envelope.*
5. *L is the* $\mathsf{ClosedParallelDiamondPremiseLedger}^{\uparrow}$ *row, recording the closed-premise ledger that any closed-star handoff must cite.*
6. *O is the obstruction-retention row, stating that the envelope still displays the missing residual-substitution premise whenever the conditional frontier is read.*
7. *G is the* $\mathsf{TasteGate}$ *readiness row for later* $\mathsf{Nontrivial}$ *and* $\mathsf{FieldFaithful}$ *instances over the displayed envelope.*
8. *H records componentwise* hsame *transport for peak windows, residual-substitution boundaries, residual joins, frontier rows, closed-premise ledgers, obstruction retention, TasteGate readiness, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a confluence-audit query through $W, R, J, F, L, O, G, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteWindowMetaCICDiamondEnvelope}^{\uparrow}$, $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$, $\mathsf{MetaCICResidualJoinDeterminacy}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, $\mathsf{ClosedParallelDiamondPremiseLedger}^{\uparrow}$, BHist, hsame, Cont, $\mathsf{TasteGate}$, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowMetaCICDiamondEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows $W, R, J, F, L, O, G, H, C, P, N$. It contains no coordinate for full residual-substitution compatibility, a premise-free parallel diamond, arbitrary closed Church–Rosser, subject reduction, evaluator equality, quotient conversion equality, selected joins, or kernel consistency.

Theorem 6063.2 (Finite-window MetaCIC diamond-envelope NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWindowMetaCICDiamondEnvelope}^{\uparrow}$ *carrier*

$$E = (W, R, J, F, L, O, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteWindowMetaCICDiamondEnvelope}^{\uparrow}}$ *surface consists exactly of bounded peak-window exposure through W, residual-substitution boundary retention through R, residual-join determinacy through J, parallel-diamond frontier handoff through F, closed-premise ledger exposure through L, obstruction retention through O, TasteGate readiness through G, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6063.1. Rows W, R, J, F, L, O are the confluence-facing envelope data, while G, H, C, P, N are the structural certificate data.

The residual-window read starts with W and R. The peak, radius, and two outgoing observations are bounded by W, and the residual-substitution boundary row R keeps the missing compatibility premise visible before any diamond-facing handoff can be consumed.

The join and frontier rows are then read through J, F, L. The residual-join determinacy row records a budgeted candidate join, the frontier row exposes only the conditional parallel-diamond route, and the closed-premise ledger records the closed handoff that such a route would consume.

The obstruction and structural rows finish the surface. Row O prevents the envelope from being read as a solved residual-substitution theorem, and G, H, C, P, N reserve the TasteGate instance surface, transport the rows, replay the audit query, source the packet, and name it. Since no carrier coordinate contains unrestricted confluence, subject reduction, evaluator equality, quotient conversion equality, selected joins, or kernel consistency, the listed rows exhaust the local NameCert surface. □

Theorem 6063.3 (Finite-window MetaCIC diamond-envelope handoff)**.** *Every confluence-audit consumer of an accepted* FiniteWindowMetaCICDiamondEnvelope$^{\uparrow}$ *carrier factors through*

$$W, R, J, F, L, O, G, H, C, P, N.$$

The consumer may inspect the bounded peak window, residual-substitution boundary, residual-join determinacy row, parallel-diamond frontier, closed-premise ledger, obstruction-retention row, TasteGate readiness, transport, replay, provenance, and local name. It cannot bypass this route to obtain full residual-substitution compatibility, a premise-free parallel diamond, arbitrary closed Church–Rosser, subject reduction, evaluator equality, quotient conversion equality, selected joins, or kernel consistency.

Proof. Start with a confluence-audit query. The only entrance to the envelope is the finite peak-window row W, and the only residual-substitution premise surface is R.

The local join route is constrained by J. It records a budgeted candidate join for the displayed residual window, so the consumer may not detach the join row into a global diamond theorem.

The frontier and closed-premise route is constrained by F and L. These rows expose the conditional parallel-diamond frontier and the closed parallel-diamond premise ledger, but they do not supply the missing residual-substitution compatibility proof.

Finally O, G, H, C, P, N preserve the same boundary under obstruction retention, TasteGate readiness, transport, replay, provenance, and local naming. Every confluence-audit consumer therefore remains inside the finite envelope route. □

Theorem 6063.4 (Finite-window MetaCIC diamond-envelope subject slice)**.** *Any subject-reduction-facing consumer of an accepted* FiniteWindowMetaCICDiamondEnvelope$^{\uparrow}$ *packet may inspect only the bounded peak window W, residual-substitution boundary R, residual-join determinacy row J, parallel-diamond frontier F, closed-premise ledger L, and obstruction-retention row O before reaching TasteGate, transport, replay, provenance, and local naming rows. It cannot turn the envelope into subject reduction, evaluator equality, quotient conversion equality, or kernel consistency.*

Proof. Project the carrier of Definition 6063.1. The subject-facing entrance is still the finite envelope tuple, so the only confluence data visible before the structural rows are W, R, J, F, L, O.

Apply Definition 6063.2. The obligation surface assigns bounded peak exposure to W, residual-substitution boundary retention to R, residual-join determinacy to J, parallel-diamond frontier handoff to F, closed-premise ledger exposure to L, and obstruction retention to O.

Finally use Definition 6063.3. The handoff already blocks full residual-substitution compatibility, premise-free diamonds, subject reduction, evaluator equality, quotient conversion equality, selected joins, and kernel consistency. The present statement records the subject-reduction slice of that boundary; it is not itself a confluence or subject-reduction theorem. □

Theorem 6063.5 (Finite-window MetaCIC diamond-envelope TasteGate scope)**.** *The later Lean side must provide* Nontrivial *and* FieldFaithful TasteGate *instances for* FiniteWindowMetaCICDiamondEnvelope$^{\uparrow}$ *at the displayed finite carrier surface*

$$W, R, J, F, L, O, G, H, C, P, N.$$

Those instances must certify that the packet is neither empty nor field-forgetting: every accepted carrier visibly retains the bounded peak window, residual-substitution boundary, residual-join determinacy row, parallel-diamond frontier, closed-premise ledger, obstruction-retention row, transport, replay, provenance, and local NameCert data.

Proof. The readiness row G in Definition 6063.1 is tied to the whole envelope, not to the residual-join row alone.

Nontriviality must exhibit an accepted packet with all displayed rows present. FieldFaithfulness must show that deleting any of $W, R, J, F, L, O, H, C, P, N$ changes the readable carrier surface. Thus the TasteGate burden remains exactly at the finite residual-window diamond-envelope boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowMetaCICDiamondEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteWindowMetaCICDiamondEnvelope}^{\uparrow}$ packet is generated from a bounded MetaCIC peak-window row, residual-substitution boundary row, residual-join determinacy row, parallel-diamond frontier row, closed parallel-diamond premise ledger row, obstruction-retention row, Nontrivial and FieldFaithful TasteGate readiness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteWindowMetaCICDiamondEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6063.1, Definition 6063.2, Definition 6063.3, and Definition 6063.5 seed the finite residual-window diamond envelope for MetaCIC confluence-audit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteWindowMetaCICDiamondEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close residual-substitution compatibility, a premise-free parallel diamond, arbitrary closed Church–Rosser, subject reduction, evaluator equality, quotient conversion equality, selected joins, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, peak-window exposure, residual-substitution boundary retention, residual-join determinacy, parallel-diamond frontier handoff, closed-premise ledger exposure, obstruction retention, TasteGate nontriviality, FieldFaithful coverage, transport, replay, provenance, and local naming for BEDC.Derived.FiniteWindowMetaCICDiamondEnvelopeUp.

Chapter 6064

A Concrete Naming Certificate for $\mathsf{UniformCauchyModulusExtractor}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy convergence, the $\mathsf{UniformCauchyModulusExtractor}^{\uparrow}$ packet records the finite readback by which one displayed uniform Cauchy witness yields an explicit modulus row before any regular rational handoff or terminal Real seal is consumed. It sits over the Real uniform surface of chapter 1624, the explicit-modulus sequence route of chapter 1705, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet makes finite uniform modulus extraction visible as NameCert data rather than leaving it distributed across later sequence, completion, or Real-facing chapters.

Definition 6064.1 (Uniform Cauchy modulus extractor carrier)**.** *A* $\mathsf{UniformCauchyModulusExtractor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (U, S, M, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the uniform-Cauchy source row, naming the displayed family, tail comparison, and uniformity request from which an extraction is attempted.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, recording the finite observation windows inspected from the same source.*
3. *M is the extracted* $\mathsf{CauchyModulus}^{\uparrow}$ *row, storing the stage bound selected for each dyadic tolerance request.*
4. *W is the window-realization row, recording that the selected stage from M governs all retained stream windows in S.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to translate requested radii, slack rows, comparison budgets, and dyadic refinements.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row opened only after U, S, M, W, D have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available downstream of the extracted modulus and regular readback.*
8. *H records componentwise* hsame *transport for the source, schedule, extracted modulus, window realization, dyadic ledger, readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a uniformity request through $U, S, M, W, D, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* UniformCauchyModulusExtractor$^{\uparrow}$, RealUniformStructure$^{\uparrow}$, EffectiveCauchySequence StreamName$^{\uparrow}$, CauchyModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{UniformCauchyModulusExtractor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, S, M, W, D, R, E, H, C, P, N$. It has no coordinate for a selected host limit, quotient stream equality, ambient Real$^{\uparrow}$ *completeness, countable choice, a hidden modulus oracle, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.UniformCauchyModulusExtractorUp.UniformCauchyModulusExtractorTasteGate single carrier alignment`

Theorem 6064.2 (Uniform Cauchy modulus extractor NameCert obligations)**.** *For every accepted* UniformCauchyModulusExtractor$^{\uparrow}$ *carrier*

$$X = (U, S, M, W, D, R, E, H, C, P, N),$$

the local NameCert$_{\text{UniformCauchyModulusExtractor}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the uniform-Cauchy source, stream schedule, extracted modulus, window realization, dyadic tolerance ledger, regular rational readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *uniform-source exposure, requiring the extraction request to display the source row U and the finite stream schedule S before any modulus row is exported;*
3. *finite modulus extraction, requiring M to be read as a displayed stage ledger and not as an external selector or hidden oracle;*
4. *dyadic tolerance exactness, requiring D to account for requested radii, slack rows, comparison budgets, and tolerance conversions consumed by M and W;*
5. *RegSeqRat and Real routing, requiring R and E to remain downstream of U, S, M, W, D;*
6. *transport, replay, provenance, and local naming stability for the same displayed rows through H, C, P, N.*

No uniform-Cauchy-modulus-extractor obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.UniformCauchyModulusExtractorUp.TasteGate.UniformCauchyModulusExtractorNameCertObl`

Proof. Carrier admission is projection from Definition 6064.1. The accepted packet exposes exactly the uniform-Cauchy source U, finite schedule S, extracted modulus M, window realization W, dyadic ledger D, regular readback R, Real seal E, and structural rows H, C, P, N.

The extraction row is forced to be finite. The source and schedule rows are displayed before M, and the dyadic ledger D supplies the tolerance conversions that make the selected stages meaningful inside the packet.

The downstream route is then fixed by the EffectiveCauchySequence and Real uniform surfaces. The regular rational readback R can only consume the displayed modulus, window, and tolerance rows, and the Real seal E is visible only after that readback has been exposed.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since no host selector, quotient equality, ambient completeness theorem, hidden oracle, Lean target, or bridge certificate appears among the rows, the listed obligations exhaust the local NameCert surface. □

Theorem 6064.3 (Uniform Cauchy modulus extractor readback route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformCauchyModulusExtractor}^{\uparrow}$ *carrier factors through the finite route*

$$U \longmapsto S \longmapsto M \longmapsto W \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives a displayed uniform-Cauchy source, finite stream schedule, extracted modulus, window realization, dyadic tolerance ledger, regular readback, Real seal, transport, replay, provenance, and local naming before it can inspect any endpoint-facing result.

Proof. Project the carrier of Definition 6064.1. The only regular readback row is R, and the only Real seal row is E.

The source route comes first. The uniform-Cauchy request is displayed by U, the finite observations are named by S, the extracted stage ledger is M, and W records that the chosen stages govern the retained windows.

The dyadic accounting row D then supplies the tolerance budget consumed by the readback. Hence R is downstream of the source, schedule, extracted modulus, window realization, and tolerance ledger, while E is downstream of R.

The structural rows preserve this route and add no analytic coordinate. Therefore every endpoint-facing read has exactly the stated finite factorization and cannot bypass it through excluded host or completeness data. □

Falsifiable prediction: Every accepted $\mathsf{UniformCauchyModulusExtractor}^{\uparrow}$ read that reaches a RegSeqRat or Real boundary without displaying the uniform-Cauchy source, finite StreamName schedule, extracted CauchyModulus row, window realization, DyadicRatCore tolerance ledger, transport, replay, provenance, and local naming rows refutes the packet.

Independence witness: real-uniform-structure, effective-cauchy-sequence, streamname, cauchy-modulus, dyadicratcore, regseqrat, real: $\mathsf{UniformCauchyModulusExtractor}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a uniform-Cauchy source, finite schedule, extracted modulus, window realization, tolerance ledger, regular readback, terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyModulusExtractor}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformCauchyModulusExtractor}^{\uparrow}$ packet is generated from a displayed uniform-Cauchy source, finite StreamName schedule, extracted CauchyModulus row, window realization, DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyModulusExtractor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6064.1, Definition 6064.2, and Definition 6064.3 seed the finite uniform modulus extraction route for Real and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyModulusExtractor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected host limits, quotient stream equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, countable choice, hidden modulus oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-source exposure, finite modulus extraction, dyadic tolerance exactness, RegSeqRat and Real routing, transport, replay, provenance, and local naming for BEDC.Derived.UniformCauchyModulusExtractorUp.

Chapter 6065

A Concrete Naming Certificate for $\mathsf{BoundedCauchyInterval}^{\uparrow}$

Bishop–Bridges style constructive interval and Cauchy data enter this chapter through a finite packet: a closed rational interval bracket, a regular rational sequence, a finite observation schedule, and a dyadic tolerance ledger are displayed before any $\mathsf{Real}^{\uparrow}$ seal or completion-facing consumer can read an endpoint. The $\mathsf{BoundedCauchyInterval}^{\uparrow}$ packet sits over the real-name seal of chapter 38, the regular rational readback of chapter 301, the finite window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the located regular route of chapter 2376, and the finite located interval net of chapter 2385. It also consumes chapter 3834: the displayed B, S, R, D, L, F, E route is the finite interval-level instance where completion unit and bind laws preserve bracket, stream-window, regular-readback, and Real-seal rows. It supplies Real and Completion routes with a bounded interval-level Cauchy packet, not quotient streams, selected limits, choice, or ambient completeness.

Definition 6065.1 (Bounded Cauchy interval carrier)**.** *A* $\mathsf{BoundedCauchyInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, S, R, D, L, F, E, H, C, P, N)$$

with the following displayed rows:

1. *B is a bounded rational interval bracket, recording two rational endpoints, an order witness, and the interval membership window used by every later read.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation schedule for the Cauchy name inside the bracket.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from S.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radii, endpoint slack, and bracket-preserving comparison rows.*
5. *L is the* $\mathsf{LocatedRegSeqRat}^{\uparrow}$ *locatedness row for the same regular rational readback.*
6. *F is the* $\mathsf{HeineBorelLocatedInterval}^{\uparrow}$ *finite-net handoff row for the displayed bracket and located readback.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row read only after B, S, R, D, L, F are displayed.*
8. *H records componentwise* hsame *transport for the bracket, stream schedule, regular readback, dyadic tolerance ledger, locatedness row, finite-net handoff, and real seal.*

9. *C records displayed* Cont *replay from a bounded Cauchy interval request through B, S, R, D, L, F, E and then to the structural rows.*
10. *P is the* Pkg *provenance over* $\mathsf{BoundedCauchyInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedRegSeqRat}^{\uparrow}$, $\mathsf{HeineBorelLocatedInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedCauchyInterval}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected limits, countable choice, open-cover compactness, host real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.BoundedCauchyIntervalUp.BoundedCauchyIntervalTasteGate single carrier alignment`

Theorem 6065.2 (Bounded Cauchy interval NameCert obligations)**.** *For every accepted* $\mathsf{BoundedCauchyInterval}^{\uparrow}$ *carrier $I = (B, S, R, D, L, F, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedCauchyInterval}^{\uparrow}}$ *surface consists exactly of bracket admission, finite stream-window admission, regular rational readback, dyadic tolerance exposure, located regular-sequence handoff, finite located-interval net handoff, terminal* $\mathsf{Real}^{\uparrow}$ *seal admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Consequently every Real or Completion consumer of the packet must read the route

$$\begin{aligned} &B, S, R, D \\ &\longrightarrow L, F \\ &\longrightarrow E, H, C, P, N \end{aligned}$$

and cannot replace it by quotient streams, selected limits, countable choice, open-cover compactness, host real equality, or ambient completeness.

Proof. Project the carrier of Definition 6065.1. The only available rows are the bracket, stream schedule, regular readback, dyadic tolerance ledger, locatedness row, finite-net handoff, terminal real seal, and structural BEDC rows.

Use the sibling surfaces named in chapter 126, chapter 301, and chapter 291. They force each finite Cauchy request to pass through a displayed window, regular readback, and dyadic tolerance ledger before a real seal is visible.

Then apply the located and interval handoff routes of chapter 2376 and chapter 2385. These rows bind locatedness and finite interval-net coverage to the same displayed bracket and readback. The final $\mathsf{Real}^{\uparrow}$ seal of chapter 38 is therefore reached only through $B, S, R, D, L, F, E, H, C, P, N$. □

Theorem 6065.3 (Bounded Cauchy interval regular-seal handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedRegSeqRat}^{\uparrow}$, $\mathsf{HeineBorelLocatedInterval}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedCauchyInterval}^{\uparrow}$ *carrier $I = (B, S, R, D, L, F, E, H, C, P, N)$ receives the same bounded regular-seal surface: finite observations through S, regular readback through R, dyadic tolerance and bracket slack through D, locatedness through L, finite interval-net handoff through F, and the terminal real seal through E.*

The handoff exports no completion carrier beyond these rows. In particular, a consumer cannot read a selected limit, quotient stream representative, global compactness theorem, host real equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness proof from the packet.*

Proof. Begin with Definition 6065.2. It fixes the public route through $B, S, R, D, L, F, E, H, C, P, N$.

For regular-sequence consumers, the route is already displayed by chapter 301 after the finite window and dyadic ledger of chapter 126 and chapter 291. For located consumers, chapter 2376 uses the same regular readback and tolerance data.

For interval and Real consumers, chapter 2385 supplies the finite interval-net row and chapter 38 supplies the terminal seal. Since the carrier contains no coordinate outside the displayed finite route, the handoff cannot introduce quotient streams, selected limits, global compactness, countable choice, host equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedCauchyInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedCauchyInterval}^{\uparrow}$ packet is generated from a bounded rational interval bracket, a finite StreamNameUp observation schedule, a RegSeqRatUp regular readback, a DyadicRatCoreUp tolerance ledger, a LocatedRegSeqRatUp locatedness row, a HeineBorelLocatedIntervalUp finite-net handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedCauchyInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6065.1, Definition 6065.2, and Definition 6065.3 seed the bounded interval-level Cauchy packet for the Real and Completion route through finite stream, regular-rational, dyadic, located, interval-net, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedCauchyInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, open-cover compactness, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bracket preservation, finite-window regular readback, dyadic tolerance exposure, locatedness, interval-net handoff, Real seal admission, and structural row exhaustion for BEDC.Derived.BoundedCauchyIntervalUp.

Chapter 6066

A Concrete Naming Certificate for $\mathsf{AbsoluteContinuity}^{\uparrow}$

Following Folland and Rudin, the $\mathsf{AbsoluteContinuity}^{\uparrow}$ packet names the finite epsilon–delta partition surface used to read absolutely continuous real functions before any measure-theoretic completion is available. It sits between the regulated-function schedules of chapter 1906, the finite partition-variation ledgers of chapter 398, the variation-measure consumers of chapter 3593, and the terminal real-name seal of chapter 38. The packet records only finite interval partitions, endpoint reads, dyadic tolerance ledgers, componentwise transport, continuation replay, provenance, and local naming rows.

Definition 6066.1 (AbsoluteContinuity carrier)**.** *An* $\mathsf{AbsoluteContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, \Pi, E, \Delta, X, D, R, V, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval-domain row, read through the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint surface of chapter 38.*
2. *Π is the finite partition family: a displayed finite list of interval subfamilies with endpoint rows, length rows, and common-refinement rows.*
3. *E is the epsilon-budget row, recording the finite positive tolerance request that the packet answers.*
4. *Δ is the delta-budget row, recording the displayed finite bound on the total length of the selected interval subfamily.*
5. *X records the* $\mathsf{Real}^{\uparrow}$ *endpoint reads, or their regular rational names when the endpoint is read through a sibling regular-name route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing interval lengths, endpoint differences, epsilon rows, and delta rows by finite dyadic observations.*
7. *R is the source row, read from either a* $\mathsf{RegulatedFunction}^{\uparrow}$ *step schedule of chapter 1906 or a* $\mathsf{BoundedVariation}^{\uparrow}$ *finite partition ledger of chapter 398.*
8. *V is the finite variation-control row consumed by chapter 3593 when the endpoint-difference ledger is repacked as variation data.*

9. *H records componentwise* hsame *transport for interval domain, finite partition family, epsilon budget, delta budget, endpoint reads, dyadic tolerance ledger, source row, variation-control row, provenance, and local naming.*
10. *C records displayed* Cont *replay from an epsilon request to a delta row, then to a finite interval subfamily, endpoint reads, dyadic comparisons, source schedule, and variation-control handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{AbsoluteContinuity}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{VariationMeasure}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{AbsoluteContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, \Pi, E, \Delta, X, D, R, V, H, C, P, N$. It has no coordinate for host function quotients, measure completion, selected suprema over all partitions, ambient Lebesgue integration, or unlisted endpoint representatives.

Lean4 ✓ `BEDC.Derived.AbsoluteContinuityUp.AbsoluteContinuityTasteGate single carrier alignment`

Theorem 6066.2 (AbsoluteContinuity NameCert obligations)**.** *For every accepted* $\mathsf{AbsoluteContinuity}^{\uparrow}$ *carrier $A = (I, \Pi, E, \Delta, X, D, R, V, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AbsoluteContinuity}^{\uparrow}}$ *surface consists exactly of interval-domain admission, finite partition-family admission, epsilon-budget admission, delta-budget admission,* $\mathsf{Real}^{\uparrow}$ *endpoint reads,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance comparisons, regulated-function or bounded-variation source routing, variation-control handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from host function quotients, measure completion, selected suprema, ambient Lebesgue integration, and unlisted endpoint representatives.*

Proof. Project the carrier of Definition 6066.1. The analytic coordinates are exactly the interval row I, finite partition family Π, epsilon row E, delta row Δ, endpoint reads X, dyadic tolerance ledger D, source row R, and variation-control row V.

The source row is already confined to displayed BEDC data. If it is read through $\mathsf{RegulatedFunction}^{\uparrow}$, the schedule has passed through the finite step-envelope route of Definition 1906.5. If it is read through $\mathsf{BoundedVariation}^{\uparrow}$, it is a finite partition-variation ledger over the rows of chapter 398.

The structural rows H, C, P, N transport, replay, source, and name those same displayed coordinates. Since no carrier row names a host quotient, completed measure object, selected supremum, ambient integral, or hidden endpoint representative, none of those objects belongs to the NameCert surface. □

Theorem 6066.3 (AbsoluteContinuity finite variation control)**.** *Every accepted* $\mathsf{AbsoluteContinuity}^{\uparrow}$ *packet whose epsilon–delta row is read on a displayed finite interval subfamily exposes variation control only through*

$$I, \Pi, E, \Delta, X, D, R, V, H, C, P, N.$$

The handoff to $\mathsf{BoundedVariation}^{\uparrow}$ *and* $\mathsf{VariationMeasure}^{\uparrow}$ *is the finite endpoint-difference ledger D, V over the displayed partition family Π; it is not a host total-variation read, a measure completion, a selected supremum, or a quotient of functions.*

Proof. Start with an epsilon request in E. The continuation row C first replays the delta row Δ and the displayed interval subfamily in Π, so the request is already confined to finitely many endpoint rows.

Read the endpoint values through X and the dyadic comparisons through D. These rows give only finite endpoint-difference observations and finite length comparisons, all over the interval domain I.

The source row R then supplies either a regulated step schedule or a bounded-variation partition ledger. In both cases, the downstream variation handoff is repacked into V before any consumer in chapter 398 or chapter 3593 can read it.

Thus the exposed variation control is the displayed finite ledger D, V over Π. The carrier has no coordinate from which a host total variation, measure completion, selected supremum, quotient function, or ambient completeness principle could be obtained. □

Theorem 6066.4 (AbsoluteContinuity no-escape boundary)**.** *The* $\mathsf{AbsoluteContinuity}^{\uparrow}$ *public boundary exports finite interval-domain rows, finite partition families, epsilon and delta budget rows,* $\mathsf{Real}^{\uparrow}$ *endpoint reads,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, regulated-function or bounded-variation source rows, finite variation-control handoff rows, visible* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. It exports no measure completion, host function quotient, selected supremum over all partitions, ambient Lebesgue integral, hidden endpoint representative, or bridge claim.*

Proof. Inspect the carrier coordinates in Definition 6066.1. Every exported analytic read is one of the finite rows $I, \Pi, E, \Delta, X, D, R, V$, and every structural read is one of H, C, P, N.

Apply the NameCert-obligation theorem. It identifies the same rows as the complete certificate surface and keeps the source route inside the regulated-function and bounded-variation chapters.

Finally apply the finite variation-control theorem. Any variation-facing consumer reaches only the displayed endpoint-difference and partition ledger, so there is no route to a completed measure object, quotient function, selected supremum, ambient integral, hidden endpoint representative, or bridge theorem. □

Theorem 6066.5 (AbsoluteContinuity scoped kernel route)**.** *The carrier, NameCert-obligation surface, finite variation-control theorem, and no-escape boundary jointly bind* $\mathsf{AbsoluteContinuity}^{\uparrow}$ *to the concrete BEDC route through* $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{VariationMeasure}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert. *Every accepted public read factors through the displayed carrier tuple before any downstream variation or integration-facing consumer sees it.*

Proof. Project the carrier tuple from Definition 6066.1. It lists the interval, partition, tolerance, endpoint, source, variation, transport, continuation, provenance, and naming rows available to the packet.

Use Definition 6066.2 to identify those rows as the local obligation surface. The theorem also records the exclusions that keep absent analytic objects outside the packet.

Use Definition 6066.3 for downstream consumers. It forces the bounded-variation and variation-measure handoff to pass through the displayed finite partition ledger and dyadic tolerance rows.

The no-escape boundary of Definition 6066.4 then exhausts the public interface. Hence the scoped kernel route is exactly the displayed tuple and its listed BEDC dependencies. □

Closure status for $\mathsf{NameCert}_{\mathsf{AbsoluteContinuity}^{\uparrow}}$.

Constructive story: An $\mathsf{AbsoluteContinuity}^{\uparrow}$ packet is generated from an interval-domain row, a finite partition family, epsilon and delta budget rows, Real endpoint reads, a dyadic tolerance ledger, a regulated-function or bounded-variation source row, a finite variation-control handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbsoluteContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6066.1, Definition 6066.2, Definition 6066.3, Definition 6066.4, and Definition 6066.5 seed the finite epsilon–delta partition surface over $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, and $\mathsf{VariationMeasure}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbsoluteContinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function quotients, measure completion, selected suprema, ambient Lebesgue integration, hidden endpoint representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, epsilon–delta partition routing, finite variation-control handoff, transport, provenance, and no-escape for BEDC.Derived.AbsoluteContinuityUp.

Chapter 6067

A Concrete Naming Certificate for $\mathsf{MonotoneBarModulus}^{\uparrow}$

Following Brouwer and Troelstra–van Dalen on monotone bars, fan bounds, and constructive choice sequences, the $\mathsf{MonotoneBarModulus}^{\uparrow}$ packet records the finite handoff by which a displayed monotone bar yields a modulus surface for current Real and Completion consumers. It sits after the fan-bound certificate of chapter 400, the barred-spread replay of chapter 1675, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite BHist route from bar evidence to requested windows; it is not countable choice, open-cover compactness, branch selection, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6067.1 (Monotone bar modulus carrier)**.** *A* $\mathsf{MonotoneBarModulus}^{\uparrow}$ *carrier is a finite packet*

$$K = (T, B, D, W, R, E, H, C, P, N)$$

whose rows have the following roles:

1. *T is the monotone bar row. It records displayed prefix decisions and the rule that a barred prefix remains barred along every displayed extension.*
2. *B is the finite fan-depth ledger. It records the bounded depth obtained from the admitted fan surface, as finite data rather than as an open cover or an infinite branch search.*
3. *D is the modulus handoff row. It translates the visible bar-depth ledger into the index budget requested by downstream readers.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which Real and Completion consumers request finite observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same requested windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the bar, fan-depth, modulus, window, and readback rows have been displayed.*
7. *H stores componentwise* hsame *transport for the monotone bar, fan-depth ledger, modulus handoff, StreamName windows, RegSeqRat readback, Real seal, continuation, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from monotone-bar inspection through the fan-depth ledger, modulus handoff, StreamName windows, RegSeqRat readback, and the terminal Real seal.*

9. *P is the* Pkg *provenance over* MonotoneBarModulus$^\uparrow$, FanTheorem$^\uparrow$, BrouwerBarInduction$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{MonotoneBarModulus}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $T, B, D, W, R, E, H, C, P, N$. It has no coordinate for countable choice, open-cover compactness, selected branches, quotient equality of streams, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.MonotoneBarModulusUp.TasteGate.MonotoneBarModulusTasteGate single carrier alignment`

Theorem 6067.2 (Monotone bar modulus nonescape)**.** *Every* StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, *or Completion-facing read of an accepted* MonotoneBarModulus$^\uparrow$ *carrier factors through*

$$T, B, D, W, R, E, H, C, P, N.$$

The read may use the displayed monotone bar and its finite fan-depth ledger to obtain a modulus budget, but it cannot extract countable choice, open-cover compactness, a selected branch, quotient stream equality, or ambient Real$^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.MonotoneBarModulusUp.TasteGate.MonotoneBarModulusNonescape`

Proof. Project the carrier of Definition 6067.1. The only analytic-facing rows are the StreamName window W, the RegSeqRat readback R, and the Real seal E.

Replay the continuation row C. It first exposes the monotone bar row T, then the finite fan-depth ledger B, then the modulus handoff row D. Only after those rows are visible can a consumer open W, read R, and reach E.

The rows H, P, N preserve and name the same route. Since no carrier coordinate stores a branch selector, quotient stream equality, an open-cover compactness principle, countable choice, or ambient completeness, none of those principles can be exported by the packet. □

Theorem 6067.3 (Monotone bar modulus NameCert obligations)**.** *For every accepted* MonotoneBarModulus$^\uparrow$ *carrier $K = (T, B, D, W, R, E, H, C, P, N)$, the local* NameCert$_{\text{MonotoneBarModulus}^\uparrow}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the monotone bar, fan-depth ledger, modulus handoff, StreamName window, RegSeqRat readback, Real seal, transport, continuation, provenance, and naming rows;*
2. *monotone bar stability, requiring extension reads to stay inside the displayed bar row T;*
3. *finite fan-depth extraction, requiring the depth budget to be read from B through the fan surface of chapter 400;*
4. *modulus handoff exactness, requiring every downstream budget request to pass through D before reaching W, R, E;*
5. *analytic boundary nonescape, requiring every Real or Completion-facing read to use the route of Definition 6067.2.*

No local obligation is stored outside these five rows.

Proof. Carrier admission is the tuple displayed in Definition 6067.1. The classifier can inspect only the listed coordinates, so the first obligation is exactly the projection of $T, B, D, W, R, E, H, C, P, N$.

The monotone bar and fan-depth clauses are read directly from T and B. The bar row gives only displayed prefix decisions and extension preservation, while the fan-depth ledger supplies only the bounded depth exposed by the finite fan certificate.

The modulus handoff clause is the row D. It is placed before W, R, E in the continuation route, so every downstream window or readback request consumes the displayed budget before reaching a Real-facing seal.

The analytic boundary is Definition 6067.2. It forces every StreamName, RegSeqRat, Real, or Completion consumer through the displayed finite rows and prevents escape through the excluded principles. □

Theorem 6067.4 (Monotone bar modulus Real handoff)**.** *An accepted* $\mathsf{MonotoneBarModulus}^{\uparrow}$ *carrier supplies Real and Completion consumers with only the following handoff:*

$$\mathsf{BrouwerBarInduction}^{\uparrow}, \mathsf{FanTheorem}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{MonotoneBarModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff records the finite passage from monotone bar evidence and a fan-depth ledger to StreamName windows, RegSeqRat readback, and a Real seal; it does not provide a separate compactness or choice principle.

Proof. Read the provenance row P together with the continuation row C. The source side names the monotone bar evidence against the barred-spread surface of chapter 1675 and the bounded fan surface of chapter 400.

The middle of the route is exactly the window and readback pair W, R, which points to chapter 126 and chapter 301. The terminal row E points to chapter 38.

Thus the handoff is a named finite route through the displayed rows of the carrier. The excluded principles are not fields of the tuple, so the Real and Completion consumers receive only the stated finite modulus surface. □

Falsifiable prediction: Every accepted $\mathsf{MonotoneBarModulus}^{\uparrow}$ Real or Completion-facing read factors through a displayed monotone bar row, finite fan-depth ledger, modulus handoff row, StreamName window, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: fantheorem, brouwer-bar-induction, streamname, regseqrat, real: $\mathsf{MonotoneBarModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries monotone bar evidence, a finite fan-depth ledger, a modulus handoff, analytic windows, readback, terminal sealing, transport, continuation, provenance, and local naming while refusing choice, compactness, branch selection, quotient streams, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneBarModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MonotoneBarModulus}^{\uparrow}$ packet is generated from a displayed monotone bar row, a finite fan-depth ledger, a modulus handoff row, StreamName windows, RegSeqRat readback, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneBarModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6067.1, Definition 6067.2, Definition 6067.3, and Definition 6067.4 seed the finite monotone-bar-to-modulus handoff for Real and Completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneBarModulus}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.MonotoneBarModulusUp`

Bridge status: none

Not claimed: This chapter does not close countable choice, open-cover compactness, branch selection, quotient stream equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone bar stability, finite fan-depth extraction, modulus handoff exactness, analytic boundary nonescape, and TasteGate field faithfulness for BEDC.Derived.MonotoneBarModulusUp.

Chapter 6068

A Concrete Naming Certificate for $\mathsf{MetricCompletionAdjoint}^{\uparrow}$

Following Kelley and Bishop–Bridges, the $\mathsf{MetricCompletionAdjoint}^{\uparrow}$ packet records the metric-specific adjoint surface by which a separated metric source enters a completion object and by which uniformly continuous maps out of the source extend through the same finite L10 route. It sits after the metric completion packet of chapter 1506, the Cauchy filter completion of chapter 1569, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the uniform completion interface of chapter 1473. The packet is a human-origin completion-adjunction carrier; it does not assert host quotient equality, selected Cauchy limits, ambient metric completeness, or a detached categorical adjunction outside the displayed rows.

Definition 6068.1 (MetricCompletionAdjoint carrier)**.** *A* $\mathsf{MetricCompletionAdjoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, U, X, F, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the metric source row, recording the separated metric carrier, distance tolerance ledger, and finite source windows inspected by the completion request.*
2. *U is the completion unit row, routing the metric source into the* $\mathsf{MetricCompletion}^{\uparrow}$ *and* $\mathsf{UniformCompletion}^{\uparrow}$ *surfaces without choosing a host representative.*
3. *X is the universal extension route, matching uniformly continuous source maps with their completion-facing extensions as finite ledger data.*
4. *F is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *row, recording the Cauchy-filter completion face consumed by the extension route.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular rational name produced by the displayed completion window.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after M, U, X, F, R have been displayed.*
7. *H records componentwise* hsame *transport for the metric source, unit, extension, Cauchy-filter completion, readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$M, U, X, F \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionAdjoint}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionAdjoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, U, X, F, R, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected limits, host continuous maps, countable choice, ambient completeness, or an external adjunction theorem.

Lean4 ✓ `BEDC.Derived.MetricCompletionAdjointUp.TasteGate.MetricCompletionAdjointTasteGate`
`single carrier alignment`

Theorem 6068.2 (Metric completion adjoint NameCert obligations)**.** *For every accepted* $\mathsf{MetricCompletionAdjoint}^{\uparrow}$ *carrier*

$$A = (M, U, X, F, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricCompletionAdjoint}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-source exposure through M, completion-unit exposure through U, universal-extension routing through X, Cauchy-filter completion exposure through F, regular rational readback through R, Real seal handoff through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The projection exposes the metric source, completion unit, universal extension route, Cauchy-filter completion row, regular rational readback, terminal Real seal, transport, continuation, provenance, and local naming rows.

The analytic obligations are exactly the visible metric and completion rows. The source row supplies the inspected metric data, the unit row admits it into the completion surface, the extension row records the finite universal route, and the Cauchy-filter row supplies the completion face consumed by the route.

The readback and seal obligations are downstream of those rows. The $\mathsf{RegSeqRat}^{\uparrow}$ row and $\mathsf{Real}^{\uparrow}$ seal may be consumed only after the metric, unit, extension, and Cauchy-filter rows have been displayed. Since the carrier contains no coordinate for quotient equality, selected limits, host maps, countable choice, ambient completeness, or a detached adjunction theorem, no additional local obligation can be read. □

Theorem 6068.3 (Metric completion adjoint finite extension route)**.** *Every completion-facing consumer of an accepted* $\mathsf{MetricCompletionAdjoint}^{\uparrow}$ *packet factors through*

$$\mathsf{MetricCompletion}^{\uparrow},\ \mathsf{CauchyFilterCompletion}^{\uparrow},\ \mathsf{UniformCompletion}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

by reading the displayed rows $M, U, X, F, R, E, H, C, P, N$. The handoff supplies a finite metric completion-adjunction route, not quotient completion equality, selected Cauchy limits, host real equality, countable choice, ambient completeness, or an external categorical adjunction.

Proof. Start with the metric source and unit rows. The source row M fixes the displayed metric carrier and tolerance window, while U records the finite admission into the metric and uniform completion surfaces.

Next read the universal route and completion face. The row X is the only extension route stored by the packet, and the row F is the only Cauchy-filter completion face available to that route.

Finally pass through the readback and terminal seal. The row R exposes the regular rational name and E exposes the Real seal only after M, U, X, F are present. Transport, replay, provenance,

and naming preserve the same route, so the consumer receives finite adjunction data and no excluded host object. □

Falsifiable prediction: Every $\mathsf{MetricCompletionAdjoint}^{\uparrow}$ read factors through metric source, completion unit, universal extension route, CauchyFilterCompletion, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any completion-facing conclusion is consumed.

Independence witness: metriccompletion, cauchyfiltercompletion, regseqrat, real, uniformcompletion: $\mathsf{MetricCompletionAdjoint}^{\uparrow}$ is not bijective to any listed sibling because it binds the metric source, completion unit, universal extension route, Cauchy-filter completion face, regular rational readback, Real seal, transport, replay, provenance, and local naming in one finite adjunction packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionAdjoint}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionAdjoint}^{\uparrow}$ packet is generated from a metric source row, completion unit row, universal extension route, CauchyFilterCompletion row, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionAdjoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6068.1, Definition 6068.2, and Definition 6068.3 seed the finite metric completion-adjunction packet over metric completion, Cauchy filter completion, uniform completion, regular readback, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionAdjoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected Cauchy limits, host real equality, countable choice, ambient metric completeness, Lean verification, bridge checking, or a detached host adjunction theorem.

Upgrade path: Obligation closure requires checked carrier admission, metric-source exposure, completion-unit exactness, universal-extension routing, Cauchy-filter completion compatibility, readback and Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionAdjointUp.

Chapter 6069

A Concrete Naming Certificate for MetaCICTypedConversionResidualFrontier$^{\uparrow}$

The MetaCICTypedConversionResidualFrontier$^{\uparrow}$ packet realizes the decidability-frontier question of chapter 9386 as finite BEDC data. It sits beside the decidability boundary of chapter 749, the bounded-normal conversion bridge of chapter 3439, the conversion endpoint seal of chapter 4113, the decidable conversion frontier of chapter 4097, and the subject-reduction obstruction of chapter 731. The packet names the residual frontier where bounded normal computation, typed conversion, and finished-normal evidence must remain visible together; it does not turn the bounded checker into an unrestricted closed conversion decider.

Definition 6069.1 (MetaCIC typed-conversion residual-frontier carrier)**.** *A* MetaCICTypedConversionResidualFront *carrier is a finite* BHist *packet*

$$F = (W, R, B, E, Q, O, H, C, P, N)$$

with the following displayed rows:

1. *W is the typed-window row, recording the closed typed terms, their type boundary, and the finite context window inspected by the conversion request.*
2. *R is the residual-frontier row, retaining the redex and subject-reduction obstruction data that cannot be erased by bounded computation.*
3. *B is the bounded-normal comparison row, recording the fuel, two bounded normalizer outputs, and the Boolean comparison accepted by the checker.*
4. *E is the finished-normal witness row, requiring the compared outputs to be finished closed normal forms before a conversion endpoint can be read.*
5. *Q is the refusal row, rejecting any conversion read that omits the typed window, residual frontier, bounded comparison, or finished-normal witness.*
6. *O is the endpoint-obstruction row, exposing the* MetaCICConversionEndpointSeal$^{\uparrow}$ *handoff while retaining the subject-reduction obstruction as a separate coordinate.*
7. *H records componentwise* hsame *transport for W, R, B, E, Q, O and the local naming row.*
8. *C records displayed* Cont *replay from a typed conversion request through $W, R, B, E, Q, O, H, P, N$.*

9. *P is the* Pkg *provenance over* MetaCICTypedConversionResidualFrontier$^{\uparrow}$, MetaCICDecidableBoundary$^{\uparrow}$, BoundedNormalConversionBridge$^{\uparrow}$, MetaCICConversionEndpointSeal$^{\uparrow}$, MetaCICDecidableConversionFrontier$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{MetaCICTypedConversionResidualFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, R, B, E, Q, O, H, C, P, N$. It has no coordinate for unrestricted closed beta-conversion, fuel-erased normalization, quotient syntax equality, evaluator equality, subject-reduction discharge, confluence, or kernel consistency.

Theorem 6069.2 (MetaCIC typed-conversion residual-frontier NameCert obligations)**.** *For every accepted* MetaCICTypedConversionResidualFrontier$^{\uparrow}$ *carrier*

$$F = (W, R, B, E, Q, O, H, C, P, N),$$

the local NameCert$_{\text{MetaCICTypedConversionResidualFrontier}^{\uparrow}}$ *surface consists exactly of typed-window exposure through W, residual-frontier exposure through R, bounded-normal comparison through B, finished-normal witness exposure through E, refusal stability through Q, endpoint-obstruction routing through O, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier. The visible rows are the typed window, residual frontier, bounded comparison, finished-normal witness, refusal, endpoint-obstruction route, and structural rows.

The typed conversion obligations are W, R, B, E. The window fixes the typed closed terms under discussion, the residual frontier keeps the obstruction data visible, the bounded comparison records the finite normalizer outputs, and the finished-normal witness certifies that the endpoint read is not merely a fuel-bounded observation.

The refusal and endpoint-obstruction rows preserve the boundary. They reject reads that omit any of the four typed conversion rows, and they keep the conversion endpoint seal separate from subject-reduction discharge. Since no carrier coordinate contains unrestricted conversion, fuel-erased normalization, quotient syntax equality, evaluator equality, confluence, or kernel consistency, the listed rows exhaust the NameCert surface. □

Theorem 6069.3 (MetaCIC typed-conversion endpoint frontier)**.** *Every typed conversion consumer of an accepted* MetaCICTypedConversionResidualFrontier$^{\uparrow}$ *packet factors through the finite route*

MetaCICDecidableBoundary$^{\uparrow}$, BoundedNormalConversionBridge$^{\uparrow}$, MetaCICConversionEndpointSeal$^{\uparrow}$, MetaCICDecida

with $W, R, B, E, Q, O, H, C, P, N$ displayed. The route exports a residual-frontier packet for bounded normal comparison and finished-normal endpoint evidence; it does not export unrestricted closed conversion, subject-reduction discharge, confluence, or kernel consistency.

Proof. Begin with the typed window. The row W fixes the closed typed terms and their finite context-facing boundary before any checker result is read.

Next read the bounded and residual rows together. The row B records the bounded normal comparison, while R retains the residual and subject-reduction obstruction data that prevent the comparison from becoming an unrestricted conversion theorem.

Finally consume the endpoint evidence. The row E supplies the finished-normal witness, O routes the endpoint seal while retaining the obstruction, and Q rejects bypass reads. Transport, replay, provenance, and naming preserve the same finite route, so the consumer receives endpoint-frontier data only. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICTypedConversionResidualFrontier}^{\uparrow}$ read displays typed-window, residual-frontier, bounded-normal comparison, finished-normal witness, refusal, endpoint-obstruction, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before a typed conversion endpoint is consumed.

Independence witness: metacicdecidableboundary, bounded-normal-conversion-bridge, metacic-conversion-endpoint-seal, metacic-decidable-conversion-frontier, metacic-subject-reduction-obstruction: the residual-frontier carrier is not bijective to any listed sibling because it binds typed-window data, residual obstruction, bounded normal comparison, finished-normal witness, endpoint refusal, endpoint seal routing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICTypedConversionResidualFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICTypedConversionResidualFrontier}^{\uparrow}$ packet is generated from typed-window data, residual-frontier data, bounded-normal comparison, finished-normal witness, refusal, endpoint-obstruction routing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICTypedConversionResidualFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6069.1, Definition 6069.2, and Definition 6069.3 seed the finite residual frontier for typed MetaCIC conversion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICTypedConversionResidualFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unrestricted closed beta-conversion, fuel-erased normalization, quotient syntax equality, evaluator equality, subject-reduction discharge, confluence, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked typed-window exposure, residual-frontier retention, bounded-normal comparison, finished-normal witness, endpoint refusal, endpoint-obstruction routing, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICTypedConversionResidualFrontierUp.

Chapter 6070

A Concrete Naming Certificate for HyperbolicPattersonSullivanShadow$^{\uparrow}$

Following Patterson and Sullivan on hyperbolic limit-set shadows, the HyperbolicPattersonSullivanShadow$^{\uparrow}$ packet records a finite shadow ledger for boundary-weight readout. It sits after the visual-metric certificate of chapter 3866, the boundary-shadow route of chapter 3813, the Busemann-boundary certificate of chapter 3732, and the geodesic-flow carrier of chapter 3856. The packet names a displayed Patterson–Sullivan shadow surface over finite boundary, window, counting, transport, replay, provenance, and local naming rows; it is not a completed conformal density, quotient limit set, ambient ergodic theorem, host hyperbolic group action, or global measure construction.

Definition 6070.1 (Hyperbolic Patterson-Sullivan shadow carrier)**.** *A* HyperbolicPattersonSullivanShadow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, V, W, C, R, H, K, P, N)$$

with the following displayed rows:

1. *B is the boundary basepoint row, naming the finite Busemann-boundary face from which the shadow is observed.*
2. *V is the* HyperbolicVisualMetric$^{\uparrow}$ *row, displaying the visual metric comparison used to read the boundary shadow.*
3. *W is the shadow-window row, recording the finite boundary-shadow aperture and the accepted visible window.*
4. *C is the critical exponent and counting-budget row, recording the finite growth bound under which the shadow ledger is admitted.*
5. *R is the Busemann transport row, tying the basepoint, visual metric, shadow window, and counting budget to one boundary-facing route.*
6. *H records componentwise* hsame *transport for B, V, W, C, R, K, P, N.*
7. *K records displayed* Cont *replay from boundary-basepoint admission through visual-metric read-back, shadow-window exposure, critical-exponent counting, and Busemann transport.*
8. *P is the* Pkg *provenance over* HyperbolicPattersonSullivanShadow$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicBoundaryS HyperbolicBusemannBoundary$^{\uparrow}$, HyperbolicGeodesicFlow$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicPattersonSullivanShadow}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $B, V, W, C, R, H, K, P, N$. It has no coordinate for a completed conformal density, quotient limit set, ambient ergodic theorem, host group action, global measure construction, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.HyperbolicPattersonSullivanShadowUp.HyperbolicPattersonSullivanShadowTasteGate single carrier alignment`

Theorem 6070.2 (Hyperbolic Patterson-Sullivan shadow NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicPattersonSullivanShadow}^{\uparrow}$ *carrier $S = (B, V, W, C, R, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPatters}}$ *surface consists exactly of boundary-basepoint admission, visual-metric row exposure, shadow-window admission, critical-exponent and counting-budget ledger exposure, Busemann transport, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. These five NameCert obligations are carrier admission for B, V, W, C, route exactness through R, transport stability through H, replay stability through K, and provenance-local-name exhaustion through P, N.*

Proof. Project the carrier of Definition 6070.1. The displayed tuple exposes the boundary basepoint, visual-metric row, shadow-window row, critical exponent and counting budget, Busemann transport, and the structural rows.

The first obligation is carrier admission: B, V, W, C are the only geometric and counting rows admitted by the packet. The second obligation is route exactness: R ties those rows into one Busemann-transport route before any shadow ledger can be read.

The remaining obligations are structural. The row H gives componentwise hsame transport, K replays the same route by displayed Cont, and P, N record provenance and local naming. Since the carrier has no coordinate for a completed conformal density, quotient limit set, ambient ergodic theorem, host group action, global measure construction, Lean verification, or bridge checking, these rows exhaust the NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicPattersonSullivanShadow}^{\uparrow}$ read must expose a boundary basepoint, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ row, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ window, critical-exponent counting budget, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before it exports a public shadow ledger.

Independence witness: hyperbolic-visual-metric, hyperbolic-boundary-shadow, hyperbolic-busemann-boundary, hyperbolic-geodesic-flow: no listed sibling is bijective to $\mathsf{HyperbolicPattersonSullivanShadow}^{\uparrow}$ because this packet jointly carries boundary-basepoint admission, visual comparison, shadow-window exposure, critical-exponent counting, Busemann transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPattersonSullivanShadow}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicPattersonSullivanShadow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6070.1 and Definition 6070.2 seed the finite Patterson–Sullivan shadow ledger through boundary basepoints, visual metrics, shadow windows, counting budgets, Busemann transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicPattersonSullivanShadow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed conformal densities, quotient limit sets, ambient ergodic theorems, host hyperbolic group actions, global measure constructions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, visual-metric exposure, shadow-window admission, critical-exponent counting, Busemann transport, replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.HyperbolicPattersonSullivanShadowUp.

Constructive story: A HyperbolicPattersonSullivanShadow$^{\uparrow}$ packet is generated from a boundary basepoint, visual-metric row, shadow-window row, critical-exponent counting-budget row, Busemann transport, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 6071

A Concrete Naming Certificate for $\mathsf{CauchyCondensationIntegralBridge}^{\uparrow}$

Following Cauchy and Bishop–Bridges constructive analysis, the $\mathsf{CauchyCondensationIntegralBridge}^{\uparrow}$ packet records the finite comparison bridge between dyadic condensation tails and integral-test windows. It sits after the theorem-level condensation surface of chapter 3727, the integral-window route of chapter 2259, the dyadic tolerance ledger of chapter 291, the regular rational readback corridor of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite handoff surface for Real and Completion consumers; it is not a quotient stream, a selected infinite sum, a host function equality, an ambient integral, countable choice, or a completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 6071.1 (CauchyCondensationIntegralBridge carrier)**.** *A* $\mathsf{CauchyCondensationIntegralBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (K, I, D, W, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the accepted* $\mathsf{CauchyCondensationTheorem}^{\uparrow}$ *row, exposing the monotone source tail, dyadic schedule, original block sums, condensed dyadic terms, and Cauchy-criterion handoff.*
2. *I is the accepted* $\mathsf{CauchyIntegralTest}^{\uparrow}$ *row, exposing the nonnegative monotone observation, the Darboux or Riemann integral tail-window row, and the regular Cauchy series-tail row.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger that compares the dyadic block endpoints used by K with the finite integral-window endpoints used by I.*
4. *W is the common finite window schedule. It lists the block indices, interval endpoints, tolerances, and comparison rows inspected before any regular readback is exported.*
5. *Q is the bridge comparison row, recording that the condensation tail and the integral window are read over the same displayed tolerance budget.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from D, W, Q.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row attached to the regular readback.*
8. *H records componentwise* hsame *transports for the condensation row, integral row, dyadic ledger, window schedule, comparison row, readback, real seal, replay, provenance, and local name.*

9. *C records displayed* Cont *routes from each finite precision request through the dyadic and integral windows to R and E.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyCondensationIntegralBridge}^{\uparrow}$, $\mathsf{CauchyCondensationTheorem}^{\uparrow}$, $\mathsf{CauchyIntegralTest}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationIntegralBridge}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient streams, host functions, selected sums, ambient integrals, arbitrary real equality, countable choice, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 6071.2 (CauchyCondensationIntegralBridge NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCondensationIntegralBridge}^{\uparrow}$ *carrier $J = (K, I, D, W, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensatior}}$ *surface consists exactly of carrier admission for the displayed eleven-row packet; condensation-row exposure through K; integral-window exposure through I; dyadic endpoint and tolerance comparison through D; finite schedule coverage through W; bridge comparison exposure through Q;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R;* $\mathsf{Real}^{\uparrow}$ *sealing through E; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Proof. Project the accepted packet $J = (K, I, D, W, Q, R, E, H, C, P, N)$. The projection exposes exactly the condensation theorem row, integral-test row, dyadic ledger, finite window schedule, bridge comparison, regular readback, real seal, transport, replay, provenance, and local name.

Read a finite tail request through K and I. The condensation side supplies dyadic block endpoints and condensed terms, while the integral side supplies the matching tail-window row. The dyadic ledger D is the only comparison surface between those two rows.

Now inspect W and Q. They bind the finite block indices, integral endpoints, and tolerance budget before R can be produced, so neither side can export a separate quotient stream, host function, selected sum, or ambient integral.

The structural rows H, C, P, N transport, replay, source, and name that same route. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 6071.3 (CauchyCondensationIntegralBridge dyadic tail exactness)**.** *Every accepted* $\mathsf{CauchyCondensationIntegralBridge}^{\uparrow}$ *carrier preserves the dyadic tail route of* $\mathsf{CauchyCondensationTheorem}^{\uparrow}$ *before it enters an integral window. Concretely, a consumer can read the bridge comparison only through the finite path*

$$K, D, W, Q \longmapsto R, E, H, C, P, N,$$

where K supplies the condensation tail rows, D supplies the dyadic tolerance ledger, and W, Q record the common comparison window.

Proof. Begin with an accepted bridge carrier and project K. By the condensation theorem packet, the monotone source, dyadic schedule, block sums, condensed terms, and Cauchy handoff are already displayed before the bridge reads them.

Read D against that displayed dyadic schedule. The tolerance ledger compares only finite endpoints and finite dyadic budgets, so the bridge does not select a new tail, quotient a stream, or appeal to an ambient real limit.

Finally use W, Q, R, E, H, C, P, N. The window and comparison rows attach the dyadic tail to the regular readback and real seal along the same displayed route, while the structural rows preserve that route componentwise. □

Theorem 6071.4 (CauchyCondensationIntegralBridge integral-window handoff)**.** *Every accepted* $\mathsf{CauchyCondensationIntegralBridge}^{\uparrow}$ *carrier hands an integral-test window to Real and Completion consumers only after the condensation-side dyadic tail and the integral-side tail window have been matched by* D, W, Q*. The handoff exports the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *and the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, but exports no host function equality, ambient integral object, selected infinite sum, quotient stream, countable-choice schedule, or completeness principle.*

Proof. Project the integral-test row I. Its finite tail-window data is the only integral-facing input available to the bridge, and it is read beside the nonnegative monotone observation and regular Cauchy series-tail row already named by $\mathsf{CauchyIntegralTest}^{\uparrow}$.

Use the dyadic exactness theorem above to align the same request with K, D, W, Q. The bridge comparison cannot reach R until both the condensation tail and the integral window have been displayed under the shared tolerance budget.

Read the seal row E through R and the structural rows. Since the carrier contains no host function equality, ambient integral coordinate, selected sum, quotient stream, countable-choice schedule, or completeness field, the Real and Completion handoff is exactly the finite regular readback route. □

Theorem 6071.5 (CauchyCondensationIntegralBridge obligation handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CauchyCondensationIntegralBridge}^{\uparrow}$ *carrier must read*

$$K, I, D, W, Q, R, E, H, C, P, N$$

in order: condensation theorem row, integral-test row, dyadic endpoint ledger, finite window schedule, bridge comparison row, regular readback row, Real seal row, hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert*. The route exports no host summability, quotient stream equality, selected infinite sum, ambient integral, countable choice, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The first available rows are K and I, so every Real or Completion consumer must begin with the condensation theorem surface and the integral-test window surface.

The comparison rows come next. The dyadic ledger D, window schedule W, and bridge comparison row Q bind the two source rows to one finite tolerance budget before any regular readback is exposed.

Only then may the consumer read R and E. These rows provide the $\mathsf{RegSeqRat}^{\uparrow}$ readback and the $\mathsf{Real}^{\uparrow}$ seal, and they do not add host summability, quotient stream equality, a selected infinite sum, an ambient integral, countable choice, or a completeness theorem.

Finally H, C, P, N transport, replay, source, and name exactly the displayed route. Since the carrier fields are exhausted by $K, I, D, W, Q, R, E, H, C, P, N$, no excluded object can be exported by the handoff. □

Falsifiable prediction: An accepted $\mathsf{CauchyCondensationIntegralBridge}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading the displayed rows K, I, D, W, Q, R refutes the carrier surface.

Independence witness: cauchy-condensation-theorem, cauchy-integral-test, dyadicratcore, regseqrat, real: no listed sibling supplies the whole bridge packet $J = (K, I, D, W, Q, R, E, H, C, P, N)$, because each sibling contributes only a condensation theorem row, an integral-window row, a dyadic ledger, a regular readback, or a terminal seal while this chapter binds them to one finite comparison certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationIntegralBridge}^{\uparrow}}$.

Constructive story: A CauchyCondensationIntegralBridge$^{\uparrow}$ packet is generated from a CauchyCondensationTheorem row, a CauchyIntegralTest row, a DyadicRatCore endpoint and tolerance ledger, a finite shared window schedule, a bridge comparison row, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyCondensationIntegralBridge}^{\uparrow}}$, obligation)

Scope closed: Definition 6071.1, Definition 6071.2, Definition 6071.3, Definition 6071.4, and Definition 6071.5 close the obligation handoff between condensation tails and integral windows over DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{CauchyCondensationIntegralBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host summability, quotient stream equality, selected infinite sums, ambient integrals, countable choice, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires explicit dependency scope for Real and Completion consumers of BEDC.Derived.CauchyCondensat

Chapter 6072

A Concrete Naming Certificate for $\mathsf{OptionalSampling}^{\uparrow}$

Following Doob, the $\mathsf{OptionalSampling}^{\uparrow}$ packet names the bounded optional-sampling surface that sits between the finite optional-stopping certificate of chapter 383 and the martingale-convergence preparation route of chapter 2246. It consumes the probability, random-variable, conditional-expectation, martingale, stopping-time, and optional-stopping rows already displayed by those siblings, and it exports only a bounded stopped-window handoff. It does not introduce unbounded stopping-time choice, almost-sure quotient equality, or a completed measure carrier.

Definition 6072.1 (Optional sampling carrier)**.** *An* $\mathsf{OptionalSampling}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, X, E, M, T, O, B, L, H, C, Q, N)$$

with the following displayed rows:

1. *P is the consumed* $\mathsf{ProbSpace}^{\uparrow}$ *probability-source row.*
2. *X is the finite* $\mathsf{RandomVar}^{\uparrow}$ *endpoint family read by the stopped window.*
3. *E is the* $\mathsf{CondExp}^{\uparrow}$ *conditional-expectation face used by the martingale law.*
4. *M is the finite* $\mathsf{Martingale}^{\uparrow}$ *adapted-window row.*
5. *T is the bounded* $\mathsf{StoppingTime}^{\uparrow}$ *decision row.*
6. *O is the* $\mathsf{OptionalStopping}^{\uparrow}$ *stopped-window row over the same martingale and bound.*
7. *B is the bounded sampling-window row, displaying the lower and upper stopping indices and the finite horizon in which both are read.*
8. *L is the martingale-law handoff row, recording that the sampled endpoint comparison is read through E, M, T, O, B.*
9. *H records componentwise* hsame *transport for the displayed probability, random-variable, conditional-expectation, martingale, stopping-time, optional-stopping, sampling-window, and law rows.*
10. *C records displayed* Cont *replay from the bounded stopping decision to the sampled-window comparison.*
11. *Q is the* Pkg *provenance over* $\mathsf{OptionalSampling}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{StoppingTime}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. N is the local $\mathsf{NameCert}_{\mathsf{OptionalSampling}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $P, X, E, M, T, O, B, L, H, C, Q, N$. No coordinate names an unbounded stopping theorem, a selected almost-sure representative, a completed measure space, or an ambient martingale convergence theorem.

Lean4 (definition) `BEDC.Derived.OptionalSamplingUp.TasteGate.OptionalSamplingUp`
Lean4 ✓ `BEDC.Derived.OptionalSamplingUp.TasteGate.OptionalSamplingTasteGate single carrier alignment`

Theorem 6072.2 (Optional sampling NameCert obligations)**.** *For every accepted* $\mathsf{OptionalSampling}^{\uparrow}$ *carrier $S = (P, X, E, M, T, O, B, L, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{OptionalSampling}^{\uparrow}}$ *surface consists exactly of carrier admission for P, X, E, M, T, O, B, L, classifier transport through H, bounded stopped-window exactness through O, B, C, martingale-law handoff through E, M, L, provenance-local-name exhaustion through Q, N, and no-escape from the displayed bounded stopping rows.*

Proof. Project the carrier of Definition 6072.1. The probability, random-variable, conditional-expectation, martingale, stopping-time, optional-stopping, bounded-window, and law-handoff rows are the only mathematical coordinates of the packet.

Carrier and classifier obligations are immediate from those coordinates. Rows P, X, E, M, T, O, B, L admit the bounded sampling surface, while H transports it componentwise and C replays the same finite route.

The stopped-window exactness is bounded because O and B expose the finite horizon before the handoff row L is read. The martingale-law handoff is therefore consumed through E, M, T, O, B, L, not through a host stopping theorem.

Finally Q, N exhaust the provenance and local naming rows. Since no carrier coordinate contains unbounded stopping-time choice, almost-sure quotient equality, completed measure data, or convergence, the NameCert surface exports none of those objects. □

Theorem 6072.3 (Optional sampling bounded stopping handoff)**.** *Every optional-sampling read consumed by* $\mathsf{MartingaleConvergence}^{\uparrow}$ *factors through the displayed bounded stopping rows T, O, B, L of an accepted* $\mathsf{OptionalSampling}^{\uparrow}$ *carrier. The handoff exports the finite stopped-window comparison over* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, *and* $\mathsf{Martingale}^{\uparrow}$ *rows, and exports no unbounded stopping-time choice, almost-sure quotient equality, completed measure carrier, or ambient convergence theorem.*

Proof. Start with an accepted $\mathsf{OptionalSampling}^{\uparrow}$ carrier. The stopping decision is the bounded row T, and the stopped process is exposed only through the $\mathsf{OptionalStopping}^{\uparrow}$ row O inside the finite sampling window B.

The martingale-law handoff is L. By Definition 6072.2, L is read after the conditional-expectation and martingale rows E, M and after the bounded stopped-window rows T, O, B.

Thus a downstream $\mathsf{MartingaleConvergence}^{\uparrow}$ consumer receives only the displayed finite route. The packet has no coordinate for unbounded stopping-time choice, almost-sure quotient equality, measure completion, or convergence, so the handoff cannot export any of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{OptionalSampling}^{\uparrow}}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OptionalSampling}^{\uparrow}}, \mathsf{seed})$
Scope closed: Definition 6072.1, Definition 6072.2, and Definition 6072.3 seed the bounded optional-sampling packet over displayed probability, random-variable, conditional-expectation, martingale, stopping-time, optional-stopping, transport, replay, provenance, and local naming rows.
Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OptionalSampling}^{\uparrow}}, \mathsf{unformalized})$
Bridge status: none

Not claimed: This chapter does not close unbounded optional sampling, almost-sure quotient equality, completed measure carriers, martingale convergence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, bounded stopped-window exactness, martingale-law handoff, provenance exhaustion, no-escape, and TasteGate field faithfulness for BEDC.Derived.OptionalSamplingUp.

Constructive story: An OptionalSampling$^{\uparrow}$ packet is generated from displayed ProbSpaceUp, RandomVarUp, CondExpUp, MartingaleUp, StoppingTimeUp, OptionalStoppingUp, bounded sampling-window, martingale-law handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Chapter 6073

A Concrete Naming Certificate for $\mathsf{HyperbolicGromovProduct}^{\uparrow}$

The $\mathsf{HyperbolicGromovProduct}^{\uparrow}$ packet realizes the boundary-shadow and visual-metric comparison route of chapter 9463 as finite basepointed NameCert data. It sits after the visual-metric packet of chapter 3866, the Busemann-boundary packet of chapter 3732, the boundary-shadow packet of chapter 3813, and the observer-expansion packet of chapter 4167. The packet names only a displayed Gromov-product comparison surface; it does not complete the boundary, select geodesic representatives, import a host hyperbolic space, or identify visual metrics by quotient equality.

Definition 6073.1 (Hyperbolic Gromov product carrier)**.** *A* $\mathsf{HyperbolicGromovProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (B, V, U, S, E, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the basepoint row naming the finite observer base from which the product is read.*
2. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *comparison row.*
3. *U is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *boundary-distance row.*
4. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *visual-boundary shadow row.*
5. *E is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *observer-expansion row tying the comparison to the focused route.*
6. *R is the Gromov-product readback row, recording the finite basepointed comparison extracted from B, V, U, S, E.*
7. *H records componentwise* hsame *transport for basepoint, visual-metric, Busemann-boundary, boundary-shadow, observer-expansion, readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from basepoint admission through visual-boundary shadow comparison to the Gromov-product readback.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicGromovProduct}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}$ $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicGromovProduct}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, V, U, S, E, R, H, C, P, N$. It has no coordinate for a completed ideal boundary, a selected geodesic-ray quotient, a host hyperbolic group action, or a global visual metric.

Theorem 6073.2 (Hyperbolic Gromov product NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicGromovProd}$ *carrier $G = (B, V, U, S, E, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicGromovProduct}^{\uparrow}}$ *surface consists exactly of basepoint admission through B, visual-metric comparison through V, Busemann-boundary exposure through U, visual-boundary shadow admission through S, observer-expansion anchoring through E, Gromov-product readback through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6073.1. The geometric data are exactly the basepoint, visual metric, Busemann boundary, boundary shadow, observer-expansion, and readback rows.

The obligation surface reads each geometric coordinate once. Row B admits the basepoint, V supplies the visual comparison, U supplies the Busemann boundary face, S supplies the visible shadow row, E anchors the observer-expansion route, and R records the product readback.

The remaining rows are structural. Transport is componentwise through H, replay is displayed through C, and P, N provide provenance and local naming. Since no carrier coordinate contains a completed boundary, selected quotient, host hyperbolic action, or global visual metric, the NameCert obligations do not export those objects. □

Theorem 6073.3 (Hyperbolic Gromov product boundary-shadow handoff)**.** *Every boundary-shadow or visual-metric consumer of an accepted* $\mathsf{HyperbolicGromovProduct}^{\uparrow}$ *packet factors its Gromov-product read through the displayed rows*

$$B, V, U, S, E, R, H, C, P, N.$$

The handoff preserves the basepoint row, visual-metric comparison, Busemann-boundary exposure, boundary-shadow row, observer-expansion route, product readback, transport, replay, provenance, and local name; it exports no completed boundary, quotient geodesic equality, host hyperbolic group action, or global visual metric.

Proof. Begin with the accepted carrier. Its basepointed comparison is not read from a host metric space; it is the displayed row R over B, V, U, S, E.

Apply Definition 6073.2. The visual-metric and boundary-shadow information enters only through V and S, while the Busemann and observer-expansion rows U, E keep the boundary comparison attached to the focused route.

Finally transport and replay the same rows through H, C, P, N. The carrier has no coordinate for completed boundaries, quotient geodesic equality, host group actions, or global visual metrics, so the handoff remains finite and local. □

Falsifiable prediction: A $\mathsf{HyperbolicGromovProduct}^{\uparrow}$ read is rejected whenever its basepoint row or visual-boundary shadow row is absent.

Independence witness: hyperbolic-visual-metric, hyperbolic-busemann-boundary, hyperbolic-boundary-shadow, hyperbolic-observer-expansion: no listed sibling is bijective to $\mathsf{HyperbolicGromovProduct}^{\uparrow}$ because this packet jointly carries basepoint admission, visual-metric comparison, Busemann-boundary exposure, boundary-shadow readback, observer-expansion anchoring, product readback, transport, replay, provenance, and local naming rows.

The Lean follow-up for this packet must provide `Nontrivial` and `FieldFaithful` instances in `lean4/BEDC/Derived/HyperbolicGromovProductUp/TasteGate.lean`; the paper packet records the finite NameCert surface those instances must preserve.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicGromovProduct}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicGromovProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6073.1, Definition 6073.2, and Definition 6073.3 seed the finite basepointed Gromov-product packet over visual-metric, Busemann-boundary, boundary-shadow, observer-expansion, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicGromovProduct}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed ideal boundaries, quotient geodesic equality, host hyperbolic group actions, global visual metrics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked basepoint admission, visual-metric comparison, Busemann-boundary exposure, boundary-shadow readback, observer-expansion anchoring, product readback, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.HyperbolicGromovProductUp.

Constructive story: A $\mathsf{HyperbolicGromovProduct}^{\uparrow}$ packet is generated from a basepoint row, HyperbolicVisualMetricUp row, HyperbolicBusemannBoundaryUp row, HyperbolicBoundaryShadowUp row, HyperbolicObserverExpansionUp row, Gromov-product readback, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Chapter 6074

A Concrete Naming Certificate for $\mathsf{UniformCauchyWindowExhaustion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{UniformCauchyWindowExhaustion}^{\uparrow}$ packet records the finite Cauchy-window exhaustion surface used by real-completion consumers before any completed real object is exposed. It sits over the uniform Cauchy criterion of chapter 435, the finite stream-window route of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names finite exhaustion data, not quotient streams, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6074.1 (Uniform Cauchy window exhaustion carrier)**.** *A* $\mathsf{UniformCauchyWindowExhaustion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, T, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row of finite stream windows inspected by the exhaustion request.*
2. *T is the uniform threshold row, assigning each displayed tolerance request a single threshold that governs all later windows named by S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii, dominance checks, and comparison budgets used by T.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row assembled from the window observations in S after the threshold and dyadic rows have been displayed.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, T, D, R have been replayed.*
6. *H records componentwise* hsame *transport for the stream-window, threshold, dyadic-ledger, regular-readback, real-seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite route*

$$S, T, D \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{UniformCauchyWindowExhaustion}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{UniformCauchyWindowExhaustion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, a countable-choice selector, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.UniformCauchyWindowExhaustionUp.TasteGate.UniformCauchyWindowExhaustionUp`
Lean4 ✓ `BEDC.Derived.UniformCauchyWindowExhaustionUp.TasteGate.UniformCauchyWindowExhaustionTasteGate`
`single carrier alignment`

Theorem 6074.2 (Uniform Cauchy window exhaustion NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchyWindowExhaustion}^{\uparrow}$ *carrier $U = (S, T, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyWin}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed stream-window row, uniform threshold row, dyadic tolerance ledger, regular rational handoff, real seal, transport, replay, provenance, and local naming row;*
2. *finite-window exposure, requiring every exhaustion read to inspect the* $\mathsf{StreamName}^{\uparrow}$ *row S before it can consult T, D, R, E;*
3. *uniform-threshold exactness, requiring the threshold row T to govern all later windows named by S for the same displayed tolerance request;*
4. *dyadic-to-regular handoff, requiring the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D to feed the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R before the* $\mathsf{Real}^{\uparrow}$ *seal E is visible;*
5. *ledger refusal, excluding quotient streams, selected limits, countable choice, host real equality, and ambient real completeness as certificate data.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 6074.1. The accepted inventory is exactly $S, T, D, R, E, H, C, P, N$, so every local obligation must be read from those rows.

The finite-window and uniform-threshold rows are upstream. A consumer cannot read a regular rational handoff until the displayed stream windows S, the threshold row T, and the dyadic tolerance ledger D have supplied the requested tail comparison.

The real seal is downstream of the regular handoff. The row R records the $\mathsf{RegSeqRat}^{\uparrow}$ readback assembled from the same windows and budgets, and E seals only that displayed readback.

Transport by H, replay by C, provenance by P, and local naming by N preserve the same route. Since quotient stream equality, selected limits, countable choice, host real equality, and ambient real completeness have no carrier coordinate, the five listed rows exhaust the local certificate surface. □

Falsifiable prediction: Any accepted $\mathsf{UniformCauchyWindowExhaustion}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read without the displayed StreamName windows, uniform threshold row, DyadicRatCore tolerance ledger, transport, replay, provenance, and local NameCert rows refutes the carrier.

Independence witness: UniformCauchyCriterion, StreamName, RegSeqRat, DyadicRatCore, and Real are not individually bijective with $\mathsf{UniformCauchyWindowExhaustion}^{\uparrow}$ because the packet jointly carries finite windows, one uniform threshold row, a dyadic tolerance ledger, a regular rational handoff, a Real seal, componentwise transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyWindowExhaustion}^{\uparrow}}$.

Constructive story: A UniformCauchyWindowExhaustion$^{\uparrow}$ packet is generated from finite StreamName windows, a uniform threshold row, a DyadicRatCore tolerance ledger, RegSeqRat handoff, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{UniformCauchyWindowExhaustion}^{\uparrow}}$, seed)

Scope closed: Definition 6074.1 and Definition 6074.2 seed the finite uniform Cauchy-window exhaustion surface over StreamName, threshold, dyadic tolerance, RegSeqRat, Real, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{UniformCauchyWindowExhaustion}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.UniformCauchyWindowExhaustionUp.TasteGate.UniformCauchyWindowExhaustionTasteGate\_singl`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-threshold exactness, dyadic tolerance routing, RegSeqRat handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.UniformCauchyWindowEx

Chapter 6075

A Concrete Naming Certificate for $\mathsf{PointedGromovHausdorff}^{\uparrow}$

Following Gromov and Burago–Burago–Ivanov, the $\mathsf{PointedGromovHausdorff}^{\uparrow}$ packet records compact-metric comparison with displayed basepoints. It sits after the ordinary comparison carrier of chapter 2104, the compact-metric surface of chapter 129, the metric source of chapter 57, the scalar Hausdorff-distance route of chapter 3653, and the basepoint-sensitive observer rows of chapter 6073. The packet names a finite pointed comparison surface; it is not a quotient compactum, a selected optimal pointed correspondence, a completed moduli space, or an ambient isometry theorem.

Definition 6075.1 (Pointed Gromov–Hausdorff carrier)**.** *A* $\mathsf{PointedGromovHausdorff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Y, x_0, y_0, K_X, K_Y, R, D, B, H, Q, U, T, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two compact-metric endpoint names, each read through the* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{CompactMetric}^{\uparrow}$ *source rows.*
2. *x_0 and y_0 are the displayed basepoint rows attached to the two endpoints before any comparison row is public.*
3. *K_X and K_Y are the endpoint compact-metric certificates consumed by the ordinary* $\mathsf{GromovHausdorff}^{\uparrow}$ *route.*
4. *R is the finite pointed correspondence table, containing the ordinary correspondence rows and the displayed pair (x_0, y_0).*
5. *D is the dyadic distortion ledger for endpoint distances along the displayed correspondence rows.*
6. *B is the basepoint preservation ledger, recording that the pointed correspondence reads the pair (x_0, y_0) as distinguished rather than as an anonymous correspondence row.*
7. *H records the* $\mathsf{HausdorffDistance}^{\uparrow}$ *and* $\mathsf{HausdorffMetric}^{\uparrow}$ *comparison rows used to read the compact-subset distance data attached to the same finite table.*
8. *Q records the optional observer handoff to the* $\mathsf{HyperbolicGromovProduct}^{\uparrow}$ *basepoint-sensitive comparison surface when such a consumer is present.*

9. *U records componentwise* hsame *transport for endpoints, basepoints, compact-metric rows, correspondence rows, distortion bounds, basepoint preservation, comparison handoffs, replay, provenance, and local naming rows.*
10. *T records displayed transport of the pointed comparison surface across accepted endpoint and basepoint renamings.*
11. *C records displayed* Cont *replay of the route*

$$X, Y, x_0, y_0, K_X, K_Y \longmapsto R \longmapsto D, B \longmapsto H, Q \longmapsto U, T.$$

12. *P is the* Pkg *provenance over* PointedGromovHausdorff$^{\uparrow}$, GromovHausdorff$^{\uparrow}$, CompactMetric$^{\uparrow}$, Met$^{\uparrow}$, HausdorffDistance$^{\uparrow}$, HyperbolicGromovProduct$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{PointedGromovHausdorff}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, x_0, y_0, K_X, K_Y, R, D, B, H, Q, U, T, C, P, N$. It has no coordinate for unpointed quotient compacta, selected optimal correspondences, completed moduli spaces, host equality of compact metric spaces, or ambient isometry of pointed completions.

Lean4 ✓ `BEDC.Derived.PointedGromovHausdorffUp.TasteGate.PointedGromovHausdorffTasteGate single carrier alignment`

Theorem 6075.2 (Pointed Gromov–Hausdorff NameCert obligations)**.** *For every accepted* PointedGromovHausdorf *carrier*

$$G = (X, Y, x_0, y_0, K_X, K_Y, R, D, B, H, Q, U, T, C, P, N),$$

the local NameCert$_{\text{PointedGromovHausdorff}^{\uparrow}}$ *surface consists exactly of endpoint admission, basepoint admission, compact-metric support, pointed-correspondence admission, dyadic distortion exactness, basepoint preservation, Hausdorff-distance comparison, optional basepoint-sensitive observer handoff, componentwise transport, displayed replay, provenance, and local naming through the displayed rows of G.*

Proof. Project the carrier of Definition 6075.1. The endpoint rows X, Y, K_X, K_Y give the same compact-metric surface consumed by GromovHausdorff$^{\uparrow}$, while x_0, y_0 are additional rows attached before any correspondence is read.

The pointed correspondence row R and the distortion ledger D provide the ordinary comparison data. The row B then marks the distinguished pair (x_0, y_0) as preserved by that correspondence, so the basepoint information is not recovered from an unpointed quotient.

The comparison handoffs H, Q read the same finite table through Hausdorff-distance and basepoint-sensitive observer surfaces. The structural rows U, T, C, P, N transport, replay, source, and name exactly those displayed rows.

Since no further coordinate appears in the carrier, the listed rows exhaust the local NameCert obligations and export no selected optimal correspondence, completed moduli object, host equality, or ambient isometry theorem. □

Theorem 6075.3 (Pointed-to-unpointed forgetful route)**.** *Every ordinary* GromovHausdorff$^{\uparrow}$ *consumer of an accepted* PointedGromovHausdorff$^{\uparrow}$ *carrier factors through the forgetful route*

$$X, Y, K_X, K_Y, R, D, H, U, T, C, P, N.$$

The pointed rows x_0, y_0, B remain available only to pointed consumers. Forgetting them recovers the ordinary compact-metric comparison surface, but it does not allow the unpointed carrier to inspect, preserve, or compare basepoints.

Proof. Start with the accepted carrier and erase the basepoint-specific rows x_0, y_0, B. The remaining endpoint, compact-metric, correspondence, distortion, Hausdorff-distance, transport, replay, provenance, and local-name rows have the same shape as the ordinary comparison route of Definition 2104.3.

A pointed consumer may read the erased rows before forming its comparison claim. An ordinary consumer cannot, because the target $\mathsf{GromovHausdorff}^{\uparrow}$ surface contains no basepoint coordinate and no basepoint preservation ledger.

Thus the forgetful route is constructive and finite: it projects the pointed packet to the ordinary comparison rows, while preserving the refusal stated in Definition 2104.4. Basepoint comparison requires the pointed carrier itself. □

Closure status for $\mathsf{NameCert}_{\mathsf{PointedGromovHausdorff}^{\uparrow}}$.

Constructive story: A $\mathsf{PointedGromovHausdorff}^{\uparrow}$ packet is generated from two compact-metric endpoints, displayed basepoints, finite pointed correspondence rows, dyadic distortion bounds, a basepoint preservation ledger, HausdorffDistanceUp comparison rows, an optional HyperbolicGromovProductUp observer handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointedGromovHausdorff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6075.1, Definition 6075.2, and Definition 6075.3 seed the finite pointed compact-metric comparison packet over endpoints, basepoints, correspondence, distortion, Hausdorff-distance, observer handoff, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointedGromovHausdorff}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.PointedGromovHausdorffUp.TasteGate.PointedGromovHausdorffTasteGate\_single\_carrier\_al`

Bridge status: none

Not claimed: This chapter does not close selected optimal pointed correspondences, quotient compacta, completed moduli spaces, host compact-metric equality, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, basepoint admission, pointed-correspondence admission, dyadic distortion exactness, basepoint preservation, comparison handoffs, transport, replay, provenance, and local naming for BEDC.Derived.PointedGromovHausdorffUp.

Chapter 6076

A Concrete Naming Certificate for $\mathsf{CauchySequenceComplete}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchySequenceComplete}^{\uparrow}$ packet records Cauchy-sequence completeness as finite BEDC NameCert data before any $\mathsf{Real}^{\uparrow}$ or complete-metric consumer receives an endpoint. It sits over the finite window discipline of chapter 126, the regular rational readback of chapter 301, the real-name seal of chapter 38, and the ordered Cauchy completion boundary of chapter 3735. The packet names the direct Cauchy-sequence completeness surface; it is not a quotient of Cauchy streams, a selected host limit, countable choice, or an ambient completion primitive.

Definition 6076.1 (Cauchy sequence complete carrier)**.** *A* $\mathsf{CauchySequenceComplete}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, M, R, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *family of finite windows through which the sequence entries and tail comparisons are inspected.*
2. *M is the Cauchy-modulus ledger, recording the threshold assigned to each requested tolerance and the dominance checks needed by endpoint consumers.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the windows in S and the thresholds in M.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the window, modulus, and regular readback rows have been displayed.*
5. *Q is the* $\mathsf{CompleteMetric}^{\uparrow}$ *endpoint row recording the finite completion-facing handoff visible after S, M, R, E.*
6. *H records componentwise* hsame *transport for the stream-window, modulus-ledger, readback, real-seal, complete-metric endpoint, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay of the route*

$$S, M \longmapsto R \longmapsto E \longmapsto Q.$$

8. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceComplete}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchySequenceComplete}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, M, R, E, Q, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, countable choice, open-cover compactness, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySequenceCompleteUp.CauchySequenceCompleteTasteGate single carrier alignment`

Theorem 6076.2 (Cauchy sequence complete NameCert obligations)**.** *For every accepted* CauchySequenceComplete *carrier $K = (S, M, R, E, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceComplete}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite* $\mathsf{StreamName}^{\uparrow}$ *windows, Cauchy-modulus ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{CompleteMetric}^{\uparrow}$ *endpoint row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A completion-facing consumer may read the endpoint row Q only after the same S, M, R, E route has been exposed.*

Proof. Project the carrier of Definition 6076.1. The accepted inventory is exactly $S, M, R, E, Q, H, C, P, N$, so every local obligation must be read from those rows.

The finite windows and Cauchy-modulus ledger are upstream. A consumer cannot inspect the regular rational readback R until the displayed window row S and threshold row M have supplied the requested tail data.

The endpoint handoff is downstream of the real seal. The row E seals the regular readback through $\mathsf{Real}^{\uparrow}$, and Q records only the finite complete-metric endpoint visible after the same route has been transported and replayed.

Since quotient equality, selected representatives, countable choice, open-cover compactness, host real equality, and ambient real completeness have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 6076.3 (Cauchy sequence complete Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *endpoint read exported by an accepted* $\mathsf{CauchySequenceComplete}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The handoff preserves the finite window and Cauchy-modulus route before the $\mathsf{Real}^{\uparrow}$ *seal is exposed, and it is compatible with the ordered completion boundary of chapter 3735 without importing that chapter's order-comparison rows as hidden endpoint data.*

Proof. Start with an accepted carrier $K = (S, M, R, E, Q, H, C, P, N)$. By the carrier definition, the only real-facing seal is E, and E is downstream of the windows S, the modulus ledger M, and the regular readback R.

The complete-metric endpoint row Q is read only after E. Thus an endpoint consumer sees the same displayed sequence windows, thresholds, regular rational readback, real seal, and structural rows that generated the packet.

The sibling ordered-completeness chapter supplies a comparison boundary, but this carrier does not add an order row, quotient stream equality, selected limit, or host completeness datum. The real handoff therefore remains the direct finite Cauchy-sequence completeness surface named by $S, M, R, E, Q, H, C, P, N$. □

Falsifiable prediction: Any accepted $\mathsf{CauchySequenceComplete}^{\uparrow}$ endpoint consumer that reaches a $\mathsf{Real}^{\uparrow}$ or $\mathsf{CompleteMetric}^{\uparrow}$ read without the displayed StreamName windows, Cauchy-modulus

ledger, RegSeqRat readback, transport, replay, provenance, and local NameCert rows refutes the carrier.

Independence witness: StreamName, RegSeqRat, Real, CompleteMetric, and CauchySequence-OrderCompleteness are not individually bijective with $\mathsf{CauchySequenceComplete}^{\uparrow}$ because the packet jointly carries finite sequence windows, an explicit Cauchy-modulus ledger, regular readback, a Real seal, a complete-metric endpoint row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceComplete}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceComplete}^{\uparrow}$ packet is generated from finite StreamName windows, a Cauchy-modulus ledger, RegSeqRat readback, a RealUp seal, a CompleteMetric endpoint row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySequenceComplete}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6076.1, Definition 6076.2, and Definition 6076.3 seed the finite constructive Cauchy-sequence completeness surface over StreamName, RegSeqRat, Real, CompleteMetric, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySequenceComplete}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, open-cover compactness, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-modulus exposure, RegSeqRat readback exactness, Real-seal handoff, CompleteMetric endpoint exposure, transport, replay, provenance, and local naming for BEDC.Derived.CauchySequenceCompleteUp.

Chapter 6077

A Concrete Naming Certificate for $\mathsf{RiemannSumCauchyNet}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RiemannSumCauchyNet}^{\uparrow}$ packet records the finite Cauchy-net bridge by which dyadic Riemann sums become completion-facing data without importing ambient real completeness. It sits after the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the Cauchy boundary of chapter 3413, and the finite mesh discipline of chapter 6062. The packet names the finite net of dyadic Riemann-sum approximants; it is not a host integrability theorem, a selected limit, a quotient completion, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 6077.1 (Riemann sum Cauchy-net carrier)**.** *A* $\mathsf{RiemannSumCauchyNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, W, R, M, S, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic mesh depth, endpoint budget, and comparison scale used by the net;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at that dyadic scale;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic tolerances;*
4. *M is the finite* $\mathsf{RiemannUniformMesh}^{\uparrow}$ *mesh row through which partition widths and tagged cells are inspected;*
5. *S is the dyadic Riemann-sum row, recording the finite sum visible after D, W, R, M are displayed;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the current finite approximation;*
7. *Q is the* $\mathsf{Cauchy}^{\uparrow}$ *comparison row, recording that two displayed mesh depths have a dyadic tolerance comparison inside the same finite packet;*
8. *H records componentwise* hsame *transport for the dyadic, window, readback, mesh, sum, Real, Cauchy, replay, provenance, and local naming rows;*
9. *C records displayed* Cont *replay of the route*

$$D, W, R, M \longmapsto S \longmapsto E \longmapsto Q;$$

10. *P is the* Pkg *provenance over* $\mathsf{RiemannSumCauchyNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RiemannUniformMesh}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannSumCauchyNet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, R, M, S, E, Q, H, C, P, N$. It has no coordinate for a host integral, ambient real completeness, quotient equality of nets, selected limiting value, or unrestricted choice of partitions.

Lean4 ✓ `BEDC.Derived.RiemannSumCauchyNetUp.RiemannSumCauchyNetTasteGate single carrier alignment`

Theorem 6077.2 (Riemann sum Cauchy-net NameCert obligations)**.** *For every accepted* $\mathsf{RiemannSumCauchyNet}^{\uparrow}$ *carrier $K = (D, W, R, M, S, E, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannSumCauchyNet}^{\uparrow}}$ *surface consists exactly of carrier admission; dyadic tolerance exposure through D; finite-window inspection through W; regular rational readback through R; uniform mesh exposure through M; finite Riemann-sum handoff through S; terminal Real sealing through E; Cauchy comparison through Q; componentwise transport through H; displayed replay through C; package provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 6077.1. The displayed rows are exactly $D, W, R, M, S, E, Q, H, C, P, N$, so each local obligation must be discharged by one of those finite coordinates.

The upstream route is dyadic and finite. The row D fixes the tolerance ledger, W opens only the requested finite windows, R records the regular rational readback, and M supplies the uniform mesh cells used by the Riemann-sum row.

The downstream route is sum, seal, and comparison. The row S exports only the finite dyadic Riemann sum, E seals the current approximation as $\mathsf{Real}^{\uparrow}$ data, and Q records the Cauchy comparison between displayed mesh depths.

Finally transport, replay, provenance, and local naming preserve the same packet through H, C, P, N. Since host integrals, quotient nets, selected limits, unrestricted partitions, and ambient real completeness are absent from the carrier, the listed rows exhaust the NameCert surface. □

Theorem 6077.3 (Riemann sum Cauchy-net Real-completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{RiemannSumCauchyNet}^{\uparrow}$ *packet receives a finite handoff*

$\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RiemannUniformMesh}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, Pkg, Na

The consumer may read the $\mathsf{Real}^{\uparrow}$ *seal only after the dyadic tolerance, finite-window, regular readback, uniform-mesh, and finite-sum rows have been displayed, and may read the* $\mathsf{Cauchy}^{\uparrow}$ *comparison only as a finite tolerance comparison between two displayed mesh depths. The handoff supplies no ambient completion of Riemann sums, selected integral value, quotient equality of Cauchy nets, or host real-completeness coordinate.*

Proof. Start with an accepted carrier $K = (D, W, R, M, S, E, Q, H, C, P, N)$. The Real-facing row E is downstream of the dyadic tolerance row D, finite window row W, regular readback row R, uniform mesh row M, and finite sum row S.

The Cauchy-facing row Q is also downstream of those displayed approximants. It records a finite tolerance comparison between two visible mesh depths, not a completed quotient net or a selected endpoint.

Use H, C, P, N to transport, replay, source, and name the same route. A completion-facing consumer therefore receives the finite dyadic Riemann-sum Cauchy-net packet and not an ambient real-completeness principle. □

Falsifiable prediction: If a completion-facing consumer reaches the $\mathsf{Real}^{\uparrow}$ seal E or the $\mathsf{Cauchy}^{\uparrow}$ comparison row Q without first displaying the dyadic tolerance, StreamName window, RegSeqRat readback, uniform mesh, finite-sum, transport, replay, provenance, and local NameCert rows, the $\mathsf{RiemannSumCauchyNet}^{\uparrow}$ carrier has been misread.

Independence witness: dyadicratcore, streamname, regseqrat, riemann-uniform-mesh, real, and cauchy are not individually bijective with $\mathsf{RiemannSumCauchyNet}^{\uparrow}$ because this packet jointly carries dyadic tolerances, finite observation windows, regular readback, uniform mesh rows, finite Riemann sums, Real seals, Cauchy comparisons, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannSumCauchyNet}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannSumCauchyNet}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, RiemannUniformMesh rows, a finite Riemann-sum row, a Real seal, a Cauchy comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannSumCauchyNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6077.1, Definition 6077.2, and Definition 6077.3 seed the finite dyadic Riemann-sum Cauchy-net bridge consumed by Real and completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannSumCauchyNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Riemann integrability, ambient Real completeness, quotient Cauchy nets, selected integral values, unrestricted partition choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite-window inspection, regular rational readback, uniform mesh exposure, finite-sum handoff, Real sealing, Cauchy comparison, transport, replay, provenance, and local naming for BEDC.Derived.RiemannSumCauchyNetUp.

Chapter 6078

A Concrete Naming Certificate for BoundedCauchySequence$^{\uparrow}$

Following Bishop and Bridges, a bounded Cauchy sequence is a rational-name object whose tail control and global bound are displayed before any completed real value is read. The BoundedCauchySequence$^{\uparrow}$ packet records this L10 route as finite NameCert data over the Cauchy request of chapter 3413, the StreamName windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real boundary of chapter 38. The packet supplies bounded Cauchy evidence without importing selected limits, quotient streams, countable choice, or ambient completeness.

Definition 6078.1 (Bounded Cauchy sequence carrier)**.** *A* BoundedCauchySequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, S, R, T, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the Cauchy modulus row, assigning each dyadic precision request a displayed tail index and the pairwise tail comparison rows certified by* Cauchy$^{\uparrow}$*.*
2. *S is the* StreamName$^{\uparrow}$ *finite-window ledger, listing exactly the source windows inspected by the modulus and bound requests.*
3. *R is the* RegSeqRat$^{\uparrow}$ *readback row, converting the displayed StreamName windows into regular rational sequence entries.*
4. *T is the* DyadicRatCore$^{\uparrow}$ *tolerance row, carrying the dyadic scales used by the tail comparisons and the bound ledger.*
5. *L is the dyadic bound ledger, recording a displayed dyadic bound q and certified comparisons saying that every inspected prefix entry and every modulus-controlled tail entry remains below q in absolute value.*
6. *H records componentwise* hsame *transport for the modulus, stream, readback, tolerance, bound, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a precision or bound request through M, S, R, T, L, H, P, N.*
8. *P is the* Pkg *provenance over* BoundedCauchySequence$^{\uparrow}$*,* Cauchy$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{BoundedCauchySequence}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, S, R, T, L, H, C, P, N$. It has no coordinate for quotient equality of streams, a selected limit, host sequence equality, a supremum principle, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BoundedCauchySequenceUp.BoundedCauchySequenceTasteGate single carrier alignment`

Theorem 6078.2 (Bounded Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{BoundedCauchySequence}^{\uparrow}$ *carrier*

$$B = (M, S, R, T, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedCauchySequence}^{\uparrow}}$ *surface consists exactly of Cauchy modulus admission for M, StreamName finite-window admission for S, RegSeqRat readback for R, DyadicRatCore tolerance visibility for T, dyadic bound-ledger enclosure for L, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through P, and local naming through N.*

The enclosure is monotone in the displayed tail request: increasing the requested tail index may shrink the inspected tail window, but it cannot add a bound obligation outside the rows already carried by $M, S, R, T, L, H, C, P, N$.

Proof. Project the carrier of Definition 6078.1. The tuple $M, S, R, T, L, H, C, P, N$ is the whole accepted packet, so the local NameCert can read only the displayed modulus, window, readback, tolerance, bound, transport, replay, provenance, and naming rows.

The Cauchy route begins with a precision request. The modulus row M names the tail index, the StreamName row S supplies the finite windows inspected at that index, and the RegSeqRat row R reads those windows as rational entries.

The dyadic rows then supply both estimates. The tolerance row T fixes the scale for pairwise tail control, while the bound ledger L records the global dyadic enclosure for the displayed prefix and for all entries reached through the modulus-controlled tail.

If the tail index is increased, the packet replays the same route through C and transports it through H. The bound row is not enlarged by an external supremum or selected limit; it is only reread on a smaller displayed tail surface, with provenance and local naming carried by P, N.

Since no quotient stream, selected limit, host equality, countable choice, or completeness coordinate occurs in the carrier, no additional NameCert obligation can be exported. □

Theorem 6078.3 (Bounded Cauchy consumer route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{BoundedCauchySequence}^{\uparrow}$ *packet receives bounded Cauchy evidence only through the finite route*

$$\mathsf{Cauchy}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{BoundedCauchySequence}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The consumer receives a displayed Cauchy modulus, finite rational windows, dyadic tolerances, a dyadic bound ledger, transport, replay, provenance, and local naming. It receives no selected real limit, quotient stream equality, ambient completeness principle, or host supremum.

Proof. Start with the consumer read. The only route to the bounded Cauchy evidence is the accepted carrier of Definition 6078.1.

Read M first to obtain the displayed Cauchy modulus, then S and R to expose the finite rational windows. The dyadic tolerance row T supplies the scale used by the tail comparison, and the bound ledger L supplies the displayed enclosure.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet for Real and Completion consumers. Because the carrier contains no coordinate for selected limits, quotient streams, host suprema, or ambient completeness, none of those objects can be imported by the consumer route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedCauchySequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedCauchySequence}^{\uparrow}$ packet is generated from a Cauchy modulus row, StreamName finite windows, RegSeqRat readback, a DyadicRatCore tolerance row, a dyadic bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6078.1, Definition 6078.2, and Definition 6078.3 seed the bounded Cauchy route from finite stream windows and dyadic tolerance to Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, host sequence equality, host suprema, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked Cauchy modulus admission, StreamName finite-window coverage, RegSeqRat readback, DyadicRatCore tolerance visibility, dyadic bound-ledger enclosure, transport stability, replay stability, and non-escape for BEDC.Derived.BoundedCauchySequenceUp.

Chapter 6079

A Concrete Naming Certificate for $\mathsf{CompactOscillationBarModulus}^{\uparrow}$

Following Bishop-style compact metric finite-net arguments, the $\mathsf{CompactOscillationBarModulus}^{\uparrow}$ packet realizes the compact-uniform-continuity route of chapter 9237 as a finite bar-modulus NameCert carrier. It reads compact metric finite nets from chapter 129, pointwise oscillation rows from chapter 130, dyadic tolerances from chapter 291, rational lower-bound folds from chapter 37, and the downstream uniform-modulus ledger of chapter 369. The packet records the bar-modulus handoff without importing open-cover compactness, semantic continuity, selected centers outside the finite bundle, or ambient completeness.

Definition 6079.1 (Compact fan-bar route)**.** *A* $\mathsf{CompactOscillationBarModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, F, D, R, B, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, carrying the bundled centers and located coverage histories inspected by the compact request.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise oscillation row, recording the local radius at each bundled center and the target oscillation estimate used there.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, exposing the dyadic scale of the requested oscillation bound and the source-radius cuts read by the local estimates.*
4. *R is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row, recording the positive finite minimum over the displayed local radius histories.*
5. *B is the compact bar row, the finite* $\mathsf{ProbeBundle}$ *recursion surface that orders the centers, local radii, dyadic cuts, and rational fold.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, exported only after K, F, D, R, B have been displayed.*
7. *H records componentwise* hsame *transport for the compact, oscillation, dyadic, rational-fold, bar, uniform-modulus, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through the compact net, pointwise oscillation rows, dyadic tolerance, rational lower-bound fold, compact bar, and uniform-modulus handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactOscillationBarModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOscillationBarModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, D, R, B, U, H, C, P, N$. It has no coordinate for host open-cover compactness, a semantic continuity theorem, quotient point equality, a choice-selected center outside the displayed bar, or an external modulus selector.

Lean4 ✓ `BEDC.Derived.CompactOscillationBarModulusUp.CompactOscillationBarModulusTasteGate`
`single carrier alignment`

Theorem 6079.2 (Compact fan-bar modulus extraction)**.** *For every accepted* $\mathsf{CompactOscillationBarModulus}^{\uparrow}$ *carrier*

$$O = (K, F, D, R, B, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactOscillationBarModulus}^{\uparrow}}$ *surface extracts a uniform-modulus row exactly through compact finite-net admission for K, pointwise oscillation admission for F, dyadic tolerance visibility for D, rational lower-bound fold exactness for R, finite bar recursion for B, downstream handoff for U, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Consequently every $\mathsf{UniformModulus}^{\uparrow}$ *consumer receives a tolerance-only precision row through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{CompactOscillationBarModulus}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow}.$$

Proof. Project the carrier of Definition 6079.1. The rows $K, F, D, R, B, U, H, C, P, N$ are the whole accepted packet, so every exported uniform-modulus read must pass through them.

The compact row K and the bar row B supply the finite ProbeBundle of centers. The pointwise oscillation row F attaches a local source radius and a target oscillation estimate to each displayed center.

The dyadic row D fixes the tolerance scale. The rational fold row R then records a positive lower bound over the finitely many local radius histories, producing a displayed precision history rather than an external selector.

The handoff row U receives only that folded precision and the visible oscillation estimates. Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite route.

Since the carrier has no coordinate for host open-cover compactness, semantic continuity, quotient point equality, selected centers outside the bar, or ambient completeness, the extracted uniform-modulus row cannot import those objects. □

Theorem 6079.3 (Compact oscillation bar consumer boundary)**.** *Every consumer of an accepted* $\mathsf{CompactOscillationBarModulus}^{\uparrow}$ *packet reads compact-uniform-continuity data as a finite oscillation bar. The consumer may inspect the compact finite net, pointwise oscillation rows, dyadic tolerance ledger, rational lower-bound fold, compact bar recursion, uniform-modulus handoff, transport, replay, provenance, and local naming rows, and nothing else.*

Proof. The consumer begins with the accepted carrier. By Definition 6079.1, the only analytic rows are K, F, D, R, B, U and the only structural rows are H, C, P, N.

Reading K and B exposes the finite bar. Reading F attaches local oscillation control to each center, while D and R convert the requested dyadic tolerance into a displayed lower-bound precision.

The row U is downstream of those data and is the only exported uniform-modulus coordinate. The structural rows do not add compactness, continuity, quotient, choice, or completeness objects; they only transport, replay, source, and name the same packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOscillationBarModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOscillationBarModulus}^{\uparrow}$ packet is generated from CompactMetric finite-net data, ContinuousMap pointwise oscillation rows, a DyadicRatCore tolerance row, a RatUp lower-bound fold, finite ProbeBundle bar recursion, a UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOscillationBarModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6079.1, Definition 6079.2, and Definition 6079.3 seed the compact oscillation bar route from finite compact nets and local oscillation rows to UniformModulusUp consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactOscillationBarModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host open-cover compactness, semantic continuity, quotient point equality, choice-selected centers outside the displayed bar, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact finite-net admission, pointwise oscillation admission, dyadic tolerance visibility, rational lower-bound fold exactness, finite bar recursion, uniform-modulus handoff, transport stability, replay stability, and non-escape for BEDC.Derived.CompactOscillationBarModulusUp.

Chapter 6080

A Concrete Naming Certificate for $\mathsf{EnrichedYoneda}^{\uparrow}$

Following Kelly's enriched category theory and Mac Lane's categorical account of representability, the $\mathsf{EnrichedYoneda}^{\uparrow}$ packet records the enriched functor-of-points surface as finite NameCert data. It sits over the category carrier of chapter 61, the ordinary functor and natural-transformation rows of chapter 62 and chapter 63, the enriched hom-object surface of chapter 182, and the monoidal tensor boundary of chapter 181. The packet names the finite route by which enriched representables, enriched naturality, and monoidal coherence can be replayed without importing a host enriched presheaf category, ambient ends, quotient functor categories, or external universality.

Definition 6080.1 (EnrichedYoneda seed carrier)**.** *An* $\mathsf{EnrichedYoneda}^{\uparrow}$ *seed carrier is a finite* BHist *packet*

$$Y = (C, V, O, H, F, S, U, Q, T, R, P, N)$$

with the following displayed rows:

1. *C is the consumed* $\mathsf{Cat}^{\uparrow}$ *object-and-hom boundary for the underlying ordinary category read by downstream categorical consumers;*
2. *V is the consumed* $\mathsf{EnrichedCat}^{\uparrow}$ *row, including the object boundary, enriched hom-object rows, identity rows, and enriched composition rows;*
3. *O records the chosen object row whose enriched representable is being named;*
4. *H is the enriched hom-object row assigning to each displayed object x the hom-object $V(x, O)$ in the consumed monoidal category;*
5. *F is the enriched functor-of-points row, read as the object-indexed assignment $x \mapsto V(x, O)$ together with its displayed action on enriched hom rows;*
6. *S records enriched naturality-square rows comparing the action of F against enriched composition in V;*
7. *U records monoidal-unit rows and the coherence rows needed to read identities, associators, left unitors, and right unitors through the consumed* $\mathsf{MonoidalCat}^{\uparrow}$ *boundary;*
8. *Q records componentwise* hsame *transport for the ordinary category, enriched category, chosen object, hom-object, functor-of-points, naturality, monoidal coherence, provenance, and local naming rows;*

9. *T records displayed* Cont *replay from the chosen object through enriched hom-object inspection, functor-of-points readback, naturality-square comparison, and monoidal coherence;*
10. *R is the finite readback ledger by which ordinary* $\mathsf{Functor}^{\uparrow}$ *and* $\mathsf{NatTrans}^{\uparrow}$ *consumers may read the enriched rows without receiving host functor-category equality;*
11. *P is the* Pkg *provenance over* $\mathsf{EnrichedYoneda}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{NatTrans}^{\uparrow}$, $\mathsf{EnrichedCat}^{\uparrow}$, $\mathsf{MonoidalCat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{EnrichedYoneda}^{\uparrow}}$ *row.*

The classifier relates two accepted packets exactly when these rows transport componentwise through Q and replay through the same displayed routes in T. It does not contain a coordinate for a host enriched presheaf category, external end calculus, quotient natural-transformation equality, global enriched embedding theorem, or ambient universal property.

Lean4 (definition) `BEDC.Derived.EnrichedYonedaUp.EnrichedYonedaUp`

Closure status for $\mathsf{NameCert}_{\mathsf{EnrichedYoneda}^{\uparrow}}$.

Constructive story: An $\mathsf{EnrichedYoneda}^{\uparrow}$ packet is generated from a consumed CategoryUp boundary, FunctorUp and NatTransUp consumer rows, an EnrichedCatUp hom-object surface, a MonoidalCatUp tensor-coherence boundary, a chosen object, enriched functor-of-points rows, naturality squares, componentwise transport, displayed replay, provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{EnrichedYoneda}^{\uparrow}}$, seed)

Scope closed: Definition 6080.1 seeds the finite enriched functor-of-points certificate over CategoryUp, FunctorUp, NatTransUp, EnrichedCatUp, MonoidalCatUp, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{EnrichedYoneda}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: The chapter does not close enriched Yoneda equivalence, enriched presheaf categories, end calculus, quotient functor-category equality, host universality, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, enriched hom-object exactness, functor-of-points readback, enriched naturality, monoidal coherence, transport replay, provenance, and non-escape for the same packet.

Chapter 6081

A Concrete Naming Certificate for $\mathsf{LocatedUpperDedekindReal}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedUpperDedekindReal}^{\uparrow}$ packet records the constructive cut-facing real boundary where an upper Dedekind observation is read with explicit located comparison data before a regular-Cauchy or real-seal consumer treats it as real evidence. It sits beside the $\mathsf{Real}^{\uparrow}$ completion surface of chapter 38, the rounded cut rows of chapter 436, the one-sided upper ledger of chapter 1447, the lower comparison ledger of chapter 1446, and the located real interface of **??**. It also points toward the representation comparisons of chapter 2346 and chapter 5908 without identifying their carriers.

Definition 6081.1 (Located upper Dedekind real carrier)**.** *A* $\mathsf{LocatedUpperDedekindReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, A, L, O, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DedekindCut}^{\uparrow}$ *row, read only as rounded lower-and-upper rational observation data;*
2. *A is the* $\mathsf{UpperReal}^{\uparrow}$ *row, recording the upper-side rational or dyadic observations that the consumer may inspect;*
3. *L is the* $\mathsf{LowerReal}^{\uparrow}$ *comparison row, used only to display lower-upper separation when a locatedness request asks for it;*
4. *O is the locatedness row: for each displayed rational interval $a < b$, it records either a lower-side observation below b or an upper-side observation above a inside the same finite history;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, A, L, O have been displayed;*
6. *H is componentwise* hsame *transport for the cut row, upper row, lower comparison row, locatedness row, Real seal, and structural rows;*
7. *C is the displayed* Cont *replay route for rereading the same cut-facing upper observations;*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedUpperDedekindReal}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedUpperDedekindReal}^{\uparrow}}$ *row.*

The carrier exports no quotient class of cuts, no selected representative, no trichotomy branch, no countable-choice selector, no Dedekind completeness theorem, and no completeness claim for $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ BEDC.Derived.LocatedUpperDedekindRealUp.TasteGate.LocatedUpperDedekindRealTasteGate
single carrier alignment

Theorem 6081.2 (Located upper Dedekind real NameCert obligations)**.** *For an accepted* LocatedUpperDedekindRe *carrier* $U = (D, A, L, O, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedUpperDedekindReal}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed* $\mathsf{DedekindCut}^{\uparrow}$ *row,* $\mathsf{UpperReal}^{\uparrow}$ *row,* $\mathsf{LowerReal}^{\uparrow}$ *comparison row, locatedness row,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*
2. *upper cut observation, stating that every upper-side read factors through* A *together with the upper side of* D*;*
3. *located comparison, stating that every requested rational interval* $a < b$ *is answered by the displayed row* O *together with the comparison row* L *and the upper row* A*;*
4. *Real-seal boundary, stating that a* $\mathsf{Real}^{\uparrow}$*-facing consumer reaches* E *only after the cut, upper, lower, and locatedness rows have been inspected;*
5. *representation restraint, stating that Cauchy-Dedekind bridge or equivalence consumers may cite this packet only as a finite cut-facing located upper surface.*

No obligation introduces quotient stream equality, quotient cut equality, selected representatives, trichotomy, countable choice, Dedekind completeness, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 6081.1. The displayed packet contains the cut row, upper row, lower comparison row, locatedness row, Real seal, and structural rows as finite BHist data.

The upper cut observation obligation reads D and A together. The cut row supplies rounded lower-and-upper rational observations, while the upper row exposes only the upper-side candidates and their finite comparison budgets.

The located comparison obligation is the role of O. For a displayed interval $a < b$, the packet answers through the same finite lower and upper rows, so a consumer receives located evidence without a trichotomy branch or an external order oracle.

The Real-seal boundary is E. Since E is downstream of D, A, L, O and is transported only by H and replayed only by C, a $\mathsf{Real}^{\uparrow}$-facing read cannot bypass the finite cut-facing route.

Finally the provenance row P names $\mathsf{LocatedReal}^{\uparrow}$ and the Cauchy-Dedekind comparison siblings only as dependency anchors. The packet therefore supports later bridge comparison while adding no quotient equality, selected representative, countable-choice selector, Dedekind completeness theorem, or completeness claim for $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUpperDedekindReal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedUpperDedekindReal}^{\uparrow}$ packet is generated from a DedekindCut row, an UpperReal row, a LowerReal comparison row, a locatedness row, a RealUp seal, componentwise transports, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedUpperDedekindReal}^{\uparrow}}$, seed)

Scope closed: Definition 6081.1 and Definition 6081.2 seed the finite cut-facing located upper-real surface for Real-completion and Cauchy-Dedekind comparison consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedUpperDedekindReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Dedekind completeness, quotient classes, trichotomy, countable choice, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires carrier admission, upper cut observation, located comparison, Real-seal boundary, and representation restraint for the displayed packet, with future Lean work under BEDC.Derived.LocatedUpperDedekindRealUp.

Chapter 6082

A Concrete Naming Certificate for $\mathsf{LocatedLowerDedekindReal}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedLowerDedekindReal}^{\uparrow}$ packet records the constructive lower-cut real boundary where a lower Dedekind observation is read with explicit located comparison data before a regular-Cauchy or real-seal consumer treats it as real evidence. It is the lower-side sibling of chapter 6081; it also depends on the dyadic arithmetic ledger of chapter 291, the finite observation windows of chapter 126, the regular rational handoff surface of chapter 301, and the terminal real-name seal of chapter 38. The packet displays a finite L10 lower-cut interface; it does not assume quotient cuts, selected representatives, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6082.1 (Located lower Dedekind real carrier)**.** *A* $\mathsf{LocatedLowerDedekindReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, B, U, O, Y, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DedekindCut}^{\uparrow}$ *row, read only as rounded lower-and-upper rational observation data;*
2. *B is the* $\mathsf{LowerReal}^{\uparrow}$ *row, recording the lower-side rational or dyadic observations that the consumer may inspect;*
3. *U is the* $\mathsf{UpperReal}^{\uparrow}$ *comparison row, used only to display lower-upper separation when a locatedness request asks for it;*
4. *O is the locatedness row: for each displayed rational interval $a < b$, it records either a lower-side observation below b or an upper-side observation above a inside the same finite history;*
5. *Y is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row carrying the dyadic comparison budgets used when lower observations are sampled at finite precision;*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row recording which lower-cut observations are inspected before any sequence readback occurs;*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row attached to the same windows and dyadic tolerances;*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, B, U, O, Y, W, R have been displayed;*
9. *H is componentwise* hsame *transport for the cut row, lower row, upper comparison row, locatedness row, dyadic budget, stream window, regular handoff, Real seal, and structural rows;*

10. *C is the displayed* Cont *replay route for rereading the same lower-cut observations;*

11. *P is the* Pkg *provenance over* $\mathsf{LocatedLowerDedekindReal}^{\uparrow}$, $\mathsf{LocatedUpperDedekindReal}^{\uparrow}$, $\mathsf{DedekindCut}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedLowerDedekindReal}^{\uparrow}}$ *row.*

The carrier exports no quotient class of cuts, no selected cut representative, no order trichotomy branch, no countable-choice selector, no Dedekind completeness theorem, and no completeness claim for $\mathsf{Real}^{\uparrow}$*.*

Theorem 6082.2 (Located lower Dedekind real NameCert obligations)**.** *For an accepted* LocatedLowerDedekindRea *carrier $L = (D, B, U, O, Y, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedLowerDedekindReal}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed* $\mathsf{DedekindCut}^{\uparrow}$ *row,* $\mathsf{LowerReal}^{\uparrow}$ *row,* $\mathsf{UpperReal}^{\uparrow}$ *comparison row, locatedness row, dyadic budget, stream windows, regular handoff,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*

2. *lower cut observation, stating that every lower-side read factors through B together with the lower side of D;*

3. *located comparison, stating that every requested rational interval $a < b$ is answered by the displayed row O together with the lower row B and comparison row U;*

4. *finite sampling discipline, stating that every lower observation used for a sequence handoff passes through the dyadic budget Y and the stream window row W;*

5. *Real-seal boundary, stating that a* $\mathsf{Real}^{\uparrow}$*-facing consumer reaches E only after the cut, lower, upper-comparison, locatedness, dyadic, stream-window, and regular-handoff rows have been inspected;*

6. *representation restraint, stating that the lower packet may be paired with the upper packet only as a finite cut-facing comparison surface.*

No obligation introduces quotient stream equality, quotient cut equality, selected representatives, trichotomy, countable choice, Dedekind completeness, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 6082.1. The displayed packet contains the cut row, lower row, upper comparison row, locatedness row, dyadic budget, stream windows, regular handoff, Real seal, and structural rows as finite BHist data.

The lower cut observation obligation reads D and B together. The cut row supplies rounded lower-and-upper rational observations, while the lower row exposes only the lower-side candidates and their finite comparison budgets.

The located comparison obligation is the role of O. For a displayed interval $a < b$, the packet answers through the same finite lower and upper rows, so a consumer receives located evidence without a trichotomy branch or an external order oracle.

The finite sampling discipline is the route through Y and W. A lower observation that will feed a regular sequence is first tied to dyadic precision data and then to a displayed finite window, so the handoff cannot be read from an unbounded stream or a quotient cut.

The Real-seal boundary is E. Since E is downstream of D, B, U, O, Y, W, R and is transported only by H and replayed only by C, a $\mathsf{Real}^{\uparrow}$-facing read cannot bypass the finite lower-cut route.

Finally the provenance row P names $\mathsf{LocatedUpperDedekindReal}^{\uparrow}$ only as the sibling comparison surface. The packet therefore supports later Cauchy-Dedekind comparison while adding no quotient equality, selected representative, countable-choice selector, Dedekind completeness theorem, or completeness claim for $\mathsf{Real}^{\uparrow}$. □

Theorem 6082.3 (Located lower Dedekind real regular-sequence handoff)**.** *Let $L = (D, B, U, O, Y, W, R, E, H, C, P$ be an accepted* $\mathsf{LocatedLowerDedekindReal}^{\uparrow}$ *carrier. Every downstream* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer read of the handoff row R factors through the finite route*

$$D, B, U, O, Y, W, R$$

inside the same BHist *packet, and the terminal seal E may be read only after that route has been displayed. Consequently the handoff exposes lower-cut sampling data, dyadic precision budgets, and finite stream windows, but it exposes no quotient cut, no selected real representative, no ambient completeness principle, and no order-trichotomy decision.*

Proof. Begin with the NameCert obligations of Definition 6082.2. They force every lower-side observation to read the lower row B together with the cut row D, and they force every located comparison to use the displayed row O rather than an external order oracle.

Next use the finite sampling discipline in the same obligation list. Before R can be consumed as a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, the dyadic budget Y and the finite window row W must already have been displayed. Thus the sequence-facing read is tied to finite lower-cut observations rather than to an unbounded stream.

Finally read the Real-seal boundary. The seal row E is downstream of D, B, U, O, Y, W, R, and the structural rows H, C, P, N only transport, replay, name, and package the same displayed route. The listed quotient, representative, completeness, and trichotomy readings are outside the carrier inventory and cannot be consumed here. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedLowerDedekindReal}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedLowerDedekindReal}^{\uparrow}$ packet is generated from a DedekindCut row, a LowerReal row, an UpperReal comparison row, a locatedness row, a DyadicRatCore budget, StreamName windows, a RegSeqRat handoff, a RealUp seal, componentwise transports, continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedLowerDedekindReal}^{\uparrow}}$, seed)

Scope closed: Definition 6082.1, Definition 6082.2, and Definition 6082.3 seed the finite lower-cut surface for regular-sequence and real-completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedLowerDedekindReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Dedekind completeness, quotient classes, trichotomy, countable choice, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, lower cut observation, located comparison, finite sampling discipline, Real-seal boundary, and representation restraint for the displayed packet, with future Lean work under BEDC.Derived.LocatedLowerDedekindRealUp.

Chapter 6083

A Concrete Naming Certificate for $\mathsf{DilworthDecomposition}^{\uparrow}$

Following Dilworth, the $\mathsf{DilworthDecomposition}^{\uparrow}$ packet records the finite-order decomposition theorem as a BEDC NameCert carrier: a finite $\mathsf{Poset}^{\uparrow}$ row, an antichain-width witness, a chain-cover ledger, and a matching or network-flow dual certificate are read as one finite certificate surface. It is anchored in the partial-order carrier of chapter 53, the bipartite matching surface of chapter 234, and the max-flow/min-cut route of chapter 233. The packet exports only displayed finite rows, not a host poset, not quotient order equality, and not a selected global decomposition outside the ledger.

Definition 6083.1 (Dilworth decomposition carrier)**.** *A* $\mathsf{DilworthDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (O, A, K, M, F, H, C, P, N)$$

with the following displayed rows:

1. *O is the finite* $\mathsf{Poset}^{\uparrow}$ *order row, including the carried elements, the displayed order comparison ledger, and the classifier used to compare repeated element reads.*
2. *A is the antichain-width witness row, recording a displayed antichain spine and a finite proof ledger that no larger displayed antichain is admitted by the same* $\mathsf{Poset}^{\uparrow}$ *order rows.*
3. *K is the chain-cover row, recording a finite list of chains whose union covers the carried elements and whose internal comparisons are justified by O.*
4. *M is the* $\mathsf{Matching}^{\uparrow}$ *dual-certificate row for the standard bipartite split graph of the finite order, reading augmenting-path and cover data only through the matching packet.*
5. *F is the optional* $\mathsf{NetworkFlow}^{\uparrow}$ *dual-certificate row for the same split graph, exposing the max-flow/min-cut handoff as a second route to the same width-cover equality.*
6. *H is componentwise* hsame *transport for the order row, antichain row, chain-cover row, matching or flow certificate rows, replay, provenance, and local naming.*
7. *C is the displayed* Cont *replay route*

$$O, A, K, M, F \longmapsto H \longmapsto P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{DilworthDecomposition}^{\uparrow}$*,* $\mathsf{Poset}^{\uparrow}$*,* $\mathsf{Matching}^{\uparrow}$*,* $\mathsf{NetworkFlow}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{DilworthDecomposition}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient host partial order, quotient order equality, an unlisted chain cover, a selected maximum antichain outside A, countable choice, or an infinite decomposition principle.

Lean4 ✓ `BEDC.Derived.DilworthDecompositionUp.DilworthDecompositionTasteGate single carrier alignment`

Theorem 6083.2 (Dilworth decomposition NameCert obligations)**.** *For an accepted* $\mathsf{DilworthDecomposition}^{\uparrow}$ *carrier $D = (O, A, K, M, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DilworthDecomposition}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the finite* $\mathsf{Poset}^{\uparrow}$ *order row, antichain-width witness row, chain-cover row, dual certificate rows, transport, replay, provenance, and local naming;*
2. *order exposure, requiring every chain, antichain, matching, and flow read to use the same displayed O row and its classifier;*
3. *antichain-width exposure, requiring width claims to be read through A and not through an external cardinality oracle;*
4. *chain-cover exposure, requiring every cover claim to be read through the listed chain ledger K;*
5. *dual-certificate handoff, requiring the equality between width and minimum chain cover size to factor through the* $\mathsf{Matching}^{\uparrow}$ *row M or the* $\mathsf{NetworkFlow}^{\uparrow}$ *row F;*
6. *structural replay, requiring* hsame, Cont, Pkg, *and local* NameCert *rows to preserve the same finite decomposition route;*
7. *nonescape, excluding host posets, quotient order equality, unlisted chain covers, selected maximum antichains outside the carrier, countable choice, and infinite-order decomposition data.*

No $\mathsf{DilworthDecomposition}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Project the carrier of Definition 6083.1. The finite order is O, the width witness is A, the chain-cover ledger is K, and the dual certificate rows are M and F.

The order exposure obligation is rowwise. Since the antichain, chain-cover, matching, and flow rows are all carried over O, a consumer cannot combine the antichain from one order with the chain cover or split-graph certificate from another.

The width and cover obligations are the two visible halves of the decomposition. The row A supplies the displayed antichain-width witness, while K supplies the displayed chain cover and its coverage ledger.

The dual-certificate handoff is the finite proof route. A matching-facing consumer reads M through chapter 234; a flow-facing consumer reads F through chapter 233. Both routes are tied back to the same order row O and the same width and cover rows A, K.

Finally H, C, P, N transport, replay, record provenance for, and name exactly this finite packet. Since the carrier fields are exhausted by $O, A, K, M, F, H, C, P, N$, the excluded host order, quotient equality, unlisted cover, selected antichain, choice, and infinite decomposition principles have no row in the certificate. □

Theorem 6083.3 (Dilworth chain-antichain handoff)**.** *Let $D = (O, A, K, M, F, H, C, P, N)$ be an accepted* $\mathsf{DilworthDecomposition}^{\uparrow}$ *carrier. Every chain-cover or antichain-width consumer exported by D factors through the displayed route*

$$\mathsf{Poset}^{\uparrow},\ \mathsf{Matching}^{\uparrow},\ \mathsf{NetworkFlow}^{\uparrow}$$

by reading $O, A, K, M, F, H, C, P, N$ in order. The route identifies the width row and the chain-cover row only through the displayed matching or network-flow dual certificate, and it exports no host summability of sizes, quotient order equality, selected external cover, countable choice, or infinite poset theorem.

Proof. First read the finite order row. The $\mathsf{Poset}^{\uparrow}$ packet supplies the carried elements, comparison ledger, and classifier needed before either an antichain or a chain can be inspected.

Next read the two decomposition rows. The antichain row A records the width witness, and the chain-cover row K records the finite cover together with its internal comparison checks.

The equality route is then supplied by the dual certificate. The matching row M exposes the bipartite split-graph handoff, while the network-flow row F exposes the equivalent cut route. A consumer may use either displayed certificate, but both remain downstream of O, A, K.

Transport by H, replay by C, and packaging by P, N preserve this same finite route. Therefore the public handoff is the listed BEDC packet and not an ambient Dilworth theorem over a host poset. □

Closure status for $\mathsf{NameCert}_{\mathsf{DilworthDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{DilworthDecomposition}^{\uparrow}$ packet is generated from a finite Poset row, an antichain-width witness, a chain-cover ledger, Matching and NetworkFlow dual-certificate rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DilworthDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6083.1, Definition 6083.2, and Definition 6083.3 seed the finite chain-antichain decomposition certificate over Poset, Matching, and NetworkFlow rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DilworthDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host partial orders, quotient order equality, selected external chain covers, countable choice, infinite posets, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, order exposure, antichain-width exposure, chain-cover exposure, dual-certificate handoff, transport, replay, provenance, and local naming for BEDC.Derived.DilworthDecompositionUp.

$\mathsf{PointwiseStreamName}^{\uparrow}$ routes the $\mathsf{StreamName}^{\uparrow}$ finite-window surface of chapter 126 into the $\mathsf{Real}^{\uparrow}$-facing seal of chapter 38 through the child file below.

Chapter 6084

A Concrete Naming Certificate for $\mathsf{PointwiseStreamName}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{PointwiseStreamName}^{\uparrow}$ packet records the traditional countable pointwise name as finite BEDC NameCert data. It is the countable-name neighbour of the $\mathsf{StreamName}^{\uparrow}$ finite-window surface of chapter 126; its point values are read through the dyadic ledger of chapter 291, the regular-rational gateway of chapter 301, and the terminal real-name seal of chapter 38.

Definition 6084.1 (Pointwise stream name carrier)**.** *A* $\mathsf{PointwiseStreamName}^{\uparrow}$ *carrier is a finite NameCert packet*

$$Q = (S, I, D, R, E, H, C, P, N)$$

with the following displayed coordinates:

1. *S is the certified* $\mathsf{StreamName}^{\uparrow}$ *source row.*
2. *I is the finite ledger of requested point indices and observation windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for the inspected point values.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row generated from the pointwise observations.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after the regular-rational route has been displayed.*
6. *H stores componentwise* hsame *transport for sources, indices, windows, dyadic ledgers, readbacks, seals, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a consumer request through S, I, D, R, E, H, P, N.*
8. *P is* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PointwiseStreamName}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by these coordinates. It contains no quotient stream equality, selected limit, host real equality, countable-choice row, or $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Theorem 6084.2 (Pointwise stream name finite read)**.** *Every accepted* $\mathsf{PointwiseStreamName}^{\uparrow}$ *read factors through the certified source S, requested index ledger I, dyadic tolerance row D, regular-rational readback R, and terminal* $\mathsf{Real}^{\uparrow}$ *seal E before any completion-facing consumer may inspect it. The route is a pointwise countable-name source for* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, not a quotient stream, selected limit, host equality, or completeness datum.*

Proof. Project the carrier of Definition 6084.1. The request has only the certified stream source, index ledger, dyadic row, regular readback, Real seal, transport, replay, provenance, and local naming coordinates available.

The read begins at S and I. A consumer must open the finite BHist windows for the requested point indices before it can inspect dyadic or regular-rational data.

The dyadic, regular, and Real rows are then consumed in order. Since no coordinate stores quotient equality, a selected limit, host equality, countable choice, or Real completeness, the pointwise read cannot export those data. □

Theorem 6084.3 (Pointwise stream name transport stability)**.** *Let Q_0 and Q_1 be accepted* $\mathsf{PointwiseStreamName}^{\uparrow}$ *carriers. If a displayed* hsame *route transports their certified source rows, requested index ledgers, dyadic tolerance rows, regular-rational readbacks, Real seals, replay rows, provenance rows, and local naming rows componentwise, then every pointwise read accepted for Q_0 is accepted for Q_1 with the transported finite route.*

Proof. Read the componentwise transport coordinate H in the two carriers. It identifies only the displayed StreamName source rows, requested windows, dyadic ledgers, regular readbacks, Real seals, replay rows, provenance rows, and local naming rows.

Replay the consumer request through C. The replay preserves the order of the pointwise route, so a transported read still reaches $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ only after the finite StreamName source and requested windows have been displayed.

The carrier inventory supplies the exclusion. Quotient streams, selected representatives, host real equality, countable-choice schedules, and completeness principles are not coordinates of either carrier. □

Theorem 6084.4 (Pointwise stream index stability)**.** *Let Q_0 and Q_1 be accepted* $\mathsf{PointwiseStreamName}^{\uparrow}$ *carriers. Suppose their certified* $\mathsf{StreamName}^{\uparrow}$ *source rows and requested index ledgers are componentwise* hsame*, and suppose the displayed transport also preserves the dyadic tolerance rows, regular-rational readbacks, Real seals, replay rows, provenance rows, and local naming rows. Then every requested finite* $\mathsf{StreamName}^{\uparrow}$ *window in Q_0 reaches the same ordered route through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *in Q_1.*

Proof. Project the two carriers by Definition 6084.1. The only index-facing coordinates are the certified source row S and finite requested-index ledger I.

Apply transport stability from Definition 6084.3. The componentwise hsame route carries S, I, D, R, E, C, P, N together, so the accepted pointwise read is replayed with the same source windows and requested indices.

Now use finite read from Definition 6084.2. It forces every requested window to pass first through the StreamName source and index ledger, then through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and finally the $\mathsf{Real}^{\uparrow}$ seal. Since transport preserves those rows in order, the requested-index route is stable. □

Theorem 6084.5 (Pointwise stream name L10 gateway)**.** *The* $\mathsf{PointwiseStreamName}^{\uparrow}$ *packet is consumed by the L10 Real and Completion route only as a finite pointwise source: it sends certified windows to* $\mathsf{StreamName}^{\uparrow}$*, dyadic tolerance rows to* $\mathsf{DyadicRatCore}^{\uparrow}$*, regular readback rows to* $\mathsf{RegSeqRat}^{\uparrow}$*, and terminal seal rows to* $\mathsf{Real}^{\uparrow}$*. The gateway does not assert equality of quotient streams, choose a limiting real, identify host real objects, or prove* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Combine Definition 6084.2 with the transport stability of Definition 6084.3. These two rows force every L10 read to pass through the same displayed source, index, dyadic, regular, Real, transport, replay, provenance, and naming coordinates.

The sibling chapters named in the opening paragraph supply the downstream rows. $\mathsf{StreamName}^{\uparrow}$ supplies finite windows, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies tolerance data, $\mathsf{RegSeqRat}^{\uparrow}$ supplies regular readback, and $\mathsf{Real}^{\uparrow}$ supplies the terminal seal.

Since the carrier lacks quotient equality, selected limits, host equality, choice, and completeness coordinates, the L10 gateway exports only the finite pointwise NameCert route. □

Theorem 6084.6 (Pointwise stream name L10 index determinacy)**.** *Let Q_0 and Q_1 be accepted* $\mathsf{PointwiseStreamName}^{\uparrow}$ *carriers. If two L10 reads agree on the displayed* $\mathsf{StreamName}^{\uparrow}$ *source row, the requested index ledger, and the finite window schedule, then both reads route through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row before any consumer can inspect Real-facing data.*

Proof. Begin with finite read from Definition 6084.2. It forces each L10 read to expose the source row, requested index ledger, and finite windows before dyadic, regular-rational, or Real-facing data are available.

Apply transport stability from Definition 6084.3. Agreement on the displayed source and window route transports the dyadic tolerance row, readback row, seal row, replay row, provenance row, and local naming row componentwise.

Use index stability from Definition 6084.4. The shared requested index and finite window schedule determine the ordered route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally apply the L10 gateway of Definition 6084.5. A Real or Completion consumer can inspect only the route already determined by the source, index, window, dyadic, readback, seal, transport, replay, provenance, and naming rows. □

Theorem 6084.7 (Pointwise stream vision transport)**.** *Every vision-facing* $\mathsf{PointwiseStreamName}^{\uparrow}$ *read consumed by the L10 Real and Completion route must pass through the certified* $\mathsf{StreamName}^{\uparrow}$ *source row, requested index ledger, finite window schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row already exposed by the pointwise finite-read, transport-stability, and L10 index-determinacy routes. The transported read exports no quotient stream equality, selected limit, host real equality, countable-choice schedule, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with pointwise finite read, Definition 6084.2. It forces the vision-facing read to expose the certified source row, requested index ledger, dyadic tolerance row, regular-rational readback, and terminal $\mathsf{Real}^{\uparrow}$ seal before any Real or Completion consumer inspects the pointwise name.

Apply transport stability from Definition 6084.3. Componentwise hsame carries the source, index, dyadic, readback, seal, replay, provenance, and local naming rows together, so the transported vision read remains the same finite NameCert route.

Use L10 index determinacy, Definition 6084.6. Agreement on the displayed source, requested index ledger, and finite window schedule determines the ordered route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any Real-facing data are available.

The exclusions follow from the same carrier inventory. No row stores quotient stream equality, selected limits, host real equality, countable-choice schedules, or $\mathsf{Real}^{\uparrow}$ completeness, so the vision-facing transport cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{PointwiseStreamName}^{\uparrow}}$.

Constructive story: A $\mathsf{PointwiseStreamName}^{\uparrow}$ packet is generated from a certified StreamName source, requested point windows, a dyadic tolerance ledger, regular-rational readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointwiseStreamName}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6084.1, Definition 6084.2, Definition 6084.3, and Definition 6084.5 seed the finite pointwise source route for StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointwiseStreamName}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host real equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, pointwise finite-read exposure, transport stability, L10 gateway coverage, and non-escape for BEDC.Derived.PointwiseStreamNameUp.

Chapter 6085

A Concrete Naming Certificate for $\mathsf{MetacicCandidateSnHandoff}^{\uparrow}$

The $\mathsf{MetacicCandidateSnHandoff}^{\uparrow}$ packet realizes the normalization audit map of chapter 9383 as a finite candidate-mediated strong-normalization handoff. It sits beside the finite-window diamond envelope of chapter 6063, the subject-reduction obstruction of chapter 731, the confluence audit packet of chapter 735, and the typed conversion residual frontier of chapter 6069. The packet records the supplied candidate row, closed typed term row, no-infinite-reduction projection, obstruction handoff, confluence boundary, transport, replay, provenance, and local naming data without claiming unconditional strong normalization for all closed MetaCIC terms.

Definition 6085.1 (MetaCIC candidate SN handoff carrier)**.** *A* $\mathsf{MetacicCandidateSnHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, A, S, N, O, D, F, H, C, P, L)$$

with the following displayed coordinates:

1. *T is the closed typed MetaCIC term row.*
2. *A is the candidate or candidate-set membership row supplied to the SN projection.*
3. *S is the candidate-mediated strong-normalization projection row.*
4. *N is the no-infinite-reduction row obtained from the same candidate evidence.*
5. *O is the subject-reduction obstruction handoff row.*
6. *D is the finite-window diamond-envelope row.*
7. *F is the confluence audit and typed conversion frontier row.*
8. *H records componentwise* hsame *transport for term, candidate, SN, no-infinite-reduction, obstruction, confluence, frontier, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a normalization-audit query through $T, A, S, N, O, D, F, H, P, L$.*
10. *P is* Pkg *provenance over the normalization audit map, the finite-window diamond envelope, the subject-reduction obstruction, the confluence audit packet, the typed conversion residual frontier,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
11. *L is the local* $\mathsf{NameCert}_{\mathsf{MetacicCandidateSnHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It contains no coordinate for candidate-free closed-term SN, unconditional subject reduction, unrestricted confluence, full substitution compatibility, typed conversion decidability, or closed consistency.

Theorem 6085.2 (MetaCIC candidate SN handoff obligations)**.** *For every accepted* $\mathsf{MetacicCandidateSnHandoff}^{\uparrow}$ *carrier* $K = (T, A, S, N, O, D, F, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{MetacicCandidateSnHandoff}^{\uparrow}}$ *surface consists exactly of closed typed term exposure through* T*, candidate evidence through* A*, SN projection through* S*, no-infinite-reduction projection through* N*, subject-reduction obstruction through* O*, finite-window diamond-envelope handoff through* D*, confluence and typed-conversion frontier routing through* F*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* L*.*

Proof. Project the carrier of Definition 6085.1. Each public row is displayed as one finite coordinate, and the SN row S is attached to the candidate row A rather than to the closed term row T alone.

Read the no-infinite-reduction row from the same candidate evidence. This keeps the termination consequence on the candidate-mediated route named by chapter 9383.

The remaining rows route neighboring audit consumers. The obstruction row O points to chapter 731, the diamond row D points to chapter 6063, and the frontier row F points to chapter 735 and chapter 6069. Since no row stores candidate-free SN, unconditional subject reduction, unrestricted confluence, full substitution compatibility, typed conversion decidability, or closed consistency, the NameCert surface is exhausted by the displayed packet. □

Theorem 6085.3 (MetaCIC candidate SN nonescape)**.** *Every normalization-audit read of an accepted* $\mathsf{MetacicCandidateSnHandoff}^{\uparrow}$ *packet must pass through the supplied candidate row* A *before it may cite the strong-normalization row* S *or the no-infinite-reduction row* N*. The handoff may route that finite evidence to the subject-reduction obstruction, finite-window diamond envelope, confluence audit packet, and typed conversion residual frontier, but it does not promote the evidence to candidate-free strong normalization, closed subject reduction, unrestricted confluence, full substitution compatibility, typed conversion decidability, or closed consistency.*

Proof. Start with the carrier rows T, A, S, N. The closed typed term row T is visible, but the termination rows S and N are displayed as consequences of A.

Use componentwise transport H and replay C to move the same evidence through a consumer request. Transport preserves the attachment of S and N to A, so a replayed request cannot drop the candidate row.

Finally inspect the sibling routes O, D, F. They hand the finite candidate-mediated evidence to the subject-reduction, diamond-envelope, confluence, and typed-conversion boundaries as audit data only. Those siblings are boundary packets, so the handoff exports no candidate-free SN theorem, no unconditional subject-reduction theorem, no unrestricted confluence theorem, no full substitution-compatibility theorem, no typed conversion decider, and no closed-consistency endpoint. □

Theorem 6085.4 (MetaCIC normalization audit map realization)**.** *The* $\mathsf{MetacicCandidateSnHandoff}^{\uparrow}$ *packet is the finite NameCert realization of the candidate-mediated branch of chapter 9383: it packages exactly the closed typed term, supplied candidate evidence, SN projection, no-infinite-reduction projection, subject-reduction obstruction handoff, finite-window diamond envelope, confluence audit boundary, typed conversion residual frontier, transport, replay, provenance, and local naming rows that a normalization-audit consumer may inspect.*

Proof. Apply Definition 6085.2. It lists every carrier row and identifies the candidate row as the required source of the SN and no-infinite-reduction projections.

Apply Definition 6085.3. It prevents a consumer from erasing the candidate evidence or replacing the boundary siblings by unconditional subject-reduction, confluence, substitution, typed-conversion, or consistency theorems.

Thus the vision label is realized by finite NameCert data: the handoff names the candidate-mediated SN route and the adjacent audit boundaries, while refusing the unconditional all-closed-terms reading. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicCandidateSnHandoff}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicCandidateSnHandoff}^{\uparrow}$ packet is generated from a closed typed MetaCIC term row, candidate evidence row, SN projection, no-infinite-reduction projection, subject-reduction obstruction handoff, diamond-envelope row, confluence and typed-conversion frontier row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicCandidateSnHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6085.1, Definition 6085.2, Definition 6085.3, and Definition 6085.4 seed the finite candidate-mediated SN handoff for the normalization audit map and its subject-reduction, confluence, diamond-envelope, and typed-conversion boundaries.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicCandidateSnHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close candidate-free strong normalization, unconditional subject reduction, unrestricted confluence, full substitution compatibility, typed conversion decidability, closed consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate-mediated SN projection, no-infinite-reduction projection, sibling-boundary handoff, non-escape, provenance, and local naming for BEDC.MetaCIC.closed_typed_term_sn_from_c and BEDC.Derived.MetacicCandidateSnHandoffUp.

Chapter 6086

A Concrete Naming Certificate for $\mathsf{CauchySeparatedReflection}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy presentations, the $\mathsf{CauchySeparatedReflection}^{\uparrow}$ packet records the finite separated-reflection surface needed before regular Cauchy names are consumed as separated real data. It sits over the precompletion source of chapter 1846, the regular rational readback of chapter 301, the metric source of chapter 57, the separated-reflection boundary of chapter 4151, and the terminal real-name seal of chapter 38. The packet is a finite NameCert route from Cauchy precompletion data to separated real reads; it is not quotient representative data, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6086.1 (Cauchy separated-reflection carrier)**.** *A* $\mathsf{CauchySeparatedReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, R, M, Z, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{CauchyPrecompletion}^{\uparrow}$ *source row, carrying the finite Cauchy presentation, precompletion admission, and tolerance requests visible before reflection.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the same Cauchy windows and tolerance ledger.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *source row through which the distance comparisons used by the reflection request are read.*
4. *Z is the* $\mathsf{SeparatedReflection}^{\uparrow}$ *row, recording the zero-distance classifier boundary before any separated real read is public.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after A, R, M, Z have been displayed.*
6. *H records componentwise* hsame *transport for the precompletion source, regular readback, metric source, separated-reflection boundary, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$\mathsf{CauchyPrecompletion}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{SeparatedReflection}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

8. *P is the* Pkg *provenance over* $\mathsf{CauchySeparatedReflection}^{\uparrow}$, $\mathsf{CauchyPrecompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparatedReflection}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchySeparatedReflection}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $A, R, M, Z, E, H, C, P, N$. It has no coordinate for quotient representatives, countable choice, host equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchySeparatedReflectionUp.CauchySeparatedReflectionTasteGate single carrier alignment`

Theorem 6086.2 (Cauchy separated-reflection classifier stability)**.** *For every accepted* $\mathsf{CauchySeparatedReflection}^{\uparrow}$ *carrier $S = (A, R, M, Z, E, H, C, P, N)$, classifier transport along the displayed separated-reflection route preserves the finite Cauchy-to-real surface. A consumer may read the separated* $\mathsf{Real}^{\uparrow}$ *boundary only after the* $\mathsf{CauchyPrecompletion}^{\uparrow}$ *source A,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{Met}^{\uparrow}$ *distance row M,* $\mathsf{SeparatedReflection}^{\uparrow}$ *classifier row Z, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N have all been exposed.*

Proof. Project the carrier of Definition 6086.1. The visible data are exactly $A, R, M, Z, E, H, C, P, N$, so every reflected Cauchy read starts from the displayed precompletion source and regular rational readback.

The separated boundary is then read through M and Z. The metric row supplies the distance comparisons used by the zero-distance classifier, while the separated-reflection row records the only route by which indistinguishable Cauchy data can reach a separated consumer.

Transport and replay preserve this same route. The row H compares the source, readback, metric, reflection, and real-seal rows componentwise, and C repeats the path from Cauchy precompletion data through separated reflection to the $\mathsf{Real}^{\uparrow}$ seal.

Because quotient representatives, countable choice, host equality, selected limits, and ambient real completeness have no carrier coordinate, classifier stability is exhausted by the displayed rows. No consumer can read a separated real boundary outside $A, R, M, Z, E, H, C, P, N$. □

Falsifiable prediction: Every accepted $\mathsf{CauchySeparatedReflection}^{\uparrow}$ consumer that reaches a separated $\mathsf{Real}^{\uparrow}$ read while omitting the CauchyPrecompletion source, RegSeqRat readback, MetricSpace distance row, SeparatedReflection classifier row, hsame transport, Cont replay, Pkg provenance, or local NameCert row refutes the packet.

Independence witness: cauchyprecompletion, regseqrat, metricspace, separated-reflection, real: $\mathsf{CauchySeparatedReflection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the Cauchy source, regular readback, metric source, separated-reflection boundary, real seal, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySeparatedReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySeparatedReflection}^{\uparrow}$ packet is generated from a CauchyPrecompletion source row, RegSeqRat readback, MetricSpace distance row, SeparatedReflection classifier boundary, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySeparatedReflection}^{\uparrow}}$, seed)

Scope closed: Definition 6086.1 and Definition 6086.2 seed the finite separated-reflection route from Cauchy presentation data to separated Real reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySeparatedReflection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient representatives, countable choice, host equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular readback exactness, metric-source exposure, separated-reflection stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchySeparatedRe

Chapter 6087

A Concrete Naming Certificate for FiniteApproximateFixedPoint$^{\uparrow}$

Following Brouwer, Schauder, and Bishop–Bridges finite approximation methods, the FiniteApproximateFixedPoint$^{\uparrow}$ packet records an approximate fixed-point witness as finite mesh, radius, and displacement data before any host fixed point is selected. It sits beside the Brouwer surface of chapter 2030, the Schauder surface of chapter 1923, the compact-metric surface of chapter 129, the finite-net carrier of chapter 1767, the metric-ball route of chapter 1450, and the real-name seal of chapter 38. The packet exposes the finite approximation data consumed by fixed-point arguments; it is not a host fixed-point selector, quotient equality on points, open-cover compactness theorem, or ambient completeness principle.

Definition 6087.1 (Finite approximate fixed-point carrier)**.** *A* FiniteApproximateFixedPoint$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, F, E, B, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row naming the compact metric object on which the approximation is inspected.*
2. *F is the map row, read only as a displayed continuous or uniformly controlled self-route over the same compact metric source.*
3. *E is the* FiniteEpsilonNet$^{\uparrow}$ *row listing the finite mesh centers and the mesh radius requested by the approximation.*
4. *B is the* MetricBall$^{\uparrow}$ *coverage row tying each inspected point to one displayed mesh ball.*
5. *D is the displacement ledger recording the finite comparisons between each mesh center and its image under F.*
6. *R is the* Real$^{\uparrow}$ *radius and displacement seal row used for the numerical tolerance comparisons.*
7. *S is the approximate fixed-point handoff row asserting that an accepted mesh point meets the displayed displacement tolerance.*
8. *H records componentwise* hsame *transport for the compact source, self-map, finite net, ball coverage, displacement ledger, real seal, handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a fixed-point request through $K, F, E, B, D, R, S, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteApproximateFixedPoint}^{\uparrow}$, $\mathsf{BrouwerFixedPoint}^{\uparrow}$, $\mathsf{SchauderFixedPoint}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteApproximateFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, E, B, D, R, S, H, C, P, N$. It has no coordinate for a selected fixed point, quotient point equality, arbitrary open covers, host compactness, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FiniteApproximateFixedPointUp.FiniteApproximateFixedPointTasteGate single carrier alignment`

Theorem 6087.2 (Finite approximate fixed-point NameCert obligations)**.** *For every accepted* $\mathsf{FiniteApproximateFixedPoint}^{\uparrow}$ *carrier*

$$A = (K, F, E, B, D, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteApproximateFixedPoint}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, displayed self-map route, finite ε-net, metric-ball coverage, displacement ledger, real-valued tolerance seals, approximate handoff, componentwise* hsame *transport, displayed* Cont *replay, sibling provenance, and local naming rows. Every approximate fixed-point consumer must expose the finite net E, the ball coverage B, and the displacement ledger D before it reads the handoff row S.*

Proof. Project the carrier of Definition 6087.1. The displayed tuple is the whole public packet, so the local certificate can inspect only $K, F, E, B, D, R, S, H, C, P, N$.

The compactness-facing part is finite. The compact metric row K supplies the source, the self-map row F supplies the only allowed map read, and the finite-net row E with the metric-ball row B supplies the bounded mesh coverage.

The fixed-point-facing part is approximate. The ledger D records finite displacement comparisons, the real row R supplies the numerical tolerance seals, and the handoff row S may be read only after those finite rows are accepted.

Finally H, C, P, N transport, replay, source, and name the same route. Since no selected fixed point, quotient point equality, arbitrary open cover, host compactness object, countable-choice schedule, or ambient completeness row exists in the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 6087.3 (Finite approximate fixed-point Brouwer–Schauder route)**.** *Every* $\mathsf{BrouwerFixedPoint}^{\uparrow}$ *or* $\mathsf{SchauderFixedPoint}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{FiniteApproximateFixedPoint}^{\uparrow}$ *packet receives only the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{FiniteEpsilonNet}^{\uparrow},\ \mathsf{MetricBall}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The route exposes mesh centers, coverage balls, displacement tolerances, and the approximate handoff row. It exports no exact fixed-point selector, no global fixed-point theorem, no quotient point equality, no open-cover compactness object, and no ambient completeness witness.

Proof. Start with the NameCert obligations of Definition 6087.2. A fixed-point consumer must first read the compact metric source, self-map route, finite net, ball coverage, displacement ledger, and real tolerance rows.

The Brouwer and Schauder siblings may consume that data only as a finite approximation surface. The provenance row P records those siblings, but it does not add a row selecting an exact fixed point or proving a global fixed-point theorem.

The structural rows H, C, N preserve and name the same finite route. Because the carrier has no coordinate for quotient equality, arbitrary open-cover compactness, selected fixed points, or ambient completeness, the exported route is precisely the finite approximation packet displayed above. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteApproximateFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteApproximateFixedPoint}^{\uparrow}$ packet is generated from compact metric source rows, displayed self-map rows, finite epsilon-net rows, metric-ball coverage, displacement ledgers, RealUp tolerance seals, approximate handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteApproximateFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6087.1, Definition 6087.2, and Definition 6087.3 seed the finite approximate fixed-point packet over compact metric, finite-net, metric-ball, RealUp, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteApproximateFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close exact fixed-point selection, global Brouwer or Schauder fixed-point theorems, quotient point equality, arbitrary open-cover compactness, host compactness, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net coverage, displacement-ledger exactness, Real tolerance handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteApproximateFixedPointUp.

Chapter 6088

A Concrete Naming Certificate for $\mathsf{RealCompletenessGapRouter}^{\uparrow}$

The $\mathsf{RealCompletenessGapRouter}^{\uparrow}$ packet realizes the boundary route of chapter 9238 as finite BEDC data separating permitted StreamName, RegSeqRat, DyadicRatCore, and RealUp reads from off-table completeness claims. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the exact completion boundary of chapter 1120. The packet is a gate for what may be read at the completion boundary, not an assertion of ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6088.1 (Real completeness gap-router carrier)**.** *A* $\mathsf{RealCompletenessGapRouter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, Q, D, R, A, O, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which every completion-boundary request exposes finite observations.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the displayed windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger governing the requested precision.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, Q, D have been displayed.*
5. *A is the allowed-read ledger listing the finite routes a completion consumer may inspect.*
6. *O is the off-table ledger naming refused reads: quotient streams, selected limits, host real equality, choice schedules, and ambient completeness.*
7. *T is the TasteGate obligation row requiring allowed reads to remain finite, routed, and separately auditable from refused completeness claims.*
8. *H records componentwise* hsame *transport for the window, readback, tolerance, Real seal, allowed-read, off-table, TasteGate, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a completion-boundary request through $S, Q, D, R, A, O, T, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RealCompletenessGapRouter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, RealCompletionExactBoundaryUp, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletenessGapRouter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, D, R, A, O, T, H, C, P, N$. It has no coordinate for quotient real equality, selected representatives, countable choice, host limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6088.2 (Real completeness gap-router NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletenessGapRouter}^{\uparrow}$ *carrier*

$$G = (S, Q, D, R, A, O, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletenessGapRouter}^{\uparrow}}$ *surface consists exactly of finite window exposure through S, regular rational readback through Q, dyadic tolerance visibility through D, terminal Real sealing through R, allowed-read routing through A, refused-read separation through O, TasteGate obligations through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6088.1. Its public rows are exactly $S, Q, D, R, A, O, T, H, C, P, N$, so any completion-boundary read must be witnessed by those rows.

The allowed side is finite. StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, and the Real seal are displayed separately before the allowed-read ledger is consumed.

The refused side is explicit. The off-table ledger O records quotient streams, selected limits, host equality, choice schedules, and ambient completeness as absent rows, while T states the TasteGate obligation that allowed reads remain finite and routed.

Transport and replay preserve the same split through H and C, and P, N source and name it. No additional completion object exists in the carrier, so the listed obligations exhaust the gap-router surface. □

Theorem 6088.3 (Real completeness gap-router allowed-read route)**.** *Every allowed completion-boundary read consumed from an accepted* $\mathsf{RealCompletenessGapRouter}^{\uparrow}$ *packet factors through*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

and then through the allowed-read ledger A and TasteGate row T. The same read must keep the off-table ledger O visible, so it cannot be promoted to quotient stream equality, selected-limit construction, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 6088.2. They require each accepted read to expose S, Q, D, R before the allowed-read ledger A is consumed.

The TasteGate row T then checks that the route is finite, separately auditable, and sourced by the displayed StreamName, RegSeqRat, DyadicRatCore, and RealUp rows. The row does not contain a completion theorem or a bridge credential.

Finally the off-table ledger O stays visible along the same route. Since the refused objects have no carrier coordinate, the allowed read cannot become quotient equality, selected limits, host equality, choice, or ambient completeness. □

Theorem 6088.4 (Real completeness gap-router exact-boundary separation)**.** *The* $\mathsf{RealCompletenessGapRouter}^{\uparrow}$ *route may consume* $\mathsf{RealCompletionExactBoundaryUp}$ *only as a finite sibling boundary over StreamName, RegSeqRat, DyadicRatCore, and RealUp rows. It does not convert that sibling boundary into a completed Real object, a selected representative, a quotient stream, or a host completeness theorem.*

Proof. Read the provenance row P in Definition 6088.1. It cites RealCompletionExactBoundaryUp beside the four displayed source faces, so the exact-boundary sibling is a routed dependency rather than a new coordinate of completed real equality.

Apply the allowed-read route theorem, Definition 6088.3. Any consumer must still pass through StreamName, RegSeqRat, DyadicRatCore, RealUp, the allowed ledger, the TasteGate row, and the off-table ledger.

Thus the sibling exact-boundary read remains finite and separated from the refused completion objects. The gap router exposes the boundary and the refusal ledger together, and no host completeness theorem is available for export. □

Falsifiable prediction: Every accepted $\mathsf{RealCompletenessGapRouter}^{\uparrow}$ completion-boundary read must display StreamName, RegSeqRat, DyadicRatCore, RealUp, allowed-read, off-table, TasteGate, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before any Real-facing output is visible.

Independence witness: streamname, regseqrat, dyadicratcore, real, real-completion-exact-boundary: $\mathsf{RealCompletenessGapRouter}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries allowed-read rows, off-table refusal rows, and TasteGate obligations in addition to the four finite completion-source faces.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletenessGapRouter}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletenessGapRouter}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, allowed-read rows, off-table refusal rows, TasteGate obligations, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletenessGapRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6088.1, Definition 6088.2, Definition 6088.3, and Definition 6088.4 seed the finite completion-boundary router separating allowed reads from refused completeness claims.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletenessGapRouter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected representatives, countable choice, host limit operators, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, allowed-read routing, off-table separation, TasteGate stability, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletenessGapRouterUp.

Chapter 6089

A Concrete Naming Certificate for $\mathsf{BishopCompletionSpace}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCompletionSpace}^{\uparrow}$ packet records the constructive completion-space interface as finite BEDC NameCert data. It sits after the stream-name carrier of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the Cauchy-filter completion packet of chapter 1569. The packet names the completion-space rows consumed by real and metric completion arguments; it does not assert ambient completeness, quotient equality of Cauchy objects, selected limits, countable choice, or a host completion theorem.

Definition 6089.1 (Bishop completion-space carrier)**.** *A* $\mathsf{BishopCompletionSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, Q, D, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *X is the source-space row, recording the displayed carrier, apartness or metric-facing classifier, and finite observation route used by the completion request.*
2. *Q is the regular Cauchy-name row, read through* $\mathsf{StreamName}^{\uparrow}$ *and the lawlike finite windows visible to the packet.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that bounds the inspected Cauchy windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced by the finite Cauchy data.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row consumed only after Q, D, R have been displayed.*
6. *F is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *face recording how the same Cauchy data enters the completion-facing filter route.*
7. *H records componentwise* hsame *transport for the source, Cauchy-name, dyadic tolerance, regular readback, Real seal, filter-completion face, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$X, Q, D \longmapsto R \longmapsto E \qquad \textit{and} \qquad X, Q, D \longmapsto F.$$

9. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCompletionSpace}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $X, Q, D, R, E, F, H, C, P, N$. It has no coordinate for quotient equality of Cauchy names, selected limits, ambient completeness, countable choice, host real equality, or an unrestricted completion object.

Lean4 ✓ `BEDC.Derived.BishopCompletionSpaceUp.TasteGate.BishopCompletionSpaceTasteGate single carrier alignment`

Theorem 6089.2 (Bishop completion-space NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompletionSpace}^{\uparrow}$ *carrier $S = (X, Q, D, R, E, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionSpace}^{\uparrow}}$ *surface consists exactly of source-space exposure through X, regular Cauchy-name exposure through Q, dyadic tolerance exposure through D, regular rational readback through R, Real seal handoff through E, Cauchy-filter completion exposure through F, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The source row X, Cauchy-name row Q, dyadic tolerance ledger D, regular readback R, Real seal E, and filter-completion face F are the only completion-facing data admitted by the packet.

The analytic obligations are therefore finite. A completion consumer must first display the source row and inspected Cauchy windows, then the dyadic tolerance ledger, then the regular rational readback and Real seal. The filter-completion face is read from the same displayed data and does not add a second completion object.

The structural obligations are componentwise transport, replay, provenance, and local naming. Since the carrier has no coordinate for quotient Cauchy equality, selected limits, ambient completeness, countable choice, host real equality, or an unrestricted completion object, the listed rows exhaust the NameCert surface. □

Theorem 6089.3 (Bishop completion-space Real route)**.** *Every real-facing or completion-facing consumer of an accepted* $\mathsf{BishopCompletionSpace}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{CauchyFilterCompletion}^{\uparrow}$$

by reading $X, Q, D, R, E, F, H, C, P, N$. The route exports finite Cauchy, regular-rational, Real-seal, and filter-completion rows; it exports no quotient equality, selected limit, ambient complete space, countable-choice principle, or hidden host completion.

Proof. Begin with the stream-name and Cauchy-window rows. The row Q is read only as displayed finite windows over the source row X, and the tolerance ledger D bounds those windows before any real-facing readback is public.

Next read the regular rational and Real rows. The row R exposes the regular rational name, and E seals it as a $\mathsf{Real}^{\uparrow}$ row only after X, Q, D have been displayed.

Finally read the completion face. The row F records the Cauchy-filter completion handoff over the same finite data, while H, C, P, N preserve transport, replay, provenance, and local naming. Thus every consumer receives the finite Bishop completion-space route and none of the excluded host objects. □

Falsifiable prediction: Every $\mathsf{BishopCompletionSpace}^{\uparrow}$ read must expose source-space, StreamName, dyadic tolerance, RegSeqRat readback, Real seal, CauchyFilterCompletion, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before a completion-facing conclusion is consumed.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchyfiltercompletion: $\mathsf{BishopCompletionSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source-space exposure, regular Cauchy windows, dyadic tolerance, regular rational readback, Real seal, Cauchy-filter completion face, transport, replay, provenance, and local naming in one completion-space packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompletionSpace}^{\uparrow}$ packet is generated from a source-space row, regular Cauchy-name row, dyadic tolerance ledger, RegSeqRat readback, Real seal, CauchyFilterCompletion face, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompletionSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6089.1, Definition 6089.2, and Definition 6089.3 seed the finite constructive completion-space interface over stream-name, regular rational, dyadic tolerance, Real-seal, and Cauchy-filter completion rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompletionSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.BishopCompletionSpaceUp.TasteGate.BishopCompletionSpaceTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not claim ambient completeness, quotient equality of Cauchy names, selected limits, countable choice, host real equality, bridge checking, or an unrestricted completion theorem.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-window exposure, dyadic tolerance exactness, regular rational readback, Real-seal nonescape, Cauchy-filter completion compatibility, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompletionSpaceUp.

Chapter 6090

A Concrete Naming Certificate for HyperbolicLinearizedPhaseDistance$^{\uparrow}$

The HyperbolicLinearizedPhaseDistance$^{\uparrow}$ packet realizes the linearized phase-distance reading of chapter 9463 as finite BEDC NameCert data. It sits after the boundary-shadow packet of chapter 3813, the visual-metric packet of chapter 3866, the observer-expansion packet of chapter 4167, the phase-distance observer-expansion packet of chapter 6017, the radius-ladder packet of chapter 6021, and the complex phase-surface fiber of chapter 6044. The packet names a finite boundary-shadow, visual-metric, Real-seal, transport, replay, provenance, and local naming surface; it does not assert a host hyperbolic metric space, a global visual boundary, differentiable phase flow, quotient geodesic equality, or an observer object outside the displayed rows.

Definition 6090.1 (Hyperbolic linearized phase-distance carrier)**.** *A* HyperbolicLinearizedPhaseDistance$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, V, O, \Phi, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* HyperbolicBoundaryShadow$^{\uparrow}$ *row naming the finite boundary-shadow read.*
2. *V is the* HyperbolicVisualMetric$^{\uparrow}$ *row naming the visual-metric comparison consumed by the phase distance.*
3. *O is the* HyperbolicObserverExpansion$^{\uparrow}$ *row anchoring the observer-side expansion route.*
4. *Φ is the phase-distance row, read through* PhaseDistanceObserverExpansion$^{\uparrow}$ *and the complex phase-surface fiber.*
5. *R is the regular real-readback row, displaying the* RegSeqRat$^{\uparrow}$ *and* DyadicRatCore$^{\uparrow}$ *tolerance windows used by the linearized comparison.*
6. *E is the* Real$^{\uparrow}$ *seal row for the displayed distance value.*
7. *H records componentwise* hsame *transport for boundary shadow, visual metric, observer expansion, phase distance, real readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from boundary-shadow admission through visual-metric comparison and phase-distance readback to the Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicLinearizedPhaseDistance}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$, $\mathsf{ComplexPhaseSurface}$ $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicLinearizedPhaseDistance}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, V, O, \Phi, R, E, H, C, P, N$. It has no coordinate for a host hyperbolic metric space, global visual boundary, differentiable phase flow, quotient geodesic equality, selected observer point, or hidden real-distance oracle.

Theorem 6090.2 (Hyperbolic linearized phase-distance NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicLinearizedPhaseDistance}^{\uparrow}$ *carrier $L = (B, V, O, \Phi, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicLinea}}$ *surface consists exactly of boundary-shadow exposure through B, visual-metric exposure through V, observer-expansion anchoring through O, phase-distance readback through Φ, regular real readback through R, Real-seal handoff through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 6090.1. The geometric rows are exactly the boundary-shadow, visual-metric, observer-expansion, phase-distance, real-readback, and Real-seal rows.

The distance read is linearized only as a finite route. Row B supplies the boundary shadow, V supplies the visual comparison, O anchors the observer-expansion route, Φ records the phase-distance readback, and R, E expose the regular rational and Real-seal interface.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since the carrier has no coordinate for a host hyperbolic metric space, global visual boundary, differentiable phase flow, quotient geodesic equality, selected observer point, or hidden real-distance oracle, the listed rows exhaust the NameCert surface. □

Theorem 6090.3 (Hyperbolic linearized phase-distance observer route)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicLinearizedPhaseDistance}^{\uparrow}$ *packet reads the distance route through* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, $\mathsf{PhaseDistanceObserverExpans}$ $\mathsf{ComplexPhaseSurfaceFiber}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before it receives a public comparison value. The handoff exports no host hyperbolic space, global visual boundary, quotient geodesic equality, selected observer point, or differentiable phase-flow theorem.*

Proof. Start with the boundary and visual rows. The rows B and V are the only boundary-shadow and visual-metric data admitted by the carrier, so an observer-expansion consumer cannot read a distance value before those rows are displayed.

Next read the observer and phase rows. The row O anchors the focused expansion route, while Φ records the phase-distance readback against the complex phase-surface fiber rather than against a hidden geometric object.

Finally pass through R, E, H, C, P, N. The regular readback and Real seal expose the public comparison value, and the structural rows preserve the route. Thus the observer route remains finite NameCert data and not any excluded host-level geometry. □

Falsifiable prediction: A $\mathsf{HyperbolicLinearizedPhaseDistance}^{\uparrow}$ packet is rejected whenever it cannot display boundary-shadow, visual-metric, observer-expansion, phase-distance, regular readback, Real-seal, hsame, Cont, Pkg, and local NameCert rows before exporting a comparison value.

Independence witness: hyperbolic-boundary-shadow, hyperbolic-visual-metric, hyperbolic-observer-expansion, phase-distance-observer-expansion, complex-phase-surface-fiber: no listed sibling is bijective to $\mathsf{HyperbolicLinearizedPhaseDistance}^{\uparrow}$ because this packet jointly carries boundary shadow,

visual metric, observer expansion, phase-distance readback, complex phase-fiber anchoring, Real seal, transport, replay, provenance, and local naming rows.

The Lean TasteGate route for this packet is planned to expose Nontrivial and FieldFaithful obligations for `BEDC.Derived.HyperbolicLinearizedPhaseDistanceUp`; those obligations must preserve the displayed boundary-shadow, visual-metric, Real-seal, Cont, Pkg, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicLinearizedPhaseDistance}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicLinearizedPhaseDistance}^{\uparrow}$ packet is generated from a boundary-shadow row, visual-metric row, observer-expansion row, phase-distance readback, regular real-readback row, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicLinearizedPhaseDistance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6090.1, Definition 6090.2, and Definition 6090.3 seed the finite linearized phase-distance packet over boundary-shadow, visual-metric, observer-expansion, phase-distance, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicLinearizedPhaseDistance}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host hyperbolic metric spaces, global visual boundaries, differentiable phase flows, quotient geodesic equality, selected observer points, hidden real-distance oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked boundary-shadow exposure, visual-metric exposure, observer-expansion anchoring, phase-distance readback, Real-seal nonescape, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.HyperbolicLinearizedPhaseDistanceUp.

Chapter 6091

A Concrete Naming Certificate for $\mathsf{NestedIntervalCompleteness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{NestedIntervalCompleteness}^{\uparrow}$ packet records the finite L10 route by which a bounded decreasing nested interval chain is read as a completion-facing Real seal. It sits over the closed bounded interval packet of chapter 1591, the nested interval source of chapter 320, the Cantor-intersection consumer of chapter 1421, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names completeness as displayed finite rows; it does not export a host-selected point, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6091.1 (Nested interval completeness carrier)**.** *A* $\mathsf{NestedIntervalCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, N, C, W, R, E, H, T, P, Q)$$

with the following displayed rows:

1. *B is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *endpoint row, carrying the located closed interval bounds used at the root of the chain.*
2. *N is the* $\mathsf{NestedInterval}^{\uparrow}$ *row, carrying the decreasing finite-window chain and the endpoint containment ledger.*
3. *C is the* $\mathsf{CantorIntersection}^{\uparrow}$ *handoff row, available only after the nested source and closed bounded interval rows have been displayed.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window read from the displayed nested interval chain.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from the same finite windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed after B, N, C, W, R.*
7. *H records componentwise* hsame *transport for the interval, nested source, Cantor handoff, stream window, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *T is the displayed* Cont *replay from a requested interval precision through B, N, C, W, R, E.*
9. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalCompleteness}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{CantorIntersection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *Q is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalCompleteness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for a selected host real, quotient stream equality, countable choice, trichotomy, host equality, or detached completeness theorem.

Theorem 6091.2 (Nested interval completeness NameCert obligations)**.** *For every accepted* $\mathsf{NestedIntervalComplete}$ *carrier*

$$L = (B, N, C, W, R, E, H, T, P, Q),$$

the local $\mathsf{NameCert}_{\mathsf{NestedIntervalCompleteness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *closed bounded interval admission through* B*;*
2. *nested interval admission through* N*, requiring monotone containment and displayed finite width windows;*
3. *Cantor-intersection handoff through* C*, requiring any completion-facing read to pass through the existing nested-intersection packet;*
4. *finite stream and regular rational readback through* W *and* R*;*
5. *terminal Real-seal admission through* E*;*
6. *componentwise transport, replay, provenance, and local naming through* H, T, P, Q*.*

No nested interval completeness obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 6091.1. The rows B, N, C, W, R, E are the mathematical route, while H, T, P, Q preserve and name it.

The closed bounded interval row fixes the endpoint surface. The nested interval row supplies the decreasing finite-window chain, and the Cantor-intersection row consumes that chain before any completion-facing Real seal is visible.

The stream and regular rational rows expose only finite observations and their readback. Since the carrier has no host point, quotient equality, countable choice, trichotomy, host equality, or detached completeness coordinate, the displayed rows exhaust the local NameCert obligations. □

Theorem 6091.3 (Nested interval completeness Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{NestedIntervalCompleteness}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{CantorIntersection}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the completeness read is a displayed Real-name seal generated from interval endpoints, nested containment, Cantor-intersection handoff, finite stream windows, and regular rational readback. It is not a host completeness theorem, selected point, quotient stream equality, countable choice, trichotomy, or host real equality claim.

Lean4 ✓ `BEDC.Derived.NestedIntervalCompletenessUp.NestedIntervalCompleteness real seal`

Proof. Begin with the endpoint and nested-source rows B and N. They determine the interval family visible to the packet, so a Real-facing consumer cannot start from an ambient complete line.

Read the Cantor-intersection handoff row C. This row is downstream of the displayed interval family and upstream of the finite windows, so it is the only completion-facing bridge available inside the carrier.

Finally read the stream window W, regular rational readback R, and Real seal E. The transport, replay, provenance, and naming rows preserve this same route. Because no other coordinate exists, every Real-facing consumer factors through the displayed finite path. □

Theorem 6091.4 (Nested interval completeness finite-window extraction)**.** *For every accepted* $\mathsf{NestedIntervalCompleteness}^{\uparrow}$ *carrier*

$$L = (B, N, C, W, R, E, H, T, P, Q),$$

any completion-facing $\mathsf{Real}^{\uparrow}$ *read is exposed only after the finite* $\mathsf{StreamName}^{\uparrow}$ *window row* W *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *have been displayed. Classifier transport preserves those two rows componentwise before the Real seal* E *is consumed. The extraction does not select a host real, identify quotient streams, use countable choice, invoke trichotomy, or import ambient Real completeness.*

Proof. Project the carrier of Definition 6091.1. The rows W and R are explicit coordinates of the accepted packet, while the seal E is listed only downstream of the closed interval, nested source, Cantor handoff, finite window, and regular readback rows.

Apply the NameCert obligations of Definition 6091.2. They force every completion-facing read to pass through B, N, C, W, R before E, and they require componentwise transport through H for the same displayed rows.

Finally use the Real seal route of Definition 6091.3. The route places $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ immediately before $\mathsf{Real}^{\uparrow}$, so a consumer cannot bypass W or R when consuming the seal. Since the carrier has no selected host real, quotient stream equality, countable-choice schedule, trichotomy coordinate, or ambient completeness row, the finite-window extraction is exactly the displayed witness route. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalCompleteness}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NestedIntervalCompleteness}^{\uparrow}}$, seed)

Scope closed: Definition 6091.1, Definition 6091.2, and Definition 6091.3 seed the finite nested-interval completeness route from closed bounded interval and nested interval data through CantorIntersection, StreamName, RegSeqRat, and the RealUp seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NestedIntervalCompleteness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host completeness, selected real points, quotient stream equality, countable choice, trichotomy, host equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked closed-interval admission, nested-source admission, Cantor-intersection handoff, finite-window readback, Real-seal admission, transport, replay, provenance, and local naming for BEDC.Derived.NestedIntervalCompletenessUp.

Constructive story: A $\mathsf{NestedIntervalCompleteness}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp endpoint row, a NestedIntervalUp source row, a CantorIntersectionUp handoff, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6092

A Concrete Naming Certificate for $\mathsf{GaugeLebesgueNumber}^{\uparrow}$

Following Cousin and Bishop gauge-cover arguments, the $\mathsf{GaugeLebesgueNumber}^{\uparrow}$ packet records the finite handoff from a displayed gauge cover to a positive Lebesgue-number ledger. It sits over the reusable cover row of chapter 3426, the tagged-subdivision theorem row of chapter 1861, the finite radius ledger of chapter 452, the compact metric source of chapter 129, and the rational comparison surface of chapter 37. The packet is the gauge-facing radius object consumed by compact-uniform and gauge-integration routes; it does not choose an open subcover, select a host minimum, import open-cover compactness, or assert ambient completeness.

Definition 6092.1 (Gauge Lebesgue number carrier)**.** *A* $\mathsf{GaugeLebesgueNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, G, U, F, Q, H, T, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose finite-net and located coverage data bound the gauge request.*
2. *G is the* $\mathsf{CousinCover}^{\uparrow}$ *gauge-cover row, carrying tagged cover cells and their local gauge admissions.*
3. *U is the* $\mathsf{CousinLemma}^{\uparrow}$ *subdivision row, tying the same gauge cover to a finite tagged partition.*
4. *F is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *positive-radius ledger for the displayed gauge cover.*
5. *Q is the* $\mathsf{Rat}^{\uparrow}$ *comparison row certifying that the chosen radius is positive and below the relevant gauge radii.*
6. *H records componentwise* hsame *transport for the compact source, gauge cover, Cousin subdivision, finite radius ledger, rational comparison, replay, provenance, and local naming rows.*
7. *T is the displayed* Cont *replay from a compact-cover request through K, G, U, F, Q.*
8. *P is the* Pkg *provenance over* $\mathsf{GaugeLebesgueNumber}^{\uparrow}$, $\mathsf{CousinCover}^{\uparrow}$, $\mathsf{CousinLemma}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{GaugeLebesgueNumber}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, G, U, F, Q, H, T, P, N$. It has no coordinate for arbitrary open covers, selected subcovers, host minima, quotient metric equality, countable choice, or detached compactness.

Lean4 ✓ `BEDC.Derived.GaugeLebesgueNumberUp.GaugeLebesgueNumberTasteGate single carrier alignment`

Theorem 6092.2 (Gauge Lebesgue number NameCert obligations)**.** *For every accepted* $\mathsf{GaugeLebesgueNumber}^{\uparrow}$ *carrier*

$$L = (K, G, U, F, Q, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{GaugeLebesgueNumber}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *compact metric admission through* K*;*
2. *Cousin gauge-cover admission through* G*;*
3. *Cousin-lemma subdivision compatibility through* U*;*
4. *finite Lebesgue-number radius admission through* F*;*
5. *rational positivity and lower-bound comparison through* Q*;*
6. *componentwise transport, replay, provenance, and local naming through* H, T, P, N*.*

No gauge Lebesgue-number obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 6092.1. The rows K, G, U, F, Q are the mathematical handoff, while H, T, P, N preserve and name the same displayed route.

The compact metric row supplies the finite coverage source. The Cousin cover and Cousin lemma rows keep the gauge data tied to a finite tagged subdivision rather than to an arbitrary open-cover argument.

The finite Lebesgue-number row and rational comparison row provide the positive lower radius. Since the carrier contains no selected subcover, host minimum, quotient equality, choice, or detached compactness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 6092.3 (Gauge Lebesgue number cover handoff)**.** *Every compact-uniform or gauge-integration consumer of an accepted* $\mathsf{GaugeLebesgueNumber}^{\uparrow}$ *carrier factors through*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{CousinCover}^{\uparrow} \longmapsto \mathsf{CousinLemma}^{\uparrow} \longmapsto \mathsf{FiniteLebesgueNumber}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow}.$$

Thus the exported radius is read as a finite gauge-cover lower-bound ledger over BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It is not a selected host Lebesgue number, not a general open-cover compactness proof, and not an external bridge request.*

Proof. Start with the compact metric row K and the gauge-cover row G. Together they bind the cover request to displayed finite metric and gauge data.

Read the Cousin-lemma row U. It supplies the finite tagged-subdivision compatibility needed by gauge-integration consumers and keeps the cover handoff inside the displayed gauge route.

Finally read the finite radius ledger F and rational comparison row Q. These are the only rows that export a positive radius, and they are already tied to K, G, U by the carrier. The structural rows H, T, P, N transport and name that path, so every consumer receives the same finite cover handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{GaugeLebesgueNumber}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GaugeLebesgueNumber}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6092.1, Definition 6092.2, and Definition 6092.3 seed the finite gauge-cover Lebesgue-number route over CompactMetric, CousinCover, CousinLemma, FiniteLebesgueNumber, Rat, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GaugeLebesgueNumber}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, host Lebesgue numbers, quotient metric equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact metric admission, Cousin cover admission, Cousin lemma compatibility, finite Lebesgue-number radius admission, rational comparison, transport, replay, provenance, and local naming for BEDC.Derived.GaugeLebesgueNumberUp.

Constructive story: A GaugeLebesgueNumber$^{\uparrow}$ packet is generated from a CompactMetricUp source row, a CousinCoverUp gauge-cover row, a CousinLemmaUp subdivision row, a FiniteLebesgueNumberUp positive-radius ledger, a RatUp lower-bound comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6093

A Concrete Naming Certificate for $\mathsf{EilenbergSteenrodAxioms}^{\uparrow}$

Following Eilenberg and Steenrod, the $\mathsf{EilenbergSteenrodAxioms}^{\uparrow}$ packet records the finite NameCert surface by which a homology-style theory exposes dimension, exactness, excision, homotopy invariance, and naturality obligations without importing an ambient theorem oracle. It sits over the homology carrier of chapter 98, the cohomology comparison surface of chapter 99, the finite simplicial source of chapter 238, and the homotopy route of chapter 156. The packet supplies a classical axiom ledger that downstream homology and cohomology chapters can consume as displayed rows rather than as host mathematical background.

Definition 6093.1 (Eilenberg–Steenrod axioms carrier)**.** *An* $\mathsf{EilenbergSteenrodAxioms}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (H, C, S, T, D, X, E, I, Nt, R, P, L)$$

with the following displayed rows:

1. *H is the* $\mathsf{Homology}^{\uparrow}$ *target row whose groups, boundaries, cycles, and quotient-facing claims are read only through the displayed packet;*
2. *C is the* $\mathsf{Cohomology}^{\uparrow}$ *comparison row, recording the contravariant consumer surface and coefficient-facing requests;*
3. *S is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *finite source row used when the axiom ledger is instantiated on finite complexes;*
4. *T is the* $\mathsf{Homotopy}^{\uparrow}$ *route row for maps, homotopies, and homotopy-class reads;*
5. *D is the dimension row, naming the point object and coefficient landing used by the theory;*
6. *X is the exactness row for the boundary, kernel, image, and connecting-map obligations;*
7. *E is the excision row, naming the finite subobject and removal route on which the comparison is valid;*
8. *I is the homotopy-invariance row, recording the displayed route through T rather than a host equality of maps;*
9. *Nt is the naturality row for maps of pairs and induced homology or cohomology reads;*
10. *R is the refusal ledger for host exactness, quotient-object equality, selected representatives, unbounded chain complexes, and ambient abelian-category or topological-space oracles;*

11. *P records* Pkg *provenance over* EilenbergSteenrodAxioms$^{\uparrow}$, Homology$^{\uparrow}$, Cohomology$^{\uparrow}$, SimplicialComplex$^{\uparrow}$, Homotopy$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
12. *L is the local* NameCert$_{\text{EilenbergSteenrodAxioms}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an external homology theory, global exactness theorem, quotient equality of chain representatives, countable choice of cycles, or ambient topological completeness principle.

Lean4 ✓ `BEDC.Derived.EilenbergSteenrodAxiomsUp.EilenbergSteenrodAxiomsTasteGate single carrier alignment`

Theorem 6093.2 (Eilenberg–Steenrod exactness obligation)**.** *For an accepted* EilenbergSteenrodAxioms$^{\uparrow}$ *carrier*

$$A = (H, C, S, T, D, X, E, I, Nt, R, P, L),$$

the exactness obligation visible to a downstream Homology$^{\uparrow}$ *or* Cohomology$^{\uparrow}$ *consumer is precisely the displayed row X together with the source rows H, C, S, the homotopy route T, the refusal ledger R, provenance P, and local name L. A consumer may request boundary, kernel, image, and connecting-map data only through this finite* BHist *route, and may not replace it by host exactness, quotient-object equality, selected chain representatives, countable choice, or an ambient abelian-category oracle.*

Proof. Project the carrier of Definition 6093.1. The only exactness coordinate is X, and it is displayed alongside the homology, cohomology, simplicial-source, and homotopy-route rows.

The downstream consumer therefore reads exactness after the source rows have been exposed. The row H supplies the homology-facing target, C supplies the cohomology-facing comparison, S supplies the finite simplicial carrier, and T supplies the homotopy route on which induced maps are compared.

The refusal ledger R closes the non-displayed alternatives. Since R excludes host exactness, quotient-object equality, selected representatives, countable choice, and ambient categorical oracles, the exactness obligation remains the finite row X named by the local NameCert row L. □

Theorem 6093.3 (Eilenberg–Steenrod homotopy invariance ledger)**.** *For an accepted* EilenbergSteenrodAxioms$^{\uparrow}$ *carrier*

$$A = (H, C, S, T, D, X, E, I, Nt, R, P, L),$$

the homotopy-invariance claim is the ledger row I read after the Homotopy$^{\uparrow}$ *route T and before the naturality row Nt. It records equality of induced homology or cohomology reads only as displayed NameCert data over $H, C, S, T, I, Nt, R, P, L$; it does not export host equality of maps, quotient equality of chain representatives, selected homotopy representatives, global topological equivalence, or ambient completeness.*

Proof. Start from the homotopy route row T. It is the only row in the carrier that names maps and homotopies, so a homotopy-invariance read cannot begin from a host equality of maps.

Next read the ledger row I. The row records the invariance obligation over the already displayed homology, cohomology, simplicial-source, and homotopy-route data, while Nt keeps the induced-map comparison on the same finite route.

Finally inspect the refusal and naming rows. The ledger R rejects quotient representatives, selected homotopies, global equivalence, and ambient completeness, and P, L only source and name the displayed packet. Hence the homotopy-invariance claim is a finite NameCert ledger entry, not an external theorem import. □

Falsifiable prediction: A homology or cohomology consumer that proves exactness or homotopy invariance without reading the displayed X, T, I, Nt, R, P, L rows is not consuming an accepted EilenbergSteenrodAxiomsUp packet.

Independence witness: homology, cohomology, simplicialcomplex, and homotopy are non-bijective siblings: none alone carries the complete finite ledger of dimension, exactness, excision, homotopy invariance, naturality, refusal, provenance, and local NameCert data exposed by $\mathsf{EilenbergSteenrodAxioms}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{EilenbergSteenrodAxioms}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EilenbergSteenrodAxioms}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6093.1, Definition 6093.2, Definition 6093.3, the falsifiable prediction, and the independence witness seed the finite Eilenberg–Steenrod axiom ledger for homology and cohomology consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EilenbergSteenrodAxioms}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, full classical homology theory, quotient chain equality, selected representatives, arbitrary topological spaces, countable choice, or ambient exactness or completeness.

Upgrade path: Obligation closure requires checked carrier admission, dimension, exactness, excision, homotopy-invariance, naturality, refusal-ledger, provenance, and local NameCert rows for BEDC.Derived.EilenbergSteenrodAxiomsUp.

Constructive story: An $\mathsf{EilenbergSteenrodAxioms}^{\uparrow}$ packet is generated from homology and cohomology rows, a finite simplicial source, a homotopy route, dimension, exactness, excision, homotopy-invariance, naturality, refusal, provenance, and local naming rows.

Chapter 6094

A Concrete Naming Certificate for $\mathsf{EquicontinuityModulusSelection}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the finite-net proof of Arzela–Ascoli, the $\mathsf{EquicontinuityModulusSelection}^{\uparrow}$ packet records the finite selector route that turns displayed equicontinuous family rows into a reusable modulus packet. It reads compact finite-net data from chapter 129, family-radius rows from chapter 4076, reusable modulus ledgers from chapter 369, rational lower-bound folds from chapter 37, metric source comparisons from chapter 4230, and terminal real-name seals from chapter 38. The packet names a finite selection route only; it is not an open-cover compactness proof, a selected subcover, a countable-choice principle, a host function-equality theorem, or an ambient completeness result.

Definition 6094.1 (Equicontinuity modulus selection carrier)**.** *An* $\mathsf{EquicontinuityModulusSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, E, Q, M, U, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, carrying named centers, located coverage radii, and the finite observation order.*
2. *E is the* $\mathsf{Equicontinuity}^{\uparrow}$ *family row, displaying the shared local radius data for the indexed function family over the same source metric.*
3. *Q is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row that records the positive radius ledger selected by finite recursion over K and E.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *comparison row used to transport source-distance estimates from net centers to arbitrary displayed points.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *packet exported only after K, E, Q, M have been displayed.*
6. *R is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row for Real-facing consumers of the selected modulus packet.*
7. *H records componentwise* hsame *transport for the compact-net, equicontinuity, rational-fold, metric, uniform-modulus, Real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through $K, E, Q, M, U, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{EquicontinuityModulusSelection}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{EquicontinuityModulusSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for open-cover compactness, selected subcovers, countable choice, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EquicontinuityModulusSelectionUp.TasteGate.EquicontinuityModulusSelectionTasteGate`
`single carrier alignment`

Theorem 6094.2 (Equicontinuity modulus selection NameCert obligations)**.** *For every accepted* $\mathsf{EquicontinuityModulusSelection}^{\uparrow}$ *carrier*

$$S = (K, E, Q, M, U, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EquicontinuityModulusSelection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact finite-net, equicontinuity, rational-fold, metric, uniform-modulus, Real-seal, transport, replay, provenance, and local naming rows;*
2. *compact-net exposure, requiring every selected modulus read to display K before the family-radius fold is inspected;*
3. *family-radius exposure, requiring E to supply the shared equicontinuity radius rows consumed by the finite fold;*
4. *rational-fold exactness, requiring Q to record the positive lower bound chosen by finite recursion over the displayed net and family rows;*
5. *uniform-modulus handoff, requiring U and then R to be downstream of K, E, Q, M;*
6. *structural stability, requiring H, C, P, N to preserve, replay, source, and name the same finite selection packet.*

No selection obligation is stored outside these rows.

Proof. Project the carrier of Definition 6094.1. The visible analytic rows are exactly the compact finite net, equicontinuity family radii, rational lower-bound fold, metric comparisons, uniform-modulus packet, and Real seal.

The compact-net and family-radius obligations fix the finite domain of selection. A selected radius is read as a coordinate of the displayed net and family rows, not as a host chooser.

The rational-fold row then records the finite minimum route. The metric row transports the center estimate to the displayed source comparison, and the uniform-modulus and Real rows receive only that folded ledger.

The structural rows add no selector data. They transport, replay, source, and name the same packet, so the six obligation rows exhaust the local NameCert surface. □

Theorem 6094.3 (Equicontinuity modulus selection finite-net handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *or Arzela–Ascoli-facing consumer of an accepted* $\mathsf{EquicontinuityModulusSelection}^{\uparrow}$ *carrier receives its modulus only through the finite route*

$$K, E, Q, M, U, R, H, C, P, N.$$

Here K supplies compact finite-net centers, E supplies the displayed equicontinuity family radii, Q supplies the positive rational lower-bound fold, M supplies the source-metric comparison, U supplies

the reusable uniform-modulus packet, and R supplies the terminal Real-facing seal. The handoff exports a reusable modulus packet without open-cover compactness, selected subcovers, countable choice, host function equality, or ambient Real completeness.

Proof. Start with the NameCert obligations of Definition 6094.2. They require the compact finite-net row and the equicontinuity family row before any rational fold or uniform-modulus handoff is available.

Read the finite selector route through Q. Since the fold is over the displayed net and family rows, the selected radius is a finite packet coordinate.

The metric row M and uniform-modulus row U then consume the same radius ledger, and the Real seal R is downstream of that handoff. The structural rows H, C, P, N preserve the route, so no consumer can replace it by a host selector or ambient compactness principle. □

Falsifiable prediction: Every accepted $\mathsf{EquicontinuityModulusSelection}^{\uparrow}$ read must display CompactMetric finite-net data, Equicontinuity family-radius rows, RatUp lower-bound folds, MetricSpace comparisons, UniformModulus handoff, Real seal, transport, replay, provenance, and local naming.

Independence witness: compactmetric, equicontinuity, rat, metricspace, uniformmodulus, real: $\mathsf{EquicontinuityModulusSelection}^{\uparrow}$ is not reducible to any listed sibling because it binds compact finite nets and family-radius rows to one reusable modulus handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{EquicontinuityModulusSelection}^{\uparrow}}$ **·**

Constructive story: An $\mathsf{EquicontinuityModulusSelection}^{\uparrow}$ packet is generated from CompactMetric finite-net data, Equicontinuity family-radius rows, RatUp lower-bound folds, MetricSpace comparisons, a UniformModulus handoff, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EquicontinuityModulusSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6094.1, Definition 6094.2, and Definition 6094.3 seed the finite selector route from equicontinuous family rows and compact finite nets to a reusable modulus packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EquicontinuityModulusSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, countable choice, host function equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net exposure, family-radius exposure, rational-fold exactness, uniform-modulus handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.EquicontinuityModulusSelectionUp.

Chapter 6095

A Concrete Naming Certificate for $\mathsf{EquicontinuityRadiusChoice}^{\uparrow}$

Following Bishop–Bridges constructive analysis of equicontinuous families on compact metric sources, the $\mathsf{EquicontinuityRadiusChoice}^{\uparrow}$ packet records the finite family-radius choice used before a uniform-modulus consumer reads the compact route. It sits on the compact finite-net surface of chapter 129, the displayed family-radius surface of chapter 4076, the graph and pointwise-control rows of chapter 130, the reusable ledger of chapter 369, the positive-radius fold of chapter 37, the source-metric comparison row of chapter 4230, and the terminal real-name boundary of chapter 38. The packet chooses only among displayed finite family-radius rows; it does not supply an open-cover subcover, a countable selector, host function equality, or ambient completeness.

Definition 6095.1 (Equicontinuity radius choice carrier)**.** *An* $\mathsf{EquicontinuityRadiusChoice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, F, E, Q, M, U, A, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, including named centers, located coverage radii, and the finite order in which centers are inspected.*
2. *F is the finite family-index row, listing exactly the functions whose equicontinuity radii are available to the packet.*
3. *E is the* $\mathsf{Equicontinuity}^{\uparrow}$ *family-radius row over F, displaying the common source-radius choices at the compact-net centers.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *positive lower-bound fold row over the displayed family and compact-net radius ledger.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *source comparison row used to move from center estimates to arbitrary displayed source points.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row reached only after K, F, E, Q, M have been displayed.*
7. *A is the downstream* $\mathsf{Real}^{\uparrow}$ *seal for Real-facing reads of the chosen family-radius packet.*
8. *H records componentwise* hsame *transport for the compact-net, finite-family, equicontinuity, rational-fold, metric, uniform-modulus, Real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a family-radius request through $K, F, E, Q, M, U, A, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{EquicontinuityRadiusChoice}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{EquicontinuityRadiusChoice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a hidden family selector, selected subcover, countable choice, host function equality, quotient Real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EquicontinuityRadiusChoiceUp.EquicontinuityRadiusChoiceTasteGate single carrier alignment`

Theorem 6095.2 (Equicontinuity radius choice NameCert obligations)**.** *For every accepted* EquicontinuityRadiusCh *carrier*

$$R = (K, F, E, Q, M, U, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EquicontinuityRadiusChoice}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact finite-net, finite-family, equicontinuity, rational-fold, metric, uniform-modulus, Real-seal, transport, replay, provenance, and local naming rows;*
2. *finite-family exposure, requiring every radius choice to be indexed by the displayed row F;*
3. *compact-net exposure, requiring the same compact finite-net row K to supply the centers and coverage radii consumed by the family-radius fold;*
4. *equicontinuity-radius exactness, requiring E to display the family radii before Q records a positive lower bound;*
5. *uniform-modulus handoff, requiring U and then A to be downstream of K, F, E, Q, M;*
6. *structural stability, requiring H, C, P, N to preserve, replay, source, and name the same finite family-radius packet.*

No family-radius choice obligation is stored outside these rows.

Proof. Project the carrier of Definition 6095.1. Its visible rows are exactly the compact finite net, finite family index, equicontinuity radius row, rational lower-bound fold, metric comparison, uniform-modulus handoff, Real seal, and structural rows.

The finite-family and compact-net exposure clauses fix the two finite domains of the choice. A chosen radius is therefore a displayed coordinate of F and K, not an ambient selector.

The equicontinuity row E supplies the available radii, and Q records the positive lower-bound fold over those displayed rows. The metric row M is the only source-comparison row available to transport the estimate.

Finally U, A, H, C, P, N receive, seal, transport, replay, source, and name the same packet. Since none of those rows adds choice data, the listed obligations exhaust the local NameCert surface. □

Theorem 6095.3 (Equicontinuity radius choice finite-family handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{EquicontinuityRadiusChoice}^{\uparrow}$ *packet receives its family radius only through the finite route*

$$K, F, E, Q, M, U, A, H, C, P, N.$$

The route first displays the compact finite net K and finite family row F, then reads the equicontinuity radius row E, folds the positive rational bound through Q, transports the source estimate

through M, and hands the result to U and A. It is a finite family-radius handoff, not a hidden selector, selected subcover, countable-choice family, host function equality, quotient Real equality, or ambient completeness principle.

Proof. Begin with the NameCert obligations of Definition 6095.2. They require K and F before any radius choice can be read by a uniform-modulus consumer.

The family-radius row E is then consumed over those displayed finite domains. The rational row Q records the lower-bound fold, and the metric row M supplies the source comparison needed by the handoff.

The consumer row U and Real seal A are downstream of the same fold. Transport, replay, provenance, and local naming preserve the route, so the packet exports exactly the finite family-radius choice displayed above. □

Falsifiable prediction: Every accepted $\mathsf{EquicontinuityRadiusChoice}^{\uparrow}$ read must display CompactMetric finite-net data, a finite family row, Equicontinuity family radii, RatUp lower-bound folds, MetricSpace comparisons, UniformModulus handoff, Real seal, transport, replay, provenance, and local naming.

Independence witness: compactmetric, equicontinuity, continuousmap, rat, metricspace, uniformmodulus, real: $\mathsf{EquicontinuityRadiusChoice}^{\uparrow}$ is not reducible to any listed sibling because it binds a finite family-radius row to a compact finite-net lower-bound fold and a uniform-modulus handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{EquicontinuityRadiusChoice}^{\uparrow}}$ **.**

Constructive story: An $\mathsf{EquicontinuityRadiusChoice}^{\uparrow}$ packet is generated from CompactMetric finite-net data, a finite family row, Equicontinuity radius rows, RatUp lower-bound folds, MetricSpace comparisons, a UniformModulus handoff, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EquicontinuityRadiusChoice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6095.1, Definition 6095.2, and Definition 6095.3 seed the finite family-radius choice route from compact nets and displayed equicontinuity rows to a uniform-modulus consumer.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EquicontinuityRadiusChoice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, hidden family selectors, countable choice, host function equality, quotient Real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-family exposure, compact-net exposure, equicontinuity-radius exactness, rational-fold exactness, uniform-modulus handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.EquicontinuityRadiusChoiceUp.

Chapter 6096

A Concrete Naming Certificate for $\mathsf{CompleteMetricCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompleteMetricCriterion}^{\uparrow}$ packet records the finite Cauchy-limit criterion needed before an L10 completion route can hand a Cauchy object to a metric or real-facing consumer. It sits between the filter-base and Cauchy-filter surfaces of chapter 1601 and chapter 333, the completion boundary of chapter 1569, the metric completion surface of chapter 1506, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the criterion as finite BEDC data; it does not quotient filters, select limits, use host equality, invoke countable choice, or assume ambient completeness.

Definition 6096.1 (CompleteMetricCriterion carrier)**.** *A* $\mathsf{CompleteMetricCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, W, T, R, M, L, H, K_0, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row read through a displayed* $\mathsf{FilterBase}^{\uparrow}$ *source and the finite requests admitted by that base;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule selecting the finite windows used when a Cauchy request asks for tail or neighbourhood evidence;*
3. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same finite requests;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback assembled from the scheduled windows and dyadic tolerances;*
5. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *completion-boundary row exposed only after C, W, T, R have been replayed;*
6. *L is the candidate* $\mathsf{Real}^{\uparrow}$ *limit seal read from the displayed completion route;*
7. *H records componentwise* hsame *transport for Cauchy-filter, filter-base, window, tolerance, readback, completion, real-seal, provenance, and naming rows;*
8. *K_0 records displayed* Cont *replay of the route*

$$C, W, T, R \longmapsto M \longmapsto L;$$

9. *P is the* Pkg *provenance over* $\mathsf{CompleteMetricCriterion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, W, T, R, M, L, H, K_0, P, N$. There is no coordinate for quotient filters, selected representatives, selected limits, host equality, countable-choice schedules, or ambient completeness of the metric or real carrier.

Lean4 ✓ `BEDC.Derived.CompleteMetricCriterionUp.CompleteMetricCriterionTasteGate single carrier alignment`

Theorem 6096.2 (CompleteMetricCriterion NameCert obligations)**.** *For every accepted* $\mathsf{CompleteMetricCriterion}^{\uparrow}$ *carrier $K = (C, W, T, R, M, L, H, K_0, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompleteMetricCriterion}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed Cauchy-filter, filter-base, window, tolerance, readback, completion, real-seal, transport, replay, provenance, and naming rows;*
2. *Cauchy-window exactness, requiring every Cauchy request to be witnessed by the same C, W, T, R rows before completion data are read;*
3. *completion handoff, requiring the* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *row M to be downstream from the displayed Cauchy route;*
4. *Real seal nonescape, requiring the limit row L to be read only after M and never through quotient filters, selected limits, host equality, countable choice, or ambient completeness;*
5. *provenance and local naming, requiring H, K_0, P, N to transport, replay, package, and name the same finite route.*

Proof. Carrier admission is projection from Definition 6096.1. The packet lists exactly the Cauchy-filter, filter-base, finite-window, dyadic tolerance, regular readback, completion, real-seal, transport, replay, provenance, and local naming rows.

Cauchy-window exactness is read from C, W, T, R. A Cauchy request first consumes the displayed filter row and finite schedule, then checks the dyadic tolerance ledger, and only then exposes the regular rational readback.

The completion handoff is the row M. Since M is downstream from C, W, T, R, a completion-facing consumer receives the finite Cauchy route rather than a quotient filter or chosen representative.

The real seal L is downstream from M and is preserved by H and K_0. The provenance and local naming rows P, N therefore certify exactly the displayed finite route, while the excluded host principles have no carrier coordinate. □

Theorem 6096.3 (CompleteMetricCriterion Cauchy-limit handoff)**.** *Every limit-facing read exported by an accepted* $\mathsf{CompleteMetricCriterion}^{\uparrow}$ *carrier factors through the finite route*

$$C, W, T, R \longmapsto M \longmapsto L \longmapsto H, K_0, P, N.$$

The route supplies the Cauchy-filter and filter-base request, finite stream window, dyadic tolerance ledger, regular rational readback, completion boundary, real-seal row, transport, replay, provenance, and local naming. It refuses quotient filters, selected limits, host equality, countable choice, and ambient completeness as routes to the same limit.

Proof. Start with an accepted carrier $K = (C, W, T, R, M, L, H, K_0, P, N)$. By Definition 6096.1, the only route to a completion-facing read begins with C, W, T, R.

The row M is the sole completion boundary. It records the $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{CauchyFilterCompletion}^{\uparrow}$ handoff after the finite Cauchy route has been displayed, so the consumer cannot replace the route by a quotient filter or a selected completion point.

The row L is the terminal $\mathsf{Real}^{\uparrow}$ seal. Transport through H and replay through K_0 keep L attached to the same finite request, and P, N package that route as the local certificate.

Since the carrier has no coordinate for host equality, countable choice, or ambient completeness, the handoff proves exactly the finite route stated in the theorem. □

Falsifiable prediction: Any accepted $\mathsf{CompleteMetricCriterion}^{\uparrow}$ read that reaches a $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ seal without the displayed CauchyFilterUp, FilterBaseUp, StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, hsame, Cont, Pkg, and local NameCert rows refutes the carrier.

Independence witness: cauchyfilter, filterbase, streamname, dyadicratcore, regseqrat, metriccompletion, cauchyfiltercompletion, real: none is bijective to $\mathsf{CompleteMetricCriterion}^{\uparrow}$ because this packet jointly carries Cauchy requests, finite windows, dyadic tolerances, regular readbacks, completion handoff, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteMetricCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteMetricCriterion}^{\uparrow}$ packet is generated from a CauchyFilter row over a FilterBase route, StreamName windows, DyadicRatCore tolerances, RegSeqRat readbacks, a MetricCompletion or CauchyFilterCompletion handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteMetricCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6096.1, Definition 6096.2, and Definition 6096.3 seed the finite Cauchy-limit criterion route needed by L10 completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteMetricCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient filters, selected limits, host equality, countable choice, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-window exactness, completion handoff, Real seal nonescape, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.CompleteMetricCriterionUp.

Chapter 6097

A Concrete Naming Certificate for $\mathsf{ClassifierFormingLearning}^{\uparrow}$

The $\mathsf{ClassifierFormingLearning}^{\uparrow}$ packet realizes the classifier-forming learning route of section 9462.14 as finite NameCert data. It records parameter motion, loss observations, classifier shift, training residue, audit export, and TasteGate commitments before any consumer may call the episode certified learning discovery. The packet is downstream from the registry export surface of chapter 1216, the machine-readable audit interface of chapter 1232, the positive interpretability discovery boundary, NameCert governance, and the GroundCompiler audit-map surface of chapter 836.

Definition 6097.1 (ClassifierFormingLearning carrier)**.** *A* $\mathsf{ClassifierFormingLearning}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, A, S, Q, R, G, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the dataset or task row whose accepted observations are read only through displayed histories;*
2. *A is the parameter-motion row recording the before-and-after training state without treating motion itself as discovery;*
3. *S is the classifier-shift row, naming the finite decision boundary or equivalence-class change certified by the packet;*
4. *Q is the loss, score, or benchmark residue row, kept as evidence residue rather than as the learning object;*
5. *R is the registry-export row tying the learning claim to public status and refusal boundaries;*
6. *G is the audit-interface and GroundCompiler map row that makes the packet machine-readable for later checking;*
7. *T is the* TasteGate *row requiring nontriviality and field faithfulness for the displayed classifier-shift carrier;*
8. *H records componentwise* hsame *transport for dataset, parameter, classifier-shift, residue, registry, audit, TasteGate, provenance, and naming rows;*
9. *C records displayed* Cont *replay from training evidence through classifier shift, residue ledger, registry export, audit map, TasteGate, provenance, and local naming;*

10. *P is the* Pkg *provenance over* ClassifierFormingLearning$^{\uparrow}$, RegistryExportSurface$^{\uparrow}$, MachineReadableAuditInterface$^{\uparrow}$ *positive-interpretability-discovery-facing packets,* GroundCompilerAuditMap$^{\uparrow}$, BHist, hsame, Cont, Pkg, TasteGate, *and* NameCert *rows;*

11. *N is the local* NameCert$_{\text{ClassifierFormingLearning}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, A, S, Q, R, G, T, H, C, P, N$. Parameter motion and loss reduction are admissible evidence rows, but they are not identified with learning unless the classifier-shift row S and the TasteGate row T are present.

Theorem 6097.2 (ClassifierFormingLearning NameCert obligations)**.** *For every accepted* ClassifierFormingLearning *carrier $L = (D, A, S, Q, R, G, T, H, C, P, N)$, the local* NameCert$_{\text{ClassifierFormingLearning}^{\uparrow}}$ *surface consists exactly of carrier admission, dataset/task exposure, parameter-motion residue, classifier-shift exposure, loss and benchmark residue, registry export, machine-readable audit handoff, GroundCompiler audit-map handoff, TasteGate nontriviality and field faithfulness commitments, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

No obligation may be discharged by parameter motion alone, lower loss alone, benchmark improvement alone, memorized records, shortcut performance, or unregistered interpretability prose.

Proof. Project the carrier of Definition 6097.1. The displayed inventory is exactly $D, A, S, Q, R, G, T, H, C, P, N$, so every accepted learning claim must be read from those finite rows.

The parameter row A and residue row Q are evidence ledgers. They can support the claim only after the classifier-shift row S is present, because the NameCert surface names classifier formation rather than motion or lower loss by itself.

The registry and audit rows R, G make the claim exportable and machine-readable. The TasteGate row T records that later Lean work must provide nontriviality and field-faithfulness instances for this displayed carrier.

Finally H, C, P, N transport, replay, package, and name the same route. Since the excluded substitutes have no carrier coordinate, they cannot discharge the NameCert obligations. □

Theorem 6097.3 (ClassifierFormingLearning metric nonescape)**.** *Every metric-facing read exported by an accepted* ClassifierFormingLearning$^{\uparrow}$ *carrier factors through*

$$D, A, S, Q, R, G, T, H, C, P, N.$$

Parameter motion, loss reduction, and benchmark movement remain ledger rows inside the packet. They become certified learning discovery only when the classifier-shift row, registry export, machine-readable audit handoff, GroundCompiler audit-map handoff, TasteGate commitments, transport, replay, provenance, and local naming rows are all displayed.

Proof. Begin with a metric-facing read of the carrier. The definition exposes parameter and loss data through A and Q, but those rows are downstream evidence and not the classifier named by the packet.

The classifier-shift row S is the decisive learning row. The route then passes through registry export R and audit handoff G, so the claim remains publicly checkable and machine-readable rather than a private score report.

The TasteGate row T keeps nontriviality and field faithfulness attached to the same carrier. Componentwise transport and continuation replay preserve the rows, and P, N package the accepted route.

Therefore metric improvement cannot escape the packet boundary. Without the classifier-shift and TasteGate rows, the read remains residue rather than a certified ClassifierFormingLearning$^{\uparrow}$ claim. □

Falsifiable prediction: A $\mathsf{ClassifierFormingLearning}^{\uparrow}$ packet with parameter motion and loss reduction but no classifier-shift row is rejected by the NameCert surface.

Independence witness: machine-readable-audit-interface, registry-export-surface, positive-interpretability-discovery-facing packets, namecert, groundcompiler-audit-map: none is bijective to $\mathsf{ClassifierFormingLearning}^{\uparrow}$ because dropping any one row loses a distinct obligation: audit readability, public export, interpretability-facing classifier evidence, local naming, or compiler-audit trace.

The Lean follow-up must provide explicit $\mathsf{Nontrivial\ ClassifierFormingLearning}^{\uparrow}$ and $\mathsf{FieldFaithful\ ClassifierFormingL}$ instances in `TasteGate.lean`. Those instances must preserve the rows $D, A, S, Q, R, G, T, H, C, P, N$ so a checked TasteGate theorem can separate classifier shift from parameter motion and loss residue.

Closure status for $\mathsf{NameCert}_{\mathsf{ClassifierFormingLearning}^{\uparrow}}$.

Constructive story: A $\mathsf{ClassifierFormingLearning}^{\uparrow}$ packet is generated from dataset/task rows, parameter-motion residue, classifier-shift evidence, loss and benchmark residue, registry export, machine-readable audit handoff, GroundCompiler audit-map handoff, TasteGate commitments, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClassifierFormingLearning}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6097.1, Definition 6097.2, and Definition 6097.3 seed the finite certified classifier-formation route over learning evidence, audit export, TasteGate commitments, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClassifierFormingLearning}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, classifier correctness for a particular model family, benchmark validity, causal explanation, or metric improvement as learning by itself.

Upgrade path: Obligation closure requires checked carrier admission, classifier-shift exposure, metric nonescape, registry export, audit-map handoff, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.ClassifierFormingLearningUp.

Chapter 6098

A Concrete Naming Certificate for $\mathsf{LocatedSequenceSupremum}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedSequenceSupremum}^{\uparrow}$ packet records the finite BEDC surface for taking a supremum of a located bounded real sequence. It sits over the sequence boundary of chapter 1415, the regular rational readback of chapter 301, the real-name seal of chapter 38, and the located-upper-bound route of chapter 1427. The packet is sequence-level supremum data; it does not assert Dedekind completeness for arbitrary subsets, open-cover compactness, a selected maximizing index, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6098.1 (Located sequence supremum carrier)**.** *A* $\mathsf{LocatedSequenceSupremum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, W, R, L, U, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *source row, carrying the bounded sequence surface to be inspected.*
2. *W is the finite window ledger listing the sequence entries whose bound and approximation requests are currently visible.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed sequence windows.*
4. *L is the located upper-bound row, recording finite evidence that requested rational cuts are either below some displayed sequence value or above a displayed upper bound.*
5. *U is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *handoff row, read only after B, W, R, L have been exposed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row naming the supremum candidate after the located sequence data have been displayed.*
7. *H records componentwise* hsame *transport for the source, window, readback, located-bound, handoff, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a rational bound request through the same rows.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedSequenceSupremum}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSequenceSupremum}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary subset completeness, a Dedekind-completeness principle, a selected maximizing index, quotient equality of real names, countable choice, or host-level supremum.

Lean4 ✓ `BEDC.Derived.LocatedSequenceSupremumUp.LocatedSequenceSupremumTasteGate single carrier alignment`

Theorem 6098.2 (Located sequence supremum NameCert obligations)**.** *For every accepted* $\mathsf{LocatedSequenceSupre}$ *carrier* $S = (B, W, R, L, U, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedSequenceSupremum}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded sequence source, finite windows, regular rational readback, located upper-bound row, located-supremum handoff, real seal, transport, replay, provenance, and local naming; window coverage requiring every supremum request to read* W *before* R*; locatedness requiring* L *to answer rational cut requests before* U *is consumed; and nonescape excluding arbitrary subset completeness, selected maximizers, quotient real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedSequenceSupremumUp.LocatedSequenceSupremumCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 6098.1. The accepted packet displays exactly $B, W, R, L, U, E, H, C, P, N$.

The sequence read begins with B and W. The bounded real sequence row supplies the source, while the finite window ledger specifies which sequence entries are available for the current rational request.

The regular readback and locatedness rows are R and L. They convert the displayed windows into $\mathsf{RegSeqRat}^{\uparrow}$ evidence and answer the lower-or-upper side of the located cut request before the $\mathsf{LocatedSupremum}^{\uparrow}$ handoff row U is exposed.

Finally, E, H, C, P, N seal, transport, replay, source, and name the same data. Since the carrier has no coordinate for arbitrary subset data, selected maximizers, quotient equality, countable choice, or ambient completeness, the listed obligations exhaust the NameCert surface. □

Theorem 6098.3 (Located sequence supremum Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedSequenceSupremum}^{\uparrow}$ *carrier receives the supremum candidate only through the route*

$$\mathsf{BoundedRealSequence}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{LocatedSupremum}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In particular, the real seal E *is read only after the bounded sequence row* B*, finite window ledger* W*, regular readback row* R*, located upper-bound row* L*, and located-supremum handoff* U *have been displayed through* H, C, P, N*.*

Proof. Start from an accepted carrier $S = (B, W, R, L, U, E, H, C, P, N)$. A $\mathsf{Real}^{\uparrow}$ consumer has access to the real seal only at the row E.

The row E is downstream of the displayed sequence route. The consumer must first read the bounded source B, inspect finite windows W, convert them through R, and consume the located cut evidence L before the $\mathsf{LocatedSupremum}^{\uparrow}$ handoff U names a supremum candidate.

Transport and replay through H and C preserve that order, while P, N only record provenance and local naming. Thus the handoff reaches $\mathsf{Real}^{\uparrow}$ without importing an arbitrary-subset completeness principle or a selected maximizing index. □

Lean4 ✓ `BEDC.Derived.LocatedSequenceSupremumUp.LocatedSequenceSupremumCarrier real handoff`

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSequenceSupremum}^{\uparrow}}$**.**

Constructive story: A LocatedSequenceSupremum$^{\uparrow}$ packet is generated from a bounded real sequence row, finite sequence windows, RegSeqRat readback, a located upper-bound row, a LocatedSupremum handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedSequenceSupremum}^{\uparrow}}$, seed)

Scope closed: Definition 6098.1, Definition 6098.2, and Definition 6098.3 seed the sequence-level located supremum route over bounded real sequences and Real-facing handoff rows.

Formal verification: FormalStatus(NameCert$_{\text{LocatedSequenceSupremum}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Dedekind completeness, arbitrary subset suprema, selected maximizing indices, quotient real equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, finite-window coverage, RegSeqRat readback, located cut response, LocatedSupremum handoff, Real seal preservation, transport, replay, provenance, and local naming for BEDC.Derived.LocatedSequenceSupremumUp.

Chapter 6099

A Concrete Naming Certificate for $\mathsf{ScottContinuous}^{\uparrow}$

Following Scott's domain-theoretic treatment of continuous maps and the later domain-theory accounts of directed-complete orders, the $\mathsf{ScottContinuous}^{\uparrow}$ packet records morphisms that preserve directed suprema and Scott-open observation as finite BEDC naming data. It sits over the domain carrier of chapter 4164, the directed-complete order surface of chapter 5905, the lattice-facing supremum discipline of chapter 5155, and the Scott-open interface of chapter 5950. The packet names a displayed continuity carrier; it does not assert a host function space, quotient map equality, selected pointwise supremum proof, arbitrary topological inverse image, or semantic completeness theorem.

Definition 6099.1 (ScottContinuous carrier)**.** *A* $\mathsf{ScottContinuous}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, G, D, O, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{DCPO}^{\uparrow}$ *or* $\mathsf{ScottDomain}^{\uparrow}$ *row, exposing the source order, directed-family schedule, supremum row, compact-basis data when present, and local NameCert surface.*
2. *T is the target* $\mathsf{DCPO}^{\uparrow}$ *or* $\mathsf{ScottDomain}^{\uparrow}$ *row, exposing the target order, directed-family schedule, supremum row, compact-basis data when present, and local NameCert surface.*
3. *G is the graph row, recording the finite source-target read used by the continuity packet rather than a host function object.*
4. *D is the directed-supremum preservation ledger. For every displayed directed schedule admitted by S, it records that the graph read in G carries the source supremum row to the target supremum row visible in T.*
5. *O is the Scott-open inverse-image row. Every accepted Scott-open observation on the target is replayed through chapter 5950 as a Scott-open observation on the source.*
6. *H records componentwise* hsame *transport for the source row, target row, graph row, directed-supremum ledger, inverse-image row, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from a source read, target read, directed-supremum preservation request, or Scott-open inverse-image request through S, T, G, D, O, H.*

8. *P is the* Pkg *provenance over* $\mathsf{ScottContinuous}^{\uparrow}$, $\mathsf{ScottDomain}^{\uparrow}$, $\mathsf{DCPO}^{\uparrow}$, $\mathsf{CompleteLattice}^{\uparrow}$, $\mathsf{ScottTopology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{ScottContinuous}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, G, D, O, H, C, P, N$. It has no coordinate for a host exponential object, quotient equality of maps, pointwise choice of directed suprema, arbitrary inverse-image topology, or unrecorded semantic continuity proof.

Lean4 ✓ `BEDC.Derived.ScottContinuousUp.ScottContinuousTasteGate single carrier alignment`

Theorem 6099.2 (ScottContinuous NameCert obligations)**.** *For every accepted* $\mathsf{ScottContinuous}^{\uparrow}$ *carrier $F = (S, T, G, D, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ScottContinuous}^{\uparrow}}$ *surface consists exactly of source admission, target admission, graph-row admission, directed-supremum preservation through D, Scott-open inverse-image replay through O, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every continuity consumer must read $S, T, G, D, O, H, C, P, N$ before treating the morphism as public.*

Proof. Project the carrier of Definition 6099.1. The source and target order data are S and T, the finite morphism presentation is G, the continuity ledgers are D and O, and the structural rows are H, C, P, N.

The directed-supremum obligation reads the directed schedule and supremum row exposed by S, then checks the target supremum row exposed by T through the graph row G. Thus preservation is attached to displayed dcpo or domain data and not to a host function space.

The Scott-open obligation reads target opens through the Scott-topology packet and replays their inverse image as source Scott-open data. The replay uses the same graph row and the same directed-supremum ledger, so it cannot introduce an arbitrary topological inverse-image operation.

Rows H, C, P, N transport, replay, source, and name this finite packet. Since quotient map equality, selected supremum witnesses, host exponentials, and semantic completeness are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 6099.3 (ScottContinuous directed-supremum stability)**.** *Every accepted* $\mathsf{ScottContinuous}^{\uparrow}$ *packet preserves directed-supremum visibility under componentwise transport and continuation replay. If a consumer reads a directed source schedule through S and the preservation ledger D, any transported or replayed read of the same continuity packet factors again through*

$$S, T, G, D, O, H, C, P, N.$$

Thus directed-supremum preservation remains a finite ledger over displayed dcpo or domain rows and never exposes a host function equality, selected pointwise lub proof, or hidden target supremum oracle.

Proof. Start with a directed-supremum preservation read. By Definition 6099.1, the read reaches D only after the source row S, target row T, and graph row G are displayed.

Use Definition 6099.2. Componentwise transport through H preserves the same carrier rows, and Cont replay through C repeats the displayed route rather than generating a second continuity source.

The provenance and local naming rows P, N identify the same packet after the replay. Because selected pointwise lub proofs, host function equality, and hidden supremum oracles are not coordinates of $S, T, G, D, O, H, C, P, N$, the transported read remains the same finite directed-supremum ledger. □

Theorem 6099.4 (ScottContinuous domain handoff)**.** *Let $F = (S, T, G, D, O, H, C, P, N)$ be an accepted* $\mathsf{ScottContinuous}^{\uparrow}$ *carrier whose source and target rows are* $\mathsf{ScottDomain}^{\uparrow}$ *packets. Any downstream domain-semantic consumer of F must first read the source domain row, target domain row, graph row, directed-supremum preservation ledger, Scott-open inverse-image row, transport, replay, provenance, and local naming rows. The handoff exports no host domain morphism, quotient map equality, selected basis enumeration, or ambient semantic interpretation.*

Proof. Project the source and target coordinates. The domain-facing information available to the consumer is precisely the pair of $\mathsf{ScottDomain}^{\uparrow}$ rows S, T plus the graph and continuity rows G, D, O.

Apply the NameCert obligations of Definition 6099.2. They force every public continuity read through $S, T, G, D, O, H, C, P, N$ before a downstream consumer can use it as a morphism of domain packets.

Finally use the Scott-domain and Scott-topology sibling surfaces cited at the chapter start. They provide directed-supremum and Scott-open observation rows as finite NameCert data. Since the continuity carrier merely links those rows and lacks a host morphism coordinate, the handoff is the displayed finite packet rather than an ambient semantic interpretation. □

Closure status for $\mathsf{NameCert}_{\mathsf{ScottContinuous}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ScottContinuous}^{\uparrow}$ packet is generated from source and target dcpo or domain rows, a graph row, directed-supremum preservation, Scott-open inverse-image replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ScottContinuous}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6099.1, Definition 6099.2, Definition 6099.3, and Definition 6099.4 seed the finite Scott-continuity interface over dcpo, domain, complete-lattice, and Scott-topology rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ScottContinuous}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function spaces, quotient map equality, selected directed-supremum witnesses, arbitrary inverse-image topology, semantic completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed-supremum preservation, Scott-open inverse-image replay, transport, replay, provenance, local naming, and a concrete Lean target for BEDC.Derived.ScottContinuousUp.

Chapter 6100

A Concrete Naming Certificate for $\mathsf{BlackBoxDecompositionCertificate}^{\uparrow}$

The $\mathsf{BlackBoxDecompositionCertificate}^{\uparrow}$ packet realizes the decomposition surface of section 9462.18 as finite NameCert data. It sits beside the classifier-preserving route of chapter 590, the classifier-typing surface of chapter 489, the self-classifier row of chapter 871, and the smuggling-pattern refusal classifier of chapter 1329. The packet names a certificate-deficit carrier for supported behavior; it is not a host interpretability theorem, not a semantic explanation oracle, not a model-internals extractor, and not a verification-hardening certificate.

Definition 6100.1 (BlackBoxDecompositionCertificate carrier)**.** *A* $\mathsf{BlackBoxDecompositionCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, S, C, F, M, L, D, E, H, R, P, N)$$

with the following displayed rows:

1. *B is the behavior row, recording the displayed behavior, scope, evidence packet, observation protocol, and stability claim being decomposed.*
2. *S is the support-candidate row, naming the classifier candidate that supports the behavior through prediction, correlation, intervention, formal constraint, or hybrid evidence.*
3. *C is the classifier row, read through* $\mathsf{ClassifierTyping}^{\uparrow}$*,* $\mathsf{ClassifierMorphism}^{\uparrow}$*, or* $\mathsf{TheorySelfClassifier}^{\uparrow}$ *before the support claim is public.*
4. *F is the certificate-field row, listing source, pattern, classifier, stability, and ledger-policy fields visible for the support claim.*
5. *M is the missing-field row, recording exactly which certificate fields are absent or incomplete for the declared scope.*
6. *L is the ledger row, recording attached ledger evidence, required residue, recorded residue, and ledger-policy status.*
7. *D is the deficit row, measuring unrecorded or incomplete critical residue in the decomposition.*
8. *E is the closed-explanation state row, requiring NameCert-completeness, ledger-completeness, scope seal, and not-claimed boundary before a behavior is no longer black-box relative to the support candidate.*

9. *H records componentwise* hsame *transport for behavior, support, classifier, field, missing-field, ledger, deficit, explanation-state, replay, provenance, and naming rows.*
10. *R records displayed* Cont *replay from a black-box query through $B, S, C, F, M, L, D, E, H$.*
11. *P is the* Pkg *provenance over* $\mathsf{BlackBoxDecompositionCertificate}^{\uparrow}$*, section 9462.18,* $\mathsf{ClassifierTyping}^{\uparrow}$*,* $\mathsf{ClassifierMorphism}^{\uparrow}$*,* $\mathsf{TheorySelfClassifier}^{\uparrow}$*,* $\mathsf{SmugglingPatternClassifier}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BlackBoxDecompositionCertificate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, S, C, F, M, L, D, E, H, R, P, N$. It has no coordinate for hidden model semantics, unrecorded classifier support, host explanation equality, oracle access to internal weights, or a formal-verification verdict.

Theorem 6100.2 (BlackBoxDecompositionCertificate NameCert obligations)**.** *For every accepted* $\mathsf{BlackBoxDecompositionCertificate}^{\uparrow}$ *carrier $Q = (B, S, C, F, M, L, D, E, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BlackBoxDecomp}}$ *surface consists exactly of behavior admission, support-candidate admission, classifier-row exposure, certificate-field exposure, missing-field exposure, ledger exposure, deficit exposure, closed-explanation-state exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A downstream black-box-decomposition consumer must read all twelve rows before claiming that a behavior has reached closed-explanation state.*

Proof. Project the carrier of Definition 6100.1. The behavior and support rows are B, S, the classifier-facing row is C, the certificate and ledger rows are F, M, L, D, E, and the structural rows are H, R, P, N.

The classifier row is read through the sibling classifier surfaces named in the chapter introduction. Thus support for the behavior cannot be treated as an unrecorded semantic relation or host interpretability judgment.

The field, missing-field, ledger, and deficit rows separate certificate completeness from ledger completeness. The closed-explanation state row E can be public only after those rows are displayed together with the scope seal and not-claimed boundary.

Rows H, R, P, N transport, replay, source, and name the same finite packet. Since hidden model semantics, internal-weight oracles, host explanation equality, and verification-hardening verdicts are absent from the carrier, these rows exhaust the local NameCert obligations. □

Theorem 6100.3 (BlackBoxDecompositionCertificate deficit non-closure)**.** *Let $Q = (B, S, C, F, M, L, D, E, H, R,$ be an accepted* $\mathsf{BlackBoxDecompositionCertificate}^{\uparrow}$ *carrier. If the missing-field row M is empty and the deficit row D records nonempty ledger deficit, then the closed-explanation state row E cannot be read as satisfied. The packet remains a ledger-deficit black-box certificate rather than a closed explanation.*

Proof. Read the carrier rows. Empty M records certificate-field completeness, while nonempty D records remaining ledger deficit for the same support claim.

Use Definition 6100.2. The closed-explanation state row E requires both certificate completeness and ledger completeness before a consumer can leave black-box status on the sealed scope.

The hypotheses supply only the first condition and deny the second. Therefore the accepted packet cannot expose E as satisfied; it remains a certificate with ledger deficit, not a closed explanation. □

Theorem 6100.4 (BlackBoxDecompositionCertificate classifier handoff)**.** *Every accepted* BlackBoxDecompositionC *packet hands its support-candidate row to downstream consumers through the displayed classifier rows C, H, R, P, N. The handoff may cite classifier typing, classifier morphism, theory self-classification, and smuggling-pattern refusal surfaces, but it exports no host interpretability relation, hidden model semantics, selected explanation object, or formal-verification verdict.*

Proof. Project the classifier row C. By Definition 6100.1, it is the only row that connects the behavior support candidate to classifier-facing siblings.

Apply the NameCert obligations of Definition 6100.2. They require the classifier row to remain attached to behavior, support, field, missing-field, ledger, deficit, and explanation-state rows before any public handoff.

Finally use the classifier-morphism, classifier-typing, theory-self-classifier, and smuggling-pattern-classifier sibling references in the chapter introduction. They provide finite classifier and refusal surfaces, not semantic access to model internals. Thus the handoff is a finite NameCert route through C, H, R, P, N and not a hidden explanation oracle. □

Falsifiable prediction: Any accepted BlackBoxDecompositionCertificateUp packet with empty missing-field family and nonempty ledger deficit cannot satisfy closed-explanation state.

Independence witness: classifiertyping, classifiermorphism, theoryselfclassifier, and smuggling-patternclassifier are non-bijective siblings: none alone carries the complete behavior, support-candidate, certificate-field, missing-field, ledger-deficit, closed-explanation-state, transport, replay, provenance, and NameCert surface exposed by $\mathsf{BlackBoxDecompositionCertificate}^{\uparrow}$.

The Lean follow-up must provide $\mathsf{Nontrivial\ BlackBoxDecompositionCertificate}^{\uparrow}$ and FieldFaithful BlackBoxDecom instances for the displayed carrier before any checked TasteGate marker can support a closure upgrade.

Closure status for $\mathsf{NameCert}_{\mathsf{BlackBoxDecompositionCertificate}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BlackBoxDecompositionCertificate}^{\uparrow}$ packet is generated from behavior, support-candidate, classifier, certificate-field, missing-field, ledger, deficit, closed-explanation-state, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BlackBoxDecompositionCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6100.1, Definition 6100.2, Definition 6100.3, and Definition 6100.4 seed the finite certificate-deficit surface for black-box decomposition.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BlackBoxDecompositionCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close hidden model semantics, host interpretability relations, selected explanation objects, formal-verification verdicts, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier-row exposure, missing-field exactness, ledger-deficit non-closure, closed-explanation-state boundary, transport, replay, provenance, local naming, Nontrivial, and FieldFaithful rows for BEDC.Derived.BlackBoxDecompositionCertificateUp.

Chapter 6101

A Concrete Naming Certificate for $\mathsf{BishopLocatedModulus}^{\uparrow}$

Following Bishop and Bridges on located constructive reals and explicit moduli for Cauchy approximation, the $\mathsf{BishopLocatedModulus}^{\uparrow}$ packet records the finite BEDC surface at which a located comparison row supplies an inspectable modulus schedule. It sits after the located-real boundary of chapter 1933, the Cauchy-modulus ledger of chapter 292, the stream-name observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names the constructive route from located comparison data to an explicit modulus row; it does not assert trichotomy, a selected real representative, quotient stream equality, ambient completeness, or a host least-bound principle.

Definition 6101.1 (Bishop located-modulus carrier)**.** *A* $\mathsf{BishopLocatedModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, \mu, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row, recording the finite apartness or interval-decision data available to the modulus request.*
2. *μ is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row extracted from that located comparison surface.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row opened by μ at the requested tolerance.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected regular rational window.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that indexes the requested precision and bounds the inspected stream window.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row consumed only after L, μ, S, R, D have been displayed.*
7. *H records componentwise* hsame *transport for located comparison, modulus, stream-window, regular readback, dyadic tolerance, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the located comparison request through modulus extraction, finite stream inspection, regular rational readback, dyadic tolerance, and the terminal Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedModulus}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host real value, countable choice over tolerances, quotient stream equality, trichotomy, ambient completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BishopLocatedModulusUp.BishopLocatedModulusTasteGate single carrier alignment`

Theorem 6101.2 (Bishop located-modulus NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedModulus}^{\uparrow}$ *carrier*

$$M = (L, \mu, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedModulus}^{\uparrow}}$ *surface consists exactly of located comparison exposure through* L*, explicit Cauchy-modulus exposure through* μ*, finite stream-window admission through* S*, regular rational readback through* R*, dyadic tolerance exactness through* D*, terminal Real seal non-escape through* E*, componentwise transport through* H*, displayed replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The tuple displays the located comparison row, the extracted modulus schedule, the finite stream window, the regular rational readback, the dyadic tolerance ledger, the terminal Real seal, and the structural rows.

The analytic obligations are ordered by the carrier. A consumer first reads L, then the schedule μ, then the window S, readback R, and tolerance ledger D before the Real seal E may be consumed.

The structural rows H, C, P, N preserve that same route under transport, replay, provenance, and local naming. Since the carrier has no coordinate for host real values, tolerance choice, quotient stream equality, trichotomy, ambient completeness, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 6101.3 (Bishop located-modulus Real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{BishopLocatedModulus}^{\uparrow}$ *packet must factor through the displayed route*

$$\mathsf{LocatedReal}^{\uparrow} \longrightarrow \mathsf{CauchyModulus}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

before it can use the local certificate. The route exports an explicit finite modulus schedule and its inspected rational windows; it exports no selected representative, quotient real equality, countable-choice selector, trichotomy row, or ambient completeness witness.

Proof. Begin with the located comparison row L. It is the only source of comparison data admitted by the carrier, so the consumer cannot begin from a host real value or a detached order decision.

Next read the modulus and tolerance rows. The schedule μ opens only the finite windows requested by the dyadic ledger D, and S records those windows as StreamName data.

Then pass through the regular readback and seal. The row R transports the inspected window into the regular rational route, and E seals the result as $\mathsf{Real}^{\uparrow}$ only after the displayed route has been read.

Finally use H, C, P, N to preserve the same finite package. No row in the carrier contains a selected representative, quotient equality, choice selector, trichotomy, or ambient completeness witness, so the Real-seal boundary cannot export any of those objects. □

Falsifiable prediction: A $\mathsf{BishopLocatedModulus}^{\uparrow}$ packet is rejected whenever a Real or completion-facing consumer claims a modulus without displaying the located comparison row, CauchyModulus schedule, DyadicRatCore tolerance, StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: located-real, cauchymodulus, streamname, regseqrat, dyadicratcore, real: no listed sibling is bijective to $\mathsf{BishopLocatedModulus}^{\uparrow}$ because this packet jointly carries the located comparison source, explicit modulus schedule, dyadic tolerance, finite observation window, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedModulus}^{\uparrow}$ packet is generated from a LocatedReal comparison row, CauchyModulus schedule, StreamName finite window, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6101.1, Definition 6101.2, and Definition 6101.3 seed the finite located-modulus route from located comparison data to explicit modulus schedules and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected real representatives, quotient real equality, countable choice over tolerances, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located comparison exposure, modulus extraction, dyadic tolerance exactness, stream-window admission, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedModulusUp.

Chapter 6102

A Concrete Naming Certificate for $\mathsf{FiniteApartnessNet}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteApartnessNet}^{\uparrow}$ packet records the finite apartness-net certificate used when a Real or completion-facing argument needs finite local separation without open-cover compactness. It reads the dyadic tolerance ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet is a finite certificate surface; it does not assert host compactness, quotient equality of real names, selected representatives, countable choice, or ambient completeness.

Definition 6102.1 (Finite apartness-net carrier)**.** *A* $\mathsf{FiniteApartnessNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (C, D, A, V, H, K, P, N)$$

with the following displayed rows:

1. *C is the finite center row, listing the displayed centers through* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback data.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, recording dyadic radii, tolerance comparisons, and the positive-radius ledger used by the net.*
3. *A is the pairwise apartness ledger, certifying apartness between distinct displayed centers at the requested dyadic scale.*
4. *V is the coverage ledger, recording that every accepted finite request is routed to a displayed center and radius before any Real-facing readback is exported.*
5. *H records componentwise* hsame *transport for centers, dyadic radii, apartness rows, coverage rows, replay, provenance, and local naming.*
6. *K records displayed* Cont *replay from a tolerance request through the same center, radius, apartness, and coverage rows.*
7. *P is the* Pkg *provenance over* $\mathsf{FiniteApartnessNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteApartnessNet}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through C, D, A, V, H, K, P, N. It has no coordinate for an open cover, a finite-subcover theorem, quotient equality of real names, a selected representative, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteApartnessNetUp.FiniteApartnessNetTasteGate single carrier alignment`

Theorem 6102.2 (Finite apartness-net NameCert obligations)**.** *For every accepted* $\mathsf{FiniteApartnessNet}^{\uparrow}$ *carrier $F = (C, D, A, V, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteApartnessNet}^{\uparrow}}$ *surface consists exactly of carrier admission for finite centers, dyadic radii, pairwise apartness, coverage, transport, replay, provenance, and local naming; radius admission through* $\mathsf{DyadicRatCore}^{\uparrow}$ *before apartness is read; coverage admission requiring each accepted request to expose a center and radius before a* $\mathsf{Real}^{\uparrow}$ *consumer sees the result; and nonescape excluding open-cover compactness, selected representatives, quotient real equality, countable choice, host real equality, and ambient completeness.*

Proof. Carrier admission is projection from Definition 6102.1. The accepted packet displays exactly C, D, A, V, H, K, P, N.

The radius and apartness obligations are read before coverage. The dyadic row D supplies the visible scale, while the apartness ledger A compares only the displayed finite centers in C at that scale.

Coverage is the row V. It can answer a finite request only by pointing back to a displayed center and dyadic radius, so a Real-facing consumer cannot read a hidden finite-subcover theorem or a selected host representative.

Finally, H, K, P, N transport, replay, source, and name the same data. Since the carrier has no coordinate for open covers, quotient real equality, countable choice, host real equality, or ambient completeness, the listed obligations exhaust the certificate surface. □

Theorem 6102.3 (Finite apartness-net RegSeqRat consumer)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteApartnessNet}^{\uparrow}$ *carrier must pass through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In particular, finite centers are read as stream names with regular rational windows, dyadic radii supply the tolerance scale, the pairwise apartness and coverage ledgers are exposed before the Real seal, and no consumer receives open-cover compactness, countable choice, quotient equality, selected representatives, host real equality, or ambient completeness.

Proof. Start from an accepted carrier $F = (C, D, A, V, H, K, P, N)$. A regular-rational consumer can see only the centers named by C and the dyadic scale named by D.

The route then exposes the finite ledgers. Pairwise apartness is read through A, and coverage is read through V only after the displayed center and radius rows have fixed the current tolerance request.

Transport and replay through H and K preserve that route, while P and N record provenance and local naming. Therefore every RegSeqRat or Real-facing read is generated by the displayed finite-net data and cannot import the excluded host principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteApartnessNet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteApartnessNet}^{\uparrow}$ packet is generated from finite centers, dyadic radii, pairwise apartness, coverage, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteApartnessNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6102.1, Definition 6102.2, and Definition 6102.3 seed the finite apartness-net route from dyadic tolerances and stream centers through RegSeqRat readback to Real-facing consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteApartnessNet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, finite-subcover extraction, quotient real equality, selected representatives, countable choice, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires center admission, dyadic-radius admission, pairwise apartness, coverage, transport, replay, provenance, and local naming for BEDC.Derived.FiniteApartnessNetUp.

Chapter 6103

A Concrete Naming Certificate for $\mathsf{MetaCICSubstitutionSpine}^{\uparrow}$

Following de Bruijn's index discipline and Barendregt's account of substitution under binders, the $\mathsf{MetaCICSubstitutionSpine}^{\uparrow}$ packet records the finite BEDC surface for the closed substitution audit fragment. It lands the audit map of chapter 9380 as a concrete NameCert spine and reads the closed-boundary packet of chapter 527. The packet is a closed-fragment substitution spine; it does not assert unrestricted substitution composition, subject reduction, host syntax quotients, hidden evaluator state, or compiler correctness.

Definition 6103.1 (MetaCIC substitution spine carrier)**.** *A* $\mathsf{MetaCICSubstitutionSpine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, V, D, Q, R, L, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed MetaCIC term row, listing the displayed source, payload, and boundary terms.*
2. *V is the de Bruijn variable ledger for the finite indices inspected by shift and substitution.*
3. *D is the cutoff-depth row recording the boundary at which closedness is tested.*
4. *Q is the closedness classifier row for the source and payload terms.*
5. *R is the closed shift row, exposed only when the closedness classifier has already been read.*
6. *L is the closed substitution row, exposed only through the same closedness classifier and depth row.*
7. *A is the closed composition audit row, recording the checked closed-fragment composition and swap surfaces.*
8. *H records componentwise* hsame *transport for terms, indices, depth, closedness, shift, substitution, composition, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay for closed substitution requests through the same rows.*
10. *P is the* Pkg *provenance over* $\mathsf{MetaCICSubstitutionSpine}^{\uparrow}$*,* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionSpine}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, V, D, Q, R, L, A, H, C, P, N$. It has no coordinate for unrestricted substitution algebra, typing preservation, subject reduction, host syntax equality, quotient terms, hidden evaluator state, or compiler correctness.

Lean4 ✓ `BEDC.Derived.MetaCICSubstitutionSpineUp.MetaCICSubstitutionSpineTasteGate single carrier alignment`

Theorem 6103.2 (MetaCIC substitution spine NameCert obligations)**.** *For every accepted* MetaCICSubstitutionSpi *carrier $S = (T, V, D, Q, R, L, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionSpine}^{\uparrow}}$ *surface consists exactly of carrier admission for displayed terms, de Bruijn indices, cutoff depth, closedness, closed shift, closed substitution, closed composition audit, transport, replay, provenance, and local naming; shift and substitution admission requiring Q and D before R or L is visible; closed-composition admission requiring A to read only the checked closed-fragment rows; and nonescape excluding unrestricted substitution composition, subject reduction, host syntax quotients, hidden evaluator state, and compiler correctness.*

Lean4 ✓ `BEDC.Derived.MetaCICSubstitutionSpineUp.MetaCICSubstitutionSpineCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 6103.1. The accepted packet displays exactly $T, V, D, Q, R, L, A, H, C, P, N$.

Closedness gates the operation rows. The rows Q and D must be exposed before the closed shift row R or the closed substitution row L can be read.

The audit row A records only the closed composition surface. It reads the already displayed operation rows and therefore cannot be reinterpreted as unrestricted substitution algebra or as a subject-reduction theorem.

Finally, H, C, P, N preserve, replay, source, and name the same finite spine. Since the carrier has no coordinate for host syntax quotients, hidden evaluator state, or compiler correctness, the listed obligations exhaust the NameCert surface. □

Theorem 6103.3 (MetaCIC substitution spine closed-term consumer)**.** *Every closed-term consumer of an accepted* $\mathsf{MetaCICSubstitutionSpine}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow} \longmapsto T, V, D, Q, R, L, A, H, C, P, N.$$

Thus a consumer may read closed shift, closed substitution, and closed composition audit data only after the closed boundary, de Bruijn index, cutoff-depth, and closedness rows have been displayed, and cannot import subject reduction, host syntax equality, quotient terms, hidden evaluator state, or compiler correctness.

Proof. Start with the closed boundary supplied by chapter 527. It gives the displayed term, closedness, shift, substitution, ledger, audit, transport, replay, provenance, and naming rows that this spine specializes.

Project the carrier rows T, V, D, Q, R, L, A. These rows force a closed-term consumer to read the de Bruijn index and cutoff-depth data before the operation rows are exposed.

Transport, replay, provenance, and local naming are then read through H, C, P, N. They preserve the same finite route, so the consumer receives only closed-fragment substitution spine data and none of the excluded host-level principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionSpine}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICSubstitutionSpine}^{\uparrow}$ packet is generated from closed MetaCIC term rows, de Bruijn index rows, cutoff-depth rows, closedness classifiers, closed shift rows, closed substitution rows, closed composition audit rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MetaCICSubstitutionSpine}\uparrow}$, seed)

Scope closed: Definition 6103.1, Definition 6103.2, and Definition 6103.3 seed the closed substitution, shift, and composition audit spine over the closed-term boundary packet.

Formal verification: FormalStatus(NameCert$_{\mathsf{MetaCICSubstitutionSpine}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.MetaCICSubstitutionSpineUp.MetaCICSubstitutionSpineCarrier\_namecert\_obligations`

Bridge status: none

Not claimed: This chapter does not close unrestricted substitution algebra, subject reduction, typing preservation, host syntax quotients, hidden evaluator state, compiler correctness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires term admission, de Bruijn index admission, cutoff-depth admission, closedness gating, closed shift, closed substitution, closed composition audit, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICSubstitutionSpineUp.

Chapter 6104

A Concrete Naming Certificate for $\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}$

The $\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}$ packet realizes the observer-expansion reading of chapter 9463 as a finite ledger for geodesic-flow windows and boundary-shadow readout. It sits after the geodesic-flow carrier of chapter 3856, the horosphere-flow ledger of chapter 4051, the boundary-shadow packet of chapter 3813, the visual-metric packet of chapter 3866, and the terminal real-name seal of chapter 38. The same finite geodesic-flow window is a downstream input for chapter 4203 when laminations read compatible flow windows and boundary-shadow rows. The packet names a finite route from geodesic flow windows to boundary-shadow ledger rows; it does not assert a host hyperbolic manifold, quotient geodesic equality, invariant measure, differentiable flow theorem, or global visual boundary.

Definition 6104.1 (Hyperbolic geodesic-flow ledger carrier)**.** *A* $\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, O, B, V, W, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row, recording the finite geodesic-flow window admitted by the packet.*
2. *O is the* $\mathsf{HorosphereFlowLedger}^{\uparrow}$ *row, recording the horosphere-side ledger that stabilizes the same window near the boundary.*
3. *B is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row, recording the boundary-shadow aperture consumed by the flow ledger.*
4. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *row, displaying the visual comparison used to read the boundary shadow.*
5. *W is the flow-window exactness row, tying the geodesic-flow segment, horosphere ledger, boundary shadow, and visual metric into one finite route.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for any displayed comparison value exported by the ledger.*
7. *H records componentwise* hsame *transport for flow, horosphere, boundary-shadow, visual-metric, window-exactness, Real-seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from flow-window admission through horosphere stabilization, boundary-shadow readback, visual-metric comparison, and the terminal Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HorosphereFlowLedger}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host hyperbolic manifold, quotient geodesic equality, invariant measure, differentiable flow theorem, global visual boundary, Lean verification, or bridge checking.

Theorem 6104.2 (Hyperbolic geodesic-flow ledger NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}$ *carrier*

$$G = (F, O, B, V, W, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}}$ *surface consists exactly of geodesic-flow window exposure through F, horosphere-ledger stabilization through O, boundary-shadow readback through B, visual-metric comparison through V, window exactness through W, Real-seal non-escape through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The tuple displays the flow window, horosphere ledger, boundary shadow, visual comparison, exactness row, Real seal, and structural rows.

The geometric obligations are finite. Row F admits the geodesic-flow segment, row O stabilizes that segment through the horosphere ledger, row B reads the boundary shadow, and row V supplies the visual comparison.

The row W binds these readings into one window-exact route before the Real seal E is available. The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming.

Since no carrier coordinate stores a host manifold, quotient geodesic equality, invariant measure, differentiable flow theorem, global visual boundary, Lean verification, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 6104.3 (Hyperbolic geodesic-flow boundary-shadow route)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}$ *packet must factor through*

$$\mathsf{HyperbolicGeodesicFlow}^{\uparrow} \longrightarrow \mathsf{HorosphereFlowLedger}^{\uparrow} \longrightarrow \mathsf{HyperbolicBoundaryShadow}^{\uparrow} \longrightarrow \mathsf{HyperbolicVisualMetric}^{\uparrow}$$

before it can export a flow comparison value. The route exports only the displayed finite flow, horosphere, boundary-shadow, visual-metric, Real-seal, transport, replay, provenance, and local naming rows.

Proof. Begin with the flow-window row F. It is the only geodesic-flow segment admitted by the carrier, so the consumer cannot read a flow value from a host manifold or global flow object.

Next pass through O, B, V. The horosphere ledger records the boundary-near stabilization, the boundary-shadow row supplies the aperture, and the visual-metric row supplies the comparison surface.

Then use W and E. The exactness row binds the same flow segment to the same horosphere and shadow rows, and the Real seal is consumed only after that finite route has been displayed.

Finally apply the structural rows H, C, P, N. They preserve the route as packet data and add no coordinate for quotient geodesic equality, invariant measure, differentiable flow, or global visual boundary. □

Falsifiable prediction: A $\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}$ packet is rejected whenever an observer-expansion consumer claims a flow comparison without displaying geodesic-flow, horosphere-flow-ledger, boundary-shadow, visual-metric, Real-seal, transport, replay, provenance, and local NameCert rows.

Independence witness: horosphere-flow-ledger, hyperbolic-boundary-shadow: $\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}$ is not bijective to either sibling because it jointly carries the geodesic-flow window, horosphere stabilization ledger, boundary-shadow aperture, visual comparison, Real seal, transport, replay, provenance, and local naming rows in one flow-ledger packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}}$ **·**

Constructive story: A $\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}$ packet is generated from a HyperbolicGeodesicFlow window, HorosphereFlowLedger row, HyperbolicBoundaryShadow aperture, HyperbolicVisualMetric comparison, flow-window exactness row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6104.1, Definition 6104.2, and Definition 6104.3 seed the finite geodesic-flow ledger route through horosphere stabilization, boundary-shadow readback, visual-metric comparison, and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicFlowLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host hyperbolic manifolds, quotient geodesic equality, invariant measures, differentiable flow theorems, global visual boundaries, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, geodesic-flow exposure, horosphere-ledger stabilization, boundary-shadow readback, visual-metric comparison, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicGeodesicFlowLedgerUp.

Chapter 6105

A Concrete Naming Certificate for $\mathsf{FiniteMetricCover}^{\uparrow}$

Following Bishop and Bridges on constructive compact metric spaces and finite covers, the $\mathsf{FiniteMetricCover}^{\uparrow}$ packet records a finite family of metric balls together with the displayed radius and coverage witnesses needed by compactness consumers. It sits between the metric carrier of chapter 57, the compact source rows of chapter 129, the finite-net coverage surface of chapter 127, the closed-ball boundary rows of chapter 1451, and the real-radius seal of chapter 38. The packet names finite cover data only; it does not assert open-cover compactness, choice of subcovers, quotient point equality, host compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 6105.1 (FiniteMetricCover carrier)**.** *A* $\mathsf{FiniteMetricCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, K, T, B, R, G, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row carrying the point carrier and distance classifier.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose compactness consumers read the finite cover through this packet.*
3. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row that supplies center admission and tolerance scheduling.*
4. *B is the finite* $\mathsf{ClosedMetricBall}^{\uparrow}$ *row family, with one displayed center and positive radius ledger for each cover cell.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *or dyadic-real radius seal row attached to the ball radii and requested tolerance.*
6. *G is the finite cover membership bundle, naming the displayed cells and their coverage witnesses as a closed* ProbeBundle*.*
7. *H records componentwise* hsame *transport for M, K, T, B, R, G and the structural rows.*
8. *C records displayed* Cont *replay from the metric source through the finite cover bundle to downstream compactness consumers.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteMetricCover}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{TotallyBounded}^{\uparrow}$*,* $\mathsf{ClosedMetricBall}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* ProbeBundle*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricCover}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open covers, selected subcovers outside G, quotient point equality, host compactness, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.FiniteMetricCoverUp.FiniteMetricCoverTasteGate single carrier alignment`

Theorem 6105.2 (FiniteMetricCover NameCert obligations)**.** *For every accepted* $\mathsf{FiniteMetricCover}^{\uparrow}$ *carrier*

$$F = (M, K, T, B, R, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteMetricCover}^{\uparrow}}$ *surface consists exactly of metric source admission, compact-metric source exposure, total-bounded center scheduling, closed metric ball boundary rows, positive radius sealing, finite membership-bundle coverage, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6105.1. The accepted packet exposes only the metric source, compact source, total-bounded finite-net schedule, closed ball family, radius seal, finite membership bundle, and structural BEDC rows.

The ball family B is read together with the radius row R. Thus each cover cell has a displayed center, a displayed radius, and a closed metric boundary row before it can be consumed by compactness-facing routes.

The membership bundle G supplies the finite coverage witnesses. The rows H, C, P, N transport, replay, source, and name that same displayed route, so no arbitrary open cover, detached selected subcover, quotient equality, host compactness, or ambient completeness coordinate is introduced. □

Theorem 6105.3 (FiniteMetricCover refinement stability)**.** *Let*

$$F = (M, K, T, B, R, G, H, C, P, N)$$

and

$$F' = (M', K', T', B', R', G', H', C', P', N')$$

be accepted $\mathsf{FiniteMetricCover}^{\uparrow}$ *carriers. If componentwise* hsame *transport identifies* M, K, T, B, R, G *with* M', K', T', B', R', G' *and the second cover bundle refines the first by displayed membership witnesses, then every* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{ClosedMetricBall}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of* F' *factors through the same finite cover route as a consumer of* F.

In particular, refinement may split cells and decrease displayed radii, but it cannot add a host open-cover object, choice-selected subcover, quotient point equality, ambient compactness theorem, or detached real-completeness row.

Proof. Start with the two accepted carriers and read their common transported rows. The hsame hypotheses identify the metric source, compact source, total-bounded schedule, closed-ball family, radius seal, and finite membership bundle before any consumer reads a refinement.

The displayed refinement witnesses attach each cell of G' to a cell of G. A consumer of the refined packet therefore reaches metric and compact data through M, K, T, reads ball boundaries through B' and R', and then returns to the original finite cover route through the displayed membership map into G.

Finally use the structural rows H, C, P, N and H', C', P', N' to replay and name the same route. Since both carriers contain only finite bundle data and structural BEDC rows, the refinement cannot export any excluded open-cover, choice, quotient, host-compactness, or real-completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMetricCover}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteMetricCover}^{\uparrow}$ packet is generated from a MetricUp source row, CompactMetricUp source exposure, TotallyBoundedUp finite-net scheduling, ClosedMetricBallUp cell rows, RealUp radius seals, finite ProbeBundle coverage witnesses, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteMetricCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6105.1, Definition 6105.2, and Definition 6105.3 seed the finite metric cover route used by compact metric and closed-ball consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteMetricCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, choice-selected subcovers, quotient point equality, host compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked metric source admission, compact source exposure, finite-net scheduling, closed-ball coverage, radius sealing, refinement stability, transport, replay, provenance, and local naming for BEDC.Derived.FiniteMetricCoverUp.

Chapter 6106

A Concrete Naming Certificate for $\mathsf{HahnMazurkiewiczBoundary}^{\uparrow}$

Following Hahn and Mazurkiewicz, the $\mathsf{HahnMazurkiewiczBoundary}^{\uparrow}$ packet records the finite boundary certificate through which a compact connected locally connected metric continuum may be read before a Peano-continuum or Peano-curve consumer treats it as curve-facing data. It sits between the Peano continuum surface of chapter 2160, the finite curve-parametrization route of chapter 2078, the compact metric source of chapter 129, the continuous-map rows of chapter 130, and the terminal real-name seal of chapter 38. The packet names the boundary ledger needed for the classical Hahn–Mazurkiewicz handoff without importing an ambient topological quotient, host compactness theorem, selected parametrization, countable-choice schedule, or unrestricted real equality.

Definition 6106.1 (Hahn-Mazurkiewicz boundary carrier)**.** *A* $\mathsf{HahnMazurkiewiczBoundary}^{\uparrow}$ *carrier is a finite BEDC packet*

$$H = (K, M, C, P, B, E, T, R, N)$$

with the following visible rows:

1. *K is a compact metric source row read through* $\mathsf{CompactMetric}^{\uparrow}$*;*
2. *M is a Peano-continuum local connectedness and connectedness ledger;*
3. *C is a finite* $\mathsf{ContinuousMap}^{\uparrow}$ *curve-read row from a compact interval-facing source into K;*
4. *P is the Peano-curve parametrization boundary row that records surjective coverage only through displayed windows;*
5. *B is the boundary classifier row comparing compact-metric neighborhoods by finite* BHist *support and componentwise* hsame *transport;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint and radius data;*
7. *T is the displayed* Cont *replay ledger for boundary refinements;*
8. *R is the* Pkg *provenance row; and*
9. *N is the local* $\mathsf{NameCert}$ *row naming the packet.*

The carrier contains no host quotient space, selected Peano parametrization, global compactness theorem, countable-choice selector, quotient real equality, or ambient completeness coordinate.

Lean4 ✓ BEDC.Derived.HahnMazurkiewiczBoundaryUp.HahnMazurkiewiczBoundaryTasteGate single carrier alignment

Theorem 6106.2 (Hahn-Mazurkiewicz boundary NameCert obligations)**.** *For every carrier $H = (K, M, C, P, B, E, T, R, N)$ of Definition 6106.1, the source, classifier, stability, replay, provenance, and local naming obligations for* $\mathsf{HahnMazurkiewiczBoundary}^{\uparrow}$ *are discharged on the displayed finite rows. In particular, compact-metric reads remain on K, Peano-continuum reads remain on M, continuous-map and Peano-curve reads remain on C and P, boundary comparisons remain on B and E, and transport/replay/provenance/naming remain on T, R, N.*

Proof. Project the carrier rows of Definition 6106.1. The compact metric source, Peano-continuum ledger, continuous-map row, Peano-curve boundary, boundary classifier, real seal, replay ledger, provenance row, and local NameCert row are all displayed coordinates of the same finite packet.

The classifier obligation is read through B with BHist support and componentwise hsame transport, while endpoint and radius comparisons pass through E before any Real-facing consumer sees them. Replay is confined to T, and provenance is confined to R.

Thus every NameCert obligation is witnessed by the listed rows. Since the carrier has no coordinate for a host quotient space, selected parametrization, global compactness theorem, countable-choice selector, quotient real equality, or ambient completeness, none of those claims can be exported by the certificate. □

Theorem 6106.3 (Hahn-Mazurkiewicz boundary Peano-continuum handoff)**.** *Every* $\mathsf{PeanoContinuum}^{\uparrow}$ *or* $\mathsf{PeanoCurve}^{\uparrow}$ *consumer that reads a* $\mathsf{HahnMazurkiewiczBoundary}^{\uparrow}$ *packet must factor through the compact metric source of chapter 129, the continuous-map rows of chapter 130, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before it consumes the Peano-continuum and Peano-curve boundary rows. The handoff exports a finite boundary certificate, not a host Hahn–Mazurkiewicz theorem, not a selected surjection, and not an unrestricted quotient equality of points.*

Proof. Start with the carrier decomposition. Any consumer receives the compact metric row K, continuous-map row C, Peano-continuum ledger M, Peano-curve boundary P, boundary classifier B, and Real seal E as separate visible rows.

The Peano-continuum side can inspect local connectedness and connectedness only through M, while the Peano-curve side can inspect coverage only through P after C has supplied the finite continuous-map read. Endpoint and radius data pass through E before the boundary classifier B is consumed.

Therefore the handoff factors through the compact metric, continuous-map, and Real sibling chapters before either Peano consumer reads the boundary packet. The missing host quotient, selected surjection, and unrestricted equality coordinates remain outside the exported interface. □

Closure status for $\mathsf{NameCert}_{\mathsf{HahnMazurkiewiczBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{HahnMazurkiewiczBoundary}^{\uparrow}$ packet is generated from a compact metric source, a Peano-continuum ledger, a continuous-map row, a Peano-curve coverage boundary, a boundary classifier, a Real seal, displayed replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HahnMazurkiewiczBoundary}^{\uparrow}}, \mathsf{scopedClosed})$

Scope closed: Definition 6106.1, Definition 6106.2, and Definition 6106.3 bind the finite compact-metric, Peano-continuum, Peano-curve, continuous-map, boundary-classifier, Real-seal, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HahnMazurkiewiczBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host Hahn–Mazurkiewicz theorem, selected Peano surjection, host quotient topology, global compactness theorem, countable-choice selector, quotient real equality, ambient Real completeness, or a standard bridge.

Upgrade path: Formal verification can encode carrier admission, boundary classifier transport, continuous-map replay, Peano-continuum handoff, Peano-curve handoff, Real-seal factorization, and NameCert obligations for the displayed packet.

Chapter 6107

A Concrete Naming Certificate for $\mathsf{ConstantRegSeqRat}^{\uparrow}$

Following Bishop and Bridges on constant Cauchy names, the $\mathsf{ConstantRegSeqRat}^{\uparrow}$ packet records the stationary regular-Cauchy construction that sends one dyadic rational point to the regular rational name constantly equal to that point. It sits between the finite stream carrier of chapter 126, the regular rational readback of chapter 301, the dyadic point rows of chapter 291, and the terminal real-name seal of chapter 38. The packet supplies a visible source object for constant embedding routes without quotient stream equality, selected limits, host real equality, or ambient completion.

Definition 6107.1 (ConstantRegSeqRat carrier)**.** *A* $\mathsf{ConstantRegSeqRat}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (D, S, R, H, K, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *point row, naming the dyadic rational endpoint whose constant regular name is being formed.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *constant schedule row, recording that every inspected finite window reads the same point row D.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, carrying the stationary Cauchy proof rows and the dyadic tolerance comparisons needed by the regular rational readback.*
4. *H records pointwise* hsame *transport for the dyadic point, constant schedule, regularity row, provenance row, and local naming row.*
5. *K records displayed* Cont *replay from the point row through the constant schedule into the regularity row.*
6. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
7. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstantRegSeqRat}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, S, R, H, K, P, N. It has no coordinate for quotient stream equality, selected representatives, selected limits, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a hidden nonstationary tail.*

Lean4 ✓ `BEDC.Derived.ConstantRegSeqRatUp.ConstantRegSeqRatTasteGate single carrier alignment`

Theorem 6107.2 (ConstantRegSeqRat NameCert obligations)**.** *For every accepted* $\mathsf{ConstantRegSeqRat}^{\uparrow}$ *carrier* $C = (D, S, R, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ConstantRegSeqRat}^{\uparrow}}$ *surface consists exactly of five obligation rows: dyadic point exposure through* D*, constant schedule exposure through* S*, stationary regularity exposure through* R*, transport and replay through* H, K*, and provenance with local naming through* P, N*.*

Proof. Project the carrier of Definition 6107.1. The point row D, schedule row S, regularity row R, transport row H, replay row K, provenance row P, and local name row N are the only displayed coordinates.

The source row is dyadic. A consumer must first read D as the point supplied by chapter 291, not as a host rational endpoint outside the packet.

The schedule row is constant. The $\mathsf{StreamName}^{\uparrow}$ row S repeats the same displayed point on every finite window, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R records the stationary regularity proof rows for that schedule.

Finally H, K, P, N transport, replay, source, and name the same finite route. Since no extra coordinate stores quotient stream equality, selected limits, host equality, or ambient completion data, the five obligation groups exhaust the local NameCert surface. □

Theorem 6107.3 (ConstantRegSeqRat regularity stability)**.** *Let* $C = (D, S, R, H, K, P, N)$ *and* $C' = (D', S', R', H', K', P', N')$ *be accepted* $\mathsf{ConstantRegSeqRat}^{\uparrow}$ *carriers. If the point rows* D *and* D' *compare by the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *classifier and the constant schedules are transported pointwise through* H, H'*, then the stationary* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row of* C *transports to the stationary regularity row of* C'*. Thus a constant stream preserves regular Cauchy regularity under pointwise classifier transport.*

Proof. Read the point comparison first. The only source data for either carrier is the displayed dyadic point row, so a pointwise classifier comparison relates every inspected constant-window entry.

Use the schedule rows next. Because S and S' are constant schedules, transporting the point comparison along H and H' transports every finite StreamName window without introducing a new tail or selector.

The regularity rows are stationary. The same dyadic tolerance comparison that witnesses the pointwise transport also witnesses each regular Cauchy window, since both schedules repeat the transported point. The replay rows K, K' preserve this route into the $\mathsf{RegSeqRat}^{\uparrow}$ readback.

Therefore the accepted regularity row transports from R to R'. The argument uses only displayed point, schedule, regularity, transport, replay, provenance, and local naming rows, so it adds no quotient stream equality or host real equality. □

Theorem 6107.4 (ConstantRegSeqRat Real-seal nonescape)**.** *For every accepted* $\mathsf{ConstantRegSeqRat}^{\uparrow}$ *carrier* $C = (D, S, R, H, K, P, N)$*, any* $\mathsf{Real}^{\uparrow}$*-facing constant-embedding read must consume the displayed route*

$$D, S, R, H, K, P, N$$

before the terminal $\mathsf{Real}^{\uparrow}$ *seal is available. Thus the read passes through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *point row, the* $\mathsf{StreamName}^{\uparrow}$ *constant schedule, the stationary* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, pointwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{ConstantRegSeqRat}^{\uparrow}}$ *support.*

The terminal seal exposes no quotient stream equality, selected limit, host real equality, arbitrary Cauchy-name existence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 6107.1. The only public source rows are the displayed dyadic point row D, constant schedule row S, stationary regularity row R, transport row H, replay row K, provenance row P, and local naming row N.

Apply Definition 6107.2. It identifies these rows as the full local NameCert obligation surface, so a Real-facing constant embedding cannot read a hidden representative or a second completion coordinate.

Use Definition 6107.3 for the stationary regularity step. The constant schedule transports each finite window through the same dyadic point row and the same regularity ledger, preserving the ordered route into the terminal seal.

Therefore every accepted Real-facing read consumes D, S, R, H, K, P, N before the $\mathsf{Real}^{\uparrow}$ seal is available. Since no accepted coordinate records quotient stream equality, selected limits, host equality, arbitrary Cauchy-name existence, or ambient completeness, none of those objects is exposed by the seal. □

Falsifiable prediction: Every accepted $\mathsf{ConstantRegSeqRat}^{\uparrow}$ read must expose a DyadicRatCore point row, a StreamName constant schedule, a stationary RegSeqRat regularity row, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any Real-facing constant embedding may consume it.

Independence witness: dyadicratcore, streamname, regseqrat, real: none is bijective with $\mathsf{ConstantRegSeqRat}^{\uparrow}$ because this packet jointly carries a dyadic point, a constant StreamName schedule, stationary RegSeqRat regularity, transport, replay, provenance, and local naming for the same constant-name construction.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstantRegSeqRat}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstantRegSeqRat}^{\uparrow}$ packet is generated from a DyadicRatCore point row, a constant StreamName schedule, stationary RegSeqRat regularity rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstantRegSeqRat}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6107.1, Definition 6107.2, and Definition 6107.3 seed the finite stationary regular-Cauchy construction over DyadicRatCore, StreamName, RegSeqRat, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstantRegSeqRat}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, selected limits, quotient stream equality, host real equality, arbitrary Cauchy-name existence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, constant schedule exposure, stationary RegSeqRat regularity, pointwise transport stability, replay, provenance, local naming, and non-escape for BEDC.Derived.ConstantRegSeqRatUp.

Chapter 6108

A Concrete Naming Certificate for $\mathsf{CompactnessCompletionRoute}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley compact-metric practice, the CompactnessCompletion packet records the finite route by which compact-metric finite-net data are read into completion-facing Cauchy windows before any real seal or completion boundary may be consumed. It sits over the compact metric source of chapter 129, the complete-metric boundary of chapter 128, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the Cauchy completion surface of chapter 360. The chapter names a finite bridge from compact finite covers to completion-facing Cauchy readback; it does not assert open-cover compactness, choose a convergent subnet, quotient Cauchy streams, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6108.1 (Compactness completion route carrier)**.** *A* $\mathsf{CompactnessCompletionRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, T, C, W, R, E, H, Q, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only the finite metric observations and compact-source identifiers read by the packet.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net coverage row, or equivalently the finite net schedule attached to the displayed compact metric source.*
3. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *or Cauchy-completion boundary row that records where completion-facing Cauchy requests may land after the finite-net route has been read.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row whose displayed observations are generated from the finite-net coverage schedule.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W and the dyadic tolerance ledger, before any real seal is public.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *or completion-seal row reached only after M, T, C, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the compact source, finite-net coverage, completion boundary, stream windows, regular readback, real seal, continuation, provenance, and local naming rows.*

8. *Q records displayed* Cont *replay from compact-source finite nets through completion-facing Cauchy windows and back to the same regular readback rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactnessCompletionRoute}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactnessCompletionRoute}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, a selected subnet, quotient stream equality, countable choice, host metric completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactnessCompletionRouteUp.CompactnessCompletionRouteTasteGate single carrier alignment`

Theorem 6108.2 (Compactness completion route NameCert obligations)**.** *For every accepted* $\mathsf{CompactnessCompletionRoute}^{\uparrow}$ *carrier* $K = (M, T, C, W, R, E, H, Q, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactnessCompletionRou}}$ *surface consists exactly of carrier admission for the ten displayed rows; finite-net coverage admission from M to T; completion-boundary admission through C; stream-window generation through W; regular rational readback through R; terminal real or completion sealing through E; componentwise transport through H; displayed replay through Q; provenance through P; and local naming through N.*

Lean4 ✓ `BEDC.Derived.CompactnessCompletionRouteUp.CompactnessCompletionRouteCarrier namecert obligations`

Proof. Project the carrier of Definition 6108.1. The analytic rows are precisely the compact source M, finite-net coverage T, completion boundary C, stream windows W, regular readback R, and terminal seal E.

The NameCert obligations follow the order of those rows. A consumer first reads the compact metric source, then the finite-net coverage row, then the completion-facing boundary, and only then the stream and regular-rational readback rows.

The structural rows H, Q, P, N transport, replay, source, and name the same route. Since no excluded object appears in the carrier, the obligation surface cannot export open-cover compactness, selected subnets, quotient streams, countable choice, host completion, or ambient real completeness. □

Theorem 6108.3 (Compactness completion nonescape)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompactnessCompletionRoute}^{\uparrow}$ *carrier must read the visible route*

$$M, T, C, W, R, E, H, Q, P, N.$$

In particular, a consumer moving from $\mathsf{CompactMetric}^{\uparrow}$ *finite-net data toward* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *readback cannot bypass the displayed stream windows, cannot substitute a detached Cauchy representative, and cannot import open-cover compactness or ambient real completeness.*

Lean4 ✓ `BEDC.Derived.CompactnessCompletionRouteUp.CompactnessCompletionRouteNonescape`

Proof. Start from the compact metric source M. The only compactness-facing data admitted by the packet are the finite-net coverage rows in T, so any completion-facing read begins with the displayed finite schedule rather than with an open-cover theorem.

Next read C, W, R, E in order. The completion boundary C identifies the permitted Cauchy-facing landing surface, the stream windows W display the finite observations, the regular readback R records the Cauchy name data, and the seal E remains terminal.

Finally inspect H, Q, P, N. These rows preserve the same route under transport and replay. They provide no coordinate for a detached representative, quotient stream, selected subnet, host completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so the consumer cannot leave the displayed carrier. □

Theorem 6108.4 (Compact finite-net completion handoff)**.** *Let $K = (M, T, C, W, R, E, H, Q, P, N)$ be an accepted* $\mathsf{CompactnessCompletionRoute}^{\uparrow}$ *carrier. The finite-net coverage row T and the stream-window row W determine the only handoff by which compact-metric data enter completion-facing Cauchy readback. Thus every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *read from the packet is tied to the same compact source M, completion boundary C, transport row H, replay row Q, provenance row P, and local name N.*

Lean4 ✓ `BEDC.Derived.CompactnessCompletionRouteUp.CompactnessCompletionRouteFiniteNetHandoff`

Proof. Read T as the finite-net coverage admitted over the compact metric source M. It records the displayed coverage schedule and does not itself choose a limit point or completed object.

The stream windows W are generated from that schedule before the regular readback R can be consumed. The handoff to C and E therefore carries exactly the finite windows and regular Cauchy readback named by the carrier.

Transport, replay, provenance, and local naming preserve the same rows. Any readback that omits T or W would use a coordinate absent from Definition 6108.1, so it is not a read of the accepted packet. □

Falsifiable prediction: An accepted $\mathsf{CompactnessCompletionRoute}^{\uparrow}$ consumer that reaches $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ completion-facing data without displaying the compact finite-net row T and the $\mathsf{StreamName}^{\uparrow}$ window row W refutes the carrier surface.

Independence witness: compactmetric, completemetric, streamname, regseqrat, dyadicrat-core, real, real-cauchy-completion: no listed sibling supplies the whole ten-row packet $K = (M, T, C, W, R, E, H, Q, P, N)$, because each sibling contributes only a compact source, completion boundary, finite window, regular readback, dyadic ledger, real seal, or completion-facing boundary while this chapter binds the finite-net route through transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactnessCompletionRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactnessCompletionRoute}^{\uparrow}$ packet is generated from a compact metric source row, finite-net coverage row, completion boundary row, stream-window row, RegSeqRat readback row, Real or completion seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactnessCompletionRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6108.1, Definition 6108.2, Definition 6108.3, and Definition 6108.4 seed the finite compactness-to-completion readback route over compact-source, finite-net, completion-boundary, stream-window, regular-readback, seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactnessCompletionRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subnet extraction, quotient Cauchy streams, countable choice, host metric completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{CompactnessCompletionRoute}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, finite-net coverage admission, completion-boundary admission, stream-window generation, regular readback, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactnessCompletionRouteUp.

Chapter 6109

A Concrete Naming Certificate for $\mathsf{NewtonPolygon}^{\uparrow}$

Following Newton and Dumas, the $\mathsf{NewtonPolygon}^{\uparrow}$ packet records the finite lower-hull surface attached to a displayed polynomial with valued coefficients. It sits after the coefficient carrier of chapter 50, the dyadic valuation rows of chapter 2106, the non-archimedean source of chapter 100, the comparison surface of chapter 54, the convex carrier of chapter 208, and the finite face ledger of chapter 209. The packet names a finite valuation/polytope certificate rather than a host convex-hull oracle, algebraic-closure theorem, Puiseux expansion chooser, quotient polynomial equality, or selected root branch.

Definition 6109.1 (NewtonPolygon carrier)**.** *A* $\mathsf{NewtonPolygon}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, V, T, Q, F, S, H, C, P, N)$$

with the following displayed rows:

1. *A is the polynomial coefficient row, read through the normalized coefficient surface of* $\mathsf{Poly}^{\uparrow}$*.*
2. *V is the dyadic valuation row for every displayed nonzero coefficient, read through* $\mathsf{DyadicValuation}^{\uparrow}$ *and the surrounding* $\mathsf{Padic}^{\uparrow}$ *scale source.*
3. *T is the* $\mathsf{TotalOrder}^{\uparrow}$ *comparison ledger ordering exponent and valuation pairs without importing trichotomy outside the displayed row.*
4. *Q is the lower convex hull row, a finite* $\mathsf{ConvexSet}^{\uparrow}$ *and* $\mathsf{Polytope}^{\uparrow}$ *face packet over the point ledger (i, V_i).*
5. *F is the finite lower-face ledger selecting exactly the faces visible from below.*
6. *S is the slope ledger, recording for each lower face the displayed ordered valuation difference and exponent-length readback.*
7. *H records componentwise* hsame *transport for coefficient, valuation, order, lower-hull, face, slope, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from coefficient inspection through valuation exposure, order comparison, lower-hull admission, face selection, slope reading, transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{NewtonPolygon}^{\uparrow}$*,* $\mathsf{Poly}^{\uparrow}$*,* $\mathsf{DyadicValuation}^{\uparrow}$*,* $\mathsf{Padic}^{\uparrow}$*,* $\mathsf{TotalOrder}^{\uparrow}$*,* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{Polytope}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{NewtonPolygon}^{\uparrow}}$ *row.*

The classifier reads two accepted carriers only through $A, V, T, Q, F, S, H, C, P, N$. It has no coordinate for host convex-hull computation, quotient polynomial equality, selected roots, algebraic closure, Puiseux branches, ambient real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.NewtonPolygonUp.NewtonPolygonTasteGate single carrier alignment`

Theorem 6109.2 (NewtonPolygon NameCert obligations)**.** *For every accepted* $\mathsf{NewtonPolygon}^{\uparrow}$ *carrier $G = (A, V, T, Q, F, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{NewtonPolygon}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the polynomial coefficient row, dyadic valuation rows, total-order comparisons, lower convex hull, lower-face ledger, slope ledger, transport, replay, provenance, and local naming rows;*
2. *valuation readback, requiring every displayed coefficient used by the polygon to expose its dyadic valuation through V before it contributes to Q or S;*
3. *lower-hull stability, requiring componentwise* hsame *transport of coefficient valuations and order comparisons to transport the lower convex hull row Q and the finite lower-face ledger F;*
4. *face-slope classifier transport, requiring each accepted lower face to read its slope from the same ordered endpoint valuations and exponent-length row before a consumer can classify a side of the polygon;*
5. *ledger nonescape, excluding host powersets of points, quotient polynomial equality, host convex-hull or polytope algorithms, selected roots, algebraic closure, Puiseux branch selection, ambient real completeness, Lean verification, and bridge checking.*

No Newton-polygon obligation is stored outside $A, V, T, Q, F, S, H, C, P, N$.

Proof. Project the accepted carrier. The polynomial row A supplies the finite coefficient list, while V supplies valuation readback only for coefficients displayed by that list and the surrounding p-adic or dyadic scale rows.

Read the comparison and hull rows next. The total-order row T compares the finite exponent-valuation pairs, and the convex/polytope rows Q, F record the lower hull and its lower faces as finite BEDC ledgers rather than as an ambient convex-hull computation.

For each lower face, the slope ledger S reads the two endpoint valuations and the finite exponent-length row before any classifier result is exported. Componentwise hsame transport in H and displayed replay in C preserve that same route across accepted carriers.

Finally inspect P and N. They record provenance and local naming for precisely the displayed rows A, V, T, Q, F, S, H, C, and the carrier contains no coordinate for host powersets, quotient polynomial equality, selected roots, algebraic closure, Puiseux branch choice, ambient real completeness, Lean verification, or bridge checking. The listed rows therefore exhaust the $\mathsf{NewtonPolygon}^{\uparrow}$ NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{NewtonPolygon}^{\uparrow}}$.

Constructive story: A $\mathsf{NewtonPolygon}^{\uparrow}$ packet is generated from finite polynomial coefficient rows, dyadic valuation rows, total-order comparisons, lower convex hull and face rows, slope ledger rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NewtonPolygon}^{\uparrow}}$, seed)

Scope closed: Definition 6109.1 and Definition 6109.2 seed the finite valuation/polytope certificate surface over polynomial, dyadic valuation, p-adic, total-order, convex-set, and polytope rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NewtonPolygon}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim algebraic closure, root existence, Puiseux expansions, host convex-hull computation, quotient polynomial equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, valuation readback, lower-hull stability, face-slope classifier transport, provenance, and ledger exhaustion for BEDC.Derived.NewtonPolygonUp.

Chapter 6110

A Concrete Naming Certificate for $\mathsf{DiniDerivativeWindow}^{\uparrow}$

Following Saks and Bishop–Bridges constructive analysis, the $\mathsf{DiniDerivativeWindow}^{\uparrow}$ packet records the finite window surface by which a real-valued interval observation exposes upper and lower Dini rows before any differentiability-boundary consumer may read them. It sits below the broader Denjoy–Young–Saks boundary of chapter 5829, and it uses the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation schedule of chapter 126, and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291. The chapter names only a finite Dini-window carrier; it does not claim measure-theoretic alternatives, almost-everywhere differentiability, selected derivatives, or ambient real completeness.

Definition 6110.1 (DiniDerivativeWindow carrier)**.** *A* $\mathsf{DiniDerivativeWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (I, F, U, L, O, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval-cell row naming the inspected source cell and its endpoint readback surface.*
2. *F is the function-observation window row, storing the finite source-target observations visible at the inspected cell.*
3. *U is the upper Dini row, containing the displayed upper right, upper left, and two-sided upper difference-quotient bounds for the window.*
4. *L is the lower Dini row, containing the corresponding lower right, lower left, and two-sided lower bounds.*
5. *O is the oscillation cell, recording the finite comparison between the upper and lower rows at the displayed tolerance scale.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that orders the finite observations.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the scheduled rational observations.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the windowed difference quotients.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal visible only after I, F, U, L, O, S, R, D have been replayed.*
10. *H records componentwise* hsame *transport for the interval, observation, Dini-row, oscillation, schedule, readback, tolerance, seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from a Dini-window request through finite observations, regular readback, dyadic tolerance, and the Real seal.*
12. *P is the* Pkg *provenance over* $\mathsf{DiniDerivativeWindow}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniDerivativeWindow}^{\uparrow}}$ *row.*

The carrier has no coordinate for a measure structure, an almost-everywhere classifier, a selected derivative, quotient real equality, trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.DiniDerivativeWindowUp.DiniDerivativeWindowTasteGate single carrier alignment`

Theorem 6110.2 (DiniDerivativeWindow NameCert obligations)**.** *For every accepted* $\mathsf{DiniDerivativeWindow}^{\uparrow}$ *carrier* $W = (I, F, U, L, O, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DiniDerivativeWindow}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the interval cell, function-observation window, upper Dini row, lower Dini row, oscillation cell, StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance, Real seal, transport, replay, provenance, and local naming rows;*
2. *Dini-row separation, requiring the upper row U and lower row L to remain distinct visible rows before an oscillation cell can compare them;*
3. *schedule-readback exactness, requiring every inspected observation to pass through S and R before the tolerance ledger D is consulted;*
4. *Real-seal handoff, requiring E to remain downstream of the finite Dini window and never upstream of it;*
5. *ledger refusal, excluding measure-theoretic alternatives, almost-everywhere claims, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 6110.1. The packet displays exactly the interval, observation, upper Dini, lower Dini, oscillation, schedule, readback, tolerance, Real-seal, transport, replay, provenance, and local naming rows.

The Dini-row separation is forced by the row list. The oscillation row O reads both U and L, but neither row is identified with the other, and neither can be replaced by the schedule, readback, tolerance, or seal rows.

Replay by C gives the only consumer route. A request passes through I, F, U, L, O, S, R, D before it can reach E, while H, P, N transport, source, and name the same route. Hence no off-packet measure principle, selected derivative, quotient equality, or completeness coordinate can supply an additional obligation. □

Theorem 6110.3 (DiniDerivativeWindow Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-,* $\mathsf{RegSeqRat}^{\uparrow}$*-, or* $\mathsf{StreamName}^{\uparrow}$*-facing read of an accepted* $\mathsf{DiniDerivativeWindow}^{\uparrow}$ *packet factors through the finite route*

$$I, F, U, L, O, S, R, D \longmapsto E \longmapsto H, C, P, N.$$

Thus a consumer can inspect interval cells, function-observation windows, upper and lower Dini rows, oscillation cells, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance rows, a terminal Real seal, transport, replay, provenance, and local naming. It cannot read a measure structure, an almost-everywhere theorem, a selected derivative, quotient real equality, trichotomy, countable choice, or ambient completeness from the packet.

Proof. Start with any read aimed at the Real seal, regular readback, or stream schedule. Carrier admission exposes those rows only as components of the packet in Definition 6110.1.

Use the NameCert obligations of Definition 6110.2. The request must pass through the displayed interval cell, function-observation window, separated upper and lower Dini rows, oscillation cell, schedule, readback, and dyadic tolerance ledger before the Real seal can be read.

The structural rows preserve the same dependency. Transport by H and replay by C cannot add a hidden measure space, selected derivative, quotient equality, trichotomy, choice principle, or completeness theorem, while P and N source and name only the displayed finite route. □

Falsifiable prediction: Every accepted $\mathsf{DiniDerivativeWindow}^{\uparrow}$ Real-facing or readback-facing read factors through finite interval cells, function-observation windows, upper and lower Dini rows, an oscillation cell, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance rows, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: denjoy-young-saks, real, regseqrat, streamname, dyadicratcore: no listed sibling supplies the whole DiniDerivativeWindow packet, because each sibling contributes only a broader Dini boundary, terminal real seal, rational readback, observation schedule, or tolerance ledger while this chapter binds the finite Dini window in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniDerivativeWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{DiniDerivativeWindow}^{\uparrow}$ packet is generated from interval cells, function-observation windows, upper and lower Dini rows, oscillation cells, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance rows, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniDerivativeWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6110.1, Definition 6110.2, and Definition 6110.3 bind the finite Dini-window carrier and its Real-seal nonescape route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniDerivativeWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure-theoretic alternatives, almost-everywhere differentiability, selected derivatives, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, Dini-row separation, oscillation-cell exactness, stream-readback-dyadic exactness, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.DiniDerivativeWindowUp.

Chapter 6111

A Concrete Naming Certificate for MetaCICDischargeInversionBoundary$^{\uparrow}$

The MetaCICDischargeInversionBoundary$^{\uparrow}$ packet realizes the four subject-reduction discharge rows of section 9386.2 as a finite inversion boundary. It sits beside the discharge socket of chapter 719, the subject-reduction frontier of chapter 730, the redex frontier of chapter 1008, the proof-search frontier of chapter 4284, and the critical-path packet of chapter 765. The carrier names the finite boundary at which beta-substitution, application-argument stability, lambda-domain preservation, and Pi-domain preservation can be inspected as rows; it does not prove any of those rows and does not export a closed subject-reduction theorem.

Falsifiable prediction: An accepted MetaCICDischargeInversionBoundary$^{\uparrow}$ consumer that reads a subject-reduction discharge route without displaying the beta-substitution, application-argument, lambda-domain, Pi-domain, obstruction, socket, transport, replay, provenance, and local naming rows refutes the carrier.

Independence witness: subject-reduction-discharge-socket, metacic-subject-reduction-frontier, metacic-redex-frontier, metacic-proof-search-frontier, metaciccriticalpath: none is bijective to MetaCICDischargeInve because this packet jointly binds four discharge rows, an obstruction row, a socket boundary, inversion routing, TasteGate readiness, transport, replay, provenance, and local naming.

The Lean TasteGate for this packet will provide explicit Nontrivial MetaCICDischargeInversionBoundary$^{\uparrow}$ and FieldFaithful MetaCICDischargeInversionBoundary$^{\uparrow}$ instances. Those instances must keep the discharge rows B, A, L, P, the obstruction row O, the socket row S, the inversion route V, the TasteGate row T, and the structural rows H, C, Q, N as separate fields before any checked carrier-alignment theorem can serve as the public gate.

Definition 6111.1 (MetaCICDischargeInversionBoundary carrier)**.** *A* MetaCICDischargeInversionBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, A, L, P, O, S, V, T, H, C, Q, N)$$

with the following displayed rows:

1. *B is the beta-substitution preservation discharge row.*
2. *A is the application-argument type-stability discharge row.*
3. *L is the lambda-domain subject-reduction discharge row.*
4. *P is the Pi-domain subject-reduction discharge row.*

5. *O is the obstruction row recording that the four-row interface is not replaced by a closed subject-reduction theorem.*
6. *S is the* $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ *row that names the finite socket through which the four rows are consumed.*
7. *V is the inversion route row, recording which discharge row a subject-reduction branch asks to inspect.*
8. *T is the TasteGate readiness row requiring Nontrivial and FieldFaithful separation of the displayed fields.*
9. *H records componentwise* hsame *transport for the discharge, obstruction, socket, inversion, TasteGate, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a branch inspection request through the socket, inversion route, selected discharge row, obstruction boundary, and TasteGate row.*
11. *Q is the* Pkg *provenance over* $\mathsf{MetaCICDischargeInversionBoundary}^{\uparrow}$, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, *the four MetaCIC discharge rows,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICDischargeInversionBoundary}^{\uparrow}}$ *row.*

The carrier contains no closed subject-reduction proof, no replacement fifth discharge row, no host typing oracle, no quotient syntax equality, and no hidden axiom channel.

Theorem 6111.2 (MetaCICDischargeInversionBoundary NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICDischargeInversionBoundary}^{\uparrow}$ *carrier $M = (B, A, L, P, O, S, V, T, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICDischargeInversionBoundary}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the four discharge rows, obstruction row, socket row, inversion route, TasteGate row, transport, replay, provenance, and local naming rows;*
2. *four-row coverage, requiring the beta-substitution, application-argument, lambda-domain, and Pi-domain rows to remain distinct visible inputs;*
3. *inversion exactness, requiring the route row V to select among B, A, L, P without replacing any selected row by O, S, T, H, C, Q, or N;*
4. *socket preservation, requiring every discharge read to pass through S before a branch-specific row is inspected;*
5. *TasteGate separation, requiring the Nontrivial and FieldFaithful obligations for the displayed carrier fields;*
6. *ledger refusal, excluding a closed subject-reduction theorem, host typing oracle, quotient syntax equality, hidden axiom channel, or fifth discharge row.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 6111.1. The packet displays exactly four discharge rows, an obstruction row, a socket row, an inversion route, a TasteGate row, and the structural transport, replay, provenance, and naming rows.

Use the four-row ledger exactness of Definition 719.8. The socket already separates beta-substitution, application-argument, lambda-domain, and Pi-domain inputs, and it does not allow a fifth discharge row or an obstruction row to stand in for one of them.

The inversion route V refines only which of the four rows is being inspected. The route can be transported by H and replayed by C, while Q, N source and name the same finite packet, but none of those rows creates a closed subject-reduction proof or a host typing oracle.

TasteGate readiness records the remaining admission discipline. Nontriviality distinguishes packets with missing discharge fields from accepted packets, and field faithfulness preserves the displayed row order, so the local NameCert surface is exactly the finite surface listed above. □

Theorem 6111.3 (MetaCICDischargeInversionBoundary socket nonescape)**.** *Every subject-reduction-facing read of an accepted* $\mathsf{MetaCICDischargeInversionBoundary}^{\uparrow}$ *carrier factors through the socket-preserving route*

$$S, V, (B, A, L, P), O, T \longmapsto H, C, Q, N.$$

The read may inspect the four discharge rows, the obstruction row, the socket boundary, the inversion route, TasteGate readiness, transport, replay, provenance, and local naming. It cannot obtain a closed subject-reduction theorem, a replacement discharge row, a host typing oracle, quotient syntax equality, or a hidden axiom channel.

Proof. Start with a subject-reduction-facing read. The carrier exposes the socket row S as the public entry to the four discharge inputs, so the read cannot directly inspect B, A, L, or P without passing through S.

Apply Definition 6111.2. The inversion route V selects among the four displayed rows only after the socket boundary is visible, and the obstruction row O remains a boundary row rather than a discharge proof.

The TasteGate row T and structural rows H, C, Q, N preserve that same inventory. Since the carrier has no coordinate for a closed theorem, replacement row, host typing oracle, quotient syntax equality, or hidden axiom channel, none can escape through a public read. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICDischargeInversionBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICDischargeInversionBoundary}^{\uparrow}$ packet is generated from beta-substitution, application-argument, lambda-domain, Pi-domain, obstruction, discharge-socket, inversion-route, TasteGate, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICDischargeInversionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6111.1, Definition 6111.2, and Definition 6111.3 bind the finite discharge-inversion boundary and its socket nonescape route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICDischargeInversionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not prove any subject-reduction discharge row, close subject reduction, supply a host typing oracle, quotient syntax equality, hidden axiom channel, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, four-row coverage, inversion exactness, socket preservation, TasteGate nontriviality, field faithfulness, socket nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICDischargeInversionBoundaryUp.

Chapter 6112

A Concrete Naming Certificate for BishopDiagonalCauchySequence$^{\uparrow}$

Following Bishop and Bridges on diagonal arguments for regular Cauchy names, the BishopDiagonalCauchySequence packet records the constructive diagonal readback of a displayed family of regular rational Cauchy names as finite NameCert data. It sits after the diagonalization route of chapter 3782, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers one visible diagonal Cauchy sequence route without quotient streams, selected limits, countable choice, trichotomy, or ambient Real$^{\uparrow}$ completeness.

Definition 6112.1 (Bishop diagonal Cauchy sequence carrier)**.** *A* BishopDiagonalCauchySequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, I, S, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the family row, naming the finite inspected portion of a family of regular rational Cauchy names.*
2. *I is the diagonal-index row, recording the unary stage selector used to read the family along the Bishop diagonal.*
3. *S is the* StreamName$^{\uparrow}$ *window row, displaying the finite windows inspected from each selected source name.*
4. *T is the* DyadicRatCore$^{\uparrow}$ *tolerance row, carrying the dyadic budgets and comparison ledgers used by the diagonal read.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the diagonal sequence obtained from F, I, S, T.*
6. *E is the* Real$^{\uparrow}$ *seal row consumed only after the regular rational diagonal readback is visible.*
7. *H records componentwise* hsame *transport for the family, index, stream, tolerance, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Real or Completion precision request through the diagonal selector into the regular rational readback.*
9. *P is the* Pkg *provenance over* BishopDiagonalCauchySequence$^{\uparrow}$, RegularCauchyDiagonalization$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopDiagonalCauchySequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, I, S, T, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, countable choice, a selected host limit, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopDiagonalCauchySequenceUp.BishopDiagonalCauchySequenceTasteGate`
`single carrier alignment`

Theorem 6112.2 (Bishop diagonal Cauchy sequence NameCert obligations)**.** *For every accepted* $\mathsf{BishopDiagonalCauchySequence}^{\uparrow}$ *carrier*

$$D = (F, I, S, T, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopDiagonalCauchySequence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *family and diagonal-index exposure through F and I;*
2. *finite stream-window exposure through S;*
3. *dyadic tolerance and comparison exposure through T;*
4. *regular rational diagonal readback through R;*
5. *terminal Real-facing seal through E;*
6. *structural transport, replay, provenance, and local naming through H, C, P, N.*

No diagonal Cauchy obligation is stored outside these rows.

Proof. Project the carrier of Definition 6112.1. The displayed coordinates are exactly the family, diagonal-index, stream-window, dyadic-tolerance, regular-readback, Real-seal, transport, replay, provenance, and local naming rows.

The family and selector rows expose the diagonal source before any Cauchy read is available. The stream and tolerance rows then supply the finite inspected windows and dyadic budgets used by the diagonal readback.

The regular rational row R is downstream of those rows, so the Real-facing seal E can be consumed only after the $\mathsf{RegSeqRat}^{\uparrow}$ diagonal sequence is visible. The structural rows H, C, P, N transport, replay, source, and name the same finite route.

Since the carrier contains no quotient stream, choice functional, selected host limit, trichotomy row, host equality row, or ambient-completeness row, the listed obligations exhaust the local NameCert surface. □

Theorem 6112.3 (Bishop diagonal Cauchy sequence Real handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BishopDiagonalCauchySequence}^{\uparrow}$ *carrier must read the diagonal route*

$$\mathsf{RegularCauchyDiagonalization}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

before treating the diagonal sequence as a completed real-name boundary. The handoff exports only the displayed family row, diagonal-index row, finite stream windows, dyadic tolerance ledger, regular rational readback, Real seal, and structural rows.

Proof. Start from the obligation surface in Definition 6112.2. It orders the diagonal family and selector before stream windows, dyadic tolerances, regular readback, and Real seal data.

Apply the sibling diagonalization route Definition 3782.3. The diagonal read becomes Real-facing only through the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ seal rows.

The replay row C sends a Real or Completion precision request through exactly that route, while H, P, N preserve, source, and name it. Therefore the handoff cannot bypass the four-object L10 seal or export quotient streams, selected limits, countable choice, trichotomy, host equality, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{BishopDiagonalCauchySequence}^{\uparrow}$ read must expose a regular-Cauchy diagonalization row, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any Real or Completion consumer receives it.

Independence witness: regular-cauchy-diagonalization, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the whole ten-row packet $D = (F, I, S, T, R, E, H, C, P, N)$, because each sibling contributes only diagonal selection, finite windows, tolerance rows, regular readback, or terminal Real sealing while this chapter binds the route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopDiagonalCauchySequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopDiagonalCauchySequence}^{\uparrow}$ packet is generated from a displayed family of regular rational names, a diagonal-index row, StreamName windows, DyadicRatCore tolerance ledgers, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopDiagonalCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6112.1, Definition 6112.2, and Definition 6112.3 seed the finite constructive diagonal Cauchy sequence route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopDiagonalCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal-index exposure, finite-window exposure, dyadic-tolerance exactness, RegSeqRat readback, Real-seal handoff, structural stability, and non-escape for BEDC.Derived.BishopDiagonalCauchySequenceUp.

Chapter 6113

A Concrete Naming Certificate for $\mathsf{CompactUniformRadiusMinimumStability}^{\uparrow}$

Following Heine–Cantor and Bishop constructive analysis, the $\mathsf{CompactUniformRadiusMinimumStability}^{\uparrow}$ packet records the finite stability boundary for the radius-minimum fold used in compact uniform-continuity arguments. It sits after the compact metric source of chapter 129, the ProbeBundle lower-bound fold of chapter 4118, the finite-radius stability route of chapter 5203, the metric comparison surface of chapter 57, the rational lower-bound rows of chapter 37, and the uniform-modulus consumer of chapter 369. The packet exposes classifier stability of the finite minimum as concrete NameCert data rather than hiding it inside a fold step.

Definition 6113.1 (Compact uniform radius-minimum stability carrier)**.** *A* $\mathsf{CompactUniformRadiusMinimumStabili}$ *carrier is a finite* BHist *packet*

$$M = (K, B, Q, S, G, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row whose centers carry local radius witnesses.*
2. *B is the finite* $\mathsf{ProbeBundle}$ *row listing the radius witnesses, fold order, and bundle membership classifier.*
3. *Q is the* $\mathsf{Rat}^{\uparrow}$ *positive lower-bound row produced by the finite minimum fold.*
4. *S is the classifier-stability row, recording that componentwise transport of the bundle rows preserves the selected minimum radius ledger.*
5. *G is the* $\mathsf{Met}^{\uparrow}$ *comparison row used by the compact-uniform triangle estimate.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, downstream of K, B, Q, S, G.*
7. *H records componentwise* hsame *transport for compact-source, ProbeBundle, rational-fold, stability, metric, uniform-modulus, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through the finite bundle, radius-minimum fold, stability check, metric comparison, and uniform-modulus handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformRadiusMinimumStability}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ProbeBundle}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusMinimumStability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, B, Q, S, G, U, H, C, P, N$. It has no coordinate for host open-cover compactness, semantic continuity, a hidden minimum selector, quotient metric equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ BEDC.Derived.CompactUniformRadiusMinimumStabilityUp.CompactUniformRadiusMinimumStabilityTasteGa
single carrier alignment

Theorem 6113.2 (Compact uniform radius-minimum stability obligations)**.** *For every accepted* $\mathsf{CompactUniformRadiusMinimumStability}^{\uparrow}$ *carrier*

$$M = (K, B, Q, S, G, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusMinimumStability}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *compact finite-net admission through K;*
2. *finite ProbeBundle membership and fold-order exposure through B;*
3. *rational lower-bound exactness through Q;*
4. *classifier stability of the selected minimum ledger through S;*
5. *metric comparison and uniform-modulus handoff through G, U;*
6. *structural transport, replay, provenance, and local naming through H, C, P, N.*

No radius-minimum stability obligation is stored outside these rows.

Proof. Project the carrier of Definition 6113.1. The finite compact source, ProbeBundle row, rational fold, stability row, metric row, uniform-modulus row, and structural rows are exactly the displayed coordinates.

The compact source and bundle rows expose the finite list of radius witnesses. The rational fold row Q records the selected positive lower bound as a history over B, not as an external selector.

The stability row S is then read before any uniform-modulus consumer receives Q. It checks that componentwise transport of the compact-source and bundle classifiers preserves the lower-bound ledger used by the fold.

Finally G, U, H, C, P, N route the stable radius minimum into the uniform-modulus handoff. Since the carrier contains no hidden open-cover compactness, semantic continuity, quotient metric equality, or ambient-completeness coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 6113.3 (Compact uniform radius-minimum uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformRadiusMinimumStability}^{\uparrow}$ *carrier receives the finite precision ledger only after reading*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{ProbeBundle}, \quad \mathsf{Rat}^{\uparrow}, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{UniformModulus}^{\uparrow}.$$

The handoff factors through the displayed radius-minimum stability row S, so classifier transport of the finite bundle cannot change the uniform-modulus radius without first changing a visible compact-source, bundle-membership, rational-fold, or metric-comparison row.

Proof. Start from Definition 6113.2. The consumer can reach U only after K, B, Q, S, G have been exposed.

Read the finite minimum fold as in Definition 9237.5. The lower-bound row is produced by finite recursion over the ProbeBundle, so its classifier is determined by displayed bundle membership and rational comparison rows.

Now apply the stability row S. It transports the same finite fold through componentwise hsame data before the metric comparison and uniform-modulus rows are replayed.

Thus the exported uniform-modulus radius is stable under exactly the displayed compact-source, bundle, rational-fold, metric, transport, replay, provenance, and naming rows. No host open-cover proof, hidden selector, quotient metric equality, or ambient completeness row can alter the handoff. □

Falsifiable prediction: Every $\mathsf{CompactUniformRadiusMinimumStability}^{\uparrow}$ read must expose CompactMetric finite-net data, ProbeBundle membership and fold order, RatUp lower-bound exactness, radius-minimum classifier stability, MetricSpace comparison, UniformModulus handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: compactmetric, probebundle, rat, metricspace, uniformmodulus: no listed sibling supplies the whole ten-row packet $M = (K, B, Q, S, G, U, H, C, P, N)$, because each sibling contributes only compact-source, finite-bundle, rational-fold, metric-comparison, or uniform-modulus rows while this chapter binds radius-minimum stability with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusMinimumStability}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformRadiusMinimumStability}^{\uparrow}$ packet is generated from CompactMetric finite-net data, ProbeBundle membership and fold order, RatUp lower-bound exactness, radius-minimum classifier stability, MetricSpace comparison, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformRadiusMinimumStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6113.1, Definition 6113.2, and Definition 6113.3 seed the finite classifier-stability surface for compact-uniform radius-minimum folds.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformRadiusMinimumStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host open-cover compactness, semantic continuity, hidden minimum selection, quotient metric equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ProbeBundle fold-order exposure, rational lower-bound exactness, classifier stability, metric comparison, uniform-modulus handoff, and non-escape for BEDC.Derived.CompactUniformRadiusM

Chapter 6114

A Concrete Naming Certificate for $\mathsf{FiniteSelectionSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FiniteSelectionSequence}^{\uparrow}$ packet records the finite selector surface used when a Real or Completion argument inspects only bounded windows of a regular Cauchy route. It sits between the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The point of the packet is not to choose a sequence from an infinite family; it is to expose the already bounded selector rows that a diagonal or tail-budget consumer may read without countable choice.

Definition 6114.1 (FiniteSelectionSequence carrier)**.** *A* $\mathsf{FiniteSelectionSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, D, R, T, C, P, N)$$

with the following displayed rows:

1. *W is a finite list of selected* $\mathsf{StreamName}^{\uparrow}$ *windows, each tagged by the request index and the bounded precision at which it is read.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *threshold ledger for those windows.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W and D.*
4. *T stores componentwise* hsame *transport for the window, dyadic, readback, replay, provenance, and local naming rows.*
5. *C stores displayed* Cont *replay for the finite request trace.*
6. *P is the* Pkg *provenance over* $\mathsf{FiniteSelectionSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
7. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSelectionSequence}^{\uparrow}}$ *row.*

The classifier for accepted carriers compares only the displayed rows W, D, R, T, C, P, N. It has no coordinate for countable choice, an infinite selector, a selected subsequence, quotient streams, or an ambient Real completion principle.

Lean4 ✓ `BEDC.Derived.FiniteSelectionSequenceUp.FiniteSelectionSequenceTasteGate single carrier alignment`

Theorem 6114.2 (FiniteSelectionSequence NameCert obligations)**.** *For every accepted* $\mathsf{FiniteSelectionSequence}^{\uparrow}$ *carrier*

$$S = (W, D, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteSelectionSequence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed StreamName windows, dyadic thresholds, RegSeqRat readbacks, transport, replay, provenance, and local naming rows;*
2. *classifier stability under componentwise* hsame *replacement of the displayed rows;*
3. *finite window exhaustion, requiring every consumer read to occur at one of the listed request-index and precision pairs in* W*;*
4. *no-choice nonescape, requiring the carrier to expose no countable selector, selected subsequence, quotient stream, or ambient completion datum;*
5. $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, requiring any Real-facing read to pass through* R *after the displayed StreamName and dyadic rows.*

No $\mathsf{FiniteSelectionSequence}^{\uparrow}$ *obligation is stored outside these rows.*

Lean4 ✓ `BEDC.Derived.FiniteSelectionSequenceUp.FiniteSelectionSequenceCarrier namecert obligations`

Proof. Project the accepted carrier. Its coordinates are exactly W, D, R, T, C, P, N, so carrier admission and classifier stability are coordinatewise statements over the finite BHist packet.

Every retained read is indexed in W, and every tolerance used by that read is listed in D. The readback row R is downstream of those two rows, so a Real-facing consumer reaches $\mathsf{RegSeqRat}^{\uparrow}$ before it reaches any $\mathsf{Real}^{\uparrow}$ seal.

Since the carrier has no field for a countable selector, selected subsequence, quotient stream, or ambient completion principle, transport, replay, provenance, and local naming cannot export such a field. This gives the advertised no-choice boundary. □

Theorem 6114.3 (FiniteSelectionSequence window exhaustion)**.** *Let* $S = (W, D, R, T, C, P, N)$ *be an accepted* $\mathsf{FiniteSelectionSequence}^{\uparrow}$ *carrier. Any Real or Completion consumer that cites* S *must read a finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through one of the displayed windows in W *and one of the displayed thresholds in* D*. It cannot introduce a later window, an unrecorded dyadic tolerance, a host-selected subsequence, or a countable-choice selector.*

Lean4 ✓ `BEDC.Derived.FiniteSelectionSequenceUp.FiniteSelectionSequenceWindowExhaustion`

Proof. The consumer request is replayed by C, and C is part of the finite packet named by N. Therefore each request has a displayed row in W and its tolerance is one of the rows of D.

The $\mathsf{RegSeqRat}^{\uparrow}$ readback row R is the only row connecting those finite observations to the Real-facing seal. The remaining coordinates T, P, N transport, source, and name the same finite route, so they cannot add windows, tolerances, subsequences, or countable-choice selectors. □

Falsifiable prediction: Every $\mathsf{FiniteSelectionSequence}^{\uparrow}$ Real or Completion-facing read factors through displayed StreamName windows, dyadic thresholds, RegSeqRat readbacks, componentwise transport, replay, provenance, and local naming before reaching a $\mathsf{Real}^{\uparrow}$ seal.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{FiniteSelectionSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite selector-window list, dyadic threshold ledger, RegSeqRat readback, transport, replay, provenance, and local naming while refusing countable choice, selected subsequences, quotient streams, and ambient completion.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSelectionSequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteSelectionSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6114.1, Definition 6114.2, and Definition 6114.3 seed the finite selector-window route from StreamName windows through dyadic thresholds and RegSeqRat readbacks to Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteSelectionSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, selected subsequences, quotient stream equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, finite window exhaustion, no-choice nonescape, RegSeqRat and Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteSelectionSequenceUp.

Constructive story: A $\mathsf{FiniteSelectionSequence}^{\uparrow}$ packet is generated from finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ thresholds, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6115

A Concrete Naming Certificate for $\mathsf{CantorSpaceUniformModulus}^{\uparrow}$

Following Brouwer's fan theorem and Troelstra–van Dalen's constructive treatment of bars, the $\mathsf{CantorSpaceUniformModulus}^{\uparrow}$ packet records the finite prefix-depth route by which a Cantor-space function obtains a uniform modulus from a fan-bar certificate before any Real or Completion consumer reads the result. It sits beside the fan-bar Real route of chapter 1707, the Cantor prefix surface of chapter 1475, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the downstream tolerance-only consumer of chapter 369. The packet is a finite NameCert surface for a fan-theorem modulus on Cantor space; it does not assert open-cover compactness, select an infinite branch, quotient streams, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6115.1 (CantorSpaceUniformModulus carrier)**.** *A* $\mathsf{CantorSpaceUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, A, B, S, D, R, U, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *row, carrying the decidable bar and the fan-bar depth bound.*
2. *A is the* $\mathsf{CantorSpace}^{\uparrow}$ *address row, exposing the finite Boolean prefix cylinder on which the modulus is inspected.*
3. *B is the finite bar-depth ledger, recording exactly which prefix depth is sufficient for every retained Cantor address.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that turns the retained prefixes into finite source windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger consumed by the modulus request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the stream windows and dyadic tolerances.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row that receives the fan depth as the exported uniform precision.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, readable only after F, A, B, S, D, R, U have been displayed.*
9. *H stores componentwise* hsame *transport for the fan, Cantor address, bar-depth, stream-window, dyadic-tolerance, regular-rational, uniform-modulus, real-seal, replay, provenance, and local naming rows.*

10. *C stores displayed* Cont *replay from a consumer request through the finite prefix-depth route.*
11. *P is the* Pkg *provenance over* CantorSpaceUniformModulus$^{\uparrow}$, FanTheorem$^{\uparrow}$, CantorSpace$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, UniformModulus$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{CantorSpaceUniformModulus}^{\uparrow}}$ *row.*

The classifier for accepted carriers compares only the displayed rows $F, A, B, S, D, R, U, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected branches, quotient stream equality, an external modulus selector, selected Real limits, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorSpaceUniformModulusUp.CantorSpaceUniformModulusTasteGate single carrier alignment`

Theorem 6115.2 (CantorSpaceUniformModulus NameCert obligations)**.** *For every accepted* CantorSpaceUniformM *carrier*

$$M = (F, A, B, S, D, R, U, E, H, C, P, N),$$

the local NameCert$_{\text{CantorSpaceUniformModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed fan, Cantor-prefix, bar-depth, stream-window, dyadic-tolerance, regular-rational, uniform-modulus, Real-seal, transport, replay, provenance, and local naming rows;*
2. *fan-bar depth exactness, requiring B to expose precisely the depth supplied by F for the retained Cantor prefix cylinder A;*
3. *Cantor-prefix window exposure, requiring every source read to pass through A and then S before any rational or Real-facing consumer may inspect it;*
4. *dyadic tolerance exactness, requiring D to be the only tolerance ledger read by R and U;*
5. RegSeqRat$^{\uparrow}$ *readback, requiring the regular rational row R to be downstream of the finite stream windows and dyadic tolerances;*
6. UniformModulus$^{\uparrow}$ *handoff, requiring the exported uniform precision U to be the fan-depth row rather than a host-selected modulus;*
7. *Real-seal nonescape, requiring E to be terminal and to add no ambient completeness, selected limit, or quotient-stream equality;*
8. *ledger refusal, requiring H, C, P, N to transport, replay, source, and name only the displayed finite route.*

No CantorSpaceUniformModulus$^{\uparrow}$ *obligation is stored outside these rows.*

Lean4 ✓ `BEDC.Derived.CantorSpaceUniformModulusUp.CantorSpaceUniformModulusCarrier namecert obligations`

Proof. Project the accepted carrier. The row inventory is exactly $F, A, B, S, D, R, U, E, H, C, P, N$, so carrier admission and ledger refusal are coordinate exhaustion.

The fan-bar depth row is read through F and B. The Cantor address A restricts the read to a finite Boolean prefix cylinder, so the depth used by the modulus route is the displayed fan-bar depth rather than an open-cover or branch-selection datum.

The source-window route then passes through S. Dyadic tolerance is supplied only by D, and the regular rational row R reads those windows and tolerances before the uniform-modulus consumer sees the handoff.

Finally, U exports the fan-depth precision to the $\mathsf{UniformModulus}^{\uparrow}$ surface, while E seals the downstream Real read. Since the carrier contains no selected branch, quotient stream equality, external selector, selected Real limit, or ambient completeness row, no such datum can escape through H, C, P, N. □

Theorem 6115.3 (CantorSpaceUniformModulus sibling route)**.** *Every Real or Completion-facing consumer of an accepted* $\mathsf{CantorSpaceUniformModulus}^{\uparrow}$ *carrier factors through the sibling route*

$$\mathsf{FanTheorem}^{\uparrow} \longmapsto \mathsf{CantorSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto$$

In particular, the fan-modulus dependency is the finite Cantor-space neighbour of chapter 1707, and the exported precision is read by the tolerance-only consumer surface of chapter 369.

Lean4 ✓ `BEDC.Derived.CantorSpaceUniformModulusUp.CantorSpaceUniformModulusSibling route`

Proof. Read the carrier in the order specified by Definition 6115.1. The fan and Cantor rows provide the only prefix-depth source, and the stream, dyadic, and regular-rational rows are the only readback route.

The uniform-modulus row U can therefore consume only the displayed depth and tolerance rows. The Real seal E is downstream of that handoff, so a completion-facing consumer receives the same finite route and no ambient compactness or completeness principle. □

Falsifiable prediction: Every $\mathsf{CantorSpaceUniformModulus}^{\uparrow}$ Real or Completion-facing read factors through the displayed fan row, Cantor prefix row, bar-depth ledger, StreamName window row, dyadic tolerance ledger, RegSeqRat readback row, UniformModulus handoff row, Real seal, transport, replay, provenance, and local naming.

Independence witness: fantheorem, cantorspace, bishop-fan-modulus, uniformmodulus: CantorSpaceUniformMo is not bijective to any listed sibling because it jointly carries the fan-depth row, Cantor prefix cylinder, stream-window readback, dyadic tolerance ledger, regular rational row, UniformModulus handoff, Real seal, and structural support while refusing open-cover compactness, selected branches, quotient streams, external modulus selectors, selected Real limits, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorSpaceUniformModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorSpaceUniformModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6115.1, Definition 6115.2, and Definition 6115.3 seed the finite fan-depth route from Cantor prefixes to StreamName, dyadic tolerance, RegSeqRat, UniformModulus, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorSpaceUniformModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite branches, quotient stream equality, external modulus selection, selected Real limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fan-bar depth exactness, Cantor-prefix window exposure, dyadic tolerance exactness, RegSeqRat readback, UniformModulus handoff, Real-seal nonescape, transport, replay, provenance, local naming, and ledger refusal for BEDC.Derived.CantorSpaceUniformModulusUp.

Constructive story: A $\mathsf{CantorSpaceUniformModulus}^{\uparrow}$ packet is generated from a finite $\mathsf{FanTheorem}^{\uparrow}$ row, $\mathsf{CantorSpace}^{\uparrow}$ prefix row, fan-depth ledger, $\mathsf{StreamName}^{\uparrow}$ window row, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, $\mathsf{UniformModulus}^{\uparrow}$ handoff row, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6116

A Concrete Naming Certificate for RegularCauchySubsequenceModulus$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the RegularCauchySubsequenceModulus$^{\uparrow}$ packet records the finite modulus surface that turns a displayed Cauchy source into a regular subsequence schedule before the RegSeqRat$^{\uparrow}$ and Real$^{\uparrow}$ handoff is read. It sits between the CauchyModulus$^{\uparrow}$ source of chapter 292, the dyadic arithmetic ledger of chapter 291, the finite window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the accelerated source interface of chapter 1781. The chapter makes the Cauchy-to-regular-real subsequence modulus explicit as NameCert data rather than treating it as an ambient extraction step.

Definition 6116.1 (Regular Cauchy subsequence modulus carrier)**.** *A* RegularCauchySubsequenceModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, S, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the source* CauchyModulus$^{\uparrow}$ *row, naming the Cauchy tail modulus from which the subsequence schedule is read.*
2. *S is the extracted subsequence schedule row, recording the monotone stage requests and their finite cofinality checks.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tail-budget ledger, carrying dyadic radii, slack comparisons, and the precision budget consumed by S.*
4. *W records the finite* StreamName$^{\uparrow}$ *windows inspected at the stages displayed by S.*
5. *R is the* RegSeqRat$^{\uparrow}$ *handoff row opened only after Q, S, D, W have been displayed.*
6. *E is the downstream* Real$^{\uparrow}$ *seal row reached from the regular readback.*
7. *H records componentwise* hsame *transport for the source modulus, schedule, dyadic budget, stream windows, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Cauchy tail request through $Q, S, D, W, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* RegularCauchySubsequenceModulus$^{\uparrow}$, CauchyModulus$^{\uparrow}$, FastCauchyModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceModulus}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $Q, S, D, W, R, E, H, C, P, N$. It has no coordinate for a choice-selected infinite subsequence, quotient stream equality, host sequence equality, host real equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a hidden fast-modulus oracle.*

Lean4 ✓ `BEDC.Derived.RegularCauchySubsequenceModulusUp.RegularCauchySubsequenceModulusTasteGate`
`single carrier alignment`

Theorem 6116.2 (Regular Cauchy subsequence modulus surface)**.** *For every accepted* RegularCauchySubsequenceM *carrier*

$$M = (Q, S, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceModulus}^{\uparrow}}$ *surface consists exactly of five obligation rows: source Cauchy modulus exposure through Q, extracted subsequence schedule exposure through S, dyadic tail-budget and finite-window precision through D, W, RegSeqRat and Real handoff through R, E, and structural transport with replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 6116.1. The accepted packet displays only the source modulus row Q, schedule row S, dyadic budget row D, stream-window row W, regular readback R, Real seal E, and structural rows H, C, P, N.

The precision argument is finite. Induct over the displayed tail-budget list in D: the empty budget exposes no stage, while the next dyadic request reads the corresponding source-modulus entry in Q, records the selected stage in S, and checks the retained window in W. The induction never asks for a global selector, because every step consumes one visible budget row.

The handoff is therefore forced. The $\mathsf{RegSeqRat}^{\uparrow}$ row R may only read the schedule and finite windows already justified by Q, S, D, W, and the $\mathsf{Real}^{\uparrow}$ seal E appears downstream of R.

Finally H, C, P, N transport, replay, source, and name the same rows. Since no coordinate stores quotient stream equality, selected subsequences, host equality, selected limits, ambient completeness, or a hidden $\mathsf{FastCauchyModulus}^{\uparrow}$ oracle, the five listed groups exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchySubsequenceModulus}^{\uparrow}$ route to a RegSeqRat or Real boundary must display a source CauchyModulus row, extracted subsequence schedule, dyadic tail budget, finite StreamName windows, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: cauchymodulus, fastcauchymodulus, dyadicratcore, streamname, regseqrat, real: none is bijective with $\mathsf{RegularCauchySubsequenceModulus}^{\uparrow}$ because this packet jointly carries the source modulus, schedule extraction, dyadic precision ledger, finite windows, regular handoff, Real seal, transport, replay, provenance, and local naming for the same Cauchy-to-regular route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySubsequenceModulus}^{\uparrow}$ packet is generated from a source CauchyModulus row, extracted subsequence schedule, DyadicRatCore tail-budget ledger, finite StreamName windows, RegSeqRat handoff, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceModulus}^{\uparrow}}$, seed)

Scope closed: Definition 6116.1 and Definition 6116.2 seed the finite subsequence-modulus interface used by Cauchy-to-RegSeqRat and Real routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, choice-selected infinite subsequences, host sequence equality, host real equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source Cauchy modulus exposure, schedule extraction, dyadic precision induction, finite StreamName window routing, RegSeqRat and Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySubsequenceModulusUp.

Chapter 6117

A Concrete Naming Certificate for $\mathsf{CertifiedModelQuality}^{\uparrow}$

The $\mathsf{CertifiedModelQuality}^{\uparrow}$ packet realizes the model-quality scope of section 9462.15 as finite certificate rows. It reads classifier support, behavior coverage, score accounting, and debt gates from displayed ledgers before any consumer may call a model-state transition a certified quality improvement. The packet sits beside the classifier-formation surface of chapter 6097, the GroundCompiler audit-map surface of chapter 836, the certificate gate of chapter 1002, and the effective replacement ledger of chapter 568.

Definition 6117.1 (CertifiedModelQuality carrier)**.** *A* $\mathsf{CertifiedModelQuality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, B, L, W, D, A, G, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the declared model-quality scope row, naming the domain, model state, admitted transformations, critical behavior family, and public protocol.*
2. *B is the certified behavior coverage row, listing the finite critical behaviors whose classifier support and local* $\mathsf{NameCert}$ *rows are displayed.*
3. *L is the model-quality ledger row, recording benefit, cost, debt, failure cases, verification status, safety boundary, shortcut risk, and not-claimed scope.*
4. *W is the public score-accounting row, reading the weighted benefit, cost, and debt comparison from L.*
5. *D is the explicit debt row whose absence blocks certification of an improvement.*
6. *A is the audit-gate row, citing* $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ *and* $\mathsf{CertificateAuditGate}^{\uparrow}$ *consumers for machine-readable checking.*
7. *G is the replacement and belief-separation row, citing* $\mathsf{EffectiveReplacementLedger}^{\uparrow}$ *and* $\mathsf{Belief}^{\uparrow}$ *only as sibling dependencies rather than as equivalent model-quality packets.*
8. *R is the quality-gate decision row, accepting only when coverage, critical debt, safety, transfer, and verification ledgers meet the public protocol.*
9. *H records componentwise* hsame *transport for scope, behavior coverage, ledger, score, debt, audit, sibling-separation, gate, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from scope inspection through coverage, ledger, score, debt, audit, sibling separation, gate, provenance, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{CertifiedModelQuality}^{\uparrow}$, $\mathsf{ClassifierFormingLearning}^{\uparrow}$, $\mathsf{GroundCompilerAuditMap}^{\uparrow}$, $\mathsf{CertificateAuditGate}^{\uparrow}$, $\mathsf{EffectiveReplacementLedger}^{\uparrow}$, $\mathsf{Belief}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CertifiedModelQuality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, L, W, D, A, G, R, H, C, P, N$. It has no coordinate for raw benchmark superiority, private evaluator preference, host semantic truth, hidden training success, unledgered classifier gain, or an equivalence between belief commitment and certified model quality.

Theorem 6117.2 (CertifiedModelQuality NameCert obligations)**.** *For every accepted* $\mathsf{CertifiedModelQuality}^{\uparrow}$ *carrier*

$$Q = (S, B, L, W, D, A, G, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CertifiedModelQuality}^{\uparrow}}$ *surface consists exactly of scope exposure, certified behavior coverage, model-quality ledger accounting, public score comparison, explicit debt attachment, audit-gate handoff, sibling-separation handoff, quality-gate decision, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 6117.1. The accepted packet displays exactly the scope row S, behavior-coverage row B, ledger row L, score row W, debt row D, audit row A, sibling-separation row G, gate row R, and structural rows H, C, P, N.

The ledger and score rows are inseparable. The score row W may compare two model states only through the benefit, cost, and debt entries shown in L, and the debt row D records the critical residue that must be accounted for before the comparison can be certified.

The audit and sibling rows keep the packet public and non-bijective. The $\mathsf{GroundCompilerAuditMap}^{\uparrow}$ and $\mathsf{CertificateAuditGate}^{\uparrow}$ entries in A make the quality read machine-checkable as audit data, while G records that $\mathsf{EffectiveReplacementLedger}^{\uparrow}$ and $\mathsf{Belief}^{\uparrow}$ are neighboring dependencies, not substitutes for model-quality certification.

Finally, R, H, C, P, N accept, transport, replay, source, and name the same finite route. Since no excluded coordinate appears in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 6117.3 (CertifiedModelQuality debt row gate)**.** *An accepted* $\mathsf{CertifiedModelQuality}^{\uparrow}$ *packet cannot certify a model-quality improvement when the debt row D is absent from the displayed carrier. In that case the score comparison remains an uncertified performance, preference, or classifier-support observation rather than a certified model-quality improvement.*

Proof. Start with the carrier projection. The quality score is read through W, and W depends on the ledger row L together with the explicit debt row D.

If D is absent, the packet has no displayed coordinate for black-box debt, ledger debt, stability debt, generalization debt, safety debt, shortcut debt, semantic debt, or verification debt. The quality gate R therefore lacks the row it must inspect before accepting the comparison.

The remaining rows still may record behavior coverage, audit handoff, or score movement, but none of them replaces D. Thus the packet refuses certification of improvement while preserving the weaker displayed observations. □

Falsifiable prediction: A $\mathsf{CertifiedModelQuality}^{\uparrow}$ packet that claims certified model-quality improvement while omitting the debt row D is rejected by the local NameCert surface.

Independence witness: GroundCompilerAuditMap, CertificateAuditGate, EffectiveReplacementLedger, Belief: none is bijective with $\mathsf{CertifiedModelQuality}^{\uparrow}$ because audit maps, gate passes, replacement ledgers, and belief commitments each omit at least one of the scope, behavior-coverage, score-accounting, debt, quality-gate, transport, replay, provenance, or local naming rows.

The Lean follow-up must provide explicit $\mathsf{Nontrivial\ CertifiedModelQuality}^{\uparrow}$ and $\mathsf{FieldFaithful\ CertifiedModelQualit}$ instances in `lean4/BEDC/Derived/CertifiedModelQualityUp/TasteGate.lean`. Those instances must preserve the rows $S, B, L, W, D, A, G, R, H, C, P, N$ so the checked TasteGate surface separates debt-aware model quality from score movement, audit-gate success, replacement-ledger availability, and belief commitment.

Closure status for $\mathsf{NameCert}_{\mathsf{CertifiedModelQuality}^{\uparrow}}$.

Constructive story: A $\mathsf{CertifiedModelQuality}^{\uparrow}$ packet is generated from model-quality scope, certified behavior coverage, ledger accounting, public score comparison, explicit debt, audit-gate handoff, sibling-separation handoff, quality-gate decision, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CertifiedModelQuality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6117.1, Definition 6117.2, and Definition 6117.3 seed the finite certificate packet for debt-aware model-quality certification.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CertifiedModelQuality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close benchmark validity, causal explanation, host semantic truth, hidden training success, global model safety, Lean checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, behavior coverage, ledger and score accounting, debt-row gate refusal, audit-gate handoff, sibling separation, transport, replay, provenance, local naming, and Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.CertifiedModelQualityUp.

Chapter 6118

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionCounit}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Mac Lane on adjunction counits, the $\mathsf{RegularCauchyCompletionCounit}^{\uparrow}$ packet records the regular-source face of the completion reflector's return map. It sits between the source-side unit of chapter 3646, the general counit packet of chapter 1539, and the monadic completion surface of chapter 378. Its readback route passes through the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ packets of chapter 126, chapter 301, chapter 291, and chapter 38. The packet names the counit face only as finite BEDC data; it is not quotient-stream equality, a chosen regular representative, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6118.1 (RegularCauchyCompletionCounit carrier)**.** *A* $\mathsf{RegularCauchyCompletionCounit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, U, Q, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the completion-facing regular source row whose accepted read is being returned.*
2. *U is the* $\mathsf{RegularCauchyCompletionUnit}^{\uparrow}$ *admission route that records how the regular source entered the reflector surface.*
3. *Q is the* $\mathsf{CauchyCompletionCounit}^{\uparrow}$ *return row restricting the general counit to the regular source face.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the returned regular name is inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row attached to the same finite windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger accounting for each precision request used by S and R.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after U, Q, S, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the completion-facing source, unit route, counit row, stream windows, regular readback, dyadic ledger, seal handoff, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from the completion-facing source through the unit route, counit row, finite windows, dyadic ledger, regular readback, and real seal.*

10. *P records* Pkg *provenance over* $\mathsf{RegularCauchyCompletionCounit}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionCounit}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionCounit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected representatives, host sequence equality, countable-choice schedules, analytic closure of the monad, ambient completion, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionCounitUp.RegularCauchyCompletionCounitTasteGate`
`single carrier alignment`

Theorem 6118.2 (RegularCauchyCompletionCounit NameCert obligations)**.** *For an accepted* $\mathsf{RegularCauchyCompletionCounit}^{\uparrow}$ *carrier* $K = (M, U, Q, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyComple}}$ *surface consists exactly of completion-facing source admission through* M*, regular unit admission through* U*, general counit restriction through* Q*, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure through* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting through* D*,* $\mathsf{Real}^{\uparrow}$ *seal handoff through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 6118.1. Its displayed coordinates are exactly $M, U, Q, S, R, D, E, H, C, P, N$.

The source and adjunction rows are M, U, Q. The unit row U records how the regular source entered the completion-facing surface, and the counit row Q records the return route restricted to that same regular face.

The finite observation rows are S, R, D. They expose stream windows, regular rational readback, and dyadic tolerance accounting before any terminal real seal is consumed.

The seal handoff E is downstream of those rows, while H, C, P, N preserve, replay, source, and name the same finite route. No other local obligation is present. □

Theorem 6118.3 (RegularCauchyCompletionCounit real-seal factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyCompletionCounit}^{\uparrow}$ *packet reaches the seal row* E *only through the displayed route*

$$M \longmapsto U \longmapsto Q \longmapsto S \longmapsto D \longmapsto R \longmapsto E$$

together with H, C, P, N*. Thus the regular counit reads the completion return as finite regular Cauchy data with stream windows and dyadic tolerance accounting, not as quotient-stream equality, a selected representative, or an ambient completion principle.*

Proof. Begin with a real-seal consumer. By the carrier definition, the only completion-facing source row available to that consumer is M.

The consumer must next pass through U and Q. These rows identify the source admission as regular and restrict the general counit return to that regular source face.

The finite readback is then forced through S, D, R. Stream windows name the inspected observations, the dyadic ledger accounts for the requested tolerance, and the regular rational row supplies the readback before E is inspected.

Finally H, C, P, N transport, replay, source, and name the same route. The seal handoff is therefore the displayed factorization, not a hidden quotient, selector, or completeness witness. □

Theorem 6118.4 (RegularCauchyCompletionCounit non-escape)**.** *No accepted* RegularCauchyCompletionCounit$^{\uparrow}$ *packet exports data outside* $M, U, Q, S, R, D, E, H, C, P, N$*. In particular, it cannot be used to recover quotient-stream equality, a chosen regular representative, host sequence equality, countable-choice schedules, analytic closure of* CauchyCompletionMonad$^{\uparrow}$*, ambient completion, or completeness of* Real$^{\uparrow}$*.*

Proof. Inspect the carrier. The completion-facing source, unit admission, counit restriction, stream-window, regular readback, dyadic ledger, seal handoff, transport, replay, provenance, and local-name rows are the only fields.

Apply Definition 6118.2. Every accepted local obligation is a projection of those rows or a structural transport, replay, provenance, or naming row for them.

Use Definition 6118.3. Every real-seal consumer passes through $M, U, Q, S, D, R, E, H, C, P, N$, so no excluded quotient, selector, host, monadic closure, ambient completion, or real-completeness object can be exported. □

Closure status for NameCert$_{\text{RegularCauchyCompletionCounit}^{\uparrow}}$**.**

Constructive story: A RegularCauchyCompletionCounit$^{\uparrow}$ packet is generated from a completion-facing regular source row, RegularCauchyCompletionUnit admission, CauchyCompletionCounit return restriction, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal handoff, componentwise transport, displayed replay, package provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyCompletionCounit}^{\uparrow}}$, seed)

Scope closed: Definition 6118.1, Definition 6118.2, Definition 6118.3, and Definition 6118.4 seed the finite regular-source counit face of the completion reflector.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyCompletionCounit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean theorem checking, quotient-stream equality, selected representatives, countable choice, host sequence equality, analytic closure of CauchyCompletionMonad$^{\uparrow}$, ambient completion, or completeness of Real$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, unit-route admission, counit restriction, finite window exposure, regular readback, dyadic tolerance accounting, seal handoff, transport stability, provenance, and non-escape for the displayed packet.

Lean4 (definition) `BEDC.Derived.RegularCauchyCompletionCounitUp.RegularCauchyCompletionCounitUp`

Chapter 6119

A Concrete Naming Certificate for $\mathsf{ConstantCauchyName}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ConstantCauchyName}^{\uparrow}$ packet records the constant Cauchy name as the finite route from a $\mathsf{DyadicRatCore}^{\uparrow}$ source row through $\mathsf{StreamName}^{\uparrow}$ constant windows, the $\mathsf{ConstantRegSeqRat}^{\uparrow}$ readback of chapter 6107, $\mathsf{RegSeqRat}^{\uparrow}$ regularity, and the terminal $\mathsf{Real}^{\uparrow}$ seal. The packet gives Real and Completion consumers a named constant-name embedding without host constants, quotient streams, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6119.1 (Constant Cauchy name carrier)**.** *A* $\mathsf{ConstantCauchyName}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, W, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row naming the dyadic rational point.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *constant-window schedule, so every requested precision opens a finite window whose entries read back to the same dyadic source row.*
3. *Q is the* $\mathsf{ConstantRegSeqRat}^{\uparrow}$ *stationary readback row.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row inherited from the stationary readback.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after D, W, Q, R have been displayed.*
6. *H stores componentwise* hsame *transport for the source, windows, readback, regularity, seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a Real-facing constant-name request through the same finite route.*
8. *P is the* Pkg *provenance over* $\mathsf{ConstantCauchyName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{ConstantRegSeqRat}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstantCauchyName}^{\uparrow}}$ *row.*

The carrier has no coordinate for host real constants, quotient stream equality, selected representatives, countable choice, trichotomy, or ambient completeness.

Lean4 ✓ `BEDC.Derived.ConstantCauchyNameUp.ConstantCauchyNameTasteGate single carrier alignment`

Theorem 6119.2 (Constant Cauchy name NameCert obligations)**.** *For every accepted* $\mathsf{ConstantCauchyName}^{\uparrow}$ *carrier*

$$K = (D, W, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstantCauchyName}^{\uparrow}}$ *surface consists exactly of carrier admission for the nine displayed rows, dyadic source exposure through* D*, constant-window exposure through* W*, stationary readback through* Q*, regularity exposure through* R*, Real sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, local naming through* N*, and non-escape from host constants or quotient streams.*

Proof. Project the accepted carrier of Definition 6119.1. The tuple lists exactly the dyadic source, constant windows, stationary readback, regularity, Real seal, and structural rows.

Read the source route in order. The dyadic point is first exposed by D; then W opens only finite constant windows; then Q invokes the $\mathsf{ConstantRegSeqRat}^{\uparrow}$ readback of chapter 6107; and then R records the same route as $\mathsf{RegSeqRat}^{\uparrow}$ regularity.

Finally E, H, C, P, N seal, transport, replay, source, and name only that displayed route. Since no carrier coordinate stores host constants, quotient stream equality, selected representatives, countable choice, trichotomy, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 6119.3 (Constant Cauchy name real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer admitted by an accepted* $\mathsf{ConstantCauchyName}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{ConstantRegSeqRat}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

before the constant name is available as Real data. Thus the constant embedding is read as a finite BEDC route and not as a host constant, quotient Cauchy class, selected limit, or ambient completeness claim.

Proof. Begin with an accepted carrier $K = (D, W, Q, R, E, H, C, P, N)$. A Real-facing read has no access to the terminal seal E until it has displayed the source row D, the constant windows W, the stationary readback Q, and the regularity row R.

Use the $\mathsf{ConstantRegSeqRat}^{\uparrow}$ obligation surface of chapter 6107. It makes the stationary rational readback a visible row between the $\mathsf{StreamName}^{\uparrow}$ windows and the $\mathsf{RegSeqRat}^{\uparrow}$ regularity surface.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Therefore every Real seal read factors through the displayed dyadic, stream, constant-regular, regular-rational, and Real rows, and the excluded host or quotient principles remain outside the packet. □

Theorem 6119.4 (Constant Cauchy name dyadic source lock)**.** *Let* $K = (D, W, Q, R, E, H, C, P, N)$ *be an accepted* $\mathsf{ConstantCauchyName}^{\uparrow}$ *carrier. Every consumer exposing the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *must first expose the same dyadic source row* D*, the same constant-window row* W*, the same* $\mathsf{ConstantRegSeqRat}^{\uparrow}$ *row* Q*, and the same* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*. No consumer may replace* D *by a host real constant, a quotient representative, a selected limit, or an ambient completeness witness.*

Proof. Project the carrier of Definition 6119.1. The terminal seal row E is downstream of D, W, Q, R, and there is no separate row from which a host constant or quotient representative could be read.

Use the NameCert obligations of Definition 6119.2. They expose the dyadic source through D, the constant-window schedule through W, the stationary readback through Q, and regularity through R as the finite public route of the packet.

Apply the Real seal theorem Definition 6119.3. It forces every $\mathsf{Real}^{\uparrow}$ consumer to factor through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{ConstantRegSeqRat}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and only then $\mathsf{Real}^{\uparrow}$.

The structural rows H, C, P, N transport, replay, source, and name the same displayed data. Therefore the source lock is part of the carrier surface, not an assertion about host real constants, quotient stream equality, selected representatives, countable choice, trichotomy, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{ConstantCauchyName}^{\uparrow}$ read must expose a $\mathsf{DyadicRatCore}^{\uparrow}$ source row, a $\mathsf{StreamName}^{\uparrow}$ constant-window schedule, a $\mathsf{ConstantRegSeqRat}^{\uparrow}$ stationary readback, a $\mathsf{RegSeqRat}^{\uparrow}$ regularity row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before any $\mathsf{Real}^{\uparrow}$ constant-name consumer may proceed.

Independence witness: dyadicratcore, streamname, constantregseqrat, regseqrat, real: none is bijective with $\mathsf{ConstantCauchyName}^{\uparrow}$ because this packet jointly carries the dyadic source, constant windows, stationary regular readback, Real seal, transport, replay, provenance, and local naming for the same constant-name route.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstantCauchyName}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstantCauchyName}^{\uparrow}$ packet is generated from a DyadicRatCore source row, StreamName constant windows, a ConstantRegSeqRat stationary readback, RegSeqRat regularity, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ConstantCauchyName}^{\uparrow}}$, seed)

Scope closed: Definition 6119.1, Definition 6119.2, and Definition 6119.3 seed the finite constant-name route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{ConstantRegSeqRat}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ConstantCauchyName}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host real constants, quotient stream equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, constant-window exposure, stationary readback, regularity, Real seal, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.ConstantCauchyNameUp.

Chapter 6120

A Concrete Naming Certificate for $\mathsf{KolmogorovExtensionFiniteWindow}^{\uparrow}$

Following Kolmogorov's consistency principle for finite-dimensional distributions, the KolmogorovExtensionFiniteWi packet records only the finite-window surface that a BEDC probability consumer may inspect before any infinite product construction is requested. It sits over the probability carrier of chapter 184, the distribution ledger of chapter 186, the measurable random-variable rows of chapter 185, the finite observation windows of chapter 126, and the regular rational readback of chapter 301. The packet names finite marginal windows and their compatibility rows; it does not import infinite product measures, countable choice, a host sigma-product construction, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6120.1 (Kolmogorov finite-window carrier)**.** *A* $\mathsf{KolmogorovExtensionFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, W, \mu, \pi, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index-window ledger, naming the inspected coordinate set and its included subwindows.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule used to read the finite coordinate windows.*
3. *μ is the family of finite* $\mathsf{Distribution}^{\uparrow}$ *rows over the displayed windows, read inside the probability context of* $\mathsf{ProbSpace}^{\uparrow}$*.*
4. *π is the marginal-projection row, recording how a larger displayed window restricts to a smaller displayed window.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed probabilities and comparison tolerances.*
6. *H records componentwise* hsame *transport for I, W, μ, π, R.*
7. *C records displayed* Cont *replay from a marginal request through window exposure, distribution readback, projection, and rational comparison.*
8. *P is the* Pkg *provenance over* $\mathsf{KolmogorovExtensionFiniteWindow}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*,* $\mathsf{Distribution}^{\uparrow}$*,* $\mathsf{RandomVar}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KolmogorovExtensionFiniteWindow}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite sample space, product sigma algebra, countable selection of cylinder representatives, completed measure, host random process, or ambient real-completeness principle.

Lean4 ✓ `BEDC.Derived.KolmogorovExtensionFiniteWindowUp.KolmogorovExtensionFiniteWindowTasteGate single carrier alignment`

Theorem 6120.2 (Kolmogorov finite-window NameCert obligations)**.** *For every accepted* KolmogorovExtensionFini *carrier* $K = (I, W, \mu, \pi, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{KolmogorovExtensionFiniteWindow}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the displayed finite index windows, observation schedule, distribution rows, projection rows, readback rows, transports, replay, provenance, and local name;*
2. *window exposure, requiring every marginal request to name a displayed subwindow of* I *before a distribution row is read;*
3. *distribution compatibility, requiring each finite window to read its probability data through* $\mathsf{Distribution}^{\uparrow}$ *and* $\mathsf{ProbSpace}^{\uparrow}$ *rows;*
4. *marginal projection exactness, requiring the row* π *to compare larger-window distributions with smaller-window distributions through the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*;*
5. *nonescape, excluding infinite product measures, countable choice, host sigma-product construction, quotient random processes, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 6120.1. The tuple displays exactly the finite rows that the local certificate may name.

Window exposure follows from I and W. A request that does not name a displayed window has no route to a distribution row.

Distribution compatibility is the role of μ and P. The finite probability data are read through the existing $\mathsf{Distribution}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, and $\mathsf{RandomVar}^{\uparrow}$ sibling surfaces rather than through a host probability space.

Marginal projection exactness is recorded by π and checked through R. The same regular-rational readback compares both the larger-window and smaller-window probability values.

Finally, H, C, P, N only transport, replay, source, and name those rows. Since no omitted object is a coordinate of K, the nonescape clause is part of the local NameCert surface. □

Theorem 6120.3 (Kolmogorov finite-window marginal consistency)**.** *Let* $K = (I, W, \mu, \pi, R, H, C, P, N)$ *be an accepted* $\mathsf{KolmogorovExtensionFiniteWindow}^{\uparrow}$ *carrier. If a displayed window* J *is included in a displayed window* L *inside* I*, then every marginal read from the* L*-distribution row to the* J*-distribution row factors through*

$$I, W, \mu, \pi, R, H, C, P, N.$$

Thus the finite-window packet supplies marginal consistency for displayed windows only, and it exports no infinite product measure, countable-choice selector, host sigma-product construction, quotient stochastic process, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the inclusion $J \subseteq L$ from the finite index-window ledger I. The observation schedule W exposes exactly the coordinate windows that may be inspected.

The distribution rows μ provide the probability data for J and L. The projection row π is the only row that relates the larger displayed distribution to the smaller displayed distribution.

The comparison is read through R, then transported and replayed by H and C. Provenance and local naming through P, N preserve the same finite route.

Because the carrier has no product sigma algebra, completed infinite product measure, countable selector, or host stochastic-process coordinate, the theorem closes only the displayed finite-window marginal consistency surface. □

Falsifiable prediction: An accepted $\mathsf{KolmogorovExtensionFiniteWindow}^{\uparrow}$ consumer that reads a smaller-window distribution without displaying the containing finite window, the projection row, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: probspace, distribution, randomvar, streamname, regseqrat: no listed sibling supplies the full finite-window consistency packet $K = (I, W, \mu, \pi, R, H, C, P, N)$, because each sibling contributes only probability context, finite distribution data, measurable random-variable reads, observation windows, or rational readback while this chapter binds them to marginal projection exactness and nonescape.

Closure status for $\mathsf{NameCert}_{\mathsf{KolmogorovExtensionFiniteWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{KolmogorovExtensionFiniteWindow}^{\uparrow}$ packet is generated from finite index windows, stream observation rows, finite distribution rows, marginal projection rows, regular rational readback, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KolmogorovExtensionFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6120.1, Definition 6120.2, and Definition 6120.3 seed the finite-window marginal-consistency surface over probability, distribution, random-variable, stream-window, and regular-rational rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KolmogorovExtensionFiniteWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite product measures, countable choice, host sigma-product construction, quotient random processes, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exposure, distribution compatibility, marginal projection exactness, readback stability, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.KolmogorovExtensionFiniteWindowUp.

Chapter 6121

A Concrete Naming Certificate for $\mathsf{IntermediateValueRealSeal}^{\uparrow}$

Following Bolzano and Bishop–Bridges constructive analysis, the $\mathsf{IntermediateValueRealSeal}^{\uparrow}$ packet records the finite handoff from displayed intermediate-value bisection data to the terminal $\mathsf{Real}^{\uparrow}$ seal. It sits after the constructive intermediate-value surface of chapter 1402, the bisection route of chapter 1422, the finite window interface of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet names a finite sign-change route into a real seal; it does not claim unrestricted intermediate value, selected roots, real trichotomy, quotient real equality, countable choice, or ambient completeness.

Definition 6121.1 (IntermediateValueRealSeal carrier)**.** *An* $\mathsf{IntermediateValueRealSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (I, B, A, S, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the located interval endpoint row, exposing the lower and upper rational endpoint cells and their located-order witness.*
2. *B is the* $\mathsf{IntermediateValueBisection}^{\uparrow}$ *branch row, recording the retained finite bisection prefix and the interval chosen at the requested tolerance.*
3. *A is the intermediate-value source row, tying the branch to the displayed function, endpoint signs, and local continuity budget.*
4. *S is the sign-change ledger, containing the initial endpoint signs and the transported midpoint signs used by B.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window surface for the retained endpoint names and the bisection readback window.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W and the displayed dyadic tolerance request.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after Q has been read.*
8. *H records componentwise* hsame *transport for I, B, A, S, W, Q, R and the structural rows.*
9. *C records displayed* Cont *replay from endpoint inspection through bisection retention, stream windows, regular readback, and real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{IntermediateValueRealSeal}^{\uparrow}$, $\mathsf{IntermediateValueBisection}^{\uparrow}$, $\mathsf{IntermediateValue}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{IntermediateValueRealSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an unrestricted intermediate-value principle, a selected root, quotient equality of real names, real trichotomy, countable choice, a completed nested intersection, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 6121.2 (IntermediateValueRealSeal obligations)**.** *For every accepted* $\mathsf{IntermediateValueRealSeal}^{\uparrow}$ *carrier* $Z = (I, B, A, S, W, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{IntermediateValueRealSeal}^{\uparrow}}$ *surface consists exactly of located endpoint admission, intermediate-value source exposure, sign-change ledger admission, bisection branch retention,* $\mathsf{StreamName}^{\uparrow}$ *window admission,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback admission, terminal* $\mathsf{Real}^{\uparrow}$ *seal admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside* $I, B, A, S, W, Q, R, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.IntermediateValueRealSealUp.IntermediateValueRealSealCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 6121.1. The endpoint, source, branch, sign, window, readback, seal, transport, replay, provenance, and naming rows are the whole visible packet.

Read the analytic route first. The located endpoints in I and the source row A provide the finite sign-change request, while the sign ledger S and bisection row B record the retained branch at the requested tolerance.

The Real-facing handoff is then forced through W, Q, R. The stream windows expose only finite endpoint observations, the regular rational readback seals those observations as Q, and the terminal real-name row R is available only after that readback.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no other analytic coordinate, the listed obligations exhaust the local certificate and the excluded root-selection, quotient, trichotomy, choice, and completeness principles remain unavailable. □

Theorem 6121.3 (IntermediateValueRealSeal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* IntermediateValueRealS *packet factors through the ordered finite route*

$$\mathsf{IntermediateValue}^{\uparrow}, \mathsf{IntermediateValueBisection}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{Name}$$

The consumer receives the terminal real seal only as the endpoint of the displayed bisection, window, and regular-readback chain. It receives no unrestricted intermediate-value theorem, selected root, real trichotomy, quotient real equality, countable-choice selector, hidden completeness principle, or independent real representative.

Proof. Begin with the source and branch rows. The intermediate-value row A supplies only the displayed sign-change and continuity data, and the bisection row B selects only the retained finite branch justified by the sign ledger S.

Next read the finite observation surface. The stream row W records the windows through which the retained endpoints are inspected, and the regular rational row Q is the only readback exported from those windows.

Now seal the Real-facing endpoint. The row R is downstream of Q, so a $\mathsf{Real}^{\uparrow}$ consumer cannot bypass the bisection branch or the regular readback by reading a host root, quotient stream, selected representative, or ambient completeness witness.

The structural rows H, C, P, N preserve and name that same route. Composing these projections gives exactly the ordered handoff in the statement and no further real-facing coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntermediateValueRealSeal}\uparrow}$.

Constructive story: An $\mathsf{IntermediateValueRealSeal}^{\uparrow}$ packet is generated from located interval endpoint rows, intermediate-value source rows, a sign-change ledger, a bisection branch row, StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntermediateValueRealSeal}\uparrow}, \mathsf{seed})$

Scope closed: Definition 6121.1, Definition 6121.2, and Definition 6121.3 seed the finite route from bisection-style intermediate-value data through regular rational readback to a terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntermediateValueRealSeal}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted intermediate value, selected roots, real trichotomy, quotient real equality, countable choice, completed nested intersections, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source exposure, sign-ledger retention, bisection branch routing, StreamName window admission, RegSeqRat readback, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.IntermediateValueRealSealUp.

Chapter 6122

A Concrete Naming Certificate for $\mathsf{HyperbolicAxisShadow}^{\uparrow}$

Following Bridson–Haefliger and Beardon on hyperbolic axes and shadows, the $\mathsf{HyperbolicAxisShadow}^{\uparrow}$ packet records a finite shadow route associated to axis-like displacement data without selecting a global axis. It consumes the translation-length surface of chapter 5832, the routed geodesic-flow surface of chapter 3856, the metric-read surface of chapter 3474, the Busemann boundary surface of chapter 3732, the terminal real seal of chapter 38, and the observer-expansion vision of chapter 9463. The packet names finite axis-shadow evidence; it does not assert a selected host axis, global hyperbolic manifold, quotient boundary equality, complete geodesic line, or physical observer law.

Definition 6122.1 (HyperbolicAxisShadow carrier)**.** *A* $\mathsf{HyperbolicAxisShadow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (T, F, M, B, R, A, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *row, exposing the finite displacement-length comparison that motivates the shadow read.*
2. *F is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row, recording the routed flow window along which the shadow is inspected.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row, supplying the finite metric comparisons used to bound the visible shadow.*
4. *B is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row, recording the boundary-facing direction data through displayed Busemann rows.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by the translation-length, metric, Busemann, and shadow-size reads.*
6. *A is the finite axis-shadow ledger, relating the displacement window, flow window, metric comparison, and boundary-facing row without naming a selected axis.*
7. *S is the shadow-stability row, requiring the same visible endpoint and metric data to be replayed by T, F, M, B, R, A.*
8. *H records componentwise* hsame *transport for T, F, M, B, R, A, S and the structural rows.*
9. *C records displayed* Cont *replay from a shadow request through $T, F, M, B, R, A, S, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicAxisShadow}^{\uparrow}$, $\mathsf{HyperbolicTranslationLength}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicAxisShadow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host selected axis, a completed bi-infinite geodesic, quotient boundary equality, global hyperbolic manifold, curvature axiom, or observer-expansion law.

Lean4 ✓ `BEDC.Derived.HyperbolicAxisShadowUp.HyperbolicAxisShadowTasteGate single carrier alignment`

Theorem 6122.2 (HyperbolicAxisShadow obligations)**.** *For every accepted* $\mathsf{HyperbolicAxisShadow}^{\uparrow}$ *carrier* $Y = (T, F, M, B, R, A, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicAxisShadow}^{\uparrow}}$ *surface consists exactly of translation-length visibility, geodesic-flow routing, hyperbolic metric comparison, Busemann boundary exposure, real-valued readback, finite axis-shadow ledger admission, shadow-stability replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside* $T, F, M, B, R, A, S, H, C, P, N$*.*

Proof. Project the carrier of Definition 6122.1. The rows $T, F, M, B, R, A, S, H, C, P, N$ are the whole visible packet.

Read the geometric data first. Translation length supplies the displacement comparison, geodesic flow supplies the routed inspection window, the metric row supplies finite distance comparisons, and the Busemann boundary row supplies the boundary-facing direction data.

The finite shadow ledger is then read through A and S. These rows relate the displacement, flow, metric, boundary, and real readback data while refusing to name a selected axis or a host geodesic line.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for the excluded global geometry, the listed rows exhaust the local certificate surface. □

Theorem 6122.3 (HyperbolicAxisShadow route)**.** *Every accepted* $\mathsf{HyperbolicAxisShadow}^{\uparrow}$ *read factors through the ordered finite route*

$$\mathsf{HyperbolicTranslationLength}^{\uparrow}, \mathsf{HyperbolicGeodesicFlow}^{\uparrow}, \mathsf{HyperbolicMetric}^{\uparrow}, \mathsf{HyperbolicBusemannBoundary}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto$$

The route exports a finite shadow record tied to displayed displacement, flow, metric, boundary, and real-valued rows. It exports no selected invariant axis, host hyperbolic manifold, quotient boundary equality, completed geodesic line, curvature axiom, or global observer-expansion credential.

Proof. Start with the displacement and flow rows. The translation-length row T gives the finite length-facing comparison, and the geodesic-flow row F supplies the visible route along which the comparison is inspected.

Next read the metric and boundary rows. The metric row M bounds the finite shadow window, while the Busemann boundary row B records the boundary-facing data. The Real row R seals the numeric reads used by those comparisons.

The axis-shadow ledger A and stability row S bind those four geometric faces into one finite shadow route without selecting a host axis. The structural rows H, C, P, N then preserve and name that same route.

Composing these projections gives exactly the finite handoff in the statement. Every listed global or quotient object remains outside the carrier and cannot be exported by an accepting consumer. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicAxisShadow}^{\uparrow}$ consumer is refuted if it obtains an axis-shadow read without displaying the $\mathsf{HyperbolicTranslationLength}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, finite shadow ledger, stability, transport, replay, provenance, and local NameCert rows.

Independence witness: hyperbolic-translation-length, hyperbolic-geodesic-flow, hyperbolic-metric, hyperbolic-busemann-boundary, real: no listed sibling is bijective to $\mathsf{HyperbolicAxisShadow}^{\uparrow}$ because the packet jointly carries displacement length, routed flow, metric comparison, Busemann boundary direction, Real sealing, finite shadow ledger, stability, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicAxisShadow}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicAxisShadow}^{\uparrow}$ packet is generated from HyperbolicTranslationLength rows, HyperbolicGeodesicFlow rows, HyperbolicMetric rows, HyperbolicBusemannBoundary rows, RealUp seal rows, a finite axis-shadow ledger, stability rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicAxisShadow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6122.1, Definition 6122.2, and Definition 6122.3 seed the finite non-selected axis-shadow route over translation-length, flow, metric, boundary, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicAxisShadow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected invariant axes, completed geodesic lines, quotient boundary equality, host hyperbolic manifolds, curvature axioms, global observer-expansion laws, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, translation-length visibility, flow routing, metric comparison, Busemann boundary exposure, Real sealing, shadow-ledger stability, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicAxisShadowUp.

Chapter 6123

A Concrete Naming Certificate for $\mathsf{AbelUniform}^{\uparrow}$

Following Abel's theorem and Bishop–Bridges constructive analysis, the $\mathsf{AbelUniform}^{\uparrow}$ packet records the finite uniform-convergence boundary where RealSeries partial sums are read as RealPowerSeries radial-window data. It consumes the Abel boundary routes of chapter 1922 and chapter 1763, the power-series carrier of chapter 1583, the series tail package of chapter 2155, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names uniform Abel convergence as displayed finite rows; it is not a quotient equality of series, a selected infinite sum, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6123.1 (AbelUniform carrier)**.** *An* $\mathsf{AbelUniform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (R, S, P, W, T, Q, E, H, C, L, N)$$

with the following displayed rows:

1. *R is the finite radius-window row, listing the dyadic subradius requests and boundary-approach windows inspected by the Abel consumer.*
2. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *partial-sum row whose finite prefixes are being read inside those radius windows.*
3. *P is the* $\mathsf{RealPowerSeries}^{\uparrow}$ *row exposing the same coefficient windows, radius data, and partial-sum reads as power-series data.*
4. *W is the* $\mathsf{UniformConvergenceSeries}^{\uparrow}$ *tail-budget row, assigning a common tail threshold to every displayed radius-window request in R.*
5. *T is the* $\mathsf{AbelSummation}^{\uparrow}$ *and* $\mathsf{AbelLimitTheorem}^{\uparrow}$ *boundary row that records the Abel radial handoff after R, S, P, W have been accepted.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the synchronized partial-sum and power-series windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the Abel boundary row and the regular rational readback have been displayed.*
8. *H records componentwise* hsame *transport for the radius, RealSeries, RealPowerSeries, uniform-tail, Abel-boundary, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from each Abel uniform request through R, S, P, W, T, Q, E.*
10. *L is the* Pkg *provenance over* $\mathsf{AbelUniform}^{\uparrow}$, $\mathsf{AbelLimitTheorem}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{UniformConvergenceSeries}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelUniform}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, S, P, W, T, Q, E, H, C, L, N$. It has no coordinate for selected sums, quotient series equality, countable choice, host power-series equality, ambient completeness, or a Real seal detached from the displayed Abel uniform route.

Lean4 ✓ `BEDC.Derived.AbelUniformUp.TasteGate.AbelUniformTasteGate single carrier alignment`

Theorem 6123.2 (AbelUniform NameCert obligations)**.** *For every accepted* $\mathsf{AbelUniform}^{\uparrow}$ *carrier*

$$U = (R, S, P, W, T, Q, E, H, C, L, N),$$

the local $\mathsf{NameCert}_{\mathsf{AbelUniform}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, Abel radius-window monotonicity through R, RealSeries and RealPowerSeries partial-sum alignment through S and P, uniform-tail exactness through W, Abel boundary handoff through T, RegSeqRat readback and Real seal nonescape through Q and E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through L, and local naming through N. No obligation row supplies selected sums, quotient series equality, countable choice, host analytic equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 6123.1. Its mathematical rows are the radius-window row R, the $\mathsf{RealSeries}^{\uparrow}$ partial-sum row S, the $\mathsf{RealPowerSeries}^{\uparrow}$ row P, the $\mathsf{UniformConvergenceSeries}^{\uparrow}$ tail-budget row W, the Abel boundary row T, the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q, and the $\mathsf{Real}^{\uparrow}$ seal E.

The radius-window monotonicity is local to R. A smaller displayed radius window is read by restricting the same dyadic boundary row, while S and P keep the RealSeries prefix and RealPowerSeries partial-sum read synchronized over that window.

Uniform-tail exactness is supplied by W. For each requested tolerance, W gives one tail threshold shared by every displayed radius-window row, so the Abel boundary read in T cannot choose a separate threshold for each point of the window.

The readback and seal rows are downstream. The row Q repacks the accepted synchronized windows as regular rational data, and E exposes the terminal Real seal only after R, S, P, W, T, Q have been read.

Finally H, C, L, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for selected sums, quotient series equality, countable choice, host analytic equality, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 6123.3 (AbelUniform boundary consumer route)**.** *Every RealPowerSeries or RealSeries consumer of an accepted* $\mathsf{AbelUniform}^{\uparrow}$ *packet factors through*

$$\mathsf{RealSeries}^{\uparrow} \longmapsto \mathsf{RealPowerSeries}^{\uparrow} \longmapsto \mathsf{UniformConvergenceSeries}^{\uparrow} \longmapsto \mathsf{AbelSummation}^{\uparrow}/\mathsf{AbelLimitTheorem}^{\uparrow} \longmapsto \mathsf{Reg}$$

inside the same finite radius-window package. The consumer receives no selected sum, quotient equality of series, countable-choice schedule, host boundary-limit theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Start with the RealSeries and RealPowerSeries rows S and P. They name the same finite partial-sum windows, first as series-prefix data and then as radius-window power-series data.

Apply the uniform-tail row W. It supplies the shared threshold discipline needed by $\mathsf{UniformConvergenceSeries}^{\uparrow}$, so a boundary consumer cannot vary the tail budget independently across the displayed radius window.

Now read the Abel boundary row T. The sibling $\mathsf{AbelSummation}^{\uparrow}$ and $\mathsf{AbelLimitTheorem}^{\uparrow}$ routes are consumed only after R, S, P, W have fixed the finite radial surface.

The route then passes through $\mathsf{RegSeqRat}^{\uparrow}$ readback Q and terminal $\mathsf{Real}^{\uparrow}$ seal E, with H, C, L, N preserving the same packet. Because the refused host and quotient objects are absent from the carrier, every boundary consumer remains inside the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{AbelUniform}^{\uparrow}$ boundary read exposes a radius-window row, RealSeries partial-sum row, RealPowerSeries row, UniformConvergenceSeries tail budget, Abel boundary row, RegSeqRat readback, RealUp seal, componentwise transport, displayed replay, provenance, and local NameCert before a Real-facing consumer can inspect the endpoint.

Independence witness: abel-limit-theorem, abel-summation, realpowerseries, uniform-convergence-series, regseqrat, real: none is bijective to $\mathsf{AbelUniform}^{\uparrow}$ because this packet jointly carries radius-window monotonicity, RealSeries and RealPowerSeries partial-sum alignment, one uniform tail budget, Abel boundary handoff, regular rational readback, terminal real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelUniform}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelUniform}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6123.1, Definition 6123.2, and Definition 6123.3 seed the finite uniform Abel boundary over radius windows, RealSeries partial sums, RealPowerSeries rows, UniformConvergenceSeries tail budgets, RegSeqRat readback, and the RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelUniform}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected sums, quotient equality of series, countable choice, host analytic equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius-window monotonicity, partial-sum alignment, uniform-tail exactness, Abel boundary handoff, readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.AbelUniformUp.

Constructive story: An $\mathsf{AbelUniform}^{\uparrow}$ packet is generated from radius-window rows, RealSeries partial sums, RealPowerSeries rows, UniformConvergenceSeries tail budgets, AbelSummation and AbelLimitTheorem boundary rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6124

A Concrete Naming Certificate for $\mathsf{WorldModelClassifier}^{\uparrow}$

The $\mathsf{WorldModelClassifier}^{\uparrow}$ packet realizes the classifier-certification branch of section 9462.16 as finite NameCert data. It sits beside the action-ledger surface of chapter 290, the statistical decision surface of chapter 231, the probability context of chapter 184, the measurable observation rows of chapter 185, and the certified-quality boundary of chapter 6117. The packet certifies scoped latent recovery, identifiability, transfer, and residue rows; it does not assert global representation truth, hidden causal sufficiency, unrestricted planning success, or model-quality completeness.

Definition 6124.1 (WorldModelClassifier carrier)**.** *A* $\mathsf{WorldModelClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, L, C, I, T, Q, E, H, R, P, N)$$

with the following displayed rows:

1. *S is the scoped source row, recording the observation carrier, admitted latent carrier, probability context, random-variable reads, pair protocol, transition family, and assumption ledger.*
2. *L is the latent-recovery row, exposing the recovered coordinate, invariant, state, or feature comparison used by the classifier.*
3. *C is the classifier row, naming the world-model relation read from L.*
4. *I is the identifiability row, recording equivalence mode, bound, gauge freedom, residual cases, and not-claimed latent domains.*
5. *T is the transfer row, routing the certified classifier to policy, hypothesis-test, or model-quality consumers.*
6. *Q is the* $\mathsf{CertifiedModelQuality}^{\uparrow}$ *readback row for scoped quality claims.*
7. *E is the residue ledger, recording shortcut risk, finite-sample residue, distributional boundary, intervention failure, and planning-transfer boundary.*
8. *H records componentwise* hsame *transport for S, L, C, I, T, Q, E.*
9. *R records displayed* Cont *replay from source rows through recovery, classifier, identifiability, transfer, quality, and residue rows.*
10. *P is the* Pkg *provenance over* $\mathsf{WorldModelClassifier}^{\uparrow}$, $\mathsf{Policy}^{\uparrow}$, $\mathsf{HypothesisTest}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CertifiedModelQuality}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{WorldModelClassifier}^{\uparrow}}$ *row.*

The carrier contains no coordinate for unscoped latent truth, host causal sufficiency, hidden distributional law, unrestricted policy optimality, or quality claims outside the displayed source and residue rows.

Theorem 6124.2 (WorldModelClassifier NameCert obligations)**.** *For every accepted* $\mathsf{WorldModelClassifier}^{\uparrow}$ *carrier* $W = (S, L, C, I, T, Q, E, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WorldModelClassifier}^{\uparrow}}$ *surface consists exactly of carrier admission; scoped source exposure through* $\mathsf{ProbSpace}^{\uparrow}$ *and* $\mathsf{RandomVar}^{\uparrow}$*; latent-recovery exposure; classifier-row exactness; identifiability ledger exposure; transfer routing to* $\mathsf{Policy}^{\uparrow}$*,* $\mathsf{HypothesisTest}^{\uparrow}$*, or* $\mathsf{CertifiedModelQuality}^{\uparrow}$*; residue nonescape; componentwise transport; displayed replay; provenance; and local naming.*

Proof. Carrier admission is projection from Definition 6124.1. The displayed packet lists the source, recovery, classifier, identifiability, transfer, quality, residue, and structural rows.

The source exposure is S. It names the probability and random-variable context before recovery or transfer can be read.

The classifier is exposed by L, C, I. Recovery produces the comparison surface, the classifier row names it, and the identifiability row records the equivalence mode, bound, gauge freedom, and residual cases.

The transfer and quality rows are T and Q. They allow policy, hypothesis-test, and certified-model-quality consumers to read only the scoped classifier route.

Finally E, H, R, P, N record residue, transport, replay, provenance, and local naming. Since the omitted objects are not carrier coordinates, the obligation surface is exhausted by the displayed rows. □

Theorem 6124.3 (WorldModelClassifier transfer and residue boundary)**.** *Let* $W = (S, L, C, I, T, Q, E, H, R, P, N)$ *be an accepted* $\mathsf{WorldModelClassifier}^{\uparrow}$ *carrier. Any* $\mathsf{Policy}^{\uparrow}$*,* $\mathsf{HypothesisTest}^{\uparrow}$*, or* $\mathsf{CertifiedModelQuality}^{\uparrow}$ *consumer that reads the world-model classifier must traverse*

$$S, L, C, I, T, Q, E, H, R, P, N.$$

The route exports scoped latent recovery, identifiability, transfer, and residue ledgers, but it exports no global representation truth, unledgered distribution shift, unrestricted policy optimality, hidden causal sufficiency, or model-quality completeness.

Proof. Start from the consumer request. The only transfer row is T, and it is downstream of the source, recovery, classifier, and identifiability rows.

Read S, L, C, I first. These rows display the scoped observation and probability context, the recovered latent comparison, the classifier relation, and the identifiability ledger.

The quality readback Q and residue ledger E are part of the same finite packet. They force policy, hypothesis-test, and certified-quality consumers to preserve finite-sample, distributional, intervention, shortcut, and planning-boundary residue.

Transport and replay through H, R and provenance through P, N do not add hidden truth or optimality coordinates. Therefore every exported read is confined to the displayed route. □

Falsifiable prediction: A $\mathsf{WorldModelClassifier}^{\uparrow}$ packet is refuted whenever a policy, hypothesis-test, or certified-model-quality consumer reads classifier quality without displaying the scoped source row, latent-recovery row, identifiability row, transfer row, and residue ledger.

Independence witness: policy, hypothesis, probspace, randomvar, certified-model-quality: none is bijective to $\mathsf{WorldModelClassifier}^{\uparrow}$ because this packet binds scoped latent recovery, classifier

exactness, identifiability, transfer, quality readback, and residue ledger rows in one carrier, while each sibling supplies only action selection, statistical decision, probability context, observation measurability, or quality certification.

Lean follow-up must provide `Nontrivial WorldModelClassifierUp` and `FieldFaithful WorldModelClassif` in `TasteGate.lean` before the carrier can be treated as a TasteGate field-faithful object.

Closure status for $\mathsf{NameCert}_{\mathsf{WorldModelClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{WorldModelClassifier}^{\uparrow}$ packet is generated from a scoped source row, latent-recovery row, classifier row, identifiability ledger, transfer row, certified-quality readback, residue ledger, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WorldModelClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6124.1, Definition 6124.2, and Definition 6124.3 seed the finite classifier route for scoped latent recovery, identifiability, transfer, quality readback, and residue ledgers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WorldModelClassifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global representation truth, hidden causal sufficiency, unrestricted policy optimality, unledgered distribution shift, model-quality completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source exposure, latent-recovery exposure, classifier exactness, identifiability ledger, transfer routing, quality readback, residue nonescape, transport, replay, provenance, and local naming for BEDC.Derived.WorldModelClassifierUp.

Chapter 6125

A Concrete Naming Certificate for $\mathsf{FiniteSubcoverLedger}^{\uparrow}$

The $\mathsf{FiniteSubcoverLedger}^{\uparrow}$ packet records the finite subcover handoff used by the compact-uniform-continuity route of chapter 9237. It sits over a $\mathsf{CompactMetric}^{\uparrow}$ source row, a $\mathsf{TotallyBounded}^{\uparrow}$ finite-net schedule, the dyadic radius rows of chapter 291, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer, packaging the finite ProbeBundle cover-selection route as NameCert data rather than as an open-cover compactness theorem.

Definition 6125.1 (Finite subcover ledger carrier)**.** *A* $\mathsf{FiniteSubcoverLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, T, B, D, S, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose metric windows and compact source provenance are visible to the cover request.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net schedule naming the centers and mesh tolerance used to inspect the cover.*
3. *B is the finite* ProbeBundle *cover spine whose entries are the only cover candidates admitted by the ledger.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius and comparison ledger attached to the same finite cover spine.*
5. *S is the selected finite subcover row, displayed as a sublist of B with its inherited radius data.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row that consumes the finite subcover ledger for compact-continuity arguments.*
7. *H stores componentwise* hsame *transport for the compact source, net schedule, cover spine, dyadic ledger, subcover row, uniform-modulus handoff, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a compact-uniform request through the finite cover spine and into the uniform-modulus handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteSubcoverLedger}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSubcoverLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open covers, selected infinite subcovers, host compactness, quotient point equality, countable choice, or ambient completeness.

Lean4 (definition) `BEDC.Derived.FiniteSubcoverLedgerUp.FiniteSubcoverLedgerUp`
Lean4 ✓ `BEDC.Derived.FiniteSubcoverLedgerUp.FiniteSubcoverLedgerTasteGate single carrier alignment`

Theorem 6125.2 (Finite subcover ledger obligations)**.** *For every accepted* $\mathsf{FiniteSubcoverLedger}^{\uparrow}$ *carrier*

$$L = (K, T, B, D, S, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteSubcoverLedger}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, compact-source exposure through* K*, finite-net exposure through* T*, finite* ProbeBundle *cover admission through* B*, dyadic radius accounting through* D*, finite subcover display through* S*,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff through* U*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, local naming through* N*, and non-escape from host open-cover compactness.*

Proof. Project the carrier of Definition 6125.1. The only cover candidates available to the packet are the finite entries of B, and the only source coverage data are the compact source K, finite-net schedule T, and dyadic radius ledger D.

Read the selected subcover row S as a displayed finite sublist of the same ProbeBundle spine. Because S inherits its radii from D and its source coverage from K, T, the ledger never invokes an arbitrary open cover or a selected infinite subcover.

Finally route the ledger into U and the structural rows H, C, P, N. The $\mathsf{UniformModulus}^{\uparrow}$ consumer receives exactly the finite subcover handoff, while host compactness, quotient point equality, countable choice, and ambient completeness remain outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{FiniteSubcoverLedger}^{\uparrow}$ read must expose the $\mathsf{CompactMetric}^{\uparrow}$ source, the $\mathsf{TotallyBounded}^{\uparrow}$ finite-net schedule, the finite ProbeBundle cover spine, the $\mathsf{DyadicRatCore}^{\uparrow}$ radius ledger, the selected finite subcover row, the $\mathsf{UniformModulus}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: compactmetric, totallybounded, dyadicratcore, uniformmodulus: none is bijective with $\mathsf{FiniteSubcoverLedger}^{\uparrow}$ because this packet jointly carries the compact source, finite-net schedule, finite cover spine, selected subcover row, radius ledger, uniform-modulus handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSubcoverLedger}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteSubcoverLedger}^{\uparrow}$ packet is generated from a CompactMetric source row, a TotallyBounded finite-net schedule, a finite ProbeBundle cover spine, a DyadicRatCore radius ledger, a displayed finite subcover row, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteSubcoverLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6125.1 and Definition 6125.2 seed the finite subcover route through $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteSubcoverLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, selected infinite subcovers, host compactness, quotient point equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, finite-net exposure, cover-spine admission, dyadic radius accounting, selected subcover display, uniform-modulus handoff, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.FiniteSubcoverLedgerUp.

Chapter 6126

A Concrete Naming Certificate for $\mathsf{RealSine}^{\uparrow}$

Following Bishop and Bridges on constructive power series, the $\mathsf{RealSine}^{\uparrow}$ packet isolates the sine series as its own finite NameCert route instead of leaving it as a local trigonometric block inside chapter 74. The packet reads the alternating odd-power coefficient ledger through $\mathsf{RealPowerSeries}^{\uparrow}$, the bounded-window convergence route through $\mathsf{UniformCauchySeries}^{\uparrow}$, the product and addition handoff through $\mathsf{CauchyProduct}^{\uparrow}$, the endpoint comparison through $\mathsf{RealEquality}^{\uparrow}$, and the terminal seal through $\mathsf{Real}^{\uparrow}$. It shares the factorial-budget discipline of chapter 1816, but its parity ledger is the odd alternating sine ledger rather than the exponential $1/n!$ ledger.

Definition 6126.1 (RealSine carrier)**.** *A* $\mathsf{RealSine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, F, B, U, M, K, P, E, Q, H, C, L, N)$$

with the following displayed rows:

1. *A is the alternating odd-coefficient ledger fixing the sine series by $a_{2k} = 0$ and $a_{2k+1} = (-1)^k/(2k+1)!$ on each inspected unary window.*
2. *F is the factorial and reciprocal dyadic budget row for the odd denominators, signs, reciprocal enclosures, and denominator-growth comparisons used by A.*
3. *B is the bounded real-window row on which the sine evaluation request is accepted.*
4. *U is the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *row proving uniform Cauchy convergence of the displayed odd alternating partial sums on B.*
5. *M is the majorant tail-budget row, using the alternating-series and factorial-growth estimates to bound every endpoint-facing tail without selecting a host infinite sum.*
6. *K is the* $\mathsf{CauchyProduct}^{\uparrow}$ *route used by sine addition, odd-parity product splitting, and compatibility with the cosine-side sibling route in chapter 74.*
7. *P is the* $\mathsf{RealPowerSeries}^{\uparrow}$ *evaluation row exposing coefficient windows, argument powers, partial sums, and endpoint request as power-series data.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the coefficient ledger, dyadic budget, uniform Cauchy route, tail budget, product route, and power-series row have been displayed.*
9. *Q is the* $\mathsf{RealEquality}^{\uparrow}$ *classifier row for comparing accepted sine readbacks through the displayed endpoint boundary.*

10. *H is componentwise* hsame *transport for $A, F, B, U, M, K, P, E, Q, C, L, N$.*

11. *C is the displayed* Cont *replay from coefficient and factorial windows to partial sums, from partial sums to uniform Cauchy control, from the uniform route to the power-series endpoint, and from the endpoint to the Real and equality consumers.*

12. *L is the* Pkg *provenance over* $\mathsf{RealSine}^{\uparrow}$, $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{UniformCauchySeries}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{RealEquality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSine}^{\uparrow}}$ *row.*

The classifier compares accepted sine packets only through $A, F, B, U, M, K, P, E, Q, H, C, L, N$. It has no coordinate for a host sine function, analytic continuation, quotient real equality, selected infinite sum, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealSineUp.RealSineTasteGate single carrier alignment`

Theorem 6126.2 (RealSine NameCert obligations)**.** *For every accepted* $\mathsf{RealSine}^{\uparrow}$ *carrier $S = (A, F, B, U, M, K, P, E, Q, H, C, L, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealSine}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the alternating odd-coefficient ledger, factorial and reciprocal dyadic budget, bounded real window, uniform Cauchy modulus, majorant tail budget, Cauchy-product route, RealPowerSeries evaluation row, Real seal, RealEquality classifier, transport, continuation, provenance, and local naming rows;*

2. *coefficient exactness, requiring every inspected coefficient to be read from A together with the odd factorial and sign budget in F;*

3. *uniform Cauchy convergence through U and M, requiring every endpoint-facing tail to pass through the bounded-window and majorant rows before P or E is consumed;*

4. *power-series evaluation through P, requiring the endpoint request to be a* $\mathsf{RealPowerSeries}^{\uparrow}$ *read rather than a host trigonometric primitive;*

5. *endpoint classifier stability through Q, H, C, requiring accepted comparisons to preserve the displayed* $\mathsf{RealEquality}^{\uparrow}$ *boundary under componentwise transport and replay;*

6. *ledger nonescape through L, N, requiring the local packet to export no host* sin*, analytic-continuation datum, quotient real equality, selected infinite sum, countable-choice selector, or ambient completeness witness.*

Proof. Carrier admission is projection from Definition 6126.1. The accepted packet displays exactly the rows $A, F, B, U, M, K, P, E, Q, H, C, L, N$, so every public sine read has a visible coefficient, convergence, endpoint, classifier, and structural source.

Coefficient exactness is the joint read of A and F. The ledger A fixes the even coefficients as zero and the odd coefficients as alternating reciprocal factorials, while F supplies the inspected factorial and dyadic reciprocal budgets that make those coefficients finite BEDC data.

Uniform Cauchy convergence is read through B, U, M. The bounded window B fixes the evaluation scope; U supplies the uniform Cauchy route; and M supplies the displayed tail budget before any endpoint seal may be consumed.

The endpoint and classifier rows are P, E, Q. The row P places the read inside $\mathsf{RealPowerSeries}^{\uparrow}$, E is the only $\mathsf{Real}^{\uparrow}$ seal, and Q is the only endpoint classifier boundary. The transport and replay rows H, C preserve these rows componentwise.

Finally L and N record provenance and local naming for the same finite packet. Since no listed row contains a host trigonometric function, selected limit, quotient equality, countable-choice selector, or ambient completeness principle, none of those objects is exported by the local $\mathsf{NameCert}_{\mathsf{RealSine}^\uparrow}$ surface. □

Theorem 6126.3 (RealSine power-series route)**.** *Every public read of an accepted* $\mathsf{RealSine}^\uparrow$ *packet factors through*

$$\mathsf{RealAnalytic}^\uparrow,\quad \mathsf{RealPowerSeries}^\uparrow,\quad \mathsf{UniformCauchySeries}^\uparrow,\quad \mathsf{CauchyProduct}^\uparrow,\quad \mathsf{RealEquality}^\uparrow,\quad \mathsf{Real}^\uparrow$$

before any endpoint is consumed. Consequently the public route names sine by finite alternating coefficient data, bounded-window Cauchy control, Cauchy-product handoff, endpoint equality, and Real seal data, not by a host trigonometric primitive.

Proof. Begin with a public sine read. The source theorem cluster in chapter 74 supplies the local sine partial-sum and trigonometric Cauchy-modulus material, while the standalone carrier of Definition 6126.1 repacks the relevant rows as $A, F, B, U, M, K, P, E, Q, H, C, L, N$.

The coefficient and factorial reads A, F enter $\mathsf{RealPowerSeries}^\uparrow$ through P. The bounded real window B fixes the evaluation scope, and the partial sums remain power-series data until the uniform route is accepted.

Uniform convergence is supplied by U and M. These rows place the odd alternating partial sums inside $\mathsf{UniformCauchySeries}^\uparrow$ and expose the majorant tail budget before the endpoint seal is available.

Law-facing and comparison-facing reads then pass through K, Q, E. The row K supplies the $\mathsf{CauchyProduct}^\uparrow$ handoff used by the sine addition route, Q supplies the $\mathsf{RealEquality}^\uparrow$ endpoint classifier, and E is the terminal $\mathsf{Real}^\uparrow$ seal.

The structural rows H, C, L, N preserve the same route as transport, replay, provenance, and local naming. Thus every public endpoint read factors through the displayed analytic, power-series, uniform-Cauchy, product, equality, and Real rows before the sine value is consumed. □

Falsifiable prediction: Every $\mathsf{RealSine}^\uparrow$ public read factors through an alternating odd-coefficient ledger, factorial and reciprocal dyadic budgets, a bounded real-window row, a uniform Cauchy-series modulus, a majorant tail budget, a Cauchy-product route, a RealPowerSeries evaluation row, a RealEquality classifier row, a RealUp seal, transport, continuation, provenance, and local naming.

Independence witness: real-analytic, real-exponential, realpowerseries, uniform-cauchy-series, cauchyproduct, real-equality, real: $\mathsf{RealSine}^\uparrow$ is not bijective to any listed sibling because it jointly carries the odd alternating sine coefficient ledger, factorial reciprocal budget, bounded-window uniform convergence route, Cauchy-product trigonometric handoff, endpoint equality classifier, Real seal, transport, continuation, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealSine}^\uparrow}$**.**

Constructive story: A $\mathsf{RealSine}^\uparrow$ packet is generated from the alternating odd-coefficient ledger $a_{2k} = 0$ and $a_{2k+1} = (-1)^k/(2k+1)!$, factorial and reciprocal dyadic budgets, a bounded real-window row, a uniform Cauchy-series modulus, a majorant tail budget, a Cauchy-product route, a RealPowerSeries evaluation row, a RealEquality classifier row, a RealUp seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealSine}^\uparrow}$, seed)

Scope closed: Definition 6126.1, Definition 6126.2, and Definition 6126.3 seed the finite sine power-series route through existing BEDC analytic, power-series, uniform-Cauchy, product, equality, and Real infrastructure.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealSine}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host trigonometric functions, analytic continuation, quotient real equality, selected infinite sums, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient exactness, uniform Cauchy convergence, power-series evaluation, endpoint classifier stability, ledger nonescape, and TasteGate field faithfulness for BEDC.Derived.RealSineUp.

Chapter 6127

A Concrete Naming Certificate for $\mathsf{FiniteMeasure}^{\uparrow}$

Following Halmos and Kolmogorov finite measure theory, the $\mathsf{FiniteMeasure}^{\uparrow}$ packet names the finite additive event-value ledger that measure-facing chapters use before invoking countable or completed measure structure. It sits after the event-family rows of chapter 5186, the finite tally route of chapter 5996, the finite-cell approximation surface of chapter 5884, the root event-value packet of chapter 92, and the scalar readback of chapter 38. The packet records only finite event values and their displayed finite additivity route.

Definition 6127.1 (Finite measure carrier)**.** *A* $\mathsf{FiniteMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, E, V, A, T, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SigmaAlgebra}^{\uparrow}$ *event-family row, exposing the admitted measurable events and their displayed classifier.*
2. *E is the finite event ledger, listing the particular event rows whose values are visible to the packet.*
3. *V is the finite event-value ledger, assigning to every event in E a displayed non-negative* $\mathsf{Real}^{\uparrow}$ *value.*
4. *A is the finite disjoint-additivity ledger, recording the binary and finite-family disjoint-union checks admitted by the packet.*
5. *T is the total-mass bound row, naming a displayed* $\mathsf{Real}^{\uparrow}$ *bound for the whole admitted event family.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar readback row, routing event values, sums, and the total-mass bound through the same scalar certificate surface.*
7. *H records componentwise* hsame *transport for the event-family, finite event ledger, value ledger, additivity ledger, total-mass bound, scalar readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an event-value request through S, E, V, A, T, R and then to the structural rows.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteMeasure}^{\uparrow}$, $\mathsf{SigmaAlgebra}^{\uparrow}$, $\mathsf{CountingMeasure}^{\uparrow}$, $\mathsf{SimpleFunctionApproximation}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteMeasure}^\uparrow}$ *row.*

The carrier has no coordinate for sigma-additive completion, host measure objects, quotient event equality, countable choice, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 6127.2 (FiniteMeasure NameCert obligations)**.** *For every accepted* $\mathsf{FiniteMeasure}^\uparrow$ *carrier* $F = (S, E, V, A, T, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteMeasure}^\uparrow}$ *surface consists exactly of the sigma-algebra event-family row, finite event ledger, finite event-value ledger, finite disjoint-additivity ledger, total-mass bound,* $\mathsf{Real}^\uparrow$ *scalar readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A downstream* $\mathsf{Measure}^\uparrow$*,* $\mathsf{RadonMeasure}^\uparrow$*,* $\mathsf{Egorov}^\uparrow$*,* $\mathsf{DominatedConvergence}^\uparrow$*,* $\mathsf{CountingMeasure}^\uparrow$*, or* $\mathsf{SimpleFunctionApproximation}^\uparrow$ *consumer must expose those rows before treating the packet as a finite measure substrate.*

Lean4 ✓ `BEDC.Derived.FiniteMeasureUp.FiniteMeasureCarrier namecert obligations`

Proof. Project the carrier of Definition 6127.1. The row S is the only source of measurable-event admission, while E restricts public values to the displayed finite event ledger.

Read the value and additivity rows. The ledger V supplies the visible event values, A records exactly the finite disjoint-union checks available to consumers, and T gives the displayed total-mass bound for the same event family.

The row R routes every value, finite sum, and bound through the $\mathsf{Real}^\uparrow$ scalar readback surface. Transport and replay are componentwise through H and C, so no second event equality or hidden scalar completion is introduced.

Finally P and N source and name this packet. Since the carrier contains no sigma-additive completion, host measure object, quotient event equality, countable-choice selector, or ambient Real-completeness coordinate, the listed rows exhaust the local NameCert obligation surface. □

Theorem 6127.3 (FiniteMeasure counting-measure handoff)**.** *Every accepted* $\mathsf{CountingMeasure}^\uparrow$ *packet whose finite support and event rows are read as finite event values can hand off to* $\mathsf{FiniteMeasure}^\uparrow$ *only through the displayed rows* $S, E, V, A, T, R, H, C, P, N$*. The handoff preserves the finite tally as a* $\mathsf{Real}^\uparrow$ *value row, exposes finite disjoint additivity through the ledger* A*, and exports no sigma-additive completion, host measure object, quotient event equality, countable-choice selector, or ambient* $\mathsf{Real}^\uparrow$ *completeness claim.*

Proof. Start with the finite support and tally rows supplied by $\mathsf{CountingMeasure}^\uparrow$. They determine event values only for the displayed finite event rows, so the target $\mathsf{FiniteMeasure}^\uparrow$ packet must first expose S and E.

The tally readback becomes a value row through V and R. Finite disjoint unions are then routed through A, while the total mass is bounded by T over the same event-family row.

Transport, replay, provenance, and naming are carried by H, C, P, N. These rows preserve the counting route as finite event-value data and do not add countable unions, host measures, quotient event representatives, choice-selected supports, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMeasure}^\uparrow}$.

Constructive story: A $\mathsf{FiniteMeasure}^\uparrow$ packet is generated from a SigmaAlgebraUp event-family row, finite event ledger, finite event-value ledger, finite disjoint-additivity ledger, total-mass bound, RealUp scalar readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteMeasure}^\uparrow}$, seed)

Scope closed: Definition 6127.1, Definition 6127.2, and Definition 6127.3 seed the finite additive event-value substrate consumed by MeasureUp, RadonMeasureUp, EgorovUp, DominatedConvergenceUp, CountingMeasureUp, and SimpleFunctionApproximationUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteMeasure}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close sigma-additive completion, host measure objects, quotient event equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked event-family admission, finite event-value exactness, finite disjoint-additivity, total-mass bound readback, Real scalar transport, replay, provenance, and local naming for BEDC.Derived.FiniteMeasureUp.FiniteMe

Chapter 6128

A Concrete Naming Certificate for $\mathsf{LegendrePolynomial}^{\uparrow}$

Following Legendre's polynomial family and Szego's orthogonal-polynomial presentation, the $\mathsf{LegendrePolynomial}^{\uparrow}$ packet names the finite recurrence, normalization, and interval-weight rows for the displayed family P_n without importing a host function space. It sits after the polynomial carrier of chapter 50, the orthogonal-family surface of chapter 2264, the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic endpoint and coefficient ledger of chapter 291, and the adjacent recurrence model of chapter 3480.

Definition 6128.1 (Legendre polynomial carrier)**.** *A* $\mathsf{LegendrePolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (d, P_0, P_1, R, N, O, W, Q, E, H, C, \Pi, A)$$

with the following displayed rows:

1. *d is the unary degree-window row.*
2. *P_0 and P_1 are the displayed seed polynomial rows for 1 and x inside* $\mathsf{Poly}^{\uparrow}$*.*
3. *R is the finite recurrence ledger for $(n+1)P_{n+1} = (2n+1)xP_n - nP_{n-1}$, including the dyadic coefficient rows needed for each inspected step.*
4. *N is the normalization row recording $P_n(1) = 1$ on the displayed window.*
5. *O is the* $\mathsf{OrthogonalPolynomial}^{\uparrow}$ *handoff row for the interval-weight and finite moment ledger over the real interval endpoints.*
6. *W is the finite evaluation-window row.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for inspected evaluations and coefficients.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the endpoint and evaluation reads.*
9. *H records componentwise* hsame *transport for the displayed rows.*
10. *C records displayed* Cont *replay of recurrence, normalization, orthogonality, and readback requests.*
11. *Π is the* Pkg *provenance over* $\mathsf{LegendrePolynomial}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{OrthogonalPolynomial}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{ChebyshevPolynomial}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
12. *A is the local* $\mathsf{NameCert}_{\mathsf{LegendrePolynomial}^{\uparrow}}$ *row.*

The carrier has no coordinate for host function-space equality, analytic completeness, selected infinite expansions, classical completeness, quotient real equality, or arbitrary choice of an orthogonal basis.

Lean4 (definition) `BEDC.Derived.LegendrePolynomialUp.LegendrePolynomialUp`

Theorem 6128.2 (Legendre polynomial NameCert obligations)**.** *For every accepted* $\mathsf{LegendrePolynomial}^{\uparrow}$ *carrier* $L = (d, P_0, P_1, R, N, O, W, Q, E, H, C, \Pi, A)$*, the local* $\mathsf{NameCert}_{\mathsf{LegendrePolynomial}^{\uparrow}}$ *surface consists exactly of carrier admission for the degree window, seed polynomials, finite recurrence ledger, normalization row, orthogonal-polynomial handoff, evaluation window, regular rational readback, Real seal, componentwise transport, displayed replay, package provenance, and local naming. The certificate exports no host function-space equality, analytic completeness, selected infinite expansion, classical completeness, or ambient basis theorem.*

Proof. Project the carrier of Definition 6128.1. The rows d, P_0, P_1, R, N display the finite Legendre recurrence and its normalization over the inspected degree window.

Read the orthogonal-family row O next. It is a handoff to $\mathsf{OrthogonalPolynomial}^{\uparrow}$ over the real interval and finite moment ledger, so the packet names only the displayed orthogonality surface rather than a host function space.

The consumer-facing rows W, Q, E then provide finite evaluation windows, regular rational readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal. The structural rows H, C, Π, A transport, replay, source, and name the same packet, and the excluded analytic and choice principles have no coordinate in the carrier. □

Theorem 6128.3 (Legendre polynomial orthogonal-family route)**.** *Every accepted* $\mathsf{LegendrePolynomial}^{\uparrow}$ *orthogonality read factors through*

$$d, P_0, P_1, R, N \longmapsto O \longmapsto W, Q, E \longmapsto H, C, \Pi, A.$$

Thus the Legendre packet reaches $\mathsf{OrthogonalPolynomial}^{\uparrow}$ *through a finite recurrence and normalization ledger before any downstream approximation or spectral-basis consumer may read the orthogonal-family row. The route may cite the neighboring Chebyshev recurrence surface as a sibling recurrence anchor, but it does not identify the two families or import selected infinite expansions, host function-space equality, analytic completeness, or classical completeness.*

Proof. Begin with the finite recurrence rows d, P_0, P_1, R. These rows display the degree window, the two seeds, and each inspected recurrence step using $\mathsf{Poly}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ coefficient data.

The normalization row N and the orthogonal-family row O then form the route into $\mathsf{OrthogonalPolynomial}^{\uparrow}$. This is the only row that a downstream orthogonal-polynomial consumer may read, and it is still tied to the displayed recurrence ledger.

The rows W, Q, E provide evaluation windows, regular rational readback, and the $\mathsf{Real}^{\uparrow}$ seal. Transport, replay, provenance, and local naming through H, C, Π, A preserve the same route without adding a host function space, an infinite expansion selector, analytic completeness, or classical completeness. □

Falsifiable prediction: Every $\mathsf{LegendrePolynomial}^{\uparrow}$ read factors through one degree window, two seed polynomial rows, one finite recurrence ledger, one normalization row, one OrthogonalPolynomialUp handoff, finite evaluation windows, RegSeqRat readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: polynomial, orthogonal-polynomial, real, regseqrat, dyadicratcore, chebyshev-polynomial: $\mathsf{LegendrePolynomial}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the Legendre seeds, recurrence coefficients, normalization row, orthogonal-family handoff, finite evaluation windows, regular readback, Real seal, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{LegendrePolynomial}^{\uparrow}}$.

Constructive story: A $\mathsf{LegendrePolynomial}^{\uparrow}$ packet is generated from a unary degree window, seed polynomial rows, a finite Legendre recurrence ledger, normalization at the real unit endpoint, an OrthogonalPolynomial handoff row, finite evaluation windows, RegSeqRat readback, Real seals, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LegendrePolynomial}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6128.1, Definition 6128.2, and Definition 6128.3 seed the finite Legendre recurrence certificate and its orthogonal-family route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LegendrePolynomial}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function-space equality, analytic completeness, selected infinite expansions, classical completeness, quotient real equality, Lean verification, or bridge checking for $\mathsf{LegendrePolynomial}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, recurrence ledger exactness, normalization exactness, orthogonal-family handoff, finite evaluation windows, regular readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LegendrePolynomialUp.

Chapter 6129

A Concrete Naming Certificate for $\mathsf{CauchyFilterSpace}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley filter-space practice, the $\mathsf{CauchyFilterSpace}^{\uparrow}$ packet records the finite NameCert surface of a Cauchy filter space before a regularization or completion consumer reads it. It sits over the Cauchy filter carrier of chapter 333, next to the regularized completion-facing surface of chapter 4102, and routes finite observations through the stream windows of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet is a human-known completion-facing object: it names the displayed filter-space rows that a completion route may inspect without adding quotient filters, selected limits, countable choice, separated completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6129.1 (Cauchy filter space carrier)**.** *A* $\mathsf{CauchyFilterSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, B, Q, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the point and basic-neighborhood carrier row, retaining classifier-distinct point and neighborhood names without quotienting them by convergence or host equality.*
2. *B is the* $\mathsf{CauchyFilter}^{\uparrow}$ *basis row, exposing finite filter-membership requests, directed refinements, and Cauchy pressure witnesses available to the packet.*
3. *Q is the filter-space exactness row, tying each accepted Cauchy request to the same point classifier and the same displayed filter-basis rows in X and B.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *inspection row for finite observation windows requested by completion-facing consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and Cauchy pressure rows, before any real seal is public.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *sealing row reached only after S, R and the filter-space exactness row Q have been displayed.*
7. *H records componentwise* hsame *transport for all carrier, basis, exactness, window, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through the same finite route.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterSpace}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient filter equality, a selected representative filter, a selected limit point, countable choice, separated completion, or host equality of point names.

Lean4 ✓ `BEDC.Derived.CauchyFilterSpaceUp.CauchyFilterSpaceTasteGate single carrier alignment`

Theorem 6129.2 (Cauchy filter space NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterSpace}^{\uparrow}$ *carrier*

$$F = (X, B, Q, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyFilterSpace}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the point/neighborhood carrier X, Cauchy filter basis B, filter-space exactness row Q, stream windows S, regular rational readback R, real seal E, transport H, replay C, provenance P, and local naming N;*
2. *filter-space exactness, requiring every accepted read to use the displayed point classifier and Cauchy filter rows of X, B, Q;*
3. *window and readback stability, requiring finite stream observations, rational readback, and real sealing to move only componentwise through H and to replay through C;*
4. *ledger nonescape, excluding quotient filters, host equality, selected representatives, selected limits, countable choice, separated completion, and ambient real completeness from the packet;*
5. *completion-facing handoff, exporting only $X, B, Q, S, R, E, H, C, P, N$ to regular Cauchy filter space or completion consumers before those consumers add their own regularity or completion rows.*

No other NameCert obligation is available from the Cauchy filter space packet.

Proof. Carrier admission is the projection of Definition 6129.1. The tuple lists the point/neighborhood carrier, Cauchy filter basis, exactness row, finite stream windows, regular rational readback, Real seal, transport, replay, provenance, and local naming rows.

Filter-space exactness is carried by Q. A consumer first fixes the point classifier in X and the Cauchy filter basis in B, then reads finite requests through Q, S before asking for rational or real data.

Window and readback stability are componentwise. The row H transports the displayed coordinates, and the row C replays the same route for consumers, so Cauchy pressure and readback cannot be replaced by host equality or by a detached separated-completion fact.

Ledger nonescape follows from the carrier inventory. There is no coordinate for quotient filter equality, selected representatives, selected limits, countable choice, separated completion, or ambient real completeness.

Finally the completion-facing handoff is only the displayed tuple $X, B, Q, S, R, E, H, C, P, N$. A $\mathsf{RegularCauchyFilterSpace}^{\uparrow}$ or completion consumer may use that finite filter-space surface as input, but any regularity witness, completion object, quotient, or limit belongs to the consumer packet rather than to this carrier. □

Theorem 6129.3 (Cauchy filter space completion handoff)**.** *Let $F = (X, B, Q, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterSpace}^{\uparrow}$ *carrier. Every* $\mathsf{RegularCauchyFilterSpace}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$

consumer route exported by F factors through the displayed Cauchy filter basis, filter-space exactness row, stream-window inspection row, rational readback row, real-seal row, componentwise transport, replay, provenance, and local naming rows. The route exports no quotient filter, selected limit, countable-choice selector, separated completion, host point equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start with any completion-facing read of F. By Definition 6129.1, the only source rows available to that read are the displayed point/neighborhood carrier X, Cauchy filter basis B, and exactness row Q.

The read then passes through the finite observation interface. The stream row S exposes the requested windows, the rational row R supplies the regular readback attached to those windows, and the seal row E is reached only after the same displayed route has been replayed.

The structural rows do not add new completion data. Transport is componentwise through H, replay is through C, provenance is through P, and local naming is through N.

Thus a downstream regular Cauchy filter space or completion packet can consume the finite boundary of F, but it cannot extract a quotient filter, selected limit, countable-choice selector, separated completion, host point equality, or ambient real-completeness witness from this carrier. □

Falsifiable prediction: A consumer that claims a $\mathsf{CauchyFilterSpace}^{\uparrow}$ handoff while omitting the Cauchy filter basis, filter-space exactness row, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, hsame, Cont, Pkg, or NameCert rows refutes the carrier of Definition 6129.1.

Independence witness: cauchyfilter, regular-cauchy-filter-space, streamname, regseqrat, real: $\mathsf{CauchyFilterSpace}^{\uparrow}$ binds the point/filter carrier, Cauchy filter basis, finite request exactness, stream windows, rational readback, real sealing, transport, replay, provenance, and local naming rows in one completion-facing packet; each named sibling lacks at least one of these rows as a local filter-space coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterSpace}^{\uparrow}$ packet is generated from a point/neighborhood carrier, CauchyFilter basis row, filter-space exactness row, StreamName finite windows, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyFilterSpace}^{\uparrow}}$, seed)

Scope closed: Definition 6129.1, Definition 6129.2, and Definition 6129.3 seed the finite Cauchy-filter-space surface that can feed regular Cauchy filter space and completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyFilterSpace}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.CauchyFilterSpaceUp`

Bridge status: none

Not claimed: This chapter does not claim quotient filter equality, selected representatives, selected limits, countable choice, separated completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-space exactness, window and readback stability, ledger nonescape, and completion-facing handoff for BEDC.Derived.CauchyFilterSpaceUp.

Chapter 6130

A Concrete Naming Certificate for $\mathsf{CauchyCompletionStrength}^{\uparrow}$

Following Bishop and Bridges on constructive completion and finite products, the $\mathsf{CauchyCompletionStrength}^{\uparrow}$ packet records the finite BEDC surface by which regular Cauchy completion data commute with a displayed product route. It sits over the dyadic tolerance core of chapter 291, the stream-name windows of chapter 126, the regular rational readback of chapter 301, the completion functor of chapter 423, and the terminal real-name seal of chapter 38. The packet names product-transport strength only as finite NameCert data; it does not assert quotient completion, selected limits, countable choice, host product equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 6130.1 (Cauchy completion strength carrier)**.** *A* $\mathsf{CauchyCompletionStrength}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, B, W_A, W_B, D_A, D_B, P, Q, R, E, H, C, G, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular Cauchy data are to be paired.*
2. *W_A and W_B are the corresponding* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, displaying the observations used by each source row.*
3. *D_A and D_B are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers attached to the two window rows.*
4. *P is the ?? pairing-route row, recording only the displayed product read of the two regular Cauchy sources.*
5. *Q is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff row, applied after the product route has displayed A, B, W_A, W_B, D_A, D_B.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *completion seal reached only after the paired regular readback and the completion-functor handoff are public.*
7. *E records strength exactness: every accepted product-completion read must use the displayed rows $A, B, W_A, W_B, D_A, D_B, P, Q, R$ in that order.*
8. *H records componentwise* hsame *transport for the two sources, two stream-window rows, two dyadic ledgers, product route, completion handoff, seal, exactness, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the same product-completion route.*
10. *G is the* Pkg *provenance over* $\mathsf{CauchyCompletionStrength}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *??*, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionStrength}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, B, W_A, W_B, D_A, D_B, P, Q, R, E, H, C, G, N$. It has no coordinate for quotient completion, selected limits, countable choice, host product equality, detached product representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionStrengthUp.CauchyCompletionStrengthTasteGate single carrier alignment`

Theorem 6130.2 (Cauchy completion strength NameCert obligations)**.** *For every accepted* CauchyCompletionStren *carrier*

$$S = (A, B, W_A, W_B, D_A, D_B, P, Q, R, E, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionStrength}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, two* $\mathsf{StreamName}^{\uparrow}$ *window rows, two* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledgers, ?? pairing route,* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, exactness, transport, replay, provenance, and local naming rows;*
2. *source-window compatibility, requiring W_A, D_A to read only from A and W_B, D_B to read only from B;*
3. *product-route stability, requiring P to pair the two displayed regular Cauchy sources before the completion handoff Q is consumed;*
4. *completion-seal nonescape, requiring R to be downstream of $A, B, W_A, W_B, D_A, D_B, P, Q$ and excluding quotient completions, selected limits, countable choice, host product equality, and ambient real completeness;*
5. *structural persistence through* hsame, Cont, Pkg, *and the local* NameCert *row N.*

No other NameCert obligation is available from the Cauchy completion strength packet.

Proof. Project the carrier of Definition 6130.1. Its analytic rows are exactly the two regular Cauchy sources, their finite stream windows, their dyadic ledgers, the product pairing route, the completion-functor handoff, and the terminal real seal.

The five obligation rows separate the finite data by use. Carrier admission displays every coordinate. Source-window compatibility ties each window and tolerance ledger to its own regular Cauchy source, so the two sources cannot be mixed by an ambient product equality.

Product-route stability then forces the pairing row P to be read before Q. The completion-seal row R is downstream of that displayed route, so it cannot stand for quotient completion, a selected limit, or a countable-choice schedule.

Finally H, C, G, N preserve transport, replay, provenance, and local naming for the same finite route. Since the carrier contains no further coordinate, the five rows exhaust the local NameCert surface. □

Theorem 6130.3 (Cauchy completion strength product route)**.** *Every product-completion read of an accepted* $\mathsf{CauchyCompletionStrength}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ ??,\ \mathsf{CauchyCompletionFunctor}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

by reading $A, B, W_A, W_B, D_A, D_B, P, Q, R, E, H, C, G, N$. Thus completion after pairing is visible only as the finite product route followed by the completion handoff and Real seal.

Proof. Start with a product-completion consumer. The only source rows available to it are A and B, and the only observations of those sources are the finite window rows W_A, W_B with dyadic ledgers D_A, D_B.

The consumer must next read the product route P. This route pairs the displayed regular Cauchy data before the completion-functor handoff Q is available, so a detached product representative or host product equality cannot supply the handoff.

After Q is displayed, the seal row R is the only real-facing completion row. The exactness row E records the required order, and H, C, G, N transport, replay, source, and name the same route.

Therefore every accepted read factors through the displayed RegSeqRat, StreamName, DyadicRatCore, Product, CauchyCompletionFunctor, and Real rows before the Real seal is consumed. The packet exports no quotient completion, selected limit, countable-choice principle, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletionStrength}^{\uparrow}$ read that reaches a $\mathsf{Real}^{\uparrow}$ completion seal after product pairing must display two RegSeqRat source rows, two StreamName window rows, two DyadicRatCore tolerance ledgers, a ProductUp pairing route, a CauchyCompletionFunctor handoff, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: regseqrat, streamname, dyadicratcore, product, cauchy-completion-functor, real: $\mathsf{CauchyCompletionStrength}^{\uparrow}$ binds two regular Cauchy sources, paired finite windows, paired dyadic ledgers, a product route, a completion-functor handoff, a Real seal, exactness, transport, replay, provenance, and local naming in one strength packet; each listed sibling lacks at least one of those rows as a local product-completion coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionStrength}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionStrength}^{\uparrow}$ packet is generated from two RegSeqRat source rows, two StreamName window rows, two DyadicRatCore tolerance ledgers, a ProductUp pairing route, a CauchyCompletionFunctor handoff, a RealUp seal, exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionStrength}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6130.1, Definition 6130.2, and Definition 6130.3 seed the finite product-strength surface for regular Cauchy completion over source, window, tolerance, product, completion-functor, seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionStrength}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected limits, countable choice, host product equality, detached product representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window compatibility, product-route stability, completion-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionStrengthUp.

Chapter 6131

A Concrete Naming Certificate for $\mathsf{DoublingMetricSpace}^{\uparrow}$

Following Heinonen's metric-geometry treatment of doubling spaces and Kelley's finite-cover language, the $\mathsf{DoublingMetricSpace}^{\uparrow}$ packet records a displayed metric space whose balls admit uniformly bounded finite half-radius covers. It sits over the metric carrier of chapter 57, sends finite-cover data to chapter 127, provides compact-metric neighbourhood data for chapter 129, and routes every positive-radius and terminal distance read through chapter 38. The packet names only finite ball-cover rows, radius ledgers, center bundles, transport, replay, provenance, and local naming; it does not assert open-cover compactness, select global covers, or import a host doubling theorem.

Definition 6131.1 (Doubling metric space carrier)**.** *A* $\mathsf{DoublingMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, M, B, R, K, E, T, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying point-history carrier and classifier row.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *distance row over X, read through the metric certificate of chapter 57.*
3. *B is the parent-ball request row, naming a displayed center and positive radius.*
4. *R is the* $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-radius ledger carrying the radius and its half-radius request.*
5. *K is a closed finite* $\mathsf{ProbeBundle}$ *of half-radius centers admitted by X.*
6. *E is the coverage ledger, recording that every displayed point of the parent ball in B lies in one of the half-radius balls centered by K.*
7. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *handoff row, exposing the finite center bundle and coverage rows to total-bounded consumers.*
8. *S is the* $\mathsf{CompactMetric}^{\uparrow}$ *handoff row, making the same finite-cover data available to compact-metric consumers without adding open-cover compactness.*
9. *H records componentwise* hsame *transport for X, M, B, R, K, E, T, S and the structural rows.*
10. *C records displayed* Cont *replay from metric-ball admission through the finite half-radius cover and the sibling handoff rows.*

11. *P is the* Pkg *provenance over* $\mathsf{DoublingMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DoublingMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for arbitrary open covers, selected subcovers, host compactness, quotient point equality, countable choice, ambient real completeness, or a semantic doubling-space theorem.

Lean4 ✓ `BEDC.Derived.DoublingMetricSpaceUp.DoublingMetricSpaceTasteGate single carrier alignment`
Lean4 (definition) `BEDC.Derived.DoublingMetricSpaceUp.DoublingMetricSpaceUp`

Theorem 6131.2 (Doubling metric space NameCert obligations)**.** *For every accepted* $\mathsf{DoublingMetricSpace}^{\uparrow}$ *carrier*

$$D = (X, M, B, R, K, E, T, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DoublingMetricSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the point and metric rows; positive-radius and half-radius exactness through R; parent-ball admission through B; finite center-bundle admission through K; half-radius coverage through E; total-bounded and compact-metric handoff through T and S; componentwise transport, displayed replay, provenance, and local naming through H, C, P, N; and non-escape from open-cover compactness, choice-selected covers, quotient point equality, host compactness, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 6131.1. The point row X, metric row M, parent-ball request B, radius ledger R, center bundle K, coverage ledger E, and handoff rows T, S are displayed before the local naming row is consumed.

Positive-radius and half-radius exactness are read from R. Parent-ball admission is read from B, while the finite center bundle is read from K as a closed ProbeBundle over the same source.

Coverage is the row E. Each displayed point in the parent ball is paired with a center from K and a half-radius distance read through the same metric row M.

The sibling handoffs T and S expose that cover only as total-bounded and compact-metric finite data. The structural rows H, C, P, N transport, replay, source, and name the same route, so the excluded host principles cannot be recovered from the packet. □

Theorem 6131.3 (Doubling metric space total-bounded handoff)**.** *Every* $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DoublingMetricSpace}^{\uparrow}$ *packet reads the finite route*

$\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, ProbeBundle, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert

through the rows $X, M, B, R, K, E, T, S, H, C, P, N$. In particular, total-bounded consumers receive the half-radius center bundle and coverage ledger, compact-metric consumers receive only the same finite-cover handoff, and Real-facing consumers receive radius and distance rows only after that displayed route has been read.

Proof. Start with a total-bounded consumer. The rows K and E supply the finite center bundle and coverage ledger, while B and R record the parent ball and the radius-to-half-radius step.

Next consider a compact-metric consumer. It can read the packet only through S, which is downstream of the same K, E, T finite-cover route. Thus it receives no open-cover compactness object, selected subcover, or host compactness theorem.

Finally inspect a Real-facing radius or distance read. The metric row M and radius ledger R are replayed through C and transported through H before P, N package the handoff. Therefore

every total-bounded, compact-metric, or Real-facing use remains inside the displayed finite route and cannot import quotient point equality, countable choice, or ambient real completeness. □

Falsifiable prediction: Every accepted DoublingMetricSpaceUp cover read displays one point-history carrier, one metric-distance row, one parent-ball request, one positive-radius half-step, one finite ProbeBundle of centers, one half-radius coverage ledger, one TotallyBounded handoff, one CompactMetric handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: metric, totallybounded, compactmetric, real: $\mathsf{DoublingMetricSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a metric source, radius-halving ledger, parent-ball request, finite center bundle, half-radius coverage row, total-bounded handoff, compact-metric handoff, and Real-facing radius route in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DoublingMetricSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DoublingMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6131.1, Definition 6131.2, and Definition 6131.3 seed the finite doubling metric-space cover route over metric, total-bounded, compact-metric, and Real-facing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DoublingMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, selected subcovers, host compactness, quotient point equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius-halving exactness, parent-ball coverage, total-bounded handoff, compact-metric handoff, transport, replay, provenance, and local NameCert rows for BEDC.Derived.DoublingMetricSpaceUp.

Constructive story: A $\mathsf{DoublingMetricSpace}^{\uparrow}$ packet is generated from point-history and metric rows, a parent-ball request, a positive-radius half-step, a finite center ProbeBundle, a half-radius coverage ledger, total-bounded and compact-metric handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6132

A Concrete Naming Certificate for $\mathsf{RealCauchyFilterLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealCauchyFilterLimit}^{\uparrow}$ packet names the finite Cauchy-filter-to-real limit route without treating a filter as a quotient object or choosing a representative subnet. It sits after the Cauchy-filter source of chapter 333, the StreamName windows of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal real-name seal of chapter 38. The route is a completion/filter sibling of chapter 3949: it names the limit-facing handoff, while that sibling names the functorial finite-window transport.

Definition 6132.1 (Real Cauchy filter limit carrier)**.** *A* $\mathsf{RealCauchyFilterLimit}^{\uparrow}$ *carrier is a tuple*

$$L = (F, B, W, R, D, E, H, C, P, N)$$

where F is the accepted $\mathsf{CauchyFilter}^{\uparrow}$ *source row, B is a finite filter-base observation row, W is the* $\mathsf{StreamName}^{\uparrow}$ *window service read from B, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row over those windows, D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, H is componentwise* hsame *transport, C is displayed* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyFilterLimit}^{\uparrow}}$ *row.*

The classifier compares packets only through $F, B, W, R, D, E, H, C, P, N$. It has no coordinate for a quotient filter, selected representative, choice-selected limit, trichotomy principle, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealCauchyFilterLimitUp.RealCauchyFilterLimitTasteGate single carrier alignment`

Theorem 6132.2 (Real Cauchy filter limit NameCert obligations)**.** *For every accepted carrier $L = (F, B, W, R, D, E, H, C, P, N)$ of Definition 6132.1, the local certificate surface is exhausted by Cauchy-filter admission, finite filter-base admission, StreamName window exposure, RegSeqRat readback, DyadicRatCore tolerance checking, the RealUp seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *row. No obligation row can be discharged by quotient filters, selected representatives, choice-selected limits, trichotomy, host real equality, or ambient Real completeness.*

Proof. Project the displayed carrier. Each row required by the certificate is one of $F, B, W, R, D, E, H, C, P, N$, and the only analytic source before the terminal seal is the finite filter-base row B under the Cauchy-filter source F.

Read the route through the finite windows. The row W exposes the StreamName observations supplied by B; the row R packages those observations as regular rational readback; and the row D records the dyadic tolerance comparisons needed before the terminal RealUp seal E is accepted.

Finally transport and replay the same rows. The hsame row H acts componentwise on the displayed coordinates, Cont replay C consumes only that displayed continuation, and P, N record provenance and local naming for the same finite packet. Since the carrier has no quotient-filter, selected-representative, choice-limit, trichotomy, host-equality, or completeness coordinate, the certificate cannot export those claims. □

Theorem 6132.3 (Real Cauchy filter limit regular readback)**.** *Every completion-facing consumer of an accepted* $\mathsf{RealCauchyFilterLimit}^{\uparrow}$ *packet must read the finite filter-base row B, then the StreamName window row W, then the RegSeqRat readback row R, then the DyadicRatCore tolerance row D, before it reaches the RealUp seal E. The route exports only this finite readback chain and refuses quotient filters, selected representatives, choice-selected limits, trichotomy, host equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier definition. The only path from the Cauchy-filter source F to the seal E passes through B, W, R, D in the displayed tuple.

Use the NameCert obligation theorem. It identifies the local surface with the same finite rows and therefore leaves no hidden coordinate through which a consumer could replace R by a selected limit or a quotient-filter representative.

The structural rows preserve the order rather than adding data. Transport H, continuation replay C, provenance P, and local naming N repack the finite readback chain, so the terminal seal remains a RealUp name certified by the displayed observations, not by ambient completeness or trichotomy. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyFilterLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealCauchyFilterLimit}^{\uparrow}$ packet is generated from a CauchyFilter source row, a finite filter-base observation row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCauchyFilterLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6132.1, Definition 6132.2, and Definition 6132.3 seed the finite Cauchy-filter limit packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCauchyFilterLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected representatives, choice-selected limits, trichotomy, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A Lean carrier and checked NameCert theorem are required before this packet can retire the completion-facing horizon.

Chapter 6133

A Concrete Naming Certificate for $\mathsf{RealCompletionLimitRouter}^{\uparrow}$

Following the diagonal regular-Cauchy limit target in chapter 9238, the $\mathsf{RealCompletionLimitRouter}^{\uparrow}$ packet names the finite-window router that carries a completion request only as far as the displayed source rows permit. It is a router between observation budgets, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, and the RealUp seal; it is not a theorem that $\mathsf{Real}^{\uparrow}$ is complete and it does not choose a limit representative.

Definition 6133.1 (Real completion limit router carrier)**.** *A* $\mathsf{RealCompletionLimitRouter}^{\uparrow}$ *carrier is a tuple*

$$R = (O, W, Q, D, E, H, C, P, N)$$

where O is a finite observation-budget row, W is the $\mathsf{StreamName}^{\uparrow}$ *window row admitted by that budget, Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, H is componentwise* hsame *transport, C is displayed* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionLimitRouter}^{\uparrow}}$ *row.*

The classifier reads packets only through $O, W, Q, D, E, H, C, P, N$. It has no coordinate for an unbounded diagonal limit, quotient stream equality, selected representative, countable-choice selector, host real equality, or ambient Real completeness.

Theorem 6133.2 (Real completion limit router NameCert obligations)**.** *For every accepted carrier $R = (O, W, Q, D, E, H, C, P, N)$ of Definition 6133.1, the local certificate surface consists exactly of observation-budget admission, StreamName window exposure, RegSeqRat readback, DyadicRatCore tolerance checking, RealUp sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The router cannot discharge an unbounded diagonal limit, quotient equality of streams, selected representative, countable-choice selector, host equality, or ambient Real completeness.*

Proof. Project the displayed carrier. The observation budget O is the only entry point for a completion request, and the window row W is the only StreamName service exposed by that budget.

Read the analytic route in order. The row Q packages the accepted windows as regular rational readback, the row D records the dyadic tolerance checks attached to that readback, and the row E seals the result as a RealUp name.

Finally use the structural rows. Transport H, continuation replay C, provenance P, and local naming N preserve the same finite-window route. Since no carrier coordinate names an unbounded

diagonal, quotient equality, selected representative, countable-choice selector, host equality, or Real-completeness principle, the certificate cannot export those claims. □

Lean4 ✓ `BEDC.Derived.RealCompletionLimitRouterUp.RealCompletionLimitRouterCarrier namecert obligations`

Theorem 6133.3 (Real completion limit router nonescape)**.** *Any consumer that reaches the* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{RealCompletionLimitRouter}^{\uparrow}$ *packet must first expose the finite observation budget* O*, the StreamName window row* W*, the RegSeqRat readback row* Q*, and the DyadicRatCore tolerance row* D*. The consumer may read the seal as a finite routed name, but it may not replace the route by an ambient Real completeness theorem, a selected diagonal limit, quotient stream equality, countable choice, host equality, or a hidden representative.*

Proof. Start from the carrier definition. The seal row E is downstream of O, W, Q, D in the displayed packet, so a consumer cannot reach E without first exposing those rows.

Apply the NameCert obligation theorem. It identifies the local surface as the finite router rows and structural replay rows, leaving no hidden coordinate that could supply a global completion principle.

The nonescape conclusion is therefore a row-exhaustion claim. Once $O, W, Q, D, E, H, C, P, N$ have been read, the packet has exported the finite router and nothing beyond it; selected limits, quotient streams, countable choice, host equality, and ambient Real completeness remain outside the carrier. □

Theorem 6133.4 (Real completion router schedule-family source)**.** *A completion request whose observation budget is supplied by a schedule family first consumes the* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *route of chapter 5887 before it opens the* $\mathsf{RealCompletionLimitRouter}^{\uparrow}$ *rows* $O, W, Q, D, E, H, C, P, N$*. The router may then expose the finite observation budget, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, and RealUp seal, but it cannot replace the schedule-family source by quotient stream equality, a selected limit, countable choice, host real equality, or ambient Real completeness.*

Proof. Begin with a completion request whose budget is indexed by a schedule family. The $\mathsf{CauchyModulusSpace}^{\uparrow}$ finite route and filter handoff supply that family only through finite schedule rows, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal boundaries.

Apply Definition 6133.3. Once the request reaches the router, the seal row E is downstream of the displayed rows O, W, Q, D, and the structural rows H, C, P, N replay the same finite route.

Thus the router records a sibling dependency on schedule-family modulus data before it exposes its own rows. No step adds a coordinate for quotient stream equality, selected limits, countable choice, host real equality, or an ambient Real-completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionLimitRouter}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{RealCompletionLimitRouter}^{\uparrow}$ packet is generated from a finite observation-budget row, a StreamName window row, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionLimitRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6133.1, Definition 6133.2, and Definition 6133.3 seed the finite-window router for the Real completeness route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionLimitRouter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full RealUp completeness, unbounded diagonal limits, selected representatives, quotient stream equality, countable choice, host equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window routing, RegSeqRat readback, DyadicRatCore tolerance, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionLimitRouterUp.

Chapter 6134

A Concrete Naming Certificate for $\mathsf{CauchyBornologyBasis}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Bourbaki/Kelley on bornologies, the $\mathsf{CauchyBornologyBasis}^{\uparrow}$ packet records the finite basis-level route by which Cauchy filter observations, boundedness control, metric boundedness, stream windows, rational readback, dyadic tolerances, and the terminal real seal are exposed before a completion-facing consumer may act. It sits between the Cauchy bornology of chapter 1896, the finite Cauchy filter basis of chapter 1501, the metric bornology of chapter 4091, the located Cauchy filter basis of chapter 5840, the stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter names the basis-bornology bridge needed by Real and Completion routes; it does not quotient filters, select limits, use countable choice, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6134.1 (Cauchy bornology basis carrier)**.** *A* $\mathsf{CauchyBornologyBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, G, M, S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row, exposing finite basic filter requests, directed refinements, and Cauchy-pressure witnesses.*
2. *G is the* $\mathsf{CauchyBornology}^{\uparrow}$ *row, recording which displayed Cauchy-filter requests are bounded in the bornological sense.*
3. *M is the* ***??*** *row, tying the boundedness read to a metric-ball or diameter ledger rather than to host-set inclusion.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window service used to inspect the requested basis entries.*
5. *W is the window-boundedness row, matching the displayed stream windows with the bornology rows G, M.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows and boundedness reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback available only after F, G, M, S, W, D have been displayed.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only through the displayed basis-bornology route.*

9. *H records componentwise* hsame *transport for all basis, bornology, metric, window, tolerance, readback, seal, exactness, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the same route.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyBornologyBasis}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyBornology}^{\uparrow}$, *??*, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyBornologyBasis}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, G, M, S, W, D, R, E, H, C, P, N$. It has no coordinate for quotient filters, selected limits, countable choice, host bounded-set equality, hidden Cauchy representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyBornologyBasisUp.TasteGate.CauchyBornologyBasisTasteGate single carrier alignment`

Theorem 6134.2 (Cauchy bornology basis NameCert obligations)**.** *For every accepted* $\mathsf{CauchyBornologyBasis}^{\uparrow}$ *carrier*

$$B = (F, G, M, S, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyBornologyBasis}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row,* $\mathsf{CauchyBornology}^{\uparrow}$ *row, ?? row,* $\mathsf{StreamName}^{\uparrow}$ *windows, window-boundedness row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*
2. *basis-bornology compatibility, requiring every boundedness read in G to be attached to a displayed finite basis request from F;*
3. *metric boundedness stability, requiring M and W to witness the same bounded window before D, R, E are consumed;*
4. *completion-route nonescape, excluding quotient filters, selected limits, countable choice, host bounded-set equality, hidden Cauchy representatives, and ambient real completeness from the packet;*
5. *structural persistence through componentwise* hsame*, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row N.*

No other NameCert obligation is available from the Cauchy bornology basis packet.

Proof. Project the carrier of Definition 6134.1. Its analytic rows are exactly the Cauchy filter basis, Cauchy bornology row, metric bornology row, stream-window service, window-boundedness row, dyadic tolerance ledger, regular rational readback, and terminal real seal.

The first three obligation rows separate admission from compatibility. Carrier admission displays every coordinate. Basis-bornology compatibility ties G to the finite basis requests in F, and metric boundedness stability forces M and W to describe the same visible bounded windows before the tolerance and readback rows are public.

The completion-route nonescape row follows from the same inventory. Since no quotient filter, selected limit, countable-choice schedule, host bounded-set equality, hidden Cauchy representative, or ambient completeness coordinate appears in B, none can discharge a local obligation.

Finally H, C, P, N preserve the displayed rows by transport, replay, provenance, and naming. The five rows therefore exhaust the local NameCert surface. □

Theorem 6134.3 (Cauchy bornology basis filter handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CauchyBornologyBasis}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{CauchyFilterBasis}^{\uparrow},\ \mathsf{CauchyBornology}^{\uparrow},\ ??,\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow}$$

before it can consume the terminal $\mathsf{Real}^{\uparrow}$ *seal. The handoff exports only* $F, G, M, S, W, D, R, E, H, C, P, N$ *and refuses quotient filters, selected representatives, countable choice, host bounded-set equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a completion-facing read of B. The only filter source available to the consumer is the displayed basis row F, and the only bornological controls are G and M.

The consumer must next inspect finite windows. The rows S and W display the requested window and its boundedness read, while D records the dyadic tolerance ledger tied to the same visible data.

Only after this route is displayed may R supply regular rational readback and E supply the terminal real seal. The structural rows H, C, P, N transport, replay, source, and name that same route rather than adding a quotient filter or selected representative.

Thus the handoff is exactly the finite basis-bornology route listed in the statement, and it has no place for countable choice, host bounded-set equality, or ambient real completeness. □

Theorem 6134.4 (Cauchy bornology basis Real completion boundary)**.** *An accepted* $\mathsf{CauchyBornologyBasis}^{\uparrow}$ *packet reaches a Real and Completion boundary only through the displayed rows* $F, G, M, S, W, D, R, E, H, C, P, N$*. In particular the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is downstream of the finite Cauchy filter basis, bornology, metric bornology, stream-window, dyadic tolerance, and regular rational readback rows, and no quotient filter, selected limit, countable-choice selector, detached completion object, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row can be inserted before* E*.*

Proof. Use Definition 6134.2. It identifies the complete local certificate surface and shows that the terminal seal is part of the same finite packet as the basis, bornology, metric, window, tolerance, and readback rows.

Now apply the filter handoff theorem, Definition 6134.3. Every completion-facing read reaches E only after F, G, M, S, W, D, R have been displayed and after the structural rows have replayed the same route.

The excluded objects have no carrier coordinate. A quotient filter, selected limit, countable-choice selector, detached completion object, or ambient completeness row would have to enter between R and E or replace one of the displayed support rows, but the packet exposes neither insertion point. □

Falsifiable prediction: Every accepted $\mathsf{CauchyBornologyBasis}^{\uparrow}$ read that reaches a $\mathsf{Real}^{\uparrow}$ seal must display a CauchyFilterBasis row, a CauchyBornology row, a MetricBornology row, StreamName windows, a window-boundedness row, a DyadicRatCore tolerance ledger, RegSeqRat readback, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: cauchy-filter-basis, cauchy-bornology, metric-bornology, located-cauchy-filter-basis, streamname, dyadicratcore, regseqrat, real: $\mathsf{CauchyBornologyBasis}^{\uparrow}$ binds finite filter-basis requests, bornological boundedness, metric boundedness, stream-window inspection, dyadic tolerance, regular rational readback, a Real seal, transport, replay, provenance, and local naming in one basis-level packet; each listed sibling lacks at least one of these rows as a local completion-facing coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyBornologyBasis}^{\uparrow}}$.

Constructive story: A CauchyBornologyBasis$^{\uparrow}$ packet is generated from a CauchyFilterBasis row, a CauchyBornology row, a MetricBornology row, StreamName windows, a window-boundedness row, DyadicRatCore tolerance data, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyBornologyBasis}^{\uparrow}}$, seed)

Scope closed: Definition 6134.1, Definition 6134.2, Definition 6134.3, and Definition 6134.4 seed the finite basis-bornology route for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{CauchyBornologyBasis}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected representatives, selected limits, countable choice, host bounded-set equality, detached completion objects, ambient Real$^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, basis-bornology compatibility, metric boundedness stability, filter handoff, Real completion boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyBornologyBasisUp.

Chapter 6135

A Concrete Naming Certificate for $\mathsf{CompactDiniModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Dini's theorem, the $\mathsf{CompactDiniModulus}^{\uparrow}$ packet records the finite BEDC route by which a monotone continuous family on a compact metric source exposes one uniform tolerance modulus. It sits after the compact metric source of chapter 129, the continuous-map rows of chapter 130, the finite lower-bound fold of chapter 4096, the uniform-modulus surface of chapter 369, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite Dini-modulus route without importing host-selected limits, open-cover compactness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6135.1 (Compact Dini modulus carrier)**.** *A* $\mathsf{CompactDiniModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, M, \epsilon, L, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the compact finite-net data and finite source observations consumed by the Dini fold.*
2. *F is the monotone finite family of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows, recording the displayed maps on K and the continuity ledgers inspected at the finite net.*
3. *M records monotone decrease toward the zero or limiting row, including the visible comparisons used at each displayed net center.*
4. *ϵ is the positive tolerance request, stored as a finite rational or dyadic budget before any modulus row is exported.*
5. *L is the finite compact-net lower-bound and Dini-fold row, collecting the local lower-bound comparisons and the finite maximum of the displayed center thresholds.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row obtained from K, F, M, ϵ, L.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the tolerance and comparison budgets used by L and U.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposing only the real-valued endpoint read permitted after the regular rational readback.*
9. *H records componentwise* hsame *transport for the compact source, family, monotone ledger, tolerance, Dini fold, modulus output, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from compact finite-net data through monotone-family observations, the Dini fold, regular rational readback, and the uniform-modulus output.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactDiniModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteLowerBoundFold}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactDiniModulus}^{\uparrow}}$ *row.*

The carrier exposes only compact finite-net source data, monotone continuous-family rows, tolerance budgets, finite lower-bound folds, uniform-modulus output, regular rational readback, real sealing, componentwise transport, displayed replay, provenance, and local naming. It has no coordinate for host-selected limits, arbitrary open covers, selected subcovers, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactDiniModulusUp.CompactDiniModulusTasteGate single carrier alignment`

Theorem 6135.2 (Compact Dini modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactDiniModulus}^{\uparrow}$ *carrier*

$$D = (K, F, M, \epsilon, L, U, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactDiniModulus}^{\uparrow}}$ *surface consists exactly of five analytic rows together with the structural certificate rows:*

1. *compact-source admission through K;*
2. *monotone-family admission through F and M;*
3. *finite Dini-fold exactness through ϵ and L;*
4. *uniform-modulus output through U and regular rational readback through R;*
5. *nonescape from host-selected limits, arbitrary open-cover compactness, quotient real equality, and ambient real completeness through the seal row E and the transport, replay, provenance, and naming rows H, C, P, N.*

Proof. Project the carrier of Definition 6135.1. The analytic data are the compact source K, the continuous family F, the monotone ledger M, the tolerance row ϵ, the finite Dini fold L, the uniform-modulus row U, the regular rational readback R, and the real seal E.

The compact-source obligation is exactly the admission of K. The monotone-family obligation is exactly the joint visibility of F and M, because no later row contains a separate family selector or host order comparison.

The finite Dini-fold obligation is the route through ϵ and L. The tolerance budget is fixed before the fold is read, and L stores the compact-net lower-bound comparisons together with the finite maximum of the displayed center thresholds.

The output obligation is the handoff through U and R. The row U is the only uniform-modulus output, and R is the only regular rational readback exposed before the terminal real seal.

Finally E, H, C, P, N close the packet boundary. Since the carrier has no coordinate for host-selected limits, arbitrary open covers, selected subcovers, quotient real equality, countable choice, or ambient real completeness, none of those readings can be exported by the local NameCert surface. □

Theorem 6135.3 (Compact Dini modulus uniform-convergence route)**.** *For every accepted* $\mathsf{CompactDiniModulus}^{\uparrow}$ *carrier, any consumer that reads a uniform-modulus claim must route the request through*

$$K, F, M, \epsilon \longmapsto L \longmapsto U \longmapsto R, E \longmapsto H, C, P, N.$$

Thus compact monotone convergence is exposed as displayed finite rows before any $\mathsf{Real}^{\uparrow}$ *consumer may read a uniform-modulus conclusion.*

Proof. Start with the NameCert obligations of Definition 6135.2. They place compact-source admission, monotone-family admission, tolerance budgeting, finite Dini-fold exactness, uniform-modulus output, regular rational readback, real sealing, transport, replay, provenance, and local naming in the displayed carrier inventory.

The first stage reads K, F, M, ϵ. These rows determine the compact finite-net source, the continuous family, the monotone decrease toward the zero or limiting row, and the requested tolerance budget.

The second stage reads L. This row is the only place where the finite lower-bound comparisons and the finite maximum of center thresholds are assembled, so the Dini fold cannot be bypassed by a host compactness or limit-selection argument.

The third stage reads U and then R, E. The uniform-modulus row is exported before regular rational and real consumers inspect it, and those consumers see only the routed readback and seal rows.

The final stage reads H, C, P, N. Componentwise transport, displayed replay, provenance, and local naming preserve the same route without adding analytic data. Therefore every uniform-convergence use of the packet factors through the displayed finite rows before any $\mathsf{Real}^{\uparrow}$ consumer reads the conclusion. □

Falsifiable prediction: Every accepted $\mathsf{CompactDiniModulus}^{\uparrow}$ read must expose compact-source admission, monotone continuous-family admission, finite Dini-fold exactness, uniform-modulus output, regular rational readback, real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compactmetric, continuousmap, finite-lower-bound-fold, uniformmodulus, regseqrat, real: $\mathsf{CompactDiniModulus}^{\uparrow}$ is not bijective to any listed sibling because it binds a monotone compact-family route to a finite Dini-fold row before UniformModulus and Real consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactDiniModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactDiniModulus}^{\uparrow}$ packet is generated from CompactMetric finite-net source rows, monotone ContinuousMap family rows, tolerance-budget rows, finite lower-bound Dini-fold rows, UniformModulus output rows, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactDiniModulus}^{\uparrow}}$, seed)

Scope closed: Definition 6135.1, Definition 6135.2, and Definition 6135.3 seed the finite BEDC route from compact monotone continuous-family data to a displayed uniform modulus.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactDiniModulus}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.CompactDiniModulusUp`

Bridge status: none

Not claimed: This chapter does not close host-selected limits, arbitrary open-cover compactness, selected subcovers, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-family admission, finite Dini-fold exactness, uniform-modulus output, readback and seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactDiniModulusUp.

Chapter 6136

A Concrete Naming Certificate for $\mathsf{BairePointwiseOscillation}^{\uparrow}$

Following Baire and Lebesgue on pointwise oscillation, the $\mathsf{BairePointwiseOscillation}^{\uparrow}$ packet records the finite value-window evidence by which a pointwise-limit ledger exposes an oscillation bound at named source points. It reads the source and approximant windows supplied by chapter 1604, checks the rational value windows through chapter 301, seals the endpoint observations through chapter 38, keeps the inspection schedule visible through chapter 126, and exports only the epigraph-facing handoff that chapter 1536 may consume. The packet is a local certificate for displayed oscillation data, not a topology of function spaces and not a theorem about all discontinuity sets.

Definition 6136.1 (Baire pointwise oscillation carrier)**.** *A* $\mathsf{BairePointwiseOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, F, S, Q^-, Q^+, R^-, R^+, B, H, C, P, N)$$

with the following displayed rows:

1. *X is the source-context row inherited from the* $\mathsf{BaireOneFunction}^{\uparrow}$ *packet, naming the source points and basic-open evidence inspected by the oscillation certificate.*
2. *F is the pointwise-limit family ledger of* $\mathsf{BaireOneFunction}^{\uparrow}$ *approximant observations whose two displayed value windows are being compared.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting the two finite inspection windows, the source point, and the precision request.*
4. *Q^- and Q^+ are the lower and upper* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback rows for the two displayed value windows.*
5. *R^- and R^+ are the corresponding* $\mathsf{Real}^{\uparrow}$ *seals, reached only after X, F, S, Q^-, Q^+ have been displayed.*
6. *B is the rational oscillation-bound row recording a displayed $b \in \mathbb{Q}_{\geq 0}$ with the certified window inequality $R^+ - R^- \leq b$ at the named source point.*
7. *H records componentwise* hsame *transport for the source context, pointwise-limit ledger, stream schedule, rational readbacks, real seals, oscillation bound, continuation, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a source-point request through the* $\mathsf{BaireOneFunction}^{\uparrow}$ *value windows, the* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{Real}^{\uparrow}$ *seals, the rational oscillation bound, and the lower-semicontinuous handoff surface.*
9. *P is the* Pkg *provenance over* $\mathsf{BairePointwiseOscillation}^{\uparrow}$, $\mathsf{BaireOneFunction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BairePointwiseOscillation}^{\uparrow}}$ *row.*

The carrier exports no ambient topology on a function space, no arbitrary selector of subsequences, no quotient equality of real names, no global discontinuity classification, and no completeness principle for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BairePointwiseOscillationUp.BairePointwiseOscillationTasteGate single carrier alignment`

Theorem 6136.2 (Baire pointwise oscillation NameCert obligations)**.** *For every accepted* $\mathsf{BairePointwiseOscillation}^{\uparrow}$ *carrier* $K = (X, F, S, Q^-, Q^+, R^-, R^+, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BairePointwiseOscillation}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the source context, pointwise-limit family ledger, stream schedule, lower and upper rational readbacks, lower and upper real seals, rational oscillation bound, transport, continuation, provenance, and local naming rows;*
2. *value-window admission, requiring both displayed value windows to be read from the same* $\mathsf{BaireOneFunction}^{\uparrow}$ *pointwise-limit ledger over the same source row X;*
3. *schedule coherence, requiring the* $\mathsf{StreamName}^{\uparrow}$ *row S to name the source point, precision request, and two finite approximant windows used by Q^- and Q^+;*
4. *rational readback exactness, requiring Q^- and Q^+ to feed the real seals R^- and R^+ before the bound row B is available;*
5. *oscillation-bound stability, requiring the displayed inequality $R^+ - R^- \leq b$ in B to be preserved by the componentwise* hsame *rows in H;*
6. *handoff compatibility, allowing* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *consumers to read only the displayed oscillation-bound row and the route that produced it;*
7. *ledger refusal, excluding host function-space topology, arbitrary subsequence selection, quotient equality of real names, global discontinuity theorems, and completeness of* $\mathsf{Real}^{\uparrow}$.

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 6136.1. The accepted packet exposes exactly the source context, pointwise-limit family ledger, stream schedule, two rational readbacks, two real seals, rational bound, transport, continuation, provenance, and local naming rows.

Value-window admission and schedule coherence come from the rows F and S. Both value windows are read from the same $\mathsf{BaireOneFunction}^{\uparrow}$ ledger, and S records the finite inspection windows before any rational readback can be used.

Rational readback exactness is forced by the order of the route. The rows Q^- and Q^+ feed the real seals R^- and R^+, and the bound row B is downstream of those seals.

Transport stability is componentwise. The hsame rows in H identify the displayed source, ledger, schedule, readback, seal, bound, replay, provenance, and naming coordinates, so the displayed inequality is preserved along accepted classifier moves.

The lower-semicontinuous handoff is a read of the same route. Since P and N contain no coordinate for ambient topology, arbitrary subsequences, quotient equality, global discontinuity classification, or $\mathsf{Real}^{\uparrow}$ completeness, the listed obligations exhaust the certificate. □

Theorem 6136.3 (BaireOneFunction oscillation handoff)**.** *Every* $\mathsf{BairePointwiseOscillation}^{\uparrow}$ *consumer row exported by an accepted carrier factors through the displayed* $\mathsf{BaireOneFunction}^{\uparrow}$ *value-window route*

$$X, F, S, Q^-, Q^+ \longmapsto R^-, R^+ \longmapsto B.$$

Consequently a downstream $\mathsf{LowerSemicontinuous}^{\uparrow}$ *consumer may use the rational oscillation bound and the displayed provenance of its two value windows, but it receives no host function-space topology, no arbitrary subsequence selector, no quotient equality of real names, and no global theorem about the discontinuity set of a Baire-one function.*

Proof. Start with a consumer of the oscillation-bound row B. By carrier admission, B appears only after the source row X, the $\mathsf{BaireOneFunction}^{\uparrow}$ family ledger F, the schedule S, the rational readbacks Q^-, Q^+, and the real seals R^-, R^+.

Replay the continuation row C. The source-point request first reads the pointwise-limit ledger, then selects the two finite value windows through S, checks their rational windows through Q^- and Q^+, and seals the endpoints as R^- and R^+.

The bound row is therefore a downstream finite certificate, not an independent analytic object. Transport by H preserves the same coordinates, and the provenance row P records only the named packets in the displayed route.

A $\mathsf{LowerSemicontinuous}^{\uparrow}$ consumer can read the handoff only through that route. Since no excluded coordinate is present in the packet, the handoff exports neither ambient topology nor any global discontinuity theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{BairePointwiseOscillation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BairePointwiseOscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6136.1, Definition 6136.2, and Definition 6136.3 seed the finite pointwise-oscillation packet from Baire-one value windows to lower-semicontinuous consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BairePointwiseOscillation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function-space topology, arbitrary subsequence selection, quotient equality of real names, global discontinuity classification, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, value-window admission, schedule coherence, rational readback exactness, oscillation-bound stability, handoff compatibility, and ledger refusal for BEDC.Derived.BairePointwiseOscillationUp.

Constructive story: A $\mathsf{BairePointwiseOscillation}^{\uparrow}$ packet is generated from a $\mathsf{BaireOneFunction}^{\uparrow}$ pointwise-limit ledger, a $\mathsf{StreamName}^{\uparrow}$ schedule, two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, two $\mathsf{Real}^{\uparrow}$ seals, a rational oscillation-bound row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 6137

A Concrete Naming Certificate for $\mathsf{StolzCesaroTheorem}^{\uparrow}$

Following Stolz and Cesaro, and Hardy's summability treatment, the $\mathsf{StolzCesaroTheorem}^{\uparrow}$ packet records the finite theorem surface by which quotient-difference data and denominator growth are read into a Cesaro-style averaging handoff before any regular real-sequence consumer may inspect a limit claim. It sits beside the Hardy–Cesaro mean packet of chapter 1765, the Toeplitz averaging route of chapter 1682, the regular rational sequence surface of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite handoff from inspected sequence windows to a theorem-level summability certificate; it does not assert ambient real completeness, quotient-stream equality, or an uninspected limit.

Definition 6137.1 (Stolz-Cesaro theorem carrier)**.** *A* $\mathsf{StolzCesaroTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, D, Q, C, R, E, H, T, P, N)$$

with the following displayed rows:

1. *A is the source real-sequence window row, displaying the inspected numerator and denominator observations available to the theorem packet.*
2. *D is the quotient-difference row, recording the finite ratios of successive numerator and denominator differences used by the Stolz–Cesaro test.*
3. *Q is the denominator-growth row, recording the monotone unbounded denominator evidence read by the packet before any averaging row is exposed.*
4. *C is the Cesaro or Toeplitz averaging row, read through the sibling routes named by chapter 1765 and chapter 1682.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from A, D, Q, C and the dyadic tolerance data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite sequence windows, difference quotients, denominator-growth row, averaging row, and regular readback have been displayed.*
7. *H records componentwise* hsame *transport for A, D, Q, C, R, E.*
8. *T records displayed* Cont *replay from source windows through quotient differences, growth, averaging, regular readback, and the Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{StolzCesaroTheorem}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{ToeplitzLemma}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{StolzCesaroTheorem}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient completeness theorem, quotient sequence equality, selected real limit, countable choice, or host-order convergence outside the displayed rows.

Theorem 6137.2 (Stolz-Cesaro theorem NameCert obligations)**.** *For every accepted* $\mathsf{StolzCesaroTheorem}^{\uparrow}$ *carrier $S = (A, D, Q, C, R, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{StolzCesaroTheorem}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission for the displayed packet $A, D, Q, C, R, E, H, T, P, N$;*
2. *quotient-difference exactness, requiring every tested ratio to be read through D over the source windows A;*
3. *denominator-growth and averaging compatibility, requiring Q to be displayed before the Cesaro or Toeplitz row C is consumed;*
4. *regular readback and Real seal nonescape, requiring R and E to factor through the* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *sibling surfaces rather than through quotient streams or selected limits;*
5. *structural preservation through H, T, P, N, requiring componentwise transport, displayed replay, provenance, and local naming to preserve the same theorem packet.*

Lean4 ✓ `BEDC.Derived.StolzCesaroTheoremUp.StolzCesaroTheoremTasteGate single carrier alignment`

Proof. Project the carrier of Definition 6137.1. The analytic rows are the source windows A, quotient-difference row D, denominator-growth row Q, averaging row C, regular readback row R, and Real seal row E.

The quotient test is finite because every accepted ratio is recorded in D over the windows in A. The denominator-growth row Q is read before C, so the Cesaro or Toeplitz averaging route cannot be consumed as a free summability theorem detached from the displayed denominator data.

The readback and seal rows are downstream from the same route. Since R and E are reached only through the regular rational, dyadic tolerance, and Real seal siblings, no quotient stream, selected limit, countable choice, or ambient completeness coordinate is available.

Finally H, T, P, N transport, replay, source, and name only those displayed rows. Thus the five listed obligations exhaust the local NameCert surface for the theorem packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{StolzCesaroTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{StolzCesaroTheorem}^{\uparrow}$ packet is generated from source real-sequence windows, quotient-difference rows, denominator-growth rows, Cesaro or Toeplitz averaging rows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StolzCesaroTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 6137.1 and Definition 6137.2 seed the finite theorem packet over sequence windows, quotient differences, denominator growth, averaging, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{StolzCesaroTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, host-order convergence, Lean verification, or bridge checking for $\mathsf{StolzCesaroTheorem}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, quotient-difference exactness, denominator-growth compatibility, averaging handoff, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.StolzCesaroTheoremUp.

Chapter 6138

A Concrete Naming Certificate for $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$

The $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$ packet realizes the local explanation-state non-equivalence row of section 9462.11 as finite NameCert data. It sits beside the concept registry surface of chapter 1252, the audit system of chapter 1258, the axiom-purity gate of chapter 1259, the effective replacement ledger of chapter 568, and the philosophy map target of chapter 1277. The packet names a single common-source classifier disagreement between two explanation states; it does not claim global interpretability quality, hidden semantic truth, or classifier novelty without a displayed witness.

Definition 6138.1 (Classifier novelty witness carrier)**.** *A* $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (E, E', X, J, L, H, C, P, N)$$

with the following displayed rows:

1. *E is the source explanation-state row before the classifier judgment changes.*
2. *E' is the target explanation-state row after the classifier judgment changes.*
3. *X is the common-source display row, naming the inspected objects shared by E and E'.*
4. *J is the changed judgment row, recording a displayed pair in X whose classifier value differs between E and E'.*
5. *L is the ledger row, read through the effective replacement ledger, audit system, axiom-purity gate, concept registry surface, and philosophy map target siblings.*
6. *H records componentwise* hsame *transport for E, E', X, J, L.*
7. *C records displayed* Cont *replay through the common source, changed judgment, and ledger rows.*
8. *P is the* Pkg *provenance over* $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$, $\mathsf{ConceptRegistrySurface}^{\uparrow}$, $\mathsf{AuditSystem}^{\uparrow}$, $\mathsf{AxiomPurityGate}^{\uparrow}$, $\mathsf{EffectiveReplacementLedger}^{\uparrow}$, $\mathsf{PhilosophyMapTarget}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClassifierNoveltyWitness}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden semantic classifier, global truth predicate, host equivalence relation, quotient witness, or classifier novelty value without the displayed changed judgment row J.

Theorem 6138.2 (Classifier novelty witness NameCert obligations)**.** *For every accepted* $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$ *carrier* $W = (E, E', X, J, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ClassifierNoveltyWitness}^{\uparrow}}$ *surface consists exactly of carrier admission for the two explanation-state rows, common-source display, changed judgment, ledger row, transport, replay, provenance, and local naming; classifier non-equivalence exactness through* J*; ledger visibility through* L*; and no-smuggling refusal for hidden semantic truth, host classifier equivalence, quotient witnesses, and unstated global novelty.*

Proof. Project the carrier of Definition 6138.1. The two explanation states E, E' and the common-source row X determine the finite domain on which a classifier comparison may be read.

The changed judgment row J is the only coordinate that certifies non-equivalence. It records a displayed pair in X with different classifier values, so a consumer cannot infer classifier novelty from a prose explanation, a hidden semantic relation, or a global truth predicate.

The ledger row L exposes the registry, audit, purity, replacement, and philosophy-map dependencies before the witness is exported. The structural rows H, C, P, N transport, replay, source, and name the same finite packet, so the listed obligations exhaust the NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$ consumer that asserts classifier novelty without displaying $E, E', X, J, L, H, C, P, N$ refutes the carrier surface.

Independence witness: conceptregistrysurface, auditsystem, axiompuritygate, effective-replacement-ledger, philosophymaptarget: none is bijective because $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$ simultaneously carries two explanation states, a common-source display, a changed classifier judgment, audit-facing ledger evidence, transport, replay, provenance, and local naming.

The Lean follow-up must provide $\mathsf{Nontrivial\ ClassifierNoveltyWitness}^{\uparrow}$ and $\mathsf{FieldFaithful\ ClassifierNoveltyWitness}^{\uparrow}$ instances before any checked marker for BEDC.Derived.ClassifierNoveltyWitnessUp can be cited.

Closure status for $\mathsf{NameCert}_{\mathsf{ClassifierNoveltyWitness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$ packet is generated from two explanation-state rows, a common-source display row, a changed classifier judgment row, a ledger row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClassifierNoveltyWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6138.1, Definition 6138.2, the falsifiable prediction, and the independence witness seed the finite classifier-novelty witness packet over explanation states, common source, changed judgment, ledger, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClassifierNoveltyWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global interpretability quality, hidden semantic truth, host classifier equivalence, quotient witnesses, classifier novelty without a displayed witness, Lean verification, or bridge checking for $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, changed-judgment exactness, ledger visibility, no-smuggling refusal, transport, replay, provenance, and local naming for BEDC.Derived.ClassifierNoveltyWitnessUp.

Chapter 6139

A Concrete Naming Certificate for $\mathsf{RegularCauchyApartnessReflector}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyApartnessReflector}^{\uparrow}$ packet records the finite handoff from regular Cauchy name data to located apartness reads. It sits after the stream-name surface of chapter 126, the regular rational sequence surface of chapter 301, the dyadic rational core of chapter 291, the located-real surface of chapter 1933, the terminal real-name seal of chapter 38, and the Bishop located-real completion route of chapter 3488. The packet exposes apartness as inspected finite NameCert data; it does not import trichotomy, quotient stream equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 6139.1 (Regular Cauchy apartness reflector carrier)**.** *A* $\mathsf{RegularCauchyApartnessReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, A, L, E, H, C, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, naming the inspected source positions and readback order.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational source row whose accepted windows are being compared.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and positive-gap ledger used by the apartness read.*
4. *A is the displayed apartness row, recording the finite positive separation evidence accepted for the same regular Cauchy windows.*
5. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *handoff row, exposing the located read reached from S, R, D, A.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the located-real handoff has been displayed.*
7. *H records componentwise* hsame *transport for S, R, D, A, L, E.*
8. *C records displayed* Cont *replay from regular Cauchy windows through dyadic positive-gap evidence, located-real handoff, and the Real seal.*
9. *N is both the* Pkg *provenance over the listed BEDC dependencies and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessReflecto}}$ *row.*

The classifier compares accepted packets only through $S, R, D, A, L, E, H, C, N$. It has no coordinate for trichotomy, quotient stream equality, selected limit representatives, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyApartnessReflectorUp.RegularCauchyApartnessReflectorTasteGate`
`single carrier alignment`

Theorem 6139.2 (Regular Cauchy apartness reflector NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyApartnessReflector}^{\uparrow}$ *carrier*

$$K = (S, R, D, A, L, E, H, C, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessReflector}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream windows, regular rational source, dyadic positive-gap ledger, apartness row, located-real handoff, Real seal, transport, replay, provenance, and local name;*
2. *window and readback exactness, requiring the read through S and R to be the same finite regular Cauchy window consumed by the apartness row;*
3. *apartness-row exposure, requiring every accepted positive separation read to pass through A after the dyadic ledger D has been displayed;*
4. *located-real handoff, requiring the row L to be reached only from S, R, D, A;*
5. *Real-seal nonescape, requiring E to expose only the terminal seal after the located-real handoff;*
6. *transport, replay, provenance, and local naming, requiring H, C, N to preserve and name the same displayed route.*

No obligation supplies trichotomy, quotient stream equality, selected limits, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness outside these rows.*

Lean4 ✓ `BEDC.Derived.RegularCauchyApartnessReflectorNamecertObligations`

Proof. Project the carrier of Definition 6139.1. The displayed tuple $S, R, D, A, L, E, H, C, N$ is the entire public surface, so carrier admission is admission of those rows.

Window and readback exactness are forced by the order of the tuple. The stream-name row S fixes the inspected windows, and the regular rational row R fixes the rational readback on those windows before any apartness row is available.

The apartness-row exposure is the joint role of D and A. The dyadic ledger supplies the positive-gap cells, while A records the accepted finite apartness read over those same cells.

The located-real handoff and Real seal are downstream rows. The handoff L can be read only after S, R, D, A, and the seal E can be read only after L has been displayed.

Finally, H, C, N transport, replay, source, and name the same route. Since the excluded objects are absent as carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 6139.3 (Regular Cauchy apartness located-real handoff)**.** *Let $K = (S, R, D, A, L, E, H, C, N)$ be an accepted* $\mathsf{RegularCauchyApartnessReflector}^{\uparrow}$ *carrier. Every accepted apartness read from A passes through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{LocatedReal}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as witnessed by the rows S, R, D, L, E of the same packet, with H, C, N carrying only transport, replay, provenance, and local naming for that route.

Lean4 ✓ `BEDC.Derived.RegularCauchyApartnessReflectorLocatedRealHandoff`

Proof. Start with an accepted apartness read from A. By the carrier definition, the only inspected source windows available to that read are named by S.

The regular rational readback row R is then the only source of rational observations on those windows. The positive-gap evidence for apartness must next be read through the dyadic ledger D, so the apartness row is not a detached order comparison or a trichotomy branch.

The located-real row L consumes exactly the displayed stream, regular rational, dyadic, and apartness rows. Thus the handoff is a located-real read, not a quotient-stream equality or selected representative.

After L is displayed, the terminal row E seals the same read as a $\mathsf{Real}^{\uparrow}$ name. The structural rows H, C, N preserve, replay, source, and name the route without adding ambient completeness, so every accepted apartness read passes through the displayed finite handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyApartnessReflector}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat regular rational readback, DyadicRatCore positive-gap evidence, an apartness row, a LocatedReal handoff, a Real seal, componentwise hsame transport, displayed Cont replay, provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessReflector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6139.1, Definition 6139.2, and Definition 6139.3 seed the finite apartness-reflection route from regular Cauchy windows through dyadic positive-gap evidence, located-real handoff, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessReflector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient stream equality, selected limit representatives, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking for $\mathsf{RegularCauchyApartnessReflector}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, window and readback exactness, apartness-row exposure, located-real handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyApartnes

Lean4 (statement) `BEDC.Derived.RegularCauchyApartnessReflectorUp`

Chapter 6140

A Concrete Naming Certificate for $\mathsf{MonotoneSequenceWindowCauchy}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{MonotoneSequenceWindowCauchy}^{\uparrow}$ packet records the finite handoff by which inspected monotone bounded real-sequence windows are read as regular rational Cauchy data before any $\mathsf{Real}^{\uparrow}$ seal is exposed. It sits beside the monotone-real-sequence surface of chapter 1434, the located bounded real-sequence surface of chapter 2183, the stream-name surface of chapter 126, the regular rational sequence surface of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite monotone-window route; it does not import host monotone convergence, ambient real completeness, or selected limits.

Definition 6140.1 (Monotone sequence window Cauchy carrier)**.** *A* $\mathsf{MonotoneSequenceWindowCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, B, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MonotoneRealSequence}^{\uparrow}$ *window row, displaying the finite monotonicity comparisons available to the packet.*
2. *B is the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *row, displaying the inspected boundedness interval for the same windows.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row, naming the finite stream positions and readback order consumed by the handoff.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row produced from the displayed monotone, bounded, and stream-name data.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic rational tolerances used to witness the regular Cauchy readback.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, B, S, R, D have all been displayed.*
7. *H records componentwise* hsame *transport for M, B, S, R, D, E.*
8. *C records displayed* Cont *replay from monotone windows through boundedness, stream naming, dyadic tolerances, regular readback, and the Real seal.*

9. *P is the* Pkg *provenance over* MonotoneSequenceWindowCauchy$^{\uparrow}$, MonotoneRealSequence$^{\uparrow}$, BoundedRealSequenc StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{MonotoneSequenceWindowCauchy}^{\uparrow}}$ *row.*

The carrier has no coordinate for trichotomy, an uninspected supremum, countable choice, quotient equality, selected limits, or ambient Real$^{\uparrow}$ *completeness outside the displayed rows.*

`single carrier alignment`

Theorem 6140.2 (Monotone-window regular Cauchy handoff)**.** *For every accepted* MonotoneSequenceWindowCauc *carrier $W = (M, B, S, R, D, E, H, C, P, N)$, monotone bounded finite windows determine the* RegSeqRat$^{\uparrow}$ *handoff only through displayed dyadic tolerance rows. More precisely, every consumer of R must first display the monotone comparison row M, the boundedness row B, the stream-name row S, and the dyadic tolerance row D over the same finite* BHist *packet.*

Proof. Project the carrier of Definition 6140.1. The rows M and B provide only finite monotonicity and boundedness observations, and S fixes the inspected stream positions on which those observations are read.

The handoff row R is not an independent completion theorem. It is a displayed regular rational readback whose tolerance witnesses are recorded in D. Thus a consumer cannot reach R from monotonicity alone, boundedness alone, or an uninspected limit claim.

The structural rows H, C, P, N preserve the same packet through transport, replay, provenance, and local naming. Therefore the regular Cauchy handoff is forced to pass through M, B, S, D before R is available. □

Theorem 6140.3 (Monotone-window Real seal nonescape)**.** *For every accepted* MonotoneSequenceWindowCauchy$^{\uparrow}$ *carrier $W = (M, B, S, R, D, E, H, C, P, N)$, the* Real$^{\uparrow}$ *seal row E is reached only after the monotone-window row M, boundedness row B,* StreamName$^{\uparrow}$ *row S,* RegSeqRat$^{\uparrow}$ *row R, and* DyadicRatCore$^{\uparrow}$ *row D have been displayed in the same packet.*

Proof. Read the seal coordinate in Definition 6140.1. The definition places E downstream from the monotone-window, boundedness, stream-name, regular rational, and dyadic tolerance rows.

Since P sources the packet through those sibling surfaces and C replays their displayed route, no consumer can interpret E as an ambient completeness principle or as a selected limit. The Real seal names the terminal row of the finite route and nothing outside it. □

Closure status for NameCert$_{\text{MonotoneSequenceWindowCauchy}^{\uparrow}}$.

Constructive story: A MonotoneSequenceWindowCauchy$^{\uparrow}$ packet is generated from monotone real-sequence windows, boundedness rows, stream-name rows, RegSeqRat handoff, dyadic tolerance rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\text{MonotoneSequenceWindowCauchy}^{\uparrow}}$, seed)

Scope closed: Definition 6140.1, Definition 6140.2, and Definition 6140.3 seed the finite monotone-window Cauchy packet over monotone windows, boundedness, stream naming, dyadic tolerances, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{MonotoneSequenceWindowCauchy}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close trichotomy, selected limits, countable choice, quotient equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking for MonotoneSequenceWindowCauchy$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window exactness, boundedness display, stream-name compatibility, dyadic tolerance handoff, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MonotoneSequenceWindowCauchyUp.

Chapter 6141

A Concrete Naming Certificate for $\mathsf{RegularCauchyComparisonNet}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyComparisonNet}^{\uparrow}$ packet records the finite comparison-net data needed by the Real and Completion route before any consumer asks for a completed real object. It sits between the explicit schedules of chapter 292, the regular-Cauchy diagonal route of chapter 3782, the finite stream names, the dyadic rational tolerance ledger, the regular rational readback row, and the terminal $\mathsf{Real}^{\uparrow}$ seal. The packet names a comparison surface for regular Cauchy schedules; it does not identify quotient streams, choose limits, or invoke ambient completeness.

Definition 6141.1 (Regular Cauchy comparison net carrier)**.** *A* $\mathsf{RegularCauchyComparisonNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. M *is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row for the compared regular Cauchy requests.*
2. W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the schedules in* M*.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare window values.*
4. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled dyadic comparisons.*
5. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after* M, W, D, Q *have been displayed.*
6. H *records componentwise* hsame *transport for* M, W, D, Q, E, C, P, N*.*
7. C *records displayed* Cont *replay from schedule requests through stream windows, dyadic tolerances, regular readback, and the Real seal.*
8. P *is the* Pkg *provenance over* $\mathsf{RegularCauchyComparisonNet}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and the local naming row.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonNet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, W, D, Q, E, H, C, P, N$*. It has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyComparisonNetUp.RegularCauchyComparisonNetTasteGate single carrier alignment`

Theorem 6141.2 (Regular Cauchy comparison net NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyComparisonNet}^{\uparrow}$ *carrier*

$$G = (M, W, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonNet}^{\uparrow}}$ *surface consists exactly of schedule admission for the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *rows, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance compatibility,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback compatibility,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The certificate cannot export quotient stream equality, a selected limit, countable choice, host real equality, or ambient Real completeness.*

Proof. Project the carrier of Definition 6141.1. The comparison data are precisely M, W, D, Q, E, and the structural rows are H, C, P, N.

The schedule row M opens only finite stream windows in W. The dyadic row D records the tolerance ledger for those windows, and Q reads the same data as regular rational sequence evidence before the terminal seal E is available.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since none of the displayed rows contains a quotient stream, a selected limit, a choice schedule, host real equality, or an ambient completeness principle, the listed obligations exhaust the local certificate surface. □

Theorem 6141.3 (Regular Cauchy comparison net Real-completion handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RegularCauchyComparisonNet}^{\uparrow}$ *packet must compare regular Cauchy schedules through the finite route*

$$M, W, D, Q, E, H, C, P, N.$$

The handoff sends schedule-family comparisons through finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It may be consumed by later Real and Completion packets as comparison data, but it cannot be reinterpreted as quotient stream equality, a selected limit, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the NameCert obligations. They force every accepted comparison to expose the schedule row M before a stream window in W is inspected, and they force the dyadic tolerance row D before regular readback Q reaches the Real seal E.

The regular-Cauchy diagonal route of chapter 3782 can therefore consume the packet only as finite comparison data. The single-modulus surface of chapter 292 supplies schedule discipline, while this packet records how several such schedules are compared at the Real-facing boundary.

Structural replay through H, C, P, N preserves that route. No additional row supplies quotient equality, selected limits, countable choice, host real equality, or ambient completeness, so the handoff remains a finite comparison-net packet for Real and Completion consumers. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonNet}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyComparisonNet}^{\uparrow}$ packet is generated from CauchyModulus schedule rows, finite StreamName windows, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyComparisonNet}^{\uparrow}}$, seed)

Scope closed: Definition 6141.1, Definition 6141.2, and Definition 6141.3 seed the finite comparison-net surface for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchyComparisonNet}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule comparison, window routing, dyadic tolerance compatibility, regular readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyComparisonNetUp.

Chapter 6142

A Concrete Naming Certificate for $\mathsf{BoundaryFarEndNoncenter}^{\uparrow}$

The $\mathsf{BoundaryFarEndNoncenter}^{\uparrow}$ packet realizes the boundary-fixedness-not-center rule of Definition 9463.7 as finite NameCert data. It sits beside the Poincare disk dynamics packet of chapter 4117, the hyperbolic geodesic boundary packet of chapter 3491, the hyperbolic visual boundary packet of chapter 4181, the apophatic far-end socket packet, and the circle boundary reading. The packet names a displayed boundary far-end refusal; it does not identify the far end with an interior disk center or with a hidden global object.

Definition 6142.1 (Boundary far-end noncenter carrier)**.** *A* $\mathsf{BoundaryFarEndNoncenter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, B, F, A, H, C, P, N)$$

with the following displayed rows:

1. *D is the disk/readout row, recording the visible disk surface and the inspected readout whose center interpretation is being tested.*
2. *B is the boundary far-end row, displaying the boundary-side far-end reading rather than an interior point.*
3. *F is the fixedness row, recording that fixedness is read at the boundary far end and not at the disk center.*
4. *A is the apophatic refusal row, refusing any consumer that converts boundary far-end data into center data or object-level* T*.*
5. *H records componentwise* hsame *transport for D, B, F, A.*
6. *C records displayed* Cont *replay from disk readout through boundary far-end fixedness and apophatic refusal.*
7. *P is the* Pkg *provenance over* $\mathsf{BoundaryFarEndNoncenter}^{\uparrow}$*, the hyperbolic boundary route, apophatic far-end discipline,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundaryFarEndNoncenter}^{\uparrow}}$ *row.*

The carrier has no coordinate for a privileged disk center, a selected ideal point, a quotient boundary equality, subject-substance, or object-level T *outside the displayed refusal row.*

Theorem 6142.2 (Boundary far-end noncenter obligations)**.** *For every accepted* $\mathsf{BoundaryFarEndNoncenter}^{\uparrow}$ *carrier* $Q = (D, B, F, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundaryFarEndNoncenter}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed disk/readout, boundary far-end, fixedness, apophatic refusal, transport, replay, provenance, and local naming rows; fixedness exactness through* F*; refusal visibility through* A*; and noncenter refusal for any read that treats* D *as carrying the boundary far end through an interior center.*

Proof. Project the carrier of Definition 6142.1. The disk/readout row D names only the visible surface and inspected readout, while B names the boundary far-end row.

The fixedness row F is tied to B, not to an interior center coordinate in D. The refusal row A is therefore part of the certificate surface: a consumer that reads fixedness as center data has not displayed the accepted packet.

The rows H, C, P, N transport, replay, source, and name the same finite data. Thus the listed rows exhaust the local NameCert obligations, and no hidden center, selected ideal point, quotient boundary equality, subject-substance, or object-level T can enter the accepted route. □

Theorem 6142.3 (Boundary far-end fixedness noncenter rule)**.** *For every accepted* $\mathsf{BoundaryFarEndNoncenter}^{\uparrow}$ *carrier* $Q = (D, B, F, A, H, C, P, N)$*, boundary fixedness is read only from the displayed boundary far-end row* B *together with the fixedness row* F*. Any disk-center reading of* D *that bypasses the apophatic refusal row* A *is not a consumer of the same packet.*

Proof. The carrier separates the visible disk/readout row D from the boundary far-end row B. The fixedness row F is attached to B, while A records the refusal of center collapse.

If a consumer bypasses A, it has removed the row that distinguishes boundary far-end data from center data. If it reads D as the fixed far end, it has replaced the boundary row by an interior readout. In both cases the displayed packet is not preserved, so the consumer is outside $\mathsf{BoundaryFarEndNoncenter}^{\uparrow}$. □

Falsifiable prediction: Every accepted $\mathsf{BoundaryFarEndNoncenter}^{\uparrow}$ consumer must display the boundary far-end row and apophatic refusal row before any disk-center read is rejected as noncenter data.

Independence witness: poincare-disk-dynamics, hyperbolic-geodesic-boundary, hyperbolic-visual-boundary, apophaticfarendsocket, and s1: none carries the same boundary/noncenter/refusal rows. The dynamics packet exposes disk-map evolution, the geodesic and visual boundary packets expose boundary routes, the far-end socket exposes apophatic pressure, and s1 exposes a circle boundary shape; only $\mathsf{BoundaryFarEndNoncenter}^{\uparrow}$ binds disk readout, boundary far-end fixedness, noncenter refusal, transport, replay, provenance, and local naming in one packet.

The Lean follow-up file `lean4/BEDC/Derived/BoundaryFarEndNoncenterUp/TasteGate.lean` must provide explicit $\mathsf{Nontrivial}\ \mathsf{BoundaryFarEndNoncenter}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{BoundaryFarEndNoncenter}^{\uparrow}$ instances preserving D, B, F, A, H, C, P, N before any checked carrier-alignment theorem can serve as a TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryFarEndNoncenter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundaryFarEndNoncenter}^{\uparrow}$ packet is generated from disk/readout rows, boundary far-end rows, boundary fixedness rows, apophatic refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryFarEndNoncenter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6142.1, Definition 6142.2, Definition 6142.3, the falsifiable prediction, and the independence witness seed the finite boundary-far-end noncenter packet over disk readout, boundary far-end fixedness, refusal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BoundaryFarEndNoncenter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close privileged disk centers, selected ideal points, quotient boundary equality, subject-substance, object-level T, Lean verification, or bridge checking for BoundaryFarEndNoncenter$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, boundary fixedness exactness, apophatic refusal visibility, noncenter refusal, transport, replay, provenance, local naming, and TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.BoundaryFarEndNoncenterUp.

Chapter 6143

A Concrete Naming Certificate for $\mathsf{CompactUniformRadiusTransport}^{\uparrow}$

Following Bishop and Bridges and the constructive Heine–Cantor route, the $\mathsf{CompactUniformRadiusTransport}^{\uparrow}$ packet packages the finite radius-transport step used by chapter 9237. It sits beside the compact source packet of chapter 60, the metric distance surface of chapter 57, the continuous-map carrier of chapter 130, the rational radius ledger of chapter 37, and the uniform-modulus consumer of chapter 369. The packet names a finite transport from pointwise compact-cover radii to a tolerance-only modulus ledger; it does not choose a global modulus by countable choice or by an ambient compactness principle.

Definition 6143.1 (Compact uniform radius transport carrier)**.** *A* $\mathsf{CompactUniformRadiusTransport}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, M, F, R, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-net row, including the bundled compact-cover witnesses used at the requested tolerance.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row for the source and target metric comparisons consumed by the transport.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row attached to the compact finite-net centers.*
4. *R is the* $\mathsf{Rat}^{\uparrow}$ *positive-radius and lower-bound fold ledger for the finitely many displayed radii.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row reached only after K, M, F, R have been displayed.*
6. *H records componentwise* hsame *transport for K, M, F, R, U, C, P, N.*
7. *C records displayed* Cont *replay from compact finite-net coverage through pointwise radii, rational lower-bound folding, metric triangle use, and the uniform-modulus handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{CompactUniformRadiusTransport}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusTransport}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, M, F, R, U, H, C, P, N$. It has no coordinate for an external modulus selector, an infinite cover, countable choice, open-cover compactness outside the displayed finite net, host real equality, or ambient Real completeness.

Theorem 6143.2 (Compact uniform radius transport NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformRadiusTransport}^{\uparrow}$ *carrier*

$$T = (K, M, F, R, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusTransport}^{\uparrow}}$ *surface consists exactly of compact finite-net admission, metric-distance compatibility, continuous-map pointwise-radius admission, rational lower-bound fold compatibility, uniform-modulus handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The certificate cannot export an external modulus selector, infinite cover, countable choice, open-cover compactness detached from* K*, host real equality, or ambient Real completeness.*

Proof. Project the carrier of Definition 6143.1. The compact-cover and analytic rows are K, M, F, R, U, while H, C, P, N are the structural rows that preserve the same displayed transport.

The compact finite-net row K exposes only finitely many centers and coverage witnesses. The continuous-map row F supplies pointwise radii at those displayed centers, and the rational ledger R folds the finitely many positive radii before the uniform-modulus row U is available.

Metric compatibility is read through M along the same route. Since no carrier coordinate names an external selector, infinite cover, countable-choice schedule, detached open-cover compactness theorem, host real equality, or ambient completeness principle, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.CompactUniformRadiusTransportUp.CompactUniformRadiusTransportTasteGate`
`single carrier alignment`

Theorem 6143.3 (Compact uniform radius transport handoff)**.** *Every uniform-modulus consumer of an accepted* $\mathsf{CompactUniformRadiusTransport}^{\uparrow}$ *packet receives the finite route*

$$K, M, F, R, U, H, C, P, N.$$

The handoff transports pointwise compact-cover radii through the displayed compact finite net, source and target metric rows, continuous-map local-modulus data, and $\mathsf{Rat}^{\uparrow}$ *lower-bound folding before exposing the* $\mathsf{UniformModulus}^{\uparrow}$ *row. It may be used as the radius-transport step in compact-uniform-continuity arguments, but it cannot be reinterpreted as an external modulus selector, an infinite cover, countable choice, detached open-cover compactness, host real equality, or ambient Real completeness.*

Proof. Apply the NameCert obligation theorem. It forces the compact finite-net row K before any pointwise radius can be consumed, and it forces the continuous-map row F and rational lower-bound row R before the uniform-modulus handoff U is exposed.

The compact-uniform-continuity vision of chapter 9237 uses exactly this order: finite compact-cover data first, pointwise local radii second, rational lower-bound folding third, and the tolerance-only uniform-modulus row last. Metric rows in M supply the triangle comparisons without adding a host compactness theorem.

Finally replay H, C, P, N. These rows preserve the displayed finite transport and do not create any coordinate for external selection, infinite covers, countable choice, detached open-cover compactness, host equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusTransport}^{\uparrow}}$.

Constructive story: A CompactUniformRadiusTransport$^{\uparrow}$ packet is generated from Compact finite-net rows, MetricSpace distance rows, ContinuousMap pointwise-radius rows, Rat lower-bound folds, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactUniformRadiusTransport}\uparrow}$, seed)

Scope closed: Definition 6143.1, Definition 6143.2, and Definition 6143.3 seed the finite radius-transport surface from compact pointwise radii to UniformModulus consumers.

Formal verification: FormalStatus(NameCert$_{\text{CompactUniformRadiusTransport}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close external modulus selection, infinite covers, countable choice, open-cover compactness outside the displayed finite net, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net routing, metric compatibility, continuous-map pointwise-radius admission, rational lower-bound folding, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformRadiusTransportUp.

Chapter 6144

A Concrete Naming Certificate for $\mathsf{NemytskiiOperator}^{\uparrow}$

Following Krasnoselskii and Rutickii on superposition operators, the $\mathsf{NemytskiiOperator}^{\uparrow}$ packet records the finite NameCert surface for nonlinear pointwise composition on named function spaces. It sits over the measurable-map surface of chapter 3461, the Sobolev-space carrier of chapter 5911, the complete normed-space interface of **??**, the measure rows of chapter 92, and the terminal real-name seal of chapter 38. The packet names the displayed superposition route for a nonlinear kernel and its source-function windows; it does not assert a host function quotient, global continuity theorem, PDE solvability result, selected representative, or ambient Banach-space completeness theorem.

Definition 6144.1 (Nemytskii operator carrier)**.** *A* $\mathsf{NemytskiiOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, M, F, W, I, T_0, S, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the domain and codomain row, naming the measurable source, target scalar seal, and function-space boundary inspected by the packet.*
2. *M is the* $\mathsf{MeasurableFunction}^{\uparrow}$ *row for the nonlinear kernel, exposing only displayed preimage ledgers and graph-read windows.*
3. *F is the source-function row, listing the finite function-name windows, domain probes, and scalar readbacks that may be substituted into the kernel.*
4. *W is the pointwise witness row, pairing each displayed source observation with the corresponding displayed kernel observation before any output function row is read.*
5. *I is the integrability and growth-budget row, binding the admissible source windows to the finite measure and Real rows used by the superposition request.*
6. *T_0 is the target-function row produced by the displayed superposition route, not by a host quotient of functions.*
7. *S is the* $\mathsf{SobolevSpace}^{\uparrow}$ *or function-space handoff row, available only after D, M, F, W, I, T_0 have been displayed.*
8. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row for scalar kernel values, growth budgets, norm estimates, and target-function observations.*

9. *H stores componentwise* hsame *transport for domain, measurable-kernel, source-function, witness, integrability, target-function, function-space, Real, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay from every superposition request through $D, M, F, W, I, T_0, S, R, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{NemytskiiOperator}^{\uparrow}$, $\mathsf{MeasurableFunction}^{\uparrow}$, $\mathsf{SobolevSpace}^{\uparrow}$, $\mathsf{BanachSpace}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{NemytskiiOperator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an ambient nonlinear operator theorem, quotient equality of functions, almost-everywhere representative choice, global compactness, PDE solvability, or an external Banach-space completeness claim.

Lean4 (statement) `BEDC.Derived.NemytskiiOperatorUp`

Theorem 6144.2 (Nemytskii operator NameCert obligations)**.** *For every accepted* $\mathsf{NemytskiiOperator}^{\uparrow}$ *carrier*

$$T = (D, M, F, W, I, T_0, S, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NemytskiiOperator}^{\uparrow}}$ *surface consists exactly of carrier admission for the domain row D, measurable-kernel row M, source-function row F, pointwise witness row W, integrability and growth row I, target-function row T_0, function-space handoff S, Real readback R, componentwise transport H, displayed replay C, provenance P, and local naming N. Every admitted nonlinear composition read must expose the kernel row, source windows, pointwise witness row, growth budget, target-function row, and Real seal before a Sobolev, Banach, measure, or Real consumer can read the output.*

Proof. Project the carrier of Definition 6144.1. The only analytic data available to the classifier are the displayed domain row D, measurable-kernel row M, source-function row F, pointwise witness row W, integrability row I, target row T_0, function-space handoff S, and Real row R.

The measurable-kernel obligation is read before any output claim. The preimage and graph-read surface of M fixes which nonlinear kernel observations can be paired with the source-function windows in F.

The pointwise witness and budget rows then bind the superposition route. The rows W, I, T_0, R record the displayed source-to-target observation pairs, growth and integrability budgets, target-function output, and scalar readbacks.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded host objects are not coordinates of the carrier, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.NemytskiiOperatorUp.NemytskiiOperatorNamecertObligations`

Theorem 6144.3 (Nemytskii operator measurable handoff)**.** *Every measurable-output read exported by an accepted* $\mathsf{NemytskiiOperator}^{\uparrow}$ *carrier factors through the finite route*

$$M, F, W, I \longmapsto T_0 \longmapsto R \longmapsto H, C, P, N.$$

The route exposes a measurable-kernel ledger, source-function windows, displayed pointwise substitutions, growth and integrability budgets, target-function rows, Real readbacks, transport, replay, provenance, and local naming. It does not export a host inverse-image function, almost-everywhere quotient, selected representative, global continuity theorem, or completed measure space.

Proof. Start with a measurable-output request. The request first reads the measurable-kernel row M and the source-function row F, because the output is determined only by the displayed kernel observations paired with displayed source observations.

Next the route inspects W and I. These rows bind pointwise substitution and admissible growth or integrability budgets to the same finite windows, and the target-function row T_0 is read only after those rows are fixed.

The Real readback and structural rows close the route. The scalar seal R and the rows H, C, P, N preserve the same packet, so no host inverse-image function, representative selector, quotient, continuity theorem, or measure completion is exported. □

Lean4 ✓ `BEDC.Derived.NemytskiiOperatorUp.NemytskiiOperatorMeasurableHandoff`

Theorem 6144.4 (Nemytskii operator Banach–Sobolev consumer)**.** *Every Banach–Sobolev consumer of an accepted* $\mathsf{NemytskiiOperator}^{\uparrow}$ *carrier must read the displayed route*

$$\mathsf{MeasurableFunction}^{\uparrow},\ \mathsf{Measure}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{SobolevSpace}^{\uparrow},\ \mathsf{BanachSpace}^{\uparrow}$$

through the carrier rows M, I, R, S and the source-to-target rows F, W, T_0 before it may consume transport, replay, provenance, or local naming. The handoff supplies a finite nonlinear composition interface; it does not assert a compact embedding, a global boundedness theorem, PDE solvability, quotient equality of functions, countable choice, or an ambient completeness theorem.

Proof. Use the NameCert obligations of Definition 6144.2. They force every consumer to begin with the measurable kernel and source-function rows, then pass through the pointwise witness and growth-budget rows.

The Sobolev and Banach reads are downstream of S and of the Real readback row R. Thus any function-space statement consumes only the displayed target-function row T_0, the finite budget row I, and the sibling certificates named in the provenance row.

Transport, replay, provenance, and local naming through H, C, P, N keep the same finite route. Since no compact embedding, selected representative, quotient equality, choice schedule, PDE theorem, or ambient completeness coordinate appears in the carrier, every Banach–Sobolev consumer is exhausted by the displayed handoff. □

Falsifiable prediction: An accepted $\mathsf{NemytskiiOperator}^{\uparrow}$ consumer that reaches a Sobolev or Banach read without first exposing measurable-kernel rows, source-function windows, pointwise witness rows, growth budgets, target-function rows, Real readbacks, componentwise hsame transport, Cont replay, Pkg provenance, and local naming refutes the carrier surface of Definition 6144.1.

Independence witness: measurable-function, sobolev-space, banach-space, measure, real: no listed sibling supplies the whole twelve-row packet $T = (D, M, F, W, I, T_0, S, R, H, C, P, N)$, because each sibling contributes only kernel measurability, function-space, normed-completion, measure, or scalar-seal data while this chapter binds them into one nonlinear superposition carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{NemytskiiOperator}^{\uparrow}}$**.**

Constructive story: A $\mathsf{NemytskiiOperator}^{\uparrow}$ packet is generated from a displayed domain row, MeasurableFunction kernel row, source-function windows, pointwise witness rows, growth and integrability budgets, target-function rows, Sobolev or function-space handoff data, Real readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NemytskiiOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 6144.1, Definition 6144.2, Definition 6144.3, and Definition 6144.4 seed the finite nonlinear superposition surface over displayed measurable kernels, source windows, pointwise witnesses, growth budgets, target rows, function-space handoffs, Real readbacks, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{NemytskiiOperator}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global continuity, compact embedding, PDE solvability, almost-everywhere quotient equality, selected representatives, countable choice, ambient Banach-space completeness, Lean verification, or bridge checking.
